> I'd say it's a way of humanizing the students' mathematical experience. It gets away from a traditional feeling that math is about being good, getting right answers, and having your value either internally or affirmed from, without coming from a place of feeling like those are the things that matter. Whereas the true mathematical experience is always a work in progress. It's always about developing thinking and we learn so much from our mistakes. We learn so much from thought processes that lead the wrong direction. And so it's really a sense of honoring what all students should be having as an everyday experience learning mathematics.

In common across these teachers' descriptions, whether they expressed four components or not, was that it made sense to them to treat mathematics learning as a gradual, iterative process of drafting and revising ideas, and they expressed value for drafting and revising while learning and doing mathematics in school. These teachers' talk illustrates what drafting and revising meant to them, in their mathematics classrooms, and some teachers put relatively stronger emphases on different components of "rough draft math."

Motivations for and Enactments of "Rough Draft Math"

Teachers reported multiple motivations for enacting "rough draft math," as represented in their artifacts. The first motivation below, foster productive dispositions, was reported in some manner by every teacher. However, the other two motivations (cultivate learning through revising and reflecting; empower students) were not reported by every teacher. The table below illustrates differences in reported enactments that appeared to be aligned with specific motivations for enacting "rough draft math."

Table 1: Motivations for and Enactments of "Rough Draft Math"

Motivation	Enactment
Foster productive dispositions • Develop confidence in students	Intentionally build a classroom culture where students' ideas are valued at any stage • Labeling talk as "rough drafts"

• Increase students' participation and effort • Safety for intellectual risk taking	• Rights of Learners • Protocols for discussion • Anonymous student sharing • Multiple revision experiences in class
Cultivate learning through revising and reflecting • Normalize mistakes in math • Develop metacognition	Explicitly incorporate revising into mathematics instruction • Revision routines, such as test corrections • Reflection on revising
Empower students • Shift authority to students • Disrupt school structures that control students	Decenter teachers' authority • Student self-assessment • Peer collaboration to learn

Motivation: Foster Productive Dispositions. Every participant reported an overarching motivation to enact rough drafting in math class: to foster productive dispositions among students. The most frequently associated enactment with this motivation was teachers' efforts to intentionally build a classroom culture where students' ideas were welcome and valued at any stage of their thinking. Teachers often mentioned more than one motivation for enacting rough draft math, but this was the motivation and associated enactment shared by all participants. The function or motivation of fostering productive dispositions had a range of subdimensions: develop confidence in students, create safe experiences to encourage intellectual risk taking and collaboration, and increase students' participation and effort in math class.

One of the artifacts Ms. Dougherty shared was a set of pictures of her middle grades students collaborating – standing together at white boards on the wall working on math and sitting together on the floor working in a group, and when she described her motivations for collaborative work, Ms. Dougherty talked about building classroom culture. Ms. Dougherty described that she encouraged students to verbally label their thinking as being in a rough draft stage when they shared aloud, so that students could feel more confident to participate without being judged for imperfect or incorrect thinking.

> I definitely see the language that my students use. Um, they do a lot of, they'll use the language of rough draft math. So, very often they'll raise their hand or start their thinking saying, well, I'm not sure yet, but this is what I'm thinking right now. And they have a very comfortable space and, and I commend them. So, at the beginning of the year, I do a lot of like that [by saying], "Awesome, rough draft math talking, thank you, starting out your thinking that way. Now we all know that we're going to give you the space to share and revise if you need to." Um, I think they look for revision possibilities rather than thinking of their math as a final step. Um, so they're very aware of the idea that we can look at what others are thinking, um, and constantly revise. So I think that that's been really beneficial… I think I am making moves toward getting their confidence to be stronger in mathematics. I don't just mean confidence in ability as much as just confidence in sharing their thinking, you know, just, just get something out there. Like everybody can share something, you know?

Ms. Dougherty reported that welcoming drafts and normalizing revising in mathematics class supported students' development of their confidence so that more students would participate.

To demonstrate efforts to build culture, Ms. Briggs's artifact included a photograph of "rights of learners" (Kalinec-Craig, 2017) generated by her first-grade students, such as "I have the right to be cared for and care for others." She shared that her motivation for promoting these rights was to support students' safety and willingness to participate. According to Ms. Briggs, "…when students are talking, they have that space to work through some of their disequilibrium. … students feel psychologically safe to make those mistakes and to have confusion around a topic." She also said that it was important to her to be "really instilling that love of math and, um, making kids feel like that they were experts in math is going to have a long-term impact on them." She used "rights of learners" to build a classroom culture to support her students.

Ms. Kakkar shared an artifact of a sample of students' revised work, and she also said that she wanted to increase students' risk taking and promote participation. When describing her artifact, she said that she encouraged revising by using a protocol – learning to listen / listen to learn (Wolfe, 2021) – to teach students to hear and learn from each other. She also incorporated anonymous sharing of students' solutions during whole class discussion for workshopping and revising. Ms. Kakkar said that she enacted teaching in these ways so that students could "see their progression and how could they realize it, how much it is important to, to really build upon each other's ideas?" She also said that she wanted "to make students comfortable."

Ms. Burnett provided a short video of one of her mathematics lessons, edited into segments to illustrate an in-class, multiple revision experience, and she expressed that she wanted to encourage students to take risks, to build students' confidence, and increase their participation. She said that she wanted to share this video to illustrate what a "rough draft math" lesson looked like in her class: students worked in groups on a challenging task, she purposefully selected student strategies to be shared to the whole class while peers asked one another questions about the work, students would then revisit and revise their work in groups, and then share out again. Ms. Burnett said, "it takes the pressure off the kids" to welcome rough draft thinking. She said that, regarding a success that she has had,

> Definitely confidence building. And the students are not afraid to make mistakes… I would have [in the past] some kids just sit and do nothing. They would just hold their pencil. And I knew it was like a frozen fear of, I don't wanna make a mistake. It's [rough draft math] taken that away. Those kids are just like, let's do this.

These enactments were motivated by teachers' drives to foster productive dispositions among students and to support students with participating to learn mathematics through discourse.

Motivation: Cultivate Learning through Revising and Reflecting. Although every teacher described a motivation to promote productive dispositions, not every teacher described using rough drafting to explicitly cultivate learning through revising. Ms. Apple's artifact was an example of a revising routine and protocol that she used for students to correct their tests in AP Calculus AB, and she said that she wanted to promote growth in students' thinking and awareness of that growth.

> I like the metacognition that's involved in the protocol. So really thinking about their thinking and thinking about where their mistake, misunderstanding or, misconception or misunderstanding [was]. I think of all three of those things as different, different ways to think about the problem and where it was wrong in their thought process. Because sometimes they just make a silly mistake. Sometimes they don't understand the concept and they need to go back and revise the way they think about a problem like that.

Ms. Green also shared an activity for chapter test revisions and reflection activity and a "quicker rough draft" process for a routine for in the moment revisions.

> I do it on the test, the final draft thinking on the test revisions… the revision part is when I feel like a topic has been solidified… then the quicker rough draft would be for those moments where we're in a new learning. … I use it [rough draft math] in different ways, depending on what I'm working on. So are we working [on] solidifying an idea? Are we working on learning a new idea for the first time?

Both of Ms. Green's artifacts illustrated two revision experiences, but they had different goals: working toward solidifying thinking (test revisions) or developing new ideas (discussing and revising drafts). Teachers like Ms. Apple and Ms. Green spoke about reaching a "final draft."

Motivation: Empower Students. A subset of teachers described that they wanted to enact rough draft math in their teaching to promote equity through empowering students. Mr. Vandelay shared an artifact that documenting requirements for (and purpose of) a student portfolio for their self-assessment, which was his primary grading practice; he said that he incorporated self-assessment to transfer authority to students by dismantling traditional school grading practices. According to Mr. Vandelay,

> I personally have felt since I read *Rough Draft Math*, that one of the things that really does is honors the fact that we need to rethink the way we're evaluating students, so that what we value in terms of student thinking as a process isn't undermined by grading practices … especially with students who have low status or perceived low status or low mathematical identities, they may have come through in the high school setting case years of feeling like they're not good at math, they can't do it. They've never been successful… the greater idea is sort of building on identity. And the social sense is like, why do we believe the things about ourselves as humans, as math students as all those things, and where do those beliefs come from, whose voices have formed those beliefs and who's been neglected?

Mr. Vandelay's reflection on his assessment practices illustrate the value of empowering students to evaluate themselves and illustrate his questioning of evaluation systems in school.

In addition to photograph's Ms. Dougherty shared another artifact, which was a Desmos activity for engaging students in self-reflection of their learning and self-assessment to transfer autonomy and agency to her students.

> … I've been working toward a gradeless classroom, and I know that that's sort of a whole different topic, but, for me, the gradeless classroom is really part of rough draft math, because I really want the students to have that idea of judgment being removed from their thinking. So, each week I have the students go through a reflection... it's this constant balance between letting them know like, "Hey, yeah, I am in the room, and I am the teacher, but you have control of your learning. Own it, make it what it is."

Mr. Vandelay and Ms. Dougherty's enactments and motivations illustrate that assessments are a type of teaching practice that can be enacted in different ways for different reasons. If we contrast their assessment practice of student self-assessment with the activity of test corrections shared by Ms. Green and Ms. Apple, both sets of teachers enacted rough draft mathematics, but Ms. Green and Ms. Apple wanted students to reach perhaps an externally determined learning destination, while Mr. Vandelay and Ms. Dougherty wanted to empower their students.

Discussion

As Berland and Reiser (2011) discussed, variations in teachers' enactments of an ambitious teaching practice can be understood as variations in relative emphasis of different components of a practice, perhaps emphasizing different goals. One difference between enactments of "rough draft math" was indicated by participants' talk about assessments. Some teachers reported that they engaged their students in test revisions to help their students achieve a "final draft" understanding through revising errors. In contrast, other teachers said that they engaged their students in self-assessment to promote students' agency and autonomy. Tensions between goals are possible, such as a goal of empowering students and a goal of promoting learning through revising. Some teachers may intend for students to revise to achieve a final draft, or a pre-determined understanding, which could reflect either the discipline of mathematics or the teacher as an authority. Other teachers may want students to have a voice in not only whether they learn, but what and how much they learn, as a part of their efforts to empower students.

Future research could investigate how teachers can cultivate interest in and facility with enacting "rough draft math." We focused this study on teachers who reported a high level of interest in enacting "rough draft math." An analysis of the goals that teachers reported for enacting "rough draft math" can provide promise in generating greater uptake of the practices, as teachers could be encouraged to enact "rough draft math" if they gain awareness of the range of goals they can achieve. A contribution of this study is that understanding how these teachers enacted "rough draft math" provided insight for starting points teachers might take to learn to enact ambitious teaching; teachers could consider the goals they want to achieve and learn about possible enactments that could help them achieve these goals.

Additionally, future research could observe enactments of "rough draft math," in contrast to this study, which focused on teachers' self-reports. Observations of enactments would allow for characterizing collective practices of drafting and revising, which could provide insight into collective understandings generated and ways that students engage and participate. However, studying teachers' self-reports provides insights into teachers' goals through their voices as well as which enactments they value in pursuit of these goals.

A contribution of this study is the illustration of how ambitious mathematics teaching can vary in its enactments. Although all participating teachers reported a goal of promoting students' dispositions and enactments by encouraging a culture of drafting, they varied in their emphasis of goals to (a) learn through revising and reflecting or (b) to empower students. Additionally, results illustrated how varying goals for enacting ambitious mathematics teaching could potentially be in tension. These results contribute to building a knowledge base for how mathematics teachers can put "rough draft math" into practice.

FUNCTIONAL CONCERNS THAT SHAPE TEACHERS' IN-THE-MOMENT DECISION-MAKING

Lara Jasien
CPM Educational Program
larajasien@cpm.org

Lisa Amick
University of Kentucky
lisa.amick@uky.edu

As a field, we have a limited understanding of what teachers do, what motivates them, and how they learn (Kennedy, 2016). Here, we develop a grounded framework of inquiry-based teaching in mathematics classrooms by beginning with primary evidence of teachers teaching. We seek to articulate an evidence-based account of teachers' functional (rather than aspirational) concerns so that those who support teachers — such as curriculum writers, professional learning specialists, coaches, and teacher educators — can ground their support in the realities of the work of teaching. Our research question is: "What are the functional concerns that shape teachers' decision-making in-the-moments of teaching?".

Keywords: Curriculum, Instructional Activities and Practices, Instructional Vision, Professional Development.

Vignette:

At the non-profit Mathematics Education Program *(*MEP*, pseudonym), the curriculum writing and professional learning teams frequently debate the question, "Where does the writing stop and the professional learning begin?" This is a problem of practice for them. When the writing team designs curricular features that are meant to support equitable outcomes for students, but the professional-learning team sees these curricular features being subverted in practice such that instruction does not actually change, then who is responsible for supporting teachers to enact the curriculum differently? How can these curriculum writing and professional learning teams bridge the ideals designed into the curriculum with supporting teachers to enact those ideals?*

The constraints teachers face in their local and institutional contexts of school as a workplace make answering these questions a perpetual challenge not just for MEP but for mathematics teacher educators, curriculum writers, professional learning specialists, coaches, and teachers everywhere. This is not surprising given the well-documented literature on intended versus enacted curriculum (e.g., Remillard 2005, 2014; Stein et al., 2007). Teachers have a lot to manage at multiple scales: over the span of a course, a unit, a lesson, and even within small group interactions (Ball & Cohen, 1996; Cohen, 2011; Ehrenfeld & Horn, 2020). The decisions that teachers make at each of these scales are consequential for students' learning. These decisions are big and small, conscious and unconscious. Surprisingly, these decisions often do not align with teachers' espoused beliefs about what good teaching looks like (Fang, 1996). This presents a challenge for those designing curricula and professional learning for teachers: Even if teachers know what equitable and ambitious instruction looks like and describe their practice as aligning with their beliefs about equitable and ambitious instruction, this alignment too often is not evidenced in observation. The example from MEP begins to make more sense. The problem of supporting teachers to shift their practices is not only a perpetual problem faced by MEP but is endemic to educational change.

To support teachers in making different decisions, researchers have developed reflection tools for use in professional learning and teacher education. For example, the Teaching for Robust Understanding (TRU) framework helps teachers think about dimensions of classroom activities that might serve as levers for change, helping them to be more reflective about their practice, thus more intentional, and, hopefully, more equitable in their decision-making (Schoenfeld, 2019). Other resources for teachers' decision-making are action-based, such as Smith and Stein's (2008) description of 5 Practices for orchestrating whole class mathematical discussions. Such tools are most helpful for instructional decisions made in the planning stages of instruction. In-the-moment decisions are much more difficult to influence because of the complexity and dynamism of classroom ecologies (Pfister et al., 2015). Likely because frameworks like TRU and the 5 Practices provide aspirational visions of mathematics instruction that focus on ideal models, their descriptions do not quite capture the complexity of decision-making in teaching mathematics. The simplicity of aspirational frameworks is useful for supporting teachers to try new things; yet, teachers still struggle with student-centered teaching.

Currently, our theories of and designs for teacher learning are based more on aspirational, ideal types than on nuanced, evidence-based understandings of what teachers do, what motivates them, and how they learn (Kennedy, 2016). Here, we develop a grounded framework of inquiry-based teaching in mathematics classrooms by beginning with primary evidence of teachers teaching. We seek to articulate an evidence-based account of teachers' functional—rather than aspirational—concerns so that those who support teachers, such as curriculum writers, professional learning specialists, coaches, and teacher educators can ground their support for teachers in the realities of the work of teaching. Our research question is, *What are the functional concerns that shape teachers' decision-making in-the-moments of teaching?.*

Conceptual Framework: Functional Concerns as Lived Pedagogical Responsibility

Recently, teachers' decision-making has been described through a tripartite model of pedagogical judgment (Horn, 2020), including dimensions of pedagogical action, pedagogical reasoning, and pedagogical responsibility. Pedagogical action describes the choices teachers make, whether intentional or not. Pedagogical reasoning is the logic behind these actions—the same action may be done for many different reasons. Pedagogical responsibility involves teachers' sense of obligations to ethical principles or to situational constraints such as mandates from administration. Together, these constitute the pedagogical judgment that informs teachers' decision-making.

Teachers' functional concerns involve a practical sense of pedagogical responsibility. Functional concerns are pragmatic in that they focus on elements of instruction that are within teachers' control. For example, teachers might feel an obligation to support learners' retention and transfer of content, but they focus their attention—their concern—in-the-moments of teaching on creating coherent and relevant mathematics experiences. In this way, learners' retention and transfer may be goals that emerge from teachers' sense of pedagogical responsibility, as distinguished from the phenomenon of interest here: teachers' concerns.

Teachers' functional concerns are pragmatic and grounded in teachers' lived experience of their work. There is no widely accepted theory or characterization of what teaching is or should be — teachers can view themselves as managers, mediators, actors, salespeople, role models, empowerers, and more (Kennedy, 2016). This is likely shaped by teachers' identity and experiences outside of teaching but is also likely shaped by local school and department cultures, as well as by the curriculum used.

As noted in the opening vignette and evidenced through mathematics education research (Remillard 2005, 2014), curriculum shapes but does not determine teacher's pedagogical activities. Depending on teachers' conceptual understanding of their work, it is quite possible to use a curriculum intended for inquiry in ways that reduce cognitive demand and short circuit opportunities for productive struggle. At the same time, curriculum likely does influence teachers' conceptual understanding of their work, as curriculum is one of the factors that shape school as a workplace (Kennedy, 2010; Jackson, 1968; Moore Johnson et al., 2012). For example, if the local curriculum is designed to get students to produce quick and correct answers on multiple-choice items, teachers' conceptual understanding of their work is likely shaped in ways that are unproductive for student learning.

Theoretical Framework: Conceptual Practices constitute Functional Concerns

Teachers' work is composed not just of a series of pedagogical actions but of conceptual practices — pedagogical actions and the meaning behind them. Examples of conceptual practices include building on student thinking, seeking correct answers, and offering mathematical choice.

From a situative perspective of learning, concepts are not ideas in a person's head, they are conceptual practices — "recurring patterns of purposeful activity that are distributed over people and technologies" (Hall & Horn, 2012, p. 241) in particular practices. Practices, simplistically explained, are activities and routines carried out for a particular taken-as-shared purpose with taken-as-shared meanings in a particular community (Lave & Wenger, 1991) and learning is "an active process of distributing cognition over people and things" (Hall & Horn, 2012, p. 214). Thus, conceptual practices are inextricably connected to the environments in which they take place. In teaching, conceptual practices are tied to curricula, local and national educational policies, departmental cultures, communities served, and more. Still, as mid-level concepts in teaching, teachers' conceptual practices are "more general than a particular set of actions taken in the specific context" with implications for learning that are "better instantiated (and thus more testable) than those of the more familiar Theories of education and psychology" (Lehrer & Schauble, 2004, p. 637-638).

Figure 1 offers a visualization of our conceptualization of conceptual practices as mid-level concepts in teaching. Pedagogical responsibility (part of Horn's tripartite of pedagogical judgment) is depicted as being composed of both functional and aspirational concerns, though the boundary between them is perhaps fuzzy and overlapping. Functional concerns — the topic of this manuscript — are composed of related, distinct, yet minimally overlapping conceptual practices. Each conceptual practice is composed of multiple teacher actions, represented by star shapes. The same teacher action may appear in multiple conceptual practices. Teacher actions contribute to particular conceptual practices based on the context in which the action occurs: It depends on the meaning behind the action.

Figure 1. Illustration of the relationship between pedagogical responsibility, functional concerns, conceptual practices, and teaching actions, with stars representing teacher actions.

Research Design

The mathematics curriculum used by teachers in this study was an inquiry-based support course from MEP that foregrounded student exploration, sensemaking, and relationship building. The course was ungraded and emphasized big ideas in algebra, leveraging technology to support student collaboration on complex mathematical ideas. Because inquiry-based support courses are the exception rather than the norm, the findings of this analysis should contribute to a better understanding of what it means to teach in such courses, and thus also support more nuanced understandings of how to support teacher learning.

Studying teachers' functional concerns in an inquiry-based support course is timely. In a 2019 ProQuest Social Sciences Premium Collection database search for "math*" AND "intervention" or "double dose" AND "inquiry" or "reform", only 177 peer reviewed articles in scholarly mathematics education journals were found. Of those, only 20 focused on middle and high school; and of those, only two contained research relevant to the current study on teachers' in-the-moment work of teaching (Johnson, 2001; Marshall et al., 2011).[1] In addition, because this is an inquiry course, the findings should also be relevant to teachers not in support courses but teaching heterogeneous (i.e., mixed-ability) classrooms.

Curriculum

The curriculum context for the teachers in this study was the *Big Ideas* (pseudonym) curriculum from MEP. It was designed based on a developing theory of action grounded in the assumptions of equitable, ambitious mathematics instruction: that all students can engage meaningfully in mathematics in ways that are personally and socially empowering, and that such meaningful engagement begins with enjoyable mathematical experiences in which students can exercise high levels of personal agency. Given this, the features of *Big Ideas* target four anticipated student outcomes: (1) increased engagement in and communication about mathematical sensemaking, (2) positive dispositions towards mathematics, (3) learning grade-level mathematics, and (4) stronger teacher-student relationships. Two lessons were observed in this study. Lesson 3.2 — WHEN WILL IT STOP? Representing Data with a Graph — required students to physically experiment with dropping a ball and recording their observations in Desmos. Lesson 4.11 — CAN YOU STAY ON THE PATH? Lines of Best Fit — required students to explore by plotting lines to stay in certain uncolored regions of a graph in Desmos.

Participants

We collected data from six teachers: Ms. Brewers, Ms. Ennings, Ms. Holder, Ms. Padshaw, Ms. Shea, and Ms. Walker (pseudonyms). These teachers taught in different regions across the United States in schools with different departmental cultures and serving different kinds of communities. The teachers' years of experience spanned from three years to twenty years. All teachers taught grade-level mathematics courses in addition to teaching *Big Ideas*.

Data Collection

Data collection aimed to capture teachers' talk, gestures, and movement through the classroom. Data include Swivl video-records of observations of six teachers from different locations across the United States teaching the same two lessons described above. Each lesson

[1] The other 18 articles returned in the search fell into categories of identifying the effectiveness of intervention (10) and the impact of policy (1), descriptions of interventions (2), the development of student thinking (1) and mathematical interest (1), historical overviews (1), the impact of course trajectories on career paths (1), and a discussion of methods of randomized trials (1).

was followed by a video-recorded debrief with a curriculum coach. These debriefs focused on teachers reflecting on how the lesson went, with coaches acting as thought partners rather than advisors. In addition, teacher interviews were conducted at the beginning and end of the year, but these data are not included in this analysis as interview data tended to illuminate teachers' aspirational concerns.

Data Analysis

To understand the work of teaching from teachers' perspectives, we used grounded theory's constant-comparative methods (Strauss & Corbin, 1990) and made close-to-data inferences about teachers' functional concerns in inquiry-based mathematics classrooms by looking at what was stable and variant across six teachers' enactments of and reflections on two of the same lessons.

Phase 1: Parsing the data. In the first round of analysis, we created time-indexed content logs (Derry et al., 2010) for classroom videos and teacher debriefs with their coaches. Then, we looked for recurring teacher actions — for example, circulating with and looking at the teacher's computer while talking to student groups, walking away from student groups when they have stated a correct answer (sometimes without saying anything), referencing a lesson plan, or reminding students of particular participation norms. We also attended to outcomes of these actions that seemed to satisfy teachers, allowing us to infer meaning behind the actions. We noted, for example, the ways in which teachers organized and set norms for participation structures, cared for relationships between themselves and students and between students, and held themselves and students accountable for pacing.

Phase 2: Narrating emergent themes. From the content logs of both debriefs and classroom videos, we generated descriptive, narrative memos (e.g., Cobb & Whitenack,1996; Powell et al., 2003) organized by themes for each lesson for each teacher. These themes (such as emphasis on individual students' math history and modeling curiosity) were not determined a priori, but rather were emergent from and closely tied to what became salient as we parsed each teacher's lessons and debriefs. Sometimes this process required going back to the video record to clarify or gain more nuance on a teacher's instruction.

Phase 3: Identifying conceptual practices. After identifying themes in each lesson for each teacher, the themes were compared and collapsed into broad descriptive categories (Strauss & Corbin, 1990). Collapsing qualitatively different kinds of pedagogical activities happening across the teachers allows their common conceptual practices of teaching that can be leveraged for more ecologically valid forms of professional development. We then looked through the content coded under each emergent conceptual practice and engaged in a process of defining each conceptual practice, selecting a spectrum of examples for each. This process allowed us to see how conceptual practices were both unique and related.

Collapsing conceptual practices into functional concerns. The Phase 3 examination of the distinctness of each conceptual practice resulted in four clusters of conceptual practices, with each cluster constituting a functional concern in teaching inquiry-based mathematics.

In our constant comparative analysis of six teachers teaching the same two lessons at different points in the year, we identified 15 conceptual practices. These 15 conceptual practices (codes) represent the daily work of teaching; they are inferred meanings of what teachers do and say (activities, not actions). While distinct, these conceptual practices are also related to each other, clustering together to support four overarching concepts/concerns in teaching inquiry-based mathematics.

Findings

The six teachers in this study came from different contexts but shared the same curriculum. We found that four functional concerns adequately described many of the different decisions teachers made across their classrooms. The overarching functional concerns are all mathematics teaching specific, but also differently emphasize concerns about mathematics or students. The four functional concerns were identified by examining clusters of codes that represented 15 emergently identified conceptual practices (Table 1). Most of these conceptual practices play into multiple functional concerns, including across more strongly mathematics- and student-centered concerns. The conceptual practices are located under the functional concern they most heavily constituted in the data, not the only functional concern they constituted.

Table 1. Teachers' functional concerns in the moments of teaching and the conceptual practices that most heavily constitute them

Functional Concerns	Key Conceptual Practices
Mathematical Correctness and Completeness *How can I make sure that student work is accurate, thorough, and finished?*	● Seeking final answers on a task or sub-task ● Navigating student uncertainty ● Assessing student progress ● Redirecting students' mathematical thinking ● Building on students' mathematical thinking
Mathematical Relevance and Coherence *How can I make sure that mathematics is meaningfully connected to students' prior knowledge and lives?*	● Generalizing mathematical strategies ● Connecting mathematics ● Connecting mathematics to everyday life ● Offering mathematical choices
Student Motivation *How can I make sure that students are interested enough to get started and to persevere through uncertainty and confusion?*	● Offering non-mathematical choices ● Attending to student confidence (high inference) ● Caring for relationships (high inference)
Student Access *How can I make sure that students can get started on the task and that struggle stays productive?*	● Unpacking the task ● Setting participation norms ● Organizing materials and student bodies

An abbreviated illustration of the functional concerns

Importantly, these functional concerns are neither positive nor negative. They look very different in their manifestations across the six teachers in our study. Table 2 provides example teaching profiles to illustrate how each functional concern looked different across the six teachers of this study. The table presents one conceptual practice for each teacher under each functional concern. Looking down each column provides a glimpse into the teachers' practice and looking across the rows provides a glimpse into the diversity with how conceptual practices manifest as teachers navigate their functional concerns.

Table 2. Teacher Profiles along the four functional concerns.

Brewer	Ennings*	Holder*	Padshaw	Shea	Walker*
Mathematical Correctness and Completeness					
Presses Ss** to build on their thinking by asking questions	Asks Ss questions but does not press for explanation	"Plays" a hot- and -cold game to get Ss to the correct answer	Prioritizes sensemaking over getting through the lesson and so rarely gets to closure	Accepts incorrect answers as correct and supplements with extra practice	Asks Ss to share strategies in a whole class but does not ask for connections
Mathematical Relevance and Coherence					
Asks Ss what they already know about the lesson's topic to connect to their prior learning	No evidence of connections across mathematics or daily life	References prior lessons to elicit transfer on discrete problem steps	Asks Ss what they already know about the lesson's topic to open up a pre-lesson	Creates spontaneous mini lessons to mathematize students' lives	Tells Ss about connections to prior lessons by mentioning the lessons
Student Motivation					
Expresses interest in Ss' mathematical intuitions	Expresses care for Ss through kind voice and personal greetings to students	Creates sense of urgency by using Desmos teacher dashboard during circulation	Highlights Ss' mathematical ideas and mistakes as interesting and valuable	Offers non-mathematical choices such as whether the lights should be on or off	Slows pacing to account for a perceived mismatch between ability and rigor
Student Access					
Explicitly reminds small groups of how to collaborate during every interaction	Gives students participation directions at the beginning of the task	Tells students to collaborate and addresses individual students	Pre-teaches mathematical ideas and explicitly reminds Ss of participation norms	Gives extensive directions for sometimes up to five minutes	Gives explicit participation directions but is unprepared with resources

*one observation only, **Ss = students

As is evidenced in the table, these functional concerns are not ideals but instead can look quite different in practice. Contrasting Ms. Brewer's and Ms. Shea's columns particularly highlights how differently teachers can enact these functional concerns. Being aware of the multiplicity of ways that teachers work to address these four functional concerns is critical for anyone striving to support mathematics teachers.

At the same time as the individual functional concerns are not ideals, these functional concerns as a set are not an ideal model. There is no particular emphasis or balance that everyone needs to follow; however, a simple thought experiment reveals that missing any one of these functional concerns may lead to inequitable teaching practice. For example, an overemphasis on student access and motivation and a lack of attention to mathematical correctness and completeness is often described as a characteristic of classrooms where teachers have low expectations of students' abilities. An overemphasis the other way around, for example, can describe classrooms with a "no excuses, zero tolerance" classroom culture. In such classrooms, little effort is made to meet students where they are. Productive teaching profiles can be described with all four functional concerns, although the distribution of the conceptual practices that teachers spend their time on can look very different.

Conclusion and Implications

The four functional concerns identified are not what we as educational researchers consider to be ideal. To harken back to the opening vignette, the writing team at MEP would not write curriculum to support teachers to focus on student correctness and completeness. While correctness and completeness are valued by MEP, MEP also understands that they are often overvalued in the classroom. Thus, the curriculum writers prioritize supporting teachers to focus on students' processes of collaborative problem-solving. Still, ignoring teachers' institutionally shaped functional concern for correctness and completeness presents a problem for teachers and the professional learning specialists who support them in the classroom. But, if teachers already focus on correctness and completeness, why do materials need to account for it rather than work around it? The evidence from this study suggests that even teachers using an ungraded inquiry-based curriculum and who have had a plethora of support from professional learning specialists still focus on these four functional concerns.

Because of this we argue that teachers' practical sense of pedagogical responsibility needs to be attended to in designs for learning. By attended to, we do not mean designed-out (e.g., preventing teachers from focusing on correctness), but instead, designed-in such that teachers can clearly see how these four functional concerns will be met. Since teachers will meet these functional concerns in many different ways when left to their own devices (often determined by apprenticeship of observation, Lortie, 1975), it is critical that our aspirational, idealized forms of instructional practice are designed-in through a lens of functional concerns. We wonder: Could designing curriculum, professional learning opportunities, and teacher education with these functional concerns and their conceptual practices in mind — in addition to aspirational concerns such as those articulated in the TRU framework and the 5 practices — help bridge the gulf between the ideals designed into curricula and the realities of teachers' ability to enact those ideals in the constrained contexts of school-as-a-workplace?

RELATIONSHIP BETWEEN DISCOURSE AND STUDENTS' EVALUATION OF STRATEGIES TO SUBTRACT FRACTIONS WITH MIXED NUMBERS

Kristy Litster
Valdosta State University
klitster@valdsota.edu

Beth L. MacDonald
Illinois State University
blmacd1@ilstu.edu

This mixed methods study explored the relationship between two types of small-group mathematics discourse (Reflective and Exploratory) and the quantity and type of strategies discussed. The study focused on 97 fifth-grade students, organized into 34 small groups (17 Reflective, 17 Exploratory) and the strategies they used to solve two problems (4 ½ - 3 ¾; 4-3 ¾). Results indicated that both discourse types can encourage student evaluation of multiple computational strategies. However, several factors seemed to increase or decrease the strategies discussed. In exploratory discourse, the student in the group writing the answer may limit discussion by solving the problem themself. In reflective discourse, when students all agreed on the same answer they were less likely to discuss any strategies. For both discourse types, dissonance in answers or strategies often prompted the discussion of multiple strategies to determine accuracy.

Keywords: classroom discourse; number concepts and operations; elementary school education

Factions are one of the most difficult areas for elementary students, as well in-service elementary teachers, and prospective teachers, possibly due to limited abilities to mentally represent fractions and how these mental representations relate to computational procedures (Gabriel et al., 2013; Litster, MacDonald, & Shumway, 2020). Mathematics teacher educators (MTEs) can support a deep conceptual understanding of fractions through emphasizing multiple ways of solving fractional computations (AMTE, 2017; NCTM, 2014). Learning multiple computation strategies in isolation can increase student confusion, however comparing and contrasting fraction algorithms side-by-side for the same problems or problems that differ in small but import ways may help reduce misconceptions and deepen student understanding (Newton, Willar, & Teufel, 2014). Mathematics discourse is one strategy that MTEs can use to encourage their students to evaluate a variety of computational procedures for the same or similar problems (Wachira et al., 2013).

Theoretical Perspective

Discourse can impact student retention of learning and transfer of learning to novel situations in three ways (see Fig. 1). First, it has the potential to increase opportunities to learn by promoting higher levels of cognitive demand through reasoning and justification of solution strategies (Litster, 2019). Second, it has the potential to help build the automaticity of subskills by chunking fragmented schema in long term memory for easier retrieval (Sweller & Mayer, 2015). Third, it can help refocus the sophistication of student strategies from surface to structural similarities (Georgius, 2014; Schoenfeld, 2018).

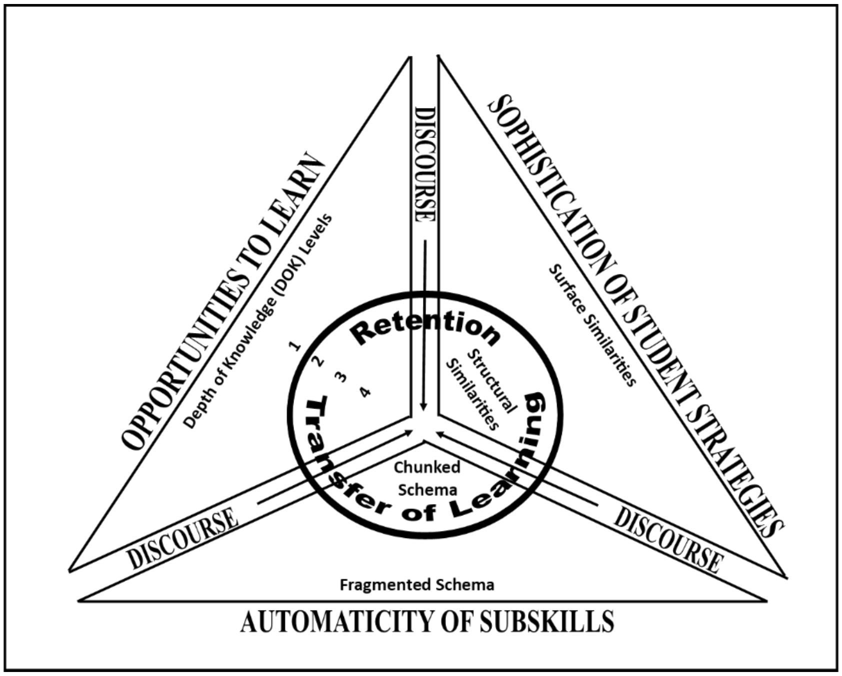

Figure 1: Influence of Discourse on Retention and Transfer of Learning

This study focuses on this third side of the triangle, sophistication of student strategies. When students develop a deeper conceptual understanding of fractional operation strategies, their retention is improved and they are more likely to transfer and apply this understanding in novel situations (Sidney & Alibali, 2015; Uttal et al., 2013). Siegler and Svetina (2006) explain that students are more likely to change their strategy only if the new strategy increases accuracy or efficiency. Novices may work backwards from a solution to identify their strategy whereas experts often work forward and tend to leave out important steps (Feldon, 2007). Discourse provides opportunities for students to see the value of new strategies as students share logical arguments around their strategy choices, which can not only focus students towards relational strategies, but also provide opportunities for chunked schemas. These discussions can also promote students to look at the structural similarities and differences between strategies.

MTEs can organize student-directed mathematics discourse in one of two ways. First, MTEs can group students into cooperative learning groups where students engage in exploratory discourse to collaboratively solve a mathematics task (Rojas-Drummond & Mercer, 2003). As students work together, they may share and evaluate a variety of strategies they may not have considered on their own to solve the problem or check their answer in order to quickly dismiss inaccurate or inefficient strategies. This co-construction of learning through explanations, redefinitions and interactions may promote a deeper understanding for multiple strategies (Wachira et al., 2013). However other researchers contest that an imbalance of power dynamics within a group engaging in exploratory discourse may limit student involvement which would decrease the strategies evaluated by the group (Walter, 2018).

Second, MTEs can provide time for students to engage with the task individually and then engage in reflective discourse using strategies such as the “Think-Pair-Show-Share” model to compare answers and strategies (Hunt et al., 2018; Walter, 2018). Time to think individually provides opportunities to evaluate potential strategies to solve the problem and write down ideas to bring to the group discussion, which can create more equitable opportunities to clearly explain their thinking for a variety of strategies (Kalamar, 2018). However other researchers contest that waiting until after the task is complete results in cumulative talk, meaning students agree with one idea and do not discuss other strategies (Rojas-Drummond & Mercer, 2003).

The purpose of this study was to evaluate the quantity and types of strategies discussed when fifth-grade students engaged in exploratory discourse (solving and discussion problems together) and reflective discourse (solving problems individually and then discussing solutions) for two related subtraction fractions problems with mixed numbers.

Methods

This mixed-methods study is part of a larger study where 97 fifth-grade students, organized into 34 small groups engaged with two real-world task-sets involving operations with fractions and decimals, for a total of 26 tasks (Litster, 2019). This study takes a closer look at student discourse relating to one of the tasks in the Harry Potter Task-Set (Task H5) to help answer the research question: What is the relationship between each discourse type (exploratory and reflection) and the quantity and types of subtraction fractional computation strategies discussed by fifth-grade students?

Participants and Procedures

Four fifth-grade classes participated in this study. The researcher organized discourse for the Harry Potter Task-Set so that half of the students (2 classes, 17 groups) engaged in exploratory discourse while the other half (2 classes, 17 groups) engaged in reflective discourse. Groups engaged in exploratory discourse were given all 13 problems in the Harry Potter task set which compares different aspects of success for the book and movie (e.g., ticket/book sales and ratings) and asked to work together to solve the problems. Groups engaged in reflective discourse were given the same problems in three separate chunks of blocked time, allowing students to work on one set of problems independently (e.g., H1-H4 on ticket/book sales) and then discussing that set of problems before working independently on the next set (e.g., H5-H9 on book/movie ratings).

Data Source and Analysis

The two main data sources in this study were students' written work and verbal discourse relating to problems 5b and 5c from the H5 task. In problems 5b and 5c (Fig. 1), students were asked to compare the difference between the average reviewer ratings for the Harry Potter and the Half-Blood Prince movie across multiple websites (i.e., Barnes & Nobles, IMDb, Amazon, iTunes, Rotten Tomatoes).

***Harry Potter & the Half Blood Prince* – Movie Adaptation**	
Source	**Average Rating (out of 5 stars)**
IMDb	$3\frac{3}{4}$
Rotten Tomatoes	$3\frac{3}{4}$
Amazon	$3\frac{3}{4}$
Barnes & Noble	$4\frac{1}{2}$
iTunes	4

5b. Compare the **difference** between the average Barnes & Nobles rating and the average IMDb rating.

5c. Compare the **difference** between the average Amazon rating and the average iTunes rating.

Figure 1: Task H5, Sub-questions 5b and 5c.

The researchers analyzed the data in three phases. First, they qualitatively coded video data to identify the types of strategies discussed by each of the 34 groups of students (Saldaña, 2015). One student in each group wore a Go-Pro camera on their chest which captured the audio and visuals for their group discussions. Students' written work (task sheets and scratch paper) was also used in this phase to verify the notations used in the discussed computational strategies. Second, the number of unique strategies were quantitatively counted to identify the number of strategies discussed by each group. Third, students' written work and verbal discussions were coded to identify any patterns that may contextualize the quantitative results.

Results

Qualitative results relating to the types of strategies identified six unique strategies discussed by students to solve Task H5. Figure 2 illustrates and explains five strategies students discussed relating to Sub-task 5b while Figure 3 illustrates and explains these same five strategies as well as a sixth unique strategy groups discussed relating to Sub-task 5c.

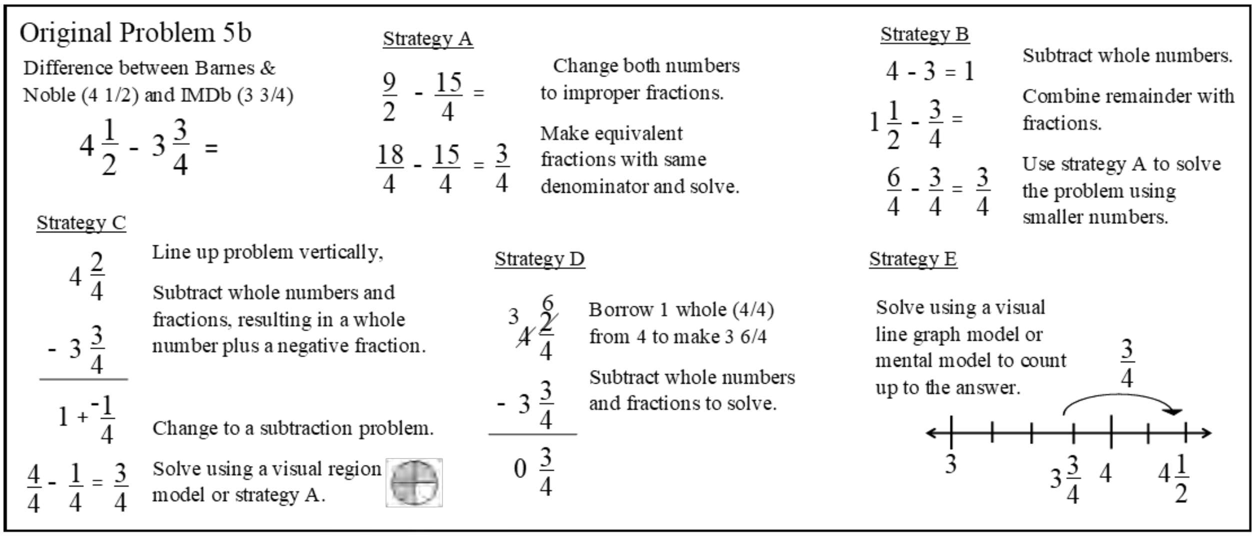

Figure 2: 5 Strategies Discussed Relating to Sub-task 5b.

As seen in Figure 2, Strategies A and B focus on procedures using equivalent fractions and the conversion of mixed numbers into improper fractions to subtract and solve the problem. Strategy C uses negative number and the relationship between addition and subtraction to solve the problem. Strategy D uses the subtraction procedure to "borrow" from whole number in order to subtract and solve the problem. Strategy E uses a number line or a mental model to count up to the answer.

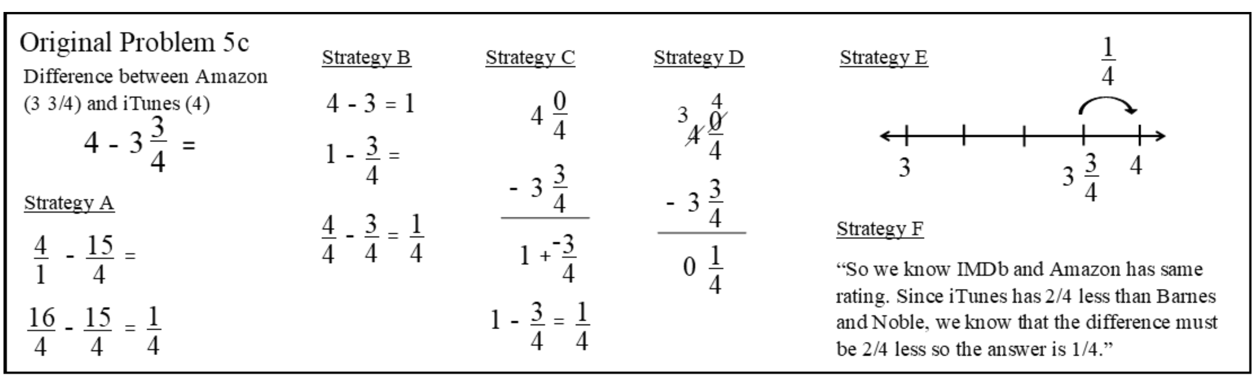

Figure 3: 6 Strategies Discussed Relating to Sub-task 5c.

As seen in Figure 2, the same five strategies discussed for sub-task 5b were also discussed for sub-task 5c. Additionally, some groups used a new strategy (F) to solve this sub-task, which involved using relational differences between the quantities in Problem 5b and 5c to mentally calculate the results.

Quantitative results identified several patterns between frequency and type of strategies discussed for each discourse type. Table 1 shows the frequency count of unique strategies discussed per group. A "0" for reflective indicates groups confirmed an answer only and did not discuss a specific strategy. "0" for exploratory indicates one student completed the task for the group independently, without discussing their strategy.

Table 1: Frequency Count of Unique Strategies Discussed per Group

	Reflective (N=17)		Exploratory (N=17)	
Strategy Count	5b	5c	5b	5c
0	4	7	1	2
1	5	2	10	8
2	5	6	3	5
3	3	1	1	2
4	0	1	2	0

As seen in Table 1, groups engaged in exploratory discourse were more likely to discuss at least one strategy; however reflective groups that did discuss strategies were more likely to discuss more than one strategy.

Table 2 shows the frequency count for the number of groups that discussed each strategy. In this table, columns do not equal the number of groups as the number of strategies discussed varied from group to group. N=Max possible number for each cell.

Table 1: Frequency Count of Unique Strategies Discussed per Group

	Reflective (N=17)		Exploratory (N=17)		Total (N=34)	
Strategy	5b	5c	5b	5c	5b	5c
A	6	6	10	11	16	17
B	3	3	7	9	10	12
C	1	1	2	1	3	2
D	1	1	3	0	4	1
E	3	5	3	5	6	10
F	0	2	0	1	0	3

As seen in Table 2, the three most common strategies across both groups were the two more traditional strategies, A (N=16/17) and B (N=10/12), as well as the visual strategy E (N=6/10). Additionally, similar strategies seemed to be discussed from one sub-question to the next.

The qualitative examination of student work showed that every strategy on the individual scratch paper for students in exploratory groups was discussed. However, only one reflective discourse group had every student in the group use the same strategy to solve problem 5b or 5c. This means that most reflective discourse groups had the potential to discuss 2-3 different fraction subtraction strategies. Unfortunately, an examination of verbal discourse showed that students were less likely to discuss the strategies used by students in the group when everyone agreed on the answer (e.g., "So I got 3/4." "Yep, me too and the next one is 1/4.") (see Table 1, strategy count 0). Only three reflective discourse groups where everyone agreed on the answer discussed all the different strategies they used to solve problems 5b and 5c. Instead, differences in answers for 5b and 5c prompted a discussion about the mathematics and student strategies. For example, when a reflective discourse group had different answers to a problem, their first action was usually a comparison of strategies to identify any errors within the procedures. Excerpt 1 below shows one example of students comparing strategies after having a difference in answers.

Matt: On this one [Q5b] I got 1 1/4
James: I got 3/4.
Matt: It's bigger cause 4 minus 3 is 1 and 3/4 minus 1/2 is 1/4. **[inaccurate Strategy B]**
James: You change that [pointing to 4 ½] to 4 2/4, which is 3 6/4 minus 3 ¾ [**Strategy D]**
Matt: Oh yea [changes answer to 3/4]
[Video 150H3, Time Stamp 5:21-5:37]

In Excerpt 2 below, a student in a reflective discourse group fixed their own mistake while sharing their strategy for the same problem.

Troy: I did 3/5
Laney: The ratings are a ¾ difference.
Adam: Yep. Did you change the denominators so [point 18/4 – 15/4 = ¾ on paper] [Strategy A]
Troy: [pointing to his paper, where he has 5 circles cut in fourths, with 4 1/2 shaded in and 3 ¾ crossed out, Strategy E] They are all cut up into different pieces and . . . but yea, it would be ¾
[Video 120H3, Time Stamp 7:46-9:23]

In a few cases, when students could not agree on an answer after sharing their own strategies, they turned to a new strategy to check their answer. Excerpt 3 is from an exploratory group that agreed on a general strategy (i.e., subtraction), worked on the problem individual, and then engaged in self-directed reflective discourse to discuss their answers to the same problem.

Anna: Well, look. Difference means subtract, right?
Tonya: Okay
Stacey: And the Barnes and Nobel were 4 ½ and IMBD were 3 ¾
[All 3 students calculating on their own paper]
Tonya: I got 1 3/4
Anna: I am thinking 1 ¼ cause 4 minus 3 is one. . . [Inaccurate Strategy B]
Stacey: [Points to 3 ¾ on her paper] I am usually wrong so . . .
Anna: But 3 ¾ you can't really do that.
Stacey: Yeah, but 3 ¾ we change this into a fraction and change this into 4 and times by 4 and make an 8 so . . . [Inaccurate Strategy A]
Tonya: But 4x4 is 16.
Anna: Oh yea, so even I got it wrong.
[All thinking]
Tonya: Look guys, 1, 2, 3 [pointing to number line] [Strategy E]
Stacey: Okay, so ¾ then.
Anna: So it would be ¾.
[Video 320H2, Time Stamp 3:22-12:22]

Five of the 17 Exploratory Discourse groups used this method to solve tasks H5b and H5c. The remaining exploratory discourse groups (n=12) worked through the problem together, sharing a single pen. The student holding the pen usually initiated which strategy their group used to solve the problem. Exploratory discourse groups were more likely to discuss multiple strategies when there was a disagreement on the validity or ease of use for a particular strategy. For example, in Excerpt 4 below, students are solving from H5c. Leah is holding the pen, but Karen has a disagreement on the validity of Leah's mental strategy.

Leah: [thinking, then writes ¼ on the paper]
Karen: But how did you get that, cause you couldn't get it that fast.
Leah: Um I . . [thinking] did it in my head?
Karen : You can't minus it in your head. That would equal [grabs scratch paper and writes 18/4 – 9/4 = 9/4, then converts to 2 ¼] 2 1/4 so how did you do that in your head. Because you have to change it into an improper fraction. This is the Barnes and Nobel one [18/4] and change it to same denominator and then improper. **[Inaccurate Strategy A]**
Bill: But this is the answer [points to 1/4.
Leah: If you take 1 off of it and spread it into 4/4 and then minus 3/4 is 1/4.
Bill: It's basically 4 0/4 – 3 ¾. Subtract wholes then the fractions.
Karen: You can't do 0 minus 3!
Bill: Yea, negative ¾ plus 1. **[Strategy C]**
Karen: But did you minus these? you have got to subtract these [points to 18/4 – 9/4]
Bill: Changing to same denominator would be 16/4 not 18. **[Correcting Error in Strategy A**, on Karen's paper to read "16/4-15/4=1/4"**]**
Karen: But I did the math.
Leah: So 4 minus 3 is 1 and then 4/4 minus 3/4 is 1/4. **[Strategy B]**
Bill: It's the same thing [pointing to the ¼ on scratch paper].
Karen: Yea, okay.
[Video 360H2, Time Stamp 3:27-13:20]

In Excerpt 5 below, Carla, Joy, and Tina used strategy A to complete problem 5b (Joy held pen), but struggled to use the same strategy to complete 5c (Tina held pen).

Joy: So first, find a common denominator [Attempting Strategy A]
Tina: Wait, then how do you turn 4 into a fraction?
Joy: So to keep it a whole number, you draw a line and put a 1 under it.
Carla: What if we subtract the wholes first, like 4 minus 3 is 1. [Strategy B]
Tina: So we would have 1 minus ¾?
Carla: And then times 4
Tina: So 4/4 and then take away ¾ . . . okay, ¼ [writes answer]
[Video 450H3-4, Time Stamp 1:00-3:49, 0:00-0:30]

In Excerpt 6 below, Amy (holding pen) is unsure about how to solve the problem and asks for help, which initiates a discussion on fraction strategies.

Amy: [Reads prompt for H5b out loud] I'm a little bit confuzzled [SIC].
Brit: Ok, so compare the difference, we are subtracting.
Chris: So, so, 4 1/2 minus 3 3/4 is you take the 3 away from the 4 and then you have one left over so 3/4 minus 4 1/2 is three left over **[Strategy B]**
Amy: Wait how is 3/4 minus 4 1/2, 3?

Brit: So, 4 minus 3 is 1 and 1 is 4/4 [draw circle and divides in 4 sections] and half [draws half circle and divided in 2 sections] then you take away 3/4 [shades in 3] and you are left with 3/4. **[Strategy E to Explain Strategy B]**

Amy: I'm a little bit confuzzled but not as much.

Chris: You try the next one [Indicating H5c]

Amy: Okay, one . . .[writes 4-3=1], two . . .[draws circle and cuts in fourths], three . . . [shades in three, writes 1/4 as answer], **[Strategy E]** I did it! Confuzzle over.

[Video 370H2, Time Stamp 5:13-9:58]

As we can see in each of these examples, dissonance created by differences in products (Excerpts 1-3) or processes (Excerpts 4-6) prompted students to move beyond simply confirming or computing answers to discussing the accuracy, reliability, or ease of use for different strategies.

Conclusions

The results in this study confirmed research that both types of discourse (reflective and exploratory) have the potential to encourage students to discuss multiple strategies (Kalamar, 2018; Wachira et al., 2013). They also confirmed fears that one student initiating the discourse in exploratory discourse may limit discussion to a single strategy (Walter, 2018) and fears that students engaging in reflective discourse may engage in cumulative talk (Rojas-Drummond & Mercer, 2003)

The results in this study also add to current research by highlighting factors that may increase or decrease the discussion of multiple strategies. For example, when students all agreed on an answer during reflective discourse, they were more likely to engage in cumulative talk; however, when there was dissonance, or differences in answers, they were more likely to discuss multiple strategies to determine accuracy. Dissonance also prompted the discussion of multiple strategies in exploratory discourse to determine accuracy.

In summary, teachers can use either discourse type to encourage students to discuss multiple ways of solving problems. Teachers may want to require exploratory discourse groups to identify two or more methods to verify their answers in order to encourage students to discuss multiple strategies to solve problems (Kazemi & Stipek, 2017). Teacher may also want to set up discourse procedures to encourage students engaging in reflective discourse to identify similarities and differences in strategies to promote discussions relating to how students solved the problems, beyond confirmation of the answer.

UNDERSTANDING PRESERVICE TEACHERS' NOTICING OF ONLINE TEACHING

Jinqing Liu	Orly Buchbinder	Merav Weingarden

The rapid move to online teaching brought about by the global pandemic highlighted the need for the educational research community to develop new conceptual tools for characterizing these environments. In this paper, we propose a conceptual framework Instructional Technology Triangle (ITT) which extends the instructional triangle of teachers, students, and content to include technology as a mediating mechanism. We use the ITT framework to analyze noticing patterns in the written reflection of a prospective secondary teacher, Nancy, who, over the course of one semester taught online four lessons integrating reasoning and proof . The fluctuations in Nancy's noticing patterns, in particular, with respect to technology, shed light on her trajectory of learning to teach online and the role of reflective noticing in this process. We discuss implications for teacher preparation and professional development.

Keywords: Teacher Noticing, Preservice Teacher Education, Online and Distance Education.

Objectives

The pivotal role of technology in teaching mathematics has been widely recognized and thoroughly researched over the last decades (Ball et al., 2018; Bray & Tangney, 2017; Clark-Wilson et al., 2020; Hillmayr et al., 2020). These studies concerned teachers' classroom practice with technology, teachers' professional development (PD) for teaching mathematics with technology and impacts of technology on mathematics teaching and learning (see Clark-Wilson et al., 2020 for an extensive review). Most of these studies were conducted in a traditional face-to-face setting. Some teaching online has been addressed, but mainly in teacher PD and Massive Open Online Courses (MOOC) (e.g., Taranto et al., 2020). However, the complete and widespread shift to online teaching brought about by the global pandemic caught teachers, students and educational communities off guard (Seaton et al., 2022). In particular, the move to online teaching revealed its the uniqueness in the technology landscape. It also highlighted the need for the educational research community to develop new conceptual and analytical tools for characterizing teaching and learning that occurs in online environments.

In this paper, we propose a conceptual framework *Instructional Technology Triangle (ITT)* which extends the seminal notion of the instructional triangle, which conceptualizes instruction as interactions between teacher and students around particular content, situated in certain environments and time (Cohen et al., 2003; Lampert, 2001). In the context of online teaching and learning, technology becomes both the environment enabling the educational process to occur and the necessary mediator between teachers, students, and content. The ITT framework captures these relationships by placing technology within the instructional triangle.

We developed the ITT framework to capture and characterize noticing patterns of prospective secondary teachers (PSTs) as they reflected on video recordings of their own online teaching. The PSTs participated in the capstone course *Mathematical Reasoning and Proving for Secondary Teachers* where they designed and taught lessons that integrated reasoning and proving within the regular mathematics curriculum (Buchbinder & McCrone, 2020). Due to the pandemic, in Fall 2020, the school teaching component moved online. The PSTs taught via *Zoom*, uploaded the recording to *Canvas* Learning Management System, where they watched and reflected on their teaching. The analysis focused on PSTs' noticing, which is an essential professional skill (Buchbinder et al., 2021; Mason, 2002; Kosko et al., 2021; Sherin et al., 2011). As we analyzed our PSTs' noticing, we were struck by the prevalence of technology-related aspects, their variety, and their change over time. To capture the richness of these data, we developed the ITT framework.

In this paper, we introduce the ITT framework and illustrate its use by analyzing one PSTs' (Nancy, a pseudonym) noticing patterns in four online lessons. We aim to *describe and characterize Nancy's noticing patterns as a way to understand how her learning to teach online evolved over time*. In addition, we triangulate data from multiple sources, such as Nancy's lesson plans, written essays and course materials, to understand possible reasons behind fluctuations in her noticing patterns, in particular with respect to the role of technology.

Conceptual Framework

Reflective Noticing

The concepts of noticing and reflection have been closely intertwined in educational literature dealing with teacher learning and professional growth (Seidel et al., 2011; Moore-Russo & Wilsey, 2014). Amongst many definitions of teacher noticing (Dindyal et al., 2021), in this study, we adopt Stockero's (2021) definition of noticing as comprised of *attending to* aspects of the classroom situation and *interpreting* them. In this study, we consider PSTs' noticing of their own teaching, as they reflect on their own classroom teaching, and use the term *reflective noticing* to describe a process that combines the tacit nature of attending and the goal-oriented nature of reflection (Buchbinder et al., 2021; Liu & Buchbinder, in press).

Teachers' reflective noticing happens with a specific context and is affected by many factors, such as individuals' knowledge, belief, experience (Schoenfeld, 2011), identity (Oyserman, 2009), and instructional practices (Liu et al., 2021; Sherin et al., 2009). Cross Francis et al. (2021) found that teachers' mathematical knowledge for teaching, efficacy, belief, emotions, and identity influenced teachers' noticing of and reflection on students' mathematics thinking.

Reflective noticing supports teachers' professional development because it engages teachers in regulating their attention resources to the teaching aspects that they perceive as important and allowing them to prioritize these aspects. Learning from reflection requires careful and critical deliberation on practice, connecting to theoretical ideas and contemplating takeaways for the future (Anderson, 2019; Wilson, 2008). Thus, it is not surprising that PSTs' reflection on the video-recordings of their own teaching was found to be beneficial to PSTs' professional learning (Buchbinder et al., 2021; Liu & Buchbinder, in press; Walshe & Driver, 2019).

The Instructional Technology Triangle Framework

The instructional triangle is a heuristic structure for describing and characterizing teacher-student-content relationships (Friesen & Osguthorpe, 2018). It highlights the nature of teaching as mutual interactions among teachers, students, and content in environments (Cohen et al., 2003; Herbst & Chazan, 2012; Lampert, 2001; Yeo & Webel, 2017). In a face-to-face setting where teachers or students interact with technology, technology can be understood as a tool or a part of the environment. In an online environment, it is impossible to avoid treating technology as a key factor in learning and instruction. Content is represented through technology, and teachers and students interact with technology and interact with each other through technology (Seaton et al., 2022). Technology is what mediates between teachers-students-content, making the educational process possible. We extend the instructional triangle framework by adding technology as an explicit component of instruction (Figure 1) to foreground the critical role of technology in an online teaching environment.

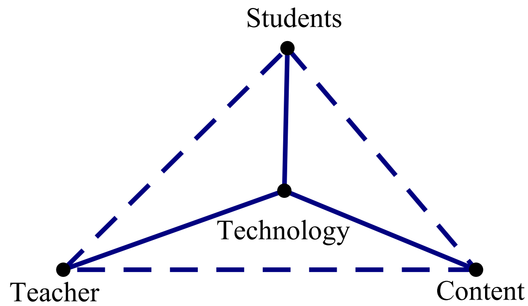

Figure 1: Instructional Technology Triangle Framework

The Instructional Technology Triangle (ITT) framework (Figure 1) considers four nodes: teacher, student, technology, and content and six sets of pair-wise relationships: student-content, student-technology, teacher-technology, teacher-student, teacher-content, content-technology. In the context of reflective noticing, we define the following ten categories. **Teacher -** considers teacher's reflection on their personality, behavioral characteristics like a voice pitch, thoughts, and self-impressions. **Students** - refers to noticing students' behavior and personalities, classroom participation and interactions with peers. **Content** refers to teacher reflection on the mathematics of the lesson and/or a rationale for including a certain content in the lesson. **Technology** involves reflecting on technology as a tool, without relating it to teaching moves or students' mathematical thinking. Noticing of **Teacher-Content** refers to teacher reflection on how they taught a content or made an instructional decision related to content. **Teachers-Students** noticing indicates attending to interactions between the teacher and the students. **Student-Content** describes reflecting on students' mathematical thinking while interacting with or responding to a mathematical question or task. **Content-Technology** refers to teacher's reflection on how technology is useful or not in representing a particular mathematical content; while **Teacher-Technology** describes teacher noticing of manage technology for effective teaching. **Student-Technology** captures the teacher's noticing of students' interaction with technology. We illustrate these categories in depth in the results section.

Methods

The Setting

This study is a part of the larger project that designed a capstone course *Mathematical Reasoning and Proving for Secondary Teachers* and studied how PSTs' mathematical and pedagogical knowledge develops during the course (Buchbinder & McCrone, 2020). The four course modules focused on the following proof themes: (1) direct proof and argument evaluation; (2) conditional statements, (3) quantification and the role of examples in proving, and (4) indirect reasoning. In each module, the PSTs strengthened their subject matter knowledge of the proof themes, learned about students' proof-related (mis)conceptions and then designed and taught to small groups of students from local schools a 50-minute lesson that integrates a particular proof theme with an ongoing topic from the school curriculum. Then, the PSTs viewed the 360-video recording of their lesson and reflected on it (Buchbinder et al., 2021). In Fall 2020, due to the pandemic, the PSTs taught their four lessons online, via *Zoom*.

Nancy was a senior mathematics education major in a high school certification track. She had robust mathematical knowledge and educational orientation, as evidenced in her high GPA, and strong performance on pre-and post-course assessment on Mathematical Knowledge for Teaching Proof and Dispositions toward Proof survey (Buchbinder & McCrone, 2021). We chose to analyze Nancy's reflective noticing since it was elaborated and rich in detail.

Data Sources and Analytic Techniques

The main data source for this paper is Nancy's reflection reports she completed on *Canvas* Learning Management System 2-3 days after teaching the lesson. For this report, Nancy watched the video of her lesson, and used the commenting feature to write a reflective comment about every five minutes, about 8-9 comments per lesson. These comments provide information about Nancy's noticing in the moment of watching the video. We analyzed Nancy's reflective comments using the Instructional Technology Triangle coding scheme. Each comment was examined for the presence of a particular code; if needed, long comments were divided into shorter thematic units and assigned separate codes. The first two authors coded the data, discussed and resolved any discrepancies. Next, we examined the distribution of codes across the coding categories and four lessons (Table 1) in conjunction with data from supplemental sources: Nany's lesson plans, reflective essays submitted along with the *Canvas* comments, and a summative essay about the course. We also relied on the course syllabus and instructional materials (the second author was the course instructor) to construct narratives explaining Nancy's noticing patterns as she participated in the sociocultural contexts of the capstone course and of the online student-teaching embedded in it.

Results

Table 1 summarizes the distribution of codes of the ITT framework identified in Nancy's reflective comments across the four lessons. The total number of codes per lesson is specified in the heading; the modal response in each column is highlighted. We briefly describe each lesson and identify the key patterns in Nancy's noticing, followed by an interpretive analysis of these patterns.

Table 1: The Distribution of Nancy's Noticing Across ITT Coding Categories and Lessons

	Lesson 1 (*N* =14)	Lesson 2 (*N* =13)	Lesson 3 (*N*=12)	Lesson 4 (*N* =16)	Total (N)
Teacher-content	36%	15%	8%	31%	13
Teacher-Student	7%	23%	17%	25%	10
Teacher-Technology	14%	8%	17%	13%	7
Student-content	14%	0%	25%	0%	5
Technology	0%	15%	8%	6%	4
Teacher	21%	0%	0%	6%	4
Student-Technology	0%	8%	0%	13%	3
Content-Technology	0%	8%	0%	6%	2
Student	0%	8%	0%	0%	1
Content	0%	0%	8%	0%	1

Lesson 1. Direct Proof and Argument Evaluation: Supplementary and Vertical Angles.

Nancy started by engaging students in a discussion of "what makes a good two-column proof?" Next, she facilitated an exploration of the Vertical Angles Theorem (VAT) where she used *GeoGebra* to manipulate intersecting lines and had students observe the changing measures of vertical angles. Nancy guided students to notice that the vertical angles remained congruent.

In this lesson, Nancy was the only one engaging with GeoGebra while students observed and made conjectures verbally. Then, Nancy guided students through writing two-column proof of the VAT first with specific numeric values of the angles and then using variables.

Table 1 shows that Nancy mostly noticed the teacher-content relation (36%), and her own actions (teacher, 21%). This pattern is not surprising considering that this is the first time Nancy taught a lesson online and her first time watching her own teaching and reflecting on it. For example, Nancy noticed her speaking habits, e.g., "I am saying 'um' a lot," and her fast speaking pace and reflected on the need to be aware of and improve her speech: "I need to slow down and not rush through explanations. I'm naturally a fast talker and when I get nervous, I tend to talk even faster … I need to work on slowing it down in the future." Nancy seldom returned to these points in the following lessons, suggesting that the heightened focus on herself was due to the novelty of video reflecting experience.

Based on the prevalence of teacher-content codes (36%), Nancy's main concern in this lesson was making sure the lesson ran smoothly and achieved the teaching goals. These included engaging students in mathematical discourse to collectively construct a two-column proof of the VAT, develop criteria for a "good" two-column proof, and have students recognize there are multiple ways to prove a theorem. Nancy constantly monitored her progress towards these goals and justified her instructional decisions. For example, Nancy noticed her effective teaching practice of developing a list of ideas for proof before writing the two-column proof as a way to address a common student challenge of completing a proof. She wrote:

> As we worked through the proof, I asked the students questions and tried to guide their thinking. I brought their attention to our ideas that we developed earlier on, and they were able to see that we could use two of those expressions to help us with our proof. I think this is important because oftentimes when faced with a proof, it can be challenging to come up with the next step, but if you have already come up with ideas before writing the proof, it can make writing the proof a little easier.

Nancy also criticized some of her teaching choices like having a pre-labeled diagram which, in her words, "defeated the purpose" of having "the students realize that we needed to generalize the angles to prove all cases". Nancy also identified areas of improvement, like managing discussions in ways that increase student mathematical engagement.

> One thing that I noticed during this period was that I didn't really ask the students for their input about generalizing the proof. I just told them that we need to generalize the proof to make sure that we show all cases of vertical angles. After doing this lesson one of my revisions is to do less telling and have the students try coming to the conclusion on their own.

Fourteen percent of Nancy's comments concerned teacher-technology, which is not surprising given this was her first time teaching ever, and online. Nancy was familiar with *GeoGebra* software but struggled to show multiple screens on Zoom: "One teaching move that I found challenging occurred when I wanted to keep the problem up, but also wanted to show the list of ideas that the students were coming up with". Student interactions with technology did not show up in Nancy's noticing possibly because she was the only one manipulating GeoGebra in this lesson.

Lesson 2: Conditional Statements: Isosceles and Equilateral Triangles

Nancy used *Prezi* with multiple examples to introduce the concepts of conditional statement and its converse. Then, students used *GeoGebra* to explore three conditional statements about triangles. For each statement, students were to determine if it is true or false (if false, construct a counterexample), then write the converse and determine whether the converse is true or false.

After the first lesson Nancy seemed to gain comfort with teaching online and shifted the mode of student engagement by having them interact with *GeoGebra*. This is reflected in the shifts in Nancy's noticing patterns toward increased focus on interaction with students (23%). She wrote:

> While going over the conditional statement "if a number is divisible by 10, then it is divisible by 5" I asked the students if they thought the statement was true or false. One student responded that he thought it was false. Instead of saying that his answer was incorrect, I asked him why he thought that and as he started to explain, I realized he was talking about a different conditional statement. I'm glad that I asked him to clarify because otherwise I wouldn't have known that he was talking about a different statement.

By following up on students' answer, rather than discarding it as incorrect, Nancy inferred from the student explanation that he offered a correct response to a different question. Nancy then was able to steer this interaction towards the lesson goals.

An important trend of Nancy's noticing in lesson 2 is the presence of all technology-related codes. Nancy reflected how she transitioned from one technology to another, e.g., "I think the transition from the *Prezi* presentation to *GeoGebra* was pretty smooth and I think I did a nice job at explaining the key aspects of GeoGebra" (technology code, 15%); how the use of technology benefited her teaching, e.g., "I really like having exit tickets because it gives me really good feedback about what the students learned and how they felt with different parts of the lesson" (teacher- technology 8%). Nancy also noticed students' difficulty interacting with each other on *Zoom* (student-technology, 8%):

> When I told the students that they could work together, no one did. I think zoom makes this hard because it's not like you can turn to your neighbor and discuss. Instead, if you want to talk, you end up talking in front of everyone which can make people nervous. Also, as a student it can seem daunting to start up a discussion with your peers. This is something I need to keep in mind for the future.

The patterns of Nancy's noticing are consistent with her use of diverse technological tools (*Prezi, GeoGebra, Google forms*) and with having students interact with *GeoGebra* directly.

Lesson 3: Quantification and the Role of Examples: Triangle Similarity Theorems

Nancy first used *Google Slides* to introduce the concepts of universal and existential statements and the role of examples in proving/disproving them. She had students find counterexamples to three universal statements (e.g., All isosceles triangles are similar) and find examples proving two existential statements (e.g., There exist two right triangles that are similar). After briefly reviewing three similarity theorems as a group, the students spent most of the class time working on Side-Side-Side (SSS) similarity proof, each typing their work on a designated slide in a shared *Google Slides* document.

One unique feature of Nancy's noticing in lesson 3 is the focus on students' learning of content (25%). For example, she noted that "the students recognized that they needed to use SSS but were unable to connect/use proportions to relate the corresponding sides"; that "a lot of them [students] didn't understand how to include proportions into the proof," and that "the students were able to come up with some counterexamples." Nancy monitored students' progress when they typed their answers into *Google Slides,* but she did not have access to their *GeoGebra* screens. Nancy's reflective comments concerned her interactions with students (17%) and with technology (17%). For example, she reflected on the affordances of *Google Slides*: "I, again, liked the use of the google slides here, because I was able to see the students' progress through the similarity proof and get an understanding of what parts they found confusing."

Lesson 4: Indirect Reasoning: Coordinate Proofs

For this lesson, Nancy adapted her cooperating teacher's lesson plan about analytic geometry proofs by integrating indirect reasoning in it. The main activity was the game "The Quadrilateral Detective," where students determined the type of quadrilateral given the coordinates of its vertices. The students also created statements involving indirect reasoning, such as "The quadrilateral cannot be a kite because otherwise it would not have parallel sides". Nancy solved one task together with the students as an illustration. To avoid the complexity of students typing algebraic symbols, Nancy suggested students write their proofs on paper and post a picture of their work into the shared *Google Slides* document.

Despite Nancy's best intentions, not all parts of the lesson proceeded as planned. She seemed to manage better during the teacher-led parts of the lesson and reflected abundantly on her instructional decisions (teacher-content, 31%). For example, "One teaching move that I liked during this lesson was creating a theme for the lesson…" ; "One teaching move that I think was good for this portion was that I had already graphed and typed out the solution to case 1 in the presentation/desmos…"; "I think it was a successful teaching move to include some exposition about indirect reasoning at the end of the lesson instead of the beginning…"

Table 1 shows that from Lesson 1 to Lesson 3 Nancy's noticing shifted from more teacher-centered to more student-centered. But in lesson 4 Nancy mostly noticed her teaching of content (teacher-content, 31%), while also reflecting on her interactions with students (teacher-student, 25% – the largest percentage of this category across the four lessons). Specifically, Nancy reflected on her attempts to press students for explanations, e.g., "why he put his x in a certain spot"; on her calling on students to "get them to participate;" on how "open ended discussion allowed the students to express their answers and explain their reasonings" and on how "providing students enough time to work on their ideas leads to richer discussions."

Nancy also reflected on how she and her students used technology (teacher-technology, 13%; student-technology, 13%). One of the aspects she noticed was the difference between her expectations about students' use of technology and the reality. Nancy expected students to write their solutions to the Quadrilateral Detective Task on paper, scan, and post to the shared *Google Slides* document. Instead, the students created new slides within that document and started typing in their solutions. While Nancy sought to optimize student use of technology by providing space to post their work, the students chose an inefficient and time-consuming approach. Nancy noticed this and reflected on ways for making improvements for future practice.

Discussion and Conclusions

In this paper, we presented the Instructional-Technology Triangle (ITT) framework, which foregrounds technology as an essential element of online learning environments, and a primary mediator between teachers, students, and content. The ITT framework contributes to the literature advocating the need for extending the basic instructional triangle (Cohen et al., 2003) to represent additional elements of instruction in general (Herbst & Chazan, 2012) and with respect to technology (e.g., Yeo & Webel, 2017). The ITT framework was developed when teaching via online videoconferencing (e.g., Zoom, Google Meet, Microsoft Teams, VooV Meeting, etc.) became a norm during the pandemic in response to the seeming lack of theoretical and analytical tools for conceptualizing teaching and teacher noticing in the online context. In this context, teaching technology is not just another element of instruction, but a necessary medium that makes this instruction possible. The content is represented through technology, and both teachers and students interact with technology and through technology. This may include navigating *multiple* types of technology (e.g., video conferencing platform, digital interactive whiteboards, virtual manipulatives) simultaneously by teachers as well as students. Thus, technology started playing an essential role in determining the quality of instruction and the quality of student learning experience. The ITT framework represents our attempt to capture this unique role of technology in the online setting.

Our study also contributes to the body of knowledge on noticing and reflection by demonstrating the utility of the ITT framework in analyzing Nancy's reflective noticing and its development over time. Nancy's first teaching experience happened to be online, and she had to adjust to it quickly. Due to her strong mathematical content knowledge, Nancy invested most energy in designing interactive activities, choosing appropriate technological tools, and interacting with students. The novelty of the experience contributed to the heightened focus on herself and on her teaching in the first lesson (Table 1). As the semester progressed, Nancy seemed to become more comfortable and confident, as evidenced in her delegating responsibility to students by having them interact with technological tools like *GeoGebra, Desmos* and *Google Slides*. Accordingly, Nancy's noticing patterns shifted in lessons 2 and 3 toward increased focus on interactions between students, content, and technology (Table 1). These patterns shifted again in lesson 4 when Nancy enacted the cooperating teacher's modified lesson plan and encountered a mismatch between her expectations of student engagement and how the lesson unfolded. The ITT allowed us to create a nuanced representation of Nancy's reflective noticing and the changes in it. The observed patterns are consistent with the noticing literature (e.g., Buchbinder et al., 2021, Sherin & van Es, 2005; Stockero, 2021) on teachers' initial inclination to focus on their actions, followed by increased noticing on student mathematical thinking. Many researchers highlight the importance of noticing students' mathematical thinking by teachers (e.g., Barnhart & van Es, 2015; Cross Francis et al., 2021; Sherin & van Es, 2009). Despite its importance, it may be unwise to use it exclusively as an indicator of quality of teacher noticing and run the risk of overlooking other aspects. As Spangler (2019) advocates, "We as teacher educators need to demonstrate the curiosity and intellectual humility that allows us to understand how and why something a teacher did or said came from a place that made sense to them" (p. 2). In this paper, we attempted to interpret Nancy's noticing from a place that made sense to her, and to foreground her rationality in the context of her teaching practice (Herbst & Chazan, 2003).

Stepping back from our study, we believe that even as the schools begin to reopen, online education will retain a substantial presence in a variety of forms, such as teacher preparation, professional development, and situations where remote learning is a necessity for some reason. The ITT framework can be broadly applied for conceptualizing and analyzing teacher-student-content interactions in an online setting, responding to the need to attend to contexts in which the teaching and learning takes place, the experiences of the participants and to their individual voices (Liu et al., 2020; PME-NA 44 Conference Theme, 2022).

NUMBER TALKS: PRELIMINARY RELATIONSHIPS BETWEEN TEACHERS' USE OF QUESTIONS AND STUDENTS' AGENCY

Beth L. MacDonald
Illinois State University

Hilary Tanck
High Point University
htanck@highpoint.edu

Number Talks are widely used across the U.S., as they uniquely place student reasoning at the center of mathematics instruction while allowing for few resources and time throughout enactment. The purpose of this brief paper is to describe how relations between teachers' use of questions and students' engagement in a Number Talk associate with students' number sense. Findings suggest students' "student-to-student dialogue" was significantly associated with teachers' "generating discussion" questions and students' number sense development.

Keywords: Number Concepts and Operations, Classroom Discourse, Instructional Activities and Practices

Number sense fundamentally predicts mathematics outcomes in future schooling experiences (e.g., Jordan et al., 2009). One set of resources designed to support students' number sense development are Number Talks (Humphreys & Parker, 2015). Number Talks are widely used across the U.S., as they uniquely place student reasoning at the center of mathematics instruction, while allowing for few resources and time throughout enactment. Parrish and Dominick (2016) describe Number Talks as a "five- to fifteen-minute classroom conversation around purposefully crafted problems that are solved mentally" (p. 13). As Matney et al. (2020) explicate, few blind reviewed papers exist examining Number Talks. The purpose of this brief paper is to describe *how relations between teachers' use of questions and students' engagement in a Number Talk associate with students' number sense*.

Theoretical Framework

Our framing draws from Cultural Historical Activity Theory (CHAT – Engeström, 1999). CHAT frames activity systems, which can be used to make visible development within a system of activity. When examining Number Talks, we recognize teachers may have activity related to their individual goals. Classrooms of students may have collective goals associated with their collective activity. Engeström explains CHAT draws from the interaction between an object and subject, which are mediated by community, rules, division of labor, and instruments. In Figure 1, the subject (teachers' use of questions) interacts with the object (students' number sense) and is mediated by students' agentic behaviors (Cobb et al., 2009). There are three less visible mediators, described here as socio-mathematical norms, Number Talk parameters, and discourse patterns (see Figure 1). Existing tension within the students' development and reorganization of their number sense, leverages change in the system (evidenced through teachers' use of questioning and mediated by students' agentic behaviors). The following sections better explain (1) teachers' use of questions, (2) students' agency, and (3) students' number sense development.

Teachers' Use of Questions

When teachers engage in Number Talks, Humphreys (2016) found teachers used eight question types: *funneling, evaluating, probing, restating, revoicing, generating discussion*, *gathering information*, and *double-checking*. These are similar to other Number Talk questioning frameworks (e.g., Conner et al., 2022, Joswick et al., 2020).

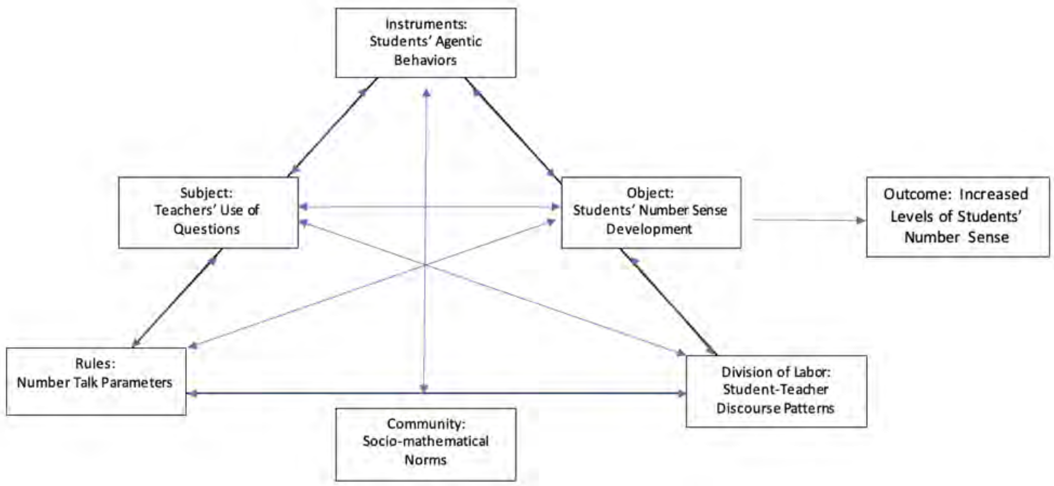

Figure 1: Cultural Historical Activity Theory (CHAT) theoretical framework

We used Humphrey's (2016) questioning framework due to the direct relationships these were found to have with students' agency during Number Talks. For instance, when teachers assessed students' reasoning by asking probing and clarifying types of questions. When one teacher asked restating questions or revoicing questions, Humphreys (2016) found students evidenced more agentic behaviors. By asking these questions, a teacher would ask a student to further explain other students' thinking. When teachers used generating discussion questions, they often asked students to contribute by adding on to other students' reasoning. Conner et al. (2022) described gathering information as questions that press students to "connect" their mathematical ideas and "engage with others' ideas." For example, when asking gathering information questions, teachers often asked students "Okay, where did you go from there?". When describing double-checking types of questions, teachers were simply confirming students' reasoning by restating their strategy in their own words. These five categories framed our structural coding and through open coding we established the additional three categories.

Students' Agency

We framed student engagement with agency and measured it with agentic behaviors. *Agency* is described as an individual's choice of how to engage in a classroom community (Cobb et al., 2009). Cobb and colleagues describe agency in relation to authority, thus, to measure students' agency, we attempted to capture students' goals, as navigated by authority in the classroom.

During Number Talks, Humpreys (2016) found students evidenced six types of agentic behaviors: *appropriates authority for sensemaking, injects an unsolicited comment, asks an unsolicited question, student-to-student dialogue, public risk taking, and shares "in process" thinking.* This study utilized these agentic for analysis.

When students engaged with the mathematics in an unprompted manner, students appropriated authority for sensemaking, injecting unsolicited comments, and/or asking unsolicited questions. When students engaged with each others' mathematical ideas directly, we categorized this as student-to-student dialogue. By evidencing vulnerability in their sense-making students were described as taking risks. Students were noted as evidencing "in-process" thinking when stating how their methods developed. Students' agency is considered as embedded in socio-mathematical norms, discourse patterns, and Number Talk parameters.

Students' Number Sense Development

To examine productive activity wherein students' construction of number was at the center, we collected data evidencing students' number sense development. To examine students' number sense development, we worked closely with David Woodward, CEO of a non-profit organization, Forefront Education, which develops number sense screeners from the research literature (e.g., Wright & Ellemor-Collins, 2018). Each tool was given to teachers to assess their students' number sense development three times throughout the academic year (fall, mid-year, spring). Scores were structured with a 3-point rubric (1, 2, or 3) for each item. The authors aggregated these scores along a 5-point scale to both capture overall number sense performance per student and variance in their number sense.

Methods

This brief paper explains baseline data from a larger Convergent Mixed Methods study (Creswell & Plano-Clark, 2011), focusing on explaining students' number sense development over time, while in Number Talk lessons. For this brief paper, we explain the results after one semester of enactment of Number Talks. Moreover, we draw from three of the five main constructs of these data to explain how teachers' use of questions related to students' number sense development.

Participants and Setting

This study initially included 20 practicing teacher participants assigned to teach grades 4-6 in a school district located in the mountain west region of the United States. Of these 20 participants, we collected complete data from 14 participants. Of these 14 participants, we purposefully chose 11 participants from a cross-reference analysis of an efficacy survey (Enochs et al., 2000) with a two-by-two factor analysis with two levels of two types of efficacy and beliefs. Participants' classroom teaching experience ranged from X to X and from X to X with the particular grade they were assigned to teach. To gather data, researchers scheduled Zoom observations and emailed number sense assessment materials.

Procedures

After analyzing survey data, we scheduled the observations. Throughout the observations, we used the following protocol: (1) open Zoom and ensure video and audio operate successfully, (2) reposition the camera and/or device to be sure students and teacher can be heard, (3) remind teacher to set up a device to audio-record the observation, (4) once a Number Talk began, both authors noted students' agentic behaviors (more in analysis section), (5) once the Number Talk finished, the authors reminded the teacher to upload the audio file in a secure box folder, and (6) closed Zoom. Audio files were transcribed and organized by teacher. The participants completed the number sense screener and uploaded the de-identified results in a secure box folder.

Analysis

Data were first qualitatively analyzed with open and structural coding schemes. These schemes were framed by the aforementioned theoretical and conceptual frameworks. Once descriptive codes were gathered from open coding, the data were revisited for structural coding and then tallied with a frequency count. Quantitative data of these frequency counts and number sense scores were analyzed with a Pearson's Correlation test. Mixed analysis took the form of convergent analysis of the frequency of questions and agency and significant correlations.

Results

Qualitative results suggest that on average teachers asked the most types of questions with the goal to "gather information" (m = 29.9, SD = 15.4). Here, teachers asked about students' solutions, such as, “And then what was the next step after that?”. On average, teachers asked “funneling” types of questions the least number times (m = 2.9, SD = 2.5). Examples of these were when teachers asked students to focus on procedural and/or solution accuracy, such as, “Were you subtracting too much or too little right here?” (see Table 1).

Table 1: Descriptive Statistics of Teachers’ Questions

Frequency of Teachers’ Questions M(SD)							
Funnel	Evaluate	Probe	Gen. Dis.	Repeats	Revoices	Gather Info.	Double Check
2.9(2.5)	3.4(3.2)	6.6(5.0)	4.7(5.3)	14.1(11.9)	6.1(2.8)	29.9(15.4)	9.3(7.6)

Qualitative results also suggest that students on average shared most often their “in-process thinking” (m = 8.0, SD = 3.1). This was often observed when students explained the processes they used to solve a computational problem. Moreover, students, on average, asked “unsolicited questions” the least number of times (m = 0.5, SD = 0.8). When students asked questions in this way, students often asked classmates to explain their solutions (see Table 2).

Table 2: Descriptive Statistics of Students’ Agency

Frequency of Students’ Agency M(SD)					
Authority	Unsolicited Comments	Unsolicited Questions	Student-to-Student	In-Process	Risk Taking
1.9(1.7)	2.4(1.8)	0.5(0.8)	2.9(3.8)	8.0(3.1)	0.9(1.3)

Quantitative results revealed significant positive correlations between “student-to-student dialogue” and students’ number sense scores (0.235, $p = 0.011$), and teachers “generating discussion” questions and “student-to-student dialogue” (0.832, $p < 0.001$). Teachers’ use of questions were not significantly correlated with students’ number sense, suggesting student-to-student dialogue acted as a mediator between number sense and teachers generating discussions.

Divergent themes suggest that when teachers asked gathering information types of questions, they did so on average about 30 times per Number Talk. Given this, it is striking that did not have any significant associations with students’ agency and students’ number sense development. However, convergent themes found that students’ “student-to-student dialogue” was significantly associated with teachers’ “generating discussion” questions. The qualitative data found teachers only asked generating discussion types of questions on average 4 to 5 times during a Number Talk, the sixth most asked question. Students engaged with student-to-student dialogue on average about 3 times throughout a Number Talk, the second most agentic behavior. Finally, it seems students’ agency acted as a mediator between teachers’ use of questions and students’ number sense development during a Number Talk.

Conclusion

Number Talks are rarely examined in a rigorous manner and with comprehensive foci (Matney et al., 2020). Findings suggest teachers can increase their generating discussion questions to leverage opportunities for student-to-student dialogue. Future work should consider how teachers’ questions, students’ agency, and number sense develops over time.

Richard Kitchen
University of Wyoming
rkitchen@uwyo.edu

This paper describes how fifth-grade English Learner students (ELs) in an urban school district develop the mathematics register during a problem-solving lesson. It provides examples of students' work to illustrate how they use the mathematics register to communicate their mathematical ideas orally and in writing. The teacher implemented teaching practices such as mathematics discourse to facilitate their students' development of the mathematics register during the problem-solving lesson. Students were engaged in a problem-solving task that involved fractions. Findings provide insights into EL students' challenges when learning the mathematics register and inform instruction about the importance of incorporating teaching practices such as paraphrasing and assessing others' reasoning to support students in learning the mathematics register through problem-solving.

Keywords: Classroom discourse, Mathematics register, Problem Solving

English Learners (ELs) population is significantly growing in U.S. schools (Abedi & Gándara, 2006; Campbell et al., 2007; de Araujo et al., 2018). Almost 10% of students enrolled in public schools in the United States are classified as ELs (NCES, 2020). As the population of ELs increase, meeting their academic needs deserve an urgent national response. ELs often have limited access to a challenging education in mathematics, adequate resources, and qualified teachers (Borjian, 2008; Dong, 2016). Research highlights several issues that influence the performance gap between ELs and monolingual speakers (see, e.g., Campbell et al., 2007; Chval & Chávez, 2012; de Araujo et al., 2018). Among these issues, language is viewed as a source of difficulty in learning mathematics, particularly for ELs required to learn the content of mathematics and English language skills simultaneously (de Araujo et al., 2018; Martiniello, 2008; Moschkovich, 2007). This paper describes how two fifth-grade mathematics classes with a high percentage of ELs (30% or more) developed the mathematics register during a problem-solving lesson. It also shows how ELs use the mathematics register when engaging in a problem-solving task.

In spring 2021, the first author worked with "Ms. Ware," a 5^{th}-grade teacher, and her students in an urban school district to conduct a case study as part of her dissertation project. One of the research goals was to examine how Ms. Ware supported her ELs in developing the mathematics register during problem-solving lessons. The research questions that we explore here are: How do ELs develop the mathematics register while engaging in a problem-solving lesson? How does Ms. Ware support ELs developing the mathematics register during a problem-solving lesson?

The Mathematics Register

The mathematics register was initially introduced into mathematics education by Halliday in 1978. He defined the mathematics register as a set of "meanings that belong to the language of mathematics (the mathematical use of natural language, that is: not mathematics itself), and that a language must express if it is being used for mathematical purposes" (Halliday,1978, p.195). The literature also refers to the mathematics register as language variations constructed by individual interactions (Schleppegrell, 2004). These variations are characterized in terms of *field* (area or subject), *tenor* (relationship between the individuals), and *mode* (organization of text or conversation) (Halliday, 1978).

The mathematics register includes semiotic resources, such as symbols, visual displays, graphs, diagrams, and language (O'Halloran, 2015). Similar to other disciplines, mathematics has its own language, and learning this discipline implies learning its language. Researchers focused on academic languages have highlighted several issues that emerge when ELs are required to use the mathematics language in informal and formal contexts (see, e.g., Barwell, 2005; Ernst-Slavit & Mason, 2011; Lucero, 2012). For example, Barwell (2005) points out that ELs often face challenges when communicating their mathematical ideas in English. He highlights that solving and writing word problems can support students in integrating mathematics content and language. Ernst-Slavit & Mason (2011) argues that ELs have limited access to mathematics classrooms in which they can consistently hear the mathematics register. Also, teachers constantly use slang, homophones, colloquialism, and idiomatic expressions that can hinder ELs' understanding (Ernst-Slavit & Mason, 2011). Lucero (2012) argues that ELs need repeated opportunities to engage in problem-solving tasks to communicate their ideas to others, define mathematics terms, and compare strategies.

Communicating mathematical ideas in oral and writing forms require students to know the knowledge of mathematics and the knowledge of the language (Wilkinson, 2018). Students need to combine everyday language, symbols, visual displays, and non-linguistic representations to communicate effectively in mathematics. Teachers should incorporate instructional strategies to help their students combine these linguistics features when communicating their mathematics ideas, and consequently, they learn the mathematics register (Moschkovich, 2014)

The mathematics register also involves linguistics features that define the communication styles (Schleppegrell, 2004; Wilkinson, 2018). For example, in an academic context, the mathematics register used can vary when the communication is oral or written (Wilkinson, 2018) Mathematics includes words borrowed from everyday English (e.g., degree, factor, relation, power, radical, product, mean, real, imaginary, rational, and natural) that can have a different meaning in other contexts than mathematics. It also involves some grammatical constructions that differ in their qualitative and quantitative meaning (e.g., *four fours*, the first *four* is an adjective while the second one illustrates a nominal status) (Pimm, 1987).

The mathematics register has two features: multiple semiotic systems and grammatical patterns (Schleppegrell, 2007). The multiple semiotic systems refer to symbol notation, oral and writing language, and visual displays to construct mathematical meaning. The grammatical patterns refer to technical vocabulary, dense noun phrases, nominalization, verbs, conjunction, and logical connectors to communicate mathematics ideas. These features work together to develop the mathematics register, and they are often used to provide mathematical arguments, justify mathematical reasoning, and build mathematical ideas and meanings (Schleppegrell, 2007).

Research Methodology

During the 2021 spring semester, I collaborated with Ms. Ware, a fifth-grade teacher, and her two 5th fifth-grade mathematics classes on three occasions. The study's goal was to examine how Ms. Ware implemented an instructional protocol called the "Discursive Mathematics Protocol" to help her ELs develop the mathematics register and how her students used the mathematics register during problem-solving lessons (see Kitchen et al., 2020, for additional information on the DMP). The DMP was built based on Polya's (1945/1986) problem-solving framework and incorporated research-based strategies and essential teaching practices. These research-based strategies are based on theories of academic language development (Barwell, 2005; Ernst-Slavit & Mason, 2011; Moschkovich, 2015) and the essential teaching practices proposed in *Principles to Actions* (NCTM, 2014) that guide teachers in facilitating their students' development of the mathematics register ad mathematical reasoning, respectively. For the three problem-solving lessons, Ms. Ware and I worked together to plan the lesson, then Ms. Ware delivered the lesson as planned, and finally, we had a debriefing session. For the planning session, we met on Zoom to discuss how we hoped to develop the problem-solving lesson, identified questions, discussed strategies and challenges students could face, discussed the mathematics register involved in the task, and how she would support her ELs to develop it. Ms. Ware and her students met in *Google Meet* for 90 minutes each group during class. I observed the lessons and, on a few occasions, interacted with Ms. Ware and her students, particularly in group discussions. In the debriefing session, Ms. Ware and I met in Zoom for 30-minutes after the problem-solving lesson to discuss what went well in the lesson, what needed improvements for the next lesson, and what adjustments were necessary to incorporate to help ELs to develop their mathematics register.

For this study, 27 students provided consent across the two classes (15 ELs and 12 non-ELs). These classrooms had a high percentage of ELs (30% or more). Most of them speak Spanish as their first language. Ms. Ware taught one group in person and another group entirely online. Each group attended mathematics classes for 90 minutes in two blocks of 45 minutes each. Ms. Ware had Due to the COVID-19, Ms. Ware and her students used a technology tool called *Pear Deck* and *Google Meet* to participate in the class. *Pear Deck* is an application to make interactive presentations in virtual meetings, and *Google Meet* is a virtual tool that allowed Ms. Ware to teach mathematics remotely. The in-person and online groups were connected through *Google Meet* in mathematics classes.

This paper describes how students used the mathematics register while engaging in a problem-solving task. We also highlight the strategies Ms. Ware's used during the lesson to help her ELs develop the mathematics register. Data collection for this study included sources such as video recording of the planning session, problem-solving lessons in *Google Meet,* the debriefing session, ELs' work samples, and class observations. The videotapes and students' work samples were analyzed inductively using interpretive methods (Creswell & Poth, 2018). Each videotape was transcribed, and they were viewed as a whole, followed by open coding to reflect on and clarify teaching strategies to deliver the problem-solving lessons and procedures to address the mathematics register inherent in the task. The analysis process went through multiple iterations to check the consistency of the findings and look at commonalities and differences across the solutions that students provided.

Problem-Solving Task implemented

In the problem-solving lesson, we used a task called 'connecting area model to context," referred to as the multiplication story task. The multiplication story task is a performed task that is publicly accessible through the Illustrative Mathematics (IM) project. This task is considered a cognitively and linguistically demanding task. Students were required to write a multiplication story problem and give a diagram with two types of shading. They needed to establish connections among a procedure (multiplication), a diagram, and a context. Also, they needed to recognize the concept of fractions as operators (Charalambous & Pitta-Pantazi, 2007) inherent in the double shading shown in the diagram. The complexity of the language of this problem appeared when students were required to create a story with a context that related to the notion of fractions as operators represented in the diagram and translate symbols into words (3/4 of 1/5).

The diagram below represents one whole. 	1. Write down an equation that represents the doubled shaded area on the diagram. 2. Write a multiplication story that could be solved using the diagram with its two types of shading. Explain how your story context relates to the diagram provided.

Figure 2: Task implemented with the DMP

Findings

We now present an example of a problem-solving lesson to illustrate how students in Ms. Ware's classroom used the mathematics register when they solved the multiplication story task. Ms. Ware followed three primary teaching practices to help her students develop the mathematic register inherent in the task. These practices included: (1) implementing socio-mathematical norms and activating previous knowledge, (2) introducing the task and reviewing vocabulary, and (3) facilitating meaningful mathematical discourse as a medium to support students in developing the mathematics register.

Ms. Ware started the problem-solving lesson by establishing some mathematical norms and directions students needed to follow during the virtual meeting. She also invited her students to participate and communicate their ideas in oral and writing form through *Pear Deck* during the lesson. Students were expected to collaborate with each other, share their reasoning, engage in mathematical discussion, negotiate the meaning of mathematical terms, and reach agreements about their mathematical ideas. Prior to the problem-solving task, Ms. Ware activated her students' prior knowledge about fractions. She had students work with model diagrams and identify unit fractions (e.g., 1/3,1/5) in both columns and rows of a rectangular diagram. Students were also asked to identify expressions represented in the area model diagram that could be derived by multiplying fractions (1/4 of 1/3). The goal of the review was to emphasize the notion of fractions as operators, which would help students work on the multiplication story task.

Following the first stage, Pólya's heuristic *Understanding the Problem* (stage1 of the DMP), Ms. ware introduced the multiplication story task. She began asking questions such as: *What is the task asking for? What do you think it means to write a multiplication story? What do you guys think we're doing?* Students discussed in small groups what the problem asked them to do. Ms. Ware allowed students to use their vocabulary and familiar language to explain what they understood about the problem. She also helped her students to understand the vocabulary used in the task, such as "story," "multiplication story," and "two types of shading." Some students provided their reasoning about the meaning of these terms. For example, Marcia, an EL, explained that: a multiplication story is "like a story that has a multiplication in it," Max, a non-EL student, said, "it is like using a story, but like using math." Similarly, students defined "two types of shading" as "overlapping" of "two types of colors." Moreover, Once Ms. Ware was satisfied that most of her students understood the task and vocabulary found in the task, she continued with the activities planned and moved to stage two of Polya's heuristic, *Create a Plan* (stage 2 of the DMP)

As Ms. Ware progressed through the lesson, she engaged her students in mathematics discourse on several occasions by allowing them to share their ideas, paraphrasing others' reasoning, providing justifications, and comparing their strategies while solving the task. Throughout the second stage of the DMP, Ms. Ware asked her students to create a plan to solve the task. She asked questions such *How could we solve this problem*? *What is our plan to solve it? What do we need to solve this problem? What two things are we looking for?* In stage 3 of Polya's heuristic, *Carry out the plan* (stage 3 of the DMP), students were required to work individually on *Pear Deck* to write an equation and a multiplication story. Then, students shared their solutions with their partners in small group discussions and justified whether the equation was related to the diagram.

During this stage, Ms. Ware engaged her students with others' reasoning. For example, Ana, an EL, wrote the numerical expression 3/4 x 1/5 to represent the area double shaded in the diagram, and she wrote the following multiplication story: "Mis. Ware ate 1/5 of a cookie; later the day, she ate ¾ of the cookie; how much did Ms. Ware eat?" Ana was able to translate "two types of shading" in the diagram into an expression (3/4 x 1/5), in which they demonstrated the ability to interpret the diagram by identifying the whole and the two factors of the multiplication. These elements are features of the mathematics register because Ana could identify the multiplication of fractions (1/5 x 3/4) shown in the diagram and use two different representations (e.g., the diagram and an equation). However, Ana’s story problem demonstrated a misconception of finding fractional pieces of the original whole rather than finding a fraction of a fraction. Ana did not find a part of a part; instead, she found a part of a whole twice. Her stories did not indicate the multiplication of the two fractions represented in the diagram. Ms. Ware used Ana’s story to generate a discussion and help her students reflect on their solutions. She asked her students to think and explain how the story could be fixed to match the diagram and the equation. She encouraged her students to use the mathematics register by assessing another student's strategy. Andrew, a non-EL student, gave his reasoning about Ana’s story:

> I think this multiplication problem isn't correct because this was like an adding problem…if you like to write in a better way to do so, it would be like: Miss Ware split and took away 1/5 of a cookie, and later in the day, she took ¾ of the piece or something like that to represent the diagram. Also, it has a lot more sense because it shows the 1/5 that she took away and then the ¾ that you ate from the 1/5.

Ms. Ware asked another student to paraphrase what Andrew said to ensure that her students understood the issue in Ana’s story. Through paraphrasing, students had the opportunity to show their understanding and use the mathematics register involved in the task. Antonio, an EL, said:

> What Aiden explained is that it [referring to Ana's problem] was an addition. So, I agree with Andrew because whenever it is multiplication, you basically have to multiply that, no matter what the denominators are, but when adding, you need to find a common denominator.

Ms. Ware revoiced Andrew’s reasoning to emphasize that the notion of a part of a part did not appear in the story. She said:

> I want to point out how she [referring to Ana’s story] has 1/5 of a cookie and then ¾ of a cookie. Right? And so, the ¾ is not referring to the 1/5. It is referring to a whole cookie. Whereas, as Andrew said, she [Ana] took 1/5 of something, and she ate ¾ of the 1/5 later. Do you guys hear the difference? Is it just a multiplication problem, or is this an addition problem?

Ms. Ware was aware that her students needed support in the mathematics register required to write their stories. Specifically, she helped them learn grammatical patterns (the second feature of the mathematics register) needed to write their stories. She took advantage of Ana's story and Andrews' ideas to highlight why their stories were not related to the multiplication expression ¾ x 1/5 and why the language used implied part of a whole twice in the story. Ms. Ware explained that because the unit is the same cookie used in the problem (1/5 of a cookie and then 3/4 of the cookie), the problem referred to the same "whole." Ana used the notion "part of a whole" when she wrote the phrase "1/5 of a cookie" and "¾ of the cookie," but the idea "part of a part" was not used in her story. Moreover, Ana's question, "how much did Miss Ware eat?" led students to think about adding the fractions to find the solution. Ms. Ware provided feedback on Ana's story. She suggested a sentence structure that she could use to enhance her problem "1/5 of something and then she ate ¾ of the 1/5 later." In this sentence, Ms. Ware provided her students a template they could use to write their story problem.". This sentence could help other students to use the notion of "part of a part" in their story problem. After engaging her students in the previous discussion, Ms. Ware asked them to return to Pear Deck to revise and re-write their story problems when needed.

As another example, Ms. Ware intentionally chose another student's solution while monitoring their work on *Pear Deck*. In her multiplication story, Alejandra, an EL, demonstrated a strong understanding of fractions as operators and used the mathematics register in her answer. Ms. Ware engaged her students to assess Alejandra's problem, and Ms. Ware and I asked Alejandra to clarify the language she used in her story.

Alejandra: My problem was Ms. Ware's daughter had a birthday party. She invited six of her friends. Ms. Ware had to get cupcakes for the party. One packet had 1/5 vanilla cupcakes, and 3/4 of those cupcakes had strawberry sprinkles on them. How many cupcakes in total had sprinkles?
Ms. Ware: ok, what makes this work?
Andrew: So, Alejandra's problem she explained that 1/5 of all of the cupcakes are vanilla and ¾ of the 1/5 has sprinkles on them, which is what the diagram shows because it shows 1/5 of the vanilla cupcakes, and then ¾ of the 1/5 is shaded, which shows that ¾ of the 1/5 have sprinkles on them.
Researcher: When you said "three-fourths of those cupcakes," what do you mean? Can you say more?
Alejandra: What I mean is that the 1/5 is the total cupcakes in the package and ¾ of those cupcakes had sprinkles on them.
Andrew: I think Alejandra…you mean by of those cupcakes is the vanilla cupcakes, because I feel like that could be a little bit confusing to some people because like… if you are trying to be very specific in making it very clear, I'd add that ¾ of the vanilla cupcakes had sprinkles on them because somebody could ask anything that when you say of those cupcakes…they might think ¾ of the chocolate cupcakes.

The excerpt above illustrates an example of how a student combined familiar language, symbols, and diagrams to write her multiplication story. In her written solution, Alejandra also used features of the mathematics register (e.g.,1/5 of all of the cupcakes are vanilla, and ¾ of those cupcakes had sprinkles on them). For Alejandra, the phrase "of those" means 3/4 of the 1/5 of vanilla cupcakes. She used undefined references (of those cupcakes) to indicate a specific antecedent in the sentence (the vanilla cupcakes). Using this word in a sentence to translate a mathematics expression into words can lead students, especially ELs, to miss data in the problem and get misconceptions about the whole used. In this sense, I asked Alejandra to clarify what she meant when she said "of those cupcakes" to help other students understand her story. During this discussion, Andrew helped to explain Alejandra's story. He highlighted the meaning of the phrase "3/4 of those cupcakes." Both Alejandra and Andrew demonstrated a high level of

English language proficiency and understanding of the mathematics register used in the story. However, it was essential to clarify the language used in the story to help other students identify the notion of "part of a part."

During the lesson, Ms. Ware devoted significant time engaging her students in meaningful mathematical discourse to help them understand the problem, engage with their peers in mathematical reasoning, revoice and paraphrase others' ideas, and communicate their mathematical ideas. She also had her students work individually on their stories and communicate their reasoning in writing. During the last stage of Polya's heuristic, *Looking Back* (Stage 4 of the DMP), Ms. Ware asked her students to return to *Pear Deck* and revise their stories. She encouraged her students to explain how their stories related to the diagram and the equation $\frac{3}{4} \times 1/5 = 3/20$ using the mathematics vocabulary learned in the class. Some students could refine their solutions and re-write their stories in this stage.

Discussion

This paper described how fifth-grade ELs in Ms. Ware's mathematics classes used and developed the mathematics register while engaging in a problem-solving lesson. Regarding the first research question, students had consistent opportunities to develop the mathematics register during the problem-solving lesson. Ms. Ware engaged her students in meaningful mathematics discourse. Multiple linguistic recourses such as everyday language, mathematics vocabulary, and visual displays were integrated to help students learn the mathematics register. Students had multiple opportunities to communicate their ideas, assess their peers' reasoning, negotiate meanings of mathematical terms, and paraphrase others' reasoning. These strategies helped students enhance and advance their mathematics register (Moschkovich, 2015; Schleppegrell, 2007). For example, students had opportunities to learn the mathematics register inherent in the task by negotiating the mathematical meaning of terms used in the problem (e.g., multiplication story, equation), using their everyday language to explain their problems (e.g., Alejandra's story). Furthermore, students assessed Ana's problem and reflected on the language used in her story and how the phrases used (e.g., "1/5 of a cookie and ¾ of the cookie") indicated part of a whole twice instead of part of a part. Moreover, ELs had the opportunity to revise their stories and incorporate the language learned to write a multiplication story that reflected the notion of the fraction of a fraction. Alejandra's problem illustrated how students used the mathematics register to write their stories and justify the language employed in their stories (e.g., ¾ of those cupcakes").

Regarding the second research question, the multiplication story task requires students to have English language skills and abilities to translate mathematics expressions into words. Ana's story illustrates that learning the mathematics register can pose challenges for ELs, specifically when students need to use the English language to translate a mathematics expression into text (O'Halloran, 2015). In this sense, Ms. Ware implemented instructional strategies to help her students develop the mathematics register. These strategies included facilitating meaningful mathematics discourse in which students had multiple opportunities to paraphrase others' ideas, assess others' strategies, and engage with their peer's reasoning (Herbel-Eisenmann et al., 2013; Moschkovich, 2015). Ms. Ware intentionally selected specific students' stories (e.g., Ana and Alejandra's stories) to help them reflects on how they could use the mathematics register to fix their stories and represent the notion of "part of a part."

The findings in this paper provide insights into the importance of supporting ELs to develop the mathematics register through problem-solving. In Ms. Ware's mathematics classes, ELs had the opportunity to apply their knowledge about fractions and their knowledge of language to write multiplication stories. Ms. Ware asked purposeful questions to help her students understand specific phrases that they could use to address the language complexity found in rich tasks such as the multiplication story task.

EXPLORING THE RELATIONSHIP BETWEEN QUALITATIVE LESSON SCORES AND QUANTITATIVE QUALITIES OF INDIVIDUAL CODES

Describing and measuring instructional quality of mathematics lessons is a common goal amongst mathematics education researchers. Such work takes several forms such as classifying and coding instructional moves and student activity or providing high-level rubric-based scores in relation to categories. In this work, we share an innovative mixed methods approach to analyzing lesson data that includes both a time-based classification of instruction and an overall scoring component. Using the Math Habits framework, our project team analyzed a set of 97 fourth-eighth grade mathematics lessons including overall scores. From this qualitative analysis, we developed quantitative models to predict overall scores and better understand the ways that individual codes do or do not contribute to overall lesson score characterizations.

Keywords: Research Methods, Instructional Activities and Practices

In this report, we share recent work aiming to further both our approach to classroom observation tool measures and our understanding of which elements of a classroom are salient in a coding process. This work is situated in a larger validation study focused on the Math Habits Tool (Melhuish, et al., 2020). The Math Habits Tool decomposes a mathematics classroom into four types of codeable activities: teaching routines, catalytic teaching habits, student habits of mind, and student habits of interaction (each of which will be expanded in the next section.) The categories capture teacher and student activity that characterize student-centered, conceptually-oriented classrooms. As in many instruments (e.g., Mathematical Quality of Instruction, Hill, 2014), qualitative coders analyze the lesson at two levels: during the lesson and holistically at the end of the lesson. While coding during the lesson involves identifying time-stamped, individual occurrences, the holistic codes use a rubric-based approached to make a subjective judgement call as to the quality of the teacher and student activity.

We frame our contribution as two-fold. First, we make a methodological contribution -- the development of a quantitative models to estimate overall lesson scores after a qualitative coding process. Notably, we go beyond just using occurrence counts for codes to characterize a class, but also introduce a measure of spread (the degree these occurrences are found at different times in the lesson). We conjectured that although spread was not an explicit portion of the coder's rubrics, it was likely to inform the qualitative evaluations at the lesson level. For example, consider this extreme version. Suppose a classroom has ten rich student contributions, but all occurred within the first five-minute interval. Then the remainder of the class was a lecture. Contrast this situation with a class where student and teachers are interacting, and ten rich student contributions occur throughout the lesson. A frequency-based approach would characterize these two classrooms in the same manner; however, it is unlikely that we would want such classes to be equivalent.

Second, in order to estimate overall lesson scores, we confronted issues of which codes "mattered" and in what ways. Specifically, whether a code occurred spread throughout a lesson sometimes mattered more than how often (and vice versa, along with other combinations). These findings have implications for researchers interested in teaching practices and students' classroom activity.

Background and Framing

Broadly, we take a social cultural approach to the mathematics classroom focusing on social interactions between people in the classroom. Knowledge is co-constructed in these interactions between students and between teacher and students. While we largely assume that individual cognition and social interactions are interrelated (as in Cobb & Yackel, 1996) where individual understanding is developed via social interactions, we focus on the observable social side. Further, we specifically attend to components of classroom interactions that may promote sense-making and mathematical argumentation inclusive of justifying and generalizing. Justifying and generalizing can support the co-construction of mathematical meaning (Brown & Renshaw, 2000; Simon & Blume, 1996) and students' development of conceptual understanding (Staples et al., 2012). Instruction aligned with such goals reflects a standards-based instructional approach (defined in Rubel, 2017 and reflected in standards documents such as the *Common Core*, National Governors Association, 2010)

We use the instructional triangle (Hawkins, 2002) to situate our analytic framing focusing on relationships between teachers, students, and content. We incorporate both Lampert (2001) and Cohen et al.'s (2003) expansion to capture the mediating role a teacher plays in the student-content relationship and the relationships between the students themselves. Figure 1 reflects the components of the BI Framework overlayed on the instructional triangle.

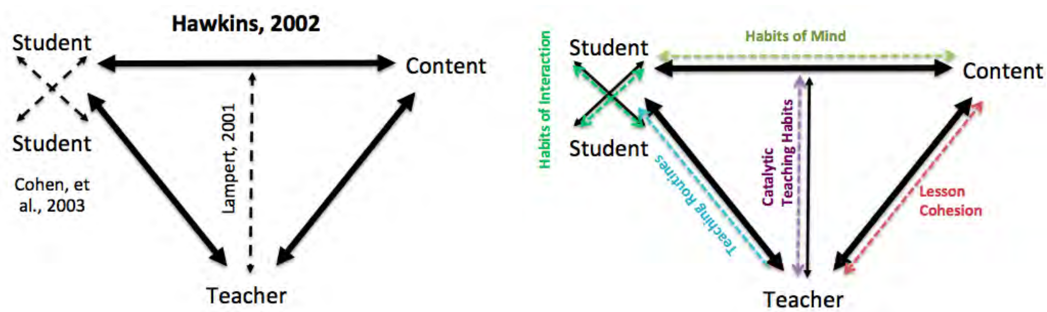

Figure 1: Instructional Triangle and the BI Framework

The blinded framework was developed to operationalize specific instructional routines, moves, and student activity that can be observed within the classroom setting. The coding categories include: Student Habits of Mind which reflect productive ways students engage in mathematics, Habits of Interactions which reflect ways students engage with each other around the mathematics, Catalytic Teaching Habits which capture specific teaching moves that may engender students in engaging with mathematics and each other's mathematical ideas, and Mathematical Productive Teaching Routines. The teaching routines are "recurring, patterned sequences of interaction teachers and students jointly enact to organize opportunities for student learning in classrooms" (DeBarger et al., 2011, p. 244). Unlike the other categories, teaching routines are not identified as instances, but rather over time intervals when they occur. Table 1 includes the categories and subcodes. Each of these categories and subcategories are rooted in the literature on promoting student-centered instruction and mathematical argumentation (e.g., Kazemi, 1998; Staples, 2007; Stein, et al., 2008; Thanheiser & Melhuish, 2022).

Table 1: BI Framework with Variable Names in Parentheticals

Student Habits of Mind	
Mathematical (MathHoM)	Representations; Connections; Mathematical structure
Reflection (ReflectHoM)	Metacognition; Reasoning with mistakes; Making meaning
Capstone (JGHoM)	Justifying; Generalizing
Student Habits of Interaction	
Private Reasoning Time (PRHoI)	Private Reasoning Time
Explaining (ExplainHoI)	Explaining my reasoning; Exploring multiple pathways
Engage with Peer (PeerHoI)	Revoicing; Comparing logic and ideas; Critiquing and Debating
Question (QuestionHoI)	Asking genuine questions
Catalytic Teaching Habits	
Private Reasoning Prompt (ThinkCTH)	Private Reasoning Time Prompt
Sharing Thinking Prompts (ShareCTH)	Prompt to share meaning; Prompt to share thinking; Prompt to share why; Prompt to share representation
Peer Prompts (PeerCTH)	Prompt to analyze strategy; Prompt to analyze mistake; Prompt to compare or connect across strategies; Prompt to revoice or make sense of strategy
Capstone Habit Prompts (JGCTH)	Prompt to justify; Prompt to notice, wonder, or conjecture
Teaching Routines	
Access (AccessTR)	Making meaning of tasks, contexts, and/or language
Public Records (RecordsTR)	Working with selected & sequenced student math ideas Teacher; Working with public records of students' mathematical thinking
Discussion (DiscussionTR)	Orchestrating productive whole class discussions
Groupwork (GroupworkTR)	Structuring mathematically worthwhile student talk; Conferring to understand students' mathematical thinking & reasoning

Methods

Data

This study draws on 96 video-recorded lessons (taken near the end of the school year) from 3 school districts stemming from diverse projects. The samples include 33 lessons from District 1 (Melhuish, et al., 2022), 31 lessons from District 2 (Sorto, et al., 2018), and 33 lessons from District 3 (Kane, et al., 2016). Data on each district can be found in Table 2.

Table 2: Demographic Information on Data Set Districts

District	Race/Ethnicity	Socio-Economic Status	Language

District 1 (grades 4 and 5)	56% White 19% Black/African American, 11% Latino/Hispanic 9% Asian	55% eligible for free and reduced lunch	6% Transitional Bilingual
District 2 (grades 6-8)	99% Latino/Hispanic	95% "economically disadvantaged"	33% Limited English Proficiency
District 3 (grades 4 and 5)	51% Black/African American, 30% White, 13% Latino/Hispanic, 4% Asian	73% eligible for free and reduced lunch	23% Limited English Proficiency

All of these lessons had previously been analyzed with the Mathematical Quality of Instruction (MQI; Hill, 2014) instrument. For the larger databases, we selected a random subset within MQI strata. For District 2, we included all middle school teachers who had opted into recording. We sampled in this manner to assure a range of instructional contexts and practices.

Qualitative Analysis

Each lesson was then coded independently by two researchers according to the BI framework. Any discrepancies were resolved via discussion. After an initial round of coding, the coded lessons were then reviewed by a third member of the research team to identify any coding drift or inconsistences across the coded lessons. Additionally, discrepancies were identified and resolved via discussion. Besides coding using the framework, each coder also assigned an overall rubric-based score for student and teacher activity. Krippendorff's α=0.79 and α=0.57 for overall student and teacher, respectively. The levels for overall teaching score are as follows: (1) No evidence of use of Teaching Routines or an attempted teaching routine (but without Catalytic Teaching Habits embedded.) (2) Use of more than one Teaching Routines; some evidence of Catalytic Habits; OR Use of only one Teaching Routine; but many (variety) of Catalytic Habits. (3) Multiple Teaching Routines; Catalytic Habits embedded; (4) Multiple Teaching Routines; Catalytic Habits embedded with pushes towards justifying and/or generalizing. The levels for overall student codes are as follows: (1) Students engaged in at most a Habit of Interaction or two and maybe a Habit of Mind; (2) Students engaged in some Habits of Mind and/or Habits of Interactions (3) Students engaged in multiple Habits of Mind and Habits of Interaction; (4) Students engaged in multiple Habit of Interaction or two and maybe a Habit of Mind with justifying and/or generalizing. As in many rubrics, the overall levels provide some guidance, but also rely on subjective judgements made by the coders. For this reason, consensus was reached through discussion.

Quantitative Analysis

In order to examine how individual codes are associated with the overall Teacher and Student codes, two summary statistics were computed for each lesson and code type: the count and the spread. The count is simply the total number of occurrences of the code during a lesson. To compute the spread, the lessons were partitioned into 10 equal intervals. The spread is the number of intervals in which a code occurred at least once. The two statistics capture the difference between number of times the behavior is observed and the consistency with which it is observed throughout the lesson.

Least Absolute Shrinkage and Solution Operator (lasso) models were used to investigate the relationship between the individual and overall codes. Lasso (James, et al., 2013, pp. 219 - 227) models use l1 regularization to prevent overfitting, reduce the variance of the coefficient estimates of a linear model, and perform variable selection. Unlike stepwise techniques used with standard least squares regression, variable selection in Lasso models does not rely on normality assumptions. The lasso coefficients minimize the quantity

$$\sum_{i=1}^{n}(y_i - \beta_0 - \sum_{i=1}^{p} \beta_j x_{ij})^2 + \lambda \sum_{i=1}^{p} |\beta_j|$$

where the y_i is the overall code for the i^{th} lesson, and the x_{ij} are the corresponding scaled versions of the count and spread summaries for individual codes. The regularization constant, λ is determined separately for the Teacher and Student models via cross-validation.

Results

In this results section, we share estimates from our models and interpretation; however, the majority of the theorizing and contextualizing of these results can be found in the Discussion section. Recall, our goal is to create a model that can take the human coders' individual timestamped BI codes to predict the human coders' overall student and teacher codes. That is, can we use the detailed BI coding with a model to generate the overall codes? To this end, we needed to examine which (if any) of the individual BI codes were having more or less impact on overall codes. In this section we present what we learned about the role of BI codes in relation to overall codes. We begin with Overall Student codes.

Table 3: Coefficients from the LASSO model for Student Codes

	Model Coefficients	
Code	**Count**	**Spread**
MathHoM	-0.208	0.443
ReflectHoM	0.143	0
JGHoM	0	0.273
PRHoI	0	0.045
ExplainHoI	0.089	0.249
PeerHoI	0	0.060
QuestionHoI	0.120	0

The coefficients for the lasso model for Overall Student code are shown in Table 3. Recall that these habits reflect observable ways that students engaged with the mathematics and with each other mathematically. The zero coefficients for the count variables for JGHoM (capstone habits of justifying and generalizing) and PRHoI (private reasoning time), and the spread variable for QuestionHoI (asking genuine questions) indicate that lasso dropped those respective count or spread variables from the model. We use *z*-scores to interpret the coefficients of the remaining predictors. For example, for a lesson with one standard deviation more ReflectHoM (reflection habits of mind) than the average lesson, the predicted overall code increases by 0.143. We can unpack the slightly more complex case of the mathematical habits of mind (MathHoM) coefficients where we see a negative relationship. Consider two lessons where the count for MathHoM differs by one. If the additional code occurs in an "empty" interval, the count and the spread both increase and the predicted overall code increases. On the other hand, if the additional code occurs in an interval where MathHoM has already been observed, the predicted overall code decreases. That is, observing the code throughout the lesson is more beneficial than simply counting a total. On the other hand, some codes only mattered in terms of count. For example, students asking a genuine question (QuestionHoI) is associated with an increase in the overall code, no matter where it occurs. That is all to say, that some codes matter where they occur in a lesson (indicated by spread) and some only matter how often they occur (indicated by count).

Table 4: Coefficients from the LASSO model for Teacher Codes

	Model Coefficients	
Code	**Count**	**Spread**
GroupworkTR	0.280	0.096
RecordsTR	0	0.241
DiscussionTR	0	0
AccessTR	0.253	0
ThinkCTH	0	0.058
ShareCTH	0	0.104
JGCTH	0.144	0
ReflectCTH	0.139	0
PeerCTH	0	0
RevoiceCTH	0.056	0.097

Table 4 provides the coefficients for the lasso model for the Overall Teacher codes. Again, we can notice that different types of activities are differently related to the overall codes. The teaching routines related to groupwork (GroupworkTR) matter both in terms of how frequently they occur (counts) and how they spread throughout the lesson (spread). In contrast, the teaching routines related to public records (RecordsTR) were only significant in terms of how spread they were throughout the lesson and the meaning making teaching routine (AccessTR) was significant only in terms of frequency, not spread. If we turn to individual teaching moves (the catalytic teaching habits), we can see spread is significant for prompts related to private think time and to share thinking (ThinkCTH; ShareCTH), but overall frequency, but not spread, is significant for reflection prompts (ReflectCTH). For teacher revoicing (RevoiceCTH), both frequency and spread were small, but positive predictors of overall score. Finally, we note that the orchestrating discussion routine (DiscussionTR) and the prompts to engage with peers' reasoning (PeerCTH) did not contribute to predicting overall teacher scores.

We also briefly share results about how closely these models fit our overall scores. Table 4 and Table 5 present a crosstabulation comparing the true and predicted codes. In grey, we have emphasized the lessons where the coder overall code matched the predicted code. For the students, the model correctly predicts 71.1% of our lessons. For the overall teacher score, the model correctly predicts 76.77% of our lessons. Further, only one lesson in each case is predicted more than one level off. We can calculate Krippendorf's α, as we would when comparing coders. For the overall teacher scores, $\alpha=0.879$ and for the overall student scores $\alpha = 0.813$. Both numbers are over 0.80 indicating substantial agreement. That is, our models are doing a relatively good job predicting the overall scores arrived at by coders.

Table 5: Crosstabulation of Overall Student Codes: True vs. Predicted

		Predicted Overall Code				
		1	2	3	4	total
Coder Overall Code	1	16	10	0	0	26
	2	2	24	6	0	32
	3	0	6	13	0	19
	4	0	1	4	15	20
Total		18	41	23	15	97

Table 6: Crosstabulation of Overall Teacher Codes: True vs. Predicted

		Predicted Overall Code				
		1	2	3	4	total
Coder Overall Code	1	24	7	0	0	31
	2	1	26	3	0	30
	3	0	4	12	1	17
	4	0	1	6	12	19
Total		25	38	21	13	97

Discussion

When we code data, we often make (explicit or implicit) inferences based on quantitative characteristics such as frequency of a code. However, when we consider a complex setting like a mathematics classroom, we often rely on subjective judgement calls about other features such as the degree it feels like a particular activity characterizes a lesson. In fact, this sort of expert judgement is why qualitative coding can be powerful. Yet, we have found that it can be quite challenging to come to agreement on lesson level scores because, by nature, coders are not noticing or perhaps not weighting elements of instruction in the same way. Our goal with this study was to develop quantitative means to estimate overall scores. We focused on the measure of spread in addition to count to avoid collapsing some of the dimensionality in a classroom.

If we consider our results, we can see that in some cases spread was more important, some cases count, and in yet others, they played out in more complex ways. We return to a couple of examples to conjecture what might account for these differences. If we turn to the overall teacher scores, we can see that both orchestrating discussion and prompts to engage with peers' ideas did not contribute to predicting overall scores. First, these are types of codes that are theoretically related. In order to orchestrate discussion, we required that multiple students are engaged with each other's ideas in some way. This typically occurs when teachers make related prompts for engagement. From a simplistic view, the rubric would reward both types of activities with higher overall scores. However, if we examine the data, we can note two features that may account for this result. First, the DiscussionTR and the PeerCTHs were only meaningfully different for teachers with an overall high score. For example, the mean spread for the DiscussionTR for overall high teachers was 3.1 (meaning, on average, discussion happened in 3 of 10 intervals) and mean count was 6.9 (meaning on average discussion happened 7 times per lesson). In contrast, spread was less than one for all other levels of overall score and less than two for mean count. Rather than gradual increases, this routine served to discriminate between high level lessons from other levels. This leads to the second point, the high-level lessons all had higher spreads and counts in other categories. Theoretically this makes sense. It is likely that in a class where a teacher orchestrates discussion, there is overlap with other teaching routines like using public records of students thinking – in many cases the discussion is about such a record. Thus, these codes are not contributing new information about the overall teaching in the lesson.

Now let's contrast two teaching routines that both were significant but in different ways. Working with public records of student thinking and selecting and sequencing (RecordTR) mattered in terms of spread whereas Making meaning of task and terms (AccessTR) mattered in terms of counts. In this case, we conjecture the way these routines operate in the classroom may account for the difference. Engaging students in making meaning around tasks and terms is a routine that comes up when students encounter an idea, task, or piece of language in which they may be unfamiliar. This is likely to occur at specific points in the lesson such as when a task is launched. In contrast, working with records of students' ideas may be threaded throughout. Thus, the number of occurrences of meaning making may be more salient than the spread of meaning making; while the spread of record use is likely a more salient feature of overall teaching.

If we turn to the student codes, we see the relationship between observed math habits of mind (including capstone habits) and overall scores are more linked to spread. These habits include things like reasoning with representations, structure, connections, and justifying and generalizing. Frequencies alone may paint a misleading picture because a single student contribution may embed many of these habits (e.g., justifying a result by use of a pattern within a table). A short span of time with high counts is not as meaningful as occurrences spaced throughout a lesson (reflected in spread), thus theoretically spread is likely to be more salient. A second explanation may be that at a certain threshold, frequency might not contribute new information. That is, a class with 20 instances and a class with 30 instances of habits of mind are both likely at a high level and the difference of 10 instances does not contribute something new. In contrast, the spread is capped at the interval number and any difference has the potential to provide meaningful information that characterizes a lesson across time.

For space limitations, we will not unpack all of the differences in how the codes are operating but will spend a brief amount of time comparing the difference in the ExplainHoI (students explaining their thinking) and the MathHoMs. Explaining mattered in terms of both count and spread, although with a relatively small coefficient for count. The threshold to explain one's thinking is much lower than the threshold for that thinking to include math habits of mind (which reflect higher level reasoning). Explaining was by far the most frequently observed student activity at all levels of overall student code. The mean number of occurrences of explain was 6.4 for the Overall Student =1 classes and 39.8 for the Overall Student=4 classes. However, for lessons that received the lowest overall score, the mean spread was less than 3 intervals whereas in highest lessons, it was nearly 9 intervals. Both frequency and spread appear to provide important information to characterize a lesson.

This leaves several questions open for future research. First, are these relationships a consequence of the coders and rubrics or a consequence of how these activities unfold in the classroom? This is work that could be further addressed with additional qualitative analysis of the classrooms as well as attention to classrooms where overall codes as assigned by the model diverged from overall code as determined by the qualitative coders. Second, how might we develop more accurate models and measures when considering coding at this grainsize? Spread and count provided a start, but other measures such as interrelated (different types of codes within a timespan), existence (binary), or alternative models (such as non-linear models) could lead to additional insights.

CONCEPTIONS OF HONDURAN SECONDARY SCHOOL TEACHERS ON THE NUMBER LINE IN SYMBOLIC MANAGEMENT TASKS

Sharon Samantha Membreño Estrada

The number line is a model that is used to measure, count, order and even operate, which requires a symbolic interpretation. Then, we investigate the conceptions of 72 in service secondary teachers, when they manage the model of the number line associated with order, spatial location and the relative position between numbers and marks. In a workshop carried out through Internet, we found that the participants consider that the usefulness of the model is in the manipulation, and they do not see the need to modify it, despite the requirements of the problem, taking for granted its usefulness and the control that resources could give them, such as the change of the numerical scale. They don't even realize the symbolic properties to interpret the numerability.

Keywords: Number line, Teacher conceptions, Artifact management

The number line can be a model for teaching, it serves for measuring, counting, ordering, or operating. Its several presentations even allow it to be used as a kind of note (Heirdsfield, 2011), where at least there is no need for homogeneous units between consecutive numbers or the properties of a homogeneous representation (Nemirovsky, 2003).

We consider that the model of the number line is more than a metaphor (Doritou & Gray, 2007) because it allows us to approach the numerical properties through a symbolic representation, and its use must consider properties such as the homogeneous representation that gives spatial meaning to the numbers according to their position. As well as to the marks and the intervals between them, these symbolic activities are the basis for numerability.

Therefore, it is desirable that the teacher takes into account that signs are regulated in a way that gives it mathematical meaning, so we investigate the conceptions of Honduran in service secondary school teachers, about their willingness to make changes to the representation according to the needs, as well as to the symbolic treatment considering the order, the spatial location and the relative position of numbers and marks on the number line to development a symbolic treatment in class.

Background

At this time, it has been established the importance of teachers acquiring three types of knowledge to develop their teaching effectively, which requires: 1) Common knowledge of the content; 2) Specialized knowledge of the content; and 3) Knowledge of content and students, as stated by Hill, et al. (2008).

In this research, we will refer to the specialized knowledge of the content, associated with the symbolic interpretation, use and management of the number line in numerability sense where the properties of homogeneity and order are highlighted, that is, the use of a model where the position of the signs are relevant both for their value, as for their relative positions associated with order and inequality to perform model functions for numerability.

The so-called number line is capable for giving body to different arithmetic operations at the basic level we can find it in the work that refers to the relations of numerical inequalities and linear inequalities (Membreño and Acuña, 2021), which requires interpreting the order, relative position and spatial location of numbers and marks since an index to symbols in an intentional way.

In general, teachers use the number line as a pedagogical tool that it is useful to the student, since it gives body with certain relationships, however, they do not always realize that it is also an abstract structure, which is a symbolic model with some restrictions (Doritou & Gray, 2010), that accepts a treatment as a representation of the numbering system and also gives body to the metaphor of numbering (Doritou & Gray, 2007).

From our point of view, although it is true that the number line gives body to the metaphor of numerability, it itself is formed by a series of signs with mathematical properties that are of two types: explicit and implicit, which must be considered for their teaching.

In the case of explicit signs, we have those that will clearly be detected and used for interpretation as in the case of numbers and the marks associated with them, the numbers have numerical value, so they acquire an ordinal position, but they are also the numerical labels for the associated marks, which allows the order of the objects represented. However, there are other implicit signs such as segments that, although relevant to interpretation, often go unnoticed, for example, when they represent the norm of the homogeneous unit of numbering or in the case of representing the solution sets of numerical inequalities and linear inequalities, (Membreño and Acuña, 2021).

Objective

We investigate the conceptions and justifications of the secondary school in service teachers when they are in a position to manage the type of representation of the model of the number line that would be used under changing conditions, which implies accepting a management on the representation, as well as the use of the signs involved in the model either marks or numbers based on the order, the spatial location and relative position of this representation when it is homogeneous.

Theoretical framework

Using models as symbolic tools

The number line is a symbolic representation, made up of signs that must be interpreted mathematically to use it as a model for teaching, which includes detecting the role of implicit and explicit signs as symbolic mediators.

The Theory of Objectification suggests that learning is linked to the use of instruments, signs or artifacts that are not aids to learning, but they are a semiotic media whose presence and use print a distinctive stamp on the constructed, becomes part of it through a semiotic mediation that allows to develop a reflective praxis, which is understood as: “what we know and how we come to know it is circumscribed by ontological positions and processes of meaning production that shape a certain kind of rationality that allows us to pose certain problems” (Radford, 2004, p. 13)

If mathematics is essentially symbolic, it is important to observe the role of the signs that allow individual to mediate knowledge and it is through them that the actions and reflections of this are oriented, so it is suitable to know the conceptions of the teachers who would be guiding their use on the signs about the representation of the number line.

Radford states that " The sign has meaning when it is related to other signs" (Radford 2006b, p. 8), so meaning would be given to the representation when the explicit signs are being related to those implicit on the number line model.

Regarding the treatment of signs, we are interested to know the use made of them either as index or symbols, Pierce (2005) which will be relevant for an adequate symbolic treatment, throughout his teaching activity by the treatment of the number line and in the use of the properties of order and homogeneity.

For the purposes of this research, on the use of signs we have incorporated the restriction of homogeneity, Nemirovsky (2003) in the number line in which the only property of the objects represented is their position in order to investigate the inclination of teachers to modify or not, the spatial conditions of it under changing conditions, as well as its interpretation of the order and spatial location of the numbers and their marks on the signs present in the use of the model.

In the present research, the symbolic management of the line is present when teachers adjust the representation of it, depending on the needs of the problems posed and the semiotic treatment is characterized by recognizing the mathematical norms of order, spatial location and relative position of the numbers and marks represented.

Methodology

About the sample

The present research explored the conceptions of 72 secondary school teachers in service from Honduras, who teach students between 12 and 15 years old, research that was developed through an online workshop as part of the Congress of Educational Mathematics (COME) in Honduras in 2021, aimed at teachers from all over of the country, the open call was freely attended by those interested in the improvement of mathematics teaching in that country.

Method

The workshop was carried out through Zoom supported using the GeoGebra classroom platform, through a questionnaire where teachers could manipulate graphic representations and interact with the researcher either in front of all participants, in a particular and instantaneous way or even leave written comments to have subsequent communication. This was useful to analyze more broadly their opinions and conceptions to management on the model of the number line.

The questionnaire was split into eight tasks associated with the management of the number line to know the conceptions of the teachers in front of tasks that require managing the number line, specifically about order and homogeneity.

In general, graphs of number lines were presented in which the position of relevant marks such as zero was asked, as well as the choice of lines where zero is not in the center and maybe they have chosen a more appropriate numerical representation. We also ask for their opinion about the treatment in class of the relevance of a representation of extreme numbers by its position. In addition, we proposed representations that require considering the relative position of given numbers, according to the available information, both in correct and incorrect cases. The reason for this being that these tasks would show us the conceptions of the teachers and the recurring schemes that their students learn in math classes.

For the analysis of the data, we have considered the choice of certain graphs as a disposition towards management. At the same time, we observe verbal indicators in the use of the terms: scale, direction and measure that are adequate to manage the representation institutionally leaving aside the symbolic interpretation.

Results and Discussion

In the first task, teachers were presented with a number line and asked to place zero on it, 62.5% placed it in the center, also 11% chose on the left most mark because they were considering only positive numbers, which could reflect their usual practice.

In the second task we asked: *"Of the number lines shown below, which one would you choose to propose to your students if you want to place the numbers 120 and – 3 on it? Explain"*

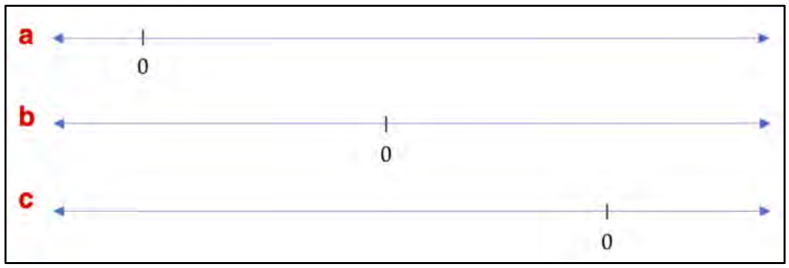

Figure 1: Task 2. Choosing the right line.

In the first part of the question, most of the teachers (59.7%) chose **a**. In the second part, the justifications were: 1) Because there is more space (40%); 2) Scales can be made to locate the points (2%); 3) A larger amount is required for positive numbers than for negative ones (6%) and they did not answer (32%).

Of the 59.7% who chose option **a.**, 58.1%. that is, 34.7% of the total, justified that there was more "space" or "distance" between the numbers, which makes us see the use and type of favorite number line that is intended to be taught in the class, as well as the type of examples that will be worked mostly are positive.

The third task asked: "*How would you explain to your students that the following number line can be used to place the numbers -200 and 5 on it?*"

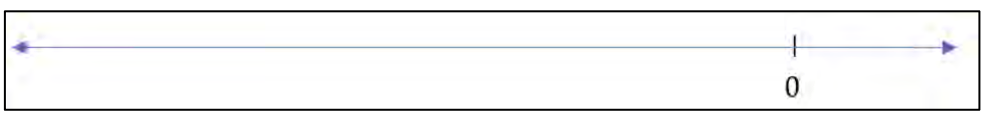

Figure 2: Task 3. Explanation of the type of line used.

Teachers who included the terms: scale, space and direction are 45.9%, who, apparently, considered change in representation, showing a form of management over representation that consists of using segments of 20 in 20 units, for example.

With the purpose to deepening the conceptions and justifications of teachers when faced with this type of task, below, we show one of their answers to this case.

> P2: I would explain to they that -200 is farther from zero, therefore a larger scale is needed to represent it, on the contrary, 5 is closer to zero, so you don't need much space.

This justification shows us that he was thinking of possibly using a scale on one side of the number line and having less space on the other side.

Other justifications for the choice of this type of line and that are associated with the scale, are the following:

P7: We can make divisions of 5 cm that represent 40 units with which to the left of the zero we would have 5 divisions and to the right side that we should divide it into 8 equal parts, where in the first division we would represent the 5.

P60: This line can be used to locate -200 because it has enough space from the zero point and can be located from 5 to 5, 10 to 10, or 20 to 20 for the negative side, and for the positive side it takes up less space because there are only 5 positives (sic).

Understanding both cases, the scale as a form to adopt the numerability in which it is intended to avoid placing many marks and their respective labels.

On the other hand, 45.8% did not answer, which possibly means that they had not had contact with this situation.

Regarding the order, spatial location, and relative position of numbers on the line, we request in the fourth task: to place the missing numbers in the marks that appear on the next number line.

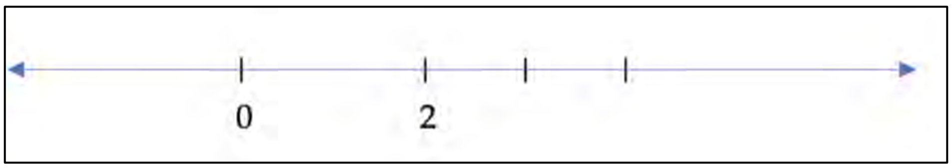

Figure 3: Task 4. Location of missing numbers.

Most teachers properly used the unit segments and correctly located the missing numbers, which would be showing that they went through the process of identifying the magnitude of the unit, only the answers of four teachers showed that they have not considered it, taking the distance from zero to 2 like the unit, hence the error. We also observed that in the treatment of the magnitude in these last answers the Gestalt relationship between background and form was present in the representation and it was not well resolved.

Insisting on the order and interpretation of the space between the numbers, we proposed the next line warning that it is wrong, then we asked to reorder it, as well as the drawing of a suitable number line.

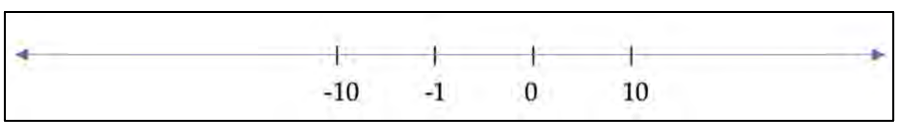

Figure 4: Task 5. Interpretation of the space between numbers.

The results tell us that 40.7% consider the unit segments, 51.4% did not answer the question, while we have 7% of teachers who either do not take distances between numbers or consider that the representation is not incorrect to no consider the relative position of the numbers.

Regarding the use of signs to place numerical values on the number line we asked to place the numbers -5, -3, -1, 4 on the next number line

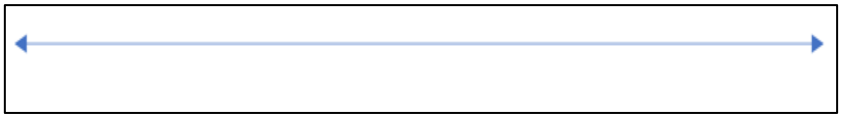

Figure 5: Task 6. Location of numbers.

In this task, the teachers (33%) used small vertical marks or points to place the requested numbers, as well as extra marks that served as a guide for the position taking care that the distance between it was relatively the same, although they were not accompanied by the respective numbers having an approximation that we can call *local position*.

There are also a few (26%) who only place the marks on the requested numbers, visually estimating their position, which suggests that they use a *global position* in this task.

In task 7, that requested to reorder an incorrect representation, from all the teachers who answered, 50% ordered the numbers properly, which shows that the order between them was not a conflict. However, in task 8 the zero was also missing, so the number line had to be rebuilt assigning the necessary space, 37.5% of the teachers resolved correctly, however, 8.3% simply added the mark and number in the middle of 1 and -1 without considering the location and the unit space.

Conclusions

In the development of the tasks, it is important to note that only half of the teachers answered consistently the tasks of the questionnaire shown in GeoGebra, possibly for two reasons: the first may be the need of the management of virtual tools, and the second because they had never faced similar situations in which they had to manage their own representation by their own.

We detected in the results a certain tendency to use some favorite representations such as placing the 0 in the center or the inclination to structures linking to the positives numbers that suggest a dominant presence of their needs to teach in the classroom. These conceptions show us a strong and utilitarian use of the model. In addition to that, when teachers agree to modify the representation, their suggestions are linked to the idea and control by mean of scale that they can rule, that apparently solves the problems of representation and interpretation in their teaching work.

The order is not a problem for them or even adding the missing numbers and the spatial location is respected in cases of need, however, it is not identified as an obligatory condition or as a symbolic need of the number line, but as a convention that must be respected, in certain cases.

The teachers' conceptions of the requirements of symbolic representation are that it is ordered and that the position has a homogeneous basis, but that it can be modified according to the scale used. This suggests that there are modifications to the representation for utilitarian purposes, but the symbolic properties that make it function as a mathematical model are not detected.

La recta numérica es un modelo que en la enseñanza es usada para medir, contar, ordenar e incluso operar, lo que requiere de una interpretación simbólica, luego indagamos las concepciones de 72 profesores cuando gestionan el modelo de la recta numérica asociada al orden, la ubicación espacial y la posición relativa entre números y marcas. En un taller por internet, encontramos que, los participantes consideran que la utilidad del modelo está en la manipulación y no ven la necesidad de modificarlo, pese a los requisitos del problema, dando por sentado su utilidad y el control que les puede dar recursos como el cambio de la escala numérica. Tampoco se percatan de las propiedades simbólicas para la interpretación de la numerabilidad y la operatividad.

Palabras clave: recta numérica, concepciones de profesores, gestión de artefactos

La recta numérica funciona como un modelo para la enseñanza, ya que sirve para medir, contar, ordenar u operar. Sus diversas presentaciones permiten incluso usarla como una especie de apunte (Heirdsfield, 2011), donde, en este último caso no hay necesidad de unidades homogéneas entre números consecutivos ni de las propiedades de una representación homogénea (Nemirovsky, 2003).

Consideramos que el modelo de la recta numérica es más que una metáfora (Doritou & Gray, 2007) porque nos permite abordar las propiedades numéricas mediante una representación simbólica y su uso debe considerar propiedades como la de la representación homogénea que da sentido espacial a los números de acuerdo con su posición, así como a las marcas y a los intervalos entre ellos, estas actividades simbólicas que son la base para la numerabilidad.

Por ello, es deseable que el profesor tenga en cuenta que estos signos están regulados de manera que le dan sentido matemático, por lo que indagamos las concepciones de profesores hondureños de secundaria en activo, sobre su disposición para hacer cambios a la representación según las necesidades, así como al tratamiento simbólico considerando el orden, la ubicación espacial y la posición relativa de números y marcas sobre la recta numérica para desarrollar un tratamiento simbólico en la clase.

Antecedentes

Actualmente, se ha establecido la importancia de que los profesores adquieran tres tipos de conocimientos para desarrollar su docencia con efectividad, lo que requiere de: 1) Conocimiento común del contenido; 2) Conocimiento especializado del contenido; y 3) Conocimiento del contenido y de los estudiantes, tal como lo afirma Hill, Ball, et al. (2008).

En esta investigación nos referiremos al conocimiento especializado del contenido, asociado a la interpretación simbólica, al uso y la gestión de la recta numérica en tareas de numerabilidad donde se destacan las propiedades de la homogeneidad y el orden, esto es, el uso de un modelo donde la posición de los signos es relevante tanto por su valor, como por sus posiciones relativas asociadas al orden y a la desigualdad para desempeñar funciones de modelo para la numerabilidad.

La llamada recta numérica es susceptible de dar cuerpo a distintas operaciones aritméticas en los niveles básicos, en particular, la podemos encontrar en el trabajo que se refiere a las relaciones de desigualdades numéricas y de las inecuaciones lineales (Membreño y Acuña, 2021), lo cual requiere de interpretar el orden, la posición relativa y la ubicación espacial de números y marcas desde índices a símbolos de una manera intencional.

En general, los profesores usan la recta numérica como una herramienta pedagógica que sirve como ayuda para el estudiante, ya que da cuerpo a ciertas relaciones, sin embargo, no siempre se percatan de que también es una estructura abstracta, que es un modelo simbólico con algunas restricciones (Doritou & Gray, 2010), que acepta un tratamiento como representación del sistema numérico y que además da cuerpo a la metáfora de la numeración (Doritou & Gray, 2007).

Desde nuestro punto de vista, si bien es cierto que la recta numérica da cuerpo a la metáfora de la numerabilidad, ella misma está formada por una serie de signos con propiedades matemáticas que son de dos tipos: explícitas e implícitas, las que deben ser consideradas para su enseñanza.

En el caso los signos explícitos tenemos aquellos que claramente serán detectados y utilizados para la interpretación como en el caso de los números y las marcas asociadas a ellos, los números tienen valor numérico por lo que adquieren una posición ordinal, pero también son las etiquetas numéricas para las marcas asociadas, lo que permite el orden de los objetos representados. Sin embargo, hay otros signos implícitos como los segmentos que, aun siendo relevantes para la interpretación, pasan frecuentemente desapercibidos, por ejemplo, cuando representan la norma de la unidad homogénea de la numeración o en el caso de representar los conjuntos solución de desigualdades numéricas e inecuaciones lineales, (Membreño y Acuña, 2021).

Objetivo

Pretendemos investigar las concepciones y las justificaciones del profesor de secundaria cuando está en condiciones de gestionar el tipo de representación del modelo de la recta numérica que se usaría bajo condiciones cambiantes, lo que implica aceptar una gestión sobre la representación, así como el uso de los signos involucrados en el modelo ya sean marcas o números con base en el orden, la ubicación espacial y la posición relativa de esta representación cuando es homogénea.

Marco teórico

Uso de modelos como herramientas simbólicas

La recta numérica es una representación simbólica, formada por signos que deben ser interpretados matemáticamente para usarlo como un modelo para la enseñanza, lo que incluye detectar el papel de los signos implícitos y explícitos como mediadores simbólicos.

La Teoría de la Objetivación sugiere que, el aprendizaje está ligado al uso de instrumentos, signos o artefactos que no son ayudas para el aprendizaje, sino medios semióticos cuya presencia y uso imprimen un sello distintivo sobre lo construido, llega a ser parte de éste a través de una mediación semiótica que permite desarrollar una praxis reflexiva, la cual se entiende como: “(lo) que conocemos y la manera en que llegamos a conocerlo esta circunscrito por posiciones ontológicas y procesos de producción de significados que dan forma a cierta clase de racionalidad que permite plantear ciertos problemas" (Radford, 2004, p. 13)

Si la matemática es esencialmente simbólica, es importante observar el papel de los signos que permiten al individuo mediar el conocimiento y es a través de ellos que se orientan las acciones y reflexiones de este, por ello es conveniente conocer las concepciones de los profesores que estarían orientando su uso sobre los signos presentes en la representación de la recta numérica.

En particular, Radford afirma que "El signo tiene significado cuando está relacionado con otros signos" (Radford 2006b, p. 8), por lo que se le daría significado a la representación cuando se están relacionando los signos explícitos con los implícitos sobre el modelo de la recta numérica.

Respecto al tratamiento de los signos, nos interesa detectar el uso que se hace de ellos ya sea como índices o símbolos, Pierce (2005) lo que será relevante para un adecuado tratamiento simbólico, a lo largo de su actividad docente, en el tratamiento de la recta numérica y en el uso de las propiedades de orden y homogeneidad.

Para los fines de esta investigación sobre el uso de los signos hemos incorporado la restricción de la homogeneidad, Nemirovsky (2003) de la recta numérica en la que la única propiedad de los objetos representados es su posición con el fin de para indagar la inclinación de los profesores para modificar o no, las condiciones espaciales de la recta numérica bajo condiciones cambiantes, así como de su interpretación del orden y la ubicación espacial de los números y de sus marcas sobre los signos presentes en el uso del modelo.

En la presente investigación, la gestión simbólica de la recta está presente cuando los profesores ajustan la representación de la recta numérica, dependiendo de las necesidades de los problemas planteados y el tratamiento semiótico se caracteriza por reconocer las normas matemáticas de orden, ubicación espacial y posición relativa de los números y marcas representadas.

Metodología

Sobre la muestra

La presente investigación exploró las concepciones de 72 profesores de secundaria de Honduras, que atienden estudiantes de entre 12 y 15 años, investigación que se desarrolló mediante un taller en línea como parte del Congreso de Matemática Educativa (COME) en Honduras en el año 2021, dirigido a profesores de todo el país, la convocatoria abierta fue atendida libremente por los interesados para la mejora de la enseñanza de las matemáticas en dicho país.

Método

El taller se desarrolló vía Zoom apoyado en el uso de la plataforma GeoGebra classroom, a través de un cuestionario donde los profesores podían manipular representaciones gráficas e interactuar con la investigadora ya sea frente a todos los participantes, de manera particular e instantánea o incluso dejar comentarios por escrito para tener comunicación posterior, esto fue útil para analizar más ampliamente sus opiniones y concepciones de su gestión sobre el modelo de la recta numérica.

El cuestionario estaba dividido en ocho tareas asociadas a la gestión de la recta numérica con el fin de conocer las concepciones de los profesores frente a tareas que requieran de gestionar la recta numérica, específicamente sobre el orden y a la homogeneidad.

De manera general, se presentaron gráficas de rectas numéricas en las que se preguntaba por la posición de marcas relevantes como el cero, así como la elección de rectas en donde el cero no está en el centro y puede ser una más adecuada representación numérica. Solicitamos también su opinión sobre el tratamiento en clase de la pertinencia de una representación de números extremos por su posición. Además, les propusimos representaciones que requieren considerar la posición relativa de números dados, según la información disponible, tanto en casos correctos como incorrectos. Debido a que estas tareas nos mostrarían las concepciones de los profesores y los esquemas que aprenden sus estudiantes en las clases de matemáticas.

Para el análisis de los datos, hemos considerado la elección de ciertas gráficas como una disposición hacia la gestión, al mismo tiempo observamos indicadores verbales en el uso de los términos: escala, dirección y medida que son adecuados para gestionar la representación institucionalizada, dejando de lado la interpretación simbólica.

Resultados y Discusión

En la primera tarea, se les presentó a los profesores una recta numérica y se les pidió ubicar al cero en ella, 62.5% lo colocan en el centro, también el 11% eligió en el extremo izquierdo posiblemente porque estaban considerando los números positivos, lo que podría ser reflejo de su práctica usual.

En la segunda tarea pedimos: *"De las rectas numéricas que se muestran abajo ¿Cuál elegiría para proponérsela a sus estudiantes si desea colocar sobre ella los números 120 y – 3? Explique"*

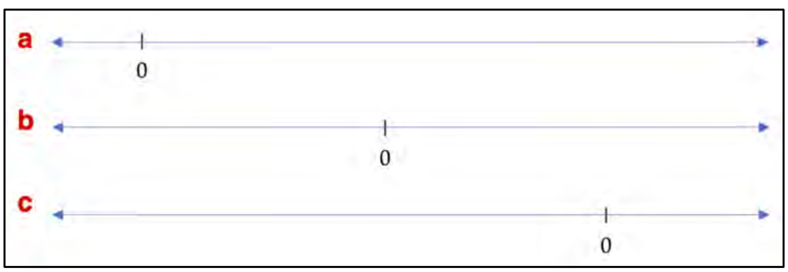

Figura 1: Tarea 2. Elección de la recta adecuada.

En la primera parte de la pregunta la mayoría de los profesores (59.7%) elije **a**. En la segunda, algunas de las justificaciones son: 1) Porque hay mayor espacio (40%); 2) Se puede hacer escalas para ubicar los puntos (2%); 3) Se requiere una cantidad mayor para los números positivos que para los negativos (6) y no contestaron (32%).

Del 59.7% que eligieron la opción **a.**, el 58.1%. es decir, el 34.7% del total justificaban que había más "espacio" o "distancia" entre los números, lo que nos hace ver que el uso y el tipo de recta favorito están pensadas para impartir la clase, así como el tipo de ejemplos que serán mayormente positivos.

En la tercera tarea se solicita: "*¿Cómo les explicaría a sus alumnos que se puede utilizar la siguiente recta numérica para colocar sobre ella los números -200 y 5?"*

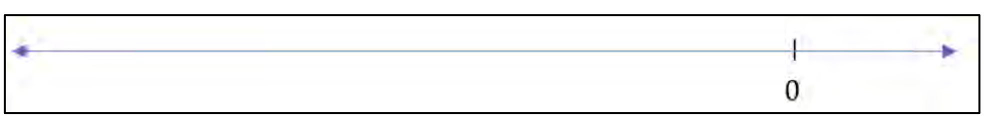

Figura 2: Tarea 3. Explicación del tipo de recta usada.

Los profesores que incluyen los términos: escala, espacio y dirección son el 45.9%, quienes, al parecer, consideran algún tipo de cambió en la representación, mostrando una forma de gestión sobre la representación que consiste en usar segmentos de 20 en 20 unidades, por ejemplo.

Con el fin de profundizar en las concepciones y justificaciones de los profesores cuando se enfrentan a este tipo de tareas, a continuación, mostramos una de sus respuestas para el caso.

P2: Les explicaría que el -200 está más alejado del cero, por lo tanto, se necesita una escala más grande para representarlo, por el contrario, el 5 está más cerca del cero, así que no es necesario mucho espacio.

Justificación que nos muestra que posiblemente está pensando en utilizar una escala en un lado de la recta numérica y en el hecho de contar con menos espacio al otro lado.

Otras justificaciones para la elección de este tipo de recta y que están asociadas con la escala, son las siguientes:

P7: Podemos hacer divisiones de 5 cm que representen 40 unidades con lo cual a la izquierda del cero tendríamos 5 divisiones y a la derecha una sola que deberíamos dividirla en 8 partes iguales donde en la primera división representaríamos el 5.

P60: Esta recta se puede utilizar para ubicar -200 porque tiene el espacio suficiente desde el punto cero y se puede ir ubicando de 5 en 5, de 10 en 10, o de 20 en 20 para los lados negativos, y para los lados positivos ocupa menos espacio porque solo son 5 positivos.

Entendiendo en ambos casos, la escala como una forma de numerabilidad en la que se pretende evitar colocar muchas marcas y su respectiva etiqueta.

Por otro lado, el 45.8% no contestó, lo que posiblemente significa que no habían tenido contacto con esta situación.

Respecto al orden, ubicación espacial y la posición relativa de números sobre la recta, solicitamos en la cuarta tarea: colocar los números faltantes en las marcas que aparecen en la siguiente recta numérica.

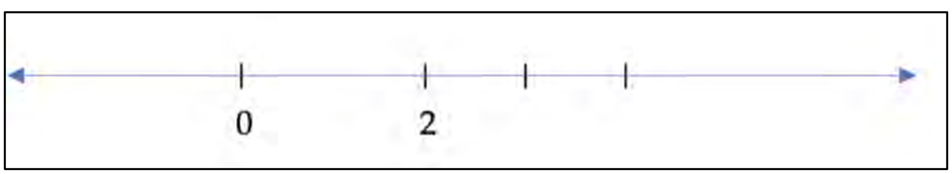

Figura 3: Tarea 4. Ubicación de números faltantes.

La mayoría de los profesores utilizan adecuadamente los segmentos unitarios y ubican correctamente los números faltantes, lo que estaría mostrando que pasan por el proceso de identificación de la magnitud de la unidad, sólo las respuestas de cuatro profesores muestran no haberla considerado, tomando la distancia del cero al 2 la unidad de ahí el error. Observamos también que en el tratamiento de la magnitud en estas últimas respuestas no se resuelve bien la relación Gestalt entre fondo y forma presentes en la representación.

Insistiendo sobre el orden y la interpretación del espacio entre los números, propusimos la siguiente recta advirtiendo que está incorrecta, pedimos reordenarla, así como el dibujo de una recta adecuada.

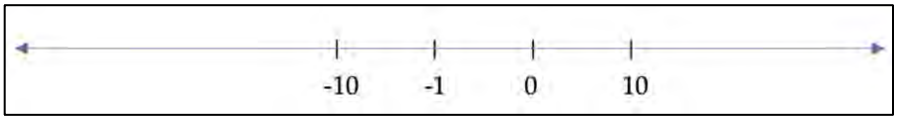

Figura 4: Tarea 5. Interpretación del espacio entre los números.

Los resultados nos dicen que el 40.7% respeta los segmentos unitarios, que el 51,4% no contestan la pregunta, mientras que tenemos 7% de profesores que o bien no respetan distancias entre números o consideran que no la representación no es incorrecta dejando de considerar la posición relativa de los números.

En lo relativo al uso de signos para colocar valores numéricos sobre la recta numérica pedimos colocar los números -5, -3, -1, 4 en la siguiente recta numérica

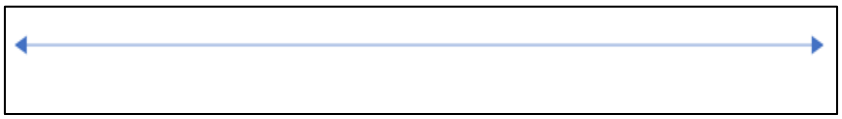

Figura 5: Tarea 6. Ubicación de números.

En esta tarea, los profesores (33%) usaron pequeñas marcas verticales o puntos para colocar los números solicitados, así como marcas extras que le sirven de guía para la posición cuidando que las distancia entre ella sea relativamente la misma, aunque no estén posición local.

También hay unos pocos (26%) que sólo colocan las marcas sobre los números solicitados, estimando la visualmente su posición, lo que nos sugiere que usan una estimación global en esta tarea.

En la tarea 7 que solicitaba reordenar una representación incorrecta todos los profesores que contestaron (50%) ordenaron adecuadamente lo que muestra que el orden entre ellos no es un conflicto, sin embargo, en la tarea 8 faltaba además el cero, por ello se debía rehacer la recta asignando el espacio necesario, el 37.5% de los profesores resolvió correctamente, sin embargo, el 8.3% simplemente agregó la marca y el número en medio del 1 y el -1 sin considerar la ubicación y el espacio unitario.

Conclusiones

En el desarrollo de las tareas es importante notar que solamente la mitad de la cantidad total de profesores respondió consistentemente las tareas del cuestionario mostrado en GeoGebra, posiblemente por dos razones: la primera se puede deber al manejo de las herramientas virtuales y la segunda, porque nunca se habían enfrentado a situaciones similares en las que tenían que gestionar la propia representación por su cuenta.

Detectamos en los resultados cierta tendencia del uso de algunas representaciones favoritas como la de colocar el 0 en el centro o la inclinación por estructuras ligadas a los positivos que sugieren una presencia dominante de sus necesidades en el salón de clase, estas concepciones muestran un uso fuerte y utilitario del modelo. Además, cuando los profesores aceptan modificar la representación ésta está ligada a la idea y al control que les da la escala que pueden dominar, lo que al parecer resuelve los problemas de representación e interpretación en su labor docente.

El orden no es un problema para ellos o incluso agregar los números faltantes y la ubicación espacial es respetada en los casos de necesidad, sin embargo, no se identifica como una condición obligada ni como una necesidad simbólica de la recta numérica, sino como una convención que debe ser respetada, en ciertos casos.

Las concepciones de los profesores respecto a los requisitos de la representación simbólica son que esta es ordenada y que la posición tiene una base homogénea, pero que puede ser modificada según la escala que se use. Lo anterior sugiere que hay modificaciones a la representación con fines utilitarios, pero no se detectan las propiedades simbólicas que lo hacen funcionar como un modelo matemático.

EXPANDING PROFESSIONAL NOTICING TO EXAMINE TEACHERS' DECISION-MAKING DURING INTERVENTION IN SMALL GROUPS

Byungeun Pak
Utah Tech University
byungeun.pak@dixie.edu

This study explores what affects teachers' decision-making when they intervene in small groups. I draw specifically on professional noticing to examine teachers' decision-making. Working with two novice teachers, I observed their mathematics lessons in which both teachers used small groups as an instructional structure to teach mathematical concepts and conducted follow-up interviews to have them elaborate on their intervention. The analysis of both teachers' elaboration on their specific intervention indicates that two teachers decided to intervene in small groups based on interpretations of certain actions as patterns, meaning what teachers have constructed working with students over weeks or months, not only what happened at the moment. This finding suggests that conceptualization of profession noticing needs to be expanded. Implications for research and teacher educators are offered.

Keywords: Elementary School Education; Teacher Education; Teacher Noticing; Group Work

Leslie, a fourth-grade teacher, has students work together with each other in small groups to solve a mathematical task. The teacher notices one student with head down and two students talking quietly to each other in a group of three students. The teacher approaches the group and decides to intervene in the small group by encouraging the student who has his head down to participate actively in the group work and the two students to include the other student in their group work. A question arises in terms of the teacher's decision-making: What affects the teacher's decision-making of how to intervene? This teacher's decision might be based on what she noticed in the immediate moment and on the understanding the teacher has constructed while working with students over weeks or months. In this paper, I try to answer this question by examining how two beginning teachers explained their decision-making related to how to intervene in small groups in mathematics instruction. I draw particularly on the framework of professional noticing (Jacobs, Lamb, & Philips, 2010) to investigate the two beginning teachers' decision-making.

Perspectives

There are different ways for researchers to conceptualize teacher noticing (See Jacobs and Spangler (2018) and Sherin, Russ, and Colestock (2011) for details). I draw specifically on professional noticing (Jacobs et al., 2010) in this paper because it helps us understand what informs teachers' decision-making. In general, professional noticing consists of three interrelated cognitive components- attention (what teachers attend to in classroom activity), interpretation (how they make sense of what they attend to) and decisions of how to respond (how they plan to respond). Even though these three components "are tied together conceptually and temporally" (Sherin et al., 2011, p. 81), I view interpretation as an important component that can inform what affects teachers' decision-making during teachers' intervention in small groups.

The current dominant assumption of professional noticing as a practice is that it can inform "teachers' in-the-moment decision-making" (Jacobs & Spangler, 2018, p. 772). Viewing professional noticing as part of in-the-moment decision-making indicates that teachers make decisions about how to respond to what happens because they interpret what happens as something to respond to immediately and urgently. For example, Leslie in the scenario might have attended to the head-down student, interpreted his action as being off-task, and decided to encourage them to work together because she felt an immediacy of correcting his off-task action. Alternatively, she could attend to the head-down student, interpreted his action as a sign of boredom, and decided to have the two students include the head-down student.

There has been an argument in which the notion of professional noticing should be expanded. Louie (2018) pointed to "the limitations of conceptualizing teacher noticing in terms of individual teachers' skill at internal mental processes" (p. 68). She argued that the current conceptualization does not explain that noticing is socially and culturally constructed. It needs to be expanded to recognize impacts of socially and culturally constructed ideas, such as deficit views, related to students and their behavior on what teachers notice, which affects teacher's decision-making. Her argument suggests that teachers' decision-making might be not simply based on what they interpret as immediate and urgent but also certain ideas constructed in the long term. Building on this idea, I argue for considering *patterns*, meaning what teachers have constructed working with students over weeks or months, to be a part of what affects their decision-making.

Teachers might make decisions of how to respond based on *patterns* they have observed of students in terms of actions and what happened as a result of the actions, not simply their in-the-moment noticings. *Patterns* teachers have observed over weeks or months shape teachers' perceptions. When teachers attend to certain actions, they may see them as *patterns* and interpret such actions based on *patterns*. As such, interpreting certain behaviors as *patterns* is not likely to be the same as noticing something immediate and urgent in that it is shaped by teachers' perceptions of students built up over weeks or months.

In terms of intervention in small groups, noticing certain *patterns* might affect teachers' decisions of how to intervene in small groups. Leslie in the scenario earlier might interpret the student's action (of his head down) as typical behavior based on what she had observed repeatedly over months and decide to respond to such action. Literature on intervention in small groups knows little of what affects teachers' decision-making drawing on teacher noticing and professional noticing.

In this paper, I argue that teachers might make decisions of how to respond to students and their behaviors in the context of small groups not only based on the current dominant conceptualization of noticing (what happens at the moment) but also on the expanded conceptualization (*patterns*). As such, the purpose of this paper is to understand what affects teachers' decision-making when they intervene in small groups in mathematics instruction drawing on both the current and expanded conceptualizations of teacher noticing.

Methods

To collect data, I worked with two beginning teachers, Leslie and Marva (pseudonyms). They were novice teachers in the sense that they were in their second or third year in teaching careers in 2018-2019. Leslie taught fourth grade students in a city area. Marva taught first grade students in an urban area. I recruited them because they reported they implemented small groups regularly as an instructional structure to teach mathematical concepts and decided to participate in the study. To collect the data, I conducted three stimulated recall interviews per teacher. Before each stimulated recall interview, I first video-recorded the entire length of a mathematics lesson. As a result, I obtained video recordings of six different mathematics lessons, three of which came from each teacher. Watching each video recording on my own, I identified four or five short moments of intervention in each video where I could see teachers intervene in and interact with students in a productive way (e.g., encouraging students to participate actively in group work or asking students to explain their strategies). During each stimulated recall interview, I had the teacher watch each intervention I had identified prior to the interview. After watching each intervention, I asked the teachers questions building on three components of professional noticing to elaborate on what they noticed, what they thought was happening in the small group, and why they intervened in the small group the way they did. The interview data were audio-recorded and fully transcribed for analysis. The data sources were 24 intervention excerpts, four of which were obtained from each of the six interview transcripts. Each intervention excerpt consisted of two parts- 1) a transcript of intervention and 2) teachers' elaboration on their intervention. There were three steps I took to analyze the data. First, I read through an intervention transcript and the teacher's elaboration to make sense of attention, interpretation, and decisions of how to intervene in small groups. Second, I examined how the teachers explained their intervention in each intervention excerpt in terms of interpretation of what happened in small groups, whether it was based on immediacy or *patterns* over time. Third, by comparing each interpretation, I identified certain regularities related to interpretation across intervention excerpts.

Finding(s)

As a result of the data analysis, I found that two teachers decided to intervene in small groups based on interpretations of certain actions as *patterns*, not only what happened at the moment. To illustrate this finding, I present a part of an excerpt of interaction between Leslie and a group of students. This excerpt comes from Leslie's first lesson. In this lesson, the students were asked to work together on choosing ingredients to make the meal from the list on the worksheet. They had to figure out the cost of dinner by adding the cost of ingredients that they chose to make the meal. This intervention happened when, as she was monitoring the classroom, Leslie looked at the numbers on the worksheet that a group of four students (Alice, Jacob, Fred and Bob) had worked on. The teacher began to initiate conversation with the small group by asking questions.

1. Leslie: (Points to some numbers on the worksheet expecting to hear from anyone in the small group) So what's going on over here? What's this?
2. Fred: This is the number of- (interrupted by Leslie who asked another student questions).
3. Leslie: Alice, what's this? What are all the numbers over here?
4. Alice: This is, uh, addition problem ... for this.
5. Leslie: What's two plus six? What's that?
6. Alice: Eight (answers quietly.)
7. Leslie: But where did you get those numbers from? I don't see two and six.
8. Alice: (Points numbers the group chose on the worksheet) From the dollars... [inaudible] … two numbers.
9. Leslie: Okay. So you're taking just the dollars and adding them up?
10. Alice: Yeah.
11. Leslie: Okay. Jacob, do you think that's the best way of doing this?

This excerpt showed Leslie's decision-making based on what she thought happened at the moment. According to the teacher's elaboration in relation to this intervention, when she looked at the numbers on the group's worksheet, she was wondering "if they were estimating" or "if they were just taking the number, the dollar values, or what they were going on." Leslie attended to what she saw on the worksheet and interpreted what the students did as something she needed to respond immediately. Based on her sense of its immediacy, she decided to ask the small group questions to make sure they were doing right.

Leslie's elaboration on her intervention in relation to her intervention in this excerpt also showed how the teacher's decision-making was based on *patterns*, not only on what happened at the moment. In Line 2, Fred tried to answer Leslie's question in Line 1. She interrupted his initiation to talk. She chose to call on Alice first to ask questions. The teacher was asking Alice to explain the group's strategy to solve an addition problem they created. From Line 3 to Line 10, she intervened in the small group by asking students to explain their mathematical thinking. After listening to Alice's explanation, she shifted her attention from Alice to Jacob to ask him to evaluate Alice's explanation (Line 11). Leslie's elaboration on this specific intervention shows that she interpreted Fred's initial response (Line 2) as *patterns* she has known of what might happen when she allows Fred to talk. She interpreted their actions as *patterns* she has constructed of how Fred, Alice, and Jacob might do in group work without her intervention. Fred "could have just taken over and been writing the answers" and Alice and Jacob "could have been sitting there the whole time." Otherwise, it would have been possible for her to not interrupt Fred so that he could continue to provide his explanation. Instead, however, she decided to call on Alice first to ask questions. Like shown in the example above, both teachers' decision-making during intervention was affected by *patterns*, not only what they interpreted as something immediate and urgent.

Discussions and Implications

I demonstrated how *patterns* (what teachers have constructed working with students over weeks or months) could affect teachers' intervention in small groups. There are two points to discuss. First, this paper contributes to expanding the current dominant conceptualization of professional noticing based in-the-moment noticings. Like shown in Louie's (2018) argument, the notion of professional noticing should be expanded, in this paper, to include patterns as part of what affects teachers' decision-making during intervention. The expanded conceptualization of professional noticing could be applied to teachers' decision-making in other teaching contexts, such as whole class or independent work. Second, this paper provides a more detailed understanding of what affects teachers' decision-making during intervention in small groups. Literature on intervention in small groups has not attended to teachers' decision-making using teacher noticing and professional noticing. Based on this study, researchers with an interest in intervention in small groups may examine how *patterns* affect teachers' intervention in small groups in a productive way. A few questions to explore include: what types of patterns do teachers notice? How would patterns be related to socially and culturally constructed ideas (e.g., deficit views towards minority students)? In terms of teacher education, teacher educators may need to support novice teachers to be aware of what affects their decision-making during intervention in small groups in mathematics instruction. Teacher educators may design an instructional activity in which novice teachers analyze their elaboration on their interaction with students in small groups to examine how *patterns* affect their decision-making.

Productive use of student mathematical thinking is a critical aspect of effective teaching that is not yet fully understood. We have previously conceptualized the teaching practice of building on student mathematical thinking and the four elements that comprise it. In this paper we begin to unpack this complex practice by looking closely at its third element, Conduct. Based on an analysis of secondary mathematics teachers' enactments of building, we describe the critical aspects of conducting a whole-class discussion that is focused on making sense of a high-leverage student contribution.

Keywords: Classroom Discourse, Communication, Instructional Activities and Practices.

The mathematics education community has advocated using students' mathematical thinking as a critical component of whole-class instruction (e.g., Association of Mathematics Teacher Educators, 2017; National Council of Teachers of Mathematics, 2014). Elsewhere, we have argued that some instances of in-the-moment student thinking are particularly high-leverage and, if taken advantage of productively, can be used to engage students in a whole-class discussion focused on making sense of the important mathematical ideas that underlie the student thinking (Leatham et al., 2015). Taking advantage of such instances, however, requires that a teacher coordinate a collection of teaching actions into a coherent practice. Furthermore, certain aspects of this practice do not occur naturally in whole-class instruction (Stockero et al., 2020). Thus, taking advantage of such instances is a complex practice.

Grossman and colleagues (2009) have described the decomposition of teaching practices into their "constituent parts" (p. 2069) for the purpose of better understanding and improving teachers' ability to engage in complex practices. We have previously conceptualized the teaching practice of *building on student mathematical thinking* and decomposed it into four elements that comprise the practice: "(1) *Establish* the student mathematics of the MOST so that the object to be discussed is clear; (2) *Grapple Toss* that object in a way that positions the class to make sense of it; (3) *Conduct* a whole-class discussion that supports the students in making sense of the student mathematics of the MOST; and (4) *Make Explicit* the important mathematical idea from the discussion" (Leatham et al., 2021, p. 1393). In this paper we further decompose the practice of building on student thinking by looking closely at its third element, Conduct. Specifically, we examine this research question: What are critical aspects of the Conduct element of building as revealed through teachers' attempts to enact the practice?

Literature Review

Conducting a whole-class discussion that engages students in making sense of an instance of student mathematical thinking is a complex teaching practice that requires deliberate actions by the teacher. Research on teacher moves during whole-class discussion sheds some light on a range of teacher actions that can support student sense making. Some actions prompt students to make sense of an individual student contribution by, for example, pressing for justification (e.g. Drageset, 2014; Ellis et al., 2019), asking probing questions that encourage other students to engage with specific details of the contribution (e.g., Webb et al., 2019), requesting that students evaluate the correctness of an idea (e.g., Drageset, 2014; Bishop et al., 2016), or asking students to reflect on an idea to advance their mathematical understanding (e.g., Ellis et al., 2019). Other teacher actions support students in making sense of how ideas are related, such as positioning one student contribution relative to another (Webb et al., 2019) and requesting that students make connections among two or more contributions (Lineback, 2015; Bishop et al., 2016). Still other actions keep students focused on the contribution that they are making sense of, such as putting aside contributions that are unrelated to the idea at hand (Dragset, 2014), and redirecting students' attention (Lineback, 2015) to the idea that is the focus of the sense-making discussion.

Although all of these individual moves have potential, in general, to support student sense making, we have come to understand that conducting a whole-class discussion focused on making sense of a particular student contribution requires a coordinated collection of teacher moves. Smith and Stein (2018) articulated one such coordinated collection of moves for orchestrating a whole-class discussion around a high-cognitive demand task. Their 5 Practices have been widely used to support teachers in facilitating mathematical discussions when the teacher has an opportunity to monitor students' work, and then intentionally select and sequence the solutions they wish to incorporate in the follow-up discussion. When a high-leverage instance of student thinking emerges in the moment during a whole-class discussion, however, a different collection of actions is needed to conduct a whole-class discussion around that student contribution. We define this collection of actions as the teaching practice of building on student mathematical thinking (Leatham et al., 2021; Van Zoest et al., 2016).

Theoretical Framework

When we discuss the teaching practice of building, we are focused on building on a high-leverage instance of student mathematical thinking that emerges during whole-class instruction. More specifically, we focus on building on MOSTs (**M**athematically **O**pportunities in **S**tudent **T**hinking), which are described in Leatham et al. (2015). MOSTs are instances of student mathematical thinking that are related to significant mathematics and that create an opportunity in that moment they are shared to engage the class in joint sense making of the mathematics embedded in the instance.

When we say *building on a MOST* we mean the teaching practice that takes advantage of the opportunity that a MOST provides (Van Zoest et al., 2016). We define *building on a MOST* (hereafter referred to as *building*) as making a MOST "the object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea" (Van Zoest et al., 2017, p. 36). As mentioned earlier, *building* is comprised of four elements: (1) *Establish*; (2) *Grapple Toss*; (3) *Conduct*; and (4) *Make Explicit* (Leatham et al., 2021). This paper focuses on the third element, Conduct, but we frame our discussion of this element by first sharing some detail about the first two elements. Two important aspects of Establish are establishing precision by taking steps to assure that the MOST is "clear, complete, and concise" enough for the students to engage in making sense of it (Leatham et al., 2021, p. 1395) and then establishing the precise MOST as an object to be discussed. Once the MOST is established, it is then grapple tossed—offered to the class in a way that positions them to make sense of it. The key aspects of a Grapple Toss are an explicitly established object and an action that students are to apply to that object—actions such as justify or make sense of.

Methods

Twelve practicing secondary school mathematics teachers worked with us to study the theorized practice of building. These teacher researchers used four mini tasks (see Figure 1) in their classrooms that were designed to elicit particular MOSTs; this allowed them to enact the practice of building in a context where there would be a predictable MOST. We compared the 27 resulting videotaped enactments to our theorized conceptualization of building by coding the enactments for teacher actions that seemed to either facilitate or hinder the overall practice of building. Our analysis included identifying critical aspects of each element, as well as subtleties of each. In this paper we report what we learned about the Conduct element of building, specifically the aspects of this element and actions teachers might take to increase the likelihood that students will productively engage in a collaborative discussion focused on making sense of a peer's contribution.

(a) Percent Discount The price of a necklace was first increased 50% and later decreased 50%. Is the final price the same as the original price? Why or why not?	**(c) Points on a Line** Is it possible to select a point B on the y-axis so that the line $x + y = 6$ goes through both points A and B? Explain why or why not. (b) Variables Which is larger, x or $x + x$? Explain your reasoning.	**(d) Bike Ride** On Blake's morning bike ride, he averaged 3 miles per hour (mph) riding a trail up a hill and 15 mph returning back down that same trail. What was his average speed for his whole ride?

Figure 1: The Four Mini Tasks Used to Create Instantiations of Building

Context of the Conduct Element

Once a MOST has emerged during a class discussion, been established as a precise object, and grapple tossed to the class, the teacher enacts the Conduct element— perhaps the most complex element of building. The overarching goal of Conduct is to keep the whole-class discussion focused on the MOST as the teacher facilitates the class's movement toward making sense of the mathematics of the MOST. In essence, making sense of the MOST and the mathematics associated with it becomes a new mini-discussion that the class becomes temporarily engaged with before returning to the larger discussion. Thus, conducting a discussion about a MOST requires a different collection of coordinated actions than those that a teacher might engage in other circumstances (such as after they have students work on a task and then collect ideas about that task). Once a teacher decides to build on a MOST, we have found that it is unproductive to continue to collect ideas about a broader task or anything other than ideas related to the MOST. In fact, our data suggest that doing so is detrimental to taking advantage of the opportunity the MOST provided to make sense of important mathematics.

Before discussing the specifics of the Conduct element, we begin by providing a "big picture" overview of the teacher actions that take place while effectively carrying out this element of the building practice. Note that this overview is not meant to oversimplify the complex activity of conducting a discussion about a MOST, but to help the reader think about how specific teacher actions might coordinate to carry out the nuances of the work. When a student contributes an idea during Conduct, the teacher first determines whether the mathematics underlying that contribution will help students make sense of the MOST–whether it is a MOST-related contribution (MRC). The subsequent sequence of teacher actions depends on that determination. If a teacher determines that the contribution is not MOST-related (a non-MRC), we have found that a productive teacher action is to gracefully put aside the idea (Drageset, 2014) and recenter the MOST as the focus of the discussion. If the teacher determines that the idea is an MRC, we have found a productive sequence of actions is to first establish the MRC and then make a move that invites students to connect the MRC to the MOST itself—to make sense of how the new idea helps to make sense of the MOST. In essence, the flow of the Conduct element is a repetition of this pattern, since in doing the work of responding to either a MRC or non-MRC, the teacher sets students up to continue to contribute their ideas to make sense of the MOST. We elaborate on the details of these teacher actions in the following sections.

Is the Student Contribution MOST-related?

When conducting a discussion around a MOST, it would be ideal if all of the contributions that students add to the discussion helped to make sense of the MOST. Students do not always do or say what a teacher might want or expect, however. In order to keep the discussion focused on making sense of the MOST, each time a new contribution is shared during the Conduct element, the teacher needs to begin their work by determining whether the contribution is actually a MOST-related contribution (MRC). This determination informs the teacher's subsequent actions.

Determining whether a contribution is an MRC may require the teacher to clarify what the student has said or expand the contribution to get a sense of the student's reasoning. After the teacher has sufficient information to infer the mathematics of the contribution, they then must ask themself, "Is the mathematics of this contribution directly related to the MOST?" (rather than, for example, a contribution that shares another idea about a broader task that students have worked on) and "Will it help students make sense of the MOST?" If both answers are yes, the contribution is an MRC. Otherwise, it is not. In general, for a contribution to be MOST-related, it needs to have the same underlying mathematics as the MOST.

In the following sections, we elaborate on the work that our data suggest a teacher needs to engage in after they determine whether a student contribution is an MRC. We first discuss actions around contributions that are not MRCs, and then actions that support the class's sense-making around an MRC. As we discuss these actions, we will share examples from our data based on whole- class discussions of the tasks designed to elicit MOSTs in Figure 1.

The Student Contribution is Not an MRC

If the teacher determines that a student contribution is not an MRC, our data suggests that it is best to redirect the conversation back to the MOST by *putting aside* the unrelated contribution and recentering the MOST as the focus of the conversation. The action of *putting aside* is adapted from the work of Drageset (2014) who stated that "redirecting actions might be used to put aside suggestions without too much discussion to keep the class concentrated and in order not to lose the line of thought" (p. 300). Recentering the MOST draws on the work of Lineback (2015) who talks about a type of "focus redirection" in which the teacher "refocus[es] the students on an earlier discussion topic" (p. 432). In the case of building, the MOST that is under consideration would be the earlier discussion topic. In this section we elaborate on the ways that the putting aside and recentering might occur.

One way we saw teachers put aside a non-MRC and recenter the MOST was by simply reminding students that they are to be making sense of the MOST. For example, in the Points on a Line task, a common shared solution was "Yes. Point B is $(0,3)$ because you get $3 + 3 = 6$," including the explanation that they took the *x*-value for the equation $x + y = 6$ from point A and the *y*-value from point B. Despite being asked to make sense of this particular student contribution, in the ensuing discussion students often offered other approaches to solve the task itself, such as “If you write the equation in slope-intercept form, the y-intercept is (0, 6).” This contribution is a non-MRC because the underlying mathematics related to slope-intercept form is different from the mathematics of the MOST (related to what it means for a point to be a solution to an equation). In this situation, the teachers said things like, “That’s another interesting approach, but right now we want to be making sense of the claim that Point B is $(0,3)$ because $3 + 3 = 6$.” This statement validates the contribution but immediately puts it aside and recenters the MOST as the focus of the discussion. In our data, we have found that it is essential to not only put aside a non-MRC, but to also redirect the conversation by recentering the MOST; this recentering provides guidance to focus students’ subsequent contributions. Other teacher actions that supported recentering included gesturing to the public record of the MOST while reminding the class that the MOST is what they are currently discussing, and re-grapple tossing the MOST to re-engage students in sense-making around that contribution. These actions for handling a non-MRC are seen on the left side of Figure 2.

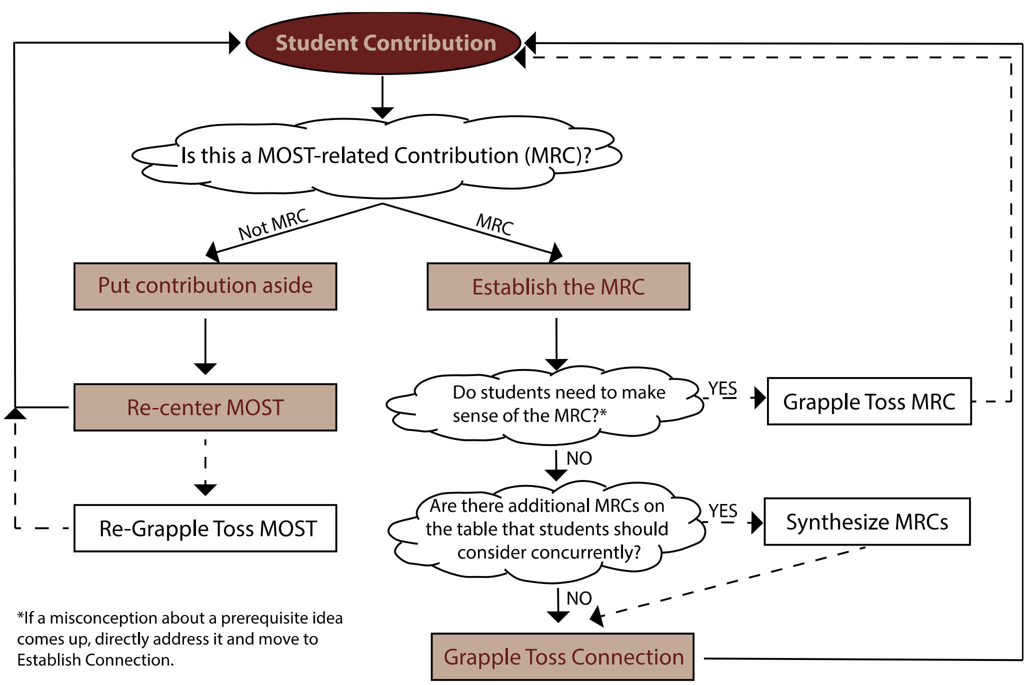

Figure 2: The Conduct Element of Building

The Student Contribution is an MRC

If it is determined that a student contribution is an MRC, the teacher’s focus should be on weaving this MRC into the conversation about the MOST. Prior to doing this weaving, we have found that the teacher needs to ensure that everyone in the class understands the essence of the MRC they will consider. Our data indicate that this involves two essential actions—establishing the MRC, and positioning students to connect the MRC to the MOST in a way that allows them to use the MRC to help make sense of the MOST. We first talk about these two essential actions when working with an MRC (the tan boxes on the right side of Figure 2) and then discuss other considerations when working with an MRC (the white boxes on the right side of Figure 2).

Establishing the MRC. Our data suggests that prior to weaving an MRC into the discussion, similar to establishing the MOST, the teacher should first establish the MRC as clear, complete, and concise (Leatham et al., 2021). For example, recall that in the Points on a Line task, the

MOST that emerged was that the point B (0, 3) was the point that satisfied the conditions of the problem because $3 + 3 = 6$. In the discussion of the MOST, Joelle (all names are pseudonyms) said, "Well, I mean, it doesn't ever, I don't know, I just feel like there's no, it doesn't say that the x and y are coming from different points, I just don't know how that would work." With so much hedging, it was necessary for the teacher to hone in on the key aspect of what Joelle said to make her statement concise, and clarify her statement in the process. He did so by saying "Okay so you're describing this [the teacher points at the MOST written on the board, 'Yes, use (0,3) because 3+3=6'] as taking x and y from different points." The teacher made this statement with a tone indicating that he was seeking confirmation from Joelle that he had interpreted her statement correctly. His gesture to the board also clarified that Joelle's contribution was describing the approach used in the MOST. Teacher moves to establish the MRC have the impact of making the MRC clear, complete and concise for the rest of the students in the class.

Grapple Toss Connection. Asking students to consider how an MRC helps them make sense of the MOST is an important aspect of the Conduct element. When there is an MRC on the table, the teacher needs to make a move to position not only the MOST, but also the MRC, as the object of the discussion. The *grapple toss connection* tells students the action they are to take on the MRC and the MOST—to connect the MRC to the MOST in a way that positions the students to use the MRC to help make sense of the MOST. Because a connection necessarily implies tying two things together, we have found that an important aspect of the grapple toss connection is clearly identifying the two ends of the connection, the established MRC and the MOST. Without clearly defining both ends of the connection, some students may not know what object they are to consider. In addition, we have found that the teacher needs to clearly define the action that students are to take on that object. Failing to do so often leaves students wondering what they are to think about, rather than putting them in a sense-making situation. The reason this is called a grapple toss connection is because the action-defining move resembles the Grapple Toss of the MOST, but the object that is tossed is the connection between the MRC and the MOST.

We have seen some variations in how a teacher connects an MRC to the MOST. One of the most productive connecting actions we have seen in terms of helping students use the MRC to make sense of the MOST—the purpose of the Conduct element—is explicitly asking students to relate the new information (the MRC) to the MOST. For example, in the Percent Discount Task, the common MOST is the response that the original and final price are the same because you are adding and subtracting 50%. In the discussion of the MOST, Kaleb contributed the following MRC using a sample necklace price of $32, "If you add the half of 32, which is 16, it would equal 48. [*teacher writes "If you add ½ of the 32, 32+16 = 48" on the whiteboard*.] But, if you subtract the half of 48, it would give you 24 which is not the original price." The teacher responded to this MRC by saying, "Okay, so, if you add half of the original, 16, that would give you 48 and then if you subtract half of the 48, it would be 24? So what does that have to do with the original claim here? How does that prove or disprove it?" Here we see the teacher identify both ends of the connection by restating Kaleb's contribution and asking how it relates to "the original claim"— the MOST. The fact that the original claim is recorded on the whiteboard strengthens the connection because students can refer to the public record to recall exactly what the original claim was. Not only does the teacher clearly identify both ends of the connection but they also identify an action, "prove or disprove", that the students are expected to take as they consider the connection between the MRC and the MOST. This grapple toss connection clearly positions students to make sense of the connection between the MRC and the MOST.

Another way we have seen teachers connect the MRC and the MOST is to ask students to consider conflicting information. In this case, the teacher typically highlights that there is in fact a conflict, and then asks students to make sense of that conflict. For example, after an MRC surfaced in the discussion of the Percent Discount task, the teacher said, "So in Bruce's argument, [the initial and final price are] not the same but Jaden was saying it would be the same cause you would just add 5 and minus 5. So how do we know which one we're supposed to do?" In this response, we see the teacher connecting the MRC (Bruce's argument) to Jaden's claim (the MOST) by highlighting the contradiction that is now on the table and asking students the action-defining question, figuring out "which one we're supposed to do." Pointing to Jaden's claim on the board, restating a portion of the claim, and explicitly referencing Bruce's argument when contrasting it with Jaden's all support having a clear object of consideration.

In summary, when integrating MRCs into the discussion of a MOST, we have found that explicitly defining both ends of the connection puts students in a position where they are able to use the new information provided in the MRC to make sense of the MOST. A second important aspect of the grapple toss connection is to define some type of mental action the students are to carry out when considering how the MRC helps them make sense of the MOST.

Other Considerations. After an MRC is established, but prior to the grapple toss connection, we have found that additional teacher actions are sometimes needed. These moves–grapple tossing the MRC itself and synthesizing the ideas that are on the table–only seem necessary when it is clear that they will better position students for the grapple toss connection.

Grapple Tossing the MRC. Before they are asked to make sense of the connection between the established MRC and the MOST, we have found that sometimes students need to spend some time making sense of the MRC itself. This is important when the students do not yet appear to understand the MRC. If the teacher determines that this is the case, our data suggest that the best move is to Grapple Toss the MRC itself to the class by asking a question that positions students to make sense of that contribution (seen on the right side of the flowchart in Figure 2).

In the discussion of why the simple average of 9 mph (the MOST) is not correct in the Bike Ride task, Corbin contributed the MRC, "You're going 3 miles per hour for the same length of time as you're going 15 miles." Recognizing the potential value of Corbin's thinking to make sense of the MOST, the teacher responded, "Do you guys believe that Blake rode the bike for the same amount of time going 3 miles per hour and the same amount of time at 15 miles an hour?" In this case, Corbin's thinking was a productive contribution to the discussion because knowing the lengths of time at each speed would help students make sense of the MOST, but it wouldn't be productive to connect it to the MOST until students have had a chance to make sense of the validity of this claim. In this instance, grapple tossing just the MRC was a productive move prior to asking students to connect the MRC to the MOST because it put students in a better position to think about how the MRC might help them make sense of the MOST.

Synthesizing. After an MRC has been established but before the grapple toss connection, a teacher needs to ask themselves whether there are prior MRCs on the table that, if considered in conjunction with the new MRC, would better position students to make sense of the MOST. If so, then some synthesis needs to take place that highlights the salient aspects of the MRCs that students will be asked to collectively consider. In this case, the grapple toss connection might position the class to consider the relationship among multiple MRCs and the MOST.

For the Variables task, the common MOST is for students to say that $x + x$ is greater than x because $x + x$ is $2x$ and that is twice as big as x. After several MRCs had emerged, the teacher synthesized with the following response: "So here we have Andre's thinking that x + x is gonna be larger than x because x + x is double so it makes everything larger, right? Somebody else said 5 plus 5, would be greater than just 5, right? And Briana, now you're saying that if x were -9, then -9 is greater than -9 plus -9." In this synthesis, the teacher has tied the concrete example of x = 5 to the statement of "$x+x$ is larger than x" which is written on the board and then highlights the MRC where x = -9 by writing "-9 > -9 + -9". Note, however, that they stop short of writing or saying $x > x + x$ so the students are left to make that connection and see the contradiction. In this example, the teacher highlights the salient aspects of two MRCs and also ties one MRC to the MOST. With the appropriate grapple toss connection, the students are in a position to make sense of the MOST with a new perspective provided by the MRCs.

Discussion and Conclusion

Engaging students in whole-class discussion focused on making sense of the mathematics in an instance of student thinking is a complex teaching practice. Although past research has identified individual teacher actions that support student sense making, our work suggests that conducting such a discussion requires a coordinated collection of teacher decisions and actions. Each time a new student contribution emerges, the teacher needs to assess whether the contribution will support the joint sense making, or take students in an unproductive direction. This critical initial decision determines the teachers' subsequent decision points and actions.

There are two additional insights about the Conduct element of building that we wish to share. First is the importance of keeping the discussion focused on making sense of the object of discussion, the MOST. In our work, we have seen teachers pursue every student idea that surfaces, resulting in a discussion that meanders among ideas. Although it seems that teachers do this with good intent as a means of honoring students and their ideas, we argue that putting some ideas aside better honors the student who contributed the MOST by maintaining a focus on the important mathematics that they initially brought to the discussion.

Second, we have come to realize the importance of ensuring that students have a clear understanding of the object they are to focus on and how they are to engage with that object at any point in a discussion. During the practice of building, the discussion begins by positioning the MOST as the object that students are to make sense of. In the Conduct element, for each MRC that is contributed, students first need to understand the MRC itself, and then need to shift their attention to considering a connected object—the MRC and the MOST—and how the MRC helps to make sense of the MOST. Without a clear sense of these shifts in focus, students are unlikely to engage in a focused sense-making discussion. Thus, an important part of the teacher's work during Conduct is explicitly helping students productively focus their attention.

Decomposing complex teaching practices is an important first step in supporting teacher learning of such practices (Grossman et al., 2009). Unpacking the Conduct element of building has allowed us to better understand the complexity of the practice of building on MOSTs and positions us to move to the next stage of our work in supporting teachers to develop their abilities to productively use student mathematical thinking.

AESTHETIC DIMENSIONS OF STUDENT MATHEMATICAL CREATIVITY

Meghan Riling
Vanderbilt University
meghan.riling@vanderbilt.edu

There is a popular myth that mathematical creativity is a trait possessed by a small group of people. This is perpetuated by the lack of understanding of what influences mathematical creativity, especially in the classroom. In particular, professional mathematicians often name aesthetic experiences as a critical aspect of their mathematical creativity. Therefore, this study examines aesthetic dimensions of episodes of student creativity from the high school classroom. Several types of aesthetic experiences arose across the episodes. Students were motivated to take creative action by experiences of mystery or discomfort. Furthermore, in some instances, taking a creative action was accompanied and propelled by a sense of craziness or satisfaction.

Keywords: Affect, Emotion, Beliefs, and Attitudes; High School Education

Students must have the opportunity to be creative during mathematics class. Otherwise, they may learn that creating mathematics is for others to do; their only role is to reproduce. This is problematic because creating mathematical ideas is often necessary for practical purposes in life (e.g., crafting a personal finance plan) and can be a source of pleasure and meaning (e.g., making music or noticing patterns) (Su & Jackson, 2020). If students learn that their role with respect to mathematics is to use mathematical ideas or tools made by others, they may not be empowered to take ownership of aspects of their life with prominent mathematical components. This can be dehumanizing and could have devastating impacts (Gutiérrez, 2018).

And yet, it often seems that many students are not capable of being creative during math instruction. Some previous studies of student mathematical creativity have even been unable to detect any student creativity within the context of classroom learning (Clack, 2017; Mhlolo, 2016). I argue, though, that being mathematically creative is not an inborn trait possessed by a limited group of people, but instead a type of action that is influenced by personal, social, and cultural factors. Factors such as these have been explored in creativity in other fields (Csikszentmihalyi, 2014; Hanson, 2015), but are understudied in the case of mathematical creativity. This perpetuates the harmful myth that there are some people who can create new mathematical ideas, and others who cannot.

In mathematics, one factor that has been named by some professionals in the field as impactful in their creative process has been aesthetic experiences (Burton, 1998; Sriraman, 2004). What about students? In this paper, I examine aesthetic experiences and their role in student mathematical creativity by analyzing enacted lessons in high school mathematics classrooms. What roles can aesthetic experiences play in student mathematical creativity?

Conceptual Frameworks

In this study, I assert that mathematics is human-made and fallible (Ernest, 1998; Lakatos, 1976). Thus, human action can create new ways of doing mathematics. Creativity is the act of creating ways of doing or thinking about mathematics that were not previously possible (Riling, 2020). An action with creative mathematical potential is one that an individual takes of their own volition, rather than because of following an instruction or norm (Pickering, 1995; Sinclair, 2005). The action realizes its creative potential if it goes on to enable members of the mathematical community in which it occurs to think about or do mathematics in new ways.

Whether or not an action fulfills its creative potential is not solely based on the merits of the action, but various personal, social, and cultural forces that govern the community of mathematicians.

Because mathematics is a human endeavor, the relationship between a person and mathematics is a crucial aspect governing how mathematics develops, which I conceptualize here through *aesthetics*. Aesthetic experiences can function in multiple ways in the doing of mathematics. They may motivate a person to take some action, or they may occur as a result of a person taking an action (Brinkmann & Sriraman, 2009; Sinclair, 2004). Here I describe three forms of aesthetic experience that may play a role in student mathematical creativity.

First, aesthetic experiences can motivate the exploration of mathematics. Sinclair (2004) explains that as there are few practical reasons to pursue a great deal of the field of advanced mathematics, much of the motivation for doing so is derived from aesthetic aspects of the field. Mathematicians may become "hooked on" (p. 275) the order that can arise from completing a mathematical investigation or proof, or become intrigued by a paradox or moment of surprise. As these types of experiences have been shown to motivate mathematical activity in general, they may specially motivate mathematical action with creative potential. Thus, for the purposes of this study, a *motivating aesthetic experience* is one that prompts students to try to create new mathematical possibilities.

Sinclair (2004) also describes how an aesthetic experience can play a *generative* role in mathematics, in that people may be struck by a sense that mathematical objects or events that arise in the process of doing mathematics that they sense will be valuable or provide insight, compelling them to investigate further. It is possible that while taking an action that has the potential to create mathematics, a student might experience pleasure or excitement that generates further curiosity.

Finally, Sinclair (2004) describes the role of an aesthetic experience in considering a mathematical object that has been produced already; an *evaluative aesthetic experience*. Beauty is a particularly important form of evaluative aesthetic for many professional mathematicians (Brinkmann & Sriraman, 2009; Sinclair, 2004). This type of aesthetic experience may happen as a student regards their own work, or the work of another, and may play a part in what happens after a student has taken an action with creative potential.

Methods

To learn about the role of aesthetic experiences in student mathematical creativity, I examined enactments of secondary mathematics lessons. The lessons were designed to be aesthetically captivating for students. The lessons were analyzed by identifying instances of student action with creative potential and student aesthetic experiences, and by crafting narrative episodes of these actions and experiences, which were then examined for common themes.

Participants and Lesson Selection

The lessons in this study were enacted in high school classrooms in the northeastern region of the US, taught by teachers with 4-6 years of experience in the classroom. The teachers taught at three schools that varied in size, school type, and racial demographics (see Table 1). Each teacher taught three specially-designed lessons. These lessons were designed by small groups, including the classroom teacher, another colleague participating in the study, and university-based researchers. The topics of these lessons fell within the curricula of each course. These lessons were unique in that they were designed by teachers and researchers to provide the opportunity for aesthetic experiences. This was done by way of conceptualizing lessons as mathematical stories (Dietiker, 2015), meaning that the teachers thought of the mathematical context as a setting for the development or action of mathematical characters (e.g., numbers or geometric objects). Some teachers aimed to design stories with compelling narrative devices, such as a surprising plot twist or an air of suspense. This data set was useful for studying aesthetic dimensions of student creativity because a set of lessons designed without attention to students' aesthetic experience could fail to provide any detectable displays of student aesthetic experiences, or any variety in student aesthetic experiences.

Table 1: Participating High Schools and Students

High School	*Cooperating teachers*	*Number of participating students*	*Students' racial identification (categories >15%)*	*Mean disposition to math (1-4)*
Forte Charter Secondary (Forte)	Mr. Davis and Ms. Bacheldor	85	79% - Latinx**	2.54
Gladbury High School (GHS)	Mr. Anderson and Ms. Evans	56	58% - White**	2.73
Motion High School (MHS)	Ms. Curran and Ms. Fontaine	70	50% - Asian** 16% - Latinx**	2.81

**Based on student responses to survey items.*
***Based on demographic data reported by the state; demographics below 15% not represented in this table.*

Each specially-designed lesson was observed and audio- and video-recorded from multiple perspectives in the classroom. Some were enacted and observed for multiple classes of students, if a teacher taught multiple sections of the same course. After the lessons, all participating students completed a Lesson Experience Survey (LES). This survey included a prompt to select three descriptors to describe their experience of the lesson, out of a bank of sixteen terms. Some terms were positive (e.g., “intriguing”), some were neutral (e.g., “fine”), and others were negative (e.g., “boring”). In addition, two or three students were selected to be interviewed after each lesson. Students were typically approached about being interviewed because of some strong affective display during the lesson. For every specially-designed lesson that was filmed, the research team also observed and recorded a typical lesson in the same class of students within approximately one week, following the same observation protocols.

In order to select a group of lessons that were more likely to contain student actions with creative potential, I identified the lessons that were more frequently described on the LES with a group of target descriptors that I theorized could be selected by students to describe experiences that involved creativity (i.e., *thought-provoking*, *amazing*, *fascinating*, *fun*, *surprising*, *intriguing*, and *enjoyable*). I identified each teacher's lessons for which the highest percentage of students selected the target descriptors. Upon beginning to analyze the lessons, I began with one lesson per teacher. I iteratively added additional lessons, aiming to maintain variety in teachers and courses, until I had identified a robust set of student actions with creative potential. All lessons that were included were ones that the teachers had designed to be aesthetically engaging (see Table 2). Each lesson was transcribed, including full-group discussions and the discussions that occurred in a small group that had been filmed from an additional, close-up camera.

Table 2: Lessons Analyzed

School	*Teacher*	*Course*	*Lesson*	*High frequency descriptors*
Forte	Ms. Bacheldor	Honors Algebra 2	Extraneous solutions	Thought-provoking
Forte	Mr. Davis	AP Calculus	Derivatives of exponential functions	Intriguing, Enjoyable
Forte	Mr. Davis	AP Calculus	Solids of revolution	Fun, Enjoyable
GHS	Mr. Anderson	Algebra 2	Imaginary numbers	Thought-provoking, Surprising
GHS	Ms. Evans	Algebra 2	Introduction to inverses	Amazing, Fascinating
GHS	Ms. Evans	Algebra 2	Introduction to inverses	Thought-provoking, Enjoyable
MHS	Ms. Curran	Integrated Math 1	Geometric transformations	Amazing, Enjoyable
MHS	Ms. Curran	Integrated Math 1	Linear functions	Surprising, Fun, Enjoyable
MHS	Ms. Fontaine	Honors Integrated Math 3	Rational root theorem	Fascinating

Identifying and Categorizing Creative Actions

I next scanned the selected lessons for actions with creative potential. By creative potential, I mean actions that *could* lead to the creation of new mathematics. These are those actions that students have taken using their own agency, rather than following disciplinary or classroom norms (Pickering, 1995). In order to broaden my perspective, and thereby increase my ability to detect student creative potential, I consulted first-hand accounts of professional creators. To avoid reinforcing the narrative of mathematics' white, male history, I curated a set of professional creators who varied in medium, gender, country of origin, race and ethnicity, and age. The set of creators included individuals such as Chinese architect and conceptual artist Ai Weiwei, Black American film-maker Ava DuVernay, French-Cuban musicians Lisa-Kaindé Diaz and Naomi Diaz, of Ibeyi, and white French mathematician Sophie Germain. After learning about their creative work, I revisited the classroom data and indeed was able to identify additional student actions with creative potential.

I categorized each action with creative potential based on how the actions opened new possibility for students in the lessons (Riling, 2022). For example, *setting out* refers to instances in which students decide to embark on some kind of creative work. *Imagining* refers to the act of mentally projecting a new version of the mathematical reality. *Recognizing* involves reinterpreting some existing mathematical object in a new way. *Manifesting* is the act of taking a action that immediately changes the current mathematical context.

Identifying and Explaining Aesthetic Experiences

In order to identify any aesthetic experiences that could have had a role in students' actions with creative potential and how they developed in the classroom, I asked the following questions of the lesson data: (1) What emotions do individuals display in reference to their mathematical context? (2) Do the individuals explicitly relate their response to mathematical ideas, or do emotional displays coincide with changes in their understanding of the mathematical context? (3) What kind of aesthetic experience do the individuals appear to be having? I marked displays of emotion such as changes in vocal pitch or tone (e.g., singing or shouting), use of exclamatory language (e.g., "oh my god" or "boom"), use of explicitly aesthetic or emotional language (e.g., "mystery" or "hate"), and changes in physical behavior (e.g., smiling or dancing). I recorded my initial understanding of the type of aesthetic experience that students appeared to be having (e.g., surprise or satisfaction).

Next, I worked to establish the roles of the aesthetic factors (i.e., motivating, generative, or evaluative). I did this in part by considering when the individuals displayed evidence of having an aesthetic experience, in comparison to when the action with creative potential was taken. That is, a motivating aesthetic experience would happen before the action, a generative one would be concurrent, and an evaluative one after. In addition, in order for an aesthetic experience to be considered to have motivated an action with creative potential, there would have to be evidence that the action taken was related to the context that provoked the aesthetic response. For generative aesthetic experiences, students either would explicitly connect their affect to a mathematical object or event, or express emotion at the same time as taking an action, in the absence of any other change that could explain their expression. To be considered to be evaluative, an aesthetic expression would have to occur as the expressing student attended to a mathematical object related to the action with creative potential under consideration.

In addition to the audio and video recordings, in order to ascertain the type and role of students' aesthetic experiences, I consulted post-lesson interviews. For eight of the fourteen episodes, the student who took the action with creative potential was interviewed after the lesson. In some cases, they spoke explicitly about the action and the feelings they had related to it. For example, one student shared during their interview, "when I saw like the coefficients, with the pattern of the roots, I thought that maybe like, it's kinda crazy but maybe the coefficients are related to the polynomial." Here, the student explains how his feeling of something being "crazy" related to his actions.

I identified the episodes that seemed to contain similar dimensions within students' aesthetic experiences (e.g., all episodes that contained mysterious elements) and used memo-ing to explore the similarities in how those experiences functioned in different episodes. For example, I asked myself, "What is the role of satisfaction across these examples?" and "When does satisfaction happen in relation to creative actions?" After answering these questions for individual episodes, I constructed a model of how that type of aesthetic experience functioned with respect to actions with creative potential and to other types of aesthetic experiences. This enabled me to identify and define common dimensions in students' aesthetic experiences.

In the process of analyzing student language in relation to aesthetic experiences, I noticed that students used terms that evoked the existence of some alternative to their current accepted reality (e.g., conspiracy theories, drug use). Therefore, I examined the ways in which students described aesthetic experiences with mathematics related to the existence of a new mathematical world of some kind. This interpretation was overwhelmingly consistent with students' descriptions. Therefore, I defined the common dimensions of aesthetic experiences that I found in the episodes in terms of how they related to students' perception of the existing and/or a new mathematical world.

Findings

Within the data, when students took actions with creative potential, they sometimes seemed to be motivated by two different types of aesthetic experiences: some kind of mysterious uncertainty, or discomfort. Additionally, some actions with creative potential were accompanied by a break in mathematical reality that students referred to as "crazy," or a sense of satisfaction, which played a generative role as it spurred continued investigation, or an evaluative role as students concluded their work exploring an action with creative potential. In this section, I define *mystery*, *craziness*, *discomfort*, and *satisfaction* in terms of students' aesthetic experience with mathematics and describe how students' actions with creative potential were influenced or marked by aesthetic experiences.

Mystery

One dimension of an aesthetic experience remarked upon by students in the data was *mystery*. Mystery appeared in some instances of *imagining*, one type of action with creative potential. In several cases, students indicated feeling that their previous assumptions about the mathematical context were incorrect or incomplete in some way. This happened when students encountered something that did not make sense, such as finding that they need to take the square root of negative numbers in order to solve a problem, when they had previously been told they could not do so. After encountering such a clue, students began to doubt the general premises of the mathematical realm in which they were operating. A sense of uncertainty is inherent in mystery. For example, in the case of a group of students in a scenario that suggested that they should take the square root of negative numbers, when their teacher asked if they believed that was feasible, several students responded "I don't know." In other instances in which students sensed a mystery, they used phrases like "maybe" and "I think," conveying this lack of certainty.

Another common feature of students' references to mystery is that they referred to it broadly. For example, in one lesson, a student said "we have a situation," indicating that, in general, something about the mathematical context was amiss. She did not, however, specify exactly what the potential problem was. Another student was even less detailed, intoning "dun dun dun." This suggests that a sense of mystery might be something that students do not affix to a specific object in their mathematical context, but to the mathematical context more broadly.

Discomfort

In the lessons, students experienced various forms of discomfort as a result of the current mathematical task. This discomfort often seemed to motivate students to take actions with creative potential. Although students also can have negative emotions about other things during mathematics class, such as peer relationships or grades, I am not referring to those experiences here. One form of discomfort in the data was frustration. Frustration often occurred when students were unhappy that their attempts to solve a problem were unsuccessful. It should be noted that other students could be excited to have a problem that they could not solve quickly. To qualify as discomfort, students would have to not enjoy these experiences. Students typically demonstrated discomfort by using qualitatively negative language about mathematics. For example, "I hate *e*," or "Forty-six? Yikes." At other times, they might not verbally refer to a mathematical concept, but instead have a negative outburst (e.g., "Jesus Christ!" or "This shit's confusing") while working on a mathematical task. Another form of discomfort in the data was tedium, in which students were bored by work that they perceived as too repetitive.

In several cases, students seemed to engage in manifesting (a type of action with creative potential) in an attempt to remove discomfort. This bears something in common to students attempting to imagine their way out of a mystery. However, by manifesting, students did not return to the status quo, as the students attempted to do through imagining, but instead took an action that created a new mathematical reality. Consider that in several of these instances, the students verbally wrestled with whether or not to manifest when experiencing a state of discomfort. For example, one student who was struggling to solve an equation expressed that he was uncertain about whether he could square the equation. He asked, "Why can't we?" and then finally rejecting this felt external pressure to not square, stating, "I don't care" as he squared the equation. The evidence that students often manifested in spite of not being sure that it was allowed suggests that these students were aware that they were changing something about the mathematical context. In this way, they acted more like the students who moved toward a new mathematical reality when they experienced something crazy that they chose to explore further.

Craziness

Craziness is related to mystery in that it also indicates that students have come to doubt their current realm of known mathematics. However, it differs in that rather than only sensing that an alternate mathematical reality might exist, students are in the act of crossing over into the new realm. They are compelled to continue doing so, meaning that this aesthetic experience is generative. For example, consider a student in a lesson in which a teacher asked students to group cards that contained representations of linear functions. This student and his groupmates had begun to form pairs of cards that they believed contained representations of the same functions. When the student found out that he could make groups of more than two linear functions, he exclaimed, "more! That's crazy! There's more!" Since students who sense that something is crazy are crossing into the new reality, they can typically point to a specific mathematical object or event that provoked the feeling.

When students described a crazy aesthetic experience, they often spoke loudly in excited tones. They sometimes used language related to conspiracy theories ("it's Illuminati confirmed, bro") or drug use ("that's trippy"). These are both experiences in which an alternate version of reality is suddenly revealed, by way of learning secret information or by consuming drugs. However, the most common vocabulary that students used when expressing that they are experiencing this aesthetic is the word "crazy." It is because of the extreme frequency of this word choice that I use "crazy" to label this type of aesthetic experiences, even though it is a word I typically avoid due to its ableist connotations. To date, I have not encountered an appropriate synonym that expresses both the perceived disruption in students' understanding of the mathematical context, and the sudden onset of feelings that accompanies this shift.

Several students who took the action with creative potential of setting out seemed to be motivated by a sense that something crazy had occurred. For example, the student who found out that he could make groups of more than two linear functions then set out to learn more about individual functions in order to be able to form groups. Additionally, the student in the quadrilateral midpoint lesson set out to learn about parallelograms only after finding a parallelogram in a place that they did not expect it to appear. The feeling of craziness prompted these students to want to learn more about the possible new mathematical context. This is different from the way in which mystery functioned in the cases of *imagining*. In those cases, students responded to a prevailing sense of mystery by attempting to avoid the mystery. That is, they did not want to 'uncover the truth' and potentially create a new reality; they wanted to maintain the status quo.

Satisfaction

Evidence of the sensation of *satisfaction* also appeared in the data, accompanying several instances of recognizing. When students recognized something, be it a pattern or a familiar mathematical structure, they sometimes gasped or exclaimed a phrase such as “oh my god,” seemingly involuntarily. In some instances, the students also loudly called out to their classmates. Gaining a new perspective through which to understand the current mathematical context seemed to cause pleasure for these students. These experiences seemed to be generative, in that they compelled students to continue to investigate the implications of the action.

In some ways, satisfaction bears resemblance to the craziness that some students expressed. Both types of aesthetic experiences involved students suddenly recognizing shifts in what they knew to be the current mathematical reality. Students even used some similar language, such as “oh my god.” The difference is that, whereas the students who experienced things as being crazy were suddenly aware that a different mathematical world existed, and that the one they knew previously might even cease to exist, students who experienced satisfaction instead found evidence of being in a familiar context. For example, consider a student who recognized that an equation was in a form could be factored. Upon sensing a familiar structure, the student expressed happiness through gasps and singing. A further difference is that, whereas satisfaction is virtually always a positive feeling, the sensation of being jolted into a new reality by something that seems crazy might be enjoyable for some students, but not all, in the same way that some people enjoy the thrill of roller coasters and others do not.

Discussion

Aesthetic experiences played prominent roles in students’ creative episodes in these lesson enactments, suggesting a need for lessons to be designed with dynamic aesthetic experiences. In many cases, students seemed to be deeply impacted by their aesthetic experiences, as indicated by behaviors ranging from gasping to singing. Maybe this is why it often seems that many individuals are not capable of being creative; they have not been able to experience mathematics in a way that is conducive to mathematical creativity. I suspect that many mathematics lessons differ drastically from the dynamic enactments analyzed here, considering that mathematics is so often described as dull or boring by those who do not become professional academic mathematicians. How many more students could be moved to take action with creative potential if they were to experience suspense or mystery during their mathematics lessons?

Of course, lessons with more varied aesthetic experiences and opportunities for student creativity may make new demands of teachers, in terms of managing both behavior and mathematical ideas. The student behavior described in this study does not match the image of quiet students working diligently at their desks. It involved sudden outbursts, minor references to drugs, even the use of curse words. What new skills would teachers need to facilitate lessons in which these behaviors were not only allowed, but maybe even encouraged? This adds difficulty to the increased demands of teaching for student creativity, in which students have more control over the mathematical content of class.

Finally, these aesthetic experiences were studied within a fairly unique set of lessons, in that they were designed to be aesthetically captivating, but the lessons still aligned with standard secondary mathematics curriculum in the US. This raises the question: What other kinds of creativity might students engage in if they were to have even more diverse aesthetic experiences, such as those that integrate expressive arts or social justice topics into mathematics instruction? Future research is needed to learn what other mathematical creativity students may be capable of.

SELF-EFFICACY, INSTRUCTIONAL BELIEFS AND THE USE OF THE STANDARDS FOR MATHEMATICAL PRACTICE

Amy E. Roehrig
Illinois State University
aeroehr@ilstu.edu

Tami S. Martin
Illinois State University
tsmartin@ilstu.edu

Teachers' beliefs, knowledge, and decisions can affect the way teachers teach, and, consequently, what students learn. Self-efficacy beliefs may also interact with beliefs about the most appropriate and effective teaching and the selection of instructional practices to implement. We examined the relationships among teachers' mathematics self-efficacy, mathematics teaching self-efficacy, instructional beliefs, and use of the Standards for Mathematical Practices (SMP; NGACBP & CCSSO, 2010) for teachers who had been identified as effective teachers. We found that although the teachers scored similarly on beliefs surveys, there were some differences in their use of the SMP (NGACBP & CCSSO, 2010).

Keywords: Standards, Teacher Beliefs, Instructional Activities and Practices

Affective factors such as self-efficacy, motivation, anxiety, and confidence can be related to learning and teaching processes. Self-efficacy beliefs—beliefs about one's capacity to be successful in various situations—are situation-specific. Teachers have self-efficacy beliefs about mathematics, teaching, and mathematics teaching. These beliefs are important because they may interact with beliefs about the effective teaching practices (McLeod, 1987; Opera & Stonewater, 1987; Raymond, 1997) and the implementation of instructional practices (Peterson et al., 1989).

Mathematics teaching practices are often categorized as either student-centered (e.g., reform oriented, learner-centered) or teacher-centered (e.g., traditional). The use of student-centered teaching practices has been shown to relate positively to student learning in mathematics, as measured by increased post-test scores on a curriculum-based, researcher-constructed classroom test (Jong et al., 2010). Student-centered practices may also decrease negative affective factors, such as mathematics anxiety, in students (Alsup, 2004). There is evidence that teachers' beliefs concerning the use of student-centered practices and teacher self-efficacies influence teachers' decisions about what teaching practices to enact when teaching mathematics (Hadley & Dorward, 2011; Peterson et al., 1989). However, this evidence is largely based on self-reported teaching practices. Thus, it is not clear how self-efficacies may relate to the enacted teaching practices of teachers, as verified by an outside observer. Merriam and Tisdell (2016) noted that observation in the form of "firsthand encounters with the phenomenon" is more reliable than "a secondhand account" by teachers, who are sharing an interpretation of their own teaching practices (p. 137).

Further, the role that teachers' instructional beliefs play in mediating self-efficacies as part of teachers' decision-making processes about which instructional strategies to implement is not clearly understood (Allinder, 1994; Bandura & Wood, 1989; Klassen & Tze, 2014). And, there has been no exploration of the extent to which teachers who have been identified as effective may vary with respect to their beliefs and practices. Teachers, even effective teachers, are not monolithic. Knowing more about the breadth of ways to be effective would add nuance to our understanding of what it means to be effective. For these reasons, we explored this research question: How do effective teachers vary with respect to their instructional beliefs, mathematics self-efficacy, mathematics teaching self-efficacy, and classroom-observed uses of the Standards for Mathematical Practice (SMP; National Governors Association Center for Best Practices & Council of Chief State School Officers [NGACBP & CCSSO], 2010)?

Theoretical Perspectives

Ernest (1994) posited that an individual's learning cannot be separated from their social environment. In conversation with others and themselves (Ernest, 1994), students negotiate ideas in a way that expands their prior knowledge. Marchitello & Wilhelm (2014) reported that the mathematics component of the Common Core was based on cognitive principles and, in particular, the authors assumed that students learn by building on prior knowledge and working collaboratively with peers. In this way, the SMP are aligned with social constructivist perspectives on learning. Within a constructivist learning environment, teachers and students share knowledge, responsibility, and authority (Chung, 1991). A teacher's role is as a facilitator, rather than an expert, who creates and sustains a collaborative learning environment (Tam, 2000). Thus, social constructivism undergirds the student-centered teaching practices that we examined.

The theory of self-efficacy (Bandura, 1977), also aligned with social constructivism (Bandura, 2001), is a lens through which we interpreted how teachers' self-efficacies mediated their instructional practices and beliefs. A firm understanding of self-efficacy, not only as an affective factor of teachers, but also as a theory, aided in the interpretation of teachers' instructional beliefs and practices. According to Bandura (1997), an individual has the capacity to control their actions based on how confidently they exercise that control. Bandura (1997) described a phenomenon in which individuals make choices based on how successfully they believe they can perform a particular task. Thus, mathematics self-efficacy may influence the decision to use challenging tasks and mathematics teaching self-efficacy may influence a teacher's decision to engage in student-centered teaching practices that require coping with uncertainty about how students will respond when given the freedom to explore.

Literature Review

Those who have examined how the interplay between beliefs and practices can affect student learning (e.g., Allinder, 1994; Polly et al., 2013) have found that teachers' beliefs about teaching practices may be tied to other affective factors, including self-efficacy beliefs.

Self-Efficacy Beliefs of Teachers

Self-efficacy beliefs have the potential to influence teachers' choices about which instructional practices to use (Bates et al., 2013; Perera & John, 2020; Swars, 2005). In addition, self-efficacy beliefs potentially mediate teachers' instructional beliefs as they choose whether to use student- or teacher-centered practices (Wilkins, 2008). Such self-efficacy beliefs are based on a person's interpretation of past experiences (e.g., Bandura, 1986, 1997; Tschannen-Moran et al., 1998; Wilkins, 2008), are constructed from four sources (i.e., verbal persuasion, vicarious experiences, physiological arousal, and mastery experiences; see Bandura, 1986), and are situation specific (Pajares & Miller, 1994). People with high self-efficacy beliefs are more likely to: (a) attempt tasks they might find challenging; (b) expend more initial effort on successful completion of the task; and (c) persist when a task becomes difficult (Bandura, 1986).

Mathematics self-efficacy. Kahle (2008) defined mathematics self-efficacy—a situation-specific self-efficacy—as one's beliefs in their capability to successfully carry out a mathematical task. Using the Mathematics Confidence Scale (Dowling, 1978), Pajares and Miller (1984) found significant and positive correlations among gender, high school mathematics experience, college mathematics experience, and mathematics self-efficacy. Thus, they concluded, mathematics self-efficacy affects mathematics performance directly rather than through mediated variables (e.g., gender, prior experiences).

Mathematics teaching self-efficacy. Another type of self-efficacy, mathematics teaching self-efficacy, has been defined as the belief in one's capability to teach others mathematics (Enochs et al., 2000; Kahle, 2008; Swars, 2005). Teaching self-efficacy influences choices teachers make in teaching practices, curriculum delivery, and task choice (e.g., Gulistan et al., 2017). More specifically, high teaching self-efficacy has been linked to teachers' (a) openness to student responses and inquiry, including student engagement (e.g., Toropova et al., 2019); (b) positive responses to academic coaching (Ross, 1992); (c) high-quality instruction (Perera & John, 2020; Wilkins, 2008); and (d) positive effects on student attitudes toward mathematics (Nurlu, 2015).

Teaching Practices in Mathematics

Skemp (1978) distinguished between two types of student learning goals for teachers. Relational understanding is "knowing both what to do and why" (p. 9) whereas instrumental understanding refers to using "rules without reason" (p. 9). Student-centered practices align with relational thinking because student-centered practices are specifically designed to help students construct knowledge by having them grapple with both what procedures to use and why they work. Students who have experienced mathematics through student-centered practices viewed mathematics as creative and flexible, leading them to see a future in which they would use mathematics in their everyday lives (Boaler, 1997)

Teacher-centered practices align with instrumental understanding because the teacher is viewed as one who possesses knowledge and who should impart that knowledge to passive learners. These learners, in turn, are responsible for emulating the procedures that the teacher has demonstrated without necessarily reflecting on the reasons undergirding those procedures. For this study, because effectively implemented student-centered practices are aligned with social constructivist assumptions about learning and regarded as appropriate for the teaching and learning of mathematics (National Council of Teachers of Mathematics [NCTM], 2000, 2014; NGACBP & CCSSO, 2010; NRC, 2001; Smith & Stein, 2018), we equated effective student-centered practices with effective mathematical teaching practices.

Teachers' Mathematics Instructional Beliefs

Wilkins (2008) posited that instructional beliefs are mediated by teachers' attitudes about mathematics and mathematics teaching, and those instructional beliefs, in turn, influence instructional practices. O'Hanlon et al. (2015) described teachers' instructional beliefs—views teachers hold about the best teaching practices—as a complex system that integrates teachers' beliefs concerning the nature of mathematics with their beliefs about the relationship between the teaching and learning of mathematics. Woolley et al. (2004) classified teachers' instructional beliefs as aligned with either constructivist or traditionalist (i.e., behaviorist) approaches to learning. Yet researchers have found that such instructional beliefs sometimes conflict with enacted teaching practices (Peterson et al., 1989; Raymond, 1997; Yurekli et al., 2020).

We examined the interplay of these factors: teachers' self-efficacy beliefs, teachers' mathematics instructional beliefs, and teachers' implementations of the SMP.

Methods

Participants

For this study, we focused on two mathematics teachers who were identified as effective by both mathematics teacher educators and their school principals. Kathy and Frances (pseudonyms) both taught at the same suburban school in the midwestern United States. Kathy taught kindergarten and Frances taught Grade 5/6 mathematics.

Data Collection

To determine levels of self-efficacies, instructional beliefs, and use of effective teaching practices, we used the instruments and procedures described in this section.

Self-efficacy beliefs. To measure both mathematics and mathematics teaching self-efficacy, we used Kahle's (2008) Mathematics Teaching and Mathematics Self-Efficacy (MTMSE) survey. The MTMSE has a measured reliability of $\alpha = .942$ and produced positive results for both face and content validity. The MTMSE originally was intended for teachers who taught grade 3–6, but Kahle (personal communication, June 8, 2020) verified that the survey is suitable for elementary and middle school teachers.

We assessed mathematics teaching self-efficacy beliefs with Part 2 and Part 4 of the MTMSE survey. In Part 2 of the MTMSE teachers rated, using a Likert scale of 1 (strongly disagree) to 6 (strongly agree), their agreement with statements such as "I will generally teach mathematics ineffectively" or "I will typically be able to answer students' questions." In Part 4 of the survey, teachers rated (on a scale of 1–6, from low to high) how confident they felt about teaching specific content (e.g., fractions, decimals, shapes).

We measured mathematics self-efficacy using Part 1 and Part 3 of the MTMSE survey. These components focus on teachers' beliefs about their capabilities regarding a variety of mathematical tasks. In the survey, teachers are asked to rate their level of confidence, on a scale from 1–6, in their own ability to complete certain tasks, though they are not required to complete the tasks. One of the tasks was: "On a map, 7/8 inch represents 200 miles. How far apart are two towns whose distance apart on the map is 3 1/2 inches?"

During pre-lesson interviews, the first author asked teachers to rate their confidence about the content and the teaching of the content.

Instructional beliefs. We used an instructional beliefs survey that incorporated items from O'Hanlon et al.'s (2015) Teaching and Learning Mathematics Beliefs survey to determine whether teachers' instructional beliefs were primarily aligned with student-centered or teacher-centered instructional practices. The beliefs survey is applicable to all the teachers of Grades K–12 as the items were designed to elicit teachers' instructional beliefs about the content they teach at their own grade level. In developing the survey, O'Hanlon et al. designed items to reflect NCTM's (2000) process standards recommendations, which are aligned with the values described in the CCSS-M standards (NGA & CCSSO, 2010). O'Hanlon et al.'s items represented three perspectives: personal learning, student learning, and teaching. For this study, we used items that focused on teachers' perspectives about student learning and teaching.

Use of practice standards. To assess teachers' use of practice standards, the first author observed 5 or 6 lessons for each teacher and collected all lesson plans and materials used in those lessons. The first author also conducted short pre- and post-observation interviews to discuss the lesson plan.

To obtain a detailed description of each teacher, the first author conducted five in-person observations with the kindergarten teacher and six with the 5th and 6th grade mathematics teacher during the spring of 2021. The teacher selected the lessons for each observation. We video and audio recorded each observation. To assess the frequency with which teachers engaged students in the Standards of Mathematical Practice (SMP; NGACBP & CCSSO, 2010), we used the Mathematics Classroom Observation Protocol for Practices (MCOP^2; Gleason et al., 2015) during the observation and subsequent viewing of video data. The MCOP^2 was developed to examine aspects of teaching facilitation (TF) and student engagement (SE) for the purpose of teaching mathematics for conceptual understanding and was grounded in the Instruction as Interaction framework (Cohen et al., 2003). Gleason et al. (2017) found the MCOP^2 to have an interrater reliability for both TF ($IRR = 0.616$) and SE ($IRR = 0.669$) subscales. Teacher facilitation refers to the role of the teacher to provide lesson structure and guidance through problem solving and mathematical discourse. Student engagement refers to students fulfilling their roles as active learners within the classroom environment (Gleason et al., 2015). The MCOP^2 includes both TF and SE because an observer cannot assess whether teacher actions are effective without observing whether those teacher actions produce meaningful engagement from students. The MCOP^2 observation guide aligns with teacher implementation of the SMP. In Table 1, from Gleason et al.'s (2017) publication, we note the alignment between the MCOP^2 and the SMP. Gleason et al. (2015) recommended that multiple observations occur over a period of time so that a comprehensive view of teachers' practices can be established.

	Standards for Mathematical Practice

Table 1. Relationship between the MCOP^2 and the SMP (NGACBP & CCSSO, 2010)

Data Analysis

We did not perform statistical tests on survey data because of the small sample size. We used the quantitative tools only to estimate levels for each teacher's self-efficacies as part of a description of that teacher's beliefs and practices.

Self-efficacy beliefs. We used analysis results from the MTMSE survey for the purpose of establishing whether teachers' mathematics and mathematics teaching self-efficacy beliefs were high or low. Survey questions were worded both positively and negatively. We reordered ratings so that all statements were on a consistent scale with high scores representing more self-efficacious views. Unlike Kahle (2008), who based analysis on the sums of survey ratings, we tallied the responses for each question so that we could consider each type of self-efficacy separately. For mathematics self-efficacy, we classified teachers as having a high mathematics self-efficacy if they provided at least 17 responses (out of 31 questions) that were fours, fives, or sixes on a Likert scale. For mathematics teaching self-efficacy, we classified teachers as having a high mathematics teaching self-efficacy if they recorded at least 15 responses (out of 26 questions) that were fours, fives, or sixes.

Instructional beliefs. The survey questions were constructed both as positively and negatively worded statements. For the analysis, we again reordered ratings so that all statements were on a consistent scale with high scores representing more student-centered views. Rather than looking at the mean rating of survey items, we examined the frequencies of each level, which was more appropriate for our purpose. Following O'Hanlon et al. (2015), we classified teachers whose responses were primarily in the top half of the Likert scale (scores of 4, 5, or 6) as having instructional beliefs that aligned with more student-centered practices. In contrast, teachers for whom a majority of their responses were in the bottom half of the Likert scale were classified as having primarily teacher-centered instructional beliefs (O'Hanlon et al., 2015).

Use of practice standards. We classified teachers' use of the SMP by their scores in the relevant section of the MCOP^2. The MCOP^2 rates teachers' performance on a scale of 0–3 for each of the 16 items, with a 0 indicating the non-use or incorrect use of the item description and a 3 indicating the use of the item description. For each teacher, we reported the median scores across all observations for individual component of the scale (see Table 1). We used a median because the data were ordinal. We focused our analysis on the frequency of attaining medians at the top two rating levels (i.e., 2 and 3) within each of the SMP because those levels indicate at least an intentional effort to used student-centered practice.

Results

The purpose of this research was to determine the relationships among effective teachers' instructional beliefs, mathematics and mathematics teaching self-efficacies, and their use of the SMP. Using the collapsed rating method described above, both teachers scored similarly with respect to their instructional and self-efficacy beliefs. However, there were differences in their MCOP^2 results. In the following sections we discuss the specific results to each of the surveys and the MCOP^2 observations.

Self-Efficacy and Instructional Beliefs

We found that both teachers scored identically on the sections measuring mathematics teaching self-efficacy, meaning that both teachers felt as though they were capable of teaching mathematics in a student-centered approach. The teachers' mathematics self-efficacy survey results showed a slight difference between the two participants, Kathy scored higher than Frances (see Figure 1). However, both teachers achieved scores that we interpret as indicating a high mathematics self-efficacy, because both scores were above the cutoff score of 17.

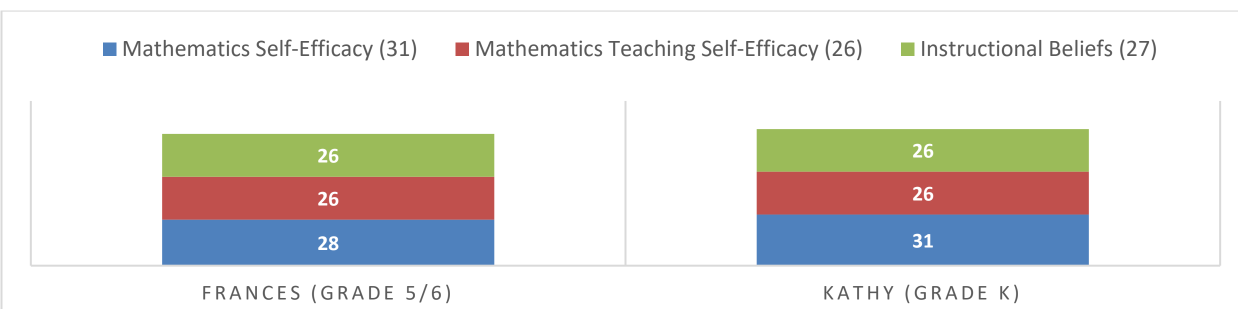

Figure 1. Beliefs Survey Results

Both teachers seemed to score similarly on instructional beliefs indicating that they both believed in a student-centered approach to teaching. Of the 26 items, each teacher selected a single 3-level rating, and their remaining 25 ratings were within the 4–6 range. However, when we examined the distribution of ratings, Frances' rated all 25 statements with a 4, whereas Kathy's ratings were all 5s and 6s (see Figure 2). Although both teachers had student-centered instructional beliefs, Kathy's beliefs may be more robustly student-centered than Frances' beliefs. We found further evidence of a possible disparity during the pre- and post-observation interviews, as Kathy spoke more frequently—without prompting—about her student-centered instructional beliefs. Frances often required prompting to discuss her instructional beliefs.

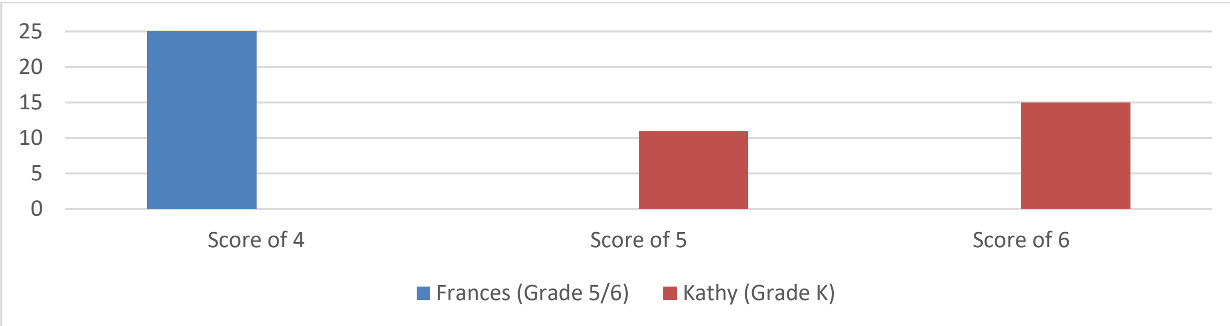

Figure 2. Specific Score Categories for Instructional Beliefs

Use of Standards of Mathematical Practice

Using the MCOP^2 observation tool, Frances received more medians of 3 than Kathy, and Frances' medians were always equal to or greater than Kathy's (see Table 2). For teacher facilitation items across all observations, Frances' median score was 3 and Kathy's was 2. For student facilitation items, Frances' median score was 2.5, whereas Kathy's median score was 2.

Table 2. Medians of Scores on the MCOP2 Across All Items and Observations

	Make sense of problems and persevere in solving them		Reason abstractly and quantitatively		Construct viable arguments and critique the reasoning of others		Model with mathematics		Use appropriate tools strategically		Attend to precision		Look for and make use of structure		Look for and express regularity in repeated reasoning	
MCOP^2 Items	K	5/6	K	5/6	K	5/6	K	5/6	K	5/6	K	5/6	K	5/6	K	5/6
1	3	3											3	3	3	3
2	1	2							1	2						
3	3	3														
4	2	3			2	3									2	3
5	2	2	2	2	2	2			2	2						
6													2	3	2	3
7			2	2			2	2								
8													3	3	3	3
9	1	3														
10					2	3					2	3				
11	2	2														
12					2	2										
13					2	3										
14	2	3														
15					2	3										
16	1	3														

Each teacher consistently facilitated the SMP in their classroom. Although Kathy received a median of 2 more often than a 3 on the MCOP^2, she regularly provided her students with opportunities to look for and make use of structure and look for and express regularity in repeated reasoning. Frances—having a median of 3 more often—provided opportunities for her students to make sense of problems and persevere in solving them, attend to precision, look for and make sense of structure, and look for and express regularity in repeated reasoning.

Relationships Among Beliefs and Practices

Although teachers had only minor variation in the robustness of their beliefs, based on their survey responses, their MCOP[2] showed somewhat greater variation in their use of the SMP in their lessons. For example, Kathy had more robust student-centered beliefs, as measured by the beliefs survey (see Figure 2); but then Kathy employed the SMP less consistently throughout the observations. Figure 3, showing the medians of level 2 and level 3 implementations of the SMP, shows that Kathy had a greater median of level 2 implementations, although her beliefs were more robustly student centered. In contrast, although Frances' student-centered beliefs were less robust, she scored a 3 across more categories.

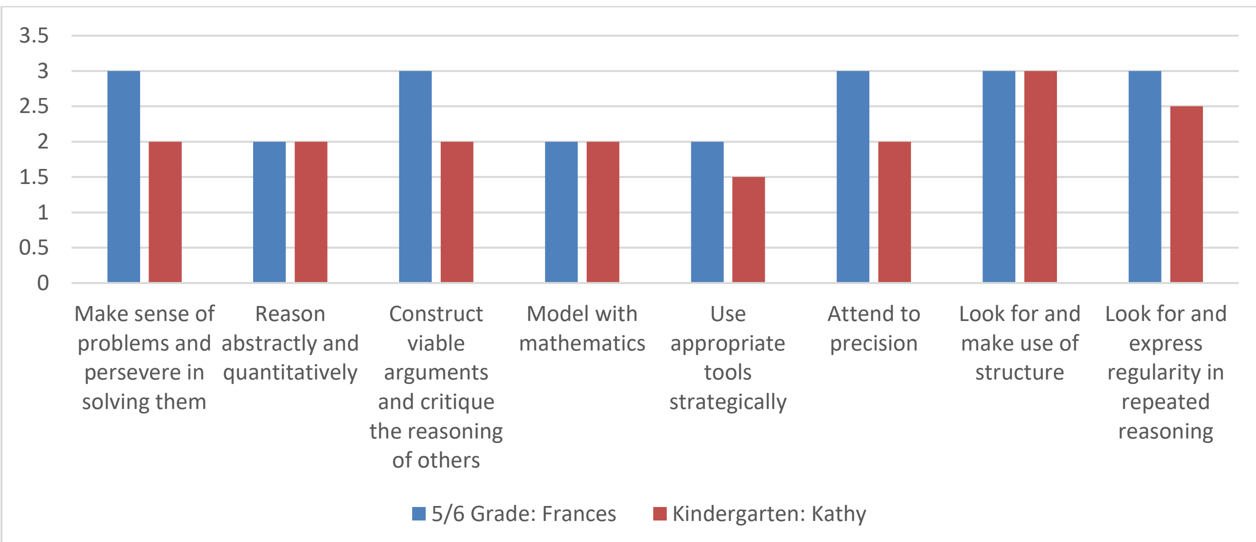

Figure 3. Median SMP Scores Across All Observations

Discussion

Echoing prior research, we noted a connection between the teachers' beliefs and their use of instructional practices (Hadley & Dorward, 2011; Peterson et al., 1989). However, there may be some differences with respect to which practices teachers use and how often they use those practices. We conjecture that our observed differences between the teachers were not simply due to grade-level differences but instead were due to the complexity of teaching and teacher beliefs. Building on prior work (e.g., Yurekli et al., 2020) by using classroom observations, we conclude that teachers with more-robust student-centered beliefs may not enact those beliefs in practice.

This study was limited by the number of participants and the pandemic context in which we observed them[1]. More research, using in-depth interviews, is needed to explore the extent to which beliefs, experiences, and other factors influence teachers' use of the SMP. Even so, this study adds to the growing body of research on the beliefs of teachers.

1 Because of the pandemic, we had limited access teachers who were teaching in person and there were many constraints to the classroom environment. Thus, the practices we observed may not have reflected teachers' typical or desired approaches.

Mathematical modeling can be a lever for equity in the elementary math classroom, as it empowers teachers to build on the knowledge and cultural resources that children bring to the classroom and empowers students to draw on their experiences and identities to inform their mathematical work. To better support this transformative synergy between mathematical modeling and equity-oriented practices, we need a tool to deepen our understanding of variations and potential trajectories of teacher practice. In this report, we briefly describe our process for developing an equity-oriented mathematical modeling classroom observation protocol. We then discuss two sample dimensions from our tool to illustrate our integrated attention to equity-focused and mathematical modeling-specific teaching practices.

Keywords: Modeling; Elementary School Education; Instructional Activities and Practices; Equity, Inclusion and Diversity

In elementary mathematics education, classroom observation tools can support teacher learning by making visible key features of instructional practice and outlining potential trajectories for developing new practices (Bostic et al., 2021; Boston et al., 2015). Observation tools also serve research by generating evidence of teachers' enactment of specific practices which can inform the design of professional learning experiences, or evaluate the effectiveness of interventions. While there are numerous observation tools focused on high-quality math teaching (e.g., MQI; Learning Mathematics for Teaching Project, 2011; M-SCAN, Walkowiak et al., 2014), tools focused specifically on teaching mathematical modeling are limited.

Mathematical modeling is an iterative process involving problem posing, and testing, validation, and revision of mathematical models to inform decision-making (Lesh & Zawojewski, 2007; Pollak, 2012). Observation tools that attend to modeling often include modeling as a single dimension (e.g., Bostic, et al., 2019; Gleason et al., 2017). Although researchers have begun to conceptualize modeling-specific protocols (e.g., Hwang, 2020), validating tools for use in elementary grades is still needed. Additionally, while there is growing recognition that mathematical modeling can be a lever for equity (Aguirre et al., 2019; Anhalt et al., 2018; Carlson et al., 2016; Cirillo et al., 2016; Suh et al., 2018; Turner et al., 2022), tools that integrate an explicit focus on modeling and equity-oriented practices are lacking. Equity-oriented tools often lack a content focus (e.g., CLASS, Pianta & Hamre, 2009; Salazar, 2018), or focus generally on standards-based mathematics instruction, but not modeling (e.g. Nava, et al., 2019).

The lack of a validated classroom observation protocol that attends, in substantive ways, to both mathematical modeling and equity-oriented, culturally responsive instruction is problematic because of the synergy between mathematical modeling and advancing equity. To address this need, our project is building on prior exploratory work that involved adapting dimensions of an existing classroom observation protocol for elementary mathematics (the M-Scan, Walkowiak et al., 2014) to focus on culturally responsive mathematical modeling in grades 3-5. In this report, we describe our development process and discuss tool dimensions that illustrate our integrated attention to equity-focused and modeling-specific teaching practices. We end with a discussion of potential uses of the classroom observation tool, and next steps in our validation process.

Equity-Focused Teaching Practices for Mathematical Modeling

Teaching mathematical modeling is challenging because modeling includes processes like posing problems, making assumptions, and testing and revising models, that are not typical in mathematics classrooms (Niss, Blum, & Galbraith, 2007). Modeling tasks are more open and less predictable than those in most lessons (Cai et al., 2018) and require teachers to know about the real-world contexts that motivate modeling problems, potential mathematical solutions, and ways to maintain rigor and support for students as they develop, refine, and communicate their models (Suh et al., 2021; Turner et al., 2021). However, there is synergy between equity-focused mathematics teaching and mathematical modeling. Modeling empowers teachers to elicit and build on the knowledge and cultural resources that students bring to the classroom and empowers students to draw on their identities and experiences to inform mathematical work and take action (Aguirre et al., 2019; Turner & Bustillos, 2017). Classroom modeling also encourages diverse student contributions and gives teachers opportunities to "recognize and reward a broader range of mathematical abilities than those traditionally emphasized" (Lesh & Doerr, 2003, p. 23). To better support teachers' learning and practices related to the transformative integration of equity-focused teaching and mathematical modeling, we need a tool to sharpen our vision and deepen our understanding of variations and potential trajectories of teacher practice.

Overview of Classroom Observation Tool Development

To develop our classroom observation tool, we followed a multi-stage process for protocol validation outlined by Bostic and colleagues (2019). *Stage 1* involved a review of observation protocols for mathematical modeling and equitable teaching practices, and research on effective teaching practices for mathematical modeling, especially in grades K-2. *Stage 2* focused on synthesizing key outcomes from the literature, and using these ideas to draft an initial version of the tool. This version included 6 dimensions, each of which focused on equity-oriented teaching practices for a specific phase of the modeling process (e.g., making sense of the context and posing problems; identifying important quantities and making assumptions). Several of the dimensions were adapted from similar dimensions in existing, exploratory tools (Foote, Aguirre, Turner & Roth McDuffie, 2020. In *Stage 3*, we assembled an expert review panel consisting of 15 scholars with expertise in mathematical modeling, equitable teaching practices, and classroom observation tools. Scholars reviewed the draft protocol and provided feedback on its alignment with the construct (i.e., to what extent do the dimensions capture key features of mathematical modeling across the elementary grades?); the range of practice captured (i.e., do the indicators capture teacher moves and supports that are appropriate for K-5 students from diverse cultural, racial, linguistic, and geographic backgrounds?); and the clarity and usability of each dimension to describe and inform practice. In *Stage 4,* we revised the tool based on our review of the literature and feedback from our expert panel. *Stage 5,* our current stage, is focused on testing the revised observation tool with video of modeling lessons from different grade levels, and from teachers with various levels of experience teaching modeling.

Dimension 1: Connections to Students' Experiences and Cultural/Community Contexts

Dimension 1 (Table 1) captures teaching practices to support connections between students' experiences and the modeling process. Unlike some of the tool's dimensions, which focus on a particular modeling phase, (see Table 2), Dimension 1 should be present throughout the cycle. Its descriptors address the degree to which the teacher sustains connections to students' experiences and cultural and community contexts. Key Terms and Ideas, listed below the descriptors, clarify the nature of the connections to be made and teacher moves that could support students' work.

Table 1: Connections to Students' Experiences and Cultural/Community Contexts

Not Present (0)	Emerging (1)	Proficient (2)	Advanced (3)
The teacher does not engage the class in making connections between the modeling context and their lives.	In one phase of the modeling process, teachers support multiple students to make connections to their experiences (lives, communities, cultures) to inform their work.	In two or more phases of the modeling process, teachers support multiple students to make connections to their experiences to inform their work.	In two or more phases of the modeling process, teachers support multiple students to make connections to their experiences to inform their work.
Key Terms and Ideas **Connections** include references to experiences related to the context or scenario, or references to understandings about a specific context, setting, scenario or activity. Connections can include connections to students' or teachers' experiences outside of school, and students'/teachers' shared experiences as members of the school community. **Teacher Support** includes teacher moves such as asking students to recall experiences related to the context to help them identify key quantities; reminding students to use what they know about a situation to help them evaluate their solution; asking students to draw on their experiences with the situation to propose revisions to their models; reminding students of a shared experience that might inform their work. Teacher support must involve prompting, probes and/or follow up and go beyond a single question, hook or statement, and beyond a teacher-provided connection that does not invite student input or response.			

Dimension 1 makes practices that advance equity while teaching mathematical modeling explicit and offers a trajectory for supporting students to connect to their experiences and cultural and community contexts. At the *emerging* level, teachers support connections in one phase of the modeling cycle, likely through a single prompt or statement. As teachers grow in their ability to support classroom modeling, they sustain connections to students' experiences throughout the cycle - perhaps by prompting students to draw on their experiences to identify important quantities, propose revisions to their model, or interpret their solution. The tool also makes clear that teachers support multiple students to connect to their backgrounds and experiences, increasing the likelihood that contributions of students from diverse backgrounds are honored.

Dimension 2: Posing Mathematical Problems

Dimension 2 (Table 2) captures practices that support students learning to pose mathematical problems. Its descriptors focus on the degree to which the teacher involves students in posing the question that drives the modeling task. Unlike typical mathematics lessons, where students must understand the problems posed by the teacher or the textbook, when students model they learn to focus on specific features of real-world problems and then translate those features into mathematical questions. Thus, supporting students in learning to pose mathematical problems requires teaching practices that are unique to mathematical modeling.

Table 2: Posing Mathematical Problems

Not Present (0)	Emerging (1)	Proficient (2)	Advanced (3)
The teacher poses the modeling problem. The problem is pre-determined by the teacher. There is no evidence of actions by the teacher to connect students' questions or wonders about the context to the problem posed.	The teacher poses the modeling problem, but the teacher makes connections between the problem posed and the questions/ wonders/ observations/ experiences that students posed about the context.	The teacher invites students to shape some components of the problem posed. Includes: supporting students to recognize math questions, inviting students to connect the problem with their wonders or to share insights about the problem posed.	The teacher consistently invites and builds on student ideas to pose and refine the modeling problem. The teacher may facilitate the discussion, but student ideas drive problem-posing.
Key Terms and Ideas **Posing problems** refers to formulating a mathematical question that can be invested through the modeling process. Problems may be descriptive, predictive, or evaluative in nature. **Teacher Connects** student ideas or wonders to the problem posed (by the teacher). The teacher might say, "You all asked about ……., that is very similar to the problem we are going to work on today. Here is our problem…" Or, the teacher may invite students to share an observation or experience related to the problem posed (by the teacher).			

Dimension 2 captures equity-oriented instruction by focusing on teaching practices that empower students to shape the mathematical questions that are asked. Teacher development in this trajectory moves from *emergent* practices that are limited to teachers making connections between students' ideas a pre-determined problem to *advanced* practices that consistently invite student contributions and allow student ideas to drive problem posing. When teachers support students in this way, they extend authority for what is legitimized as important and worthwhile mathematical work to students. Not only does this disrupt power structures present in most classrooms, it supports students in developing a critical mathematical modeling competency.

Discussion and Implications

Observation tools that combine equity-oriented teaching and a content focus advance the field by offering specific descriptions of practice and trajectories for developing effective, equity-focused mathematics teachers. Our next step is to test our tool on a larger set of modeling lessons from diverse grade levels and classroom contexts, and to conduct psychometric analysis of data generated from use of the tool (i.e., reliability analyses). We anticipate that mathematics teacher educators can use our tool to design mathematical modeling professional development experiences that center equity, and that researchers can use the tool to study potential shifts or growth in teacher practice of mathematical modeling over time. Teachers can use selected dimensions of our tool to reflect on their practice and to consider strengths and areas for growth.

This study examines the utilization of cognitive interviews longitudinally over a one-year period to collectively trace raters' response processes as they interpreted and scored with observational rubrics designed to measure teaching practices that promote equity and access in elementary and middle school mathematics classrooms. We draw on four rounds of cognitive interviews (totaling 14 interviews) that involved four raters at purposeful time points spread over the year. Findings reported in this study focus on raters' responses about one rubric, positioning students as competent. The findings point to the complexities of utilizing observational rubrics and the need to track response processes longitudinally at multiple time points during data collection in order to attend to rater calibration and the reliability and validity of resulting rubric scores.

Keywords: instructional activities and practices; research methods; measurement

In the field of education, researchers and evaluators regularly develop rubrics to assess or measure a particular construct with the intent for trained raters to apply the rubrics and assign reliable scores so that valid inferences can be drawn from the resulting data. One such example is classroom observational rubrics designed to measure mathematics teaching practices (e.g., Boston, 2012; Walkowiak et al., 2014). However, we know that using classroom observational rubrics is a complex and intense endeavor, due to the many nuances that exist in classroom interactions and instruction. Therefore, attending to how raters interpret the rubrics and apply their interpretations to assign scores is a critical type of validity evidence. That is, the response processes of raters can be utilized to evaluate if raters interpret the rubrics and apply scores as intended. In this study, we attend to raters' response processes over time using rubrics designed to measure teaching practices that promote equity and access in mathematics classrooms. The significance of this study is twofold: (1) it illustrates the complexity of one component of an interpretation/use argument (IUA) (Kane, 2016), but with longitudinal data; and (2) it draws the field's attention to the importance of iteratively examining raters' interpretations of rubric language and levels. It is critical that classroom observational rubrics generate reliable scores from which we can make valid inferences.

Background

The EAR-MI (Equity and Access Rubrics for Mathematics Instruction) is a set of classroom observation rubrics designed to focus on specific practices that support more equitable participation and access in mathematics classrooms. The EAR-MI began as a theoretically-derived and empirically validated set of instructional practices (Wilson et al., 2019). For this study, we focus on raters' interpretation of one of the instructional practices and its accompanying rubric, positioning students as competent.

When teachers position students as competent, they explicitly and publicly value, identify, and acknowledge the brilliance of their students, framing their actions and statements as intellectually valuable (Bartell, 2011). The positioning rubric emphasizes the extent to which teachers specify what students do that is productive *and* the extent to which they provide rationales as to why what was done was considered productive. Figure 1 illustrates how positioning may be elevated in a classroom, corresponding to the levels on the rubric.

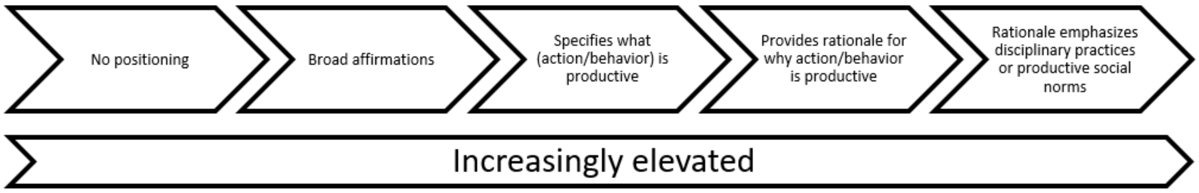

Figure 1: Positioning students as competent, increasingly elevated.

Our overarching goal in further developing the EAR-MI is to utilize Kane's (2016) "argument-based approach to validity" to systematically build an argument for validity. Kane describes the process of developing an interpretation/use argument (IUA) with claims to be evaluated with evidence. One such source of evidence is cognitive interviews to evaluate if the scoring is being applied accurately and consistently (Groves et al., 2009; Willis, 2005) and more specifically, to illuminate factors that could be impacting the scoring process. Cognitive interviews provide insights into four components of the raters' response processes: comprehension, retrieval, estimation, and scoring (Tourangeau, Rips, & Rasinski, 2000). Comprehension is the rater's process of understanding terms within a rubric and their combined meaning to interpret the rubric as intended. Retrieval refers to the rater recalling the necessary information or evidence in the video-recorded lesson. Estimation is the process of the rater judging the quality of the retrieved information for completeness and integrating information from their notes and memories to estimate a score. Scoring is the process of mapping the estimated response to the rubric's scale. We utilized these four components in the context of the current study to longitudinally examine raters' interpretations of the positioning rubric.

Methods

Data Collection

Participants in this study were four raters on the scoring team for the EAR-MI. Each rater completed three or four cognitive interviews, conducted one-on-one with an interviewer. Before each cognitive interview, each rater watched a video-recorded mathematics lesson (the same lesson for all participants at the given time point). During the cognitive interview, the rater talked aloud about each rubric in light of the mathematics lesson, providing justifications and evidence for the scores they assigned.

Cognitive interviews occurred at four purposeful time points (TPs) across the course of one year. Four raters participated in the *first* interview, which took place in January 2021 (TP1), after a live, four-day rubric training, before raters entered a phase called training reliability. During the training reliability phase, raters scored lessons and subsequently met with an expert rater to discuss their scores. Two raters participated in the *second* interview, which occurred in April 2021 (TP2), mid-way through the training reliability phase. At this point, raters had scored 11 lessons and participated in an additional live training, what we refer to as "construct jams". During the construct jams, raters refined and adjusted their understanding of the rubric constructs. Four raters participated in the *third* interview, which occurred in June 2021 (TP3), after the training reliability phase and before raters scored lessons for a generalizability study. Following the training reliability phase, raters' scores indicated acceptable agreement with expert scores; 83% of raters' scores matched with expert scores exactly on the last five videos scored. At this point, raters had scored 10 additional lessons post- construct jams. Four raters participated in the *fourth* interview, which occurred in November 2021 (TP4), after the generalizability study and before raters started scoring lessons as a part of the larger sample of lessons to be included in continued examination of the validity of rubric scores. All interviews were transcribed. Having cognitive interview data at four time points allows for the tracing of interpretations of the rubric over time. It is important to note that in this study, we center raters' thoughts and perspectives in an effort to understand what is working and what needs improvement in scoring procedures as we aim to produce reliable rubric scores.

Data Analysis

We focused on raters' collective interpretation of the focal rubric over the course of the four TPs. We chose the positioning rubric for two reasons. First, we are able to look across time at raters' interpretations of the rubric without changes in rubric language. This is possible because the generalizability study did not indicate that rubric changes were necessary. Second, the positioning rubric was functioning fairly well. For example, exact-match agreement rates between rater and expert scores exceeded 80%. We wanted to dive deeper with this rubric to understand the nuances that supported or hindered use from a rater perspective, particularly when everything looks like it is going well based on agreement statistics.

We reduced the 14 interview transcripts to only include when raters talked about scores for the positioning rubric. We conducted a line-by-line qualitative analysis of the raters' responses. After an initial read, we read through their responses using an open coding approach, tagging codes to the four components of the response process framework (Tourangeau et al., 2000). Codes were collapsed or fine-tuned based on a third reading of the data. We then identified themes for each component of the response process framework, focusing on the group of raters collectively, not an individual rater's development over time.

Findings

Comprehension refers to raters' interpretations of the rubric's terms and their combined meaning. Across the first three time points, raters consistently grappled with the definition of a "rationale" and identifying when a rationale was present. As displayed in Figure 1, positioning is elevated when a teacher includes a rationale for why the student's action or idea is considered productive. In some instances, raters were "on the fence of whether or not [a teacher's comment] was a rationale" (TP3). Sometimes, the raters pondered the level of clarity and/or explicitness of the rationale (e.g., "I think it could be debatable because it's not 100% explicit, but this [teacher action] demonstrates the ability to provide rationales, but they are not necessarily clear" [TP3]). At TP4, the raters were much more decisive and did not grapple with the term as evidenced by "I'm going to stick with [my score] because I don't see a rationale."

Retrieval is the process of recalling the necessary information in relation to the rubric. Raters scored the lesson immediately after watching the lesson. They also utilized structured notetaking and applied "soft scoring" approximately every 20 minutes. "Soft scoring" means pausing and recording a score that represents what has happened so far in the lesson. The processes of structured notetaking and soft scoring were implemented between TP2 and TP3. Raters described how soft scoring "helps me calibrate and make sure that I know what I have strong evidence for" (TP3). Between TP1 and TP2, the positioning rubric changed from a rubric based on preponderance of evidence to highest evidence because the intent is to acknowledge a teacher's potential for implementing the equitable teaching practice of positioning students as competent. A direct implication of this change was evident in raters' ability to retrieve information for scoring efficiently, with less emphasis on finding every instance of positioning within a lesson: "I don't really have to search too far [in my notes] because I felt the earlier instance was stronger" (TP3).

Estimation occurs when the rater estimates a score based on notes and recollection of the video. With the exception of TP4, raters tended to ponder the distinctions between the levels on the rubrics. One rater described "the distinction between a two and a three is still kind of blurry….it would be hard for me to teach someone else what counts as a three. I'm not sure if I could articulate it clearly" (TP3). Here, the rater grappled with the levels on the rubric; this grappling corresponds to the uncertainty described earlier about the term, "rationale".

Scoring is the actual application of a score on the rubric. Across the four TPs, the raters became increasingly more confident, particularly at TP4 ("I'm always confident now"), when they spent less time grappling with the rubric and its terms, did not verbalize or demonstrate indecisiveness, and moved more quickly to assigning the score.

Discussion

While our work is situated within the context of the EAR-MI, we present our discussion as three broader recommendations for researchers, both for those who are designing rubrics to measure a target construct and for those who utilize rubrics. Both groups should critically and carefully consider raters' interpretations and scoring applications. First, the cognitive interviews shed light on reasons for our raters' misinterpretations. If we did not have the cognitive interview data, our awareness of issues with the term, "rationale", would be less robust. Implementing cognitive interviews, whether in the context of the development of new rubrics or in the application of existing rubrics, is critical for understanding the nuances of raters' interpretations. Cognitive interviews also center the voices of raters and their perspectives about the important work they are doing. Second, we implemented procedures that resulted in better and more efficient retrieval of relevant information for scoring. The structured notetaking and soft scoring turned out to be fruitful as raters became more proficient with the rubric. When utilizing rubrics to score data, we recommend researchers attend to the process, not just the resulting scores. The systematic examination of these processes and their influence on raters seems to be an important component of collecting and evaluating evidence of validity. Finally, based on our read of the literature in mathematics education and beyond, cognitive interviews are typically implemented at one (or maybe two) TPs, and often only in the context of the initial development of a rubric. Our data suggests that iterative, longitudinal implementation of cognitive interviews is significant in improving raters' scoring procedures and thought processes. We were able to iteratively provide training to raters (as in the example of the "construct jams") throughout the year of these four rounds of cognitive interviews. In summary, the use of classroom observational rubrics to document and measure teaching practices is messy, but exciting work. Cognitive interviews at multiple time points serve as a mechanism for attending to the production of reliable scores such that valid inferences can be made when utilizing rubric data.

This descriptive study attended to the extent to which we see evidence of the presence of four practices that promote equity and access in 141 grades 3-8 mathematics lessons in the United States. We found that lessons generally showed evidence of some incorporation of the practices but often not at the highest level. Teachers in this sample engaged in social coaching at a relatively high level, across elementary and middle school classrooms. Teachers tended to do less with respect to supporting connection and engagement between student context and the math learning environment. We also found statistically significant differences between elementary and middle school lessons in positioning students as competent and supporting a nurturing environment by proactively building relationships and productive classroom culture. We offer possible interpretations and a few brief implications of these findings.

Keywords: Equity, Inclusion, and Diversity; Elementary School Education; Middle School Education; Instructional Activities and Practices

Instruction that meets national standards for student learning (National Council of Teachers of Mathematics, 2000; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) is considered "ambitious" because it is more demanding and requires more of teachers than the prior focus on procedural competence (Lampert et al., 2010; Lampert & Graziani, 2009). However, ambitious mathematics instruction remains uncommon and opportunities for students to develop the understandings outlined in the *Standards* are not distributed equally (Banilower et al., 2018; Boston & Wilhelm, 2017). This is particularly true for students of color and students for whom English is not their first language (e.g., Nasir & Cobb, 2002; Gutstein & Peterson, 2005). Recently, there has been progress towards identifying specific instructional practices that support historically marginalized groups of students, particularly as they participate in more rigorous mathematics. In order for teachers to develop and implement the identified practices, they need support in understanding distinctions between strong and weak examples of the practices (Goodwin, 1994; Grossman et al., 2013; Little 2003).

The Equity and Access Rubrics for Mathematics Instruction

Gutiérrez (2012) specified four dimensions to attend to the extent to which learning environments support historically marginalized groups of students and might be characterized as aiming for equity: access, achievement, identity, and power. Access and achievement comprise the "*dominant axis*" of equity, while identity and power make up what Gutiérrez called the "*critical axis*" of equity. The EAR-MI (Equity and Access Rubrics for Mathematics Instruction) is a set of classroom observation rubrics developed to capture seven practices that support marginalized students particularly along the dominant axis in gaining access to and more equitably participating in rigorous mathematics activity (Wilson et al., 2019). The EAR-MI was designed by carefully observing the practices of middle school teachers in classrooms characterized by "*Standards*-based" instruction where historically marginalized students have been successful (Wilson, accepted). In this paper, we examine the classroom instruction of elementary and middle grades teachers to investigate the extent to which we see evidence of the presence of practices from four of the rubrics that produced reliable results and remained unchanged across two generalizability studies of the EAR-MI. Specifically, we ask the following question: To what extent are grades 3-8 teachers using some of the practices that support equity and access outlined in the EAR-MI?

Building an Argument for Validity

One intended use of the EAR-MI is to support researchers to assess teachers' progress in enacting mathematics teaching practices that support equity and access. Since the initial empirical study that described the identified classroom practices (Wilson et al., 2019), a set of rubrics were developed and have undergone numerous revisions. The rubrics were revised based on feedback from experts in ambitious and equitable mathematics teaching as well as experts in rubric development. Additional revisions were made based on multiple rounds of pilot coding and feedback from raters who were trained to use the rubrics. We then engaged in a generalizability study to understand how the rubrics were functioning. Based on the results of the initial generalizability study, we removed several rubrics due to a lack of variation in score distribution and we made revisions to several other rubrics to reduce rater variance or to improve the score distribution. We then engaged in a second generalizability study with the revised set of rubrics. The following four practices have rubrics that remained the same through both generalizability studies, and, hence, are the focus of this analysis: positioning students as competent; social coaching; supporting connection and engagement between student context and the math learning environment; and supporting a nurturing environment by proactively building relationships and productive classroom culture.

Four Focal Practices

Based on initial evidence of validity from the first generalizability study, the rubrics that correspond with the four focal practices had scores that demonstrated variability across lessons, and variability was mostly attributed to the lesson and not to differences across raters.

Positioning students as competent. Positioning students as competent is about teachers explicitly and publicly valuing, identifying, and acknowledging the brilliance of their students and framing their actions and statements as intellectually valuable (Bartell, 2011). Note, this is not "appointing" or "giving" students competence. Whether or not a teacher recognizes it, all students already have the capability and know-how to do important and brilliant things. The rubric that attends to this practice emphasizes the extent to which teachers specify what students do that is "productive" as well as the extent to which they provide rationales that support listening students as well as those being positioned in understanding why what was done was considered productive.

Social coaching. Coaching is one way teachers can support students in negotiating productive ways of participating and meeting expectations without decreasing the rigor of the task at-hand. Specifically, social coaching is about teachers deliberately intervening, scaffolding, or providing additional supports to help as students engage with one another (e.g., as they work in cooperative groups or present their thinking to one another). The rubric that attends to this practice focuses on the extent to which the teacher provides concrete suggestions in support of social participation. In addition, this rubric attends to how often the teacher provides rationales for their suggestions.

Supporting connection and engagement between student context and the mathematics learning environment. This practice is about connecting students' lives to discussions and interactions that take place in mathematics classrooms by making the most of connections between the mathematics discussed in class and the everyday lives of students. In particular, teachers may attend to aspects of students' lives and incorporate them into the curriculum (Ladson-Billings, 1995; Banks & McGee, 2001; Gay, 2002), or they may provide learning opportunities that make the mathematics problems discussed in class feel experientially real for students (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013).The rubric that attends to this practice focuses on the extent to which there are connections between mathematics and students' contexts, and whether the connections involve students through dialogue.

Supporting a nurturing environment by proactively building relationships and productive classroom culture. This practice is about establishing personal relationships and developing a sense of community in the classroom (Timmons-Brown & Warner, 2016). This practice often involves the teacher building rapport with students and reinforcing "classroom values." The rubric that attends to this practice emphasizes the extent to which the teacher connects with students in ways that are substantial or that are reciprocated. It also attends to the extent to which the teacher highlights or reiterates classroom values.

Method

Sample

This research project draws on extant classroom video data from two prior research projects, the Responsive Classroom Efficacy Study (RCES) study (Rimm-Kaufman et al., 2014) and the Middle-School Mathematics and the Institutional Setting of Teaching (MIST) study (Cobb et al., 2018). The RCES lessons included in this study were collected in upper elementary classrooms (grades 3-5) during the 2008–09, 2009-10, and 2010-11 school years, and the MIST lessons were collected in middle school classrooms (grades 6-8) during the 2009-10 and 2010-11 school years. The districts and schools within each district varied in their student demographics (see Table 1).

Table 1: District Student Demographics (Rounded)

District	Number of Students	% White	% Black	% Hispanic	% ELL	% Free/ reduced price lunch
RCES	175,000	45	10	20	15	20
MIST-A	35,000	30	40	15	10	65
MIST-B	80,000	15	25	60	30	70
MIST-C	160,000	15	30	65	35	85
MIST-D	95,000	55	35	5	5	55

We hired and extensively trained 5 raters to use the EAR-MI rubrics. At the conclusion of several months of training, rater reliability was assessed with multiple measures including percent exact agreement with an expert score across the last five lessons rated, as well as across 21 lessons scored as a part of training. We consider the five most recently scored lessons because we expected agreement between the raters and expert to improve over time due to ongoing learning. Table 2 shows that exact agreement based on the last five relative to overall was higher for Positioning and Proactive, was similar for Social Coaching, and was slightly lower for Context.

Examining raters' scores relative to the expert scores and relative to each other across the 21 lessons included in training, we calculated Cohen's kappa, Fleiss's kappa, and Krippendorff's alpha (Table 2). Rater consistency with the expert tended to be higher than relative to one another. Generally speaking, kappa and alpha statistics above .20 indicate fair agreement and above .40 indicate moderate agreement (Klein, 2018). Agreement rates with the expert were generally fair or moderate. The Intraclass Correlation Coefficients (ICC) allow us to measure consistency in raters' scores relative to each other. Higher ICCs indicate that scores are trending in similar directions. The ICCs observed in our training data were all above .50, except social coaching which was .40.

For this analysis, we drew on data coded as part of two consecutive generalizability studies, and selected the four focal practices because the related rubrics remained the same and produced reliable results across the two generalizability studies. We analyzed a sample of 141 lessons, representing 65 teachers. This resulted in 83 upper elementary lessons, and 58 middle school lessons. For the purpose of this analysis, a set of scores was generated for each of these lessons through one of two different methods: 1) Expert scores, or 2) Averaging scores across raters. The expert scores resulted from lessons used for bi-weekly drift checks, and the other lessons were scored by three or more raters, and those scores were averaged to create a unique score for each rubric for each lesson. Rubrics include 5 discrete score points. By taking the average across raters, resulting scores could take on any value between 0 and 4.

Table 2: Measures of Rater Agreement

	Positioning	Social Coaching	Context	Proactive
Training				
% Exact Agreement (Last 5 Videos)	83.3%	53.3%	63.3%	73.3%
% Exact Agreement (Overall)	71.4%	53.2%	66.7%	55.6%
Relative to the Expert				
Cohen's Kappa	.53	.29	.53	.37
Fleiss's Kappa	.53	.29	.52	.35
Krippendorff's Alpha	.53	.29	.52	.35
Relative to Other Raters				
Cohen's Kappa	.39	.20	.41	.28
Fleiss's Kappa	.39	.19	.41	.28
Krippendorff's Alpha	.39	.19	.41	.28
Intraclass Correlation	.54	.40	.71	.51

Analysis

This study reports on a descriptive analysis of scores assigned by raters, based on four rubrics designed to assess the four focal practices: positioning students as competent (POSITIONING), social coaching (SOCIAL COACHING), supporting connection and engagement between student context and the mathematics learning environment (CONTEXT), and supporting a nurturing environment by proactively building relationships and productive classroom culture (PROACTIVE). With the unique set of scores for each lesson, we examined the score distributions for the four practices as well as compared score distributions for the middle and elementary school sub-samples. We utilized two-sample t-tests to determine whether perceived differences between the elementary and middle school sample means were statistically significant. A limitation of this analysis is that it does not take into account the nested nature of the lessons within teachers or the order of the lessons for teachers. Future analyses will investigate the influence of these factors on the results included in this report.

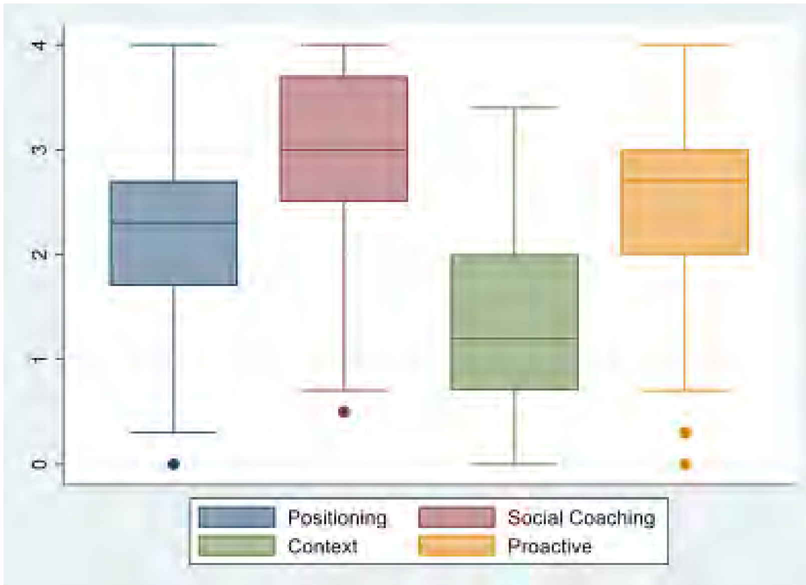

Figure 1: Box Plots Demonstrating Score Distributions for Four Focal Practices

Table 3: Descriptive Statistics for Scores Related to Four Focal Practices

	Overall (n=141) Mean (SD)	Middle (n=58) Mean (SD)	Elementary (n=83) Mean (SD)	Grade band T-test P-value
Positioning	2.20 (0.71)	2.05 (0.61)	2.31 (0.75)	p=.033*
Social Coaching	3.01 (0.75)	3.02 (0.80)	3.00 (0.72)	p>.05
Context	1.30 (0.87)	1.38 (0.92)	1.24 (0.84)	p>.05
Proactive	2.46 (0.67)	2.60 (0.43)	2.36 (0.79)	p=.035*

Note: * denotes statistically significant at the p<.05 level.

Results

Overall, the practices vary significantly in their score distributions (see Figure 1). Of the four focal practices, social coaching had the highest mean (m=3.01, see Table 3), and the score distribution is shifted considerably higher than for the other practices (see Figure 1). A mean of about 3 for social coaching can be interpreted as lessons in which the teacher provided concrete suggestions for social participation with occasional rationales for following those suggestions. The practice with the second-highest mean (m=2.46) was proactive (i.e., supporting a nurturing environment by proactively building relationships and productive classroom culture), which is between levels 2 and 3. For a level 2, the teacher made just one substantial attempt to connect with students (e.g., the teacher sharing personal information about their life). For a level 3, the teacher made more than one substantial attempt to connect with students. The practice with the next highest mean was positioning students as competent (m=2.20), which corresponds between levels 2 and 3. At a level 2, we see lessons where the teacher positions at least one student as competent by specifying what the student did that was productive, but does not provide a rationale for why it was productive (e.g., “Great strategy”). At a level 3, the teacher provides rationales that may not be clear or that may not be focused on disciplinary practices of mathematics like generalizing, justifying, and making connections among multiple representations (e.g., “Using the lines on your paper is a great strategy because your work will be neat and structured and it will be easier to find your answer”). The focal practice with the smallest mean (m=1.30), but also the largest standard deviation (SD=0.87) was context (i.e., supporting connection and engagement between student context and the mathematics learning environment). At a level 1, either the connections to students’ contexts are superficially related to the math task or the students do not participate meaningfully in the discussion of the context (e.g., with a math problem about the perimeter of a lake, the teacher might say, “Raise your hand if you have seen a lake before”). At levels 2 and above, the connections to students’ contexts are substantially related to the math task, with different levels of student participation for levels 2-4. At a level 2, students participate using brief or one-word responses, and at a level 4, multiple students participate in developing a shared understanding of the connections to the context.

Dividing the sample into middle school and elementary school lessons revealed additional nuance with respect to some of the practices (see Table 3). First, there were no statistically significant differences between the elementary and middle school lesson sample means for context and social coaching. There were statistically significant differences for positioning and proactive, and they were in opposite directions. In particular, middle school lessons received significantly lower scores with respect to positioning students as competent ($p<.05$). A middle school mean at a level 2 indicates that, on average, middle school teachers did not provide rationales for their statements that positioned students as competent, whereas a mean of 2.31 for elementary lessons suggests that more elementary teachers provided some sort of rationale in their lessons. The significant difference between means was in the opposite direction for proactive. In other words, middle school lessons received higher scores with respect to supporting a nurturing environment by proactively building relationships and productive classroom culture. This means that there were more teachers in middle school lessons (when compared with elementary school lessons) who made more than one substantial attempt to connect with students. These grade band differences are interesting and warrant further investigation. In the discussion we offer several possible interpretations as well as implications for researchers and teacher educators.

Discussion

Our analysis of four practices that support equity and access in mathematics lessons highlighted interesting differences between the average middle school lesson and the average elementary school lesson with respect to positioning students as competent and proactively building relationships. On average, in elementary lessons compared with middle school lessons, more teachers tended to provide rationales when specifying what the students did that was productive while positioning them as competent. The rubric attends specifically to the explicit ways that teachers position students. With this in mind, it could be that middle school teachers position students as competent in ways that are mostly implicit and thus would not be documented as outlined in the rubric (e.g., some teachers position students by calling them up to the board and asking them to demonstrate their mathematical strategies in the front of the class). It is important to note, that we are not saying that implicit positioning cannot be useful.

However, one theme that we have found across the practices (and especially with the practice of positioning) is that the most supportive implementations of the practices usually reveal the often invisible “rules of the game” being played in mathematics classrooms that may not be apparent to students, particularly students who historically have been minoritized and marginalized in these contexts. In other words, what we have found is that the more transparent and explicit teachers can be in supporting their students the better. These transparent and explicit moves could support students in more directly accessing what is going on and what they are being asked to do, which may empower them in finding their *own* individual ways of “doing math”.

On the other hand, in our sample, the average middle school lesson was rated significantly higher than the average elementary school lesson with respect to proactively building relationships. It could be that teachers in elementary classrooms connect with students in more superficial ways. Alternatively, we note that the distinctions within this rubric attend to the extent to which there are reciprocal personal connections and bonds being built between teachers and students while working on mathematics problems. Knowing that teachers of elementary-aged students tend to teach all subject areas and are usually the instructor for their students throughout the whole school day, it is possible that elementary teachers compartmentalize and make these types of substantial connections at other times during the school day (e.g., some teachers facilitate discussions about their own lives and inquire about their students’ lives during “Calendar Time” or “Circle Time on the Carpet”). However, we are finding that these rich interpersonal connections are particularly important when teachers and students are working on mathematics as it is one way to support students in "showing up" completely and as their whole selves. These interactions also support students in viewing their teachers as approachable, which we have seen improve student participation both in terms of who participates and how they participate. In general, we find that these reciprocal interpersonal connections support the development of a space in which students, particularly those whose voices and natural ways of being are typically pushed to the margins, are likely to feel seen and to be comfortable being their authentic selves. These interactions also support relationships that help students feel safe and secure to take the necessary risks involved in “doing math” (e.g., knowing that disagreeing with shared ideas is common and can be non-threatening or knowing that they are free to make rough draft or not fully formed conjectures while discussing mathematics in class).

As we work to support mathematics teachers to go beyond high-quality mathematics instruction and specifically attend to equity and access in mathematics classrooms, we need more guidance about concrete practices that teachers can engage in (Grossman et al., 2013). This analysis is part of a larger effort to both specify those practices and develop research tools that can be used to assess teachers’ progress as they work to provide instruction that aims towards equity in their mathematics classrooms. At this stage of the validation process, the attention in the EAR-MI rubrics is on whether the teacher engages in particular practices and not with which of the students the practices are enacted. Once we have established meaningful differences between scores on the rubrics, a possible extension would be to combine the EAR-MI rubrics with a participation-focused approach like the EQUIP (Reinholz & Shah, 2018) to attend to whether there are patterns in with whom the teacher enacts particular practices. By attending to individual students in the classroom, we could more intentionally address aspects of the critical axis, specifically highlighting how individual students experience specific aspects of instruction in a mathematics classroom.

The field of mathematics education needs additional research specifically focused on tools for researchers and practitioners that attend to the extent to which mathematics learning environments support historically marginalized groups of students. With the evidence that teachers are not consistently enacting practices that support historically marginalized students, it is clear that teachers would benefit from learning more about these practices and how to enact them in mathematics classrooms. Teacher educators and professional development providers can use these practices and related rubrics to help teachers understand the practices and important distinctions in how they get enacted. By discussing important principles that guide work with students (e.g., the importance of building relationships with students), and pairing those with specific practices described by the rubrics, teachers can begin to envision how to enact those principles with students (e.g., see Pruitt-Britton et al., 2022).

In this study, we explore the synergies between students' mathematical and computational thinking as they engage in an open-ended computing "Quilts" project. The activity aims to create a culturally relevant learning environment in which students have opportunities to code personalized quilts that demonstrate their culture and values. An open-coding process was used to analyze team projects. The results of the study suggested that the computational medium gave students flexibility to devise multiple design plans using the power of mathematics and opportunities to test their chosen approaches. Some of the plans included defining functions, using geometric transformations and estimating coordinates. The code provided insights into the students' familiarity with mathematical concepts, level of abstraction and precision in their calculations. Each team created unique quilts that demonstrate multiple values such as freedom, equity and personal life experiences such as music, family, and homeland.

Keywords: Computational Thinking, Mathematical Thinking, Culturally Relevant Pedagogy

Culturally relevant pedagogy (CRP) (Ladson-Billings, 1995) has been used to create engaging and personally relevant learning opportunities, in particular for traditionally underserved and marginalized students (Enyedy & Mukhopadhyay, 2007). CRP not only focuses on students' achievement in a learning environment. It also supports students' development of critical consciousness about inequities while acknowledging and accepting their cultural identity (Ladson-Billings, 1995). In this study, we explore the synergies between students' mathematical and computational thinking as they engage in an open-ended computing "Quilts" project. In the project, students express their values and thoughts by designing their own quilts as a team, using the flexibility of a computing medium and the power of mathematical thinking.

A growing number of studies is exploring the connection between computational thinking and mathematics learning (Barcelos et al., 2018). The majority of these studies mainly focused on teaching programming skills with a limited or no explicit connection to key mathematical ideas and concepts (Hickmott et al. 2018). A limited number of recent studies (e.g. Alegre et al., 2020; Schanzer et al. 2015) explore the connection between mathematical and computing concepts. However, few studies use culturally relevant computing tasks. Aligned with Li et al. (2020)'s perspective, we believe that computational thinking is more about thinking than computing. This study will present examples of how students used various mathematical strategies as they code personalized quilts that reflect their own values, lives and cultures.

Method

We analyzed the data gathered from the end of year Cultural Quilts project of the year-long Introduction to Computational Thinking (ICT) course that is designed to foster 9th graders' understanding of mathematics and teach programming. The quilts activity aims to create a culturally relevant learning environment in which students have opportunities to code personalized quilts. This activity also enables them to demonstrate their programming skills and use mathematical knowledge such as geometric transformations, and functions.

The activity has 3 phases. In the first phase, students research about the history of quilts and reflect on the relevance of quilts in American history (e.g. quilts have been used to carry over traditions across generations). In the second phase, students work in teams to design a quilt that has a common theme but is made by patching several patterns together. The theme represents values that are important for the team. In the third phase, each student needs to create a geometric pattern and decorate it with symbols related to the values chosen by the team. Finally, all the decorated patterns made by each team member are put together in a single quilt design, and the students write a reflection on how the final quilt is related to the chosen values.

To design quilts, students used CodeWorld, which is an integrated coding platform designed for young students, where the code is based on constructing basic shapes (polygons, circles) and performing geometric transformations (translations, rotations, scalings) on them. These simple instructions can be combined to create very elaborate designs.

Data Sources and Analysis

We collected the data from 352 projects from students in 14 different schools. The data set included code of 1) selected symbols and geometric shapes 2) each team members' pattern (a patch of the whole quilt formed of geometric shapes and symbols) and 3) team's final quilt. It also included the theme of the final quilt and a written description of the values, culture and life demonstrated in the quilt. Two researchers engaged in an open-coding process (randomly selected half of the projects) to identify the mathematical strategies being used in the code and the major themes in students' descriptions.

Findings

In the initial phase of dynamic quilts design, the majority of the students used mathematical estimation to decide how to partition the output window, where to place their geometric shapes and symbols to create their individual patterned patch. A few students used precise mathematical calculations in this process. Figure 1 shows an example for both approaches.

```

Figure 1: Mathematical estimation (on the left) and precise calculation (on the right)

As they created their quilts, students used various mathematical strategies such as 1) define function(s) to construct repetitive patterns (24%), 2) use geometric transformations to set positions relative to other object(s) (37%) 3) create each object systematically (e.g. by defining its coordinates considering their size, output size etc.) (22%) 4) create objects unsystematically (e.g. by defining its coordinates without considering the locations of the other objects) (17%). In some codes, they used multiple strategies. The elegance of their code varied depending on the mathematical approach students used to create objects and patterns. Figure 2 shows an example of how one team (3 students) used the first strategy while creating an object (a pattern formed by geometric shapes) for their quilt.

```
s71 = combined[s(0,"red"),s(1,"green"),s(2,"yellow"),s(3, "blue")]
  where
  s(r,c) = painted(rotated(translated(rotated(solidRectangle(8,8), 45),
                                      (u62,u62)), r*90), c)
  u62 = 67/24
```

Figure 2: Creating an object by defining functions

To create the object in figure 2, students defined a function, s, that takes a rotation index (r) and a color (c). In the definition of s, the construction starts with an 8x8 square, which is rotated 45 degrees, then translated, then rotated again by a multiple of 90 degrees given by the argument r, and finally painted in the given color c. The squares are created in the order given in the first line of the code (red, green, yellow, blue) and then combined to make a single object out of them. Note that the order in the list also determines which squares partially cover other squares, as the first one is on top, the second one is right below it, and so on. As seen in figure 3, to complete the pattern, the students created a small 4x4 blue square and placed it on top of the red one. Alternatively, to avoid the problem with the overlap, they could have constructed an L-shaped object and rotated it 4 times.

```
s7 = combined[painted(translated(rotated(solidRectangle(4,4), 45),
                                  (u62+0.1,-0.025)), "blue"),
              s71]
```

Figure 3: Pattern completion

Each team member created different objects and combined all objects to create the team's final quilt (See Figure 4). The final code is composed of 258 lines.

Figure 4: Unified Quilt

The students explained how their quilt represents their values, as follows:

> The values of generosity, respect, etc. contribute to the sense of unity which is what this quilt is all about. Every quilt comes together to make one single quilt that is better than any of them alone. This represents humans in a lot of ways.

Other students also represented various themes in their projects. For instance, 47.5% of the quilts represented the importance of family and friends in their lives, 21% represented life needs such as shelter, food and safety, 17% of the quilts represented the importance of freedom and peace, 12.5% represented southern culture, 8.75% represented students' homelands. Some quilts represented more than one aspect. 59% of the quilts are combined in harmony, each patch represents an aspect of the overall theme (See figure 5) and 41% are not combined in harmony

(See figure 4), each patch may not represent an aspect of an overall theme or the quilt lacks an overall theme.

In another quilt named “Black teens” students described their final quilt (See Figure 5) as:

> Morals, hobbies, and heritage are important because it makes up a person's beliefs and can decide the actions that they choose to take. K. made symbols about Kongo, S. made symbols about cotton, and I made symbols with music notes and paints.

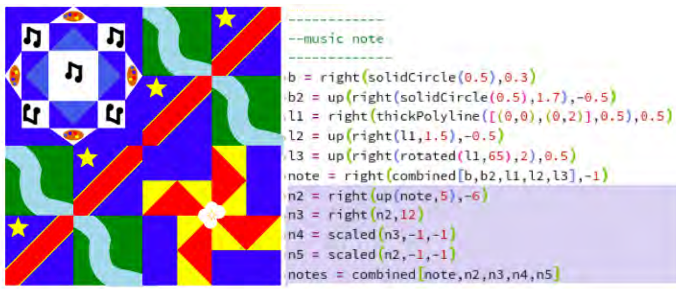

Figure 5: Black Teens Quilt

In the top-left patch in figure 5, a student built a note at the center and then made four copies at different corners. The code not highlighted shows how the student built a single note by combining circles and a segment [thickPolyline]. The highlighted code shows how the student translated the initial note to the two upper corners (n2 and n3), and then they used a reflection in each coordinate direction [scaled(...,-1,-1)] to get to the lower two notes (n4 and n5).

Results and Discussion

The results of this study suggest that students’ codes gave insights about how they used mathematics to design their quilt. The code gave detailed information about students’ mathematical strategies, which mathematical concepts they used correctly and the level of abstraction in their mathematical thinking. In addition, the computational medium gave students flexibility to devise multiple design plans using the power of mathematics (Barcelos et al., 2018) and opportunities to test their chosen approaches. The open-ended nature of the quilt task enabled students to engage in higher order thinking. To design their unique quilts, students had to figure out what procedures to use and why. This dynamic formative feedback had a potential to foster an understanding of the conceptual underpinnings of mathematical procedures (Guzdial & Shreiner 2021). In addition to synergies between mathematics and computation, this activity created a learning environment that was personally relevant to the students. As diSessa (2018) suggested “the freedom to take … ideas and put them to personal use [in this case expressing their values and beliefs tied to their cultural heritage]” (p. 14) makes the tasks personally relevant to the students and creates personal variations in the designed quilts.

Keywords: Research Methods, Technology

Gathering evidence of teachers' classroom instruction has been a hallmark of data collection in mathematics education research. In-person data collection, though often preferable, has become increasingly challenging in recent years, partly due to COVID-19, but also because of logistical challenges (e.g., cost, travel, time) associated with collecting classroom observation data (Namey et al., 2020). Given that research typically occurs near higher education institutions, voices outside these areas are often underrepresented. These challenges have implications around geographic equity, researchers' resources, and time. We explore the possibilities of remote data collection as a means of capturing key aspects of teachers' mathematics instruction.

Previous research on observation protocols that used video versus live coding primarily utilized quantitative methodologies (e.g., Casabianca et al., 2013; Curby et al., 2016) where researchers looked for significant differences using statistical tests. Gridley and colleagues (2018) found no significant differences between live and video coding for their observation protocol, but suggested there might be qualitative differences that were not captured. For example, the informal conversations between the teacher and researcher, the richness of data from being immersed in a bustling classroom, the ability to pause and rewind video, or having an entire research team together to watch video. Understanding aspects of protocols best suited for video or live observations is needed to develop and refine instruments for remote data collection, in order to ensure coding video captures key aspects of instruction, as if the researchers were in the classroom.

Through mixed methods (Creswell & Plano Clark, 2018) we will identify differences in live and video recorded classroom observations with our goal to revise an existing observation protocol to use with video-recorded lessons so we can diversify participants and decrease logistical challenges. Data collection includes live observations of classroom instruction using the *Flipped Mathematics Instruction Observation Protocol* (Otten et al., 2018; Otten et al., 2021) while simultaneously using a 360° video camera. Two researchers will complete the protocol during a live observation and two different researchers will complete it using the video recording. Then the researchers will come together and identify possible differences in coding between the live and video recordings in order to refine the protocol for video recorded observations. Our ultimate goal is to mitigate the dissonance of in-person versus live recordings and work towards a more harmonious approach for collecting observation data that attends to geographic equity, resources, and time.

DEVELOPING EXPERTISE IN TEACHING THAT IS RESPONSIVE TO CHILDREN'S MATHEMATICAL THINKING: A CASE STUDY

Amy Dunning
University of Illinois Springfield
ahewi2@uis.edu

Victoria R. Jacobs
University of North Carolina at Greensboro
vrjacobs@uncg.edu

This poster presents the 3-year story of Ms. Brown, showcasing her development of expertise in teaching that is responsive to children's mathematical thinking. In the first two years, Ms. Brown was a fifth-grade teacher, and in the final year, she served as a mathematics coach. Throughout the study, she was engaged in a 3-year professional development (PD) that was part of a larger project, *Responsive Teaching in Elementary Mathematics* (Empson & Jacobs, 2021). The PD was designed to help teachers develop expertise in teaching that is responsive to children's thinking, with an emphasis on teaching fractions. Research-based frameworks of both children's thinking and instructional practices were central to this work (Jacobs et al., 2019).

We identified growth storylines for Ms. Brown in relation to three instructional practices linked to teaching that is responsive to children's mathematical thinking: (a) anticipating children's mathematical thinking (Stein et al., 2008); (b) noticing children's mathematical thinking (Jacobs et al., 2010); and (c) questioning children's mathematical thinking (Jacobs & Empson, 2016). Data for this case study included 7 classroom observations (2–3 per year), 19 individual interviews (6–7 per year), 4 focus group conversations (1–2 per year), and two written assessments, one each for anticipating and noticing children's mathematical thinking.

Using constant comparative analysis, we identified growth storylines for Ms. Brown's anticipating, noticing, and questioning of children's mathematical thinking. Overall, children's thinking became increasingly centered and addressed in more depth with each instructional practice. Further, Ms. Brown became increasingly confident in her use of children's thinking in these practices. For example, Ms. Brown began by struggling with noticing children's thinking in written work. In an interview early in the first year, she shared: "I've really been trying to take [written work] home and look through the work, and I don't know fully what I'm looking at yet." During the second year, her confidence and ability to notice children's thinking increased, and she highlighted this growth in an interview: "That's been the biggest growing for me over the past 2 years, how to look at your students' work." During the third year, Ms. Brown demonstrated further growth not only in her own confidence but also in her ability and desire to help others notice children's thinking in written work. In an interview about her mathematics coaching, Ms. Brown stated how she encouraged her mentee to work on noticing: "For the first 2 weeks, I just want you to notice. I want you to be able to come to me and say here are some things I notice about my kids' work." These examples provide a brief glimpse of Ms. Brown's growth storyline for the instructional practice of noticing children's mathematical thinking.

This case study contributes to the literature on teaching that is responsive to children's mathematical thinking (see, e.g., Robertson et al., 2016). We provide rich examples of the three instructional practices and their development over time. Implications for ways to foster that development are also presented.

CREATIVITY IN PROVING: IMPLEMENTING A GROUP REFLECTION ACTIVITY

Keywords: Reasoning and Proof, Instructional Activities and Practices, Undergraduate Education, Metacognition

Proof and creativity are foundational to the work of mathematicians (Karakok et al., 2015; Sriraman, 2004). For this reason, it is essential that creativity be encouraged in proof-based university mathematics courses (Mann, 2006; Schumacher & Seigel, 2015) and that students have opportunities to explicitly reflect upon their creativity when proving (Savic et al., 2017). Given the current emphasis on collaborative learning in such courses, we explore one possible way to promote explicit reflection on creativity among undergraduate students as they work together to co-construct proofs (i.e., the implementation of a modified version of the Creativity-in-Progress Reflection on Proving (CPR; Savic et al., 2017). We adopt a theoretical framing of intersubjectivity (Matusov, 1996; Sawyer, 2019) and social metacognition (Chiu & Kuo, 2009) to answer the research question, how do undergraduate students in an Introduction-to-Proof (ITP) course use the CPR to reflect upon their experiences in collaborative proving? Providing a picture of how students use a tool such as the CPR will provide a foundation for future research aimed at understanding the effectiveness of the CPR in promoting explicit reflection upon creativity in collaborative proving and supporting students' development as creative provers.

Context and Methods

This study was conducted in an undergraduate ITP course at a large public university in the United States. This course facilitated an inquiry-based learning environment centered around small-group work. We implemented the CPR group reflection activity (Heath et al., in press) following collaborative group proving activities that occurred during different course modules (a) Logic and Grammar of Mathematics (early in semester), (b) Direct and Indirect Proof Methods (mid semester), and (c) Set Theory (late semester). For each implementation, we analyzed video data of student groups engaging in group reflection using the CPR.

Results

Each implementation followed a similar trajectory where students (a) worked in small-groups to collaboratively prove a given conjecture, (b) used the CPR to reflect on their proving process as a group, and (c) used the CPR to reflect on their individual contributions to the group's proof, and (d) reconvened as a small-group to debrief and discuss their overall observations on creativity in proving. As an example, during the Logic module, small groups were tasked with, "Let A, B, and C be logical statements and prove the following: $(A \wedge B) \vee C$ is logically equivalent to $(A \vee C) \wedge (B \vee C)$." Analysis of video data of group reflection following this task revealed two central themes. First, there was a general difference in approach between groups with respect to how they reached a consensus during their discussion of the CPR. Second, the CPR helped facilitate the recollection of group members' contributions to their group proving that were previously undervalued or unnoticed. This poster will, for each implementation, describe the process of implementing the CPR and report the themes observed in the groups' reflections. These processes and themes will inform the continued refinement of the CPR and provide future directions for our research regarding how to implement of the CPR in a collaborative setting.

Keywords: Elementary school education, Instructional Activities and Practices, Teacher Beliefs, Teacher Knowledge

More than 50 years ago, Kieren (1971) asked: "For whom, for which topics, and with what materials are manipulative and play-like activities valuable?" (p. 232). Since then, most curricula around the world have been promoting or even prescribing the use of manipulatives to teach mathematics at the elementary level. However, the questions asked by Kieren are still relevant as recent research continues to show mixed results when it comes to the efficiency of manipulatives (Carbonneau, Marley & Selig, 2013). The ways in which manipulatives are used by teachers should be considered to better understand how this use can contribute to mathematical learning. In addition, Puchner, Taylor, O'Donnell, & Fick (2008) underlined that "[...] teachers need support making decisions regarding manipulative use, including when and how to use manipulatives to help them and their students think about mathematical ideas more closely" (p. 323). According to Hatfield (1994), Swan & Marshall (2008), and Johnson, O'Meara & Leavy (2020), the use of manipulatives decreases across grades as some teachers tend to believe that manipulatives can be childish or that their use could be a hindrance to the development of abstraction. Those studies also report some factors identified by teachers as discouraging the use of manipulatives (e.g., availability of material, cost, time, distraction) or encouraging it (e.g., visual aid, hands-on learning, building a better understanding). However, we know little about how teachers choose a specific manipulative to use, when and why they use them.

In this project, we aim to better understand teachers' practices around manipulatives and to help them develop meaningful ways of using them. Our first step was to develop a survey around the use of manipulative that will be distributed during spring 2022 to a random sample of elementary teachers from Québec, Canada. Building from previous surveys found in math education literature, we modified and enriched the different questions based on our collaboration with teachers (Jeannotte & Corriveau, 2020; Corriveau & Jeannotte, 2015). The first version was administered to 5 teachers who provide feedback to clarify questions through interviews. The last version is composed of 3 sections. The first section is about demographic information. The second section deals specifically with teachers' use of manipulatives. The third is specific to the pandemic situation. In this poster presentation, we will present the rationale behind some questions from section 2 and some preliminary results.

Keywords: Affect, Emotions, Beliefs, and Attitudes; Informal Education; Instructional Activities and Practices; Undergraduate Education

Many higher education institutions in the United States provide mathematics tutoring services for undergraduate students. These informal learning experiences generally result in increased final course grades (Byerly & Rickard, 2018; Rickard & Mills, 2018; Xu et al., 2014) and improved student attitudes toward mathematics (Bressoud et al., 2015). In recent years, research has explored the beliefs and practices of undergraduate and, sometimes graduate, peer tutors, both prior to (Bjorkman, 2018; Johns, 2019; Pilgrim et al., 2020) and during the COVID-19 pandemic (Gyampoh et al., 2020; Mullen et al., 2021; Van Maaren et al., 2021). Additionally, Burks and James (2019) proposed a framework for Mathematical Knowledge for Tutoring Undergraduate Mathematics adapted from Ball et al. (2008) Mathematical Knowledge for Teaching, highlighting the distinction between tutor and teacher. The current study builds on this body of work on tutors' beliefs by focusing on mathematical sciences graduate teaching assistants (GTAs) who tutored in an online setting during the 2020-2021 academic year due to the COVID-19 pandemic. Specifically, this study addresses the following research question: What were the mathematical teaching beliefs and practices of graduate student tutors participating in online tutoring sessions through the mathematics learning center (MLC) during the COVID-19 pandemic?

The graduate students in this study were part of a multi-institution implementation of a multiple component graduate teaching training program, Promoting Success in Undergraduate Mathematics through Graduate Teaching Assistant Training (PSUM-GTT; Harrell-Williams et al., 2020), which was developed with the intent to strengthen the teaching skills of mathematical sciences GTAs to help the undergraduate students they currently serve as GTAs and to position them to become more effective instructors if they become faculty. GTAs at three institutions participated in a teaching seminar offered by their department and a Critical Issues in Undergraduate STEM Education seminar and received peer mentoring from more advanced graduate students and support from a peer TA Coach.

During the Spring 2021 semester, ten GTAs who had tutoring assignments instead of teaching assignments participated in structured interviews about their beliefs and practices. These GTAs had completed the teaching seminar and MLC-specific training. The interview protocol used modified items from the Pilgrim et al. (2020) tutor-focused survey based on The Teacher Beliefs Interview (TBI; Luft & Roehrig, 2007). The interview data are being coded using the modified coding scheme from Pilgrim et al. (2020), which involves using categories describing the responses on a continuum from more tutor-focused to more student-focused experiences. Results regarding graduate student tutors' beliefs will be summarized and presented in this poster.

HAVE WE CUT OURSELVES OFF AT THE NECK? CENTERING RELATIONALITY AND HUMANITY IN OUR RESEARCH

Charlotte Sharpe
Syracuse University
cjsharpe@syr.edu

Nicole Fonger
Syracuse University
nfonger@syr.edu

Keywords: Research methods, Design Experiments, Teacher Educators

"Humans – feeling, living, breathing, thinking humans – do research. When we try to cut ourselves off at the neck and pretend an objectivity that does not exist in the human world, we become dangerous, to ourselves first, and then to the people around us (Hampton, 1995, p. 52).

This poster summarizes the developing praxis of two mathematics education researchers who consider themselves community-engaged scholars, design researchers, and community partners with public school educators in our city. Recently we have both reflected on our tendency to quietly append mentions of *human connection* to our research manuscripts in humble but brief "closing thoughts" or acknowledgements. We reduce to a sentence or two the months or years we've spent building relationships with students, teachers, and communities, and the patience and kindness they have shown us by inviting us into their spaces. Here we assert that relegating 'connectedness' to the hidden corners of manuscripts is a symptom of personal or academic fear: fear of looking too emotional, too feminine, or too soft in the bid for legitimacy among the bench scientists. Or perhaps we are afraid that making and talking about connections with practitioners or research subjects makes us accountable to them, and vulnerable (Howard & Hammond, 2019; McDevitt, 2021). *What if I care too much about this research*? We join with other critical scholars who challenge the notion of rational objectivity as a fiction of the colonial worldview (Wilson, 2003; Hampton, 1995). By allying ourselves through genuine connections with the students, teachers, school leaders, parents, and other community members in our research, we trade the illusion of objectivity for the vulnerability of feeling (Hampton, 1995; Halle-Erby, 2020). Examining our own research using Indigenous theories and methodologies of *relationality*, we argue in this poster that human connections are not a fringe benefit, a lubricant, or even a foundation of "real research." Instead, we contend that human connection and relationship but should be a goal of mathematics educational research.

This poster represents our first steps adopting the Indigenous theoretical and methodological framework of *relationality* (Hampton, 1995; Wilson, 2003; Steinhauer, 2002) for use in writing and research in mathematics education. To demonstrate the utility of this framework for the PME-NA community, we present a *relationality* analysis of our own past and current writing projects, discussing the affordances and vulnerabilities in privileging human connections as a research pursuit. For example, in examining a manuscript for which she has recently received a "revise and resubmit," Author 1 identifies a problematic absence of discussion of the way friendship, trust, fear, excitement, and disappointment emerged in a sequence of mediated field experiences for pre-service teachers in an elementary classroom. Using the relationality framework, the authors will use this text, as well as Author 2's developing book proposal, as concrete examples of how we might rehumanize mathematics education scholarship and research design by centering connections and relationality. We include implications for how we might incorporate relationality in studies of children's mathematical thinking as well, giving examples from recent PME-NA plenaries that honor relationality in timely and critical ways (Frank, 2021; Marchant & Jones, 2021; Kalinec-Craig, 2021).

Chapter 16:

Technology and Learning Environment Design

LEVERAGING TECHNOLOGY IN A SOCIAL JUSTICE MATHEMATICS LESSON: MODELING HEALTHY FOOD PRIORITY AREAS WITH SCRATCH

David Johnson	Jean Ciscell	Kimberly Corum
Towson University	Towson University	Towson University
djohns77@students.towson.edu	jcisce1@students.towson.edu	kcorum@towson.edu

Keywords: Social Justice, Computing and Coding, Modeling

Using mathematics to understand and address social issues can empower students to act as agents of change in their communities (Gewertz, 2020). Despite calls from education researchers to integrate social justice issues into K-12 mathematics (NCSM & TODOS, 2016), teachers rarely engage in this type of instruction (Bartell, 2013). In our task, students decide where to place a grocery store in a local neighborhood that has been classified as a healthy food priority area (HFPA or food desert) and write a program in Scratch that models different ways of traveling to the grocery store. By using Scratch in this task, students are exposed to coding which can increase their fluency in mathematics and digital literacy as well as promote future careers in STEM (Amador & Soule, 2015). Integrating coding into the mathematics classroom can also support students' ability to visualize abstract concepts, develop authentic problem-solving skills, and explore real-world applications of mathematics (Germia & Panorkou, 2020).

We implemented the *Food from Scratch* task with two groups of students. The first group consisted of 16 university students enrolled in a required course for secondary math and science education majors. This implementation consisted of one 75-minute session that took place in November 2021. The second group consisted of 18 elementary and middle school aged students who participated in math enrichment tasks offered through a university-community partnership program. This implementation consisted of two 60-minute sessions that took place on consecutive Saturdays in December 2021. The activity sequence for the *Food from Scratch* task consisted of five parts: (1) analyzing a neighborhood map to record what students notice and wonder, (2) determining the unit rate for different methods of travel (i.e., walking, driving), (3) selecting a grocery store location, (4) modeling travel from different locations to their grocery store using Scratch, and (5) engaging in a mathematical analysis of their grocery store placement (e.g., distance to their grocery store, average travel times for walkers versus drivers, accessibility of their grocery store based on data collected from Scratch).

Analysis of students' written work and Scratch programs revealed key themes across both implementations: accessibility, prior knowledge of the coordinate plane, and understanding of unit rates. Students were constantly aware of how their decision making affected the people in the community and wanted to ensure an equitable grocery store location for residents. In doing so, students used their knowledge of a coordinate plane to construct various routes of travel and utilized rich mathematical reasoning to justify their grocery store placements. For example, students from the first implementation calculated the distance between different points while students from the second implementation considered the difference in unit rates between walkers and drivers when reflecting on their grocery store placement. Students were able to apply their knowledge of the coordinate plane and unit rates to justify their ideal location of a grocery store in a HFPA in their community. By addressing a social justice issue that is facially neutral (all people should have access to healthy food options) and utilizing students' prior mathematical knowledge, our findings from *Food from Scratch* task could prove helpful for educators wanting to utilize similar tasks that integrate social justice issues and modeling with technology.

IDENTITY AND POSITIONING DURING A TECHNOLOGY-ENHANCED MATHEMATICS TASK: WHO TAKES THE STAGE?

Samantha Fletcher
Middle Tennessee State University
scf3a@mtmail.mtsu.edu

Kristen Fye
University of North Carolina at Charlotte
krfye@uncc.edu

It is important that mathematics teachers cultivate the positive identities of their students, as identity is an essential dimension for equity in mathematics education (AMTE, 2017; Gutiérrez, 2012). Consequently, an important role of the mathematics teacher is to foster students' positive mathematics identities to create an equitable mathematics learning environment. Identities can be developed through positioning, meaning recognizing discursive actions as social acts within storylines familiar to participants in discourse (Harré & van Langenhove, 1991). The way students are positioned has been shown to positively and negatively affect their learning as they develop mathematics identities (Bishop, 2012; Tait-McCutcheon & Loveridge, 2016; Wood, 2013), suggesting it is a crucial component of identity development. From a perspective of storylines, mathematics identity can be thought of as "the repetition of 'performances' in mathematics learning contexts that generates our recognition of ourselves in certain ways as learners of mathematics" (Darragh, 2015, p. 85). As a student performs their mathematics identity, those they are interacting with are audience members that recognize and interpret the performance in different ways. In the context of a technology-enhanced mathematics task, students participate in the mathematics actively through their actions with the technology, so technology use can be thought of as part of their performance. The purpose of this study was to investigate how two students' mathematics identities were cultivated through being positioned as the mathematical expert – by themselves, each other, and the teacher – when engaging in a technology-enhanced mathematics task. We address the research question: How are mathematics identities performed and leveraged by students during a technology-enhanced mathematics task?

In this pilot case study, two ninth-grade students (age 14) attended an in-person after school session to engage with a task designed to leverage the power of sliders in Desmos to enhance and empower their learning around key characteristics of the sine function (i.e., amplitude, midline, and period). As they engaged in the activity, we collected screen capture recordings of their work with Desmos. We drew from Darragh (2015) to develop an analytical framework for examining their mathematical discourse, which, over time, constitutes their mathematical identities. Each instance of a student being the performer (which then made the teachers and the other student the audience) served as our unit of analysis, which Darragh referred to as "the stage." New stages presented themselves when the performer of mathematical expertise shifted as a result of social acts during the discourse. As a research team, we coded the performer/mathematical expert and the action which caused the shift in each stage. Preliminary findings indicate the teachers positioned the students as the performer/mathematical expert through questioning, and one student de-positioned herself as the performer/mathematical expert when struggling with the mathematical concepts. Additionally, both students were simultaneously positioned as the performer/mathematical expert when they grappled with or agreed on mathematical ideas. Although performer/mathematical expert was not always the person driving the technology, the actions with the technology were leveraged in their discourse. Implications for fostering positive identity development with technology-enhanced tasks will be shared.

EXAMINING CONTENT AND STRUCTURE OF FLIPPED ALGEBRA I VIDEOS

Jaepil Han
University of Missouri
jaepilhan@mail.missouri.edu

Zandra de Araujo
University of Florida
zdearaujo@coe.ufl.edu

Courtney Vahle
University of Missouri
courtneyvahle@mail.missouri.edu

Samuel Otten
University of Missouri
ottensa@missouri.edu

Keywords: Online and Distance Education, High School Education, Technology

Flipped instruction is an instructional model in which content is delivered via video lessons students typically watch as homework. The increase in teachers' implementation of flipped instruction in conjunction with the rise of virtual schooling due to the COVID-19 pandemic has heightened attention and interest in the videos used to deliver content in mathematics classrooms. Despite the proliferation of such videos, little attention has been given to aspects of lecture videos in mathematics, such as what constitutes flipped lecture videos or how each lecture video is structured. To this end, the purpose of this study was to answer the question, What is the content and structure of lecture videos used in flipped Algebra I classrooms?

As part of a larger research project studying flipped Algebra I instruction, we analyzed the video structure (i.e., how each video introduced, explored, and summarized the mathematics content) of 59 lecture videos from 13 Algebra I teachers employing flipped instruction came from school districts of varying sizes throughout the state. Based on the shift of the images on the screen, the team identified the types, lengths, and sequences of video segments and summarized the purpose of each segment in addition to the basic instructional features and quality (e.g., focus, rationale, unmitigated errors) and video production (e.g., creator, interactive features) adapted from Authors (Han et al., 2019; Otten et al., 2021).

The teachers typically assigned just one video per lesson and each video ranged from 41 seconds to 23 minutes and 18 seconds with an average of 8 minutes and 8 seconds. All videos functioned to deliver content, so-called lecture videos. The videos were primarily composed of definitions, worked examples, and problem solutions. The most common sequence of video segments aligned with the typical model of direct instruction, rule-example-practice (Okeeffe, 2013). Given the videos' alignment with direct instruction, it is not surprising the segments comprising the teachers' videos largely centered on procedures and the enactment of those procedures. Interestingly, *Introduction*, *Worked Example*, and *Definition* were present in nearly every video (72.88%, 93.22%, and 62.71%, respectively) and constituted the majority of video duration (3.12%, 68.59%, and 17%, respectively). Other segment types (e.g., *Try Example*, *Solution*, *Homework*, *Conclusion*) only took up less than 6% of video duration in total.

Across the videos, there were no differences in terms of the content and structure of the videos and they were largely modeled after the textbook. Thus, as we have argued elsewhere (de Araujo et al., 2017), the videos are a form of digital textbook delivered by the teacher. Our findings shed light on the content and structure of the videos used in flipped classrooms. In addition, it provides a better understanding of current implementation of flipped instruction in Algebra 1 and a snapshot of how teachers aim to help students learn outside of the classroom environment, which potentially inform us of supports that we may offer teachers to improve the segments that they are using or promote alternative purposes and structures for the videos.

COMPARING EXPERT AND NOVICE TEACHERS' NOTICING WITH EYE-TRACKING IN 360 VIDEO

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Chris Lenart
Kent State University
clenart4@kent.edu

Qiang Guan
Kent State University
qguan@kent.edu

Keywords: Teacher Noticing; Technology

Teacher noticing involves attending to pedagogically significant events amongst an array of occurrences in the classroom, and using one's professional resources to reason about those events (Jacobs et al., 2010; van Es et al., 2017). Initially, more novice teachers may focus on the teacher or generic classroom behaviors, while more knowledgeable teachers focus on students and those students' mathematical reasoning (Huang & Li, 2012; Teuscher et al., 2017). Scholars studying teachers' eye-tracking data with standard videos have found preservice teachers (PSTs) attempt to focus on more students, with less time per student, and usually those proximally closer to the camera, whereas inservice teachers (ISTs) are more focused (Huang et al., 2021). In a similar manner, analysis of PSTs viewing of 360 video has found that those attending to students' mathematics with more specificity tend to focus on fewer students for longer durations (Kosko et al., 2021) and position students more in the center of their field of view (FOV) (Kosko et al., 2022). This scholarship provides evidence that where teachers gaze with their eyes (Huang et al., 2021) and turn their body/head (Kosko et al., 2022) are related to what and how they attend to in the classroom. The present study represents an effort to combine both technological approaches by examining ISTs (n=4) and PSTs' (n=10) professional noticing in relation to their eye-tracking data within a 360 video on the Commutative Property of Multiplication. Analysis of written noticing suggest that ISTs attended to students' reasoning about the property while PSTs focused on students' procedural knowledge. Results from eye-tracking data suggest ISTs (42.46%) and PSTs (47.23%) gazed at children for similar proportions of time. However, ISTs showed evidence of looking at different students and their work, as conveyed with larger average gaze distances from students (U=34.00, p=.048).

INTEGRATIONS OF TECHNOLOGY AND CULTURALLY SUSTAINING MATHEMATICS PEDAGOGY FOR PRESERVICE TEACHERS

Idrissa Presley-Peterson
University of Florida
ipresleypeterson@ufl.edu

Hyunyi Jung
University of Florida
hyunyi.jung@coe.ufl.edu

Keywords: Technology, Culturally Sustaining Pedagogy, Elementary Preservice Mathematics Teachers

The objective of this study is to examine how elementary preservice teachers (PSTs) design and reflect on culturally sustaining mathematics lesson plans by utilizing instructional technology. Culturally sustaining pedagogy (CSP) values the development of student cultural competency, emphasizing the ever-changing states of student cultures and sociopolitical contexts surrounding students' lives (Paris, 2012). Technology is a tool that can support CSP and accessible STEM education, due to adaptability, engagement, and opportunities for student representation (Galbraith et al., 2001). The Association of Mathematics Teacher Educators [AMTE] (2017) emphasized the importance of preparing future teachers to deeply understand ways to increase equity and access for every student's mathematical success and the roles of technology in enhancing access to mathematics learning (AMTE, 2017). As teacher educators of elementary PSTs, we aimed to support their capacity to develop culturally sustaining mathematics lessons that incorporate instructional technology.

The participants of this study were PSTs enrolled in two sections of a mathematics education course for an inclusive elementary education program at a public Southeastern university in the U.S. PSTs interacted with weekly lessons on math-based technology, featuring instructional design and collaborative media, and learned about ways to teach mathematics to culturally and linguistically diverse students. All technology components were selected for potential integration into culturally sustaining mathematics teaching. Examples were game-based applications, augmented or virtual reality, real-time collaborative software, and digital note taking tools. Data include PSTs pre/post-surveys, weekly written reflections on the use of technology in mathematics classrooms and CSP, culturally sustaining mathematics lesson plans with technology integration, and microteaching of the lessons. Our preliminary data analysis on PSTs' work indicates that they gained an understanding of diverse technological tools, integration into mathematics teaching, and systemic barriers they were facing. For example, PSTs reflected upon ways to utilize students' funds of knowledge and instructional technology, to design and implement mathematics lesson plans that cultivate equitable learning experiences for all students. They discussed ways to honor students' cultures and identity by using technology in mathematics curricula while acknowledging the systemic barriers to implementing ideal lessons in an educational setting. In our poster session, we will showcase the utilization of technology to promote culturally sustaining mathematics teaching to address equity and universally accessible curriculum design. The specific ways PSTs created technology-based, culturally sustaining lesson plans to promote students' understanding of mathematics will provide insights into curricular designs for a similar course and PSTs' perspectives on these learning opportunities. We will create a space for discussion in which teacher educators share their experiences of incorporating technology and/or culturally sustaining pedagogy into programs. We hope to build future collaborations to support the learning of PSTs in multiple teacher education programs.

CONTENT KNOWLEDGE AND TEACHER NOTICING: THE CASE OF VERTICAL ASYMPTOTES

Demet Yalman Ozen
Middle Tennessee State University
dy2i@mtmail.mtsu.edu

Nina G. Bailey
University of North Carolina Charlotte
nbaile15@uncc.edu

The practice of teacher noticing (TN, i.e., attending, interpreting, and deciding how to respond; Jacobs et al., 2010) when focused on students' mathematical thinking in a technology-mediated learning environment is a core component of technological pedagogical content knowledge (TPACK; Niess, 2005) and is essential for mathematics instruction (Jacobs & Spangler, 2017). Some researchers conceptualize content knowledge as the foundation of TPACK (Lee & Hollebrands, 2011). This conceptualization, coupled with research that has found that content knowledge influences teachers' interpretations of students' understanding on paper and pencil tasks (e.g., Dick, 2017), suggests that it is important to study this relationship in the context of technology-mediated learning environments. Thus, we investigated the relationship between preservice secondary mathematics teachers' (PSMTs') content knowledge and their practice of TN of students' mathematical thinking in a technology-mediated learning environment. The content focused on the key characteristics of rational functions—specifically the existence and location of vertical asymptotes.

This study was situated in a course focused on teaching secondary mathematics with technology in Spring 2021. The course had an emphasis on supporting PSMTs in developing TPACK in general and TN very explicitly. All PSMTs were math majors and had successfully completed at least through Calculus 2. PSMTs completed two assessments, one focused on content and one on the practice of TN. The content assessment asked PSMTs how they would explain to a student why the vertical asymptote of a rational function is at a given value(s). The TN assessment presented PSMTs with a video clip of a pair of secondary students working on a technology-mediated task in which they used sliders to explore the parameters of rational functions to reason about the existence and locations of vertical asymptotes. The content assessment was scored based on PSMTs' reasoning (e.g., correct and complete, correct but incomplete, incorrect). The TN assessment was analyzed using a coding rubric which focused on PSMTs' skills of attention to and interpretation of students' spoken and written mathematical thinking and technology engagement. To develop the TN assessment coding rubric, we identified the mathematically significant details of the students' exploration in the video clip and included three levels (i.e., lacking, limited, and robust) on each of the four components similar to the coding scheme used by Jacobs et al. (2010). We then compared the TN evidence with the PSMTs reasoning about the existence and location of vertical asymptotes to assess any trends. Findings include that PSMTs who provided correct and complete responses to the content assessment provided either limited or robust evidence for their interpretations on the TN assessment. In comparison, PSMTs who responded with incorrect components on the content assessment provided lacking interpretation evidence on the TN assessment. Thus, preliminary findings suggest that although there may be a connection between PSMTs' knowledge of vertical asymptotes and the TN skill of attending, there is likely a stronger connection between PSMTs' knowledge of vertical asymptotes and the skill of interpreting in a technology-mediated learning environment. A full analysis will be presented along with implications for supporting PSMTs as they develop both content knowledge and TN.

This research synthesizes studies that used a Digitalized Interactive Component (DIC) to assess K-12 student mathematics performance during Computer-based-Assessments (CBAs) in mathematics. A systematic search identified ten studies that categorized existing DICs according to the tools that provided language assistance to students and tools that supported students problem solving. We report on the one study that involved students with learning disabilities and three studies involved English Language Learners. One study focused on assessing geometry content and four studies targeted on number and operations understanding. For other studies included a mixture of mathematics domains. Mixed results were reported as to the effectiveness of the availability of DICs. The research suggests that older children were more likely to benefit from availability of the DIC than younger children, and that DICs have greater impact on students with special needs.

Keywords: Computerized mathematics tests, mathematics assessment, Interactive digitalized components

While there are multiple literature reviews evaluating the effectiveness of Computer-based-Assessment (CBA), no systematic review was found in evaluating the effects of Digitalized Interactive Components (DICs) that are used in CBAs. Computer- based-assessments (CBA) have been widely used in national and international large-scale tests as part of recent reform efforts stressing teaching, learning and testing in digital contexts. Important CBAs include high-stake state standard assessments (e.g., the Partnership for Assessment of Readiness for College and Careers, PARCC, the Smarter Balanced Assessment), the national report card (National Assessment of Educational Progress, NAEP), and the international comparison assessments (e.g., Program for International Student Assessment, PISA). The shift towards implementing CBAs for assessment can be an important improvement during testing, potentially impacting students' engagement, interpretations, and responses to test items (Jerrim, 2016).

CBAs are created to optimize learning goals and assessment techniques through high-quality tests (Smoline, 2008), and to improve the participation and performance of students with disabilities (Flowers et al., 2011). Computers provide the opportunity to offer tasks that display animated or dynamic changes in different aspects over time: Interactive games, simulations, and microworlds, that can be made by computers, enable exploring problems, discovering rules, forming relationships, and developing successful strategies. Computers also can help students deal with complicated data sets (Ridgway & McCusker, 2003). In a study to compare CBAs with pen-and-paper assessments (PPAs) for students with a read-aloud accommodation, Flowers et al. (2011) found that students prefer CBAs and report that they perform better when CBAs are available. According to Hoogland and Tout (2018), CBAs have advantages over traditional paper and pencil assessments (PPAs) in: Supporting the assessment of high-level mathematical thinking process, illustrating authentic problems from our real-life settings to implement mathematical concepts, and building tests and analyzing results through complicated psychometric processes with new techniques in scoring and reporting.

Digital-Interactive-Components

As a key element of CBA, DICs are part of the item stem with which students can interact and employ to answer the question. For example, an interactive ruler is an on-screen ruler that students can use to measure the length of objects in the screen. DICs commonly used in the current CBAs include, but are not limited to, drag-and-drop, annotations, changing the color of a shape upon clicking, etc. The NAEP items that have access to the touch-screen tablets mode include DICs such as using a read-aloud tool, making digital notes, adjusting screen themes, highlighting texts, dynamic texts, interactive maps, embedded digital calculators, interactive graphs, and virtual simulations (National Center for Educational Statistics, NCES, n.d.).

DICs enable practitioners to measure students' knowledge and skills in ways more authentic to a CBA environment (Bergner & von Davie, 2019; Lissitz & Jiao, 2012; Masters & Gushta, 2018), and to improve the measurement of student learning by targeting constructs that are otherwise difficult to capture with the PPA mode (Bennett et al., 2008; Chen & Perie, 2018; Jerrim, 2016). DICs are expected to offer benefits to make CBAs over traditional PPAs by engaging students in simulated real-world tasks and measuring aspects of a construct that cannot be measured with PPA items (Huff & Sireci, 2001). Some interactive tools require students to work with them in the process of producing products/responses, a more authentic form of measurement (Archbald & Newmann, 1988; Bennett, 1999; Harlen & Crick, 2003; Huff & Sireci, 2001; Masters & Gushta, 2018; McFarlane, et al., 2000). Interactive features of DICs have the potential to improve assessment accessibility for some disadvantaged groups, such as students with disabilities and English Learners (ELs). Further, technologies involving the use of DIC tools can enable the collection of real-time process data that could offer diagnostic assessment information for educators to support improved teaching and student learning (Jiang et al., 2021). Despite the potential benefits of DIC inclusion in CBAs and the emerging trend of their inclusion in testing, implementations of DICs in testing have been challenging.

A first challenge in current assessment practices is the lower percent of DICs in all CBA items. Despite the fast-growing research on educational technology (Lindner, 2020), many of the studies in the literature focus on technology as a tool for instruction, whereas sparse research has been conducted on technology as a tool for assessment (Cheng & Basu, 2009). Moreover, even with knowledge from the current CBA literature, computerized test items often apply traditional formatting similar to PPAs, such as multiple choice, true-and-false, and fill-in-the-blanks (Cheng & Basu, 2009), whereas the use of interactive features in rarely reported (Dindar et al., 2015).

A second challenge in the current assessment implementation of DICs lies in the poor design of existing DICs. Invalidated DICs might introduce construct-irrelevant variance even if students have mastered the content domain, thus diminishing validity and utility of scores for students of certain subgroups. Russel and Moncaleano (2019) examined the use and construct fidelity of technology-enhanced items employed in international K12 large-scale assessment programs, and reported that only 40% of the technology-enhanced items has good fidelity in measuring the aimed construct. In particular, a sizable percentage of drag-and-drop items has a low level of fidelity. Likewise, student cognitive interviews in NAEP 2016 indicated that students experienced tremendous confusions when interacting with DICs. More than half of the students encountered various difficulties using DICs, even though more than half of the students had experiences with similar tools. Their confusion centered around figuring out how to use the tools to respond to the assessment items rather than applying the tools in their problem solving.

Even more alarmingly, poorly designed DIC tools can become a source of bias towards students from under-represented groups. Studies show that students need to be trained to use computerized items that involve DICs since the absence of learning to use the tools properly can negatively impact potential benefits of DICs (Olson, 2005). Students with less access to learn digital skills are more vulnerable to benefit with potentially negative impacts on their performance using poorly designed DIC features (Jerrim, 2016; Schatz, et al., 2010; Stickney et al., 2012). The extent to which a disparity might be present for some students is still largely unexplored (Wang et al., 2021). According to Buzick, (2021), with the exception of embedded calculators, students with disabilities showed an even lower frequency of using any DICs than their peers without disabilities, even though all embedded DICs were rarely used in all students. It still remains unclear what roles specific types and features of DICs play in measuring students' knowledge and skills, and how these features might impact the performance of student subgroups. For example, research to date has yet to examine the degree to which items with DIC yield construct irrelevant variance for different subgroups of students with different socioeconomic status (SES) and gender.

Although there have been systematical reviews pertinent to comparing the different effects of PPA and CBA for K12 students on mathematics related measures, there is an absence of research reviews specifically on the availability and effects of existing DICs. To this end, we offer a research synthesis with the goal of exploring the use of interactive tools from research studies investigating students' mathematics performance. Questions that guide our review are:

1. What existing DICs are available for use in assessing student learning mathematics in the literature of CBA in mathematics? Specifically, what are the main features and purpose of the tools? How effective are they in capturing student performance? What student characteristics, such as age, gender, ability level, influence the effectiveness of these interactive tools?
2. What mathematics domains are involved in the reviewed DIC studies? Are the DICs more effective within certain mathematical content domains? Are certain item features more or less relevant?

Method

Search Procedures

For this literature review, we followed guidelines from the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA; Moher et al. 2009) and three approaches were completed to accurately search for peer-reviewed journal articles. We conducted (a) an electronic search of databases with key words related to computer-based assessment, (b) another round of electronic search of databases with key words of specific DIC types, and (c) an ancestral search to identify any additional relevant articles.

First, we searched five databases: Academic Search Premier, ERIC, ProQuest Education Database, Teacher Reference Center, and APA PsycInfo (including PsycArticles). Within the abstracts of English studies, we searched using a combination of the following terms: "Computer based, assessment, mathematic*" and "Computer based, Test*, mathematic*" The total of the resulted studies was 1589, which were screened to 39 potentially viable studies for inclusion, based on titles and abstracts. Full-text review of each study led to an inclusion of eight articles for this synthesis.

Secondly, we also searched additional key words emphasizing interactive features with the above databases, with combined terms of "interactive technology", "computer* feature", "digit* feature", "interact* computer*", as well as specific DICs from the studies identified from the first round of search, including "calculator" "glossary" "drag drop" "animat*" and "digit* ruler." Every single phrase was attached using AND condition with the two terms "assessment" and "mathematic*." The total of the resulted studies was 444 and 2 additional studies were identified.

Thirdly, we examined the included studies reviewed by related meta-analysis or review synthesis. Specifically, we reviewed mathematics studies included in the three prior meta-analyses that was conducted by Kingston (2009), Wang et al. (2007), and by Kingston (2009) that reviewed research comparing PPA vs. CBA effects. No additional studies were identified beside these three meta-analysis studies.

Inclusion and Exclusion Criteria

In the research synthesis we only included quantitative studies that investigated the effectiveness of using DICs in assessing mathematics performance for K-12 students. Studies included in the review were required to meet all the three criteria: (a) inclusion of quantitative data of students' mathematics assessment results in CBA with specific DICs; (b) all participants were K-12 students; and (c) studies were published in peer-reviewed journals in English. Ten studies were identified, including six studies comparing a DIC condition with a non-DIC condition, and four studies exploring specific features of DIC conditions.

The following types of studies were excluded: (a) those that provided feedback or corrections in an assessment (e.g., Hippisley et al., 2005); (b) those based on computer-based programs with DICs as interventions rather than assessments (e.g., Crawford et al., 2016; Gambari et al., 2014; Ninness et al., 1998); (c) unpublished dissertations, conference presentations, technical reports (e.g., Bridgeman & Potenza, 1998; Christensen et al., 2014; Price et al., 2014); (d) qualitative studies (Pantzare, 2012); (e) focusing on non-mathematics subjects (e.g., Koong & Wu, 2010 on social studies; Cheng & Basu, 2009 on science); (f) those with participants not in K-12 (e.g., Arslan et al., 2020; Gallagher et al., 2002; Gulley et al., 2017; Mavridis & Tsiatsos, 2017), or (g) no specific DICs described (e.g., Logan, 2015).

Coding Procedure

The first and second author developed a coding scheme that included the following variables: (a) author(s) and the year of publication, (b) number of participants, (c) \DIC description, (d) participants' age or school grade level, (d) participants' other characteristics such as ability level, SES, El, etc., (e) mathematics content involved, (f) research design, (g) independent and dependent variable(s) and their means (M) and standard deviations (SD), (h) effect size (ES), and (i) narrative research findings. Coding reliability was found by calculating the percentage of agreement between two independent raters on 30% of the studies found in the first stage of searching and screening. The inter-rater reliability was 90.91%.

Results

Types of Existing DICs

To address our first research question regarding the availability of existing interactive tools and their effectiveness that were reported in the review literature of (K-12) mathematics CBAs, based on the functions of the DICs reviewed in this study, we categorized the existing DICs into two major types: (a) DICs that provided language or vocabulary assistance, and (b) DICs that enabled students to construct solutions. Four studies were conducted to investigate the impact of implementing interactive tools that provided language or vocabulary glossaries (Calhoon et al., 2000; Cohen, et al., 2017; Cohen et al., 2020; Roohr & Sireci, 2017). Six studies were found under the second category of effectiveness (Adesina et al., 2014; Applegate, 1993; Kong et al., 2018; Jiang et al., 2021; Ninaus et al., 2017; Threlfall et al., 2007).

Language tools. For the effectiveness category, four studies addressed the use of pop-glossary in mathematics assessment for students who have language or reading problems. Roohr and Sireci (2017) compared the effects of two DICs: A pop-up glossary tools and sticker paraphrasing tool for English language learners (EL s). Findings reported that the pop-up glossary did not provide definitions for all the words or phrases in the test, but only for those that were underlined. For example, when a student clicks on the underlined words or phrases, a window appears with a clarification using definitions, pictures, synonyms, or animations. The sticker paraphrasing tool is intended to provide less difficult paraphrasing after clicking on an icon. More than 2000 students participated in the study. The results show that students used the sticker paraphrasing tool more frequently than the pop-up glossary tool (d = -0.34). Regarding the item-level response time in seconds, results showed that all students took longer on the items that provided either of the two DICs compared with the items that did not provide DICs (d = 0.17). Unfortunately, this study did not report student scores, so we do not know if students scored higher or lower on items with DICs than items without DICs, or if students scored higher on items with one DIC than items with the other DIC.

Two other studies specifically examined the effects of the glossary pop-up tool. Cohen et al. (2017) investigated the impact of using pop-up English glossaries with audio through randomized controlled trials. More than 32,000 third- and-seventh-grade students participated in the study. The items were selected based on experts' judgements of the likelihood that EL s may encounter language difficulties when solving the problems. Math items from a field test were randomly selected to be provided with a pop-up English glossary, whereas the other items were not provided with the pop-up glossary. The results showed that the pop-up glossary slightly inhibited students' performance on mathematics assessments. In the subsequent study about the pop-glossaries, Cohen et al. (2020) scaled up the previous study and over 60000 students from 3rd-grade to 11th-grade participated. Results show that the pop-up glossary accommodation overall was effective for mathematics assessment and did not degrade the measured construct. However, ES could not be obtained for these two studies.

The reading-aloud tool is another DIC that falls into the first category of language assistance tools. Calhoon, et al. (2000) investigated the differences between using a teacher-read and a computer-read tool with and without video. They found that teacher-read tools, computer-read, and computer-read tools with video increased students’ scores on mathematics performance assessment in comparison to the traditional PPA without any reading accommodations. No significant difference was found among these three conditions.

Tools for constructing problem solutions. The second category of DICs identified from the reviewed papers deals with enabling or assisting test takers to construct responses or solutions by interacting with prompts from the computer screen. Adesina et al. (2014) investigated a computerized tool that enabled students to construct responses with an interactive digital device. Two panes were provided to students: the problem pane and the answer pane. The problem pane showed the worded problem and the answer pane showed students’ responses. The problem pane allows the exam taker to drag numeric values using one or both hands. The user could touch and hold two numeric values simultaneously. The touch-and-drag feature activated a menu that contained the main four symbols of the arithmetic operations (i.e., +, -, O, ÷). After selecting one of these symbols a numeric keypad and a text box were displayed. The study investigated the usability and applicability of the tool and compared study students' performance using PPAs, with 39 fifth grade participants. Results reported no significant difference between mathematics scores using the DIC and their corresponding scores in the traditional PPA condition, suggesting access to the DIC did not influence students' scores.

Applegate (1993) investigated the impact of a response-construction tool to test children's analogical reasoning. He compared student performance with a DIC condition and a PPA condition on geometry items and involved 24 kindergarteners. In the DIC condition, a joystick was used to enter data in the response portion. The examinee needed to put the cursor anywhere on the top graphic shapes and press the fire button. The examinee could choose a shape or color. If the correct object was chosen, then it was displayed in an empty box. If the incorrect color was chosen, then all objects were shaded with that color. The study revealed that the DIC condition is significantly more difficult than the PPA condition.

Threlfall et al. (2007), Kong et al., (2008) and Jiang (2021) examined the effects of a pull-and-drag tool. The tool in Threlfall et al., (2007) allowed students to select number cards and put them in boxes to perform an arithmetic operation). This study found that changing from PPA to CBA made little difference in testing validity and legitimacy, and also indicated that some PPA items showed poorer validity than the corresponding equivalent CBA items with DICs, possibly because an equivalent CBA version was less cognitive-demanding and made the problem solving process easier, for example, the pull-and-drag DIC might decrease the likelihood of making mistakes such as using numbers that are not mentioned in the question. Kong et al. (2018) compared the response time differences between computers and tablets on items either with a DIC (e.g., drag-and-drop) or without a DIC (e.g., filling- in-the blank, multiple choice). However, this study did not compare either students' accuracy or response time between items with the "drag-and-drop" DIC and items without a DIC. Jiang et al. (2021) studied students' performance on drag-and-drop items in a large-scale assessment (i.e., National Assessment of Educational Progress, NAEP) in the fourth and eighth graders. The results also revealed that students who answered the item correctly spent shorter time to respond compared to their peers who responded incorrectly.

Effects of tools. Mixed results of the DIC effectiveness were reported in two DIC categories. In all studies that compared differences in students' scores between a DIC condition and a non-DIC condition, only one study (Applegate, 1993) used a between-subject design and provided needed data to calculate an ES, whereas all other studies with a within-subject design did not provide needed data to calculate an ES. Consequently, we were unable to conduct a meta-analysis to estimate an overall effect size for each DIC category. Instead, we summarized the mixed findings, which seem to favor a positive effect of language tools -- two studies (Calhoon et al., 1997; Cohen et al., 2020) reported positive effects, one (Cohen et al., 2017) reported negative effects, and one did not report student accuracy scores. There also seemed to be a negative effect of the response construction category DIC, with two non-significant effects (Adesina et al., 2014; Threlfall et al., 2007), and one negative effects (Applegate, 1993).

Roles of Student Characteristics

To explain the varying effectiveness reported in research studies on the same type of DIC, we further examined whether and how student characteristics (e.g., age, grade level, ability level, EL status) and item features (e.g., mathematics subjects) were related to the effectiveness of DICs. Although we could not calculate weighted effect sizes or perform a meta-regression to detect any significant moderating effects, we identified some patterns, including the following: (a) DICs may inhibit young' children' performance whereas support older children's performance, and the positive effects of DICs increase with age or grade level, and (b) DICs seemed to have different effects in different subgroups, and generally speaking, it appeared to produce greater influences, either positive or negative, on students who were in greater need of help. For example, the language DICs had greater influence on ELs than non-EL students (Cohen et al., 2017; Cohen et al., 2020) and EL students also tended to use the language DICs more frequently (Roohr & Sireci, 2017); and across all 6 studies comparing non-DICs with DICs, students with disabilities benefited from the DIC (Calhoon et al. 2000) and general-education students did not show any changes (Adesina et al., 2014; Threlfall et al., 2007). However, the sample with gifted students was inhibited in a DIC condition (Applegate, 1993). Due to the limited number of studies available, we interpreted these patterns as a hypothesis for future research to verify, rather than as validated conclusions from this synthesis. Well-designed DICs could provide accommodations to address the special needs of students with disabilities and Els, and hence offer promise to make the assessments more assessable and equitable for these special student populations. With poorly-designed DICs, disadvantages can be exacerbated with special student populations by creating extra barriers and demanding greater cognitive load.

Effects of Mathematics Domains

Regarding the influence of mathematics domains and item features, the current findings reported mixed effects in both geometry items and numerical items. It is reasonable to expect that students might obtain greater benefits on geometry items than numerical items because geometry assessment items rely heavily on visual presentations for which DIC features may play a more effective role by enabling students' interactions with diagrams. However, three studies (Applegate, 1993; Cohen et al., 2020; Trelfall et al., 2017) that involved a form of geometry assessment suggested mixed findings. This may be partially attributed to the nature of the items intended to be measured, confounded by other variables such as text or perhaps the less-than-satisfactory geometry DIC effects to the very few available DICs. In the reviewed studies no DICs that might be particularly useful for geometry problem solving, such as drawing supplemental lines, rotations etc., were included, suggesting the need for further research in order to gain richer understanding of the potential benefits of well-designed geometry DICs.

Discussion

This study synthesized prior studies that examined the effects of specific Digitalized-Interactive-components (DICs) in computer-based assessment (CBA). Research questions included: What DICs were available in the literature of CBA in mathematics; what were the main features of these DICs, and how effective were they? How did students' age, gender, and ability level influence performance with the interactive tools? And what mathematical content domains were involved, and whether the DIC effectiveness was influenced by mathematics domains or item features? We systematically searched the literature and reviewed 10 studies that met our inclusionary criteria. The small number of studies identified suggested a need for more research in this important field. While CBA has already been widely implemented in high-stakes, large-scale assessments and DIC is an essential component to ensure the effectiveness of CBA, very little empirical data is available as to the effectiveness of DICs. Although in educational practice, there have been greater use of a variety of DICs that have been developed and used in school practice, results of our systematic search revealed that these DICs that are widely used in school-assessment practice were never validated, suggesting that the research base is lagging behind educational practice. We also discovered that 7 out of the 10 studies were published after 2014, including six studies published in 2017 –2021, suggesting that this is a topic gaining increased attention by the research community.

We categorized DICs that were used as a language tool, and DICs that were used to enable students to construct solutions. Both categories of DICs do not reflect the numerous DIC types in actual practice. For example, NAEP assessments, with the touch-screen tablets mode, have made available DICs such as the read-aloud tool, making digital notes, adjusting screen themes, highlighting texts, dynamic texts, interactive maps, embedded digital calculators, interactive mathematical graphs, and virtual simulations (NCES, n.d). However, most of these DICs are not included in any of the reviewed articles. Also, lacking were some sophisticated DICs that can be found in some commercial online assessment programs such as rotating/flipping/transforming images, digital rulers, annotations. Such a mismatch between the limited types of DICs in research papers and the rich resources of DIC options in practice certainly reflects the gap between the research and the rapid development of technology in the assessment industry. Ideally, educational practice should be guided by education theories and validated by evidence from rigorous educational research; however, in actual school practice it seems that the assessment industry has moved much faster than the tools included by researchers in the studies. Earlier literature (Kim, 1998; Logan, 2015; Smolinsky et al, 2020; Wang et al., 2007) shows that some DICs in practice inhibited, rather than supported students' mathematical problem solving during a CBA. Also, there remains a concern that a CBA with poorly designed DICs could create greater assessment biases against disadvantaged students (Pan, 2016). More research is warranted to ensure the development and validation of science-based assessment tools based on educational theories and cognitive principles.

A limitation of this synthesis is the sparsity of research available - only 10 studies found in peer-reviewed journals. Because access to technical reports produced by some testing companies or organizations (e.g., Educational Testing Service, or American Institute of Research) was not available, a decision was not to include these non-peer-reviewed reports. Moreover, insufficient information was available in the research publications, making us unable to calculate an ES for within-subject design studies. Therefore, the DIC effects and possible influences of participant characteristics and item features were presented as an overall summary of the findings of the related reviewed studies, rather than as a result from a rigorous meta-regression. Therefore, cautions need to be applied to the findings, such as DICs may inhibit young' children' performance whereas support older children's performance, and the positive effects of DICs increase with age or grade level, and DICs seemed to have different effects in different subgroups, and generally speaking, it appeared to produce greater influences, either positive or negative, on students who were in greater need of help.

Conclusions

In the field of mathematics assessment, numerous studies were conducted to investigate the impact of implementing computerized tools, but few studies have examined the effectiveness of implementing DICs. We identified 10 studies that implemented a DIC in a mathematics assessment. The DICs were categorized into two groups: Interactive tools that provided language or vocabulary assistance, and interactive tools that enabled students to construct solutions and ideas. DICs may have differential effects on children of varying ages, and appeared to produce greater influences, either positive or negative, on students who were in greater need of help. Further research studies should be conducted to investigate the effectiveness of implementing DICs in assessing mathematics performance of K-12 students of different ages and with varying special needs. The need for continued research that has the potential to gain greater insight into what knowledge can be gained when struggling students have access to appropriate tools is clear.

INTERACCIÓN CON REPRESENTACIONES DINÁMICAS PARA ARGUMENTAR SOBRE LA VALIDEZ DE UNA CONSTRUCCIÓN GEOMÉTRICA

INTERACTION WITH DYNAMIC REPRESENTATIONS TO ARGUE ABOUT THE VALIDITY OF A GEOMETRY CONSTRUCTION

María Alejandra Calderón González

lmorenoa@cinvestav.mx

Desde la matemática educativa, gran variedad de estudios se ha enfocado en analizar la presencia de la tecnología digital desde diferentes puntos de vista. Quienes abordan la prueba y la argumentación se han resistido a que se presenten resultados con un componente tecnológico, debido a la idea de formalidad asociada estos términos, lo que ha aumentado la tensión existente entre la naturaleza teórica y empírica de la matemática. Teniendo en cuenta que con la presencia de entornos como DGS el estudiante puede acceder a representaciones dinámicas, nosotros buscando entender el impacto de la interacción con estas representaciones en los argumentos que proponen los estudiantes. Para esto realizamos un estudio de tipo exploratorio y descriptivo cuyos resultados muestran que la interacción con representaciones dinámicas brinda a los estudiantes herramientas de validación diferentes a las del papel.

Palabras clave: Razonamiento y prueba.

Introducción y antecedentes

Argumentar y validar proposiciones son habilidades que el ser humano necesita para desenvolverse en sociedad. Desde muy temprano, uno de los objetivos educativos consiste en promover la participación de los estudiantes para la comprensión y desarrollo de argumentos. Por ejemplo, la NCTM (2000) propone que "Al final de la escuela secundaria, los alumnos deberían estar capacitados para comprender y elaborar demostraciones matemáticas, es decir, argumentos que consisten en deducciones o conclusiones lógicamente rigurosas a partir de hipótesis" (p. 59). Todo esto es analizado desde la perspectiva del profesor (Bleiler et al, 2014; Lesseig et al, 2019; Dickerson y Doerr, 2014), desde las producciones del estudiante (Buchbinder y Zaslavsky, 2011), y desde la incorporación de la tecnología digital (Leung y Or, 2007; Olivero y Robutti, 2001; Sinclair y Robutti, 2012).

En el salón de clases el profesor es quien usualmente promueve el desarrollo de argumentos y pruebas, por lo que se han desarrollado investigaciones en las que se exploran las ideas que tienen los profesores sobre este tema (Bleiler et al, 2014; Lesseig et al, 2019). Un hallazgo en este sentido es que los profesores consideran la formalidad y la lógica como factores relevantes para determinar la validez de un argumento y más aún cuando son profesores con pocos años de experiencia (Dickerson y Doerr, 2014). Sin embargo, para algunos autores (Wittmann, 2021; de Villiers, 2004) este énfasis formalista sobre la prueba inhibe la importancia de la comprensión, por lo que se propone que para la educación matemática el objetivo sea que los estudiantes desarrollen distintos tipos de *razonamientos* que les permitan comprender y argumentar por qué una proposición es válida (Hanna, 2014).

La geometría es una de las áreas de las matemáticas en la que el desarrollo de argumentos y pruebas se puede dar de manera natural, ya que "los métodos geométricos son, hasta cierto punto, una combinación de ver y razonar, ya que, allí, la razón comprueba los desarrollos lógicos, y los guía sobre lo que los ojos ven en la figura" (Northrop, 1968, p.131). En particular, el razonamiento se desarrolla sobre una figura, de modo que la figura es parte constitutiva del proceso argumentativo. Esta misma idea es compartida por Netz (1988) quien afirma que, en el caso de la geometría griega clásica, el diagrama es la esencia de la prueba.

En clase de geometría se busca que los estudiantes expresen sus razonamientos para ilustrar la generalidad de un hecho a partir del diagrama, sin embargo, esto no siempre es posible debido a que generalizan a partir de un solo caso (Stylianides y Stylianides, 2017). Por ejemplo, piensan que la mediana y la mediatriz de un triángulo son el mismo objeto porque al trazarlas con regla y compás estás coinciden para el triángulo construido (isósceles). Este tipo de situaciones han hecho que la incertidumbre sobre la generalidad de un hecho sea una pieza clave para incentivar en los estudiantes la necesidad de producir pruebas deductivas (Buchbinder y Zaslavsky, 2011). Sin embargo, cuando las representaciones son dinámicas (e.g., presentadas en GeoGebra) se puede generar un alto nivel de certeza mediante el arrastre de puntos de una construcción y la observación de que las propiedades se mantienen a través de las distintas figuras resultantes. Esta percepción de la permanencia de una propiedad (que ya no sería accidental), es lo que lleva a proponer otras estrategias y funciones de la prueba diferentes a la tradicional (de Villiers, 2004). Además, el acceso a una pantalla digital ha promovido el estudio del impacto de las tecnologías digitales en el cambio sufrido en los razonamientos y las pruebas que proponen los estudiantes.

Existe un gran número de investigaciones en las que se analiza desde diferentes perspectivas el uso de geometría dinámica en procesos de argumentación y prueba. Algunas se han enfocado en tipificar los argumentos que proponen los estudiantes, concluyendo que la mayoría son de tipo empírico (Morales et al.,2021); otros estudios han buscado analizar cómo la interacción con los objetos de la geometría dinámica puede servir como trabajo previo para proponer y construir pruebas deductivas/teóricas (Leung y Or, 2007; Olivero y Robutti, 2001; Dello-Iacono, 2021). Sin embargo, también se ha reconocido que la interacción con representaciones dinámicas puede llevar a nuevas formas de razonamiento genuinas (Moreno-Armella y Brady, 2018) y por lo tanto a establecer nuevas ideas sobre lo que significa una prueba cuando se trabaja con representaciones digitales. El estudio que aquí se reporta, investigó ¿cómo es la interacción entre el estudiante y las representaciones dinámicas al momento de realizar construcciones y argumentar sobre su validez?

Teniendo en cuenta la importancia de la interacción entre el estudiante y las representaciones dinámicas, a continuación, presentamos el constructo teórico de la *co-acción*, el cual extiende algunas ideas de génesis instrumental. Además, presentaremos una visión general de la argumentación que no expresa la necesidad de un nivel de formalidad.

Perspectiva Teórica

Cada vez más las estructuras curriculares están siendo habitadas por la tecnología digital mediante los sistemas de representación que reaccionan de inmediato a las acciones del estudiante, permitiendo, por una parte, que algunas actividades que se pueden adelantar con lápiz y papel se desarrollen de una forma más eficiente y se eviten errores de cálculo —la herramienta como *amplificadora*—. Sin embargo, la ejecutabilidad de estas representaciones hacen posible que el estudiante pueda transformar sus conocimientos y acceder a ideas nuevas —la herramienta como *reorganizadora conceptual*—. Esto es particularmente tangible en los entornos de geometría dinámica (Moreno-Armella y Sriraman, 2005).

La acción de *arrastrar* un vértice de un triángulo, por ejemplo, genera una respuesta del medio digital que gradualmente va develando la naturaleza estructural de la construcción que se haya realizado. Hay allí un espacio de exploración nuevo para el estudiante, pues la pantalla digital es un espacio que *dialoga* con el estudiante a través de las representaciones digitales. La ejecutabilidad de las representaciones se traduce en la capacidad de respuesta del medio durante una exploración y contribuye al desarrollo de nuevas maneras de pensar. Termina generándose una dialéctica que ha sido estudiada como la génesis instrumental (Rabardel y Beguin, 2005), pero en un salón de clases se aprende *de, con y a través* de los otros. Hay formas de articular el pensamiento propio con el pensamiento de los demás incluidas sus experiencias con el medio digital presente. Esta *co-acción cognitiva* (Hegedus y Moreno-Armella, 2010) es un rasgo central de la mediación instrumental.

Si bien las posibilidades abiertas por los medios digitales de cómputo numérico y visualización han cuestionado la demostración tradicional sobre papel y lápiz como único criterio de validación matemático, ubicados en el terreno de la educación matemática y viendo la *construcción del sentido* como un objetivo central del aprendizaje, consideramos que hay, aparte del tradicional, otros caminos para construir la justificación de una proposición (digamos geométrica) en el salón de clases. La exploración de una situación geométrica (nuestro interés aquí) encuentra una respuesta *teóricamente controlada* del lado del mediador digital—por ejemplo, Geogebra. Al adelantar una exploración, el estudiante encuentra en la pantalla una respuesta a sus acciones a través de la plasticidad de las representaciones. De esa manera su entendimiento matemático va encontrando y desechando rutas de aproximación a una respuesta plausible a un problema o a una demanda de justificación. Por lo tanto, los argumentos matemáticos pueden ser abordados desde una perspectiva general como una línea de *razonamiento* que pretende mostrar y/o convencer de que un resultado (una declaración general sobre un objeto, una solución a un problema, un cálculo) es correcto (Sriraman y Umland, 2020; Hanna, 2020). Nuestro trabajo responde a las líneas aquí trazadas.

Metodología

Situamos nuestra investigación dentro de un enfoque cualitativo centrado en comprender, profundizar y describir fenómenos a través de la perspectiva de los participantes (Hernández et al., 2010). En este caso buscamos comprender la interacción con las representaciones dinámicas al momento de argumentar. Seguimos la línea de las investigaciones exploratorias y descriptivas (Steffe y Thompson, 2000) ya que buscamos familiarizarnos con los modos y formas de operar de los participantes.

Los participantes fueron 6 profesores de matemáticas que estaban llevando un curso de geometría como parte de un programa de maestría. Para este reporte, describimos el caso de Ana quien manifestó no estar familiarizada con los contenidos de geometría (ya que nunca ha enseñado esta materia y solo llevó un curso sobre este tema durante su licenciatura) y quién demostró gran destreza con el manejo de GeoGebra.

El cuestionario propuesto a los participantes consistía en seis construcciones que debían realizar y argumentar por qué su solución era válida. Posteriormente se realizó una entrevista semi estructurada a cada participante con el fin de profundizar en sus argumentos/ razonamientos y en la interacción con el medio digital.

Para el análisis de los datos se extrajeron los fragmentos de la entrevista en los que se evidenciaba un proceso donde: los estudiantes realizaban acciones sobre el medio digital, interpretaban la respuesta del medio (la información de la pantalla) y esta información los llevaba a realizar nuevas acciones. En general, nosotros analizamos cómo este proceso contribuyó a que los estudiantes pudieran argumentar sobre la validez de su construcción.

Resultados

En esta sección analizamos las interacciones de los estudiantes con el entorno digital, en particular, la naturaleza de los argumentos que se producen gracias a dicha interacción. Encontramos tres usos que describimos a continuación.

GeoGebra como amplificador

El entorno es, en un momento inicial, un amplificador que le permite a los estudiantes hacer explícitas sus ideas sobre las circunferencias, elipses, mediatrices y demás objetos geométricos. En ese momento sus ideas aún no han sido afectadas por el nuevo sistema de representación. Lo ilustramos primero con el trabajo de Ana, quien aborda el problema: dado un ángulo y una recta transversal a los lados del ángulo hallar un punto sobre la transversal equidistante de los lados del ángulo. En su respuesta Ana afirma que el punto buscado está en la intersección de la bisectriz y la transversal, por lo que durante la entrevista se le solicita que realice la construcción, dando paso al siguiente dialogo.

[1]E: ¿Qué trazaste ahí?
[2]A: Una bisectriz.
[3]E: ¿Por qué la bisectriz?
[4]A: Porque la bisectriz me va a dar todos los puntos que equidistan de (…) de ambos lados.

La construcción de Ana está guiada por su conocimiento teórico, por lo que el medio digital (GeoGebra) se usa como una herramienta que le permite construir la bisectriz del ángulo dado de manera casi idéntica a cómo lo haría con lápiz y papel.

En cuanto al argumento, Ana *concluye* que el punto de intersección entre la bisectriz y la transversal equidista de los lados del ángulo porque existe una *regla general* vinculada a la bisectriz que le permite afirmar dicha equidistancia (línea 4, diálogo anterior).

GeoGebra como reorganizador conceptual

El medio se ha convertido en un reorganizador conceptual cuando el razonamiento del estudiante trae indeleble la presencia del mediador digital, de modo que el estudiante reconfigura sus argumentos incluyendo la *respuesta* del mediador. Esto se ilustra cuando Ana debe probar que los puntos de la bisectriz equidistan de los lados de un ángulo, hecho que usualmente se prueba determinando dos triángulos congruentes, sin embargo, Ana usa otra estrategia (ver Figura 1) y dice:

[5]A: ¿Por qué equidista? Porque, pues (…) puedo dibujar esta circunferencia con centro aquí (señala H) que es tangente a este lado y a este (señala los dos lados del ángulo).
[6]E: Ok. Y, ¿el poder dibujar esa circunferencia me permite verificar la equidistancia?
[7]A: Aja (mueve constantemente el punto B por la pantalla).
[8]E: ¿Por qué? ¿qué característica da (…)? ¿por qué no una elipse, o un cuadrado?
[9]A: Ah, pues porque la distancia del centro a cualquier punto, pues es la misma, desde aquí que desde aquí (señala dos puntos de la circunferencia).

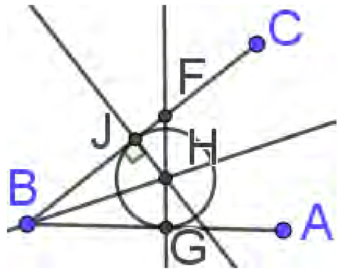

Figura 1: Construcción de Ana para probar una propiedad de la bisectriz

Para probar que los puntos de la bisectriz equidistan de los lados del ángulo, Ana guiada por sus *conocimientos* sobre las propiedades de las circunferencias (línea 9) *construye* una circunferencia con centro en H que es tangente a uno de los lados del ángulo (BC), anticipando que la circunferencia resultará tangente al otro lado. La *respuesta* dada por el medio gracias a la exactitud de los trazos y la geometría *incrustada* en ese medio permite que Ana configure su argumento basado en lo que ve en la pantalla. En este mismo sentido, Ana usa la función de arrastre para ilustrar la generalidad del hecho cuando *arrastra* uno de los puntos de la construcción y la *respuesta* que le da el medio es que la circunferencia permanece tangente a ambos lados del ángulo.

Sobre el argumento de Ana, ella *concluye* que los puntos de la bisectriz equidistan de los lados del ángulo porque puede dibujar una circunferencia que es tangente a los dos lados del ángulo (línea 5). En este caso, la garantía del argumento es una regla que establece como general gracias a sus conocimientos sobre las propiedades de la circunferencia y la co-acción con la representación dinámica. La presencia del medio dinámico en el argumento de Ana se presenta en dos momentos: primero con la exactitud de los trazos, ya que si estuviera trabajando en el papel podría no darse la tangencia o sería *su voluntad* la que haría que la circunferencia resultara tangente. El segundo momento se presenta cuando ella mueve un punto de la construcción, en este caso el vértice del ángulo, característica que diferencia el trabajo en el medio digital y el papel y lápiz.

GeoGebra como guía

El medio digital es "experto en geometría" de modo que puede impactar el razonamiento del estudiante a través de un proceso en donde se plantean hipótesis o conjeturas. Esto puede darse con la observación persistente de un hecho que modifique las ideas geométricas del estudiante, lo que ocurriría al evaluar la respuesta del medio digital. Este proceso dialéctico lo observamos cuando se le propone a Ana construir la bisectriz de un ángulo sin utilizar la herramienta que viene preconstruida en el medio digital —GeoGebra en este caso— y después que pruebe que efectivamente es la bisectriz.

[10]A: Déjame lo pruebo.
[11]E: ¿Qué cosa vas a probar?
[12]A: Si (…) si trazando alguna de estas rec(…) sí, alguna de éstas (señala a HJ y HG en la figura 1) me da este punto de aquí (señala a H), y ese punto, pues va a ser parte de la bisectriz.

Ana construye un ángulo NML y un punto O sobre MN, después construye una recta perpendicular a MN por O e intenta construir una recta perpendicular a ML, pero solo mueve el apuntador sobre el segmento ML (ver Figura 2) y se da cuenta que el punto no puede ser ubicado arbitrariamente cuando dice:

[13]A: “No puede ser cualquiera”.

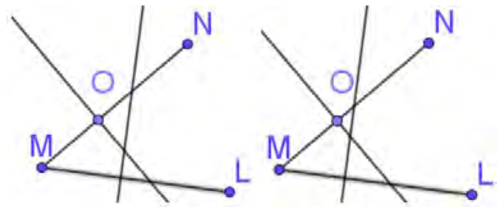

Figura 2: Arrastre de Ana para construir la perpendicular deseada

En este caso, la construcción de Ana está guiada por su intuición y la *respuesta* del medio digital se puede interpretar como la posible ubicación de la recta perpendicular a ML y el punto de intersección de las dos rectas perpendiculares. La respuesta del medio es interpretada por las ideas previas que tiene Ana gracias a la interacción con su representación anterior (línea 12), las cuales le permiten afirmar que el punto sobre ML debe tener alguna característica particular que desconoce (línea 13).

Continuando con su exploración, Ana empieza a usar GeoGebra como un medio que *guía* su razonamiento, ya que construye un punto P en el segmento LM y la recta perpendicular a dicho segmento por P, después determina el punto Q como la intersección de las dos rectas perpendiculares y construye la circunferencia con centro en Q y radio QO, por último, mueve P hasta que parece que la circunferencia con centro en Q es tangente a ML por P.

La construcción de la circunferencia por parte de Ana muestra la presencia de un hecho geométrico que ha sido adquirido gracias a la interacción con el medio digital, en el que una recta es bisectriz si y solo sí al construir una circunferencia con centro en la bisectriz y tangente a un lado del ángulo resulta tangente al otro lado (línea 5). Esta idea se ha incorporado a la construcción del objeto bisectriz que tiene Ana, y ahora hace parte de sus herramientas conceptuales que le permiten probar si un punto es un punto de la bisectriz o no.

Continuando con la interacción con el medio digital, Ana conjetura sobre la ubicación de P (por ejemplo, que es punto medio de ML) y realiza las construcciones respectivas, pero gracias las respuestas del medio digital a través del arrastre, ella comprende que sus hipótesis no son correctas. Mueve el punto P sobre el segmento ML y observa que el punto de intersección entre la circunferencia y la recta perpendicular a ML se mueve cuando P se mueve, por lo tanto, determina dicho punto de intersección como R y decide usar la herramienta “Rastro”. Esta última le muestra el lugar geométrico de R cuando P se mueve (ver Figura 3), pero al ver el resultado Ana afirma que necesitaría conocer P y decide cambiar su estrategia.

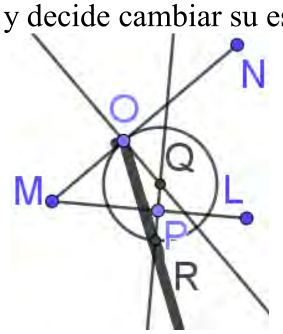

Figura 3: Uso de la herramienta “Rastro”

Aquí subrayamos dos tipos de interacción con el medio digital, en la primera, Ana busca dentro de sus conocimientos geométricos ideas que le permitan plantear hipótesis sobre la ubicación de P y en este caso la *respuesta* del medio digital es la ubicación del punto solicitado por Ana, como el punto medio de ML y esta respuesta es contrastada con las ideas previas de Ana. En la segunda interacción, ella no parte de ideas geométricas, sino del comportamiento de la representación digital de los objetos, de modo que la *respuesta* del medio muestra el comportamiento del punto R. Entonces, Ana busca asociar esta respuesta con su conocimiento previo y al no poder hacerlo, decide usar otra estrategia.

Ana decide volver a explorar la configuración inicial (la que se presenta en la Figura 1) y después de mover los punto A, B y C decide construir una circunferencia con centro en M y radio MO.

[14]: Y, ¿esa circunferencia por qué se te ocurrió?

[15]: (mueve el punto P hasta que la circunferencia con centro en Q resulta tangente a los dos lados del ángulo) ¡Ah, sí es!

Al ver que su nueva hipótesis resulta ser correcta Ana decide eliminar el punto P que había construido y ahora lo construye como punto de intersección de la circunferencia con centro en M con el segmento ML. Pero, esta vez no construye Q como punto de intersección de las dos perpendiculares, sino que lo determina con punto medio de OP y construye la recta MQ como bisectriz. Para probar que la recta es la bisectriz ella construye la circunferencia con centro en Q y radio QO, pero como Q no es el punto de intersección de las dos rectas perpendiculares, entonces la circunferencia no resulta ser tangente a los lados del ángulo (ver Figura 4). Ana mueve los puntos de su construcción y duda que la recta construida sea la bisectriz, entonces decide usar la herramienta "bisectriz" que la construye a partir de tres puntos y nota que la recta bisectriz coincide con MQ, por lo que reevalúa la construcción de la circunferencia con centro en Q. Por último, Ana construye la circunferencia con centro en la intersección de las dos perpendiculares y así comprueba que la recta construida es la bisectriz del ángulo LMN.

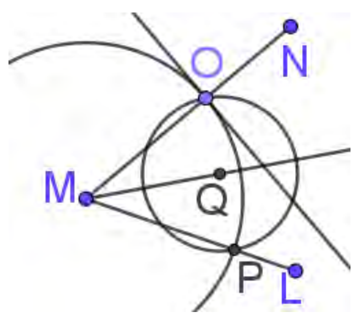

Figura 4: Construcción de circunferencia que no es tangente a ambos lados del ángulo

En general, la construcción de Ana está guiada por las observaciones sobre la representación *ejecutable* y el constante diálogo con el medio digital. Este medio se usa como un recurso que le permite *explorar* partiendo de hipótesis (como la idea que se ilustra en la Figura 2) o buscando hipótesis gracias a la interacción con la representación dinámica—estrategia presentada en Figura 3 y cuando explora nuevamente la Figura 1.

Sobre el argumento de Ana, ella *concluye* que la recta construida es la bisectriz del ángulo porque puede construir una circunferencia que es tangente a los dos lados del ángulo y permanece tangente ante el arrastre. En este caso, la garantía del argumento es una *regla de* *validación digital* que ha mostrado tener incorporada a sus conocimientos (línea 5). Afirmamos que esta es una regla de validación digital ya que cuando el medio responde con una circunferencia que no es tangente (Figura 4), ella piensa que la recta construida no es bisectriz, porque una idea sobre este objeto que forma parte de sus conocimientos previos es que: una recta es bisectriz si y sólo si se puede trazar la circunferencia tangente.

Un hecho que resulta interesante del proceso de Ana es que cuando traza la recta bisectriz y el medio responde haciendo coincidir dicha recta con la recta ya construida a saber, MQ (Figura 4), ella no usa dicha coincidencia para argumentar que la recta construida sea la bisectriz del ángulo. Solo cuando construye la circunferencia tangente considera que ha probado que su construcción es correcta. Las reglas de validación están vinculadas al proceso continuo de formación y adquisición de conceptos.

Palabras finales

Este trabajo ha permitido observar diferentes interacciones cuando se recurre a la mediación de las representaciones dinámicas durante las tareas de construcciones geométricas y cómo dicha mediación afecta los procesos de validación. Reportamos tres usos del medio digital: i) como un socio constructivo en donde la respuesta del medio no hace parte del argumento, ii) como un medio de prueba en donde la interacción con el medio desempeña un rol importante en el argumento, y iii) El medio digital como un guía que corrige y da indicios del camino a seguir, al igual que en el caso anterior la interacción con el medio es crucial en el argumento.

Las diferentes interacciones que analizamos permitieron observar formas híbridas de interacción, es decir, presencia de ideas geométricas previamente desarrolladas en un medio de lápiz y papel que se manifiestan en medio de un razonamiento adelantado en el contexto de la geometría dinámica. Los razonamientos de Ana se auxilian de los recursos que ofrece el medio digital para establecer que la circunferencia siempre será tangente al otro lado del ángulo. En efecto, Ana razona sobre una representación que le brinda información diferente a la que tenía en un medio estático. Pero ¿se podría afirmar que la prueba de Ana es deductiva? Este cuestionamiento nos lleva a plantearnos una pregunta que es todavía más amplia: *¿qué caracteriza una prueba deductiva en el medio digital?*

Ofrecemos aquí un punto de partida hacia la caracterización de una *prueba digital*.

INTERACTION WITH DYNAMIC REPRESENTATIONS TO ARGUE ABOUT THE VALIDITY OF A GEOMETRY CONSTRUCTION

INTERACCIÓN CON REPRESENTACIONES DINÁMICAS PARA ARGUMENTAR SOBRE LA VALIDEZ DE UNA CONSTRUCCIÓN GEOMÉTRICA

From mathematics education, a great variety of studies have focused on analyzing the presence of digital technology from different points of view. Those who work with proof and argumentation have resisted presenting results with a technological component, due to the idea of formality associated with those terms, which has increased the existing tension between the theoretical and empirical nature of mathematics. Taking into consideration that with the presence of environments such as dynamic geometry software (DGS) the student can access to dynamic representations, we seek to understand the impact of the interaction with these representations on the arguments proposed by the students. For this, we carried out an exploratory and descriptive study whose results show that the interaction with dynamic representations provides students with validation tools different from those on paper.

Keywords: Reasoning and Proof.

Introduction and background

To argue and to validate propositions are skills that human beings need to function in society. From very early on, one of the educational objectives is to promote the participation of students for the understanding and development of arguments. For example, the NCTM (2000) proposes that "By the end of secondary school, students should be able to understand and produce mathematical proofs —arguments consisting of logically rigorous deductions of conclusions from hypotheses—and should appreciate the value of such arguments" (p. 56). All this has been analyzed from the perspective of the teacher (Bleiler et al, 2014; Lesseig et al, 2019; Dickerson and Doerr, 2014), from the student's productions (Buchbinder and Zaslavsky, 2011), and from the incorporation of digital technology. (Leung and Or, 2007; Olivero and Robutti, 2001; Sinclair and Robutti, 2012).

In the classroom, the teacher is the one who promotes the development of arguments and proofs, consequently, research has been developed to explore the teachers' ideas on this subject. (Bleiler et al, 2014; Lesseig et al, 2019). A finding is that teachers with few years of experience consider formality and logic to be relevant factors that determine the validity of an argument (Dickerson & Doerr, 2014). However, some authors (Wittmann, 2021; de Villiers, 2004) consider that this formalist emphasis on proof inhibits the importance of the comprehension process. Under this last perspective, it is concluded that the objective, in mathematics education, should be for students to develop different types of reasoning that allow them to understand and argue about the validity of a proposition (Hanna, 2014).

Geometry is one of the areas of mathematics in which the development of arguments and proofs can occur, because geometric methods are, to a certain extent, a combination of seeing and reasoning, since reason verifies logical developments and guides them about what the eyes see in the figure (Northrop, 1968). The reasoning, in geometry, is developed on a figure, so that the figure is a constituent part of the argumentative process. This same idea is shared by Netz (1988) who states that, in the case of classical Greek geometry, the diagram is the essence of the proof.

In geometry class, students are expected to express their reasoning to illustrate the generality of a fact from the diagram, however, this is not always possible because they usually generalize from a single case (Stylianides and Stylianides, 2017). For example, they think that the median and perpendicular bisector of a triangle are the same object because when they are drawn with a ruler and compass, they coincide for the constructed triangle (isosceles). These types of situations have made uncertainty about the generality of an important fact in promoting the need to produce deductive proofs in students (Buchbinder & Zaslavsky, 2011). However, when the representations are dynamic (e.g., presented in GeoGebra) a high level of certainty can be generated by dragging points of a construction and observing that the properties are maintained across the different resulting figures. This perception of the permanence of a property (which would no longer be accidental), is what leads to proposing strategies and functions of the proof that are different from the traditional one (de Villiers, 2004). In addition, access to a digital screen has promoted the study of the impact of digital technologies on the change suffered in the reasoning and proofs proposed by students.

There are many investigations in which the use of dynamic geometry in argumentation and proof processes is analyzed from different perspectives. Some have focused on typifying the arguments proposed by students, concluding that most of them are empirical (Morales et al., 2021); Other studies have analyzed how interaction with dynamic geometry objects can serve as preliminary work to propose and build deductive/theoretical proof (Leung and Or, 2007; Olivero and Robutti, 2001; Dello-Iacono, 2021). However, it has also been recognized that the interaction with dynamic representations can produce new forms of genuine reasoning (Moreno-Armella and Brady, 2018) and therefore establish new ideas about what a proof means when working with digital representations. The study reported here investigated how is the interaction between the student and the dynamic representations when making constructions and arguing about their validity?

Considering the importance of the interaction between the student and the dynamic representations, we present the theoretical construct of co-action, extending some ideas of instrumental genesis. We will present an overview of the argumentation that does not express the need for a level of formality.

Theoretical perspective

More and more curricular structures are being inhabited by digital technology through representation systems that react immediately to student actions, allowing, on the one hand, that some activities that can be developed with pencil and paper, are carried out in a more efficient way, and avoid calculation errors —the tool as an amplifier—. However, the executable nature of these representations makes it possible for the student to transform their knowledge and access new ideas —the tool as a conceptual reorganizer—. This is particularly tangible in dynamic geometry environments (Moreno-Armella and Sriraman, 2005).

The action of dragging a vertex of a triangle, for example, generates a response from the digital environment that gradually reveals the structural nature of the construction that has been made. There is a new exploration space for the student since the digital screen is a space that dialogues with the student through digital representations. The performance of the representations translates into the responsiveness of the medium during an exploration and contributes to the development of new ways of thinking. It ends up generating a dialectic that has been studied as instrumental genesis (Rabardel and Beguin, 2005), but in a classroom you learn from, with and through others. There are ways to articulate one's own thinking with the thinking of others, including their experiences with the present digital medium. This cognitive co-action (Hegedus and Moreno-Armella, 2010) is a central feature of instrumental mediation.

Although the possibilities opened by the digital means of numerical computation and visualization have questioned the traditional proof on paper and pencil as the only mathematical validation criterion, located in the field of mathematics education and seeing the construction of meaning as a central objective of learning, we consider that there are, apart from the traditional one, other ways to build the justification of a proposition (let's say geometric), in the classroom. The exploration of a geometric situation (our interest here) finds a theoretically controlled response from the side of the digital mediator—for example, GeoGebra. By advancing an exploration, the student finds on the screen a response to her actions through the plasticity of the representations. In this way, the mathematical understanding of it finds and discards routes of approximation to a plausible answer to a problem or to a demand for justification. Therefore, mathematical arguments can be approached from a general perspective as a line of reasoning that aims to show and/or convince that a result (a general statement about an object, a solution to a problem, a calculation) is correct (Sriraman and Umland, 2020; Hanna, 2020). Our work responds to the lines described before.

Methodology

We place our research within a qualitative approach, which is focused on understanding, deepening, and describing phenomena through the perspective of the participants (Hernández et al., 2010). In this case we seek to understand the interaction with the dynamic representations when the student proposes arguments. We follow the line of exploratory and descriptive research (Steffe and Thompson, 2000) as we seek to familiarize ourselves with the ways and means of operating of the participants.

The participants were 6 mathematics teachers who were taking a geometry course as part of a master's program. For this report, we describe the case of Ana who said she wasn't familiar with the contents of geometry (because she has never taught it and only took one course during her undergraduate degree) and who showed great skills in using GeoGebra.

The questionnaire proposed to the participants consisted of six constructions that they had to make and argue why their solution was valid. Subsequently, a semi-structured interview was conducted with each participant to deepen their arguments/reasoning and their interaction with the digital medium.

For the analysis of the data, the fragments of the interview were extracted in which a process was evidenced where the students carried out actions on the digital medium, they interpreted the response of the medium (the information on the screen) and this information led them to carry out new actions. In general, we analyze how this process contributed to the students being able to argue about the validity of the construction.

Results

In this section we analyze the interactions of students with the digital environment, particularly the nature of the arguments that are produced thanks to said interaction.

GeoGebra as an amplifier

The environment is, initially, an amplifier that allows students to make explicit their ideas about circles, ellipses, perpendicular bisectors, and other geometric objects. At that time her ideas have not yet been affected by the new system of representation. We illustrate this idea with the work of Ana, who solves the following problem: given an angle and a line transversal to the sides of the angle, find a point on the transversal equidistant from the sides of the angle. In her written solution proposal, Ana states that the point sought is at the intersection of the bisector and the transversal, so during the interview she performs the construction, which leads to the following dialogue:

[1]E: What did you draw there?
[2]A: A bisector.
[3]E: Why the bisector?
[4]A: Because the bisector will give me all the points that are equidistant from (...) both sides.

Ana's construction is guided by her theoretical knowledge, so the digital medium (GeoGebra) is used as a tool that allows her to construct the bisector of the given angle almost identically to how she would do it with pencil and paper.

Regarding the argument, Ana concludes that the point of intersection between the bisector and the transversal is equidistant from the sides of the angle because there is a general rule linked to the bisector that allows her to affirm said equidistance (line 4, previous dialogue).

GeoGebra as a conceptual reorganizer

The digital environment has become a conceptual reorganizer when the student's reasoning is transformed by the presence of the digital mediator, so that the student reconfigures her arguments including the mediator's response. This is illustrated when Ana must prove that the points of the bisector are equidistant from the sides of an angle, a fact that is usually proved by determining two congruent triangles, however, Ana uses another strategy (see Figure 1) and says:

[5]A: Why equidistant? Because, well (...) I can draw this circumference with center here (points to H) that is tangent to this side and to this (points to the two sides of the angle).
[6]E: Ok. And does being able to draw a circle allow me to check the equidistance?
[7]A: Ujum (constantly drag point B around the screen).
[8]E: Why? what characteristic does it give? why not an ellipse, or a square?
[9]A: Ah. Well, because the distance from the center to any point is the same, from here as from here (indicates two points on the circumference).

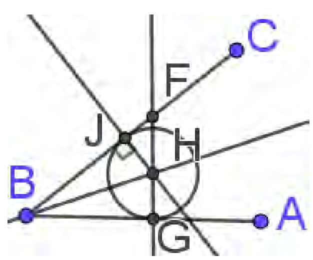

Figure 1: Construction of Ana to prove a bisector property

To prove that the points of the bisector are equidistant from the sides of the angle, Ana, guided by her knowledge of the properties of circles (line 9), constructs a circle with center at H that is tangent to one of the sides of the angle (BC), anticipating that the circumference will be tangent to the other side. The response given by the representation, thanks to the accuracy of the lines and the geometry embedded in that environment, allows Ana to configure her argument based on what she sees on the screen. In this same sense, Ana uses the drag function to illustrate the generality of the fact when she drags one of the points of the construction and the response given by the environment is that the circumference remains tangent to both sides of the angle.

Regarding Ana's argument, she concludes that the points of the angle bisector are equidistant from the sides of the angle because she can draw a circle that is tangent to both sides of the angle (line 5). In this case, the guarantee of the argument is a rule that she establishes as general thanks to her knowledge of the properties of the circle and the co-action with the dynamic representation. The presence of the dynamic environment in Ana's argument is evidenced in two moments: first with the accuracy of the lines, since if she were working on paper the tangency might not occur or it would be her will that would make the circumference tangent. The second moment occurs when she drags a point of the construction (in this case the vertex of the angle), since it is an action that is allowed by the digital environment and differentiates it from working with paper and pencil.

GeoGebra as a guide

The digital environment is "expert in geometry" so that it can impact the student's reasoning through a process where hypotheses or conjectures are raised. This can occur from the persistent observation of a fact that modifies the geometric ideas of the student. This would occur when evaluating the response of the digital medium. We observe this dialectical process when Ana is proposed to construct the bisector of an angle without using the tool that is pre-built in the digital environment – GeoGebra in this case – and then she proves that it is indeed the bisector.

[10]A: Let me try it.
[11]E: What are you going to try?
[12]A: If (...) if tracing any of these (...) if any of these (points to HJ and HG in Figure 1) it gives me this point here (points to H), and that point, well, it will be part of the bisector.

Ana constructs an angle NML and a point O on MN, then constructs a line perpendicular to MN through O and tries to construct a line perpendicular to ML, but just moves the pointer over segment ML (see Figure 2) and realizes that the point cannot be arbitrarily located when it says:

[13]A: Can't be anyone.

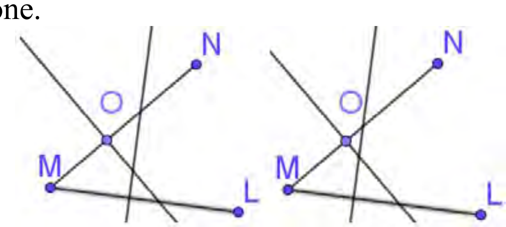

Figure 2: Ana dragging to build the desired perpendicular line

In this case, Ana's construction is guided by her intuition and the response from the digital environment can be interpreted as the possible locations of the perpendicular line to ML and the possible points of intersection of the two perpendicular lines. The response of the environment is interpreted by the previous ideas that Ana had thanks to her interaction with her previous representation (line 12), which allow her to affirm that the point on ML must have some characteristic that she does not know (line 13).

Continuing her exploration, Ana begins to use GeoGebra as an environment to guide her reasoning, as she constructs a point P on segment LM and the line perpendicular to that segment through P, then determines point Q as the intersection of the two lines perpendiculars and constructs the circle with center at Q and radius QO. She finally moves P until it seems that the circle with center at Q is tangent to ML through P.

The construction of the circumference by Ana shows the presence of a geometric fact that has been acquired thanks to the interaction with the digital environment, in which a line bisects an angle if and only if when a circle is constructed with center on the bisector and tangent to one side of the angle becomes tangent to the other side (line 5). This idea has been incorporated into Ana's construction of the bisector object, and now it is part of her conceptual tools that allow her to state whether a point is a bisector point or not.

Continuing with the interaction with the digital environment, Ana conjectures about the location of P (for example, that it is the midpoint of ML) and performs the respective constructions, but thanks to the responses of the digital environment through the drag, she understands that her hypotheses are not correct. She moves the point P on the segment ML and observes that the point of intersection between the circumference and the perpendicular line to ML moves when P moves, therefore, she names R as point of intersection and decides to use the "Trace" tool. The latter shows her the locus of R when P moves (see Figure 3). Seeing the result, Ana affirms that she would need to determine P and decides to change her strategy.

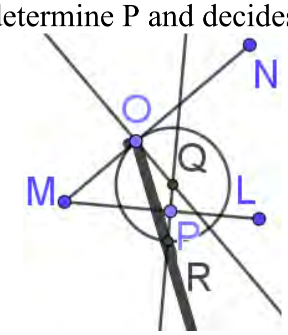

Figure 3: Using the "Trace" tool

Here we underline two types of interaction with the digital environment. In the first, Ana searches within her geometric knowledge for ideas that allow her to hypothesize about the location of P. In this case, the response of the digital environment is the location of the point requested by Ana, as the midpoint of ML, and this is contrasted with Ana's previous ideas. In the second interaction, she does not start from geometric ideas, but from the behavior of the digital representation of objects, so that the answer that is observed on the screen is the behavior of point R. So, Ana tries to associate this response with her prior knowledge and, unable to do so, decides to use another strategy.

Ana decides to re-explore the initial configuration (the one shown in Figure 1) and after moving points A, B and C, she decides to build a circle with center M and radius MO.

[14]: And why did you come up with that circumference?

[15]: (drag point P until the circle centered at Q is tangent to both sides of the angle) Ah, yes, it is!

Seeing that her new hypothesis turns out to be correct, Ana decides to eliminate the point P that she had constructed and now constructs it as the point of intersection of the circle with center in M with the segment ML. But this time she does not construct Q as the point of intersection of the two perpendiculars, but rather she determines it with the midpoint of OP and constructs the line MQ as a bisector. To prove that the line is the bisector, she constructs the circle with center at Q and radius QO, but since Q is not the point of intersection of the two perpendicular lines, then the circle does not turn out to be tangent to the sides of the angle (see Figure 4). Ana moves the points of her construction and doubts that the constructed line is the bisector, so she decides to use the "bisector" tool that constructs it from three points and notices that the bisector line coincides with MQ, so she reevaluates the construction of the circle with center at Q. Finally, Ana constructs the circle with center at the intersection of the two perpendiculars and thus checks that the constructed line is the bisector of the angle LMN.

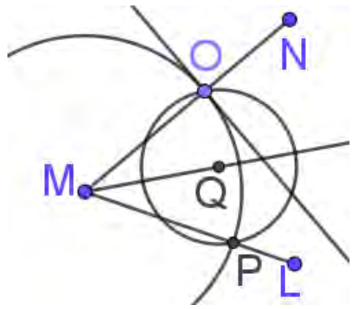

Figure 4: Construction of a circle that is not tangent to both sides of the angle

In general, the construction of Ana is guided by the observations about the executable representation and the constant dialogue with the digital environment. This environment is used as a resource that allows you to explore starting from hypotheses (such as the idea illustrated in Figure 2) or searching for hypotheses thanks to the interaction with the dynamic representation—strategy presented in Figure 3 and when exploring Figure 1 again one—.

On Ana's argument, she concludes that the constructed line is the bisector of the angle because she can construct a circumference that is tangent to the two sides of the angle and remains tangent during the drag. In this case, the argument guarantee is a digital validation rule that she has built into her knowledge (line 5). We affirm that this is a digital validation rule because when the environment responds with a circumference that is not tangent (Figure 4), she thinks that the constructed line is not a bisector, because an idea about this object that is part of her previous knowledge is that a line is a bisector if and only if the tangent circle can be drawn.

An interesting fact about Ana's process is that when she draws the bisecting line and the environment responds by matching said line with the already constructed line, namely MQ (Figure 4), she does not use said coincidence to argue that the constructed line is the bisector of the angle. Only when she constructs the tangent circle does she consider that she has proven that her construction is correct. Validation rules are linked to the continuous process of concept formation and acquisition.

Final words

This work has allowed us to observe different interactions when the mediation of dynamic representations is used during geometric construction tasks and how this mediation affects the validation processes. We report three uses of the digital environment: i) as a constructive partner where the response of the environment is not part of the plot, ii) as a test environment where the interaction with the environment plays an important role in the plot, and iii) The digital environment as a guide that allows contrasting and finding solution strategies. As in the previous case, interaction with the environment is crucial in the argument.

The different interactions that we analyzed allowed us to observe hybrid forms of interaction, that is, the presence of geometric ideas previously developed in pencil and paper that manifest themselves during advanced reasoning in the context of dynamic geometry. Ana's reasoning is aided by the resources offered by the digital medium to establish that the circumference will always be tangent to the other side of the angle. Indeed, Ana reasons about a representation that gives her different information from what she had in a static medium. But could it be said that Ana's proof is deductive? This questioning leads us to ask ourselves a question that is even broader: what characterizes a deductive proof in the digital medium?

We offer here a starting point towards the characterization of a digital evidence.

THE ADAPTED IGS FRAMEWORK: DESIGNING DESMOS TASKS

Kayla Chandler
East Carolina University
chandlerk@ecu.edu

Charity Cayton
East Carolina University
caytonc@ecu.edu

Research has identified specific frameworks that focus on the design and evaluation of mathematics technology tools and tasks (McCulloch et al., 2021a). One of those identified, the IGS Framework (Sherman & Cayton, 2015), has proven to be a useful tool to assist teachers in designing technology tasks that use the affordances of a specific math tool as a reorganizer (Pea, 1985) to support students' high-level thinking (Sherman et al., 2017; Cayton & Chandler, Under Review). This study adapted the IGS Framework to examine in-service teachers' design of Desmos tasks in an asynchronous, paid professional development. Findings indicate when teachers designed a task that used Desmos as a reorganizer along an explicitly stated goal for student thinking, the result was a task of high potential cognitive demand.

Keywords: Technology, Professional Development, Instructional Activities and Practices

Setting mathematical goals and selecting tasks that promote reasoning and sense making serve a central role in guiding instruction (National Council of Teachers of Mathematics, 2014). When adding the use of technology to the scenario, a teacher must consider the mathematical goals and how to leverage the affordances of the technology tool to support student thinking (Association of Mathematics Teacher Educators, 2017; Conference Board of the Mathematical Sciences, 2012).

When considering tasks that use technology, research is limited regarding the cognitive demand of tasks teachers use or to what features of a tool a teacher attends when considering a task (Sherman et al., 2017; Bray & Tangney, 2017; Sherman, 2014). Rather, most studies about technology use in mathematics classrooms focus on the type of technology used (e.g., Goos & Bennison, 2006; Pierce & Ball, 2010), barriers to incorporating technology (e.g., Ertmer et al., 1999; Washira & Kenngwe, 2011), positioning of the technology (e.g., Goos et al., 2003) and the reasons teachers decided whether or not to use technology (e.g., Goos, 2005; Zbiek & Hollebrands, 2008). Additionally, in a nationwide survey regarding the frameworks mathematics teacher educators use in their work of preparing secondary mathematics teachers to teach with technology, only five of 17 identified frameworks address the design and evaluation of technology tools and tasks (McCulloch et al., 2021a). Altogether, these findings indicate there are few tools available to teachers to support them in evaluating, revising, and designing cognitively demanding tasks that use technology to support students' mathematical learning.

Framework

The IGS Framework (Sherman & Cayton, 2015) identifies goals for students' mathematical thinking based on Sinclair's (2003) design principles along each row (i.e., dimension) and each column contains descriptions to help the teacher distinguish whether technology is used as an amplifier or as a reorganizer (Pea, 1985) with respect to a particular goal. While these goals are described separately within the IGS Framework, it is important to note that they are not mutually exclusive. It is also important to note that, while potentially related, these are different from a teacher's mathematical goals for a task. Research based on the IGS Framework found it to be a productive tool for both pre-service (Sherman et al., 2017) and in-service teachers (Cayton &

Chandler, under review) in creating technology tasks that are of high cognitive demand, as well as a reorganizer in relation to student thinking.

The Adapted IGS Framework (Figure 1) was created by adapting the IGS Framework to move away from language specific to dynamic geometry software (e.g., sketch) to be more inclusive of math action technologies more broadly (e.g., task). Additionally, emphasis was added to words like static and dynamic to further draw attention to how the technology is being used. The purpose of this qualitative study was to consider the ways in which in-service mathematics teachers utilized the Adapted IGS Framework to design tasks that use Desmos.

		Technology Used As	
		Amplifier Students could achieve the same goal without the technology.	**Reorganizer** The mathematical goal of the task would be difficult to achieve without the technology.
Goals	**Questions to Ask Yourself**	**Use of Design Principles**	
Make mathematically meaningful observations; look for invariant relationships	Do the task and prompts use the *dynamic* aspects of the technology in a way that would be difficult or impossible to replicate without its use?	Students create multiple *static* examples, either by construction or dragging, and reason from those static examples. For example, students are prompted to make observations or generalizations based on a table or static measurements without reference to the technology.	The task allows for continuous dragging, and students are guided to examine measurements or relationships *dynamically*. Students are required to make or explain observations or generalizations based on their dynamic use of the technology.
Mathematical exploration; use appropriate tools strategically	How does technology support mathematical exploration?	The task and prompts guide students to investigate the same example or a set of examples to explore mathematical connections or invariances. Freedom with respect to technology use does not provide alternative paths if students are all investigating the same example(s).	The task and prompts allow students to explore their individual observations of mathematical concepts, connections, or invariances based on their *dynamic* use of the technology. The task supports students' mathematical exploration by providing alternative paths.
Make and test conjectures; modify thinking; foster curiosity	Does the technology provide feedback? Do the prompts encourage or require students to use feedback?	The task is limited by restrictive construction or does not provide feedback to allow students to explore their conjectures. Prompts do not explicitly guide students to test conjectures.	The technology provides feedback or allows students to test and refine conjectures. Prompts explicitly guide students to use the technology to test conjectures.

Figure 1: The Adapted X Framework

Methods

This study included 13 in-service teachers in an online, paid professional development (PD), representing a range of teaching experience, from one to over 30 years. Most teachers had between 11-20 years of experience, with a group average of 15.6 years. Self-reported comfortability with Desmos included three teachers with minimal experience, eight that used Desmos once or twice a week, and two reported using Desmos almost daily. The four-week, asynchronous PD focused on utilizing Desmos for teaching and learning mathematics and consisted of seven self-paced modules. The first four modules provided an overview of tools within Desmos, while the remaining three modules focused on pedagogical considerations when using Desmos. During the last two modules, participants were 1) introduced to the Adapted IGS Framework, 2) analyzed Desmos tasks using the Adapted IGS Framework, and 3) revised a task so that technology would be used as a reorganizer for one of the goals for students' thinking. In the culminating activity participants selected one goal for students' thinking (i.e., target dimension) to design a task that used Desmos as a reorganizer with respect to that goal. Written rationales articulating design choices related to their target dimension were also required.

Data Sources and Analysis

The data sources for this study consisted of the teachers' designed tasks and their written rationales. The unit of analysis was the identified goal for student thinking. Data was collected, blinded, and analyzed following the completion of the PD. Tasks were independently coded as using technology as an amplifier or a reorganizer along all three dimensions of the Adapted IGS Framework. Interrater reliability for coding tasks along each goal for student thinking was 87%. Discrepancies were resolved through synchronous re-analysis and discussion. This analysis was done without knowledge of the participants' identified goal for their task design.

Analysis of cognitive demand was also independently coded using the Potential of the Task Rubric within the Instructional Quality Assessment Toolkit for Mathematics (Matsumura et al., 2008; Boston, 2012). Interrater reliability for level of cognitive demand was 100%. For the third level of coding, written rationales were examined to discern the identified goal for student thinking and to determine if participants successfully attained their target goal.

Findings

As noted above, each of the 13 tasks were coded as amplifier or reorganizer along each dimension of the Adapted IGS Framework prior to considering participants' identified goal for student thinking (e.g., row/dimension of the framework). Recall, these identified goals were for students' thinking, not the mathematical goals. However, interpreting this analysis proved to be more difficult than previous iterations due to variation in how well participants clearly identified their goal for student thinking. Of the 13 participants, only six clearly identified a single goal for student thinking, as directed in the assignment. Five did not explicitly identify their goal for student thinking, and two participants stated they were trying to design a task to be a reorganizer along all three dimensions of the Adapted IGS Framework. Since five participants did not identify their goal for student thinking, we could not ascertain if they met their design intentions.

Thus, we decided the unit of analysis should be each goal that was explicitly identified by a teacher. Table 1 shows a summary of these results with respect to each chosen target dimension. There were seven instances where participants successfully designed a task that was a reorganizer for their specified goal (58%, met). Results for the potential level of cognitive demand analysis revealed that for every task that used technology as a reorganizer, the result was a task of high potential cognitive demand.

Table 1: Summary of Results

Target Dimension	Teacher Identifier	Met Goal	Cognitive Demand
Row 1	T5, T9, T12	Yes	High
	T3	No	Low
Row 2	T12	Yes	High
	T9	No	High
	T4, T10	No	Low
Row 3	T6, T9, T12	Yes	High
	T1	No	High
Did not explicitly identify	T8, T13	-	High
	T2, T7, T11	-	Low

Discussion

We echo the sentiments many have expressed lately with challenges related to conducting research during Covid (e.g., Kalinec-Craig, 2021). This study was not without its challenges. Interpretation of the results proved more difficult than anticipated because teachers did not complete the task design assignment as instructed. The assignment asked teachers to identify one goal for students' thinking from the Adapted IGS Framework; however, some teachers identified more than one goal for students' thinking from the framework and others neglected to explicitly state any goal for students' thinking. Due to the asynchronous nature of the PD, we were unable to ascertain why this was the case.

Despite the challenges presented in this asynchronous PD, one promising result was if a teacher designed a task that was a reorganizer along the identified goal for student thinking, then the task was also of high cognitive demand. This is a result that has been consistent across three iterations of this work, including a variety of contexts (e.g., in-service/pre-service teachers, face-to-face courses/hybrid courses, undergraduate/graduate) and two different technologies (e.g., dynamic geometry software and Desmos) (Cayton & Chandler, under review (n=14); Sherman et al., 2017 (n = 15); as well as this study (n = 7)). In other words, when teachers use the IGS Framework or the Adapted IGS Framework to design a task that leverages the affordances of the math action tool as a reorganizer, the consistent result has been a high cognitive demand task.

When teachers implement high cognitive demand tasks, learners are provided more equitable learning opportunities to engage in high level thinking (Aguirre et al., 2013). Thus, we propose that the Adapted IGS Framework offers the potential to support teachers in creating tasks that improve learning conditions for all learners. Yet, there is still more work needed. As noted in McCulloch et al. (2021a), the frameworks we are using in our preparation of teachers do not address the issue of equity. As such, we are considering how we might incorporate the recommendations from McCulloch et al. (2021b) to position all learners as explorers of mathematics when using technology into revisions of the Adapted IGS Framework. Our hope is that by updating the framework, we can help support teachers in understanding practical ways they can make use of math action technologies to engage students in deeper mathematical learning.

STUDENTS' IMPRESSIONS OF EQUATION-SOLVING WORKED EXAMPLES IN AN ONLINE ENVIRONMENT

Avery H. Closser	Hannah Smith	Jenny Yun-Chen Chan
Worcester Polytechnic Institute	Worcester Polytechnic Institute	Worcester Polytechnic Institute
ahclosser@wpi.edu	hcsmith2@wpi.edu	jchan2@wpi.edu

Worked examples are an effective form of instructional support. As online tools are increasingly used for instruction, designers should optimize how worked examples are presented to support students. We present a small exploratory study on 92 algebra students who rated and evaluated formats of worked examples on equation-solving as part of a larger experiment. We found that students' ratings of the worked examples aligned with their posttest scores. Further, across conditions, explanations of students' ratings revealed themes of worked example speed, equation-solving process, and content review. These findings provide considerations for researchers and teachers creating worked examples for online algebra learning environments.

Keywords: Algebra and Algebraic Thinking, Online and Distance Education, Metacognition, Technology.

Worked examples effectively help students learn math procedures by displaying the step-by-step problem-solving process (e.g., Booth et al., 2015; Carroll, 1994; Foster et al., 2018). However, worked examples are typically presented as static images with limited research on the impacts of alternative formats of worked examples. As online tools become more prevalent in classrooms, worked examples should be intentionally designed to optimize learning in online environments. Further, since prior work has shown a positive association between students' actual and perceived learning gains from online instructional materials (Whitehill et al., 2019), students' perceptions of worked examples should inform their design. Here, we explore students' perceptions of worked examples presented in *static*, *sequential*, or *dynamic* formats.

We consider two competing theoretical perspectives. First, perceptual scaffolding (e.g., visual cues that direct students' attention to important information in instructional materials) can support students' cognitive processes and increase learning (Harrison et al., 2020; Gibson, 1969; Kirshner, 1989). Online tools present opportunities to design worked examples which use dynamic transformations and display the connections between steps. These worked examples may help guide students' attention to make connections about the problem-solving process. Second, worked examples that minimize extraneous complexity can decrease students' cognitive load and improve learning (Schwartz et al., 2016; Sweller et al., 2019). By this logic, students may find that worked examples with dynamic transformations take more effort to study: these examples might increase students' cognitive load rather than decrease it.

We have found comparable learning gains among students who viewed different worked example formats (Smith et al., 2022). Here, we report an exploratory analysis of how those students perceived the worked examples and why they found them to be helpful or unhelpful. We explore: 1) *Are students' posttest scores correlated with their rating of the worked examples?* 2) *Which themes emerge in students' explanations for their ratings?* 3) *How do the themes vary across students who viewed worked examples with different degrees of dynamic presentation?*

Methods

A total of 230 grade-school algebra students from North and Central America completed a larger online experiment investigating how the format of worked examples impacted learning gains in an online tutoring system (Smith et al., 2022). Of those students, 92 rated the helpfulness of the worked examples and provided a rationale, thus were included in the analyses.

We recruited teachers who already used the tutoring system with their classes. At their discretion, teachers assigned this one-hour study to students as an online problem set during class or as homework. Students worked at their own pace to complete the assignment. First, they completed an eight-item pretest on algebraic equation solving (e.g., solve for x in $8(2x + 9) = 56$; reliability: KR-20 = 0.86). Next, they were randomly assigned to one of six experimental conditions varying in the worked example presentation. Within each condition, students completed six problem pairs consisting of one worked example and one practice problem. Next, students completed the posttest (reliability: KR-20 = .89) matching the structure of the pretest. Half of the pretest and posttest problems directly mirrored the equation structure in the worked examples whereas the other half used similar but different equation structures. Last, students were asked how much they agree with the statement: "*The worked examples were helpful for learning how to solve equations*". Students rated the statement (1 = Strongly Disagree; 6 = Strongly Agree) and were prompted to explain their rating.

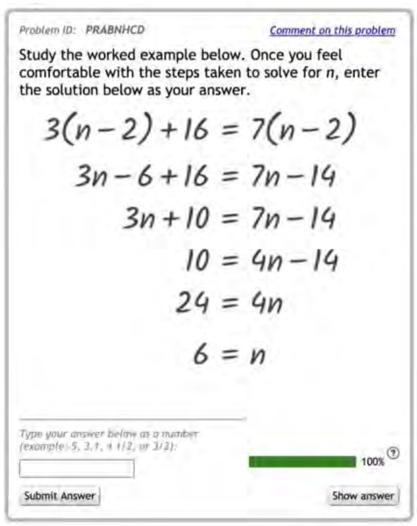

Figure 1: A Static Worked Example

The six worked example conditions of the larger study varied in their *extensiveness* (i.e., displaying major problem steps or every transformation) and degree of *dynamic* presentation (i.e., static, sequential, or dynamic). Here, we focus on how students perceive worked examples displayed with different degrees of dynamic presentation as supported by online tools so we do not further describe or discuss the variations in the extensiveness of worked examples. First, students in the *static* conditions viewed images of worked examples as they might be displayed in a textbook (Figure 1). Second, students in the *sequential* conditions viewed worked examples as looping GIF videos that presented the worked examples line-by-line in approximately 3-second intervals, creating a history of the derivation over time. Third, students in the *dynamic* conditions viewed looping videos that demonstrated the transformation process through a screen recording. For example, to simplify $2(x - 3) = 8$, students would watch as the 2 is dragged over the parentheses to create the transformed expression, $2x - 6 = 8$ (Figure 2).

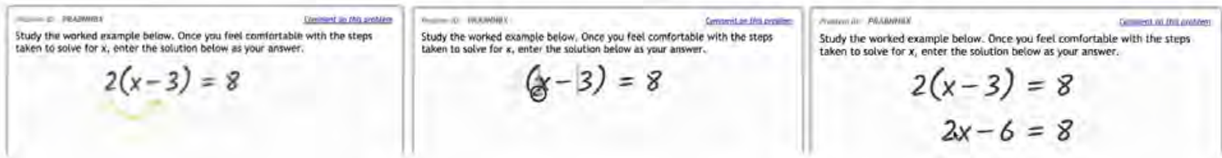

Figure 2: Dynamic Presentation of Worked Examples with Fluid Transformations

Results

We first conducted a partial correlation between students' perceived helpfulness and their posttest performance while controlling for pretest performance (M = .38, SD = .37). Students who scored higher on the posttest also rated the worked examples as more helpful, $r(90)$ =.24, p = .02. A scatter plot also illustrated a positive, albeit weak, association between students' posttest performance and perceived helpfulness of the worked examples (Figure 3).

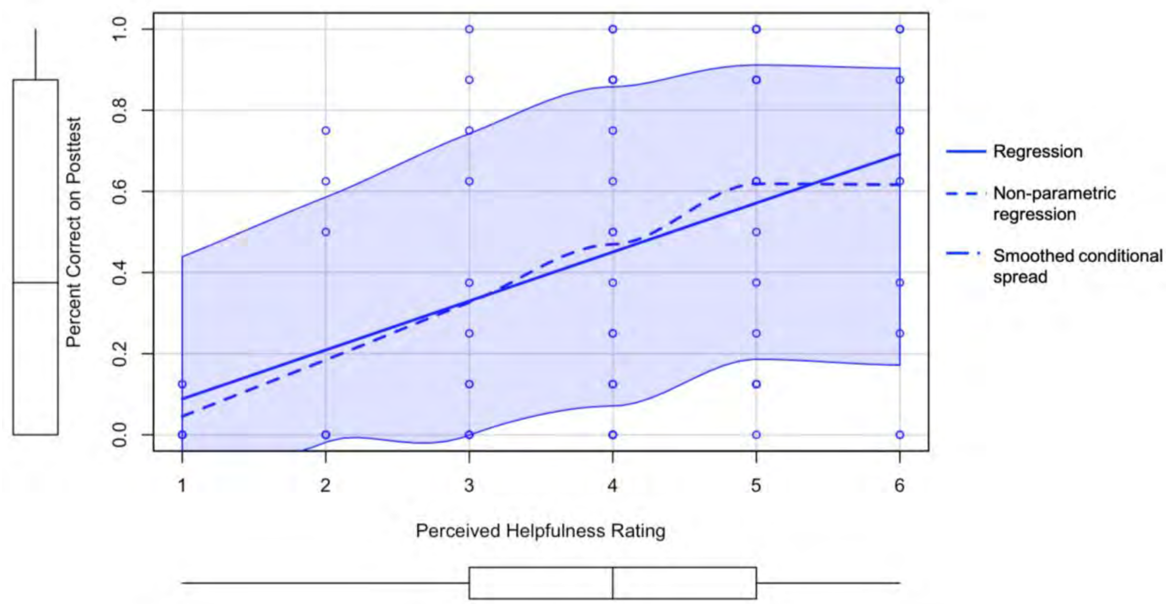

Figure 3: Scatter Plot of Students' Perceived Helpfulness Rating and Posttest Performance

Next, we identified themes in students' explanations indicating why they found the worked examples to be helpful or not. Three themes emerged: the *speed* of the worked examples, the *process* within the worked examples, and the worked examples as *review* material. After identifying and defining these themes, two researchers individually coded responses that included one of these themes and compared how these themes emerged across students who viewed static (n=29), sequential (n=38), or dynamic (n=25) worked examples.

First, four students (three in dynamic conditions; one in sequential) commented on the *speed* of the worked examples, expressing that the worked examples were displayed too quickly. One student in a dynamic condition noted that the worked examples "*were helpful but they went too fast*" and another student expressed that having a pause button (rather than the looping video) might change the way they study the example.

Second, nine students noted that the worked examples demonstrated the *process* for equation solving. For example, one student in a dynamic condition wrote, "*The examples were helpful because it showed the full procedures on how they got the answer*". Of the nine students, five were in dynamic, two in sequential, and two in static conditions. A Chi-square test comparing the number of students noting vs. not noting that the process revealed no significant difference across the three types of conditions, $\chi^2(2, 92)=4.11$, $p=0.13$.

Third, ten students noted that the worked examples or the assignment as a whole served as a *review*. For example, one student in the dynamic condition expressed, "*Doing all these refreshed my mind on how to do equations with variables. It was very helpful and I believe it helped improve my skill*". Three of those students were in dynamic, four in sequential, and three in static conditions. A Chi-square test comparing the number of students noting vs. not noting about review revealed no significant difference across the condition types, $\chi^2(2, 92)=0.05$, $p=0.98$.

Discussion

The results align with existing research and provide considerations for designing online algebra worked examples. First, these results support prior work on students' ability to gauge their learning (Whitehill et al., 2019) by showing that their perceived helpfulness of worked examples was positively associated with their posttest scores. Second, these results reveal features that students notice when studying worked examples: the speed of the worked example, the equation-solving process, and connecting examples with course content. Third, these themes did not emerge more often in one condition than another, potentially suggesting that students may attend to these elements when evaluating any worked examples.

Multiple students in the sequential and dynamic conditions commented that the *speed* of the worked example videos was too fast, indicating that the worked examples in the GIF video format may have increased the cognitive demand on students rather than serving as a helpful tool. Next, students across conditions noted that the worked examples demonstrated the problem-solving *process*, suggesting that all three formats may have provided visual cues that help with connection-making as a form of perceptual scaffolding. Finally, multiple students commented on the content as a *review*; studying the worked examples in a brief experimental context may have cued their prior knowledge to improve equation solving (Sidney, 2020).

Importantly, our sample size limited the analyses conducted and conclusions we were able to draw. Further, not every response included one of the themes identified; many students simply wrote, "*I don't know*" or "*it was good*". This narrowed our sample for comparisons across conditions. For example, since only four students across two of the conditions noted the speed of the worked examples, we did not conduct a Chi-square test for statistical comparisons. However, the students' comments provide suggestions for future iterations of sequential and dynamic worked examples. When designing these worked examples, it would be worthwhile to consider a slower video speed. Alternatively, since research has shown that undergraduate students can effectively self-regulate their use of worked examples for learning (Foster & Dunlosky, 2018), it may be worthwhile to explore how algebra students learn from worked examples with features that provide more autonomy (e.g., speed setting or pause).

Looking ahead, it would be worthwhile to conduct a larger study using refined iterations of these worked example formats and more targeted questions for students. For instance, asking, "What would you change about this worked example and why?" and "Which worked example format do you prefer and why?" may provide further insights about which features of worked examples students notice. Future studies should also consider long-term impacts from worked example practice with alternative presentations. Ultimately, we aim to offer suggestions that guide algebra teachers in designing online worked examples to support student learning.

THE TEACHER'S ROLE IN SUSTAINING COGNITIVE DEMAND WITH DESMOS

Victoria Delaney
Stanford University
vdoch@stanford.edu

Teachers play a crucial role in influencing students' cognitive demand during mathematics tasks. This study investigates the interaction between teachers and cognitive demand when digital technologies are integrated during students' enactment of such tasks. The research includes a video analysis of two eighth grade teachers' task launches and enactments of six student small groups using Desmos to solve a high-demand task. The findings indicate that the teachers' launches had less overall impact on students' cognitive demand and Desmos use than their ensuing small-group interactions, including how they related Desmos to the task's goals.

Keywords: Curriculum, Middle School Education, Technology, Teacher Knowledge

As digital technologies become more commonplace in classrooms, there is increasing demand for teachers to instruct students with such technologies to better prepare for career and college readiness (National Governors Association, 2010). Yet despite general agreement toward incorporating these tools, there are few standardized practices that instruct teachers on how and when to use digital technologies for learning (Greenhow, Robelli, & Hughes, 2009). As a result, the ways in which teachers frame the role of such technologies to students in a math task's launch and following enactment of the task may differ, impacting how students view digital technologies in relation to solving rigorous problems. Taking two middle school math teachers' classrooms as contrasting case studies, I ask: how do teachers' framing of digital technology during a high-demand mathematics task impact the cognitive demand of the task (a) during the task launch and (b) during students' enactment of the task?

Theoretical Framework

This study examines the changes in cognitive demand throughout a rigorous mathematics task and the interactions between teachers, students, and digital technology during its enactment. To situate this work, I use Stein and colleagues' definition of a *mathematical task* as the arrangement of mathematics within the task, combined with the resources provided to solve it. *Cognitive demand,* the primary variable of interest, refers to the cognitive processes required of students to navigate a task, identify key information, and activate prior knowledge that is useful for constructing solutions (Doyle, 1983). The current study focuses on a *high cognitive demand* task (Stein & Smith 1998), which requires students to make conceptual connections, use multiple representations and consider multiple solution strategies. Because cognitive demand is adapted and negotiated by teachers and students throughout enactment (Remillard, 2005), a key goal of this research is to examine its changes when digital technologies are present and when teachers play a central role in encouraging students' uses of such technologies.

This study takes an in-depth examination of students' uses of Desmos, a *dynamic representational technology* (Vahey et al., 2020), which can automate graphing, give instantaneous feedback, and display multiple modes of representation. Such technologies may potentially alter the cognitive demand of the task and influence how students learn mathematics (Sherman, 2014). However, technology's potential to mediate task outcomes may be contingent on how teachers frame them to students and how students take up such tools. Because teachers' framing of digital technologies in relation to the task's outcomes varies, there is currently mixed evidence of digital technology's efficacy in relation to students' learning. Some studies point toward positive learning outcomes when students express aptitude for using technology to solve problems (e.g., Hollebrands, 2003; Gökçe, & Güner, 2022) although there is not yet clear consensus on how the role of the teacher impacts student outcomes.

Methods

Broader Context

This study is one component of a larger research-practice partnership conducted between a West Coast research university and Urban Unified School District (UUSD), where many students are from non-dominant cultural and linguistic communities (UUSD, 2020). UUSD strives to provide a high-quality mathematics education for its students, and as such, developed a task-based curriculum that aligns with the Common Core State Standards (Borko et al., 2017). As part of its long-term vision for implementing the curriculum, UUSD identified and recruited Teacher Leaders (TLs) in 6th-8th grades to participate in professional development workshops six times per year. The goal of each workshop was for TLs to deeply understand the curriculum and facilitate professional development around it to their own mathematics departments.

Task Selection

The Washing Machine Problem is a high demand, *Doing Mathematics* (Boston & Wolf, 2006) task taken from UUSD's 8th grade curriculum (see Figure 1). It requires students to analyze various costs mathematically in order to give advice to "Elena" toward purchasing a washer and dryer or continuing to visit her local laundromat. The task's design purposefully omits critical information, such as how often Elena does laundry, so that students can grapple with the task's inherent ambiguity and practice voicing their assumptions explicitly. As such, the task does not have a single "correct" solution. Rather, the challenge of solving the task comes from how students draw upon multiple representations and solution strategies when solving it.

Figure 1: The Washing Machine Task, as Written in the District Curriculum

"Elena doesn't have a washing machine or dryer. She is considering buying one so that she doesn't have to go to the Laundromat. She wants to know if it makes sense financially to buy a washer and dryer. Each load of laundry at the Laundromat costs $1.25 for the washing machine and $1.50 for the dryer. A top-loading washer costs $250, and each load costs $0.26 for water and energy. A front-loading washer costs $400, and each load costs $0.09 for water and energy. A dryer costs $300, and each load costs $0.35 for energy. **What should Elena do? Give her some advice.**"

Teacher Participants

Two teachers from UUSD were selected based on their integration of Desmos during instruction of *The Washing Machine Problem* in Spring 2017. Annie, the first teacher, was involved in the research-practice partnership as a TL during the time of the study. Tia, the second teacher, was involved in a different professional learning program supported by UUSD. Although the district maintained an initiative to support technology use in the classroom, the extent to which Tia and Annie used Desmos with students prior to the task is unknown.

Data Sources and Analysis

Data for this project were obtained from video recordings from both teachers' classrooms while instructing *The Washing Machine Problem*. Recordings contained both the launch of the task and the enactment by students in small groups. Three recordings were taken from each classroom and were subjected to additional screening for visual and audio quality. Each teacher's launch was additionally captured in a separate recording from start to finish.

The research team rated and coded units of mathematical conversation ("conversation units" e.g., sequences of talk where students discussed mathematical ideas) according to the Instructional Quality of Assessment (IQA) Rubric (Boston & Wolf, 2006). We identified (1) changes in students' cognitive demand throughout the task and (2) instances where Desmos was used and the teacher participated in student interactions. Both researchers rated and coded independently, reaching 87.4% agreement, then met to resolve remaining disagreements.

Findings

Teachers' Launches

Annie announced that students would solve a system of equations and give advice. She presented the task as a series of steps: first, students would create three equations to model the two different washing machines and laundromat options. Then, students would graph their equations in Desmos, where Desmos was mandated as part of the second step of solving. Finally, students would give advice for the best washer-dryer combination. We rated the cognitive demand of Annie's launch as a 2: *Procedures without Connections.* This launch focused on a sequence of procedures for students to follow, which removed ambiguity and reduced opportunities for multiple solution strategies. Although Annie informed students to produce multiple representations, there was little question on how to do so. The focus of the launch seemed more suited toward completion of a sequence of steps than on non-algorithmic thinking.

Tia opened the task by situating it in the experiences of her students: "Who here has ever been to a laundromat?" She gave an overview of the three models, including how to build them. Then, she encouraged multiple solutions and representations of the three models, and presented Desmos as a strategic, optional tool. Tia ended the launch by directing students to construct a poster of their results. We rated the cognitive demand of Tia's launch as a 3: *Procedures with Connections*. Tia's explanation of how to build the linear models slightly lowered the cognitive demand from the task as written. However, unlike Annie, Tia left open and encouraged multiple solutions and representations, which preserved the most challenging aspects of the task.

Student Enactments

Although Annie's launch initially lowered cognitive demand, her three student groups spent substantially more time in high demand activity (see Table 1). Compared to Tia's students, Annie's used Desmos earlier in the task, which allowed them to analyze their models' mathematical features and compare multiple representations for a longer duration. Because they spent more time critically comparing their models, two of Annie's three groups realized that the task did not contain a single correct answer; rather, their perception of the "best" model depended on their interpretations of unknown variables, such as how often Elena did laundry.

Annie's small-group interactions were imperative to students' successes. When she approached each group, Annie routinely asked students to revoice their ideas aloud, then asked probing questions (e.g., "What assumptions are you making?" to focus students' thinking on mathematically relevant information provided by Desmos. By directing students to Desmos, she helped students connect affordances of the technology with the goal of the task. Her interactions routinely raised cognitive demand or maintained it at a level 3 or 4 (see Table 2).

Table 1: Student groups' cognitive demand during enactment, by teacher

	Annie's Students		Tia's Students	
IQA Level	Minutes	Conversation Units	Minutes	Conversation Units
Level 1	0.3	1	5.0	7
Level 2	17.2	**34**	**37.8**	**86**
Level 3	19.7	27	13.5	24
Level 4	**22.4**	17	6.9	10

Table 2: Student groups' shifts in cognitive demand during small-group interactions

	Increase	No change	Decrease		Increase	No change	Decrease
Annie	6	10	0	**Tia**	2	12	5

Tia's students spent a majority of the task in level 2 (see Table 1) despite her initial preservation of the task's rigorous aspects. Compared to Annie's students, Tia's small groups took longer to reach the analytic portion of the task, expressing more confusion on how to create their models. Two of the three groups did not know how to use Desmos, requiring an additional tutorial from Tia before they could use it for graphing. These groups did not finish the task or engage in any interpretive comparisons of the models before enactment ended. The sole group that was familiar with Desmos used it immediately and was responsible for all of the level 4 activity in Table 1, successfully solving the task and recognizing the ambiguity inherent in it.

Tia's interactions with students often maintained low demand or lowered demand, although there were a few instances where she assisted students in becoming unstuck and entering high-demand activity. When she visited small groups, Tia encouraged students to build off of one another's ideas. However, students' ideas were not always high-demand or mathematically correct. Furthermore, Tia desired that all students work together and at the same pace, which encouraged frequent low-demand tutoring conversations where the tutor tended to focus on the reproduction of their own work. Finally, when the focus was not on equitable groupwork, Tia aided students by directly telling them what to do (e.g., "You need to add the costs together to find the slope.") Demand was kept low because Tia often prioritized correctness without connecting it back to the goals of the task or highlighting the affordances of Desmos.

Discussion and Conclusion

The degree of divergence between Tia and Annie's approaches to launching and facilitating *The Washing Machine Problem* had varying impact on their students. Tia's focus on equitable groupwork and procedural precision, as well as her choice to frame Desmos as an optional tool, kept cognitive demand low and discouraged students from using Desmos until it was absolutely necessary. In contrast, Annie foregrounded demanding analytic components of the task, anticipated the necessity of Desmos in allowing students to access those components, and bridged students' Desmos use to the task's goals during small group interactions. This work suggests that, although digital technologies are becoming more commonplace in the classroom, teachers must first establish congruence between the learning goals, the features of the task and technology that are highlighted in the launch, and their interactions with students. Furthermore, they must understand their role in maintaining cognitive demand throughout the launch (Jackson et al., 2013) and task enactment (Stein, Engle, Smith, & Hughes, 2008).

ELEMENTARY STUDENTS' EMERGENT USE OF PARENTHESES WHEN WRITING EXPRESSIONS IN A SANDBOX DIGITAL LEARNING GAME

Christopher Engledowl
New Mexico State University
chriseng@nmsu.edu

Ted Stanford
New Mexico State University
stanford@nmsu.edu

Developing competency with writing numeric expressions that include grouping symbols is an important goal of early algebra (Stephens et al., 2017). In this study, we draw on numeric expressions written by 473 fourth and fifth grade students from 10 schools and 29 teachers as they played a digital learning game in order to examine their use of grouping symbols. We describe use of parentheses as being of three types: Type 1 are trivial, Type 2 indicate the order things should be done in, but are unnecessary, and Type 3 are necessary. Preliminary results show that regardless of whether a student played the game for much longer, the use of Type 2 and Type 3 parentheses increased as students became more experienced players. The sand box style of the game design appears to have played a role in students feeling free to experiment with different types of parentheses. Future research is needed on the sophistication development.

Keywords: Algebra and Algebraic Thinking, Technology, Number Concepts and Operations

The field of *early algebra* (Stephens et al., 2017) has established itself as a promising developmental pathway to support students' later learning of formal algebra (Blanton et al., 2015; Venenciano et al., 2020), which has a long-standing role as a gatekeeper to higher level mathematics and college entrance (Slaught, 1908; Moses & Cobb, 2001; Knuth et al., 2006; Martin et al., 2010). One of the foundational big ideas of early algebra involves learning about expressions (Blanton et al., 2015). Expressions have not only had a longstanding place in the elementary school curriculum (NCTM, 2000; CCSSM, 2010), but also in the MET II and the latest AMTE (2017) standards for preservice teachers.

Despite the fact that the topic of order of operations has been, and continues to be, a point of hot debate amongst the general population—resulting even in popular press articles discussing it, such as the New York Times article about mathematicians' sentiments on the social media firestorm (Chang, 2019)—few studies have documented students' struggles and successes with using grouping symbols (e.g., Papadopoulos & Gunnarsson, 2018). Moreover, most studies have largely focused on how students perform when they are presented with different types of structures of expressions (Gunnarsson et al., 2016). Perhaps this combination of lack of research and widespread misunderstanding is why there have been recent suggestions for using a different model for order of operations (Taff, 2017). In this study, we present preliminary results documenting how 4th and 5th grade students used grouping symbols while beginning to learn how to write numeric expressions in the context of a digital mathematics learning game.

Background and Framing

Blanton et al. (2015) described the following five big ideas of early algebra: a) Equivalence, Expressions, Equations, and Inequalities, b) Generalized Arithmetic, c) Functional Thinking, d) Variable, and e) Proportional Reasoning. In this study, the project key idea we are focusing on is *Write and Interpret Numeric Expressions*, which overlaps with Blanton et al.'s first big idea of early algebra. In the current study, students wrote dozens to hundreds of numeric expressions while playing a digital learning game. When writing the expressions, based on the need, sometimes it was not necessary to write them with any specific reason in mind. However, the longer students played the game, and in order to be more intentional about what they were creating in the game, students had to write expressions with intent. For instance, writing an expression that would evaluate to the value of 4 and also include two different operations and one set of parentheses. Such thinking is in line with the expectations that Blanton et al. had for the third graders in their study, such as having students be able to "identify different ways to write an expression" (p. 48).

Earlier research has distinguished *necessary* from *unnecessary* parentheses, sometimes referred to as *superfluous* (Gunnarsson et al., 2016). We have found it helpful in this study to refine this distinction into three types. Type 1 parentheses are trivial in the sense that they give no instructions about the order of operations. Examples of expressions with Type 1 parentheses are (2) + 3, (2 + 3), and the extra set of parentheses in ((2 + 1)) × 3. Note that Type 1 parentheses are not mathematically incorrect, in that they are not ambiguous and are evaluated correctly under standard procedures and by machine calculators. Moreover, Type 1 parentheses may naturally occur as intermediate steps in simplifying an expression, or in substituting one expression for an equivalent one. Type 2 parentheses are those which do give instructions as to the order that operations should be evaluated in, but the instructions are superfluous, either because of the standard order of operations, or because of the mathematical properties of operations. Examples of expressions with Type 2 parentheses are 4 + (3 × 1) and 2 + (3 + 1). Type 3 parentheses are those which are necessary, in that the expression would evaluate to a different outcome without them. An example with Type 3 parentheses is 2 × (3 +1).

Method

Participants and Setting

This study stems from a larger project involving an early algebra intervention incorporating two games and an interactive tool, as well as associated lesson plans. Some of the information shared in this method section has been similarly described elsewhere (Engledowl, 2020; Engledowl et al., 2021). This study focuses on the expressions that 473 students, from 10 schools and 29 teachers' classrooms, wrote while playing a digital mathematics learning game called *Agrinautica* (available at mathsnacks.org).

Digital Learning Game

The digital mathematics learning game, *Agrinautica*, is a sandbox-style game that was designed to align with the larger project's key idea of *Writing and Interpreting Numeric Expressions*. This key idea also aligns with Blanton et al.'s (2015) big idea of *Equivalence, Expressions, Equations, and Inequalities*. In this game, players first select a world and then set out to populate it with plants, animals, and artifacts. To create them, players write numeric expressions. Depending on the number of operations, the number of sets of parentheses, and the value the expression evaluates to (an integer from 1–9), different species of plants, animals, and artifacts are created and players can place them in their world. For instance, to create a plant called *Vinus duoclus* (see Figure 1), a player must write an expression that evaluates to the value 2, includes two types of operations, and has no parentheses.

Figure 1: Screenshots from *Agrinautica* of field guide (left) and how plants are created

Data Sources and Analysis

From February through May of 2019, game telemetry data was collected from all participants—whether they played at school or at home. This data included every expression they wrote and subsequent plant that was made, every button they clicked on—such as if they viewed the field guide that shows every possible item with a description of what is necessary to include in the expression to create each item—as well as associated date and time stamps. Both the time spent and the number of total actions taken varied widely across the study group, and we are using here the number of total actions taken as a measure of the amount of game play for a given student. We divided the students into two equal-sized groups, according to the number of total actions they took. For each student, we recorded all unique expressions, in the order that they were first created. Some students entered many repeated, identical expressions, but these were not counted for the purpose of this analysis. Expressions such as 1+1 and (1+1) were counted as different, even though the game would consider them the same expression for the purpose of creating a plant. Then, all the expressions within the group were combined, maintaining the order in which they were created, and now with many duplicates possible since different students often made the same expression. This list was divided into quarters in order to create the tables below. This division into quarters keeps all students' first expressions together, and their second, and so on, and since the number of unique expressions created varied widely from one student to another, students who made more unique expressions are represented more heavily in the later quarters than students who made fewer. This is one reason we analyzed the two groups separately, to be sure we were capturing a pattern of increasing sophistication as game play progressed, and not just an overall difference between students. After students were grouped, we totaled the number of expressions that were categorized as Type 1, Type 2, or Type 3.

Findings

Preliminary results can be seen in Tables 1 and 2. Table 1 shows the number of times each type of use of parentheses was used for students who took between 20–399 total game actions. Table 2 shows this same information for students who took between 400 and 3,844 actions. From these two tables, there is evidence that student use of Level 1 parentheses remained relatively constant over time—that is, the total number being used didn't change as students gained experience writing more expressions. *Agrinautica* does not reward students for using these kinds of parentheses, but it also does not penalize their use—they are simply ignored. Thus, it is unclear why they continued to be used. Student use of Level 2 parentheses was found to increase as students wrote more expressions. Similarly, student use of Level 3 parentheses also increased as students wrote more expressions. Both of these are expected results because *Agrinautica* allows their use in creating plants, animals, and artifacts. However, *Agrinautica* does not specify that parentheses must be used in one of these two ways to create any particular plant, and does not prioritize Level 3 over Level 2. And yet, we observed student use of both types of parentheses increasing over time.

Table 1: Number of expressions created with certain types of parentheses for students who completed 20–399 total actions

Time Created	Type 1	Type 2	Type 3
1st Quarter	134	147	68
2nd Quarter	117	163	75
3rd Quarter	114	329	108
4th Quarter	104	519	192
Total	469	1158	443

Table 2: Number of expressions created with certain types of parentheses for students who completed 400–3844 total actions

Time Created	Type 1	Type 2	Type 3
1st Quarter	394	887	395
2nd Quarter	439	2217	1047
3rd Quarter	372	2598	1326
4th Quarter	363	3204	1511
Total	1568	8906	4279

Discussion and Implications

Preliminary results indicate that as students played longer, they tended to engage more in in using Type 2 and Type 3 parentheses—that is, they began to increase their use of parentheses in meaningful ways. For instance, when attempting to create items in the field guide listed under *Artifacts*, the item called “Unknown alien device 9” requires three types of operations and two sets of parentheses. To create this item, it is perhaps the most likely situation in which a student would be faced with creating an expression in which the parentheses would fall into Type 3—the use of parentheses changes the value the expression evaluates to. This is because it is more likely that student would use a subtraction symbol or multiplication symbol between two sets of parentheses, thus requiring use of the distributive property with the second set of parentheses. However, it is still possible that a student could have written such an expression without Type 3 parentheses. Thus, it is interesting to see an increase in their use for both groups of students as they became more experienced with playing the game. In contrast to prior studies (e.g., Gunnarsson et al., 2016), by providing an environment in which students’ expression writing could occur in a risk free environment, there appears to be evidence of broad success in encouraging the increase of sophistication in expression writing over time. Further research is needed to understand the nuances of the patterns in their development.

A BAKHTINIAN LENS ON THE EFFICACY OF DIALOGIC INSTRUCTIONAL VIDEOS

Michael Foster
San Diego State University
Mfoster8969@sdsu.edu

Inquiry into the role of dialogic instructional videos is still in its infancy. There is a need to better understand if dialogic instructional videos are viable and how to best understand the impact they have on students. To date, the limited findings paint the use of dialogic videos in a positive light, but the results are at times inconsistent. Within this project I attempt to leverage the theoretical writings of Mikhail Bakhtin to explain these inconsistencies and to shed a new explanatory light on why dialogic instructional videos can be effective.

Keywords: Technology, Online and Distance Education, Learning Theory

Introduction

Instructional videos have continued to grow in popularity, and for good reason. Videos allow students to engage with content at their own pace and repeatedly (Lin & Michko, 2010; Vidergor & Ben-Amram, 2020), they broaden who has access to information (Parslow, 2012), and videos present an alternative to traditional instruction (e.g., flipped classrooms, Fyfield et al., 2019). The more options the better, but some forms of instructional videos are better than others – particularly for conceptually deep subject material like mathematics.

The most common and widely used form of instructional videos within mathematics education are those that follow the model set forth by Khan Academy (Bowers, Passentino, & Conners, 2012). This form of instructional video contains a "talking hand", or a voice dictating with a virtual pen, describing a procedure that is presented on a virtual whiteboard. Under the goal of providing open access to content, the "talking hand" model of instructional videos has been extremely successful with millions of worldwide users (Kelly & Rutherford, 2017; Noer, 2012).

The main issue with this form of video – particularly for mathematical content – is its emphasis on procedures (Bowers, Passentino, & Connors, 2012). With videos typically lasting less than 10 minutes, it is difficult for deep conceptual meaning to emerge for the presented mathematical content (Danielson & Goldenberg, 2012). Within that time viewers can be reminded of, or learn new, procedures (e.g., how to find a derivative), but establishing conceptual understanding takes time (e.g., that a derivative is a function for instantaneous rate of change). Instead of challenging the status quo through a new medium of technology, the "talking hand" style of instructional videos serves as reinforcement for the conception of mathematics as a set of facts to be memorized and enacted given the proper context (Bowers, Passentino, & Connors, 2012).

Another issue for "talking hand" videos, and other forms of online instructional videos (e.g., asynchronous lectures), is the lack of student voices (Lobato, Walker, & Walters, 2017). These models of video emphasize the exposition of content by a knowledgeable teacher, as opposed to the inclusion of inexperienced student voices. Student voices are important because they can serve as voices that resonate with the thoughts and difficulties of the viewer – voices of fellow learners (Chi, Kang, & Yaghmourian, 2017). As online instructional videos and distance learning, more generally, grows in popularity there are less opportunities for students to engage with and experience fellow students' voices (McKendree et al., 1998). Instructional videos could fill that void, but exposition focused videos do not.

An alternative to the dominant approaches to instructional videos gaining traction in math education are dialogic videos (e.g., https://calcvids.org/, Kolikant & Broza, 2011, Lobato, Walker, & Walters, 2017). Foremost, dialogic videos contain people engaged in a dialogue. This means that the videos contain conversations and attempts at creating new meaning or new ways of experiencing (Alrø & Skovsmose, 2004). Fundamentally, this form of instructional videos can emphasize students' voices. There are typically two people within these videos – one student and a teacher (e.g., Muldner, Lam, & Chi, 2014), or two students (e.g., Lobato, Walker, & Walters, 2017). Importantly, the voices of the students within these videos are engaged in a process of meaning making, and the meaning making process may produce deeper conceptual understanding for the viewer than simply viewing a set of procedures.

To date, there is a limited body of empirical research into the experiences of the viewers of dialogic videos. The central focus within this literature is on the learning outcomes of dialogic videos in comparison to those of monologic videos (e.g., Chi, Roy, & Hausmann, 2008; Craig, Driscoll, & Gholson, 2004; Muldner, Lam, & Chi, 2014; Muller, Sharma, & Reimann, 2008). Taking a quantitative approach, these studies have reported mixed findings (Gholson). The trend in the research suggests that dialogic videos lead to significant differences in learning outcomes, but the differences in findings across studies is not easily explained.

Within this theoretical paper I forward a lens into these contradictory findings based on the writings of Bakhtin that I believe can begin to explain the supposed contradictions and can be applied to future inquiry into students' experiences with dialogic instruction videos. This project is guided by the following research question: Does a Bakhtinian framework illuminate reasons for the inconsistency in learning outcomes of dialogic versus monologic quantitative studies and can Bakhtinian framework be applied to a wider range of literature on dialogic instruction videos.

Theoretical Framework

The following section presents a brief introduction to the philosophical writings of Bakhtin. This will include a definition of dialogue that will frame the Bakhtinian concept of voice and the subsequent introduction to the constructs of internally persuasive and authoritative voices.

Bakhtinian Dialogue

For Bakhtin, dialogue is an omnipresent interaction between an individual and the other (Morson, 2004; Mustova, 2007). Bakhtin (1981) defines the other as everyone external to an individual. While interacting with the other, words enter the individual's mind and begin to interact with the web of meaning emanating from that individual's experience with the word. As Bakhtin (1981) famously wrote:

> …language, for individual consciousness, lies on the border between oneself and the other. The word in language is half someone else's. It becomes 'one's own' only when the speaker populates it with his own intentions, his own accent, when he appropriates the word, adapting it into his own semantic and expressive intention. Prior to this moment of appropriation, the word does not exist in a neutral and impersonal language (it is not, after all, out of a dictionary that the speaker gets his words!), but rather it exists in other people's mouths, in other people's concrete contexts, serving other people's intentions: it is from there that one must take the word, and make it one's own. (p. 293)

As an individual engages with the use of a word they are simultaneously engaging with the history of that word and the intended meaning behind the other's use of the word. Through dialogue, an individual can begin to appropriate the word through a personal interpretation and negotiation of historical and local meanings. In the colloquial sense, a conversation with another person can be seen as a dialogue, but a Bakhtinian dialogue is a subjective internal process that does not need another person's physical presence. Dialogue only requires words and meanings.

Bakhtin, working in the early 20th century, was a literary scholar (Bakhtin, 1981). Critiquing genres that are unchanging and containing fixed features (e.g., every epic contains a hero), Bakhtin appreciated themes and characters that grew and changed as the story, and the genre as a whole, progressed. For Bakhtin (1981), the epitome of literature was the genre of the novel because the novel contained evolving dialogue between characters, between author and character, and between author and reader. Clearly, in the case of a novel, author and reader are not directly interacting, but meaning is still being negotiated. Even though there is only one voice, that of the author, in a novel there can still be a dialogue. Bakhtin's primary example of this comes from the writings of Dostoevsky. Dostoevsky is famous for his use of polyphony (i.e., multiple voices) within his writings. Through this style of writing, Bakhtin suggests, multiple perspectives can emerge, and dialogue can take place between and within characters. This dialogic experience can then be experienced by the reader.

One affordance of a Bakhtinian definition of dialogue, is an expansion of what can be considered a dialogue. A dialogue can occur between two people, between a book and a reader, or between an individual and their thoughts. Importantly, Bakhtin's dialogue emphasizes the subjective nature of constructing meaning from previous experiences, and what matters most is how the voices are experienced.

Voices

A voice is an utterance or an action and the associated meaning (Kolikant & Pollack, 2015; Silserth, 2012). For Bakhtin, voices are either experienced as internally persuasive svoice (IPV) or as authoritative voices (AV). An internally persuasive voice is voice that is experienced as open for, and enters into a process of, negotiation (Bakhtin, 1981). Authoritative voices, on the other hand, are the voices that are not negotiated. This can happen because the voice is experienced as not open for negotiation or because an attempted negotiation fails.

For Bakhtin (1986), the process of negotiation with a voice is where deep knowledge and understanding is constructed. Therefore, fostering IPV should be a goal of educators (Morson, 2004; Mustova, 2007), but IPV are subjective experiences (Bakhtin, 1981). One individual listening to the same voice as another will experience what is being said or done differently. Included in this difference in experience is a difference in negotiability of what is being said. For example, an experienced rock climber may hear the beta (jargon for suggested method of climbing a route) for a difficult climb and understand that this advice is a suggestion that is not one size fits all. Climbers of different sizes have different strengths; thus, this beta may not be suitable for a taller climber and the beta needs to be adjusted accordingly – the beta needs to be negotiated with. On the opposite side, a newer climber may hear the beta and fixate on trying to reproduce the moves exactly as it appears in the beta. The experienced climber is experiencing the voice of the beta as an IPV because they are open to and able to negotiate with it. The newer climber, on the other hand, is then experiencing the beta as an AV.

AV are antithetical to dialogue because meaning is not being negotiated. If an individual is experiencing the other's voice as authoritative, then they are not actively engaged in the dialogue. Instead, the individual takes on a more passive role in the dialogue as an information receptacle. Internally persuasive voices, on the other hand, trigger the process of appropriating the other's words and negotiating its meaning to fit one's own purposes. Bakhtin (1986) states that "Active agreement/disagreement (if not dogmatically predetermined) stimulates and deepens understanding (p. 142)". Agreement/disagreement that is predetermined are not open for negotiation and fall into the category of AV. When an active process is involved, on the other hand, the agreement/disagreement is produced by a negotiation process and would, thus, fall into the category of IPV. Together, this means that learning is best fostered by voices that are IPV. AV can produce learning, but when learning is "dogmatic" it is not as deep as the learning produced by an active negotiation process.

Considering this definition of dialogue, and the two kinds of voices, I forward a lens into the literature on student's use of dialogic videos that focuses on experiences of IPV. When greater learning is fostered, I will argue that more voices are being experienced as internally persuasive.

Methods

To find the papers reviewed within this theoretical paper a systemic review of the field was conducted. This included the use of the database ERIC-EBSCO. Allowable dates included in this search accounted for anything up to the date of the search (October 2020). Additionally, this search was limited to those with electronic access in the above database. Finally, the search terms were limited to "vicarious learning", "video", and "education" contained anywhere in the title or body of the text. This search resulted in 12 articles. Further limiting the scope of this search, the article abstracts were read and articles not focused on student learning were omitted. This process of omission was used to weed out articles focused on nursing education. Given the infancy of the field's inquiry into vicarious learning, the remaining 5 articles were read and an iterative bibliographic exploration was used to find an addition 9 articles. These 14 articles form the basis of this theoretical analysis.

Results

In the following section the limited literature on dialogic instructional videos is reviewed and then reinterpreted from a Bakhtinian perspective. This literature can be broken into two sets of findings: learning outcomes and learning practices.

Learning Outcomes

A number of research projects have sought to establish the effectiveness of learning from dialogic videos via quantitative comparative studies. Within these empirical studies, a commonality was the comparison of a treatment that used recordings (e.g., videos, audio tapes, etc.) that contains a single speaker (i.e., monologic) to resources that contained multiple speakers (i.e., dialogic). The trend within these findings suggests that dialogic videos are more favorable for learning outcomes than monologic, but there are several conflicting results.

Findings. The majority of studies found supporting evidence for the claim that dialogic videos are better than monologic (e.g., Chi, Kang, and Yaghmourian, 2017; Chi, Roy, & Hausmann, 2008; Cox, et al., 1999; Craig, Chi, & Vanlehn, 2009; Driscoll et al., 2003; Gholson & Craig, 2006; Muldner, Lam, & Chi, 2014; Muller et al., 2007; Muller, Sharma, & Reimann, 2008). For example, in one set of studies Chi and colleagues position their dialogic videos as tutoring sessions with one speaker being the tutor and all other speakers being tutees. They then compared the learning gains from viewers of the dialogic videos to viewers of a single tutor presenting the same set of information (Chi, Kang, & Yaghmourian, 2017; Chi, Roy, & Hausmann, 2008; Craig, Chi, & Vanlehn, 2009; Muldner, Lam, & Chi, 2014). These studies have found statistically significant differences in favor of the pre/post-test learning gains of the treatments who engaged with resources that contained multiple speakers, suggesting that two speakers are better than one

Some projects have found conflicting results, with either no statistical difference between viewers of monologic and dialogic videos or a difference in favor of the learning gains of viewers who engaged with monologic videos (e.g., Cooper et al., 2018; Monaghan & Stenning, 1998; Muller, Bewes, et al., 2008). For example, Cooper et al., (2018) found a statistically significant difference favoring the students who viewed monologic videos of their professor. The literature, thus, suggests that two speakers are better than one, but two speakers are not a sufficient condition for improving learning outcomes of the viewers.

Bakhtinian Lens. For Bakhtin, more learning is indicative of the presence of more IPV. The findings that support the use of dialogic videos thus suggest that dialogues foster the experiences of IPV. Multiple speakers (e.g., dialogic videos) may foster IPV if the multiple speakers are engaged in a negotiation process, and if the indirect participation with voices that are already being negotiated makes it easier for IPV to develop. The presence of negotiation within dialogic videos can establish as a norm that the voices present within the videos are open for negotiation. This could be particularly important for students who are from traditional lecture classrooms that typically contain voices that are not open for negotiation (Morson, 2004).

At times, when multiple speakers were not a sufficient condition for fostering IPV, it is possible that other features were. For example, Cooper et al (2018) found learning outcomes were improved for viewers of monologic videos, but the students viewed monologic videos that contained their professor. Compared to Chi and colleagues, whose monologue videos contain an unfamiliar tutor and learning outcomes favored dialogue viewers, it’s possible that the familiarity with the voice of the professor in Cooper and colleague’s study influenced the learning outcomes of their quantitative findings. In other words, because the students were familiar with their professor, and perhaps because of norms established in their class, the voice of the teacher was positioned as open for negotiation.

In another study, Muller, Bewes, et al. (2008) found that the presence of alternative conceptions and resolutions was more important for learning outcomes than whether the viewers engaged with monologic or dialogic videos. This suggests that the number of voices was less important than the content of the voices. Particularly, the presence of alternative conceptions appears to foster IPV. If multiple conceptions and productive struggles are presented, then the viewers would disadvantage themselves if they simply accepted information without negotiation. In the case of multiple conceptions, accepting without negotiation would lead the viewer to take on conceptions that are not accurate. When that information is eventually corrected, within the video, the viewer may be left more confused. This confusion is not evidenced by the learning gains of students who watch and are exposed to alternative conceptions (e.g., Chi, Kang, and Yaghmourian, 2017; Chi, Roy, & Hausmann, 2008; Cox, et al., 1999; Craig, Chi, & Vanlehn, 2009; Driscoll et al., 2003; Gholson & Craig, 2006; Muldner, Lam, & Chi, 2014; Muller et al., 2007; Muller, Sharma, & Reimann, 2008). Further, I believe that the presence of multiple conceptions and struggle can again produce a norm of negotiating with what is being presented. With conceptions present that are understood by the viewer to be merely possibilities, then that conception is ripe for negotiation. The viewer can determine for themselves whether or not they hold that same conception through negotiation. Additionally, when a final conception is realized within the video, and other conceptions are dispelled, the reasoning that led to the concluding conception can serve as a model for viewer’s future negotiation processes.

Practices

A small body of work has applied an analytical lens to the actions of observers by probing the effect that dialogic videos have on the behaviors of the viewers. The findings from this literature suggests that the individuals contained within the videos serve as a model for the viewers. The findings are limited, but the behavior modeled ranges from content specific practices like the construction grammar trees to broader practices like posing deep questions (Bandura, 1965; Braaksma, Rijlaarsdam, Van den Bergh, & van Hout-Wolters, 2004; Craig, Gholson, Ventura, & Graesser, 2000; Chi, Kang, & Yaghmouian, 2017; Kuhn & Modrek, 2021; Rummel & Spada 2005; Schunk Hanson & Cox, 1989). This suggests that viewers not only learn the content of dialogic videos, but that they can also learn behaviors that can benefit them as learners (e.g., productive problem-solving techniques).

From a Bakhtinian lens, these findings support the claim that dialogic videos can foster IPV. With voices defined as utterances or actions and their associated meaning, the reported modeled behaviors demonstrate the role that actions have on the viewers. Specifically, if the dialogue of the dialogic videos contains a negotiation process, then any modeled negotiation would be evidence that the viewer is experience the videos as containing IPVs.

Discussion

From a Bakhtinian perspective, dialogue is a subject experience. Whether a video contains a single expert explaining the process of Riemann approximation, or two students describing the difference between right-hand and left-hand approximations, both may be a dialogue, but one may be internally persuasive while the other is authoritative. What matters is the content of the voices and the subjective experience of those voices. What will foster more learning is when voices within the video are experienced as IPVs. The empirical literature comparing different feature of instructional videos, namely the comparison between treatments using monologic or dialogic instructional videos, are then useful in determining what can foster negotiation of voices.

While the analysis presented here is preliminary, the theoretical framework forwarded offers a starting point for future inquiry into student's use of dialogic videos. With a lack of empirical work assessing the mechanisms by which viewers of instructional videos learn, future work can extend the use of Bakhtin's voices to analyze and assess possible negotiations occurring between the viewer and the viewed.

THINKING OUTSIDE THE BOX: PREPARING ELEMENTARY TEACHERS INTEGRATE COMPUTATIONAL THINKING AND MATHEMATICS

Terrie M. Galanti
University of North Florida
terrie.galanti@unf.edu

In this report I investigate how elementary teachers in an online graduate-level computational thinking course make sense of mathematical relationships using block-based programming. Teachers were provided with a Scratch program that structures the dynamic relationship between changing height and changing volume in the context of rich mathematics task. Analysis of teachers' mathematical representations of this task revealed how teachers can construct conceptual understandings by modifying parameters within a block-based program. Implications for preparing teachers to leverage the computational thinking concepts of abstraction, dynamic modeling, and automation in teaching mathematics are discussed.

Keywords: Computational Thinking, Technology, Computing and Coding, Professional Development

With the increasing emphasis on computational thinking as a critical skill in K-12 teaching and learning (Committee on STEM Education, 2018), the mathematics education community has an exciting opportunity to broaden its conceptualization of mathematics as a school subject. Computer science, particularly at the elementary level, is often framed as a discipline that is distinct from other subjects. However, there is growing research attention on the natural overlap between computational thinking and mathematics in K-12 education with respect to structure, abstraction, and modeling in problem solving (Israel & Lash, 2019; Silva et al., 2020; Strickland et al., 2021; Weintrop et al., 2016).

Mathematics continues to be taught in many K-12 schools through a siloed approach instead of as an authentic integration of reasoning and sense-making (Li et al., 2019). Yet computational thinking, particularly in relation to programming, has the unique potential to change the way that students think about the rigor and relevance of mathematics. Li and colleagues (2020) recently described computational thinking as "searching for ways of processing information that are always incrementally improvable in their efficiency, correctness, and elegance" (p. 4). Computational thinking and mathematics are naturally and historically connected (Gadanidis et al., 2017) because of their shared emphasis on modeling and exploring quantitative relationships.

The power of computer programming as a sense-making tool in the context of K-12 mathematics activities is only beginning to be explored in elementary teacher preparation and professional development programs (e.g., Gadanidis et al., 2017; Gleasman & Kim, 2020). Preparing teachers to leverage computational thinking opportunities through mathematical representations can enrich students' exploration of patterns, structure, and sequence. When teachers provide opportunities for students to explore mathematical relationships by changing parameters within code, they can foster conceptual understandings of mathematics. There is a need to understand how teachers reason with code to design professional development experiences that build teachers' abilities to make this overlap explicit (Kotsopoulos et al., 2019).

This study focuses on how elementary teachers made sense of one rich mathematics task using a computational thinking perspective. The following research question guided this investigation of teachers' reasoning about varying measurement quantities: How do elementary teachers enrolled in a graduate STEM education course use and describe computational thinking in their mathematical exploration of the volume of an open box?

Theoretical Background

Seymour Papert (1980) first introduced computational thinking as a constructionist approach to learning mathematics with tangible making experiences using the LOGO programming language. However, it was Wing's (2006) essay on computational thinking as a fundamental skill along with reading, writing, and arithmetic that inspired the growing call to bring more computational thinking opportunities to all children. While there is no scholarly consensus on the definition of computational thinking (Cansu & Cansu, 2019), the International Society for Technology in Education (ISTE) in conjunction with the Computer Science Teachers Association (CSTA) offer a robust definition of computational thinking in relation to mathematics. It is a problem-solving process with specific characteristics related to problem formulation; organization and analysis of data; use of abstractions such as models and simulations; efficiency of algorithmic solutions; and generalizability of solutions (ISTE & CSTA, 2011). Within the field of mathematics teacher education, we need research on developing this implicit synergy between computational thinking and mathematics, especially within professional development experiences that elementary teachers need to realize its advantages (Bull et al., 2020; English, 2018).

It is important to emphasize that programming is both a process and product of computational thinking. As such, programming within a mathematical learning context can help students solve problems and use data effectively (Weintrop et al., 2016; Wolfram, 2020). Gadanidis and colleagues (2017) explained the possibilities of "what might be" with computational thinking as they used the Scratch programming language to integrate advanced grade level geometry and probability content in a Grade 1 mathematics classroom (p. 78). They proposed seven pedagogical affordances associated with integrating computational thinking and mathematics teaching and learning. These affordances are as follows: 1*) low floor, high ceiling;* 2) *abstraction and automation;* 3) *dynamic modeling;* 4) *tangible feel;* 5) *conceptual surprise;* 6) *wide walls; and* 7) *agency*. These affordances also constitute an analytic framework that I used examine the potential of computational thinking to position teachers as both producers and consumers of mathematical knowledge (Gadanidis et al., 2017, p. 93).

Methods

As the instructor in a synchronous online computational thinking course for elementary teachers who were enrolled in a STEM+C graduate certificate program, I encouraged teachers to explore the natural relationship between computational thinking and mathematics learning in a series of mathematical tasks. Before they engaged in problem solving, the teachers analyzed computational thinking concepts and practices (Grover & Pea, 2018) and the Standards for Mathematical Practice (NGA & CCSSO, 2010) for conceptual overlap. Second, the teachers experienced three collaborative problem-solving opportunities with high cognitive demand mathematical tasks. As they built their solutions, they were encouraged but not required to explore dynamic modeling opportunities using starter code in the Scratch programming language. These open exploration tasks were centered on number sense and geometry.

Their mathematical goal in the "Thinking Outside the Box" task was to construct a box with the largest possible volume (Dodge & Viktora, 2002) by cutting congruent squares from each corner of an 8.5 x 11-inch rectangular paper. The task was aligned with Grade 5 geometric measurement standards and prompted the use of patterns to develop a solution. Teachers were provided with hyperlinks to a Google spreadsheet for recording box dimensions and volume calculations and Scratch starter code to automate the calculations of a user-specified sequence of heights (see Figure 1). The Scratch starter code created a list of 6 boxes with evenly spaced integer heights ranging from 0 to 5 and associated volumes. Teachers were able to modify the range of heights and the differences between the heights by adjusting the parameters in the code. Teachers could choose to represent their mathematical thinking as outputs of the Scratch starter code. They also reflected how they experiences the computational thinking concepts of pattern seeking, abstraction, and automation from their perspectives as learners in this task.

The unit of analysis for this study was teacher collaborative sense-making as evidenced in Google Slides artifacts (for five groups of 3-4 teachers) and instructor notes from breakout room conversations. I used the Gadanidis et al. (2017) pedagogical affordances as apriori codes to analyze how teachers interacted with the Scratch to think deeply about mathematics.

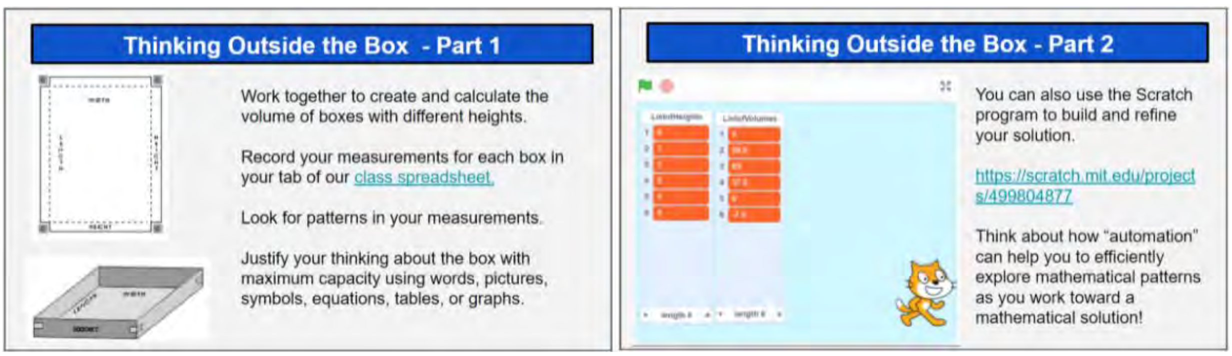

Figure 1: Task Directions – Finding the Maximum Volume of an Open-Top Box

Findings

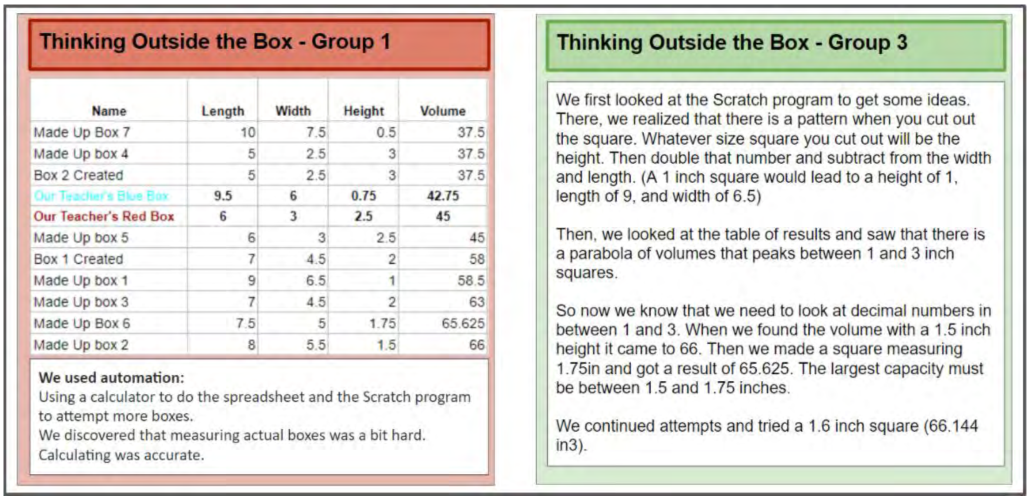
Three of the five groups chose to use of the Scratch program to examine structure and to generalize with differing outcomes. In breakout room conversations, two groups expressed *conceptual surprise* as they noticed the negative value for volume with a height of 5 inches in the Scratch program output. I encouraged these groups to think about the length and width dimensions that they were not seeing on the list of values and to tinker with the program further to explain their noticings. They further expressed *conceptual surprise* as they discovered they might not have been able to find one correct answer based on the limited precision of the code.

As Group 5 observed the *dynamic modeling* within Scratch, they generalized that as the height of the box increased, the volume decreased. However, they did not comment on the increasing and decreasing patterns with the initial height values. They "noticed that all of the heights were whole numbers and decided to experiment with decimals". The affordance of *abstraction/automation* enabled them to adjust the height parameters to increase by 0.25 inch with each iteration. They concluded that a 1.5-inch height would yield the greatest volume.

Group 1 (see Figure 2, left) used the Scratch program to extend the sense making that they had recorded in Google Sheets using box measurements and formula calculations. Because they did not order their spreadsheet rows, they did not offer evidence that they were examining patterns to see how volume was changing. Instead, they seemed to be looking for the largest volume by trial and error. Their comment that using the Scratch improved the accuracy of their calculations suggests that they needed additional support to see how the *dynamic modeling* of the program could deepen opportunities for mathematical reasoning *automating* the formula.

Group 3 (see Figure 2, right) used the Scratch-generated list structure to look for patterns in changing heights and generalized that volume was increasing and then decreasing between heights of 1 and 3 inches. They also leveraged *abstraction/automation* to change the parameters with increasingly narrow intervals of 0.5 and 0.1 inches as they concluded that the largest volume would be 1.6 inches. Their mathematical explanation offered contextual evidence of tinkering with code as a pedagogical experience in programming (Kotsopoulos, 2017).

Teachers' use of Scratch varied from a *low floor* of automating the calculation of a variety of individual volumes (Group 1) to a *high ceiling* of modifying code parameters and examining the resulting patterns (Group 3). These artifacts of teacher sense-making show how teachers can use starter code can build the reciprocal relationship between computational thinking and mathematical exploration (Weintrop et al., 2016). The Scratch program was used as a *dynamic model* of the covarying relationship between height and volume. The list structure was used as an *automated abstraction* of the volume function increased the opportunities for rich mathematical conversations about covariation, pattern seeking, and reasonable mathematical answers.



Thinking Outside the Box - Group 1

Name	Length	Width	Height	Volume
Made Up Box 7	10	7.5	0.5	37.5
Made Up box 4	5	2.5	3	37.5
Box 2 Created	5	2.5	3	37.5
Our Teacher's Blue Box	9.5	6	0.75	42.75
Our Teacher's Red Box	6	3	2.5	45
Made Up box 5	6	3	2.5	45
Box 1 Created	7	4.5	2	58
Made Up box 1	9	6.5	1	58.5
Made Up box 3	7	4.5	2	63
Made Up Box 6	7.5	5	1.75	65.625
Made Up box 2	8	5.5	1.5	66

We used automation:
Using a calculator to do the spreadsheet and the Scratch program to attempt more boxes.
We discovered that measuring actual boxes was a bit hard.
Calculating was accurate.

Thinking Outside the Box - Group 3

We first looked at the Scratch program to get some ideas. There, we realized that there is a pattern when you cut out the square. Whatever size square you cut out will be the height. Then double that number and subtract from the width and length. (A 1 inch square would lead to a height of 1, length of 9, and width of 6.5)

Then, we looked at the table of results and saw that there is a parabola of volumes that peaks between 1 and 3 inch squares.

So now we know that we need to look at decimal numbers in between 1 and 3. When we found the volume with a 1.5 inch height it came to 66. Then we made a square measuring 1.75in and got a result of 65.625. The largest capacity must be between 1.5 and 1.75 inches.

We continued attempts and tried a 1.6 inch square (66.144 in3).

Figure 2: Excerpts from Teacher Work - Using Scratch for Mathematical Sense-Making

Discussion and Implications

Analysis of the mathematical representations in this "Thinking Outside the Box" task reveal the potential for mathematics teacher educators to facilitate a productive interplay between computational thinking and mathematical sensemaking. Only two of five groups in this study modified parameters for the purpose of pattern seeking and generalization. This finding raises important questions about how professional development facilitators can scaffold deep mathematical reasoning through code. Facilitating this sense making is crucial in building elementary teacher confidence that mathematical learning can happen through computational exploration. This study shows that teachers may need further support to see code as a tool for reasoning about mathematical relationships beyond efficient calculation of answers.

There is a need for more research to conceptualize how programming "about and for the sake of" mathematics can support learning (Goldenberg et al., 2021, p. 49). Opportunities to program in Scratch in elementary schools are often framed as expressive activities outside of curriculum. Yet this study shows that carefully designed starter code can empower teachers to leverage abstraction, automation, and dynamic modeling as students investigate mathematical relationships. This knowledge can position teachers to provide all students with tools enjoy the computational nature of mathematics as a discipline.

HOW TRANSITIONS BETWEEN RELATED ARTIFACTS SUPPORT STUDENTS' COVARIATIONAL REASONING

Erell Germia	Toni York	Nicole Panorkou
Montclair State University	Montclair State University	Montclair State University
germiae1@montclair.edu	yorka1@montclair.edu	panorkoun@montclair.edu

Many studies use instructional designs that include two or more artifacts (digital manipulatives, tables, graphs) to support students' development of reasoning about covarying quantities. While students' forms of covariational reasoning and the designs are often the focus of these studies, the way students' interactions and transitions between artifacts shape their actions and thinking is often neglected. By examining the transitions that students make between artifacts as they construct and reorganize their reasoning, our study aimed to justify claims made by various studies about the nature of the synergy of artifacts. In this paper, we present data from a design experiment with a pair of sixth-grade students to discuss how their transitions between artifacts provided a constructive space for them to reason about covarying quantities in graphs.

Keywords: Instructional Activities and Practices; Mathematical Representations; Design Experiments.

Over the past three decades, mathematics educators have characterized students' reasoning about the simultaneous change of two quantities in various ways (e.g., Confrey & Smith, 1994; 1995; Saldanha & Thompson, 1998). Some proposed frameworks to describe students' progression of covariational reasoning over time (Carlson et al., 2002; Thompson & Carlson, 2017) and a handful of studies used these to examine students' reasoning of various mathematical ideas, such as the rate of change (e.g., Johnson, 2012), and scientific phenomena, such as gravity (e.g., Panorkou & Germia, 2021). To examine *what* forms of covariational reasoning students exhibit, these studies often engage students with various artifacts such as dynamic manipulatives, tables, or graphs (e.g., Castillo-Garsow, 2012; Ellis, 2011).

Multiple studies point to the role of particular artifacts or combinations of artifacts used during the learning process to explain *why* this development of students' reasoning happens or does not happen (e.g., Ellis et al., 2018). The role of technology has been to advance students' reasoning because it can be utilized to illustrate change in progress (Castillo-Garsow, 2012) as well as the ability to reverse change. For example, Johnson et al. (2016) used a Ferris wheel animation on Geometer's Sketchpad (GSP) and asked the students to click and drag the car to control the motion and graph the relationship between the car's height from the ground and its distance traveled within one revolution. Examining relationships between quantities using dynamic manipulatives before graphing has shown to advance students' conceptions of graphs of functions as a representation of coordinated change (e.g., Ellis et al., 2018). While some asked students to transition straight from the digital tool to the graph (e.g., Ellis et al., 2018; Stevens & Moore, 2016), others asked students to create a table as an intermediate artifact before transitioning to the graph (e.g., Ellis et al., 2015).

Although each study uses different technologies (GSP, GeoGebra, Desmos), often their goal is for students to connect these dynamic representations of relationships with the graphing of those relationships. One of the prevailing difficulties that students have with graphing is that they focus on the shape of the graph and ignore the relationship between the two covarying quantities that it illustrates. To explain this, Moore and Thompson (2015) distinguished between *static* or *emergent* shape thinking. Students who think statically operate on a graph as an object, such as a piece of wire. In contrast, students with emergent shape thinking illustrate an understanding of a graph as a trace (or a snapshot of a trace) in progress that depicts the relationship between two covarying quantities. To examine students' reasoning across multiple representations, we expanded the ideas of static and emergent thinking in this study to also include applying them to reasoning with simulations and tables as well as graphs. To reason emergently in this way, a student must construct a more abstracted structure of covarying quantities that is operative in each of the representational contexts, rather than being inherently tied to any one of them.

While research studying *what* forms of reasoning students develop during the transition between artifacts and *why* this might happen prevails, an examination of *how* this process happens is rarely the focus of the investigation. In this paper we argue that the *how* lens can show us specific methods and conditions in which students' actions and reasoning are influenced during the interactions with the artifacts. This can make a contribution for informing both the design of artifacts, tasks, and questioning around these ideas and also the analysis of students' reasoning during those transitions. Considering the above, this study aims to examine *how* students make connections between different representations of the same covarying quantities as they transition between artifacts, and to explore the conditions that made those transitions productive for their learning. Specifically, we aim to examine the following research question: *How may students' transitions between artifacts provide a constructive space for them to reason emergently with a graph?*

Theoretical Framework: Examining the Transitions Between Artifacts

In this paper we use the term *artifact* to refer to a tool made by humans that is used for performing a specific task (Verillon & Rabardel, 1995; Trouche, 2004). As the student interacts with an artifact, the artifact imposes on the user some affordances and constraints, which shape both the actions and the ideas emerging from the activity (Artigue, 2002; Noss & Hoyles 1996). Through their interaction with an artifact, students build an *instrument* (Verillon & Rabardel, 1995; Lagrange et al., 2001) which is a mental construction that consists in part of the artifact and in part of cognitive schemes. *Instrumental genesis,* or the process by which an artifact becomes an instrument, is therefore influenced by both the artifact's characteristics and the user's prior knowledge and experience (Rabardel, 2000).

The new instruments formed from the instrumental genesis do not develop in isolation but instead become part of a system that consists of instruments that students developed earlier (Rabardel & Bourmaud, 2003). Mariotti and Montone (2020) discussed the nature of a *synergy* between two artifacts as "an implicit or explicit reference to both artifacts [that] creates a relationship between meanings emerging from their use" (p. 113). To support students in relating these different meanings emerging from the different uses of artifacts, Soury-Lavergne (2021) proposed three characteristics of design that the group of artifacts needs to have. Specifically, she talked about making the use of each artifact necessary, what she refers to as *complementarity* between the two artifacts. To make their relation visible, she argued that there must be some form of *redundancy* of some characteristics of one artifact in the other. To her "redundancy in the system of instruments produces robustness and adaptability of the system" (p. 6). Finally, she stated that each artifact should have different constraints that would lead to students to adapt, by challenging and reorganizing their initial system of instruments. She referred to this characteristic as an *antagonism* between artifacts.

We may view each artifact as becoming a transitional instrument for the continuous (re)organization of a system of instruments. We refer to *reorganizations* (Piaget, 2001) of reasoning as the inferences we make about students' projections and reflections of particular forms of reasoning and their connections as these are (re)structured into a more coherent whole. While designs may imply a sequential instructional process from one artifact to the next, our experience shows that students' transitions do not follow a linear process but rather shift back and forth in unrestrained ways between different artifacts. Consequently, in this paper we use the term *transitions* to refer to the dynamic, continuous, and "messy" shifts (physical and cognitive) that the individual makes between artifacts as they (re)structure their system of instruments.

Methods

The findings we report here are part of a design experiment (Cobb et al., 2003) in which we iteratively developed and tested theories about both the process of learning and the nature of the synergy of artifacts that supported that learning. In this section we discuss the design and initial conjectures explored in this study as well as our methods of data collection and analysis.

Design and Initial Conjectures

Since our previous work (e.g., Panorkou & Germia, 2021) showed that students as young as sixth grade can engage in sophisticated reasoning about covarying quantities when these are presented in meaningful contexts such as scientific phenomena, we focused on the scientific phenomenon of climate in this study. We thus designed a set of artifacts based on this phenomenon, specifically involving the exploration of the covarying quantities of temperature and latitude in the earth's climate.

The first of these artifacts is the Climatic Zones simulation (Figure 1), with which students can explore how temperature and latitude covary in the earth's polar, temperate, and tropical zones. The temperature in these zones is largely determined by the distance away from the earth's equator, or latitude. To explore the simulation, students control the location of the arrow on the right side of the screen by moving their mouse into the different zones. The readouts above and to the left allow the student to observe resulting changes in the quantities. Similar to other studies (e.g., Ellis et al., 2018), our conjecture was that students' interactions with this simulation would support them in constructing their understanding of graphs as records of covariation, thereby engaging in emergent shape thinking (Moore & Thompson, 2015).

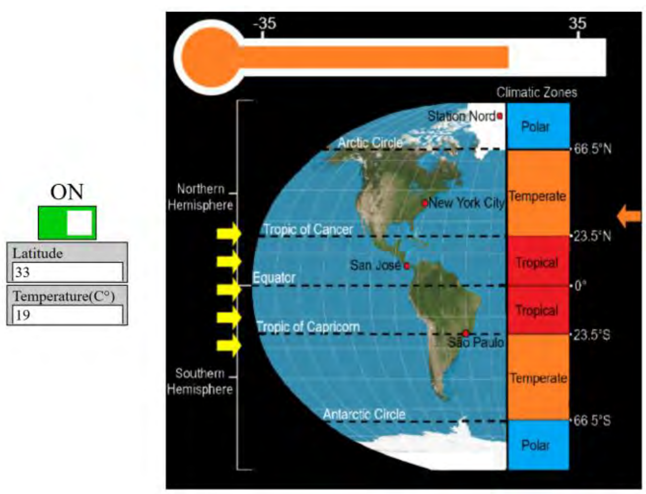

Figure 1: The Climatic Zones Simulation

We also chose to include both a table and a graph in order to explore both students' transitions between these different representations as well as how they would reorganize their systems of instruments to include each new artifact. Therefore, the next artifact we designed is a table which students were asked to use the simulation to complete a list of temperatures for given latitudes. We conjectured that this could support their emergent shape thinking since the table represents different values of the two quantities as ordered pairs. Students were then asked to complete the corresponding graph. This third artifact was designed without any scales, requiring students to create their own intervals on each axis before they could plot the values. We conjectured that this would allow us to examine how students would transition between the three artifacts to organize the data in the table as well as how they might reorganize their systems of instruments as they did so.

Finally, although this design may seem to be a strictly sequential learning activity, we set no restrictions on when or how often students could move back and forth between the artifacts as they worked. We thus expected that the students' actions and reasoning would illustrate the "messiness" of their transitions back and forth between the artifacts.

Data Collection and Analysis

The data presented in this paper was collected during a whole-class design experiment (Cobb et al., 2003) that took place in a sixth-grade classroom in the Northeast of the U.S. We conducted two 25-minute virtual sessions via Google Classroom due to COVID-19 restrictions. The students were paired off into breakout rooms where they engaged in the tasks and were interviewed by the researchers. The students' video and shared screens were recorded during the sessions. These recordings were then transcribed for the analysis.

This paper focuses on the retrospective analysis of the activity of one pair, Jami and Gaelyn. We analyzed the data in three stages. In the first stage, we identified episodes of the students' covariational reasoning and static or emergent shape thinking (Moore & Thompson, 2015). In the second stage, we reviewed each students' data chronologically in order to observe the progressions and reorganizations of their reasoning as they transitioned between the artifacts. In the third stage, we analyzed the features of the artifacts that seemed to support those progressions and reorganizations. We used the Soury-Lavergne (2021) framework of complementarities, redundancies, and antagonisms to characterize how this group of artifacts served as instruments in a system that provided a productive space for the students to reorganize their reasoning.

Findings

In this section we present examples of complementarity, redundancy, and antagonism in the order they emerged from the data.

Complementarity - Callback

We asked the students to explore the simulation and identify the quantities that change. Jami reasoned about the latitude, saying that "as you go up [using the cursor] the latitude is positive and then as you go down, the latitude is negative." She also reasoned about how the temperature changed in each climatic zone, explaining,

> Jami: The polar zone is actually very cold because it is up north [latitude], and the temperate zone since it is right between the equator where it is most hottest and the polar zone, it is pretty warm, like the average temperature, and the tropical zones are very hot because they are more close to the equator.

Her reasoning illustrated emergent shape thinking about how the closer from the equator a zone is, the hotter the temperature.

Next, we asked Jami and Gaelyn to use the simulation to complete the table (Figure 2, left). Jami shared her screen showing the simulation on the left side of the monitor and the table on the right side. The students took turns identifying the temperature using the simulation. For example, Jami stated “[negative] sixty-seven is in the latitude, the air temperature is negative 19.” Then, Gaelyn added “negative 23 is 23 degrees.” Both students transitioned between the table and simulation as they looked for the values of temperature that correspond to the given latitude. This reasoning exhibited the complementarity between these two artifacts as they referenced back to the information from the simulation to complete the table.

Latitude	Air Temperature
-67	- 19
- 47	12
-23	23
-10	24
0	35
10	31
23	26
47	8
67	- 9

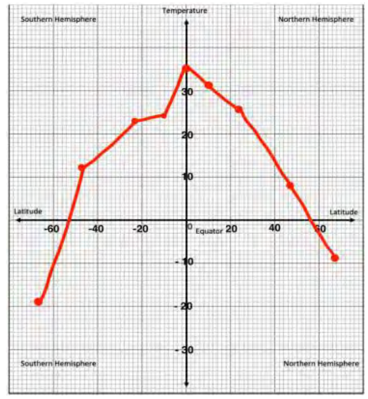

Figure 2: Gaelyn’s Completed Table and Graph

Then we asked the students to use the values in the table to create a graph showing the relationship between latitude and temperature (Figure 2, right). Gaelyn transitioned back and forth between the table and the graph as she plotted the values, reasoning,

> Gaelyn: The first thing was negative 67 to negative 19 [toggling back and forth between the table and graph]. … So that would be about here to [plotting in the first quadrant]. No wait, this is negative, so that would be about here [plotting in the third quadrant] to 19 right above the 20.

Gaelyn’s reorganization of plotting (-67, -19) from the first quadrant to the third quadrant also showed her understanding of graphing negative values. Next, Jami helped Gaelyn by guiding her with the succeeding values from the table as Gaelyn continued plotting them on the graph. Their actions of toggling between the two artifacts showed the complementarity of the table and the graph, as the former provided the information needed to create the latter.

Students’ calling back to the previous artifacts was a necessary action to collect relevant information and create the subsequent artifacts. The students needed to look for the data from the simulation to complete the table and then use the values from table to create the graph.

Antagonism

The students’ reasoning about the simulation, table, and graph also showed an antagonism in how the information in the three artifacts was encoded differently by each. Their reading of data points from the simulation and the table illustrated a straightforward encoding of information about the corresponding values of latitude and temperature. However, the graph required them to coordinate the two quantities and locate them along the x- and y-axes in order to represent the same information. As the students were plotting the points on the graph, Gaelyn moved her cursor along the y-axis and stated, “this is zero [latitude]” (Figure 3, middle). Jami also reasoned about the y-axis by stating that the “equator is right in the middle. It is the origin on the graph” (Figure 3, right).

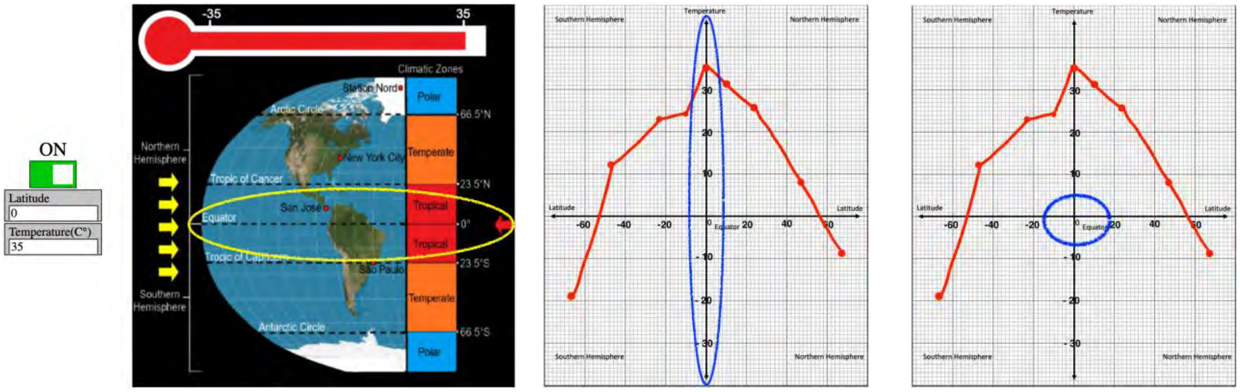

Figure 3: Relation of the Latitude of the Equator in the Simulation (left) to the Y-Axis (Gaelyn, middle) and the Origin (Jami, right) in the Graph

The students' reasoning about the location of the equator being at 0 degrees latitude and in the middle of the graph illustrated their understanding of the y-axis and origin of the graph. This also shows how the students needed to make meaning of the values on the graph, whereas they only needed to read the values from the simulation and the table.

Complementarity - Revision

Next, we asked the students to use the graph to describe the relationship between the latitude and temperature in the northern hemisphere. Gaelyn stated, "the higher the latitude, the lower the temperature," describing the relationship between the two quantities from the equator to the right side of the graph. This statement showed that she was able to identify how the latitude and the temperature in the northern hemisphere covaried in the graph. However, when we asked the students to use the graph to explain the same relationship in the southern hemisphere, Gaelyn wondered, "Would it be the opposite? So, like the lower the latitude, wait, no, never mind." Since Gaelyn was not sure about her response, Jami used the simulation to reason about the values of latitude. She stated that "if you go to the southern, the lower the latitude, because it's a negative, so when you go more negative numbers, on the number line, it gets more like lower, the numbers [moving the arrow downwards]" as shown in Figure 4. Jami probably imagined a "number line" across the different climatic regions in the simulation similar to what can be found on the graph to describe the changes in the values of the latitude. She referred to the values of the latitude as "negative numbers" to reason about "the lower the latitude" as she moved the arrow down in the simulation from temperate to polar climatic zones. In that way, she connected the change in the latitude in the simulation with the x-axis in the graph.

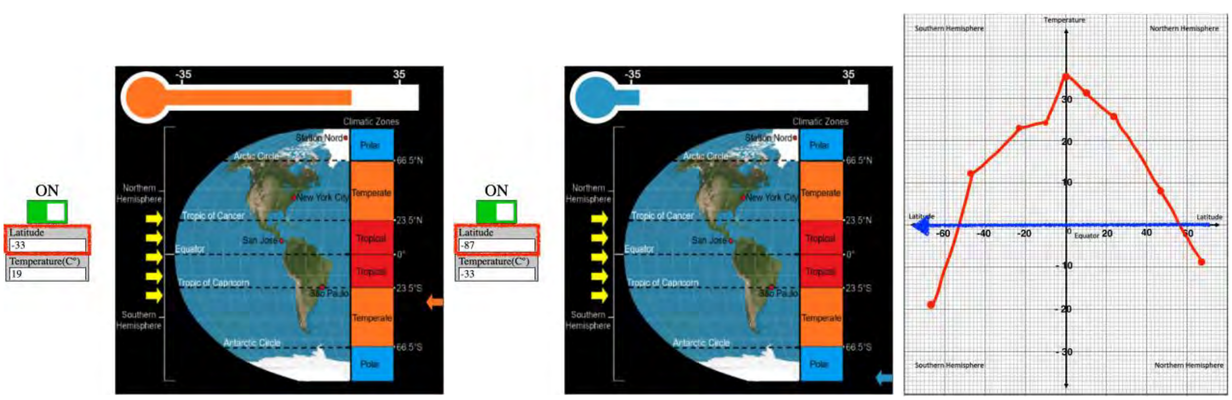

Figure 4: Jami Using the Simulation to Explain Latitude in the Graph

Associating the change in values with the direction on a number line did not seem to make sense for the students because the latitude was decreasing as Jami moved the arrow downwards in the simulation. Instead of reasoning about the negative values of latitude in the south, Gaelyn revised their discussion of latitude in terms of the distance from the equator:

> Gaelyn: … it says the same from the equator, as the distance from the equator increases, the air temperature decreases. Because we can't really say, because they're both going down [referring to the values of the latitude and temperature at the southern hemisphere], so we just have to do the distance.

Jami agreed and restated the relationship between the quantities in the southern hemisphere: "as the distance from the equator increases, the air temperature decreases."

The students' use of the two artifacts to discuss the relationship between latitude and temperature in the two hemispheres led them to revise their understanding of the latitude quantity from a positive or negative number into a measure of the distance from the equator. Since the latitudes on the right side of the graph were positive, it may have been easier for the students to express that covariational relationship than when working with the negative latitudes on the left side of the graph. The simulation allowed them to dynamically explore both regions of this relationship and became a necessary support for their reasoning about the relationship in the graph. Additionally, the students' reasoning exhibited a form of emergent shape thinking in both the graph and simulation. This shows a complementarity between the simulation and the graph as the students moved back and forth between these artifacts in order to revise their reasoning.

Redundancy

The students' activity with the artifacts also showed evidence of the redundancy of the information represented by each. For example, when we asked students to use their graph to describe the location of the highest temperature, Gaelyn reasoned that "the highest temperature, it would be right here [putting the cursor on the y-intercept of the graph] at the equator" (Figure 5). Gaelyn located the highest temperature at the y-intercept on the graph and then related the same point with the equator in the simulation where the highest temperature was also found. Jami added, "because the line is labeled temperature [making a vertical motion with her index finger]." This kind of reasoning showed the redundancy of information offered by the graph and simulation by connecting the information about the y-axis on the graph with both the location of the equator (Gaelyn) and the temperature data (Jami) from the simulation.

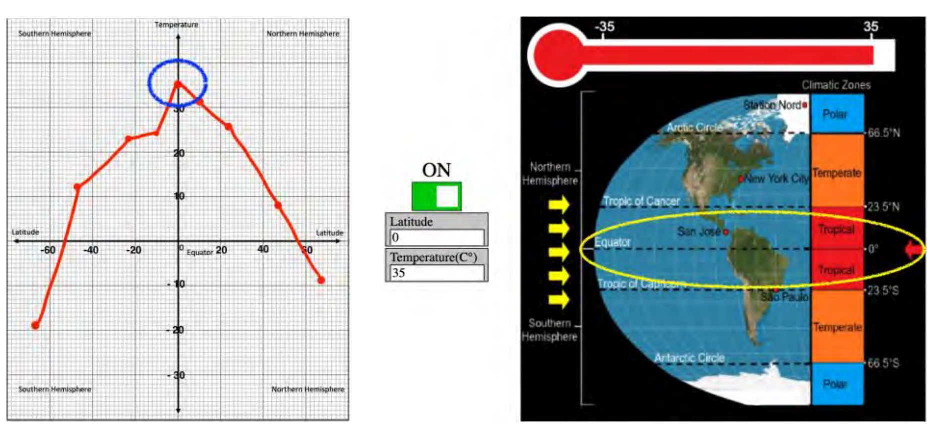

Figure 5: Gaelyn's Relation of the Highest Temperature in the Graph and the Simulation

The students' transitioning between the graph and simulation offered them opportunities to explore the similarities in the features of the two artifacts. Finding such information gave them opportunities to reason about how the quantities and their relationship are represented in both the simulation and the graph.

Conclusions

By examining *how* students transition between artifacts, our work informs the design of artifacts, tasks, and questioning that support them in making connections between different representations as they (re)organize their *systems* of instruments (Rabardel & Bourmaud, 2003). Jami and Gaelyn's transitions between the three related artifacts we designed influenced how they reasoned about the quantities and covariational relationships represented by those artifacts. Specifically, their transitions between the artifacts offered a constructive space for them to reason emergently with the graph instead of thinking about its static shape as described in the literature. Furthermore, they reasoned emergently across all of the artifacts, showing that they constructed a structure of covarying quantities not inherently tied to a particular representation.

Our findings highlight the specific forms of complementarities, antagonisms, and redundancies (Soury-Lavergne, 2021) that supported the synergy (Mariotti & Montone, 2020) between these related artifacts. The need for the students to use each artifact to create the next prompted them to reference back to previous artifacts as they continued to work. These callbacks show one kind of complementarity between the artifacts that supported the students' reasoning. The students' use of one artifact to revise their reasoning about another shows another kind of complementarity. Both of these complementarities worked hand-in-hand with the redundancy of information found between the artifacts, as the students explored and reasoned about the same features, quantities, and relationships across the different artifacts. At the same time, the antagonism between the different ways each artifact encoded this information offered a constructive space for the students to reason emergently (Moore & Thompson, 2015) across these different contexts and especially to make covariational meaning of their graphs.

Our analysis contributes to an expansion of Soury-Lavergne's (2021) work to include two possible subcategories of complementarity: callbacks to previous artifacts to support the creation of subsequent artifacts and revisions of reasoning based on the exploration of other related artifacts. More studies are needed to further investigate these identified subcategories and to look for other possible forms of complementarities, redundancies, and antagonisms in different sets of data. There is also a need to examine the similarities and differences in the progressions of reasoning among other students. For instance, it would be interesting to examine the progressions of other pairs who did not immediately reason emergently as they transitioned to the table and graph, and how the synergy between the artifacts may have influenced such progress.

Acknowledgments

This research was supported by a grant from the National Science Foundation (#1742125). The data presented, statements made, and views expressed are solely the responsibility of the authors. We would like to thank Jay Singh, Debasmita Basu, Sowmith Etikyala, and Anthony Cuviello for their help in the design of the simulation and activities.

This report focuses on problems of practices identified by 209 respondents to an electronic survey in spring 2020 and the ways MTEs called upon their TPACK to address these problems. From the data, eight problems of practice emerged: changing pedagogy to account for online contexts, rehearsals of teaching, monitoring in class student learning, student engagement, assessment, sense of community, mathematical manipulatives, and communication of mathematical concepts. Results indicate that MTEs addressed these problems, altering their teaching by adopting many new technologies and functions. These included: video conferencing applications, Desmos, virtual manipulatives, GeoGebra, Google Slides, Google Docs, Flipgrid, videos/webinars, and discussion boards. Implications for MTEs who teach or are interested in teaching online are discussed.

Keywords: Technology, Online and Distance Education, Teacher Educators

In March 2020, mathematics teacher educators (MTEs) were tasked with a rapid transition to emergency remote teaching (ERT) in response to the worldwide COVID-19 pandemic. Drawing from previous experience and accessible online resources, MTEs quickly redesigned courses to be delivered in remote synchronous and asynchronous formats. Using a survey research approach, this study examined MTEs' perceptions of transitioning their teaching to ERT, and how it impacted the quality of instruction they delivered. In the analysis of the data, we asked, what problems of practice emerged from this experience and what types of technologies were used to address them? Our work aims to describe the ways MTEs transitioned to ERT and to identify technologies that can be carried forward into future instruction of all course delivery formats (in-person, remote synchronous, remote asynchronous, hybrid).

Literature Review

Technological Pedagogical Content Knowledge (TPACK) is constructed from the interaction of individual contributing knowledge domains: Pedagogy, Content, and Technology (Angeli & Valanides, 2009). This interaction is often modeled by a Venn diagram of overlapping circles (see Figure 1) associated with each domain (Mishra & Koehler, 2006; Niess, 2005).

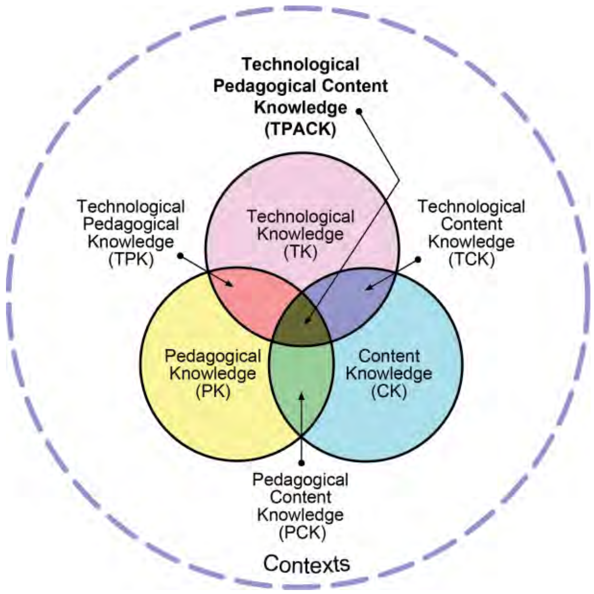

Figure 1. Mishra's (2019) updated TPACK framework.

While there are sub-sections of TPACK represented by the different shaded regions (PCK, TPK, etc.), TPACK should be thought of as a total package, more than the sum of its parts (Niess, 2005). Furthermore, Koehler and Mishra (2008) discussed how classroom contexts vary greatly, and thus there is a wide variation in the ways teachers implement their TPACK. Mishra (2019) later changed the Context in the TPACK framework to ConteXtual Knowledge (XK) to highlight that all of the knowledge domains exist in a space enclosed by the Contexts of the learning.

Porras-Hernandez and Salinas-Amescua (2013) focused on how Context influences the TPACK and represented context as concentric circles surrounding the whole, with micro (in-class learning conditions), mezzo (building or district conditions), and macro (societal conditions) factors. Much has been written about TPACK and its impact on instruction. Rosenberg and Koehler (2015) noted that only 36% of the literature on TPACK mentions Contexts, and less (14%) discusses macro-level factors. However, in Spring 2020, MTEs experienced an almost universal impact on the macro-level ConteXtual factors and this directly influenced the mezzo and micro factors. Our work leveraged this opportunity to study the ways their TPACK brought MTEs through this change.

Methods

Using the most updated understanding of TPACK (Mishra, 2019), we developed survey questions aimed at understanding how the TPACK ConteXtual change of ERT was experienced by MTEs. The Mathematics Teacher Educators' Migration to Online Teaching in Response to COVID-19 survey was for MTEs' classes that support a mathematics teacher education program for undergraduate and/or graduate students. Seven expert MTEs, an instructional technology expert, and a survey construction expert all worked to establish content validity of the survey. Two pilot surveys were given to MTEs to validate the questions. The revised survey was sent to members of the Association of Mathematics Teacher Educators in May 2020. The survey included nine demographic questions, 14 Likert scale questions, and three open-response questions.

The results of the Likert responses were compiled and all mentions of technologies were tallied and classified by type. The short answer responses were analyzed consistent with a modified version of the Qualitative Hypothesis-Generating approach (Auerbach and Silverstein, 2003). In each open response, all Relevant Text to the research question was identified. The list of Relevant Text was sorted into Repeating Ideas. From the Repeating Ideas, Themes emerged. When placed alongside the MTEs' Likert responses, the Themes told the story of MTEs instructional experiences during Spring 2020.

Results

Mentioned technologies were classified as either conveyance technologies or mathematical action technologies (Dick & Hollenbrands, 2011). C*onveyance technologies* are those used to present, communicate, share, and assess information. In contrast, *mathematical action technologies* are those like computer algebra systems and dynamic geometry software. Table 1 details the most commonly mentioned technologies in the survey results.

Table 1: Frequency and Types of Technology Used

Technology	Unique Mentions	Technology Type
Video Conferencing App	46	Conveyance
Virtual Manipulatives	14	Mathematical Action
Desmos	11	Mathematical Action
GeoGebra	9	Mathematical Action
Google Slides	7	Conveyance
Flipgrid	5	Conveyance
Google Docs	5	Conveyance
Discussion Boards	5	Conveyance
Webinars/Videos	4	Conveyance

While conveyance technologies were most mentioned overall, there was a strong presence of mathematical action technologies ($n = 34$) among the most commonly mentioned technologies. The results indicate that both types were critical to supporting MTEs as they transitioned to ERT.

In the open-ended responses, participants shared Repeating Ideas that we classified into eight problems of practice. These problems were: Changing pedagogy to account for online context, Rehearsals of teaching, Monitoring in-class student learning, Student engagement, Assessment, Sense of community, Mathematical manipulatives, and Communication of mathematical concepts. For example, one participant shared challenges related to *Monitoring in-class student learning*:

> My classes are designed around small group activities. We were able to continue these activities with Zoom breakout rooms, but my ability to monitor and interact deeply with each group was really slowed by Zoom. Unlike a physical classroom, it's impossible to catch elements of every group's conversation at once, and there is a bit of time needed to switch from breakout room to breakout room (and joining a new room can be quite disruptive to the students). (Participant #57)

To further illustrate, another participant identified challenges related to *Rehearsals of teaching*:

> The changes for my elementary methods course were significant and mostly negative. We no longer were able to complete 3 visits to work with an elementary school student and students

weren't able to practice teaching in front of their peers. Also, I had to replace classroom discussions with short written reflection papers due to my class being asynchronous, which meant that students no longer had the benefit of hearing their peers' perspectives. (Participant #104)

Through our analysis, we began to connect the problems of practice with technologies implemented to address those challenges. In these connections, we were able to see how MTEs used their TPACK to carry them through the ConteXtual changes in Spring 2020. Table 2 details these connections and can act as a resource for MTEs facing similar challenges.

Table 2: Problems of Practice Correlated with Technology Used

Problems of Practice	Mentioned Technologies
Changing pedagogy to account for online context	Flipgrid, Screencastify, Zoom videos
Rehearsals of teaching	Discussion rooms, Flipgrid
Monitoring in-class student learning	Google Docs, Jamboard, Desmos, Google Slides, Padlet, Breakout rooms
Student engagement	Breakout rooms, chat, Google Docs
Assessment	Flipgrid, Canvas, Blackboard
Sense of community	Chat, Breakout rooms
Mathematical manipulatives	Virtual manipulatives, Desmos, Zoom polls, Google Slides, Google Docs, GoodNotes
Communication of mathematical concepts	Virtual manipulatives, Desmos, Zoom polls, Google Slides, Google Docs, GoodNotes

Discussion

The rapid transition to ERT had a universal impact on the TPACK Context of MTEs. While some of this transition was negative, there is much to be learned from our collective experience. Using their TPACK, MTEs implemented technologies to solve problems in new and innovative ways. Problems of practice will persist in different forms as we move forward, and this work helps us identify the technologies that can mediate these problems. We can use these identified technologies as a resource for solutions, as inspiration for professional development, and as ways to address new problems that we are yet to encounter. The pandemic pushed us into isolation, but this work brings to light new innovations as we have gathered together again.

Asynchronous, online mathematics teacher professional development (PD) was designed to align with research on teacher professional learning as well as to support Communities of Inquiry (e.g., Garrison et al., 2000). The intervention included two actively facilitated formats and a structured independent condition, where facilitation was integrated into the design of the intervention. Participants' responses to intervention activities were analyzed using indicators of Garrison et al.'s Community of Inquiry framework, seeking to understand the ways in which the intervention enabled participant learning across facilitation formats. Analysis has implications for building the CoI framework into subsequent online asynchronous mathematics teacher PD as a way to increase teacher learning, build community, and effectively scale interventions.

Keywords: Professional Development, Teacher Knowledge, Online and Distance Education, Technology

Significance and Purpose

High-quality professional learning is widely accepted as a core component of effective teaching and learning and meaningful school reform (Borko et al., 2014; DeMonte 2013; Heller et al. 2012; Polly et al. 2015; Yoon et al. 2007). Online teacher professional development (PD) opportunities are poised to play a key role in bringing meaningful, effective professional learning to teachers on a broad scale (Killion, 2013), with experts in the field as well as policy makers advocating for more teacher PD to be delivered online (Dede et al., 2009, 2016; US Department of Education, 2010). While the range of potential designs for online PD is vast, offerings can generally be categorized as synchronous (all participants interacting in real time) asynchronous (participants work with materials at their own pace for submission and later feedback), or hybrid (involving both synchronous and asynchronous components) (Fishman, 2016).

A general consensus has emerged within the field regarding the design features of PD most likely to impact teacher and student outcomes, both in general and in mathematics specifically, such as sustained duration, content area-specificity, coherence, active/practice-based learning, collaboration, access to models of effective practice, and expert facilitation/coaching (Elmore, 2002; Garet et al., 2001; Loucks-Horsley et al., 2010; Darling-Hammond et al., 2017); how to integrate these elements in an online setting is less clear. Teachers report that the ability to access online PD anytime is very or extremely important (Parsons et al., 2019), and asynchronous forms of online PD have resulted in positive findings related to teachers' attitude and self-efficacy (An, 2018) as well as high satisfaction and relatively high levels of information sharing (Yoon et al., 2020).

This paper focuses on the ways that careful design choices support the development of a community of inquiry in an online, asynchronous video-based PD—*Video in the Middle: Flexible Digital Experiences for Mathematics Teacher Education* (VIM). A major goal of the VIM project was to demonstrate that online, asynchronous video-based teacher PD can be designed and implemented that both embodies the features recognized by the field as characterizing effective, high-quality professional learning and also democratizes such PD by increasing teacher access to engaging, meaningful practice-based professional learning.

Theoretical Framework

To integrate attention to key learnings about mathematics teacher PD with research on asynchronous online learning, the VIM project design and development is theoretically grounded in key literature on Communities of Inquiry (CoI; Garrison et al., 2001). The CoI framework emphasizes three crucial elements of a successful educational experience: cognitive presence, social presence, and teaching presence. According to the CoI framework, worthwhile learning occurs through the interaction of these three core elements.

Cognitive presence is “the extent to which the participants in a community of inquiry are able to construct meaning through sustained communication” (Garrison et al., 2001, p. 89; Anderson et al., 2001; Garrison & Archer, 2000). Garrison has argued extensively that “asynchronous online learning can create a rich cognitive presence capable of supporting effective, higher-order learning” (2003, p. 47). He suggests that this is best accomplished through a cycle of practical inquiry where participants move through four phases: (1) a *triggering* event where a problem is identified for further inquiry; (2) *exploration*, where an individual explores the issue; (3) *integration*, where learners make meaning from ideas generated during the exploration phase; and (4) *resolution*, where participants apply new skills and knowledge.

Social presence is defined as the ability of participants to project their personal characteristics into the community, thereby presenting themselves to the other participants as ‘real people,’ facilitating both enjoyment of the experience as well as the process of critical thinking they undertake (Rourke et al., 1999; Anderson et al., 1999; Garrison et al., 2001). It supports cognitive presence (and therefore cognitive objectives) through its ability to instigate, sustain, and support critical thinking among a community, and also plays a role in participant retention by ensuring that participants find interactions enjoyable and fulfilling. Richardson and Swan (2003) found that social presence positively affects both student and instructor course satisfaction, and participants who perceived high social presence learned more than those who perceived low social presence (Richardson & Swan, 2003).

Teaching presence—the intentional design, facilitation, and direction of cognitive and social processes—has three components: (1) instructional design and organization; (2) facilitating discourse; and (3) direct instruction (Garrison et al., 2000; Anderson et al., 2001; Garrison & Arbaugh, 2007). It is theorized to support and enhance social and cognitive presence.

Video in the Middle (VIM) Project Design

Drawing on the existing face-to-face PD *Learning and Teaching Linear Functions: Videocases for Mathematics Professional Development* (Seago et al., 2004), the VIM project created 40 asynchronous online mathematics PD modules and researched their effectiveness. Each two-hour module is centered around a purposefully selected video clip from a real mathematics classroom and designed to facilitate teachers’ noticing skills (van Es & Sherin, 2002) and mathematical knowledge for teaching linear functions (Ball & Bass, 2002). VIM modules are designed to be rich, research-based, open education resources that can be used in a wide variety of settings with less up-front time and resource investment than many other high-quality offerings. The modular nature of the design means that school/district PD providers can select particular modules or series of modules they feel meet the needs of their teachers, or they can choose pre-selected “pathways” of modules sequenced by the VIM research and design teams to address specific learning goals. Modules can be implemented in either a facilitated format where a PD leader responds to participants' contributions asynchronously, or in a structured independent format where participants engage in activities and respond to fellow participants' contributions without monitoring or active facilitation from a PD leader.

VIM Module Design

Each module includes the same series of common activities across three phases. In the pre-video phase, participants are introduced to the learning goals related to mathematical content knowledge and pedagogy (Seago et al., 2018). They then solve and reflect on a math task, post their work on a Community Wall, and comment on others' work. In facilitated formats, facilitators also respond to posts. Participants also consider a variety of solution strategies for the task and review a brief "Mathematician's Commentary" on the task. In the video phase, participants review the context of a video clip where students explore the task, watch the video, and analyze it through the lens of a set of framing questions. They also re-examine the solution methods in connection to the video clip and annotate an excerpt from the video transcript. They then re-watch the video with a different framing question, annotate moments in the video, and respond to annotations from fellow participants, expert math educators, and, in facilitated formats, facilitators. In the post-video phase, participants complete a reflection in response to a prompt related to the module learning goals, post their reflection on a Community Wall, and respond to others' posts. The module concludes with teachers engaging in a "Bridge to Practice" activity that asks them either to consider how they might incorporate new strategies and ideas into their own classroom practice or respond to an artifact of practice through the lens of what they have learned.

Pre-video Activities	Video in the Middle	Post-video Activities
0. Introduction to learning goals 1. Explore math task and reflect in journal 2. Share your work on the math task 3. Consider other solutions and perspectives	4. Review the context of the lesson 5. Watch video and reflect 6. Reflect on the lesson graph and solution methods 7. Annotate video transcript 8. Watch video with math educator commentary	9. Module reflection 10. Bridge to practice

Figure 1: Overview of VIM module common learning activities

Cognitive Prescence, Social Prescence, and Teaching Presence in VIM Module Design

VIM modules were designed to embody the three core elements of a community of inquiry as described by Garrison et al. (2000, 2001). Cognitive presence was built into each VIM module in the form of multiple practical inquiry cycles—for example, around the math task activity and the central video phase (table 1). Each module comprises a larger-scale practical inquiry cycle as well.

Table 1: Alignment of elements and categories of Community of Inquiry framework (Garrison et al., 2001) with VIM module activities

Categories	*Opportunities in VIM Modules*	
Triggering Event	Introduction to math task	Introduction to video (context and frame)
Exploration	Solving & reflecting on math task; sharing & comparing solution strategies	Exploring other ideas about video (math educator, facilitator, other participants)

Integration	Responding to/discussing solution strategies	Responding to/discussing video commentary
Resolution	Reconciling alternative solution methods & mathematician commentary with own ideas & method	Bridge to Practice activity

VIM modules promote social presence through Community Walls where participants post and respond to others' math task solutions and reflections as well as activities where they analyze, comment on, and respond to others' comments about the video and transcript. Prompts included:

- "After you have posted your work, take some time to look at the solutions of others. What do you notice? What do you wonder? Add comments to the posts of your peers and/or create a new post to add a general comment on the wall. Please check back later if you are the first to post."
- "As you watch, post comments at the points during the video that highlight how Debra probes Siri to explain further and how Debra's moves support Tiffany to make her explanation clearer for the class. Feel free to pause the video when reading comments and respond to them if you'd like."

In facilitated formats, facilitators also respond to posts.

The video task was also designed to foster social presence; Sherin (2004) points out that video is similar to authentic experience in that it positively affects motivation and interest. Multiple studies have found that there exists a higher level of satisfaction when teacher education courses use video rather than narrations of experience (Choi & Johnson, 2007; Moreno & Valdez, 2007).

Categories	*Opportunities in VIM Modules*	
Affective, Interactive, and Cohesive Responses	Math task Community Wall interactions	Video commentary interactions

Teaching presence was built into each VIM module with a team of veteran math educators, researchers, and educational technology designers who worked on the design and organization, without the assumption that a member of the design team would facilitate the module. Available pre-sequenced "pathways" of VIMs are another example of instructional design and organization. While in online, asynchronous settings, facilitation of discourse is often carried out by an instructor or facilitator commenting on responses, raising questions to move discussions in a particular direction, keep discourse moving efficiently, and balance participation, Garrison et al. (2000) note that facilitation is a responsibility that may be shared among some or all participants in the learning experience, particularly with adult populations. To facilitate discourse, the VIM modules, and particularly the framing and reflection questions that wrap around learning activities, guide and focus participants' interaction around the module artifacts and materials. Facilitator training materials further support PD leaders in responding to posts and guiding discussion to achieve the module learning goals. In VIM modules, subject matter knowledge is injected strategically as direct instruction through pre-selected and sequenced artifacts such as the Solution Methods document, the Mathematician's Commentary on the task, pre-embedded expert commentary on the video and transcript, and professional readings used to frame Bridge to Practice activities. To increase interaction and help participants to recognize the developmental progression of the inquiry process (Garrison & Arbaugh, 2007), VIM modules include metacognitive journal and Community Wall activities that prompt participants to consider how the module activities influenced their understand and beliefs about mathematics teaching and learning (for example, "I used to think… Now I think…").

Research Design

California middle and high school teachers were recruited to participate in a Spring 2020 pilot study to address the following research question: *Which elements of the CoI framework were evident in teacher and facilitator responses?* All teachers experienced the same sequence of four, two-hour modules for a total of eight hours of professional development over the course of twelve weeks (February through April 2020). Modules were offered in three formats: (1) project staff-facilitated (n = 17), (2) district leader-facilitated (n = 18), and (3) structured independent (n = 26). Teachers in each of the two district leader-facilitated cohorts were all from the same district, while the other two groups included teachers from various districts.

All three formats included a content focus, the same asynchronous opportunities for sharing solution methods and written reflections with colleagues, and attention to bringing what they learned into practice. Facilitated formats differed from the structured independent format in two ways: 1) pace (project-staff and district-facilitated formats asked teachers to complete one module every two weeks, while teachers in the independent format worked at their own pace, and 2) the role of the facilitator. As a clear and well-defined structure to each VIM module was established during the design phase reflecting research on teacher PD, attention to student thinking, and the importance of teacher reflection, the role of the facilitator in both the project staff- and district-facilitated formats focused on commenting on teachers' posts, encouraging teachers to complete modules, and responding to journal reflections. Project and district facilitators participated in a 90-minute video-conference orientation with project staff, including an overview of the study and timeline, VIM module structure, and online tools. Facilitators also had access to a web-based facilitator guide and video tutorial demonstrating how to use the online tools to respond to participants.

Participants

Participating teachers taught middle school math, Algebra 1, or a first-year high school math course such as Math 1 or Integrated 1.

Teachers in the district leader-facilitated condition were recruited by mathematics leaders from each of two school districts; each of the two leaders then served as the facilitator for their district group. Additional teachers were recruited from across California and randomized into either the structured independent condition or the project staff-facilitated condition. Where multiple teachers were recruited from the same district, teachers were randomly split between the two conditions. Where single teachers were recruited from a site, singleton teachers were matched by similar site location or demographics; matched pairs were then randomized into the two conditions. Of the 68 teachers who began the study, 82% completed all or nearly all study activities across the four modules.

Data Collection

In both facilitated and independent VIM cohorts, participants had eight opportunities (two opportunities per module) to engage with others' posts via Community Walls. Rourke et al. (2001) identify three categories of social presence indicators: **affective** responses (expressions of emotion, feelings, and mood), **interactive** responses (threaded interchanges of socially appreciative messages), and **cohesive** responses (serving to build and sustain a sense of group commitment). Posts and replies from all Community Walls in all cohorts were analyzed for evidence of social presence. Each post and reply showing evidence of social presence was categorized as an affective response, an interactive response, or a cohesive response. Posts and replies were categorized as *affective responses* if they included emoticons, exclamation points, or other text intended primarily to communicate mood or emotion (Kuehn, 1993; Gunawardena & Zittle, 1997). Replies were categorized as *interactive responses* if they expressed social appreciation for the original post or a previous reply. Posts and replies were categorized as *cohesive responses* if they included phatics (communication which serves to establish or maintain social relationships rather than to impart information), salutations, vocatives (addressing participants by name), or addressing the group as "we," "our," or "us." Percentages of posts showing evidence of each category of social presence were calculated for each of the three facilitation formats.

All participants also had four opportunities to engage with others' posts as well as pre-entered "Mathematics Educator" posts in the video analysis activity, an example of teaching presence through direct instruction. Responses to these posts were reviewed for evidence that they had impacted participants' thinking about the video clip or prompted them to engage in deeper reflection around moments or interactions referenced by the Mathematics Educator posts.

Findings and Discussion

Evidence of Social Presence in VIM Modules

Analysis of participants' Community Wall responses across both facilitated and independent cohorts revealed examples of affective, interactive, and cohesive responses. Analysis of Community Wall posts found that numerous posts in all three participation formats either contained or inspired replies/rejoinders that contained evidence of affect (14.8% locally facilitated, 37% project-facilitated, 10.5% structured independent):

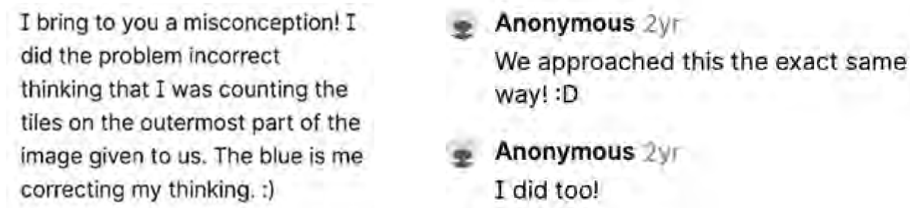

Figure 2: Affective responses in facilitated (left) and independent (right) VIM cohorts

Interactive responses were the most common type of response across all three cohorts (43.7% locally facilitated, 65.2% project-facilitated, 33.7% structured independent), with participants routinely commenting in socially appreciative ways on others' math work or reflections in response to what they found interesting or raised questions for them.

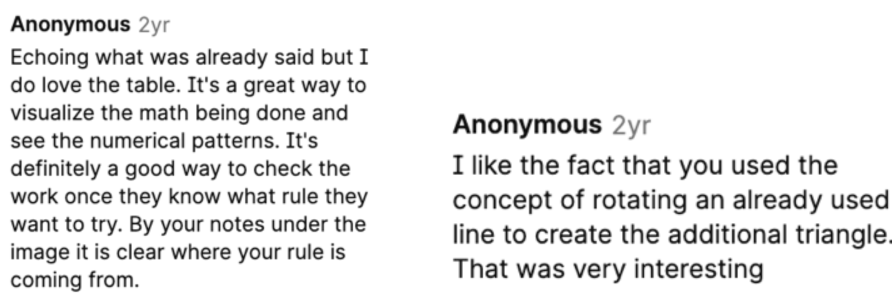

Figure 3: Interactive responses in facilitated (left) and independent (right) VIM cohorts

Cohesive responses were the least common type of response across all cohorts, with only a few examples in each (5.2% locally facilitated, 3.7% project-facilitated, 4.4% structured independent). We hypothesize that this was due in part to technological limitations that defaulted to anonymous posts and replies.

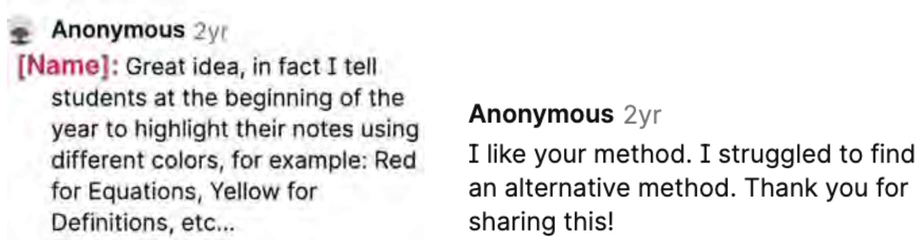

Figure 4: Phatics and vocatives as indicators of cohesive responses in facilitated (left) and independent (right) cohorts

Evidence of Teaching Presence in VIM Modules

Of the three core elements, it is perhaps teaching presence which is the least obvious in terms of how effectively it is accomplished in VIM modules given that they are designed to be used with or without active facilitation; even when used with a facilitator, interaction is significantly lighter touch as compared to the role a facilitator might play in other PD experiences. We have already seen the manner in which the intentional design and organization of VIM modules contributes to both cognitive and social presence through the selection of tasks and video, module goals, framing and reflection questions, and Community Wall prompts.

We can see evidence of the impact of direct instruction when participants are asked to comment on moments in the video and respond to other comments, including comments pre-inserted by the design team to draw teachers' attention to key moments in the video and encourage discussion around them (figure 5).

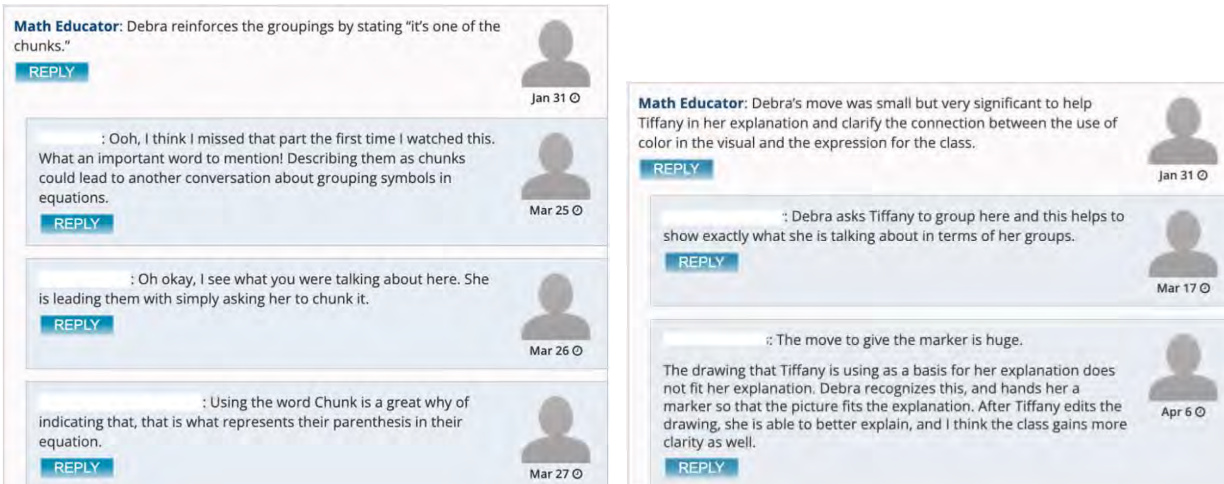

Figure 5: Positive participant responses to pre-inserted video comments from facilitated (left) and independent (right) cohorts

In facilitated cohorts, facilitation of discourse was moderately provided by human facilitators monitoring and responding to posts in order to guide discussion and probe participants' thinking. In both facilitated and structured independent cohorts, a level of in-the-moment facilitation was also provided by participants interacting with module elements/resources such as the mathematical task work, others' perspectives on the mathematics, and most critically, the central video clip. We hypothesize that the unique nature of authentic classroom video described by Sherin (2004) and the intrinsic motivation and interest it inspires for teachers in combination with the prompts, framing questions, and reflection questions fosters a level of discourse that may not otherwise be achieved in an asynchronous, online PD experience.

Conclusion

If schools and districts are to scale quality PD in a cost-effective and widely accessible manner, innovative tools and strategies that do not rely on individual providers spending extensive face-to-face time with small groups of teachers are needed (Cai et al., 2017). Highly structured online asynchronous PD opportunities—with or without active facilitation—may have a role to play in bringing effective, flexible professional learning to a significantly wider audience if they are designed in a way that reflects features of effective PD recognized by the field and supports the development of communities of inquiry. The VIM module design and pilot study provide promising evidence that this can be accomplished, while also pointing us to possible new directions for future development and research.

In particular, greater social presence may be accomplished through technology that avoids anonymous posts and allows for participant profile information and photos. Specific prompts could also be added to encourage participants to revisit previous Community Walls to review and engage with new posts. Additional opportunities for interaction with fellow participants could also be created, for example in relation to the "Bridge to Practice" activities.

There is a prevailing notion that online course modalities present challenges to teaching in ambitious ways, and thus to modeling ambitious teaching for pre-service and in-service teachers. In this paper, we report on the results of an exploratory analysis of one mathematics teacher educator's efforts to model ambitious teaching in a synchronous, online mathematics education course. We report on both the online tools central to this effort and the teaching moves for using those tools effectively. In so doing, we highlight how the teacher educator's decision to be transparent about the challenges involved in adapting instruction to an online environment presented further opportunities to model the kind of instructional experimentation central to ambitious teaching.

Keywords: Online and Distance Education, Technology, Pre-service Teacher Education

A primary goal of many mathematics education courses is to support participating teachers in learning to teach in ambitious and equitable ways, such that they can support students' attainment of rigorous mathematical learning goals (Kazemi et al., 2009). Ambitious and equitable teaching empowers students to engage in complex problem-solving and to reason mathematically. As teachers elicit and respond to students' contributions, they position students as being mathematically competent (Lampert et al., 2009) and broaden opportunities for discourse (Ghousseini et al., 2017). Ambitious and equitable teaching is, however, challenging and complex work. Mathematics teacher educators (MTEs) can support teachers in learning to enact ambitious and equitable teaching by modeling this type of teaching in education courses (Lampert et al., 2010), thereby providing teachers with opportunities to see what it looks like to enact this type of teaching effectively. Developing such a vision is an essential step in teaching in ambitious ways with students (Munter & Correnti, 2017).

Several issues, including the ongoing COVID-19 pandemic and declining enrollments in teacher education programs, have prompted many colleges and universities to shift their programs online. Many teacher educators have claimed that this shift in course delivery method presents challenges for teaching in ambitious ways (Thompson et al., 2021), and thus for modeling ambitious teaching for pre-service and in-service teachers. In many cases, these presumptions have been based on the very real challenges teacher educators faced when they rapidly transitioned courses previously designed for face-to-face instruction to emergency remote teaching (Hodges et al., 2020). Yet, it is entirely possible that carefully planned online learning experiences in mathematics teacher education can provide opportunities for teachers to see ambitious teaching in action. For example, Jung and Brady (2020) highlight the value of breakout rooms and shared Google Docs in building social norms and dialogic interactions that support reasoning and problem solving within a community of learners. Unfortunately, very few studies have closely examined the ways in which MTEs can use online teaching tools to model specific forms of ambitious teaching for teachers.

In this paper, we report on the results of an exploratory analysis of one MTE's (hereafter referred to as Professor K) efforts to model ambitious teaching in a synchronous, online mathematics education course. We focused our analysis on Professor K's efforts because the participating pre-service and in-service teachers indicated on course exit tickets and end-of-course evaluations that they had ongoing opportunities to experience ambitious teaching, despite the online modality of the course. We therefore determined that it would be illuminating to examine how Professor K provided those opportunities for the teachers in the synchronous online course. We investigated the following research questions: How did Professor K model ambitious teaching in an online, synchronous mathematics education class? What technologies did he use to model ambitious teaching in a synchronous, online mathematics education course? What instructional moves were associated with his use of the technologies?

The Synchronous Online Mathematics Education Course

The mathematics education course that is the focus of this analysis took place in a school of education at a large, public university in the Mid-Atlantic of the United States. Four pre-service teachers and four in-service teachers were enrolled in the 14-week course. Each of the weekly sessions was conducted online and synchronously over the Zoom video conferencing platform. Almost all students kept their cameras on for each class period, even though it was not required. Notably, our analysis of Professor K's teaching was retrospective, meaning Professor K was unaware of the focus of our research at the time of his teaching.

The course was designed to support teachers in deepening their mathematical knowledge for teaching in the middle grades. To accomplish this, Professor K broke the course into two-week units, each of which focused on the processes of students' learning, as well as the means of supporting that learning, for different mathematical domains relevant to teaching middle grades mathematics (e.g., ratios and proportions or expressions and equations). In other words, instead of focusing each lesson solely on mathematics, Professor K designed the lessons such that the class engaged with mathematics as teachers. While the focus of the lessons changed over the course of the semester, the general structure of each lesson stayed relatively consistent. Professor K organized each lesson around a set of editable Google slides. The slides included links to Jamboards, so that students could represent their mathematical thinking; links to Google documents that included pictures or representations of students' work; and designated writing spaces through which teachers could record their thinking and share it publicly over Zoom.

Because all eight of the participants were also in their student teaching internships, Professor K designed the course such that the activities in which teachers engaged mirrored the kinds of activities they might implement with their students. This meant he designed each lesson to provide the participating teachers with opportunities to see ambitious teaching. For example, in almost all lessons, Professor K engaged the teachers in several problem-solving tasks, each of which followed a general structure. First, he would introduce the class to a task, and thus model how teachers can support broad and active engagement. Professor K would then instruct the class to work on the task in small groups using breakout rooms. During these small groups, he would ask assessing and advancing questions and thus model listening to and responding to students' intellectual contributions. Finally, he would bring the class together to discuss their work in the primary Zoom room. In these discussions, Professor K routinely asked teachers to restate or build on previously shared ideas, in the process positioning them as being mathematically and pedagogically competent.

Conceptualizing Ambitious Teaching

In this paper, we define ambitious teaching as teaching that supports all students in not only acquiring knowledge, but also understanding, using, and generating new knowledge to solve authentic problems (Lampert & Graziani, 2009). This kind of teaching is extremely complex. It requires adaptations to practice as teachers elicit, make use of, and respond to students' thinking. Because of this complexity, it is important for MTEs to represent ambitious teaching for teachers, as doing so can clarify what ambitious teaching looks like in practice (Lampert et al., 2013). Teacher educators can then decompose the work of ambitious teaching into learnable units, often called teaching practices (e.g., launching instructional tasks), and support teachers in learning to enact those practices effectively. Thus, we see it as essential for MTEs to model ambitious teaching as part of their work with pre- and in-service teachers in both face-to-face and online settings.

Methods

Data Collection

We collected the following data from the online, synchronous mathematics education course described above: (1) participants' responses to weekly class exit tickets, (2) participants' responses to mid-semester and end-of-course evaluations, (3) video recordings of Professor K's weekly lessons, and (4) artifacts from the weekly lessons, including the participating teachers' written work as they responded to questions on Google slides, their bi-weekly homework assignments, and teachers' work as they solved mathematics tasks using Google's Jamboard application. We also interviewed Professor K to clarify his decision-making.

Data Analysis

We conducted two phases of analysis to understand how Professor K used online tools to model ambitious teaching. In the first phase of analysis, we identified a representative episode of a lesson that (a) included the use of the online tools most typical of Professor K's instruction and in which he attempted to model ambitious teaching. This involved first reviewing the weekly Google Slide sets for the course to document the types of activities in which Professor K typically engaged the teachers. We then met as a research team to discuss the nature of the activities and to look for any commonalities among them. After this meeting, we wrote a brief memo in which we outlined a general structure for the types of activities that were most typical of Professor K's teaching. Almost all the course activities followed the general structure outlined above. We then looked across the video recordings for an activity in which Professor K used this typical structure and in which he clearly intended to model aspects of ambitious teaching. This activity became the focal episode for the second phase of the analysis.

In the second phase of analysis, we watched the representative episode and coded for the forms of ambitious teaching modeled and the online tools and technologies Professor K used when modeling those forms of teaching. We then conducted a second round of coding to understand how Professor K made use of the online tools and technologies. To conduct this finer-grained coding, we drew on the idea of teaching moves. Following Jacobs and Empson (2016), we define teaching moves as directly observable units of teaching activity that share a common purpose. One type of teaching move, for example, might involve a teacher (or, in this case, teacher educator) asking a question to elicit a mathematical strategy. In this example, the move features an observable form of teaching activity (asking a question) and a specific purpose for that activity (eliciting a mathematical strategy). Focusing on teacher moves enabled us to foreground the observable forms of teaching activity that appeared central to Professor K's use of the online tools to model ambitious teaching. We engaged in consensus coding for both rounds of coding. To conclude our work, we recorded the results of our coding in a table.

Findings

Over the course of the selected episode, the participating teachers had several opportunities to experience ambitious teaching in an online, synchronous classroom environment. For example, Professor K modeled how teachers can encourage broad and active engagement in conceptually rich problem-solving tasks by introducing (i.e., launching) the instructional task in such a way as to ensure everyone could get started but without telling them exactly how to engage in the task. As the teachers explored the instructional task during small-group work time, Professor K also asked questions and listened closely to their explanations, thereby modeling how teachers can elicit and respond to students' intellectual contributions. Additionally, Professor K modeled how to broaden opportunities for discourse and position students as mathematically competent, both by asking assessing and advancing questions in small-group work time to encourage previously quiet teachers to participate *and* by calling on specific teachers to share their thinking during the whole-group discussions.

These opportunities to experience ambitious teaching appeared to rely, in part, on Professor K's implementation of several online teaching tools. Further, we found that Professor K made several teaching moves that were central to his use of these online teaching tools to model ambitious teaching for the participating teachers. Table 1 shows the online teaching tools and associated moves as organized by the phases of the instructional episode in which they occurred (i.e., the task introduction, independent and small-group work time, and concluding whole-class discussion).

In what follows, we describe the online teaching tools and many of the associated moves for each of the three phases of instruction, in the process outlining how they enabled Professor K to model ambitious teaching.

Task Launch Phase

In this phase of the episode, Professor K introduced the focal instructional task and told the teachers that they would work on the task in small groups. Professor K leveraged three online teaching tools to launch the task: (1) screen sharing Google Slides with participants in Zoom, (2) editable Google Slides that included hyperlinks to Google Docs, and (3) editable Google Slides that included templates for recording thinking during the instructional task. He used these tools to clarify expectations for what the teachers were expected to do on the instructional task and how they should participate in their small groups.

Clarifying Features of Instructional Task. Professor K shared his screen and showed the teachers the task prompt, which was written into an editable Google Slide. As shown in Figure 1, the instructional task asked the teachers to analyze students' work for a mathematics problem involving ratios and proportions. Professor K made both verbal and visual teaching moves to guide teachers through the task prompt. First, he employed in-the-moment text highlighting to emphasize his verbal instructions as he read aloud the task. Because the teachers had both shared access to the Google slides *and* Professor K was sharing his screen, the teachers were able to follow along visually with his verbal instructions.

Professor K then demonstrated how the teachers were expected to click a link in the editable Google Slides to access the students' work (see Figure 1). This ensured that the teachers were aware of how they could access the student work, and were thus able to begin working on the instructional activity. Finally, in showing the teachers the student work, Professor K noted that the student work might look different from how the teachers would typically solve such a mathematics problem.

Table 1: Teaching Moves Associated with Modeling Ambitious Teaching in Online Education Course

Phase of Episode	Online Teaching Tools	MTE Teaching Moves
Launch Introducing task to teachers	● Expectation Google Slides to establish activity goals and norms for group participation ● Hyperlinks to Google Docs for viewing student work ● Task Templates in Google Slides assigned to each small group to prompt conversation	● Share screen with task information, highlighting text on slides for emphasis ● Set expectations for interacting in the online environment ● Acknowledge difficulty of task ● Give instructions both verbally and on Google Slides ● Assign random groups ● Set up the Explore phase by suggesting group roles (Notetaker, Spokesperson, Timekeeper) ● Set an 8-minute timer
Explore Facilitating small group analysis of student work	● Zoom Breakout Rooms for small group conversations ● Task Templates in Google Slides for monitoring student progress in real-time and recording student thinking	● Give teachers 3 minutes of think time as a group ● Listen without guiding the direction of teacher conversations ● Ask purposeful content questions about proportional reasoning ● Set up Summarize phase by validating, suggesting, and encouraging participation
Summarize Synthesizing emergent themes in a whole group discussion	● Task Templates in Google Slides for instructors and teachers to compare and contrast noticings, wonderings, and connections ● Screen sharing to focus teachers' attention on individual group contributions ● Chat for participating non-verbally ● Chat for monitoring and acknowledging teacher questions and comments	● Frame whole-group discussion by referring to task templates ● Remind teachers about the goal of synthesizing themes ● Expect each group to share their thinking ● Encourage groups to question each other ● Validate class-related conversations in the chat ● Summarize big/ideas without over-contributing

He then explained that the differences between the teachers' own strategies and the students' strategies were intended to provide them with an opportunity to make sense of students' thinking on their own, thereby highlighting that the teachers were engaging in a challenging task that involved instructional problem solving. By spending time showing the teachers how they could access the instructional task, Professor K ensured that they felt prepared to engage in a complex task in an online learning environment.

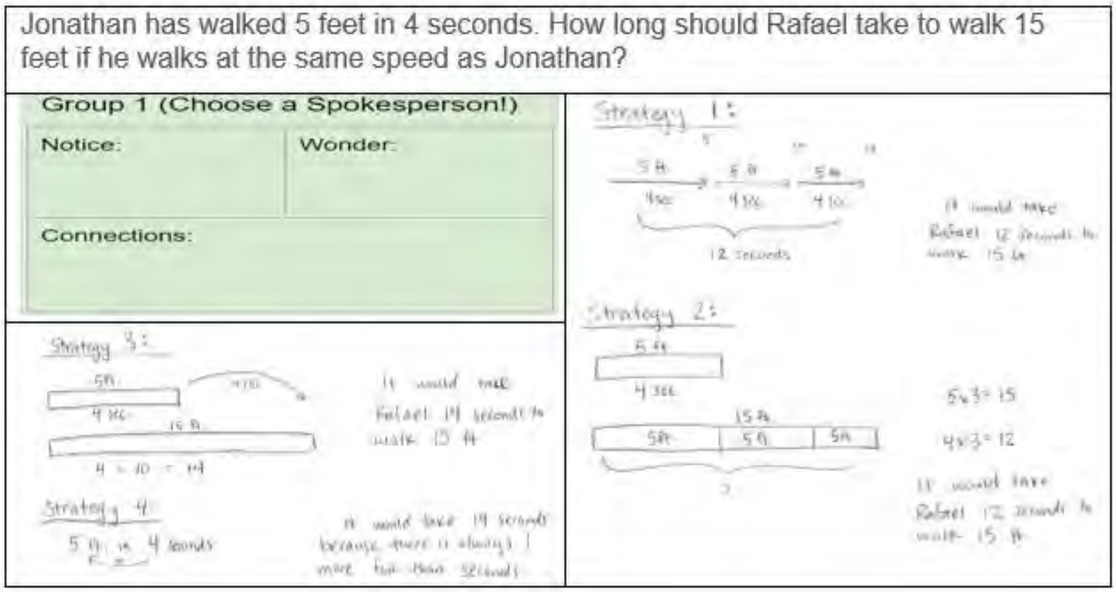

Figure 1: Walking Speeds Task

Clarifying Group Work Expectations. In addition to explaining the features of the instructional task, Professor K briefly outlined expectations for how the teachers should engage with one another as they worked in small groups. Prior to opening up the breakout groups, he encouraged the groups to assign their own roles (notetaker, spokesperson, and timekeeper to move conversation forward). This allowed the teachers to define their own participation and suggested ways in which the teachers could participate productively. He also assigned each group an editable Google Slide with a template for how the small groups could record the ideas they discussed. He then instructed the teachers to record their observations about the student work on their assigned slide. This move enabled Professor K to model a process for eliciting and making visible the teachers' thinking, and thus was an opportunity to model ambitious teaching. Further, by providing opportunities for both verbal and written communication, Professor K leveraged technology to broaden the teachers' access to the intellectual activity. As an aside, Professor K also paused to openly reflect on his efforts at continued growth in his own teaching, saying, "[I'm] trying to work on those directions - I have been trying to push myself on this." This also modeled how an improvement mindset is central to ambitious teaching.

Task Exploration Phase

In the exploration phase, Professor K supported broad and active participation in the small-group work time. He also modeled how teachers can elicit and respond to thinking. Professor K leveraged two online teaching tools to do so: (1) the editable Google Slides, which included templates for the teachers to record the results of their small-group work time and (2) the Zoom breakout rooms. He used the Google Slides to monitor all of the groups' thinking simultaneously, and visited the breakout rooms to elicit, listen to, and respond to that thinking.

Monitoring Progress in Google Slides. After releasing students to their breakout rooms, Professor K waited in the main Zoom room for approximately three minutes before checking in with the groups. This teaching move appeared to implicitly position the teachers as mathematically and pedagogically capable. It also appeared to encourage their engagement in small group discussions. As he waited, Professor K monitored the teachers' thinking by watching as they recorded their ideas on the editable Google Slides. When Professor K joined the breakout rooms, he was prepared to engage in the conversation, meaning he could more effectively model how teachers elicit and respond to thinking. Thus, within the exploration phase, the teachers had opportunities to both make meaning and simultaneously build virtual artifacts of their thinking, both of which are tenets central to ambitious teaching (Ghousseini et al., 2017).

Moving Between Breakout Rooms to Elicit, Listen to, and Respond to Thinking. After monitoring the teachers' written thinking on the Google Slides for three minutes, Professor K then entered each breakout room in turn. He spent approximately one minute in each room actively engaged in discussing the teachers' interpretations of the student work samples. The short duration of these breakout room visits communicated Professor K's confidence in the ability of each small group to make sense of the mathematics and the students' thinking.

In each visit, Professor K asked questions to elicit the teachers' thinking, listened actively as the teachers explained their thinking or discussed ideas with one another, and then asked additional assessing and advancing questions when appropriate. At times Professor K affirmed the productivity of the teachers' discourse with phrases like, "Yeah, kids think like that. Be sure to add it to your wonderings" and "You should feel like you can add that to your spokesperson's thoughts." At times he also challenged them to be ready to justify their mathematical thinking when sharing with the whole class, asking questions such as, "What do you mean by grouping?" He also prompted specific teachers to share ideas with the whole group. For example, when one of the small groups brought up a point of contention in their small-group discussions, he noted, "You should ask [the whole group] about that." Once he had checked in with each group, Professor K then moved back to the main room and continued to monitor the teachers' thinking by watching their written work on the editable Google Slides. This again positioned the teachers as both mathematically and pedagogically capable.

Summarizing the Task

In the summarizing phase, Professor K brought the teachers together to discuss their ideas as a whole group. Professor K made use of several online teaching tools during this phase of the episode, including: (1) the editable Google Slides, (2) screen sharing, and (3) the chat feature in Zoom. Throughout the summarizing discussion, Professor K reminded students of the expectations for discussing ideas in an online classroom. Specifically, he encouraged students to listen to the other groups by considering what was similar to or different from what they discussed in their own small groups. As he facilitated the summarizing discussion, Professor K attempted to both synthesize big ideas without over-contributing and also validate conversations between teachers that were occurring in the Zoom chat.

Synthesizing Big Ideas without Over-Contributing. To facilitate the discussion, Professor K shared his screen to display each group's slide in turn. This teaching move oriented the teachers to focus on one group's ideas at a time. By making this move, Professor K modeled how a teacher can facilitate discussion towards a learning goal while also avoiding the pitfall of over-contributing or over-facilitating. In other words, he chose which group would share and in what order, but he then left the subsequent discussion up to the teachers. Additionally, by sharing his screen, Professor K ensured the sharing groups did not have to worry about managing the online tools themselves, meaning they could focus on the ideas they wished to communicate.

Professor K also encouraged the teachers to question one another after the groups shared. Further, when this happened, Professor K pointed out that this was occurring in an online, synchronous class. For example, Professor K said, “We are starting to hear pushing on each other’s thinking - back and forth - which is exceptionally important for our class to be successful moving forward.” By making this comment, Professor K modeled how teachers can negotiate productive social norms, which are central to the success of ambitious teaching.

Validating Chat Conversations. Professor K also took advantage of the Zoom chat feature in the online learning environment to support broader student participation. For example, during the whole group discussion, Professor K paused, checked the chat, and noted that the teachers were “having a great conversation in the chat” without him. He highlighted this as a positive, saying, “It’s good to see people using that feature to their advantage.” This teaching move also modeled the importance of attending to varied means of participation in a lesson.

Discussion and Implications

This exploratory analysis of an online, synchronous teaching episode underscores that it is possible to model ambitious teaching in an online learning environment. We clarify how MTEs can model ambitious teaching in online mathematics education courses by highlighting several online teaching tools and instructional moves involved in the effective use of those tools. Our findings serve as a starting point for describing the work of ambitious online teaching and also point to strategies that other teacher educators might use in their own practice.

Further, the results of this analysis contribute to research aimed at characterizing effective online teaching approaches more generally (e.g., Carillo et al., 2020). Researchers often define effective online instruction as teaching that supports and facilitates a community of inquiry in which learners construct new forms of knowledge (Garrison et al., 2000). However, MTEs are obligated to not only support learners in constructing knowledge but also support them in developing as teaching professionals. In looking closely at Professor K’s instructional episode, we were struck by the very real *affordances* of an online learning environment for modeling the kind of adaptation and experimentation that is central to ambitious teaching. During instruction, Professor K was open about the intellectual challenge involved in teaching ambitiously in the online environment. He leveraged the complexities of modeling ambitious teaching in a synchronous online environment as an opportunity to lay bare his own developing practice in order for teachers to learn from his efforts to improve his teaching. In doing so, he normalized the importance of experimenting to improve, all in service of growing as a teaching professional.

Finally, while it is important for teachers to experience ambitious teaching as learners, it is also beneficial for teachers to see and consider the very real challenges involved in *learning* to teach ambitiously in a new context (Kazemi et al., 2018). Prior research indicates that supporting teachers to learn *from* models of teaching involves an explicit effort to press and support teachers to notice the instructional decisions and teaching moves represented in those models (van Es & Sherin, 2008). Though Professor K made occasional reference to his instructional decisions, these references were often spontaneous or general in nature. Future research might investigate strategies that MTEs can use to purposefully draw teachers’ attention to specific instructional decisions or moves when modeling in an online learning environment.

Engagement in the mathematics classroom through interactions with the instructor, peers, and content are necessary for an effective learning experience. As such, it is important to understand the types of interactions that teachers utilize to engage students, especially as they have had to shift from a complete face-to-face setting to various remote modalities. Utilizing four interaction types (learner-content, learner-instructor, learner-learner, and learner-interface) this paper analyzes 35 videos of classroom instruction with the purpose of describing the interactions that take place throughout the course of the mathematics lesson. While there was not a significant difference in the type of interaction and the modality of instruction, there was a significant difference in the type of interaction enacted and the modality of instruction.

Keywords: High School Education, Instructional Activities and Practices, Technology, Online and Distance Education

Introduction

While historically providing education through distance and remote learning at the K-12 level was reserved for gifted older students (Campbell & Storo, 1996), the technological advances have allowed for platforms and delivery systems that have made it a feasible means of stretching the walls of the classroom to reach all students (Offir et al., 2003). Teachers have had to contend with the preeminent mindset that distance education works best for independent, self-motivated learners (Chou et al., 2010; Corso et al., 2021) as they try to create learning opportunities that engage all learners with varying ability levels and technological skills.

Teachers tend to try to duplicate their face-to-face instruction when teaching online, which includes trying to replicate different types of classroom interactions (Battalio, 2007; Garrison & Cleveland-Innes, 2005). Interaction is seen as essential to the online educational experience and as such is a primary focus for online learning (Garrison & Cleveland-Innes, 2005). To explore the interactions secondary mathematics teachers have utilized in their online and hybrid teaching, we investigate the research question: *What types of interactions are teachers facilitating in high school mathematics classes across different modalities of online teaching?*

Theoretical Framework

Learner-content interaction is “intellectually interacting with content to bring about changes in the learner’s understanding, perspective, or cognitive structures” (Hillman et al., 1994, p. 30). Moore characterized this form of interaction as a one-way flow of information from the subject matter to the student (Lin et al., 2017) and stated that “without it there cannot be education” (Moore, 1989, p. 2). This interaction includes: conjecturing mathematics, solving problems, confirming one's work, interpreting mathematics, and making predictions.

Moore (1989) claims that learner-instructor interaction is regarded as “highly desirable by many learners-is interaction between the learner and the expert who prepared the subject material, or some other expert acting as instructor” (pp. 1–2). Offir et al. (2003) study refined the five categories of this interaction. These categories are: social, which pertains to classroom climate; procedural, which is dissemination of administrative instructions about the course; expository, which is presenting information by the teacher; explanatory, which is the teacher’s use of student input to explain content; and cognitive task engagement, which is the teacher presenting a question/task for the learners to engage in processing information.

Learner-learner interaction is the interaction between learners. Moore (1989) characterized this as the least focused by many within education but essential for younger learners where peer group interactions often aid motivation. We categorized this interaction as the presentation of a solution, responding to another learner, collaborative problem-solving, and small group discussion.

Hillman et al. (1994) recognized that another interaction dimension should be considered in technology-mediated learning environments. This type of interaction is necessary because the students must navigate technology to complete the educational task. While this could be thought of as manipulation of a mathematical object and thus learner-content, the difference lies in that content knowledge is a non-factor during the interface interaction. "Regardless of the proficiency of the learner, inability to interact successfully with the technology will inhibit his or her active involvement in the educational transaction" (Hillman et al., 1994). We operationalized this as responding to a poll or providing an answer via features of a technology medium.

Participants, Data, and Methods

Nineteen experienced high school mathematics teachers from seven districts participated in this study. Teachers had between six and 34 years of experience, with eight being the median years of experience. They had completed a 30-credit hour Master's degree or a 12-hour graduate certificate in mathematics education in Summer 2020. There were 35 videos analyzed for this study. Teachers submitted a video recording of one of their classes from the fall of 2020 (n=19) and an additional video from the spring of 2021 (n=16). Teachers either submitted videos of pre-recorded (Fall-13, Spring-4), synchronous online (Fall-13, Spring-4, hybrid (Fall-13, Spring-4), or face-to-face (Fall-13, Spring-4) instruction. These videos captured the entire class period, including breakout rooms, and were not edited before submission. COVID restrictions in each district dictated the mode of instruction. In the fall of 2020, most teachers recorded a video in advance of their class to post on their learning management system for students to view asynchronously. The videos ranged in length from five to 54 minutes in the fall of 2020 and 15 to 71 minutes in the spring of 2021.

Three levels of coding were applied to the analysis of each video. First, the type of interaction was identified (learner-content, learner-instructor, learner-learner, learner-interface) and coded. Then the second level of interaction was identified and coded. Finally, it was noted if technology was used during the activity.

The researchers, the authors of this paper, met to view a video together, clarify the unit of analysis, and define each of the codes. The unit of analysis was considered a level 2 interaction type. When there was a change in the activity type, that was treated as a new unit to code. For example, a teacher interacting with students to solve a problem would be coded (learner-instructor, solve a problem). If the teacher then provided students with directions about submitting their solution, that would be considered a new unit and coded learner-instructor, procedural (administrative). There were 1,962 total turns for this data, 366 for fall 2020 and 1,596 for spring 2021.

One video was coded together, and then six videos were assigned to pairs of researchers to determine inter-rater reliability. Agreement on units of analysis was determined (87.1%) and agreement on codes on the units that were in common was calculated (86.7%). Once inter-rater reliability was established, one researcher coded the remainder of the videos.

Data were analyzed using frequencies and Chi-square Test of Independence to determine if there were any significant associations between two categorical variables. Chi-square tests were run to determine if there were significant differences in the type of instruction and level 1 interaction types, semester of video and interaction types, and level 1 interaction and the specific level 2 interaction.

Results

First, an analysis of the number of unique interactions by the type of instruction shows that there were many more interactions in face-to-face instruction (n=928) over the two semesters than in the other types hybrid (n=525), synchronous (n=426), and pre-recorded (83).

During the 2020-2021 school year, mathematics teachers overwhelmingly utilized learner-instructor interactions (74.31%), predominately cognitive task engagement or expository. Of the learner-instructor interactions, 36.87% were cognitive task engagement, 26.32% were expository, and 13.64% were explanatory. Overall, 25.28% of the interactions were learners engaging with mathematics content. Most learner-content interactions involved students solving a problem (52.02% of learner-content interactions) or making a conjecture (44.15%). In addition,

there is evidence that teachers provided a few opportunities for their students to confirm their answers (n=18), predict (n=1), and interpret their solutions (n=0). There were very few learner-learner (n=6) and learner-interface (n=1) interactions of any type across the two videos from the participants. Of the six learner-learner interactions, all were collaborative problem solving and came from three teachers' classes. Of these six learner-learner interactions, five were in face-to-face instruction, and one was from hybrid instruction.

Due to the low numbers of learner-learner and learner-interface, only learner-content and learner-instructor were included in the next analyses. There was a significant association between the type of instruction and semester ($\chi^2(3)=246.57$, $p<0.001$). This suggests teachers provided more interactions in the spring of 2021 than in the fall of 2020. Interestingly, though there were more interactions in the spring of 2021, there was no significant association between the semester and interaction type ($\chi^2(1)=0.057$, $p=0.811$). Therefore, teachers provided the same types of interactions during the entire year, so there were no differences in instances of learner-content and learner-instructor interactions. There was also no significant association between the type of instruction and interaction type ($\chi^2(3)=2.873$, $p=0.412$). This means that teachers provided the same types of level 1 interactions regardless of the mode of delivery.

Looking at the learner-instructor interactions (n=1459), there was a significant association between the type of instruction and level 2 interaction types ($\chi^2(24)=121.638$, $p<0.001$). This suggests differences in the type of specific interactions based on the mode of instructional delivery. First, students had minimal opportunity to engage in inquiry, justification, or social interactions across all modalities, as evidenced by having percentages less than five. The percent of interactions of cognitive task engagement was similar for face-to-face (38.9%), hybrid (36.7%), and synchronous online (35.3%), but lower for pre-recorded videos (22.2%). Teachers engaged in explanations more frequently in face-to-face instruction (10.0%) than in the other modalities. Further, the percentage of expository interactions was the highest for pre-recorded videos (55.6%) and similar for face-to-face (21.4%), hybrid (28.8%), and synchronous online (28.0%). Finally, pre-recorded videos had the most procedural interactions (14.3%), followed by synchronous online (8.2%).

Similarly, of the learner-content interactions (n=496), there was a significant interaction between the type of instruction and Level 2 interaction types ($\chi^2(9)=99.842$, $p<0.001$).

Confirmation, or checking work, was most prevalent in pre-recorded videos. In fact, 25% of the learner-content interactions for pre-recorded videos were teachers having students confirm correct answers. No pre-recorded video had students conjecture. However, conjecturing was present in hybrid (28.2%), face-to-face (47.0%), and synchronous online (67.0%). Teachers very rarely had students make predictions, there was only one such learner-content interaction, and that was on a pre-recorded video. Finally, students solved a problem most often in hybrid or pre-recorded instruction (70% for each) but also had opportunities to solve problems in face-to-face (50.2%) and synchronous online (29.9%) instructional settings.

Conclusion

In this study, teachers tend to prefer to engage students in their classrooms via learner-instructor interactions. This is shown through this interaction mode utilized in 74.31% of the interactions. However, teachers also tended to rely heavily on asking questions about the material, lecturing, and answering student questions. This implies that teachers utilize whole class interaction patterns such as the I-R-E (initiation-response-evaluation) (Vogler et al., 2018), where they provide information to solicit a response, receive a response from the student, and then react to those responses to either offer more content or ask a follow-up clarification question. This whole class interaction model requires real-time feedback not available during pre-recorded lessons. The significant association between the type of instruction and the level 2 learner-instructor interaction types reflects that teachers utilized specific methods to cater to the modality of instruction. Teachers could not enact the whole class interaction patterns when using a pre-recorded video, so they relied heavily on exposition to convey information. Alternatively, once students could interact in real-time with teachers, students' responses were evaluated through explanatory interactions. Not being able to interact directly with students also probably led to an increase in having to provide procedural interactions so that the students could navigate the course materials and remain aligned with the course schedule. Once teachers and students occupied the same space, procedural interactions were less commonplace.

Though whole class interactions are a common practice, there were deviations in a quarter of the interactions to promote a more student-centered approach. Teachers allowed students to engage in the content to either perform mathematics (solve a problem 52.02%) or articulate an opinion about the nature of the content (conjecture 44.15%). While these interaction types were prevalent, there were still significant differences based on the type of instruction. There were more interactions focused on students generating correct answers in pre-recorded videos and fewer interactions focused on formulating opinions or conclusions.

While differences in the interactions that took place when teachers were teaching online or in a hybrid format were noted, future research is needed to understand better why teachers made the choices they did when teaching in these different settings. Several factors may have contributed to these differences - local policies, familiarity with technology, professional development, beliefs about mathematics teaching, time to transition courses to an online environment, and classroom management concerns, to name a few. Answers to this question may enable mathematics teacher educators to better prepare prospective and practicing teachers to support students' engagement through different types of interactions while learning online.

DESIGNING AN ONLINE VIDEO-BASED ENVIRONMENT FOR PROMOTING MATHEMATICAL ARGUMENTATION

Ho-Chieh Lin
The Ohio State University
Lin.2532@osu.edu

During the past two years, the COVID-19 pandemic has forced teachers to shift their instruction online, further exacerbating the challenges for teachers in orchestrating rich mathematics discussions. To tackle this issue, this study explored an approach that integrates online video-sharing culture (e.g., YouTube) into mathematical practices. Specifically, I designed an environment to engage children in creating and sharing mathematics how-to videos online for subsequent peer discussions. Guided by design research principles, I recruited four upper elementary children in the United States. The analysis of this qualitative study showed that the environment created offered unique opportunities for the children to communicate their ideas in a multimodal way and engage in mathematical argumentation. The findings provide insights into how an online environment can be designed to reshape children's argumentative discourse.

Keywords: Design Experiment; Instructional Activities and Practices; Online and Distance Education; Reasoning and Proof

Mathematical argumentation, a type of discourse that involves communication of mathematical ideas with reasoning, is central to the development of mathematical knowledge (Conner et al, 2014). This discourse fosters greater conceptual understanding (Wood et al., 2006) and advances academic achievement (Chapin et al., 2009; Kazemi & Stipek, 2001). Although benefits of mathematical argumentation are evident, enacting such practices in classrooms challenges many teachers (Conner et al., 2014). This problem has been exacerbated during the past two years. The COVID-19 pandemic forced in-person classes to be conducted remotely, while most teachers have little experience or support with how to engage children in mathematics discussions online. Indeed, the literature on mathematical argumentation in fully online contexts is relatively scarce as compared to that of in-person contexts. By designing a video-based online learning environment, this study addresses the necessity to investigate ways to engage learners in mathematical argumentation.

Video technologies have been used for mathematical teaching and learning in various ways, such as anchored instruction (Cognition and Technology Group at Vanderbilt, 1992) and flipped instruction (De Araujo et al., 2017). However, little is known about how videos produced by learners themselves can be leveraged for promoting mathematical argumentation. Indeed, research that explores the use of video production as a means for mathematics learning is just emerging. In a recent study that investigated how middle school students collaboratively produced mathematics tutorial videos, Oechsler and Borba (2020) found that this activity changed the classroom dynamic and engaged students in communicating mathematical ideas with multiple modes (e.g., language, gesture, image, and music). They argued that video production is a new way of expressing mathematics and its multimodal affordance prompts students to reorganize their thinking. Their findings suggest video production has the potential to foster children's mathematics discourse. It is therefore reasonable to further investigate ways to design an environment involving video production activities for promoting mathematical argumentation.

This study explored an approach that integrates children's online video-sharing culture (e.g., YouTube and TikTok) into a problem-based learning model. Specifically, this approach uses a process during which children solve math problems, create online videos to explain their strategies, and then discuss strategies after watching peers' videos. I hypothesize that when learners use templates from online video platforms to communicate their mathematical ideas, they likely attend to the validity of mathematical statements and thus engage in mathematical argumentation. The proposed approach allows an investigation into the development of an online video-based learning ecology and children's mathematics discourse. The guiding research questions are: (a) *How can an online video-based environment be designed to promote mathematical argumentation?* (b) *In what ways do children participate in mathematical argumentation in the designed environment?*

Theoretical Framework

This study is framed by the emergent perspective (Cobb & Yackel, 1996) and humans-with-media perspective (Borba & Villarreal, 2005). The emergent perspective is a version of social constructivism that attempts to explore the complementary area between sociocultural and constructivist constructs. The premise of this perspective is that learning is a constructive process that emerges when learners participate in and contribute to socially organized activities (Cobb & Yackel, 1996). According to Cobb (2007), the emergent perspective agrees with the constructivist view of learning as an adaptive process; however, it is informed by a distributed cognition view of learning as a social activity supported by cultural tools and thus expands the meaning of a learning activity. Cobb et al. (2001) argued that the tools and symbols used in the contexts are not additions to but constituent parts of learners' activity. Therefore, this view connects with the notion of semiotic mediation in the sociocultural theories, and learner's engagement in mathematics activities entails reasoning with tools and symbols (Cobb, 2007).

The idea of reasoning with tools and symbols in the emergent perspective aligns with the premise of humans-with-media perspective (Borba & Villarreal, 2005). That is, collective efforts of human (e.g., students, teachers) actors and non-human actors (e.g., computers, mobile phones) contribute to the reorganization and production of human knowledge. In this perspective, human and media technologies influence and shape each other through interaction, negotiation, and reflection. As claimed by Borba and Villarreal (2005), discourse supported by digital media is qualitatively different from oral or written language, primarily because it involves a combination of visual and audio information, such as images and music. It is therefore reasonable to assume this type of discourse can shape human thinking in a distinct way.

In this study, participants' discourse and learning are mediated by online videos they themselves created. When producing a video, a participant coordinates their verbal explanations and visual representations in a coherent way. This requires them to externalize and reorganize their mathematical ideas. When viewing a video, a participant attempts to make sense of a mathematical strategy through the verbal explanations and visual representations in the video. These online interactions are therefore multimodal through technologies, which distinguishes it from typical classroom interaction. I posit that, with an appropriate design of activities, video-based discourse has the potential to drive learners to attend to the validity of mathematical statements, leading them to productive mathematical argumentation.

To develop a video-based environment for promoting mathematical argumentation, it is important to understand how learners engage in communicating their mathematical thinking with technologies. Since this process involves collective efforts of the designer, participants, and technologies, taking the emergent and humans-with-media perspectives together enables me to conceptualize discourse and learning that occur during human-media interaction.

Methodology

In this qualitative study, I aimed to develop an environment and learning theories for video-based mathematical argumentation in an online environment. I adopted principles of design research (Cobb et al., 2003) because using video production as a means for learning mathematics has not been an established practice in typical classrooms (Oechsler & Borba, 2020). Therefore, these principles make this study interventionalist and characterized by an iterative cycle of design, enactment, analysis, and refinement. In addition, I drew on the conjecture mapping technique (Sandoval, 2014) for conceptualizing and carrying out my design. Figure 1 shows a conjecture map I have developed at the current stage of the research design process. My design conjecture is that if learners participate in the discursive practices guided by an online video-based activity structure, then the mediating processes will emerge. My theoretical conjecture is that if these mediating processes take place, they will bring about the desired learning outcomes-that is, constructing viable arguments and reorganizing mathematical ideas. The proposed activity structure will be introduced in the next section.

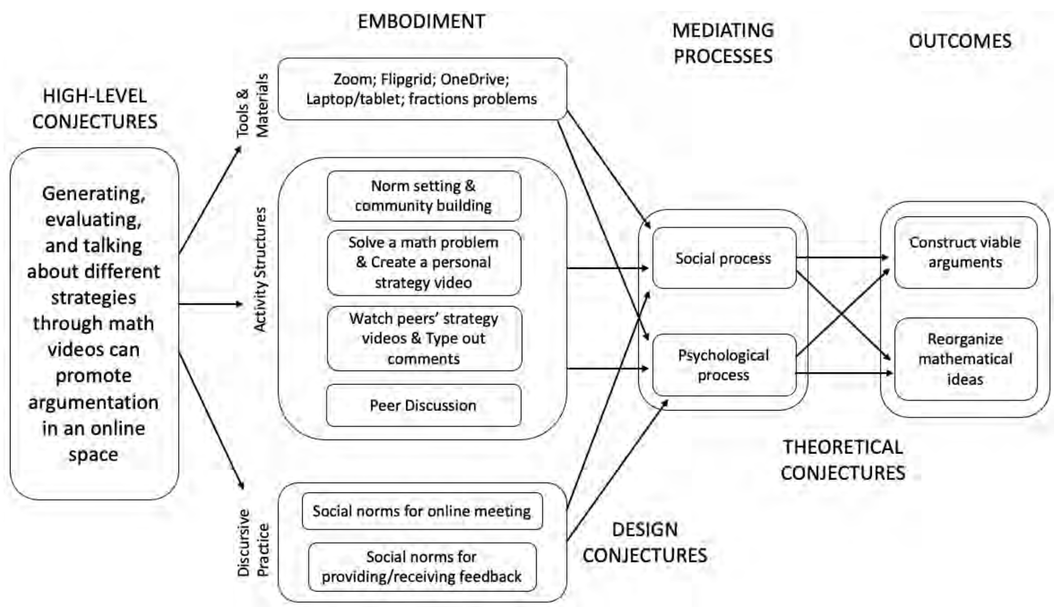

Figure 1. Conjecture map for conceptualizing this design study.

VBAS Environment

Currently, I have developed a four-phase video-based activity structure (VBAS) that aims to promote mathematical argumentation for small groups in an online space. This VBAS environment involves participants using three online technological tools: Zoom, OneDrive, and Flipgrid. Particularly, Flipgrid is a video platform that allows users to produce personal videos and disseminate them in a designated virtual community for viewing. Supported by these technologies, learners participate in a sequence of four activities: (a) setting up norms and building community, (b) independently solving a math problem and creating a strategy video, (c) watching strategy videos and taking notes, (d) discussing the strategies with a partner. Following this design, I worked with a pair of participants at a time. Since I situated my design in a problem-based model, each cycle of research sessions started with a problem-solving task. The mathematics problems employed in this study were about fraction comparisons. An example is shown in Figure 2.

> Imagine that you were invited to a home party. You saw the same pies being served at three tables of your friends: one table serves two pies with two people, another table serves three pies with three people, and the third table serves five pies with six people. Friends at each of the tables call out to you to pull up a chair and share the pies. You are to join one of the tables. Is there any helpful way that you can use math to help with your decision-making?

Figure 2. Fraction comparison problem used during a design cycle.

Rationale of the Designed Environment

The proposed environment features video production activities. When children produce a mathematics video, they realize that their explanations need to make sense to themselves first so that the viewers can understand. Such a self-explanation process can help individuals modify their existing knowledge with new information and promote their problem-solving skills (Chi et al., 1994). This may also help the children see themselves as capable mathematical thinkers.

Participants & Settings

This study is part of a larger project examining children's video-based mathematics discourse in an online environment. I recruited two fifth graders and two sixth graders in the United States, who were female Asian Americans. The participants were grouped into pairs since peer discourse is the focus of this study. During each research session, I met with one pair remotely via Zoom as they used their own computers or tablets at home. Each pair participated in a series of 60–90-minute sessions. In addition, I conducted semi-structured interviews with each participant after they completed the research sessions.

Data Collection & Data Analysis

Data collected for this study came from multiple sources: (a) video recordings of each Zoom session, (b) online math videos created by participants, (c) feedback on videos typed by participants, and (d) the researcher's memo.

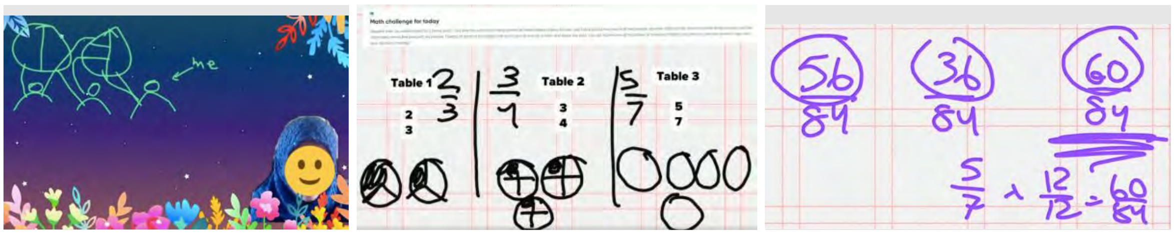
To analyze the data, I adopted the constant comparison method (Corbin & Strauss, 2014), which enables me to identify themes of significant phenomena. My analysis involved examining mathematics videos created by the participants and video recordings of research sessions to highlight and transcribe episodes in which participants generated mathematical arguments.

Results

Here I present some findings from a research cycle of VBAS that employed the problem introduced in Figure 2 and involved a pair of sixth graders, named Alissa and Nancy. Prior to this cycle, the pair had participated in two cycles of research sessions. The analysis here focuses on how the children engaged in three VBAS activities: (a) problem solving and strategy video production, (b) video viewing & commenting, and (c) peer discussion.

Problem Solving & Strategy Video Production Activity

This activity asks participants to independently solve a math problem and create a short video, less than two minutes, in which they explain their strategies. The goal is to activate their existing math knowledge and construct viable argument. As shown in Figure 3, Nancy and Alissa used different strategies in solving the problem that involves comparing fraction magnitudes. Nancy only considered the situation in the first table of the problem. She first cut each whole into halves, creating four halves. Then she distributed each half to each person. Next, she cut the remaining half into three smaller parts and shared them with three people. In contrast, Alissa considered all the situations. On the first and second table, she divided each whole into equal parts based on the number of sharers, and then each person would take one part from each whole. However, she stopped using this strategy for the third table. She probably noticed the drawing would not help her compare the magnitudes, so she switched to a more formal strategy-that is, first finding a common denominator for the three fractions, next converting all fractions to share the common denominator, and finally comparing the numerators.



(a) Nancy's work. (b) Alissa's work-part 1. (c) Alissa's work-part 2.

Figure 3. Screenshots of two participants' strategy videos.

In addition, Nancy and Alissa used different features afforded by Flipgrid to represent their video contents. Nancy's video was stylish as she put herself in the corner with a flowery frame and a starry night scene as background. In contrast, Alissa's video is more simplistic, focusing on the mathematical representations. Moreover, the pair used different background music.

Video Viewing & Commenting Activity

The third activity asks participants to individually watch each other's video twice and jot down their thoughts in a table with three sentence starters on OneDrive. The goal is to prompt a participant to examine their partner's strategy video carefully or even critically. Figure 4 displayed Nancy's contributions.

In the "I notice…" row, Nancy expressed her observation of the difference between Alissa's strategy and hers, claiming Alissa's strategy was complicated and her speech pace was fast in the video. In addition to the comments on the strategy video, Nancy stated that she understood Alissa had limited time to explain such a complicated method.

In the "I wonder…" row, Nancy expressed her inquiry about why Alissa kept using this strategy. This inquiry probably comes from the fact that Alissa had used this strategy during the previous two research cycles.

In the "I would suggest…" row, Nancy suggested Alissa try a different strategy that would make sense to lower graders. The reason why Nancy offered this suggestion is worth further investigation.

I notice…	that she is using factions in the more complicated way, and she is going fast (I understand this though, she had limited time)
I wonder…	why she always uses fractions with inequivalent denominators then changes them to common denominator fractions
I would suggest	to try a different technique, like, using a less complicated way for maybe 5th or 4th graders?

Figure 4. Screenshot of Nancy' comments.

Peer Discussion Activity

During this activity, participants' notes are screenshared, and they are encouraged to talk about their comments with their partner and respond to each other. The goal is to see if the pair would engage in mathematical argumentation. Presented below is an episode in which Nancy first talked about her comments. Note that Alissa did not show her face during this interaction.

Nancy: you always use like fractions like that, you find fractions with unequivalent denominators, and you find them equivalent denominators. How do you always… how do you always find a way to do that?

Alissa: The reason I think is because like, it's easier to compare that way and how I like, what I do to find the multiples that sometimes I'll like, multiply the number by like the other number to get multiple. Or like, I try to find, like, more like the least common multiple and I...

Nancy: How do you find a number… How do you find a number to multiply with?

Alissa: For example, like, if I try to find the common multiple of three and seven, what I would do is, I like, I do three times seven. So I would find 21.

In the above vignette, Nancy first described what she noticed about Alissa's consistent use of an algorithm that converted fractions with unlike denominators into fractions with the same denominators. She asked Alissa how she could always identify a number (i.e., common multiple) that she could convert different denominators to. Alissa first responded with a general rule, but it seemingly did not fully convince Nancy. Therefore, Nancy rephrased her question in a more specific way, and then Alissa described the rule by using an example. Their conversations continued as follows.

Nancy: But do you always like a certain technique or something? Like, try to find something they'll have in common or something?

Alissa: Oh, yeah. So like, sometimes, like, what I'll do is that I'll also try to find if I think that maybe like a number is like, maybe like there's a smaller number than that. What I tried to do with that, uhh…I'll..umm

This vignette demonstrated that Nancy went back to her original inquiry about Alissa' consistent use of such method. Alissa probably did not think about the question before because her response revealed some level of hesitance. Speculating that writing down her thoughts might help process her thinking, I thus intervened and asked if she would like to share her screen and use the Zoom whiteboard. Alissa seemed to agree, so she shared her screen immediately. She then began writing down mathematical symbols on the whiteboard while explaining a different method (see Figure 6).

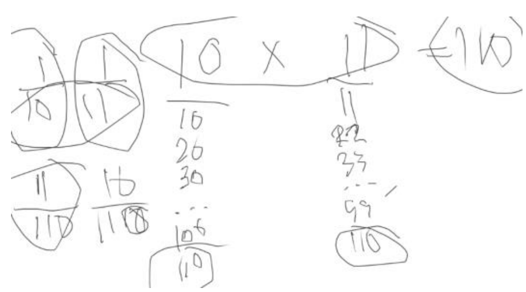


Figure 5. Alissa's writing on the whiteboard.

Alissa: [shares her screen immediately] So like, let's say I have like the numbers 10 and maybe 11. So what I would do is I would list maybe the multiples until, or what I would do is [talking while writing on the board] I would go like that and then 110, or what I would do is that I'll go 100. And like I will go umm so times one it's 10, times two, times three, and then so on and then 100 and then 110. And then I would go to 11. And then I would go like times one, times two, times three and then I don't know, then like 99, and then I get…

Nancy: 110. One thing that both have in common, okay.

Alissa: Yeah, something like that.

Nancy: So go multiply them until you find a way to find the number, okay.

Alissa: Yeah, like, so I don't usually do that. I just usually will be…uh… I'll like multiply these numbers together to get this number [circling numbers on the board].

The above vignette showed that writing might help Alissa externalize her thinking. She proposed another example and explained another way to find a common multiple for two different numbers. This method made sense to Nancy as she replied with an answer to Alissa's example and replied with her interpretations. After talking about the rule, Nancy inquired about Alissa's decision of using the rule.

Nancy: Um, okay. But why do you always use this one way?

Alissa: Because like, let's say I want to compare like 1/10 and 1/11. So they're not equal [circling 10 and 11]. I wouldn't be able to properly compare them. And like just looking at them and then like maybe deciding, I think 1/11 is bigger, really? Or 1/10 is bigger, then so it's better to go like 11 over 110, and then 10 [writes 10/110]. This one is bigger [circling 11/110].

In this vignette, Nancy 's question had potential to shift their discussion from procedure-focused to concept-focused. However, Alissa did not articulate the underlying concepts. As demonstrated in her response and Figure xx, she applied her previous example to a fraction case and showed how the algorithm worked. Nancy seemed to accept Alissa's response and proposed her suggestions as follows.

Nancy: Ok. So, umm…So if you had to explain this problem to maybe a fourth grader, how, would you use a different technique or use the same technique? with more explanation?

Alissa: I would use the same technique with more explanation. So that they would understand better because …yup!

The above episode indicates that Nancy and Alissa engaged in asking questions and justifying their ideas with limited intervention from the facilitator. Particularly, Nancy's questioning showed that she attended to Alissa's responses, and her questions prompted Alissa to develop a more comprehensive account for finding a common multiple for denominators when comparing fraction magnitudes. However, their discussions were focused on procedures. This finding is evident in a few other episodes when participants talked about their strategies toward other fraction comparison problems.

Discussion

This study investigated how an online video-based environment can be designed to support mathematical argumentation and the way children engage in mathematical argumentation in such an environment. The results indicate that the proposed environment created unique opportunities for the participants to communicate their mathematical thinking in multiple modes and engage in mathematical argumentation. The video production activity involves a multimodal process of constructing viable mathematical arguments as the children individually coordinated their verbal explanations and relevant visual representations. Moreover, the video viewing and commenting activity encouraged the children to carefully examine their partner's arguments. Since the children were asked to type comments based on their observation, they would re-watch the part they did not understand and reorganize their thinking. This process is also multimodal as the children attended to the mathematical ideas that were verbally and visually transmitted. Furthermore, the peer discussion activity allowed the children to talk about their ideas to each other in real time. Because the previous two activities have engaged participants in thinking through their arguments and their partners' arguments, they may come to this activity with inquiries or revised ideas. Therefore, a productive mathematical argumentation like the one presented in the results section could likely happen, and in humans-with-media terms (Borba & Villarreal, 2005), the videos play an acting role as important as human participants during this discourse.

The video production activity that involves participants designing math videos based on their own strategies is featured in this study. This process involves a great deal of autonomous problem-solving and decision making since participants need to figure out affordances of the video platform, activate their existing mathematics knowledge, and arrange presentation contents in a way that makes sense to themselves and their peers. In addition, the participants often added pleasant backdrops and cheerful music to their videos, which makes them appealing to the viewers. In this sense, the math videos are not merely pertaining to mathematics, but also communication and personal identity.

Much of existing literature on mathematical argumentation focuses on teacher's moves, such as questioning (e.g., Conner et al., 2014). In contrast, this study attempted to lessen the need for the facilitator to directly guide children's discourse by proposing a sequence of learner-centered activities. The VBAS design offers scaffolds to prepare children to lead their discourse by themselves. This way of positioning children as capable agents is different from that of using adult-created videos for flipped classrooms or using ready-made dialogic videos for vicarious learning, which usually involve obedience-oriented ways of problem-solving strategies and explanations. Indeed, the proposed design encourages children to not only engage in video-based discourse but also come to take ownership of their mathematical learning.

While the findings seem promising, there are limitations to this study. For instance, the participants of this study were upper elementary children who knew each other, had some experiences with video production, and felt comfortable sharing their mathematical ideas online. It is unknown how learners with different backgrounds engage in the proposed environment. Additionally, this study has not analyzed how the children's knowledge on fraction comparison developed over time throughout the sessions. These are important areas that need further research in order to understand how to better support children's mathematical argumentation in an online space.

RELACIÓN ENTRE EL RAZONAMIENTO COVARIACIONAL Y LOS ESQUEMAS DE USO EN UNA TAREA DE APROXIMACIÓN

RELATIONSHIP BETWEEN COVARIATIONAL REASONING AND USE SCHEMES IN AN APPROACH TASK

Mihály A. Martínez-Miraval
Pontificia Universidad Católica del Perú
martinez.ma@pucp.edu.pe

Martha L. García-Rodríguez
Instituto Politécnico Nacional
mlgarcia@ipn.mx

El estudio realizado tiene por objetivo analizar el cambio en las acciones mentales de un estudiante asociadas con los esquemas de uso que moviliza al resolver una tarea de aproximación al área de una región con GeoGebra. Se consideraron elementos teóricos relacionados con el enfoque del razonamiento covariacional y con el enfoque instrumental. El estudiante, luego de generar, movilizar y refinar sus esquemas de uso, hizo visibles comportamientos que se asocian con acciones mentales, como dibujar un polígono para aproximar un área y reconocer que, a más puntos sobre la gráfica, la distancia entre estos es menor y se obtiene una mejor aproximación. Es decir, los comportamientos observables pueden ser asociados con niveles de razonamiento o bien con cambios en las acciones mentales asociadas, que indican un tránsito de un nivel de razonamiento a otro.

Palabras clave: Resolución de Problemas; Tecnología; Razonamiento y Demostraciones

En la literatura, el razonamiento covariacional se identifica como una habilidad esencial para la comprensión de conceptos de Cálculo, como es el caso de la integral definida (Carlson et al., 2002), contar con esta habilidad significa entender las coordinaciones que se dan entre los valores de dos o más variables que se ponen en juego al resolver un problema (Thompson y Carlson, 2017). Kouropatov y Dreyfus (2014) manifiestan que el concepto de integral se puede desarrollar a partir de una estructura jerárquica de cuatro elementos, donde, la aproximación al área de una región con objetos geométricos es el primer nivel de dicha estructura.

Tratar de que los estudiantes relacionen el concepto de integral definida con el área bajo la curva, promueve la construcción de conocimiento matemático y de significados de los conceptos involucrados en la resolución de problemas, estas construcciones se pueden apoyar en el uso de tecnologías digitales (Santos-Trigo y Aguilar, 2018).

Las tecnologías digitales permiten experimentar con cantidades que cambian dinámicamente en tiempo real (Carlson et al., 2002). En palabras de los autores: “estas tecnologías ofrecen valiosas herramientas para (…) aplicar el razonamiento covariacional y analizar e interpretar funciones asociadas con situaciones dinámicas” (Carlson et al., 2002, p. 374). GeoGebra es un ejemplo de un sistema de geometría dinámica que, aparte de dar movimiento a las construcciones realizadas, genera un entorno de aprendizaje interactivo y visual que permite explorar cómo se relacionan las variables con la solución geométrica (Zengin, 2018).

Para conocer sobre el razonamiento covariacional que ponen en juego los estudiantes cuando utilizan GeoGebra se realizó una investigación que tuvo como objetivo *analizar el cambio en las acciones mentales de un estudiante asociadas con los esquemas de uso que moviliza al resolver una tarea de aproximación al área de una región con GeoGebra.*

Aproximación conceptual

Se consideraron elementos teóricos relacionados con el enfoque del razonamiento covariacional propuesto por Thompson y Carlson (2017) y con el enfoque instrumental desarrollado por Rabardel (1995).

Las imágenes de covariación funcionan como vehículos de operaciones mentales, expresadas a través de representaciones e impresiones de un individuo en un contexto dado, y como estas evolucionan, se pueden categorizar por niveles que surgen de forma ordenada (Carlson et al., 2002), y la evidencia de tal evolución se manifiesta en la forma en que una persona coordina los cambios en los valores de dos cantidades (Saldanha y Thompson, 1998). Una imagen de covariación está sustentada en las acciones mentales que una persona realiza, y estas pueden asociarse con el conjunto de comportamientos observables en un sujeto que resuelve un problema (Carlson et al., 2002). El constructo teórico de Thompson y Carlson (2017) consta de seis niveles de razonamiento covariacional, en este trabajo se consideran del segundo al cuarto (tabla 1) y se asocian con acciones mentales correspondientes a cada nivel en el sentido descrito por Carlson et al. (2002).

Tabla 1: Niveles de razonamiento covariacional. Adaptado de Thompson y Carlson (2017)

Niveles	Descripción
Coordinación de valores	AM4: Coordina los valores de una variable (x) con los valores de otra variable (y) con la anticipación de crear una colección discreta de pares (x, y).
Coordinación gruesa de valores	AM3: Forma una imagen general de los valores de las cantidades que varían juntos, como "esta cantidad aumenta mientras que la cantidad disminuye".
Precoordinación de valores	AM2: Imagina que los valores de dos variables varían, pero de forma asincrónica: una variable cambia, luego la segunda variable cambia, luego la primera, y así sucesivamente.

Por otro lado, Rabardel (1995) indica que los esquemas de uso se relacionan con la ejecución de tareas de índole funcional que pueden tener objetivos propios y que están relacionadas con el reconocimiento de características, propiedades y actividades específicas de GeoGebra. En este trabajo se realizaron tareas como dibujar un polígono para aproximar un área, determinar su área, hacer zoom para refinar una aproximación, entre otras. Los estudiantes tenían conocimiento de diversas herramientas de GeoGebra: función, polígono, área, zoom, utilizadas para otros temas y otros contextos, por lo que ya habían generado esquemas de uso de ellas, por lo que, en algunos casos los movilizan o refinan y, en otros, generan nuevos.

Métodos y procedimientos

En este documento se presenta el trabajo de un estudiante de los primeros ciclos universitarios al que llamaremos Juan, quien contaba con 17 años de edad. Las evidencias obtenidas fueron recolectadas mediante documentos escritos, archivos digitales y una entrevista semiestructurada que fue videograbada, así como reportes realizados por el investigador. Juan contaba con los antecedentes de haber trabajado con funciones reales de variable real, había estudiado el tema de límites, reconocía la continuidad de una función a partir de su gráfica, o de forma analítica al utilizar la definición y había realizado el cálculo del área de figuras geométricas. La tarea diseñada incluyó dos ítems y está relacionada con el concepto de integral definida mediante el área de polígono como una aproximación al área que se forma bajo la gráfica de una función y el eje X en un intervalo cerrado. El estudiante trabajó esta tarea en GeoGebra, mediante un enlace que les fue proporcionado para ello.

La figura 1 muestra una región R limitada por la gráfica de una función f y el eje X para $x \in [0; 8]$. Utilice el enlace para sus exploraciones: https://www.geogebra.org/m/mmcyf6pr.

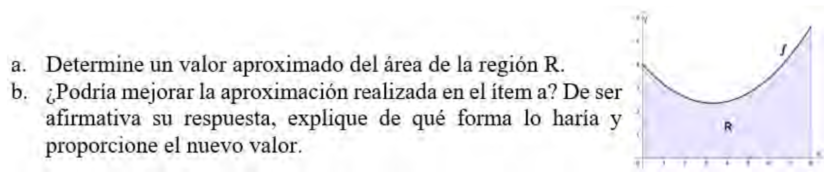

Figura 1: Aproximación con polígonos

Análisis y discusión

El estudiante movilizó su **esquema de uso polígono** para trabajar en la tarea y lo utilizó para dar una primera aproximación del área de la región R. Para el inciso (a), Juan mencionó que dibujó un primer polígono con 5 puntos sobre la gráfica de la función y al observarlo se percató de que las regiones del polígono que exceden a la región R se podían reducir al colocar más puntos sobre la gráfica de la función, por lo que dibujó un nuevo polígono con 9 puntos. Determinó su área movilizando su **esquema de uso área** y respondió al ítem (a). Cuando Juan dibuja un polígono y coloca puntos sobre la curva, se hacen visibles un conjunto de variables: (i) número de puntos sobre la gráfica de la función (vértices del polígono), (ii) distancia entre dos puntos consecutivos (lados del polígono), (iii) área del polígono y (iv) áreas excedentes.

Al visualizar los valores de las variables número de puntos y áreas excedentes muestra comportamientos de una AM2, coloca un número de puntos y observa las áreas excedentes, coloca más puntos y observa nuevamente las áreas excedentes, es decir, de acuerdo con Thompson y Carlson (2017), relaciona estas variables de manera asincrónica. El hecho de variar el número de puntos para aproximar el área solicitada es evidencia de que a Juan no le pareció suficiente colocar 5 puntos y decidió aumentar el número a 9, con lo que se aproxima mejor al área de la región R, rasgos asociados con una AM3.

La evidencia encontrada sugiere que Juan primero movilizó el **esquema de uso polígono** e hizo visible una **AM2** cuando relacionó las variables número de puntos y áreas excedentes. El movilizar nuevamente el **esquema de uso polígono** y dibujar más puntos se asocia con rasgos de una AM3, y también induce la movilización del **esquema de uso área**, con lo que enfoca su atención en una nueva variable que es el área del polígono (figura 2).

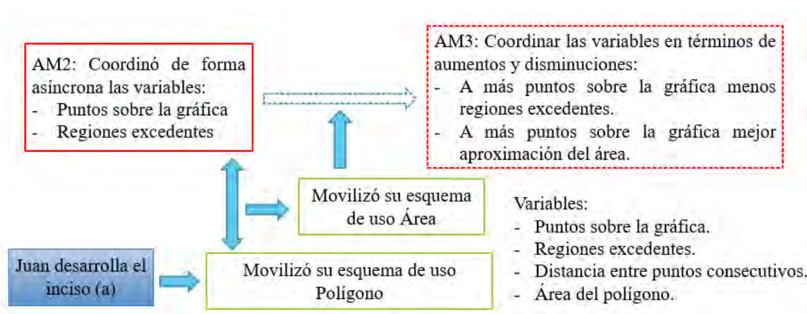

Figura 2: Relación entre las acciones mentales y la movilización de esquemas de uso

Para el inciso (b), Juan explicó que dibujó un polígono con 12 puntos para obtener una mejor aproximación, con lo que generó un **esquema de uso partición**, ya que Juan había identificado que al colocar más puntos la distancia entre ellos disminuía y se lograba una mejor aproximación, aquí Juan había puesto en juego una nueva variable distancia entre dos puntos consecutivos. Juan identificó que el aumento del número de puntos corresponde a una mejor aproximación del área de la región R y a la disminución de la distancia entre puntos consecutivos, comportamientos que corresponden a una AM3. También refinó su **esquema de uso partición** al querer aumentar el número de puntos e identificar que, para hacerlo, necesitaba modificar la escala de la gráfica utilizando la herramienta Zoom de GeoGebra. Las conjeturas de Juan las realiza a partir de la modificación del número de puntos y del área del polígono que se forma con ellos, al parecer esto lo llevó a crear una colección discreta de pares que relacionan estos valores, que es un rasgo de un comportamiento asociado con una AM4.

Conclusiones

El aporte de este trabajo al campo de la Matemática Educativa es el uso de dos aproximaciones teóricas: el razonamiento covariacional de Thompson y Carlson (2017) y el enfoque instrumental de Rabardel (1995), para generar un modelo explicativo de la evolución del razonamiento covariacional de Juan y su interrelación con los esquemas de uso cuando trabaja en una tarea con GeoGebra.

En este modelo los elementos teóricos de cada enfoque quedan entrelazados y en momentos parece que actuaran de manera simultánea. Al mismo tiempo que se pone en juego un esquema de uso, se cambia a otra acción mental, por lo que resulta difícil distinguir qué ocurre primero.

Se identifican comportamientos que ya no están asociados con una acción mental específica, por lo que pensamos que están en un tránsito de una acción mental a otra.

Agradecimientos

RELATIONSHIP BETWEEN COVARIATIONAL REASONING AND USE SCHEMES IN AN APPROACH TASK

The study aims to analyze the change in the mental actions of a student associated with the use schemes that he mobilizes when solving an approximation task to the area of a region with GeoGebra. Theoretical elements related to the covariational reasoning approach and the instrumental approach were considered. The student, after generating, mobilizing and refining his use schemes, made visible behaviors that are associated with mental actions, such as drawing a polygon to approximate an area and recognizing that, the more points on the graph, the distance between them is smaller and a better approximation is obtained. That is, observable behaviors can be associated with levels of reasoning or with changes in associated mental actions, which indicate a transition from one level of reasoning to another.

PRESERVICE TEACHERS' TASK CHOICE IN TECHNOLOGY-RICH ENVIRONMENTS

A group of 27 preservice teachers (PSMTs) from two different institutions ranked and provided a rationale for their rankings of three versions of a task presented on three different technology platforms (CODAP, Geogebra, spreadsheet). The PSMTs then worked through the tasks in detail, reranked the tasks and provided a rationale for why they either changed or maintained their ranking. More than half the PSMTs changed their ranking and almost half changed their first choice of task. Rationales for change showed increased attention to the mathematical content of the task and the possibilities for "math action technologies" (Dick and Hollebrands, 2011) available in each platform.

Keywords: Teacher Education - preservice, Technology, Teacher Beliefs

Introduction

Choosing tasks to use in lessons in order to teach mathematical concepts is a basic activity of mathematics teachers. Therefore, teachers' ability to choose tasks is critical. The purpose of this study is to compare how pre-service teachers justify their ranking of three versions of the same task presented on three different technology platforms (CODAP, Geogebra, spreadsheet), first after reviewing the instructions for the task, and then, after working through each version of the task in detail using each platform.

Literature review and relationship to research

As Sullivan et al. (2013) and others have noted, teachers generally do not have time to develop significant numbers of their own tasks and generally rely on pre-existing tasks for use in their lesson plans. Therefore, evaluation of existing tasks is an important skill for preservice mathematics teachers (PSMTs) to develop. Sullivan et al. suggest three levels of decisions to be made in evaluating and choosing a task for use: (i) whether it matches curriculum goals, (ii) whether the demand of the task is appropriate for the students, and (iii) whether the task can accommodate a variety of learners.

Dick and Hollebrands (2011) argue that advanced digital technologies available for use in mathematics education typically fall into two categories namely "conveyance technologies" and "mathematical action technologies" (MATs). McCulloch et al. (2018) in a study involving 21 mathematics teachers with experience in teaching with advanced digital technologies pose the questions "Why do teachers choose to use technology to teach mathematics? What technology tools do teachers choose to use and why? and What general factors do teachers consider when selecting a particular technology tool to use?" They conclude that ease of use, for both the teachers themselves and their students is key factor in choosing particular technologies.

At the level of task choice, advanced digital technologies add another level of complexity to the decision making in planning lessons. Building on a study by Laborde (2002) involving teachers designing activities using an advanced digital technology (in this case Cabri), Kasten & Sinclair (2009) posit that teachers choosing tasks might first be drawn to activities that simply provide "visual amplification," (p. 134), could, after some experience with technology choose tasks involving generation of data for analysis and finally reach a stage where they are choosing tasks that take advantage of unique affordances of the technology.

McCulloch et al. (2018) provide many instances of their participants arguing for the value of MATs in particular tasks that were effective in promoting student learning. McCulloch et al. (2021) go further and argue that, not only can MATs be an effective driver of student exploration and learning, but that such use is a matter of digital equity.

In our study with relatively inexperienced pre-service mathematics teachers we sought to examine the issue of evaluation of materials by studying differences between PSMTs evaluation of tasks based on a relatively cursory "static" review followed by an extended period of actually doing the task as a learner. We were particularly interested in their attention to the suitability of the tasks to the teaching of the content and, per Dick & Hollebrands (2021) their attention to the extent to which the different versions of the task exemplified MATs

Methods and Methodologies

Setting and Participants

Two groups of Pre-service Mathematics Teachers (PSMTs) (n=15 & n=12) at two different institutions were presented with the following task (see Figure 1a):

Suppose you are teaching an 8th or 9th grade class about comparing the mean and median of a set of data. You would like to give them an investigation where they "play" with some different data sets. This link: https://tinyurl.com/bdfvx5ep provides three examples of how such a task could be presented using three different technology platforms: CODAP, spreadsheet, and a pre-built Geogebra applet.

Your task is to read the example activities at the link above and rank the versions of the task from best (the one that you are the most likely to use) to worst (the one that you are least likely to use) along with a rationale for your ranking. You will submit your responses using this Google form: https://forms.gle/Tw9m6UE7caNvrgEEA during class.

a

CODAP b | Spreadsheet c | Pre-built Geogebra App d

Figure 1. Comparing Mean and Median Tasks

The three tasks posed exactly the same questions for users to answer but in the context of different technological platforms. The images of each platform (Figure 1b, c,and d) were included for PSMTs to gauge the capabilities and interactivity level that each platform might have to offer. They worked on the task for 10 minutes in the class. Then, as a homework exercise the PSMTs were asked to revisit the examples but this time work through the examples in detail and to reconsider their ranking of the tasks and complete a form ranking the tasks one more time. They were also asked to list pros and cons of each technology platform.

Data Collection

The data collected consisted of: (i) The PSMTs initial rankings and rationales for their rankings; (ii) Their work on the tasks; (iii) Their reranking of the tasks with rationale for changing (or not); (iv) Their thoughts on the pros and cons of each platform.

Data Analysis

The participants' original critiques were analyzed using the constant comparative method (Glaser & Strauss, 1967) to establish trends in the data and to develop a code book. The code book was then applied to the PSMTs explanation for either maintaining or changing their rankings and to their "pros and cons" of each technology platform.

Results

Initial analyses/critiques

Change of ranking

The first result to note is that almost two-thirds (17 of 27 (63%)) of the PSMTs changed their ranking of the activities after having worked through them in detail. Furthermore, of the 17 PSMTs who changed their ranking more than 70% (12 of 17) changed their *first* choice. Therefore, after working through the activities in detail almost half the PSMTs 12 of 27 (44.4%) changed their first choice of activity.

Table 1. PSMTs' rankings by platform

	Initial ranking			Second ranking		
	1st Choice	2nd Choice	3rd Choice	1st Choice	2nd Choice	3rd Choice
CODAP	15	8	4	18	5	4
Geogebra	8	10	9	7	12	8
Spreadsheet	4	9	14	2	10	15

Table 1 above shows that in the final rankings there was a clear overall preference for CODAP with 18 of the 27 (66.7%) participants ranking it first. This represents a change in the direction of CODAP up from 15 out of 27 in the initial rankings. It should be noted as well that of the 12 participants who changed their first choice more than half (7 out of 12) made CODAP their first choice and in only 2 instances was CODAP moved out of first place.

Another result of note was the "demotion" of spreadsheets. The spreadsheet activity was initially ranked last by 14 of 27 (51.9%) of the PSMTs of the remaining 13 PSMTs, 9 of 13 (69.2%) gave the spreadsheet a lower ranking after working through the activities.

Rationales for changing or not changing

What accounts for the change by those who changed their rankings? Before considering the rationales for the second ranking it is instructive to consider the PSMTs' rationales for the first rankings i.e. what were they telling us about what they valued before working through the task in detail. In analyzing those rationales a number of patterns emerged:

A number of PSMTs expressed concern about difficulty of usability: "With Codap, you have to teach students how to use the applet, which takes up substantial time." (I1P7 - Institution 1, PSMT 7); "I believe what will scare off the students is that the other technology platforms requires more clicking. So instead of actually learning about mean and median I think a good portion of the class will involve learning on how to use the software" (I2P10).

Interestingly some support was expressed for spreadsheets on the grounds of its utility outside of the particular task or even a school setting "Spreadsheet may not be the best but it allows for interaction with excel, which is commonly used in professions post schooling" (I1P9), "Spreadsheet is the most applicable and widely used in all kinds of jobs and tasks" (I1P10).

Usability and applicability outside the task are general issues and, in the rationales before the PSMTs worked through the task there was relatively little attention to the content of the task itself. Many PSMTs mentioned visualisation in a general sense but one PSMT wrote "I like the visualizations that CODAP and Geogebra provide. This allows students to have a visual understanding of the values. CODAP will also allow students to highlight and isolate various ideas for students to look more deeply at the ideas of mean and median" (I1P1). This level of explicit attention to the context of the task was not common.

Analysis of the rationales submitted by the PSMTs "answered" the three issues raised above. Using the software convinced some PSMTs that CODAP was "Not as hard to use as I thought" (I1P7), "I thought CODAP was complicated to operate, but it turned out to be unexpectedly convenient" (I2P3). It was also noted that "the [Geogebra] applet provided does not allow for much engagement with the software itself" (I1P9).

In addition, coding of the data showed a shift in attention towards the specifics of the task at hand. The most significant pattern to emerge, in terms of "math action technologies" Dick and Hollebrands (2011) is the number of PSMTs who noted that CODAP "combines features from both spreadsheets and Geogebra" (I2P12) to make the mathematical content of the task more visible and so "makes the comparison easier to see" (I2P6).

In the rationales for rankings after doing the tasks the PSMTs also started to pay attention to the suitability of each platform for the task. A number of PSMTs commented on the constraint placed by pre-made Geogebra applet on "math action technologies": "[The Geogebra applet] does a lot of the work for you" (I1P10); "The creativity in this applet compared to the rest is more limited" (I1P8). Many PSMTs got specific about how the platform enabled or constrained understanding mean and median, for example "even though Geogebra . . . provides visual representation of the concept . . . the comparison is my easier to see in CODAP . . . in the case of . . . two data set[s], all you need to do is . . . drag each data set to the x-axis of the graph and see the measurement of Median and Mean in numeric and graphical representation, whereas in Geogebra when you drag the data (change and manipulate data) you would not be able to see the previous data and result, unless taking a screenshot or opening a different browser" (I2P6).

In terms of the "demotion" of spreadsheets, the rationales noted the lack of visuals provided by the spreadsheet "The spreadsheet was moved to last because the only way data is displayed is a table" (I2P9), or noted that while visuals could be generated they would require some work "I find the spreadsheet rather limiting . . . If we want a visual, we have to put together a graph, which is something CODAP already has" (I1P7).

Overall, a comparison of the rationales for the pre- and post-rankings shows a shift away from generalised statements to statements that were more engaged with the understanding of the mathematics in the task.

Conclusion

Evaluating and choosing tasks for implementation in their classrooms is a vital task for teachers. Pre-service teachers, moreover, need experience in a trajectory of choosing a task, working through a task in detail and implementing the task to see the differences in their own understanding of the task at each stage of that trajectory. The research presented above engaged pre-service teachers in the first two stages of this trajectory. The results of the study were that than half the participants changed their ranking of three versions of the same task after they had worked through the tasks in detail showing how much difference there can be in understanding of a task before and after working through the task in detail. Furthermore, it was encouraging to see how much the focus of attention shifted from general statements about tasks and technology to specific attention to the mathematical content of the task and the possibilities for "math action technologies" in various platforms.

In this paper, we present the development of an investigation on the promotion of covariational reasoning in high school students (14-15 years old) in Mexico. The study consists of designing and applying a sequence of didactic activities that simulate a real situation virtually. The activities are organized through a Hypothetical Learning Trajectory supported by digital technology and elements of Cuevas-Pluvinage didactics. The activities were evaluated according to the levels of covariation proposed by Carlson and colleagues, categorizing students' achievements and difficulties for each level of understanding. The results show that the activities favor students' progress by moving from the context situation to the different representations, establishing the relationship between the variables, and identifying their functional dependence.

Keywords: Secondary Education, Technology, Algebra, and algebraic thinking.

Introduction

Variational thinking has been interpreted as a way of modeling the covariation between quantities and magnitudes, according to Vasco (2003):

> a dynamic way of thinking, which attempts to mentally produce systems that relate their internal variables so that they covary like the patterns of covariation of quantities of the same or different magnitudes in the cut-out subprocesses of reality. (p. 6)

In various investigations (Carlson et al., 2002; García, 2016; Tompson & Carlson, 2017), it has been found that the concept of covariation between variables leads to the concept of function because the covariation relationship is often expressed as a functional relationship. Despite being present from elementary algebra to calculus, it is still a topic that is a source of difficulties for students. They fail to perceive and relate the patterns between the quantities involved in the different mathematical situations presented to them. There are even studies, such as that of Aldon and Panero (2020), that have reported cases where the interpretation of the mathematical situation proposed when analyzing the variables involved, students confuse a graph with the trajectory of a moving object, from which a lack of clarity in the meaning of the axes and the interpretation of the graphical representations is inferred.

Given this problem, some studies, such as Vasco (2006), recommend that the teaching of variation should occur in various contexts that represent real situational problems for the student, that are adapted to the proposed learning objectives, and that lead to the concept of function. However, these contexts must have specific characteristics that make it possible to achieve these objectives; as mentioned by Hitt (2021), the characteristics of the environment that can contribute to the development of conceptual understanding include the teachers' approaches, the types of tasks given to students, and the use of a variety of representations.

For his part, Avila (2018) warns of the importance of variational thinking for the concept of a real function since "there is a need to establish activities in the classroom, in which school alternatives that promote the recognition of variation in situations in which the concept of function is present are raised" (p. 198).

Our study approaches activities from a variational-covariational approach with digital technology support. In the NCTM standards (2000), technology enriches the range and quality of investigations since it allows viewing mathematical ideas from multiple perspectives. The feedback enhances student learning that technology provides, and it gives teachers options for adapting instruction to student's special needs.

Theoretical Framework

Variational thinking

Since Moore and Carlson (2012) report the importance of variational and covariational reasoning for students' ability to model dynamic situations, the position we adopt regarding variational thinking corresponds to that of Maury and colleagues (2012), which is complemented by that of Moore and Carlson, since they conceive this thinking as the ability to identify phenomena of variation and change, to interpret them, describe them, quantify them, model them, transform them and predict their consequences. Developing variational thinking allows students to naturally identify phenomena of variation and change and to be able to model and transform them, which will contribute to the development of mathematical thinking processes linked to algebra, functions, and calculus.

Considering that the study has as part of its learning trajectory to involve the analysis of the coordination and functional relationship between variables, we assume as one of its central axes *the covariate reasoning,* which is defined by Carlson et al. (2002) as “the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other” (p. 357).

The framework on covariation proposed by Carlson and colleagues consists of mental actions, which provides a taxonomy to classify and analyze the behaviors that students present when engaging in covariation activities. According to the authors, there are five levels of development; however, for this research and considering the academic level, the activities were designed according to the first three levels: Level 1 (N1) Coordination, Level 2 (N2) Direction, and Level 3 (N3) Quantitative Coordination; which are presented in terms of mental actions supported by images.

Cuevas and Pluvinage Didactics

The implementation of this didactic framework is considered since it establishes didactic engineering for the planning of a mathematics program at a post-elementary level; proposing didactic principles that guide the design of tasks; for example, starting the activities with a conceptually rich problem of interest to the student, where the student is the one who solves it, and once the problem is solved, his answer must be verified—allowing the student to be an agent of action and leading him gradually towards the mathematical concept (Cuevas & Pluvinage, 2003).

Objectives

This study's objective is to design a didactic sequence that promotes the understanding of the processes of variation-covariation as an antecedent for the concept of function in high school students (14-15 years old). Activities are proposed in digital didactic environments to achieve this, which address mental actions linked to recognizing variables and their relationships. These activities aim to identify what level of covariation students reach when interacting with mathematical models that allow them to interpret, predict, describe and explain situations of functions, both linear and nonlinear. In this way, we will be able to inquire about the difficulties faced by students, categorizing them and associating them to each level of covariation.

Research Question

What levels of covariational reasoning do students achieve when interacting with scenarios designed for linear and nonlinear function covariation situations?

Methodology

This study is developed using Design-Based Research (DBR) proposed by (Bakker, 2018), consisting of the phases of preparation and design, teaching experiment, and analysis of results. For the design of our sequence of activities, we used a Hypothetical Learning Trajectory (HLT) (Simon 1995) and elements of Cuevas-Pluvinage didactics.

Phase 1: Preparation and design

The role of technology in this study is as a means of support for the simulation of our context of variation and covariation. The context used to carry out each activity consists of simulating the route of a cable car, where the student is asked to analyze the movement of the cabins in different sections of the way.

The objective of each activity is described below:

Activity #1. For this activity, mental action one (MA1) is taken into account, considering the coordination of the value of one variable with the changes in the other, i.e., in this case, it is considered whether the student goes through a process where they first try to identify the different magnitudes involved in the phenomenon: constants, parameters, and variables. Once they have identified which magnitudes vary and remain constant; students are expected to establish a functional relationship involving the magnitudes through different forms of representation (symbolic, tabular, and graphical) (see Figure 1a).

Activity #2 part 1. This activity takes into account mental action two (MA2), in which the coordination of the direction of change of one variable with the changes in the other variable is considered; that is, it is observed if it can identify the direction of change if it presents a growth or a decrease in the output value while considering the changes in the input value (see figure 1b).

Activity #2 part 2. In this activity, we consider the fourth principle of the Cuevas-Pluvinage didactics: try as much as possible every time operations that lead us to mathematical concepts are performed, to implement the inverse process.

This activity is implemented to observe if the students, by providing them with a graphical representation, can present AM1 behaviors (coordination of the two variables) and MA2 behaviors (identify that by changing one of the variables, the other one shows a decrease or an increase).

Activity #3 and #4. These activities focus on mental action three (MA3), the quantification of change. The coordination of the amount of change in the independent variable with the amount of change in the dependent variable is carried out. In this case, the student must identify accelerating (increasing) or decelerating (decreasing) variational behavior (see Figures 1c and 1d).

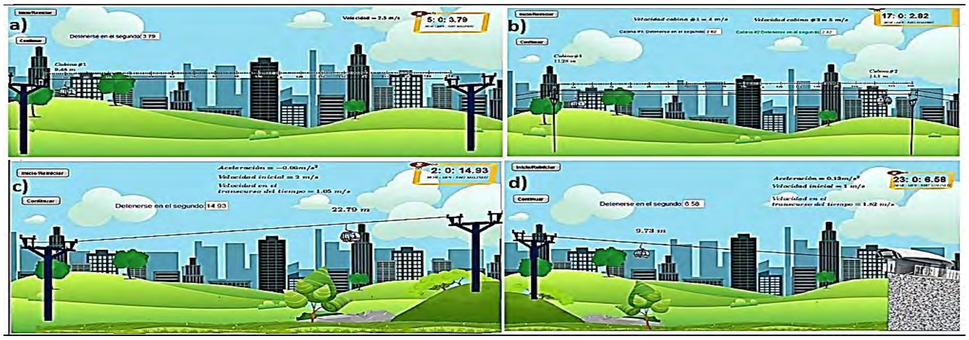

Figure 1. Scenarios used in each activity

For the particular context of this study, we have adapted the levels of covariation proposed by Carlson et al. (2002); the corresponding descriptors are shown below.

Table1. Descriptors of mental actions are used for the evaluation

Level	Description	Behaviors
Level 1 (L1) Coordination	At the coordination level, the images of covariation can support the mental action of coordinating the change of one variable with changes in the other variable (MA1)	In this case, the student must identify the different magnitudes involved in the context of the ropeway (time-hours, time-seconds, distance, speed, height), typifying the magnitudes involved in: constant, parameter, or variable. Once identified which magnitudes vary or remain constant, the student must establish a functional relationship involving the magnitudes through different forms of representation (symbolic, tabular, or graphical), which model the situation of the travel of a cabin in a section of the ropeway.
Level 2 (L2) Direction	At the direction level, the images of covariation can support the mental actions of coordinating the direction of change of one variable with changes in the other variable. The mental actions identified as MA1 and MA2 are both supported by L2 images.	In addition to the students showing Level 1, they should identify the direction of change, i.e., whether there is an increase or decrease in the output value (distance) while considering changes in the input value (time). When analyzing the graphical representations, the student must identify the functional relationships between the distance and time quantities. Subsequently, the student must determine which graphical representation grows or decreases faster than the other and justify such behavior.
Level 3 (L3) Quantitative Coordination	At the quantitative coordination level, the images of covariation can support the mental actions of coordinating the amount of change in one variable with changes in the other	The student identifies that the value of the distance decreases or increases (considering the difference between the distances) for each increment of time by intervals. Considering what magnitudes make them behave that way and how they behave (in our case, they consider what is

	variable. The mental actions identified as MA1, MA2, and MA3 are supported by L3 images.	happening with acceleration and velocity at that moment).

Phase 2: Teaching experiment

The research was conducted with 56 students in two groups (14-15 years old) in Mexico. Of which we considered 21 students since they were the ones who completed all the activities. Each student had a computer, Guided Learning and Exploration Sheets (GLES), and Interactive Virtual Didactic Scenarios (VIDS). The HLT comprises four activities, which correspond to four sessions of 50 minutes each; at the end of each session, the students handed in the GLES, and their answers were discussed as a group.

Phase 3: Analysis and results

In this article, we present the results of a student with the pseudonym Kenny, who was randomly selected from the sample. We will focus on making a detailed evaluation of his evolution in the levels of covariation during the activities presented. Kenny's case is an example of how the analysis was carried out for each student; reporting the results for all 21 students corresponds to later work in this report.

Activity #1:

In this first activity, Kenny partially achieved level 1 (MA1) because he failed to identify that the magnitude of the wire does not vary (see figure 2a); he also showed difficulties to identify what type of variation some magnitudes presented (see figure 2b).

It does not present any difficulty regarding the behavior of establishing a functional relationship in symbolic, tabular, and graphical form.

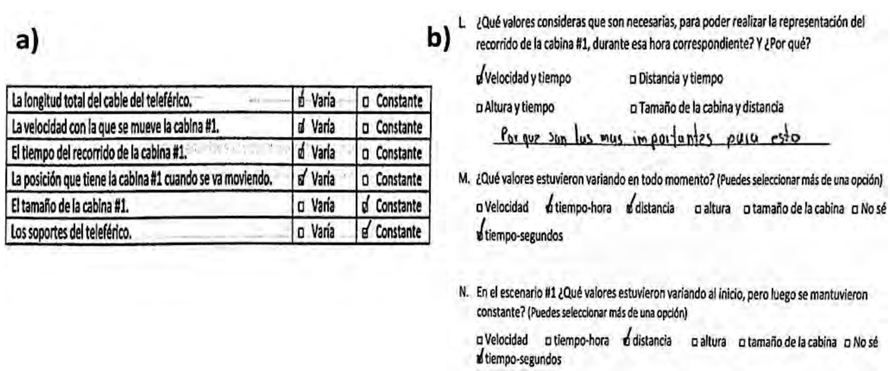

Figure 2. Kenny's response to Activity #1

Activity #2-part 1 and 2:

Kenny presents minor improvements in the behavior of MA1, identifying which magnitudes vary or which remain constant (see Figure 3a). He also shows progress in identifying magnitudes according to their type of variation. The behavior of establishing a functional relationship using different forms of representation is still present; however, we noticed that when asked to try to abstract the shape of the graph of the behavior of the phenomenon he was observing (the movement of two cabins during their ride on the cable car), Kenny opted to place points on the Cartesian plane (see Figure 3b), which shows that he needed values to be able to make this graphical representation. Therefore, Kenny has shown signs of achieving level 1.

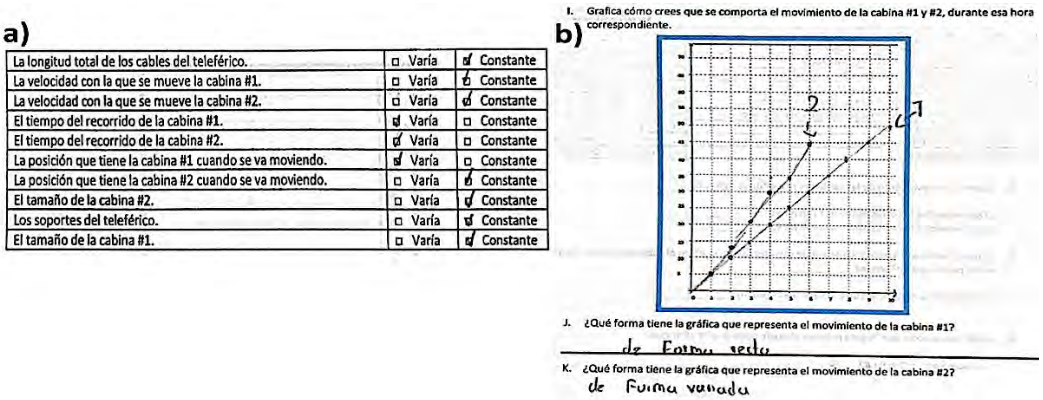

Figure 3. Kenny's response to activity #2-part 1.

Concerning MA2 behaviors, we note that Kenny manages to extrapolate and predict the distance that the cabin will travel at a specific time, which is not visible graphically (see figure 4b, section b_1). In activities #2-part 1, sections T and U (see figure 4a), and in the activity #2-part 2 (see figure 4c), Kenny manages to identify the growth pattern with the support of the graphs; we confirm the above even though in item C_1 (see figure 4c) he inverts the order of the answers. As shown in questions b_1 and b_2 (Figure 4b), it is clear that he only had confusion when exchanging the line between Booth #1 and Booth #2.

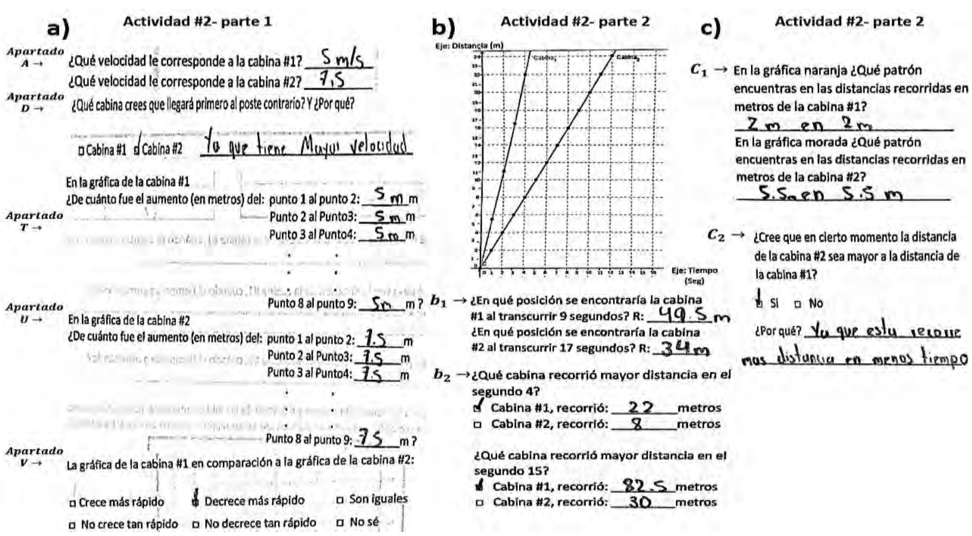

Figure 4. Kenny's response to activity #2-part 1 and 2.

Considering Kenny's confusion in the line of answer C_1 (see figure 4c), we consider as correct answer C_2 (see figure 4c) since it is sequential with answer C_1; therefore, we observe that both figure 4a and figure 4c support that Kenny identifies that one of the magnitudes causes another one to present changes of increase or decrease (see figure 4a-sections A and D and 4c-section C_2). Kenny presents difficulties when trying to select the behavior of a graph since we found that Kenny does not recognize the terms "grows or decreases faster" (see figure 4a, section V). We can conclude at this stage that Kenny shows signs of being able to reach Level 2.

Activity #3 and #4:

The evolution that Kenny has had concerning previous behaviors that presented difficulty in MA1 can be observed in activity #3 sections C, D, and E (see figure 5a), where he was able to correctly identify the type of variation that certain magnitudes presented at certain times of the cabin route, we also observe in activity #4 (see figure 5b), that Kenny shows behavior that allows him to identify the magnitudes and classify them into: constant, parameter or variable; and even manages to determine which variables are dependent on others.

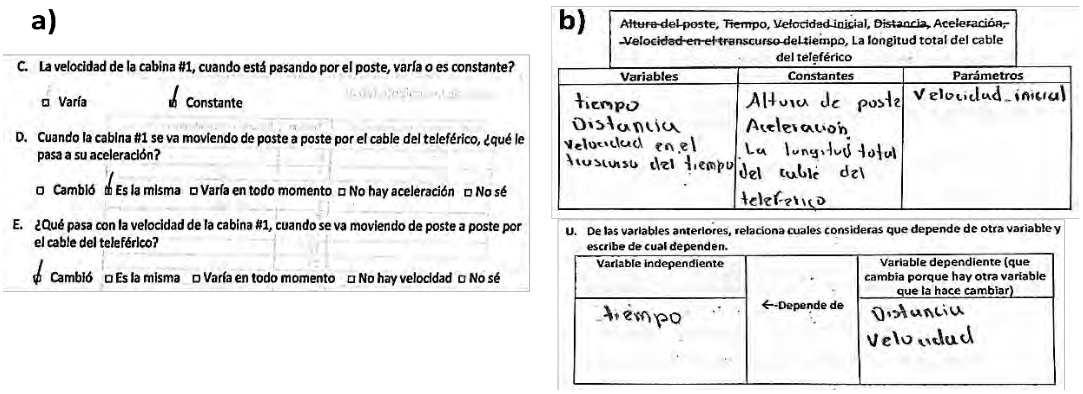

Figure 5: Kenny's response to activities #3 and #4

Another Progress of Kenny concerning MA2 behaviors is that he shows to be more familiar with the expressions "grows or decreases" and what they imply (see Figure 6a). It is worth noting that he still maintains the other MA2 behaviors previously described in the results of Activity #2-part 1 and 2 (see Figure 6b).

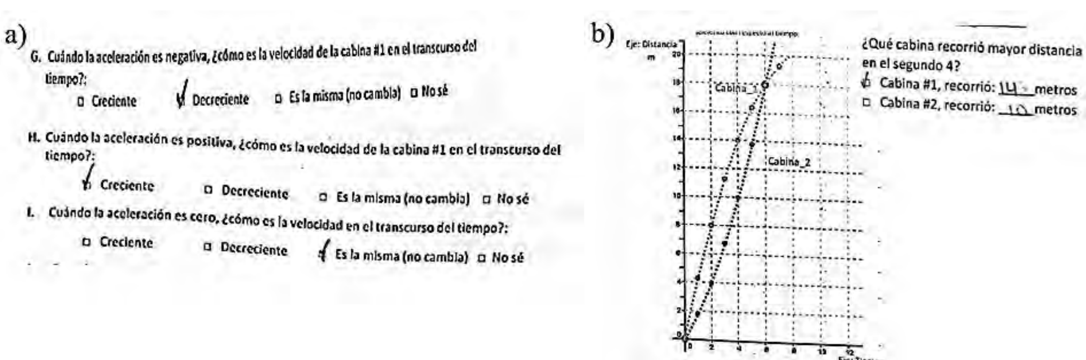

Figure 6: Kenny's response to activity #4

With all of the above, we can affirm that Kenny presents the necessary behaviors of MA1 and MA2 to place him in Level 2 of covariation.

During the analysis, we did not obtain evidence that Kenny managed to reach Level 3, despite presenting certain behaviors that allow him to identify that certain magnitudes influence others and that these cause them to behave in a certain way in certain intervals (see Figure 7a and 7b); he is not able to identify that the value of the distance decreases or increases (considering the difference between the distances) for each increment of time, by intervals (see Figure 7c).

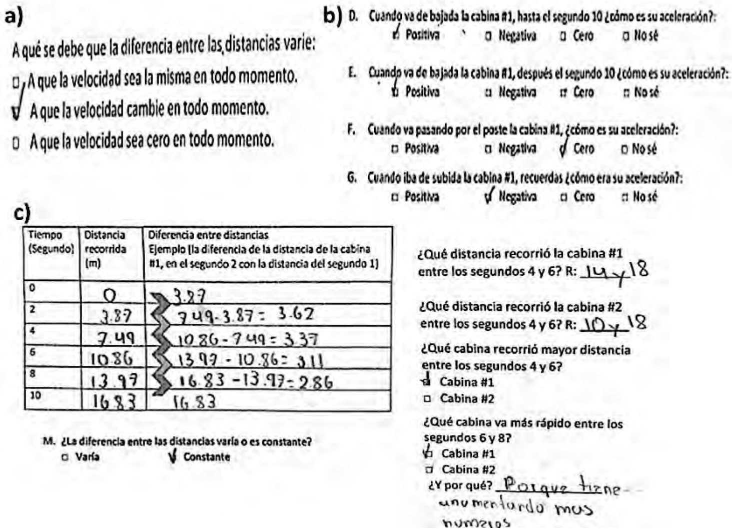

Figure 7: Kenny's response to activity #4

Discussion and conclusions

During the analysis, difficulties were observed in Kenny throughout the activities concerning some behaviors of the MAs, such as in the case of MA3, since there was no strong evidence of being able to coordinate the amount of change in one variable with changes in the other variable in certain intervals, the student could not advance to level 3 of covariation. These difficulties and the evolution of the behavior of each MA allowed us to determine that the student was able to reach level 2 of covariation. Overall, of the 21 students, only 71% managed to get N1, and of that group, only 24% achieved N2, thus answering our research question.

It is worth mentioning that the activities were developed face-to-face after a long period of sanitary confinement, which is a variable to consider. However, the VIDS instrumentation process did not present difficulty for the students in discovering the actions executed by each button, input box, and dynamic text.

The results of this research in progress are encouraging since the development of the activities allowed us to observe the evolution of Kenny's MA behaviors when interacting with the VIDS and making use of GLES; these MAs were designed in a graduated way, comparing and analyzing his improvements concerning some behaviors that, at the beginning of the first activity represented an obstacle for him. Our research is still in progress, and we consider these observations to project the redesign of activities and the learning trajectory towards a second research cycle.

En este artículo presentamos el desarrollo de una investigación sobre la promoción del razonamiento covariacional en estudiantes de secundaria (14-15 años) en México. El estudio consiste en el diseño y la aplicación de una secuencia de actividades didácticas que simulan de forma virtual una situación real. Las actividades se organizan mediante una trayectoria hipotética de aprendizaje con apoyo de la tecnología digital y elementos de la didáctica Cuevas-Pluvinage. Las actividades se evaluaron de acuerdo con los niveles de covariación propuestos por Carlson y colegas, categorizando los logros y las dificultades de los estudiantes para cada nivel de comprensión. Los resultados muestran que las actividades favorecen el progreso de los estudiantes al transitar de la situación de contexto hacia las diversas representaciones logrando establecer la relación entre las variables e identificar su dependencia funcional.

Palabras clave: Educación Secundaria, Tecnología, Álgebra y pensamiento algebraico.

Introducción

El pensamiento variacional ha sido interpretado como una forma de modelación de la covariación entre cantidades y magnitudes, de acuerdo con Vasco (2003):

> una manera de pensar dinámica, que intenta producir mentalmente sistemas que relacionen sus variables internas de tal manera que covaríen en forma semejante a los patrones de covariación de cantidades de la misma o distintas magnitudes en los subprocesos recortados de la realidad. (p. 6)

En diversas investigaciones (Carlson et al. 2002; García, 2016; Tompson y Carlson, 2017), se ha encontrado que el concepto de covariación entre variables conduce al concepto de función, debido a que la relación de covariación con frecuencia se expresa como una relación funcional. A pesar de estar presente desde el álgebra elemental hasta el cálculo, sigue siendo un tema que es una fuente de dificultades para los estudiantes; lo anterior debido a que no logran percibir y relacionar los patrones que surgen entre las cantidades involucradas en las diferentes situaciones matemáticas que se les presentan. Incluso hay estudios, como el de Aldon y Panero (2020), que han reportado casos donde la interpretación de la situación matemática propuesta al analizar las variables implicadas, los estudiantes confunden una gráfica con la trayectoria de un objeto en movimiento, de lo cual se infiere una falta de claridad en el significado de los ejes y en la interpretación de las representaciones gráficas.

Dada esa problemática, algunos estudios, como el de Vasco (2006), recomiendan que la enseñanza de la variación debe darse en una diversidad de contextos que representen para el estudiante problemas situacionales reales, que se adapten a los objetivos de aprendizaje propuestos y conduzcan al concepto de función. Sin embargo, estos contextos deben contar con ciertas características que posibiliten el alcance de dichos objetivos, tal como lo menciona Hitt (2021), las características del entorno que pueden contribuir al desarrollo de la comprensión conceptual incluyen los enfoques de los profesores, los tipos de tareas que se dan a los alumnos y el uso de una variedad de representaciones.

Por su parte, Ávila (2018) advierte de la importancia del pensamiento variacional para el concepto de función real, ya que "se observa la necesidad de establecer actividades en el aula de clases, en las que se planteen alternativas escolares que promuevan el reconocimiento de la variación en situaciones en las cuales el concepto de función está presente" (p. 198).

En nuestro estudio abordamos actividades desde un enfoque variacional-covariacional con el apoyo de la tecnología digital. En los estándares del NCTM (2000) se menciona que la tecnología enriquece la gama y la calidad de las investigaciones, ya que permite ver las ideas matemáticas desde múltiples perspectivas. El aprendizaje de los alumnos se ve favorecido por la retroalimentación que la tecnología proporciona, además ofrece a los profesores opciones para adaptar la enseñanza a las necesidades especiales de los alumnos.

Marco referencial

Pensamiento variacional

Dado que Moore y Carlson (2012) reportan la importancia del razonamiento variacional y covariacional para la capacidad de los estudiantes de modelar situaciones dinámicas, la postura que adoptamos con respecto al pensamiento variacional corresponde a la de Maury y colegas (2012), la cual se complementa con la de Moore y Carlson, ya que conciben a este pensamiento como la capacidad de identificar fenómenos de variación y cambio, para interpretarlos, describirlos, cuantificarlos, modelarlos, transformarlos y predecir sus consecuencias. Desarrollar el pensamiento variacional permite a los estudiantes identificar de manera natural fenómenos de variación y cambio; y que sean capaces de modelarlos y transformarlos, lo que contribuirá a desarrollar procesos de pensamiento matemático ligados al álgebra, las funciones y el cálculo.

Considerando que el estudio tiene como parte de su trayectoria de aprendizaje involucrar el análisis de la coordinación y la relación funcional entre variables, Asumimos como uno de sus ejes centrales *el razonamiento covariacional* el cual es definido por Carlson et al. (2002) como "las actividades cognitivas implicadas en la coordinación de dos cantidades que varían mientras se atiende a las formas en que cada una de ellas cambia con respecto a la otra" (p.357).

La propuesta de Carlson y colegas consiste en el marco de las acciones mentales, el cual proporciona una taxonomía para clasificar y analizar los comportamientos de los estudiantes al abordar actividades de covariación. De acuerdo con los autores, son cinco niveles de desarrollo; sin embargo, para los fines de esta investigación y considerando el nivel académico, las actividades se diseñaron de acuerdo con los tres primeros niveles: Nivel 1 (N1), Coordinación; Nivel 2 (N2), Dirección y Nivel 3 (N3), Coordinación Cuantitativa. Estos niveles se presentan en términos de las acciones mentales sustentadas en imágenes.

Didáctica Cuevas y Pluvinage

Se considera la implementación de este marco didáctico dado que establece una ingeniería didáctica para la planeación de un programa de matemáticas en un nivel post-elemental; proponiendo principios didácticos que guían el diseño de tareas; por ejemplo, iniciar las actividades mediante un problema conceptualmente rico y de interés para el estudiante, en donde sea él quíen lo resuelva, y una vez resuelto el problema se debe verificar su respuesta. Permitiendo al estudiante ser un agente de acción y conduciéndolo de manera gradual hacia el concepto matemático (Cuevas y Pluvinage, 2003).

Objetivo

Nuestro objetivo es el diseño de una secuencia didáctica que promueva la comprensión de los procesos de variación-covariación, como antecedente para el concepto de función en estudiantes de secundaria (14-15 años). Para lograrlo se proponen actividades en entornos didácticos digitales, los cuales abordan acciones mentales que estén ligados al reconocimiento de las variables y las relaciones entre ellas. Por medio de estas actividades se pretende identificar qué nivel de covariación logran alcanzar los estudiantes al interactuar con modelos matemáticos que le permitan interpretar, predecir, describir y explicar situaciones de funciones, tanto lineales como no lineales. De esta manera, podremos indagar acerca de las dificultades a las que se enfrentan los estudiantes, categorizándolas y asociándolas a cada nivel de covariación.

Pregunta de investigación

¿Qué niveles de razonamiento covariacional logran alcanzar los estudiantes al interactuar con los escenarios diseñados para situaciones de covariación de funciones lineales y no lineales?

Metodología

Este estudio se desarrolla mediante una investigación basada en diseño (IBD) propuesta por (Bakker, 2018), la cual consiste en las fases de preparación y diseño, experimento de enseñanza y análisis de resultados. Para el diseño de la secuencia de actividades, utilizamos una trayectoria hipotética de aprendizaje (Simon, 1995) y elementos de la didáctica Cuevas-Pluvinage.

Fase 1: Preparación y diseño

El papel de juega la tecnología en este estudio es como medio de apoyo para la simulación de nuestro contexto de variación y covariación. El contexto que se utiliza para llevar a cabo cada actividad consiste en simular el trayecto de un teleférico, en donde se le solicita al estudiante analizar el movimiento de las cabinas en distintos tramos del recorrido.

A continuación, describimos el objetivo de cada actividad:

Actividad #1. Para esta actividad se toma en cuenta la acción mental uno (AM1), considerando la coordinación del valor de una variable con los cambios en la otra, es decir, en este caso se atiende si el estudiante transita por un proceso en donde primero trate de identificar las diferentes magnitudes involucradas en el fenómeno: constantes, parámetros y variables. Una vez que han identificado cuáles magnitudes varian y cuales se mantienen constantes, se espera que los estudiantes establezcan una relación funcional que involucre a las magnitudes mediante diferentes formas de representación (simbólica, tabular y gráfica) (ver figura 1a).

Actividad #2 parte 1. En esta actividad se toma en cuenta la acción mental dos (AM2), en la que se considera la coordinación de la dirección del cambio de una variable con los cambios en la otra variable; es decir, se observa si puede identificar la dirección del cambio, si este presenta un crecimiento o un decrecimiento en el valor de salida, mientras se consideran los cambios en el valor de entrada (ver figura 1b).

Actividad #2-parte 2. En esta actividad consideramos el cuarto principio de la didáctica Cuevas-Pluvinage: intentar en lo posible, cada vez que se realicen operaciones que nos lleven a conceptos matemáticos, implementar la operación inversa.

Se implementa está actividad con el fin de poder observar si los estudiantes, al proporcionarles una representación gráfica, pueden presentar comportamientos de la AM1 (coordinación de las dos variables) y comportamientos de la AM2 (identificar que al cambiar una de las variables la otra presenta una disminución o un aumento)

Actividad #3 y #4. Estas actividades se enfocan en la acción mental tres (AM3), en la cuantificación del cambio. Se lleva a cabo la coordinación de la cantidad de cambio en la variable independiente, con la cantidad de cambio en la variable dependiente. En este caso, el estudiante debe identificar el comportamiento variacional acelerado (cada vez más grande) o desacelerado (cada vez más pequeño) (ver figura 1c y 1d).

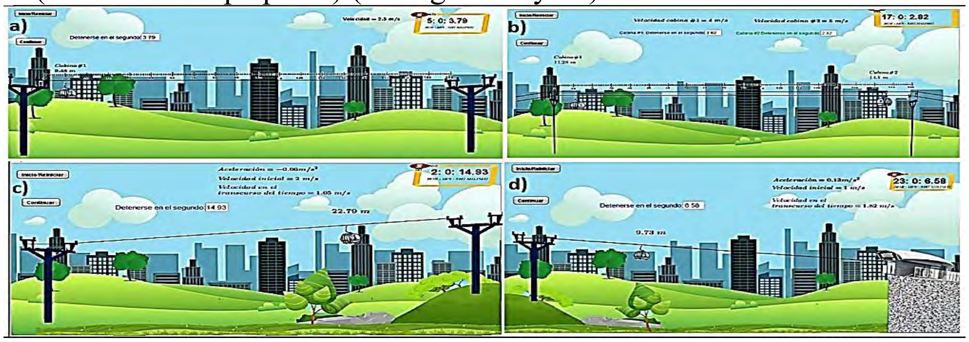

Figura 1. Escenarios empleados en cada actividad

Para el contexto de este estudio realizamos una adaptación de los niveles de covariación de Carlson et al. (2002), los descriptores correspondientes se muestran a continuación.

Tabla1. Descriptores de las acciones mentales utilizados para la evaluación

Nivel	Descripción	Comportamiento
Nivel 1 (N1) La Coordinación	En el nivel de coordinación, las imágenes de la covariación pueden sustentar a la acción mental de coordinar el cambio de una variable con cambios en la otra variable (AM1)	El estudiante identifica diferentes magnitudes involucradas en el contexto del teleférico (tiempo-horas, tiempo-segundos, distancia, velocidad, altura), clasificandolas en constante, parámetro o variable. Una vez que identifica qué magnitudes varian y cuáles se mantienen constantes, el estudiante establece una relación funcional que las involucra mediante distintas formas de representación (simbólica, tabular o gráfica), las cuales modelan el recorrido de una cabina en un tramo del teleférico.
Nivel 2 (N2) La Dirección	En el nivel de dirección, las imágenes de la covariación pueden sustentar a las acciones mentales de coordinar la dirección del cambio de una de las variables con cambios en la otra. Las acciones mentales identificadas como AM1 y AM2 ambas son sustentas por imágenes de N2.	Además de que el estudiante muestre el Nivel 1, debe identificar la dirección del cambio; i.e. si presenta un crecimiento o decrecimiento en el valor de salida (distancia) mientras considera los cambios en el valor de entrada (tiempo). Al analizar las representaciones gráficas el estudiante debe identificar las relaciones funcionales entre las magnitudes de distancia y tiempo. Posteriormente debe identificar cuál representación gráfica crece o decrece más rápido en comparación con la otra, y justificar dicho comportamiento.
Nivel 3 (N3) Cuantitativa	En el nivel de la coordinación cuantitativa, las imágenes de la covariación pueden	El estudiante identifica que el valor de la distancia disminuye o aumenta (considerando la diferencia entre las distancias) por cada incremento de tiempo, por intervalos.

	sustentar a las acciones mentales de coordinar la cantidad de cambio en una variable con cambios en la otra. Las acciones mentales identificadas como AM1, AM2 y AM3 son sustentadas por las imágenes de N3.	Considerando qué magnitudes hacen que se comporten de esa manera y su forma de comportarse (en nuestro caso que consideren que está pasando con la aceleración y la velocidad en ese momento).

Fase 2: Experimento de enseñanza

La investigación se realizó con 56 estudiantes (14-15 años) en dos grupos en México. De los cuales consideramos 21 estudiantes, que fueron los que completaron todas las actividades. Cada estudiante contaba con una computadora, hojas impresas de exploración y aprendizaje guiado (HEAG), y escenarios didácticos virtuales interactivos (EDVI). La THA está conformada por cuatro actividades, las cuales corresponden a cuatro sesiones de 50 minutos cada una, al finalizar cada sesión los estudiantes entregaban las HEAG y se discutían grupalmente sus respuestas.

Resultados

En este artículo presentamos los resultados de un estudiante con el seudónimo de Kenny, el cual fue seleccionado aleatoriamente de la muestra y nos enfocaremos en hacer una evaluación detallada de su evolución en los niveles de covariación durante las actividades presentadas. El caso de Kenny es un ejemplo de cómo se llevó a cabo el análisis para cada estudiante, reportar los resultados de los 21 estudiantes corresponde a un trabajo posterior a este informe.

Actividad #1:

En esta primera actividad, Kenny logró parcialmente alcanzar el nivel 1 (AM1), debido a que no logró identificar que la magnitud del cable no varía (ver figura 2a), también mostraba dificultades para identificar qué tipo de variación presentaban algunas magnitudes (ver figura 2b)

En lo que respecta al comportamiento de establecer una relación funcional de forma simbólica, tabular y gráfica, no presenta dificultad.

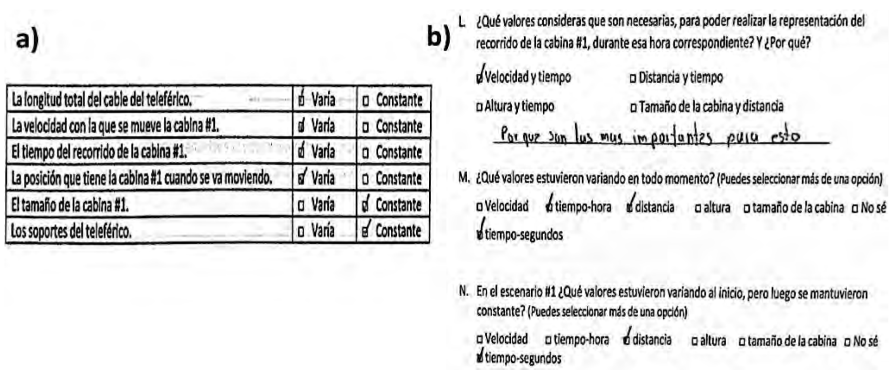

Figura 2. Respuesta de Kenny a la actividad #1

Actividad #2-parte 1 y 2:

Kenny presenta pequeñas mejorías en el comportamiento de la AM1, al identificar cuáles magnitudes varían o cuáles se mantienen constantes (ver figura 3a). También presenta un progreso en identificar magnitudes según su tipo de variación. El comportamiento de establecer una relación funcional haciendo uso de diferentes formas de representación aún sigue presente, sin embargo, notamos que al solicitarle que tratara de abstraer la forma de la gráfica del comportamiento del fenómeno que estaba observando (el movimiento de dos cabinas durante su recorrido por el teleférico), Kenny opta por colocar puntos en el plano cartesiano (ver figura 3b), lo cual muestra que precisó de valores para poder realizar esa representación gráfica. Por lo tanto, Kenny ha mostrado indicos de lograr el nivel 1.

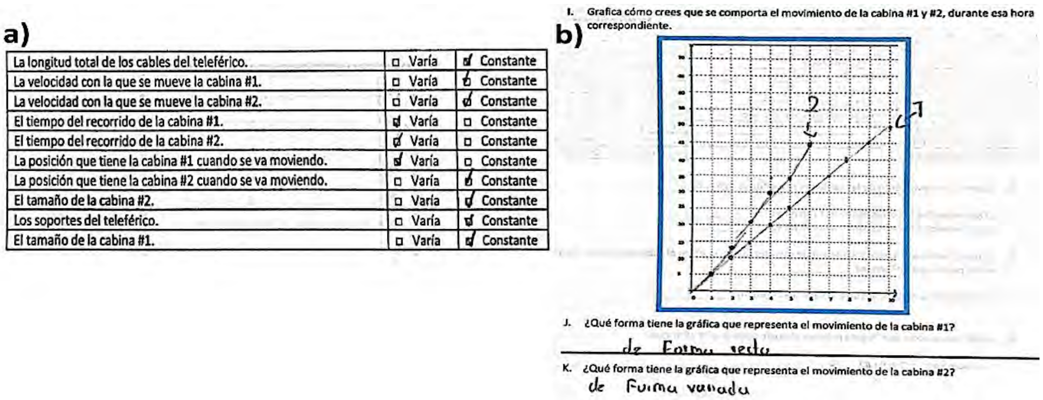

Figura 3. Respuesta de Kenny a la actividad #2-parte 1

Con respecto a los comportamientos de la AM2, notamos que Kenny logra extrapolar y predecir la distancia que recorrerá la cabina en un determinado momento, el cual no es visible de forma gráfica (ver figura 4b, apartado b_1).En las actividades #2-parte 1, apartado T y U (ver figura 4a) y en la actividad #2-parte 2 (ver figura 4c), Kenny logra identificar el patrón de crecimiento con el apoyo de las gráficas, confirmamos lo anterior a pesar de que en el item C_1 (ver figura 4c) invierte el orden de las respuestas. Por lo mostrado en las preguntas b_1 y b_2 (figura 4b) es claro que solo tuvo una confusión al intercambiar la linea entre cabina #1 y cabina #2.

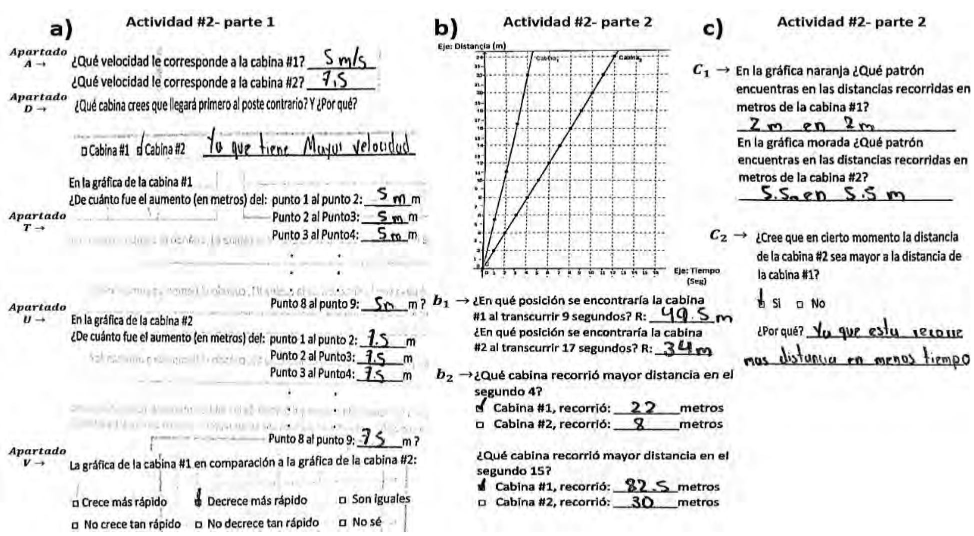

Figura 4. Respuesta de Kenny a la actividad #2-parte 1 y 2

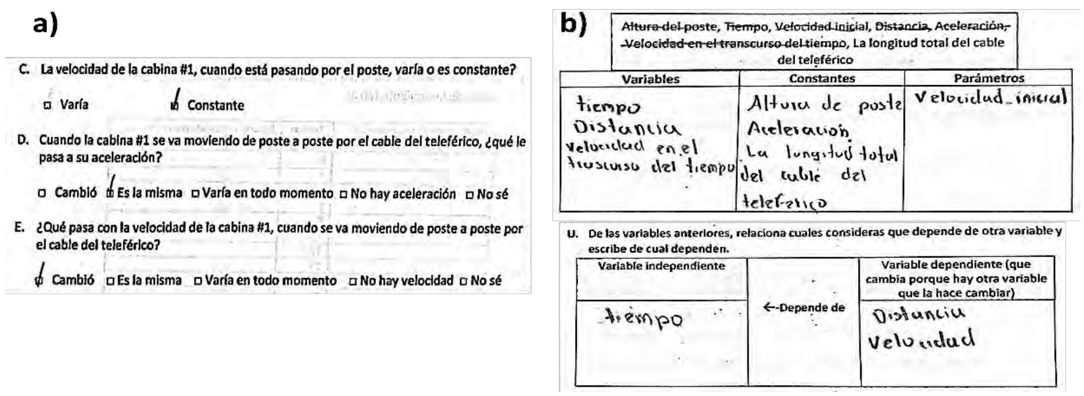
Considerando la confusión de Kenny en la línea de la respuesta C_1 (ver figura 4c), consideramos como correcta la respuesta C_2 (ver figura 4c), puesto que es secuencial con la respuesta C_1, por lo tanto, se observa que tanto la figura 4a como la figura 4c avalan que Kenny identifica que una de las magnitudes hace que otra presente cambios de aumento o disminución (ver figura 4a -apartados A y D y 4c-apartado C_2).

Kenny presenta dificultades al tratar de seleccionar el comportamiento de una gráfica, ya que, comprobamos que Kenny no reconoce los términos“crece o decrece más rápido” (ver figura 4a, apartado V). Podemos concluir en esta etapa que Kenny, presenta indicios de poder alcanzar el Nivel 2.

Actividad #3 y #4:

La evolución que ha tenido Kenny con respecto a los comportamientos previos que presentaban dificultad en la AM1, se puede observar la actividad #3 apartados C, D y E (ver figura 5a), donde pudo identificar correctamente el tipo de variación que presentaban ciertas magnitudes en determinados momentos del recorrido de la cabina, también observamos en la actividad #4 (ver figura 5b), que Kenny presenta un comportamiento que le permite identificar las magnitudes y clasificarlas en: constante, parámetro o variable; e incluso logra determinar que variables son dependientes de otras.



a)

C. La velocidad de la cabina #1, cuando está pasando por el poste, varía o es constante?
□ Varía ✓ Constante

D. Cuando la cabina #1 se va moviendo de poste a poste por el cable del teleférico, ¿qué le pasa a su aceleración?
□ Cambió ✓ Es la misma □ Varía en todo momento □ No hay aceleración □ No sé

E. ¿Qué pasa con la velocidad de la cabina #1, cuando se va moviendo de poste a poste por el cable del teleférico?
✓ Cambió □ Es la misma □ Varía en todo momento □ No hay velocidad □ No sé

b)

~~Altura del poste~~, ~~Tiempo~~, ~~Velocidad inicial~~, ~~Distancia~~, ~~Aceleración~~, ~~Velocidad en el transcurso del tiempo~~, La longitud total del cable del teleférico

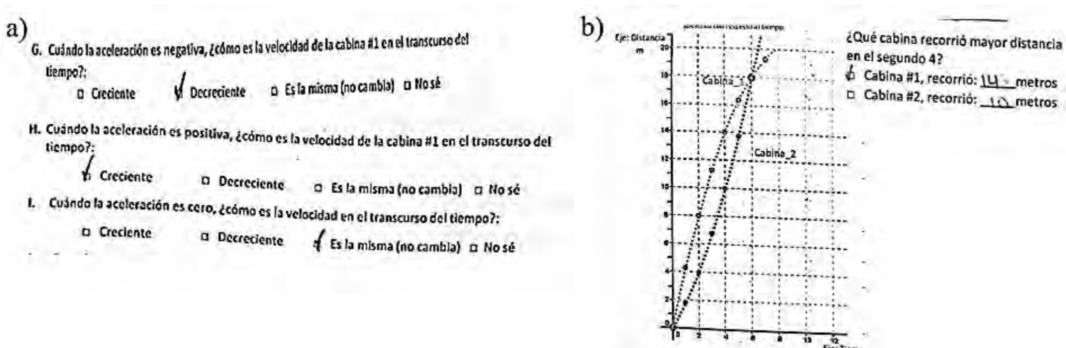
Variables	Constantes	Parámetros
tiempo Distancia Velocidad en el trascurso del tiempo	Altura de poste Aceleración La longitud total del cable del teleférico	Velocidad inicial

U. De las variables anteriores, relaciona cuales consideras que depende de otra variable y escribe de cual dependen.

Variable independiente		Variable dependiente (que cambia porque hay otra variable que la hace cambiar)
tiempo	←Depende de	Distancia Velocidad

Figura 5: Respuesta de Kenny a la actividad #3 y #4

Otro Progreso de Kenny con respecto a los comportamientos de AM2 es que desmuestra estar más familiarizado con las expresiones “crece o decrece” y lo que implica cada una de ellas (ver figura 6a). Cabe destacar que aún sigue manteniendo los demás comportamientos de la AM2, anteriormente descritos en los resultados de la Actividad #2-parte 1y 2 (ver figura 6b)



a)

G. Cuándo la aceleración es negativa, ¿cómo es la velocidad de la cabina #1 en el transcurso del tiempo?:
□ Creciente ✓ Decreciente □ Es la misma (no cambia) □ No sé

H. Cuándo la aceleración es positiva, ¿cómo es la velocidad de la cabina #1 en el transcurso del tiempo?:
✓ Creciente □ Decreciente □ Es la misma (no cambia) □ No sé

I. Cuándo la aceleración es cero, ¿cómo es la velocidad en el transcurso del tiempo?:
□ Creciente □ Decreciente ✓ Es la misma (no cambia) □ No sé

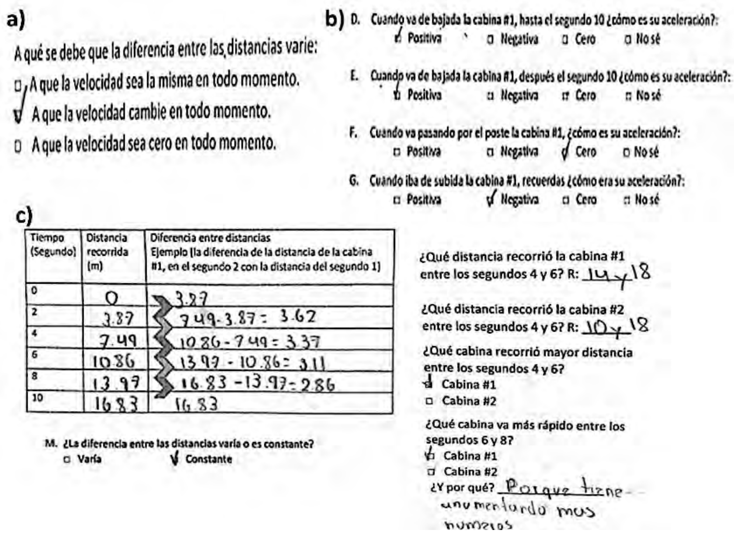
b)

¿Qué cabina recorrió mayor distancia en el segundo 4?
✓ Cabina #1, recorrió: 14 metros
□ Cabina #2, recorrió: 10 metros

Figura 6: Respuesta de Kenny a la actividad #4

Con todo lo expresado anteriormente podemos afirmar que Kenny presenta los comportamientos necesarios de AM1 y AM2 para poder ubicarlo en el Nivel 2 de covariación.

Durante el análisis no encontramos que Kenny alcanzara el Nivel 3, a pesar de presentar ciertos comportamientos que le permiten identificar que ciertas magnitudes influyen en otras, y que estas causan que se comporten de cierta forma en determinados intervalos (ver figura 7a y 7b), no logró identificar que el valor de la distancia disminuye o aumenta (considerando la diferencia entre las distancias) por cada incremento de tiempo, por intervalos (ver figura 7c).



Tiempo (Segundo)	Distancia recorrida (m)	Diferencia entre distancias Ejemplo (la diferencia de la distancia de la cabina #1, en el segundo 2 con la distancia del segundo 1)
0	0	3.87
2	3.87	7.49-3.87 = 3.62
4	7.49	10.86-7.49 = 3.37
6	10.86	13.97-10.86 = 3.11
8	13.97	16.83-13.97 = 2.86
10	16.83	16.83

Figura 7: Respuesta de Kenny a la actividad #4

Discusión y conclusiones

Durante el análisis se observaron dificultades que se presentaron en Kenny a lo largo de las actividades con respecto a algunos comportamientos de las AM, tal es el caso de la AM3, dado que no se encontraron indicios contudenetes de poder coordinar la cantidad de cambio en una variable con cambios en la otra variable en determinados intervalos, el estudiante no pudo avanzar hacia el nivel 3 de covariación. Estas dificultades y su evolución de comportamientos de cada AM, nos permitieron determinar que el estudiante logró alcanzar el nivel 2 de covariación. De forma general de los 21 estudiantes solo el 71% logro alcanzar el N1 y de ese grupo solo el 24% logro el N2 con lo cual damos respuesta a nuestra pregunta de investigación.

Cabe mencionar que las actividades se desarrollaron de forma presencial después de un largo periodo de confinamiento sanitario, lo cual es una variable a considerar. Sin embargo, el proceso de instrumentación de los EDVI no presentó dificultad en los estudiantes al descubrir las acciones ejecutadas por cada botón, casillas de entrada y textos dinámicos.

Los resultados de esta investigación en proceso son alentadores, ya que el desarrollo de las actividades permitió observar la evolución de los comportamientos de las AM de Kenny al interactuar con los EDVIs, haciendo uso de HEAG, estas AM se diseñaron de forma graduada, comparando y analizando sus mejorías con respecto a algunos comportamientos que, al inicio de la primera actividad representabán un obstáculo para él. Nuestra investigación sigue en desarrollo y consideramos estas observaciones para proyectar el rediseño de actividades y de la trayectoria de aprendizaje hacia un segundo ciclo de investigación.

CLIMATE CHANGE BY THE NUMBERS: HOW NUMERICAL ESTIMATION CAN SUPPORT SCIENCE LEARNING

Ian Thacker
University of Texas, San Antonio
ian.thacker@utsa.edu

Prompting people to estimate climate change numbers before showing them the true value can shift learners' attitudes and conceptions. Yet, interventions created for such a learning experience are not easily accessible to the general public. The purpose of this preregistered study was to address this research gap by developing and testing an openly accessible online intervention that presents participants with novel numbers about climate change after they estimate those numbers. An experimental online study design was used to investigate the impact of the intervention on undergraduate students' climate change understanding and plausibility perceptions. Findings revealed that posttest climate change knowledge was higher among those randomly assigned to use the app compared with those assigned to a control condition, and that supplementing this experience with numeracy instruction was linked with more robust gains.

Keywords: climate change education; conceptual change; numerical estimation

Misconceptions about climate change are widespread in the USA. For example, as of September 2020, only 55% of adults in the USA correctly believed that most climate scientists think that climate change is happening, suggesting that the remaining 45% hold a serious misconception (Marlon et al., 2020). Fortunately, many approaches exist that have the potential to shift these misconceptions.

Numbers found in the news or online can be a powerful tool for science learning. For example, I encourage the reader to take a moment to estimate in the following quantity: What is the percentage change in the world's ocean ice cover since 1960? The true value may surprise you (see footnote).[1] Presentation of novel data after people first estimate that data can elicit more explicit reflection on the novel evidence and integration of supported claims (Richter & Maier, 2017) and can subsequently shift people's attitudes, beliefs, and misconceptions to be more aligned with scientists, particularly with regards to climate change (Ranney & Clark, 2016; Ranney et al., 2019; Rinne et al., 2006; Thacker & Sinatra, 2022). These findings suggests that just a handful of numbers can incite conceptual change. Findings also show conceptual change occurring as a result of such interventions are moderated by people's willingness and openness to reason with new evidence (Thacker & Sinatra, 2022). However despite these promising findings, the interventions created for these studies are not easily accessible to the general public and the extent to which conceptual changes endure over time is not well known.

The purpose of this preregistered conceptual replication study (Plucker & Makel, 2021) was to address this research gap by developing and testing a novel and openly accessible online intervention that presents participants with novel numbers about climate change after they estimate those numbers. The study uses an experimental design to investigate the impact of the intervention on undergraduate students' science learning and test whether affective and motivational constructs that are hypothesized to moderate this change, as hypothesized in models of conceptual change.

[1] The change in the world's ocean ice cover since 1960 is a 40% decrease (Ranney & Clark, 2016).

Theoretical Framework

Plausibility Judgments for Conceptual Change

The Plausibility Judgments for Conceptual Change model (PJCC), proposes that novel information (such as surprising data) can be a catalyst for conceptual change because it can prompt learners to appraise or reappraise the plausibility of their existing beliefs (Lombardi, et al., 2016). When people encounter novel information such as a surprising number about climate change, they first process the information for validity—perhaps by considering the credibility of the source and estimating whether the information seems reasonable—and then make a judgment of the plausibility of the conception supported by the new information. The extent to which people explicitly evaluate the plausibility of a conception depends, in part, on their motivation, emotion, and views about knowledge (or epistemic dispositions). More explicit plausibility evaluations are thought to leads to increased potential for conceptual change. For example, when a person estimates a number, they may draw from their prior knowledge or apply quantitative reasoning skills. Such an explicitly crafted estimate may better prepare the learner to interpret and assess the validity of a scientifically accepted value when later presented with it (c.f., Lombardi et al., 2016; Richter & Maier, 2017).

Numerical Estimation

Numerical estimation is an educated guess for a quantity that can draw from a person's prior experiences and understanding of number and operations (Dowker, 2005). Understanding and estimating magnitudes of quantities is considered to be central to the development of number concept (Siegler, 2016) and represents an important skill that is emphasized in both mathematics and science K–12 standards (Cheuk, 2012).

Of the common categories of numerical estimation skills (e.g., computational estimation and numerosity; Reys & Reys, 2004), research on measurement estimation is the most relevant for this study. Measurement estimation concerns the explicit estimation of real-world measures (Sowder & Wheeler, 1989) and is useful for understanding factors that help people judge whether real-world quantities are reasonable and valid. Findings suggest that peoples' estimation accuracy and judgments of reasonableness improve when they use measurement estimation strategies, such as a tolerance for error and impression in estimates (Shimizu & Ishida, 1994; Thacker et al., 2021), flexible techniques for rounding digits (Joram et al., 1998), and use of the benchmark strategy—the use of known and given values to estimate unknown values through processes of analogy, association, mental iteration, and/or proportional reasoning (Brown & Siegler, 2001; Joram et al., 1998, Siegler, 2016). For example, when asked to estimate a "real world" quantity, a skilled learner might draw from their prior experiences, recall related quantities, and mathematically manipulate them to more accurately arrive at an estimate. Such an explicitly crafted estimate might better prepare the learner to interpret and assess the validity of a scientifically accepted value when later presented with it (c.f., Lombardi et al., 2016; Richter & Maier, 2017).

Numerical Estimation for Conceptual Change

Experimental research has found that presenting people with novel climate change numbers after they estimate them can support climate change learning, and that supplementing such an experience with instruction on numerical estimation strategies and prompts to activate reflection can positively impact learning (Ranney & Clark, 2016; Thacker & Sinatra, 2022). For example, Thacker & Sinatra (2022) found that asking people to estimate climate change numbers before presenting them with the true value led to increased climate change knowledge when compared with a control group that read an expository text about the greenhouse effect. Further, although they found no main effects of modifying the intervention with either estimation instruction or prompts to activate reflection, they did find learning gains when including *both* modifications among individuals who were willing and open to reason with new evidence. Yet, despite these promising findings, this intervention was used in a closed setting and was not openly accessible to the public. Further, the extent to which conceptual changes endured over time was not well documented. Also, no explanation or justification for the validity of the "true values" were provided, which may have dampened people's perceptions that climate change is plausible.

Preregistered Research Questions and Hypotheses

The current study aimed to test whether the findings of Thacker & Sinatra (2022) would replicate when the intervention was modified to be (a) openly accessible, (b) include estimation accuracy feedback, (c) include justification for each number estimated, and (d) when the posttest assessment was completed ten days after the intervention. Namely, I sought to answer the following preregistered research questions (for the full anonymous preregistration, see https://bit.ly/3rP2m9c):

- RQ1. To what extent would estimation of and exposure to novel climate change data using an online learning intervention improve learners' climate change knowledge and plausibility judgments compared with reading an expository text?
    - (H1) I hypothesized that people assigned to the intervention conditions would have greater knowledge at posttest when compared with people assigned to read an expository text. I anticipated no significant differences in climate change plausibility perceptions between the intervention groups and the comparison group at posttest or delayed posttest.
- RQ2. To what extent do warm constructs (i.e., mathematics anxiety and epistemic dispositions) moderate the effects of the interventions on knowledge and plausibility?
    - (H2.1) Math anxiety: I anticipated that individuals with high math anxiety would benefit less from the mathematics skills instruction. That is, I expected that math anxiety would negatively moderate the effects of the intervention modified with estimation instruction when the outcome is climate change knowledge or plausibility perceptions.
    - (H2.2) Epistemic dispositions: I anticipated that individuals with higher levels of active open-minded thinking would benefit more from the intervention and modified intervention compared with the comparison condition when the outcome was climate change knowledge. That is, I expected that active open-minded thinking would positively moderate the effects of the intervention. I also anticipated that there would be a significant main effect of active open-minded thinking on plausibility perceptions, but no significant interactions with the experimental conditions.
- RQ3. To what extent does enhancing the intervention with instruction on estimation strategies change learners' climate change knowledge and plausibility?
    - (H3) I hypothesized that supplementing the intervention with instruction on estimation skills would lead learners to report more scientific knowledge about climate change compared with those who are assigned to the intervention but without estimation instruction. I expected no significant differences in climate change plausibility between these conditions.

One additional research question was posed in the preregistration concerning whether self-reported estimation strategies differed across conditions. Related analyses are still underway.

Methods

Participants and Procedure

I formed a national online Qualtrics panel of $N = 605$ undergraduate students to participate in an experimental online survey. To obtain this sample, Qualtrics representatives initially used multiple platforms to widely share a survey link online, 2651 people initially clicked on the link to participate, but 2046 were dropped from the analysis because they either did not meet the eligibility criteria (over 18 and a full-time undergraduate student), did not pass an attention check, or because they were flagged as a "speeder" by the algorithm created by Qualtrics. There was no missing data at pretest or posttest. Of the 605 students who met this criteria, 57% agreed to participate in a followup study, and 88 (15% of the analytic sample) completed a short followup survey 10 days after completing the initial intervention.

Participants in the main analytic sample were 20.3 years old on average, 74% Female, 15% Male, 3% nonbinary/other, 56% White, 19% African American, 17% Asian American, 5% Two or More Races, and 2% American Indian or Alaskan Native. All participants (a) completed a pretest to measure their misconceptions about climate change, plausibility judgments about climate change, mathematics anxiety, and prior epistemic dispositions, (b) were directed to a web app that randomly assigned them to one of three conditions (control group that read an expository text about the greenhouse effect, the intervention, and the intervention supplemented with estimation instruction), (c) were directed back to the original survey where they completed an identical posttest of knowledge, plausibility perceptions, and a demographics questionnaire, and (d) were contacted ten days later to complete the knowledge and plausibility perceptions measured again (but only if they had initially indicated that they agreed to be contacted in the demographics section of the posttest). For a summary of the procedures, see Figure 1.

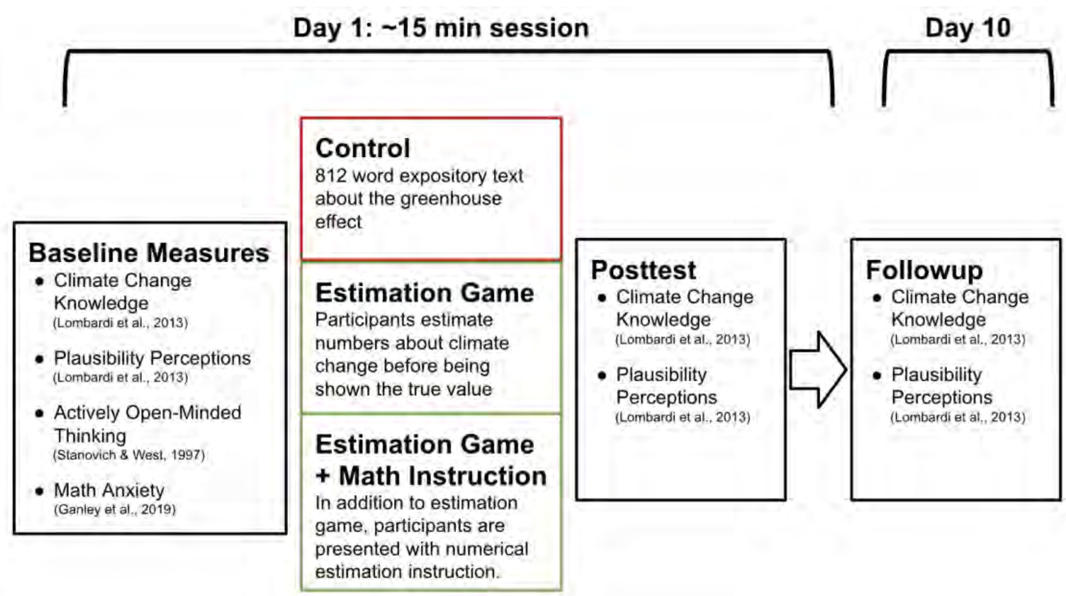

Figure 1. Visual Representation of the Survey Flow, Materials, and Procedures

Materials

All survey materials and intervention texts are available in the supplemental materials (https://bit.ly/3rP2m9c), also see Appendix A for select excerpts.

Conditions

There were three experimental conditions: the intervention group, modified intervention group, and control group. Students in the baseline intervention (also referred to as the "Estimation Game") estimated 12 climate change related numbers before being presented with the scientifically accepted answer, a short explanation to justify the scientifically accepted answer, and accuracy feedback. Students in the modified intervention condition completed the Estimation Game, but prior to the game, they engaged with instructional text that emphasized three numerical estimation strategies—tolerance for error, the benchmark strategy, and flexible rounding—with examples and two checks for understanding. These three strategies were found in prior research to be productive for this specific task (Thacker et al., 2021). Students in the control group were presented with an 812-word expository text about the greenhouse effect adapted from Lombardi et al., (2013). See Figure 1 for a summary of the procedures and Appendix A for more detailed text excerpts and screenshots). All three experimental conditions were presented in an openly accessible, open-source online web app [http://143.110.210.183/; also see Thacker et al., 2021].

Dependent variables

Climate change knowledge. Knowledge of climate change was measured using seven items adapted from the Human Induced Climate Change Knowledge measure (HICCK; Lombardi et al., 2013). Participants responded as to whether they believed that *climate scientists* would believe that certain statements are true (e.g., "Most of the world's glaciers are decreasing in size. This is evidence of climate change"). Responses were on a seven-point agreement scale. Participants completed this scale pre-intervention, post-intervention, and at the 10-day followup. All were reliable at conventional levels ($\alpha_{pre} = .65$, $\alpha_{post} = .74$, $\alpha_{followup} = .77$).

Plausibility perceptions. Perceptions of plausibility that humans are responsible for climate change were measured using four items adapted from the Plausibility Perceptions Measure (PPM; Lombardi et al., 2013). These items were intended to capture participant's *personal* positions on whether humans are responsible for climate change as they responded to statements ("Evidence from around the world shows that the climate is changing in many regions") on a six point agreement scale from 1 = *Highly Implausible (or even impossible)* to 6 = *Highly Plausible*. This scale was also completed at pretest, posttest, and during the followup and was reliable at conventional levels ($\alpha_{pre} = .81$, $\alpha_{post} = .85$, $\alpha_{followup} = .83$).

Estimation strategy reports. Participants in intervention conditions also provided open-ended descriptions of strategies that they used to estimate numbers. Coding and analysis of this variable is still underway.

Covariates

Epistemic dispositions. Baseline epistemic dispositions were measured using the Actively Open-Minded Thinking scale (AOT; Stanovich & West, 1997) that captures participants' willingness to reason with novel evidence using seven items (e.g., "People should take into consideration evidence that goes against their beliefs") using a seven point agreement scale ranging from 1 (completely disagree) to 7 (completely agree; $\alpha = .71$).

Math Anxiety. Participants also completed a Mathematics Anxiety Questionnaire (Ganley et al., 2019) consisting of nine items (e.g., "I get a sinking feeling when I think of trying to solve math problems") with five response options ranging from 1 (Not true of me at all) to 5 (Very true of me; $\alpha = .93$).

Analytic Strategy

To assess the effects of the interventions on the knowledge and plausibility outcome variables (RQ1 & RQ3), I used ordinary least squares regression with robust standard errors using a separate model for knowledge and plausibility perceptions. Predictors were the treatment condition and pre-test scores. To assess moderating effects (RQ2), I repeated these analyses after adding math anxiety and actively open-minded thinking as moderators of the treatment condition, with separate models for each moderator.

To test whether learning was retained ten days after the pre-test (an exploratory question), followup knowledge and plausibility scores were used as main outcomes in two separate regression models with experimental condition as a predictor and pretest scores as covariates.

Results

All coefficients, standard errors, and *p*-values from regression models are presented in Table 1.

RQ1: Main Effects of the Intervention. With regards to knowledge as the main outcome, participants in both intervention conditions outperformed the control group. This difference was significant for the modified intervention before and after adjusting for moderating variables and interactions, whereas for the unmodified intervention, the effect was only significant before adjusting for moderators. When plausibility perceptions were the main outcome, no significant main effects of the intervention were found. As such, H1 was confirmed.

I also used contrasts to test whether findings replicated those of Thacker & Sinatra (2022), revealing that posttest climate change knowledge was indeed higher among those in either intervention condition compared with those assigned to a control condition ($d = 0.30$, $p < .001$).

Table 1. Effects of Experimental Conditions on Posttest Knowledge and Plausibility and The Moderating Effects of Math Anxiety and Actively Open-Minded Thinking (N = 605).

	Posttest Knowledge			Posttest Plausibility Perceptions		
	No Moderator	Math Anxiety as Moderator	AOT as Moderator	No Moderator	Math Anxiety as Moderator	AOT as Moderator
	b (SE) p	*b* (SE) p	*b* (SE) p	*b* (SE) p	*b* (SE) p	*b* (SE) p
Estimation Game	**0.232******	**0.270~**	0.016	0.232	0.190	-0.521
	(0.046)	**(0.139)**	(0.244)	(0.141)	(0.430)	(0.791)
	p < .001	**p = .054**	p = .946	p = .102	p = 0.659	p = .511
Estimation Game + Estimation Instruction	**0.168******	**0.387****	**0.527***	0.161	0.249	-0.027
	(0.046)	**(0.137)**	**(0.234)**	(0.142)	(0.423)	(0.760)
	p < .001	**p = .005**	**p= .025**	p = .260	p = .556	p = .972
Moderator		-0.014	**0.146******		0.015	**0.268***
		(0.032)	**(0.034)**		(0.098)	**(0.111)**
		p = .670	**p < .001**		p = .877	**p = .016**
Intervention * Moderator		-0.013	-0.040		0.014	0.146
		(0.045)	(0.049)		(0.139)	(0.157)
		p = .774	p = .408		p = .919	p = .353
Modified Intervention * Moderator		**-0.077~**	**0.142****		-0.031	0.037
		(0.045)	**(0.047)**		(0.138)	(0.152)
		p = .084	**p = .003**		p = .824	p = .807
R2	0.464	0.472	0.537	0.626	0.626	0.638

Note: AOT = Actively Open-Minded Thinging. The comparison condition is the control condition in which participants read an expository text about the greenhouse effect. All models include pretest scores as a covariate, namely, posttest knowledge is adjusted for pretest knowedge and posttest plausibility is adjusted for pretest plausibility perceptions. Boldfaced values indicate significant results for predictors.
~p<0.1; *p<0.05; **p<0.01;***p<0.001

RQ2: Moderating Effects of Math Anxiety and Actively Open-Minded Thinking. Findings revealed significant main effects of Actively Open-Minded Thinking when knowledge and plausibility were the main outcome variable, and that it moderated the effect of estimation instruction on knowledge. Thus, I found support for H2.1 and partial support for H2.2.

RQ3: Comparison Between Intervention and Modified Intervention. Comparing only the two intervention groups revealed no significant differences after controlling for pretest scores. This was true for both outcomes: posttest knowledge (p = .180) and plausibility (p = .623).

Followup Analysis. As noted, I followed up with willing participants approximately ten days after the intervention. Because only 15% of the analytic sample (n = 88) completed the followup survey, pre-planned (but exploratory) multilevel analyses were underpowered. I therefore ran two separate regression models with followup knowledge and plausibility scores as the main outcomes, experimental condition as the main predictor, and pretest scores as covariates. Neither model revealed significant effects of either intervention or modified intervention groups when compared with the control (all conditional p > .248).

Significance

I sought to investigate whether the learning that occurs when people encounter novel statistics was enhanced with additional instruction on estimation strategies. Consistent with prior research, I found that students who learned from novel statistics performed about a third of a standard deviation better than a control group on a posttest of climate change knowledge (c.f., Ranney & Clark, 2016; Thacker & Sinatra, 2022).

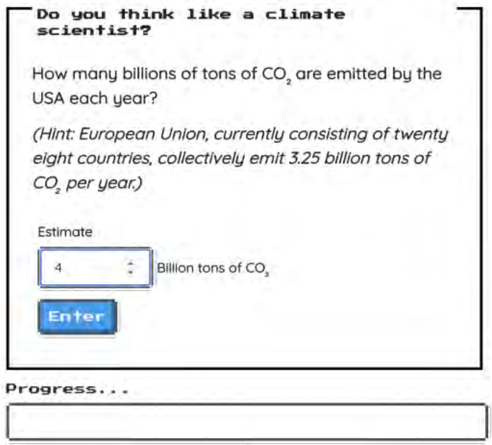
Findings also revealed that students' willingness to reason with new evidence was a predictor of learning and moderated the effects of numerical estimation instruction. These effects of Actively Open-Minded Thinking provide support for the Plausibility Judgments for Conceptual Change Model (Lombardi et al., 2016); instruction that emphasizes the explicit evaluation of evidence appears to be most effective among those willing to consider belief-discrepant information (also see Richter & Maier, 2017). Educators might thus consider pairing estimation instruction with special emphasis on the importance of keeping an open mind when examining new types of numerical evidence, even if the evidence is contrary to students' current beliefs.

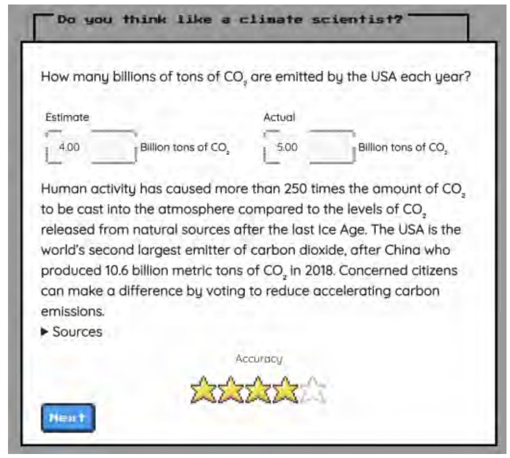
I also found no significant main effects of supplementing the Estimation Game with instruction that emphasized three key estimation strategies (tolerance for error, flexible rounding, and the benchmark strategy). This may suggest that the baseline intervention may be equally effective at encouraging explicit evaluation of quantities for most learners. It could also be that the outcome measures were not sensitive to capture the learning that occurred from this short micro-intervention. While I did find that the effects of the modified intervention was more robust to inclusion of covariates, future research should explore measuring alternate learning outcomes that are more sensitive to whether and which estimation skills were applied to support meaning-making from climate change quantities.

Another contribution of this study is that it provides mathematics instructors with a tool that enables applications of mathematical skills to learn about relevant science topics. The central intervention provides educators concerned with public understanding of science with an easily accessible learning application that can be shared and adapted to provide opportunities for students to apply numeracy skills towards making of key numbers that shape our changing environment.

Appendix A. Examples of The Experimental Conditions

Intervention Group (Screenshots from the "Estimation Game")





Modified Intervention Group (Excerpts from estimation instruction that preceded Estimation Game)

Sometimes people estimate everyday numbers in their head. For example, you might quickly estimate the cost of tax and tip in your head before ordering a meal at a restaurant. These calculations are naturally very rough and imprecise, and it is okay if your guess is not perfect…

REFERENCE NUMBERS

Numbers that you already know (reference numbers) can help you estimate numbers that you do not know. For example, if you know that about 300 pennies fit in a small, 8oz milk carton, you can use this information to estimate the number of pennies that fit in a gallon…

SIMPLIFYING NUMBERS

When using reference numbers, you may want to round values to make mental computation easier. For example, let's estimate the population of California given that the population of Kentucky is 4.47 million. Before making our estimate, we first round the Kentucky population to 4 million to make the math easier, and scale this value according to our beliefs about the size of California compared to Kentucky. If you were to guess that California…

Control Group (Excerpt of Expository Text adapted from Lombardi et al., 2013)

THE ENHANCED GREENHOUSE EFFECT

Many people have heard of the "greenhouse effect", but not everyone knows what the "greenhouse effect" is exactly. The greenhouse effect refers to the way that certain gasses in earth's atmosphere keep the planet warmer than it would otherwise be. The earth's greenhouse effect is a natural occurrence…

Note. All materials appeared within the Estimation Game environment (http://143.110.210.183/). For complete intervention materials, see the supplemental materials (https://bit.ly/3rP2m9c).

LEVERAGING TECHNOLOGY TO SUPPORT SOCIOPOLITICAL DISPOSITIONS

Nicholas E. Witt
Western Michigan University
nicholas.e.witt@wmich.edu

In this theoretical paper, it is argued that a crucial component of a critical literacy (Rubel & McCloskey, 2021) learning progression focused on Gerrymandering was the role of mathematical action technology (Dick & Hollebrands). I contend that the technology provided access to the relevant mathematics content, which contributed to an understanding of how the mathematics connects to the context. Empirical support from the implementation of the technology-based critical literacy lesson with prospective elementary and secondary mathematics teachers illustrates the emergence of a learning progression model. Implications regarding teacher education, curriculum development in K-12 classrooms, and integrating technology-based mathematics lesson set within critical literacy contexts will be discussed.

Keywords: technology, equity, social justice

The integration of innovative tools and curricular reform ideas is a challenge for many teachers. It is often easier and more efficient to rely on techniques and tools that have already been vetted and utilized previously. Thus, the need to better understand how technological tools such as *Mathematical Action Technology* (MAT) (Dick & Hollebrands, 2011), or digital technology, "…that can perform mathematical tasks and/or respond to the user's actions in mathematically defined ways," (p. xii) can be utilized effectively may be a necessary first step to encouraging more teachers to take up these practices. In addition to new tools, teachers also face challenges implementing new curricular reform efforts (Schoenfeld, 2004). In recent years, advocacy focused on teaching for the development of a sociopolitical disposition in students has become more common (NCTM, 2018; Bartell et al., 2017). Despite advocacy for integrating MAT and incorporating *critical literacy* (Rubel & McCloskey, 2021) contexts to support more equitable mathematics teaching practices, little to no research has been conducted on how these dual challenges interact with each other in practice. In this paper, I argue that we can create learning environments in which students are afforded opportunities to do mathematics which supports their ability to engage in discourse surrounding social injustices in their communities and society. I aim to describe how leveraging MAT to create a critical mathematical environment enabled prospective mathematics teachers (PMTs) enrolled in a Technology, Pedagogy and Content (TPC) course to engage with a mathematics lesson about Gerrymandering in new ways. In closing, I will describe some potential implications for pursuing the dual goals of teaching to develop a sociopolitical disposition and integrating MAT.

A Technology-Based Critical Literacy Learning Progression

In framing this discussion, I offer a learning progression which models the sequence of events that led to my students being able to articulate the mathematical concept of *compactness* and the role that it plays in instances of Gerrymandered legislative districts. The model below (see Figure 1) provides an approach to sequencing a unit or lesson to leverage the affordances of MAT to build mathematical knowledge which can then help students articulate connections between abstract mathematics and real-life applications.

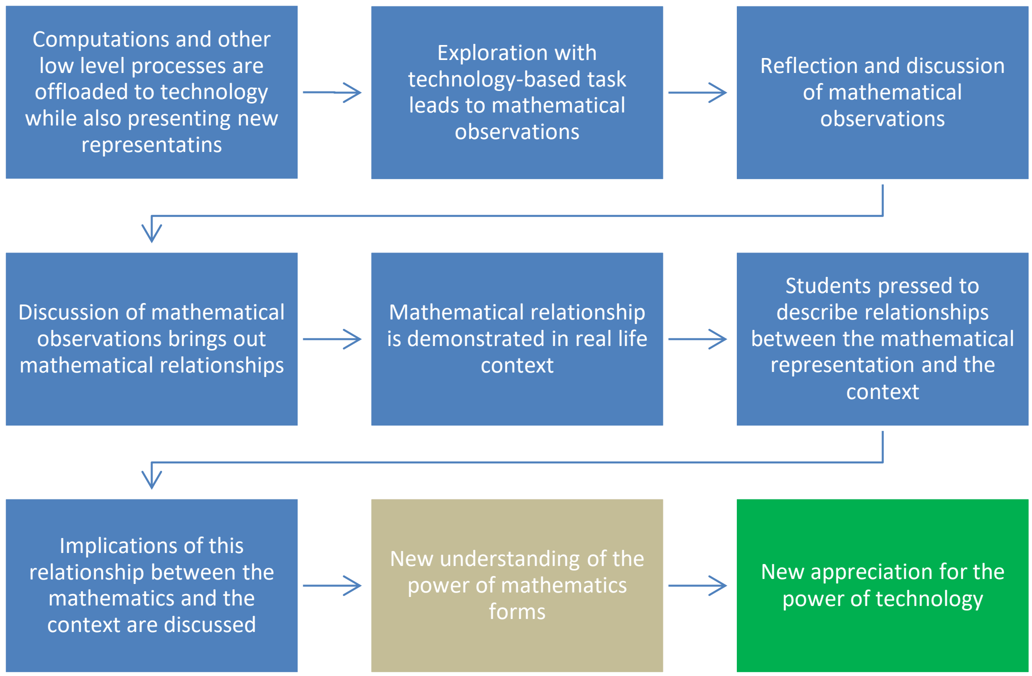

Figure 1: Technology-based critical literacy lesson progression

In Figure 1 above we see how this progression is dependent upon being able to make mathematical observations. Yet, as I will describe below, these observations may not have been possible without a dynamic representation of the polygons. In this sense, *low-cognitive demand tasks* (Stein, Grover, & Henningsen, 1997) such as computing area and perimeter and sketching each shape were offloaded onto the technology. This enabled more focus on describing important characteristics of the mathematical objects which guided the classroom discussion. The last two boxes in the figure represent hypothesized components that could serve as important extensions of this work. I highlight the final box in green because this aligns with a potential impact on the instructor whereas the gray box mostly applies to students. Though this progression above may bear some resemblance to other frameworks for teaching mathematical modelling set within real-life contexts (e.g., Cirillo, Bartell, & Wager; 2016), I aim to focus on how the leveraging of MAT, can make these lessons more viable for engaging in mathematical practices even when set withing real-life contexts.

Technology In Support of Equity

Though the ways in which technology can support equitable mathematics classrooms have been discussed by a number of scholars (e.g., Clements & Sarama, 2017; Kitchen & Berk, 2016; Dunham & Hennssey, 2008), I focus this paper on how technology can promote access to important mathematical content knowledge by supporting engagement in mathematical practices when the impracticality or tediousness of executing numerous low-level computations is offloaded onto the technology. In particular, the integration of MAT can support students' ability to do mathematics by allowing them to explore dynamic mathematical objects represented in novel ways leading them to make and test conjectures. When a large number of cases and multiple dynamic representations can efficiently be explored by students, this may support their ability to generalize their mathematical observations. In doing so, this can open up the possibility of student thinking being more focused on relationships between decontextualized mathematics and real-life applications of the mathematics. The idea that utilizing *technology as reorganizer* (Pea, 1985) can free the user to engage in higher order thinking skills has been discussed in a number of frameworks for integrating technology (e.g., Sherman & Cayton, 2015), however, it's connection to teaching within a critical literacy context is a novel contribution of the current discussion. When new mathematical understandings are developed, this can lead to a better understanding of real-life contexts that can be understood with respect to the mathematical relationships present within the context.

Teaching Mathematics in Support of Critical Literacy

Although the reasons that a teacher may choose to contextualize their mathematics lesson varies (Rubel & McCloskey, 2021), I continue this discussion by focusing on contextualization that may support the development of a sociopolitical disposition (Bartell et al., 2018). These *critical literacy* (Rubel & McCloskey, 2021) contexts may support what has been described as *teaching mathematics for social justice* (Gutstein, 2006) and may encourage students to see the power of mathematics in a new light. *Critical literacy contexts* include those which utilize mathematics to bring attention to social injustices which arise from: imbalances in power dynamics, a lack of or disproportionate allocation of resources, or unfair or discriminatory practices that target specific marginalized groups. An example of such a context might be using mathematics to understand the impacts of Gerrymandering in the U.S. redistricting process. (e.g., Berry III et al., 2020; Safi, Bush, & Desai, 2018; Rubel, Driskill, & Lesser, 2012). By engaging in a mathematics lesson devoted to helping students engage in discourse surrounding Gerrymandering, students can see how mathematics can help detect instances where a legislative district's boundary lines have been manipulated to benefit a particular political power. When this is done, voters are less likely to be represented by a person who will advocate for their needs. Gerrymandering often impacts communities of color by either breaking up high concentrations of voters of color or by ensuring these voters only have the minimum number of representatives by putting a high concentration of these voters into the same district. Thus, Gerrymandering, though practiced by both major political parties in the U.S., can have serious impacts in society due to the disenfranchisement of voters that results.

A number of challenges arise when teachers attempt to contextualize their mathematics lessons to promote critical literacy. One issue is that these topics are often seen as controversial and this may deter teachers because they fear the backlash that may occur. Another issue is that teachers may feel as though they must sacrifice mathematics goals to meet social justice goals or vice versa (Bartell, 2013). With this challenge in mind, I describe how I attempted to alleviate some of this perceived sacrifice by offloading low-level skills to the technology as I implemented an adaptation of Berry III et al.'s (2020) Gerrymandering unit.

Background on the Intervention Unit

In this section, I describe how prospective mathematics teachers (PMTs) enrolled in a technology, pedagogy, and content (TPC) course at a large midwestern university engaged in an intervention unit where they simultaneously developed their understanding of mathematics content, engaged in mathematical practices, and were able to make connections from their mathematical activity to a critical literacy context lesson based on the Gerrymandering section found in Berry III et al.'s (2020), *High School Mathematics Lesson to Explore, Understand, and Respond to Social Injustice*. In years past, the TPC course has focused on developing PMTs' *technological pedagogical content knowledge* (TPACK) (Mishra & Koehler, 2009). This ability to teach with technology and design lesson materials that leverage the affordances of MAT is developed through class discussions and readings, course assignments focused on finding and creating technology-infused resources, and a field experience where PMTs have the opportunity to design and teach a lesson that integrates MAT. The intervention unit took place during the Spring of 2021 and due to COVID-19 protocols, it was taught through a Web conferencing application. This intervention was developed to demonstrate how technology can be utilized to enhance a critical literacy context and then PMTs were asked to revise the lesson to include their own perspective to the lesson detailed below.

Throughout the transition to synchronous distance education, I frequently utilized Desmos Activity Builder (DAB) to facilitate mathematical discussions while also allowing students to engage with MAT. Desmos Activity Builder allows teachers to create activities that are similar to a set of presentation slides with the addition that these slides can contain MAT such as Desmos' Graphing Calculator application, Desmos' Dynamic Geometry Environment, and Input Boxes that allow students to provide responses that teachers can see update in real time through their Dashboard (see Figure 2 below).

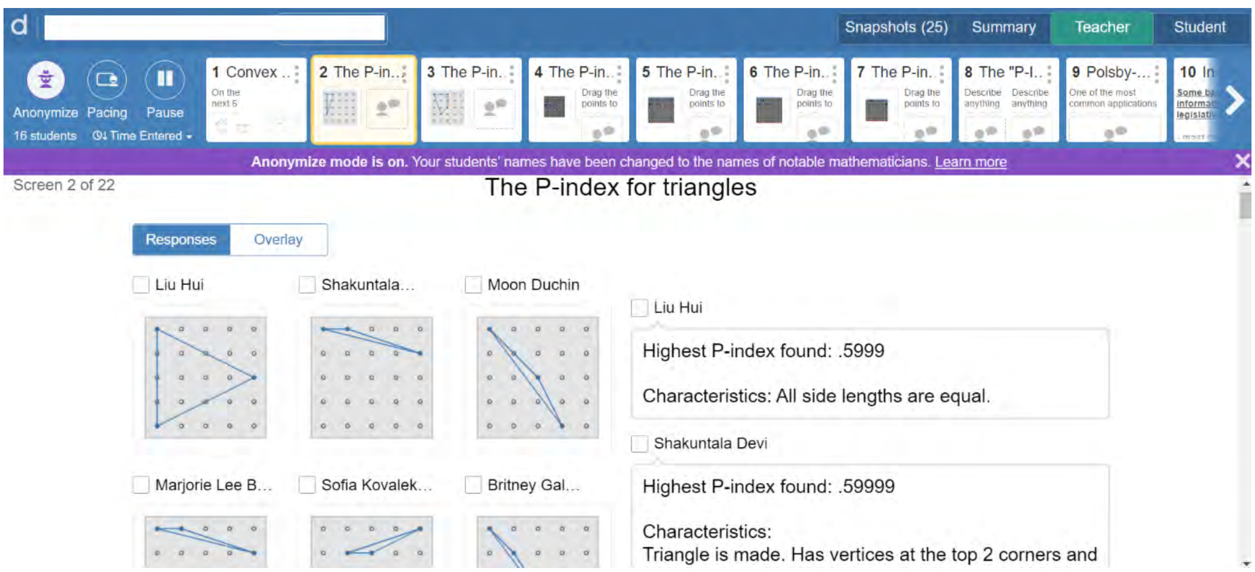

Figure 2. Desmos Activity Builder Dashboard View

As shown in the figure above, teachers can anonymize students' names (they are randomly assigned the names of mathematicians), capture their work as a Screenshot, and then select and present student work to facilitate classroom discussions. This was a common practice in the course and in particular, this lesson.

A Technology Based Lesson on Gerrymandering

In this section, I provide a detailed account of the sequences of activities that the PMTs in my course engaged in and some results of how PMTs engaged with the technology-based Gerrymandering lesson. A learning goal for the implementation of this lesson was to equip my students with the ability to answer the question of: *What connections between the mathematical context of exploring the effects of manipulating vertices of polygons can be made to the critical literacy context of Gerrymandering?*

During the implementation of the technology-based Gerrymandering lesson, PMTs accessed a set of Desmos Activity Builder slides (*available in unblinded draft*) where the first seven slides allow them to manipulate the vertices of various polygons while observing how a numerical "p-index" changes as they create different polygons. This "p-index" is commonly known as the Polsby-Popper Index, which assigns a value between zero and one that approaches one as the shape becomes closer to being a circle. This can be realized through the exploration by noting how the shapes that have the highest "p-index" are those that are as close to being a regular polygon as possible. To add a level of exploration and avoid students searching for the term "Polsby Popper" on the Web, I chose to rename this "p-index" for the first group of seven slides.

A second group of slides after the set exploring the Polsby Popper Index, provided some context for why this metric may be of interest. The second group of slides (see Figure 3 below), allows students to place a set of vertices around some maps of legislative districts in the United States. In doing so, the PMTs were later asked to consider why some districts may have a low Polsby Popper Index and some a large Polsby Popper Index.

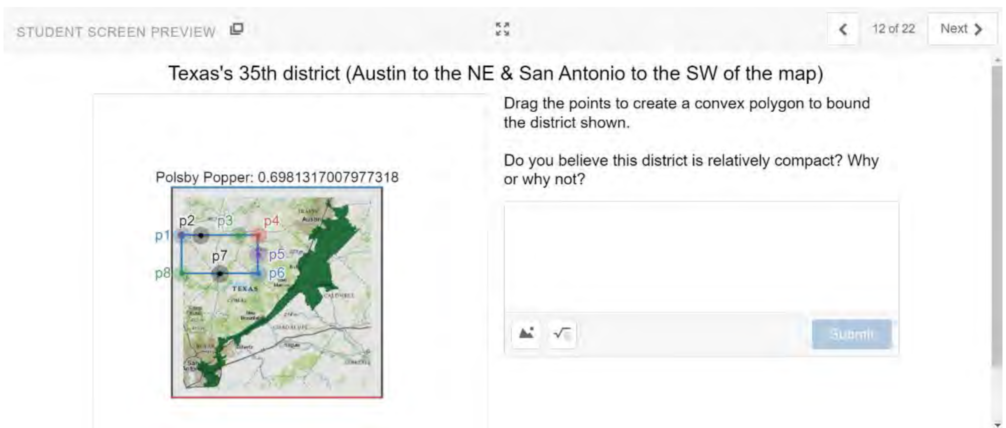

Figure 3. Estimating Compactness of U.S. Districts

This group of slides was then followed by a third group of slides where a hypothetical state's districts can be created by manipulating points surrounding sets of X's and O's representing a concentration of voters that typically vote for political party X and O. In engaging with this group of slides, PMTs were able to manipulate district lines in such a way that despite a state being composed of a majority of X's the districts could be drawn so that the districts elect the same number of representatives from the O political party (see Figure 4 below).

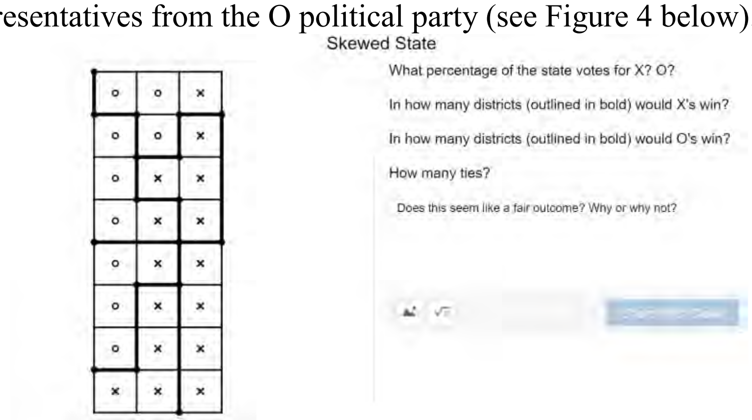

Figure 4. Gerrymandering in a Hypothetical State

Though the three groups of slides were implemented during the same class session, given the time constraints of K-12 classrooms, a similar lesson would be better suited as a sequence of three lessons with the first group of slides devoted to one lesson focused on building some intuition surrounding compactness of shapes as measured by the Polsby Popper Metric.

After the in-class activity facilitated through Desmos Activity Builder, PMTs were instructed to read a news article (https://truthout.org/articles/35-states-at-risk-of-rigged-districts-due-to-gerrymandering-report-finds/) about Gerrymandering's potential impact in the year to come and then reflect on why this is should be considered a social injustice. In addition to the reflection, they were provided with the following post-lesson prompt:

> "The Polsby-Popper Index, used to determine compactness of shapes, is found by the formula:
>
> $$PP(D) = \frac{4\pi(Area\ of\ Shape\ D)}{(Perimeter\ of\ Shape\ D)^2}$$
>
> Using this formula and what you now know about Gerrymandering, please explain why a Gerrymandered district might give a smaller value of PP(D)?"

How the MAT Supported Mathematical Exploration

In this section, I provide some description of what mathematical practices the PMTs engaged in, what new mathematical understanding appeared to emerge, and what connections they were able to make between the context of thinking about the compactness of an abstract polygon to thinking about the compactness of a shape that represents a legislative district.

During the first group of slides, PMTs explored the nature of the Polsby-Popper Index by dragging vertices of abstract polygons. As the points were dragged, the value of a "p-index" changed simultaneously. On these slides, PMTs recorded observations about what characteristics they observed in the shapes that yield the highest and lowest "p-index." At the close of this group of slides, they were asked to record observations about the shapes that occurred across all six polygon exploration slides in the group. This group of slides was effective in supporting PMTs to engage in conjecturing about the nature of the Polsby Popper Index which were then revised after further exploration and classroom discussion. Conjectures about the nature of the Polsby Popper Index were seen as a number of PMT responses were initially focused on superficial observations or less relevant properties such as the angle measures, but later responses indicate a shift in attention from angle measures to the regularity of the shape. For example, some responses regarding the hexagon exploration are shown in Table 1 below.

Table 1: Responses to the prompt "Drag the points to create the highest and lowest P-index that you can and then describe some characteristics of the shape you created"

Student (Pseudonym)	Initial Observation
Rey	"making as small of angles as I could helped to make P-index smaller"
Kris	"…a normal hexagon"

Later in the lesson these ideas appear to have been refined through the exploration and discussion so that their ideas now align more closely with what my goals for this part of the lesson were. In Table 2 below we see how these same students above refined their initial ideas above to observe something about the regularity of the shape or the ratio of the area to the perimeter.

Table 2: Refined understandings of the "p-index"

Student (Pseudonym)	Refined Understanding
Rey	"I think compactness measures how close or far apart the vertices of a shape are. Which makes the shape either close to equal in sides and angles (regular), or narrow in shape (irregular)."
Kris	"normal polygons had the highest p-index values, whereas the ones with the smallest area-to-perimeter ratio had the lowest p-index values."

Responses and ideas such as these could not have been organically developed by students in this lesson without the aid of technology. In the activity, students were able to simultaneously generate a vast number of polygons with different dimensions and have the corresponding Polsby Popper Index calculated for them. This allowed them to focus their attention on the properties of the shapes such as the regularity or the ratio of the area to the perimeter. In order for a paper-based lesson to bring out the similar ideas without being explicitly presented with these ideas, it might require students to construct a number of different polygons on either the same grid which would end up being very cluttered or it may require multiple sheets of paper. Students might then use a dissection method for calculating the area of each triangle formed through a dissection so that they could find the area of the polygon or they may count the number of grid squares within each shape. Both of these methods would be both inefficient and may be considered low cognitive demand.

Connecting the Abstract Mathematics to the Critical Literacy Context

Connecting decontextualized mathematics to contextualized problems is often challenging for students as the context can obscure the underlying concepts previously explored. In Table 3 below, the responses from Rey and Kris came from their post-lesson prompt described above. One can see that Rey mentions the role of area and perimeter, but why this may help to detect Gerrymandering is less clear. Rey does appear to see some connection between "balance" and the "weight" of votes, which I believe to be a step towards seeing a connection between district lines being drawn to produce a greater *efficiency gap* (Stephanopoulos & McGhee, 2015) and how this could disenfranchise voters when their votes are seen as having less weight. On the other hand, we see Kris make strong connections between boundaries being "stretched" and how this results in a greater perimeter for the district while not necessarily changing the area or even making the area smaller.

Table 3: Post-lesson prompt responses connecting the mathematics to Gerrymandering

Student (Pseudonym)	Response
Rey	"This formula shows that the P-index is the relationship between the area and perimeter of districts. A gerrymandered district might give a smaller value of PP(D) because they are drawn so that some districts don't "matter" as much as others. To my understanding, a smaller PP(D) shows that they have less weight in their votes. When districts are more compact, they are more balanced in their voting. When the PP(D) of all districts are closer to one

	another, this will make votes and the districts themselves more balanced. Lastly, it would reduce the racial gerrymandering that is happening.
Kris	"Gerrymandered districts are not very compact because they are often stretched far and thin and encompass regions that are far apart from each other despite other districts having closer proximity to themselves. As a shape is stretch or distorted, the relative area on the inside becomes a much smaller value in comparison to the perimeter that surrounds it. Much like how flattening a basketball maintains a constant surface area, but significantly reduces the internal volume. Therefore, the more gerrymandered a district is, the larger the denominator will be under the district's area"

The results from the previous two sections together exemplify a rather typical trajectory in the TPC course where initial ideas were developed through exploration with MAT, which led to a refinement of these initial ideas about the mathematics. This refined understanding of the mathematics supported a relatively accurate description of the connection between the mathematics discussed in the class lesson to the context of Gerrymandering.

Discussion

Within this *Technology-Based Critical Literacy Mathematics Lesson,* the role of MAT was critical in enabling my students to develop new understandings about the critical literacy context. This was done by equipping them with an ability to communicate the connections between compactness and Gerrymandering. The empirical support with prospective mathematics teachers demonstrates that with MAT, it is possible to simultaneously teach cognitively demanding mathematics content while also bringing about new understandings of social injustices. Much more work can to be done to provide support for the notion that leveraging the affordances of technology can generate novel approaches to exploring critical literacy contexts within a K-12 classroom. Future research may focus on how this type of lesson may support developing K-12 students' mathematical and technological identities as well as a critical eye towards sociopolitical contexts. Future curriculum work may focus on identifying, generating, an implementing other *Technology-Based Critical Literacy Mathematics Lessons*. Finally, the effect on teachers' dispositions regarding technology use and teaching mathematics through critical literacy contexts is also needed to understand how teachers could be better supported in implementing equitable teaching practices.

EMBODYING COVARIATION THROUGH COLLABORATIVE INSTRUMENTATION

Toni York	Steven Greenstein	Denish Akuom
Montclair State University	Montclair State University	Montclair State University
yorka1@montclair.edu	greensteins@montclair.edu	akuomd1@montclair.edu

Covariational reasoning and the creation and interpretation of graphs of covariational situations are important skills in math and science. Unfortunately, research shows that students often struggle to make meaningful connections between graphs and the covariational situations they represent. Educational activities designed to help students overcome this struggle tend to use either student-generated or automatically-generated graphs, and have students either act out covariational situations or more passively observe them. In this paper, we present the design of a tool and task that enabled two students to simultaneously embody both the creation of a graph and the covariational actions that the graph represents. Through a process of collaborative instrumentation, the students made meaningful connections between their motions and the embodied traces they created as they reasoned about the covarying quantities of height and time.

Keywords: Algebra and Algebraic Thinking, Middle School Education, Technology, Instructional Activities and Practices

Covariational reasoning, or the ability to coordinate changes in two covarying quantities (Carlson et al., 2002; Thompson & Carlson, 2017), is an important part of how students understand and use graphs. However, research shows that students of all ages often struggle to make connections between graphs and the covariational situations they represent (Oehrtman et al., 2008). For example, students commonly view graphs more as wireframe images of a situation rather than records of covariation, seeing static shapes rather than emerging traces (Moore & Thompson, 2015).

Many different educational activities have been designed and tested that attempt to support students in making these connections. One of the many decisions faced by the designers of these activities is a choice about whether to use student-generated or automatically-generated graphs. Students may create their own graphs and thus see how they are built, but many students struggle with this process and the underlying covariational meaning is lost (e.g., Mevarech & Kramarsky, 1997). Conversely, graphing utilities allow students to focus on the covariation without having to worry about the graphing process itself, but students then tend to blindly trust these automatically-generated graphs without thinking more deeply about what they represent (e.g., Cavanagh & Mitchelmore, 2000).

Similarly, designers must also choose whether students will act out the covariational situation being graphed or more passively observe it. For example, designs using motion sensors paired with automatically-generated graphs allow students to literally walk their covariation and see the resulting graph appear in real time (e.g., Duijzer et al., 2019). In contrast, designs that provide animations of a covariational situation allow students to observe or even control a covariational situation but not to physically act it out themselves (e.g., Stevens et al., 2017).

We categorize the designs resulting from these two decisions by whether or not the covariational situation and the corresponding graphing are each embodied (e.g., Lakoff & Johnson, 2000; Núñez, et al., 1999; Wilson, 2002) by the students. Some designs have tried to support student embodiment of both covariation and graph creation. For example, designs aimed at teaching kinematics to college students have used ball-and-track activities paired with student-generated graphs (e.g., McDermott et al., 1987). In these activities, students both generate the motion of a physical ball in a track they have assembled and then also graph that motion. Along with instruction and practice, McDermott et al. found that this design supported improvement in college students' covariational understanding of kinematics graphs.

However, we found no design in the literature that has students simultaneously embodying both the act of graph creation and the covariational situation being graphed. We therefore conjecture that leveraging the benefits of embodying both covariation and the corresponding graph creation at the same time may help students to make these connections between graphs and the covariational situations they represent. Our research question is thus: *What kinds of graph thinking and covariational reasoning might students engage in while working with a tool designed to support collaborative instrumentation and the simultaneous embodiment of both graphing and covariation?* Accordingly, we address this question through research framed by the theories of covariational reasoning, embodied design, instrumented activity, and intersubjectivity.

Theoretical Framework

When students coordinate two varying quantities (Thompson, 1993, 2011) by attending to and making sense of the ways the quantities change in relation to each other, they engage in *covariational reasoning* (Carlson et al., 2002; Thompson & Carlson, 2017). Covariational reasoning is fundamental to students' understandings and uses of graphs precisely because *graphs* in two dimensions are representations, or traces, of the relationship between two covarying quantities. In order to support the development of students' covariational reasoning, Moore and Thompson (2015) endorse a particular way of thinking about graphs as emergent relationships called emergent shape thinking. Whereas *static shape thinking* relies on perceptual cues and global properties of graphs as static objects, *emergent shape thinking* involves understanding a graph simultaneously as what is made (a trace in progress) and how it is made (as a record of the relationship between covarying quantities). These ways of thinking about graphs will be useful in our analysis of students' graphing activity as we aim to help them make connections between graphs and the covariational situations they represent.

As we describe below, the first author embarked on a design experiment (Cobb et al., 2003) to produce a tool to mediate the formation of these connections. The tool used in this project emerged from a design cycle informed by the theory of embodied cognition. Rather than consisting solely of computational operations on symbolic propositions that occur entirely within a disconnected mind, *embodied theories of cognition* hold that cognitive processes "must be understood in the context of [the mind's] relationship to a physical body that interacts with the world. … Hence, human cognition, rather than being centralized, abstract, and sharply distinct from peripheral input and output modules, may instead have deep roots in sensorimotor processing" (Wilson, 2002, p. 625). From this perspective, even the most complex ideas are grounded in and emergent from the lived reality of bodily experiences in the world.

Empirical evidence in support of embodiment theories of cognition (e.g., Lakoff & Núñez, 2000) has impacted mathematics education research (e.g., Abrahamson & Lindgren, 2014). In that context, mathematics must be reconceptualized and accounted for not as "an objective mathematics, independent of human understanding" but rather "in terms of the human bodily-based and situated conceptual systems from which it arises" (Núñez et al., 1999, p. 47). Accordingly, such an account should be useful for devising more effective instruction through grounded learning situations that foster meaningful mathematical understanding. Abrahamson's (2014) pedagogical framework of *embodied design* provided us with a template with which to do so as it gave language and structure to the process by which the *Graph Tracer* tool (presented below) was designed. Through *phenomenalization*, we hypothesized about the embodied schema that underlie the coordination and graphical tracing of two covarying quantities. Through *concretization*, we digitally designed and 3D printed a physical artifact with which two learners could collaboratively enact their solutions to problems that would have them enact those schema. And through *dialog*, we elicited the learners' informal enactments of covariational reasoning and supported their formalization by engaging them in reflective activity.

Lastly, in order to analyze the contribution of the collaborative aspect of two students' graphing activity, we drew on the theories of instrumented activity and intersubjectivity. Vérillon and Rabardel's (1995) theory of *instrumental genesis* provides a framework for analyzing student learning in the process through which objective artifacts become tools to be used to accomplish a task. From this perspective, an artifact (e.g., a physical or digital tool) becomes an instrument (e.g., tool, sign) when a subject (e.g., actor, learner) has integrated it into a conceptual scheme for a specific implementation of the artifact in the context of their goal-directed activity. Thus, an instrument is a *psychological* construct established by the subject's instrumental relation with the artifact. In practice, an instrumented activity is characterized by individual subject-object, subject-instrument, and object-instrument interactions.

In our case, however, with two subjects working collaboratively, we will be interested in what we refer to as the subjects' *collaborative instrumented activity*. These are captured in the range of $subject_1$-$subject_2$ instrumented interactions. Then, in tandem with this analysis, we leverage Vygotsky's (1978) notion of *intersubjectivity* to examine the interpsychological process by which the two subjects negotiate and co-construct a shared conceptual scheme for their instrumented activity through the verbal and nonverbal communications in their graphing activity. Gillespie and Cornish's (2010) notion of intersubjectivity adds some texture here by considering "the mutual awareness of agreement or disagreement" (p. 3) in addition to shared understandings and even misunderstandings. Thus, for the sake of our analysis, intersubjectivity manifests itself in participants' actions and intentionalities towards each other and in their joint movement toward negotiated and developed meanings and actions.

Methodology

In a design experiment (Cobb et al., 2003), researchers iteratively design, test, and revise both an instructional design and their theories about how that design supports student learning. The designs of the tool, task, and questioning presented in this paper emerged from the third iteration of an ongoing design experiment that seeks to produce a tool that can be used to help students make meaningful connections between height/time graphs and the kinds of real covariational situations that these graphs represent. We briefly describe the second iteration design in order to provide context for the third iteration presented in this paper.

In the second iteration, the design involved a video of simultaneous covariational motion and graph creation that students could view and explore. Specifically, a video of a vertically moving object (Figure 1, left) was played on a cell phone while the phone was slid horizontally from left to right (Figure 1, right). This action was then itself recorded to create a second video in which a height/time graph of the relationship between the original object's height and the trace of its motion could be seen. Students could then use familiar video playback controls to drag the video's progress bar back and forth and observe the graph being emergently traced by the object's motion. However, even when they were provided with an animated graphical overlay depicting the graph in the final version of the video, students still struggled to connect the horizontal movement to the vertical motion in the original video. Moreover, they were unable to imagine similar sliding videos they could rely on to create or interpret other height/time graphs.

Figure 1: Vertical Video Screenshots (left) and Sliding Video Screenshots (right)

In the current iteration of this design experiment, we sought to build on that earlier iteration to create a more grounded and embodied experience for the students than the sliding video seemed to offer. While the sliding video situated the covariational motion and the graph creation as simultaneous processes, it did not directly leverage students' own simultaneous embodiment of both of these processes. The framework of embodied design thus informed the third iteration, which yielded a design that includes a tool called the Graph Tracer (Figure 2, left) along with a set of tasks using that tool. The Graph Tracer is a 3D-printed rectangular prism with two cutouts: one on the bottom so that a paper can be slid beneath it, and one down through the top so that a marker can be inserted upright and moved up and down to draw on the paper below.

Figure 2: The Graph Tracer (left) and Collaborative Graph Tracer Use (right)

The Graph Tracer is intended to be used by a pair of students, one of whom controls the speed of the paper sliding beneath it while the other controls the up and down motion of the marker (Figure 2, right). One student thus embodies the quantity of time while the other embodies the quantity of height, and we hypothesize that through their collaborative intersubjective engagement, they both embody time and height as they work together to use the Graph Tracer. The result is the creation of a visual trace of the marker's motion over time, in other words, a height/time graph representing that motion.

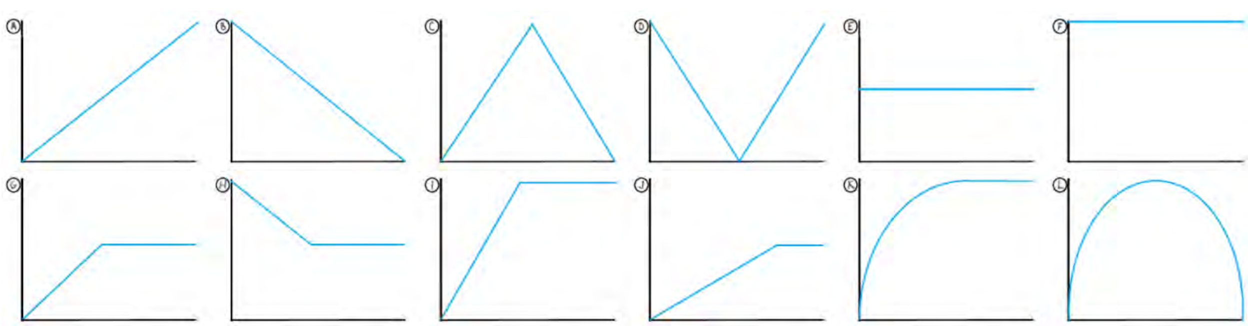

Figure 3: The Ordered Set of Traceable Graphs A-L

The task designed for use with the Graph Tracer includes a set of papers with an ordered group of preprinted graphs involving a variety of different slopes (Figure 3). A pair of students are asked to work together to use the Graph Tracer tool to trace each graph in order, reflect on their experience of doing so, and compare and contrast the different graphs. Examples of specific questions include “What did you have to do to make this graph?” and “Compare this graph to your previous graph, how is it similar or different?” The provided papers also include blank graphs, on which students can experiment with making their own traces.

As part of the design experiment, this design was tested in a task-based clinical interview (Clement, 2000; Ginsburg, 1981) with two students, “Eri” and “Robinson.” At the time of data collection, Eri was a twelve-year-old in the 7th grade who had some experience with graphing points in a coordinate plane but expressed that she was not familiar with graphing lines. Robinson, Eri’s younger brother, was a ten-year-old in the 4th grade who described having no graphing experience. The interview took place over Zoom with the designer/researcher (DR, first author) leading the interview and a partner researcher (PR, the students’ parent) in the room with the students. Collected data includes the video recording of the 45-minute interview, scanned copies of the students’ graphs, and the researchers’ field notes. Through a retrospective analysis (Cobb et al., 2003) of that data, we examined the students’ collaborative graphing activity using the Graph Tracer from both instrumented activity and covariational reasoning perspectives.

Findings

Here we present two excerpts from Eri and Robinson’s activity. The first exemplifies the intersubjective process through which the Graph Tracer became a collaborative instrument for them. The second shows how Eri leveraged her instrumented use of the Graph Tracer to revise her reasoning and apply it in a more sophisticated graphing scenario.

When they were first handed the Graph Tracer, neither Eri (Figure 4, left) nor Robinson (right) had ever seen it before or had any idea how to use it. Although we started the interview by explaining the goal of making a picture that represented height changing over time, we did not demonstrate the use of the Graph Tracer. The students thus began their explorations by enacting various ways they imagined the tool might be used, first tracing the y-axis of Graph A and then turning the Graph Tracer diagonally to trace the graph without moving the paper. At this point in their collaboratively instrumented activity, the students were interacting with each other and the Graph Tracer to develop a shared scheme for its use (Vérillon & Rabardel, 1995) but not yet with the object of the Graph A and its covariational meaning.

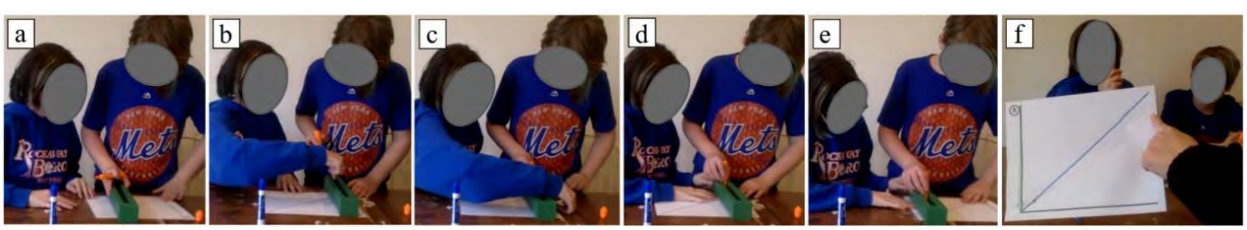

Figure 4: First Trace of Graph A

Once we clarified the constraint that the Graph Tracer must remain parallel to the y-axis, the students then started to explore how they could trace the graph by moving the paper and the marker simultaneously. Robinson first demonstrated how he thought the paper could be slid beneath the Graph Tracer (Figure 4a). Eri then used her finger to show the marker’s possible motion (Figure 4b) as she wondered, “What if you do [that slide of the paper] and you start moving [the marker] upward?" Figures 4c-e show how the pair attempted to implement their idea, first with Eri reaching over to pull the paper and then pushing from her side. They had reorganized themselves so that one person could hold the Graph Tracer while the other pulled the paper. Thus, the tool's intended (Malafouris, 2013) utilization scheme (Verillon & Rabardel, 1995) and the associated task prompted the pair's coordination of initially individual (i.e., uncoordinated movements of the pen and paper) and eventually collaborative instrumentation.

As they drew this first trace, the students began to interact with the graph as well as with each other and the Graph Tracer. In this attempt, Eri embodied the quantity of time by controlling the paper while Robinson simultaneously embodied height by controlling the marker. The pair was able to complete their trace of Graph A, but were not happy with their result (the orange line in Figure 4f; see also Figure 6). Eri had pulled the paper relatively quickly and Robinson remarked afterwards: "that was not traced." We interpret their dissatisfaction with the result as though they struggled to negotiate a collaborative scheme to enact a smooth trace.

The pair then decided to try tracing Graph A again on the same page with a different color marker and a different tracing technique. Eri asked to switch roles so that she could control the marker as Robinson controlled the paper (Figure 5a). Robinson offered a suggestion in response: "You move up slowly while I pull the paper this way." With this slower attempt and some help from the PR in steadying the paper (Figure 5b), they were better able to coordinate their actions to achieve the trace they wanted. In Figure 5c, the pair successfully completed a trace of Graph A using this new technique.

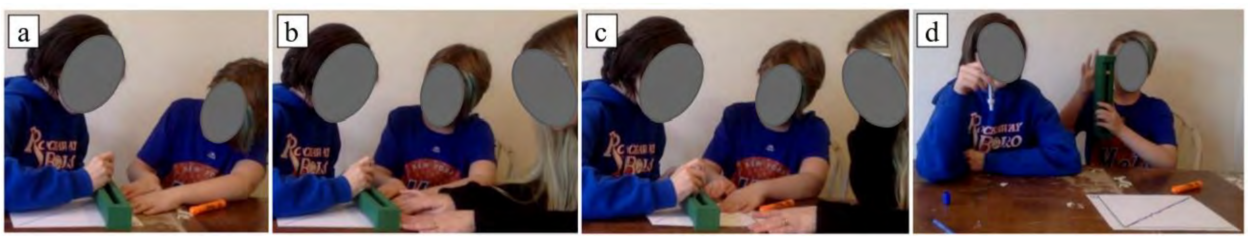

Figure 5: Second Trace of Graph A

Finally, the trace that emerged from this second attempt was placed on the table in front of the pair (Figure 5d; see also Figure 6) as they responded to the DR's question: "How did you have to move the marker to get that picture?" Robinson enacted his answer nonverbally by holding the Graph Tracer up in the air in front of himself and moving his finger slowly upwards inside the marker track. Eri motioned similarly in the air with the marker she was still holding in her hand as she also answered out loud, "I just went like... very slowly upwards."

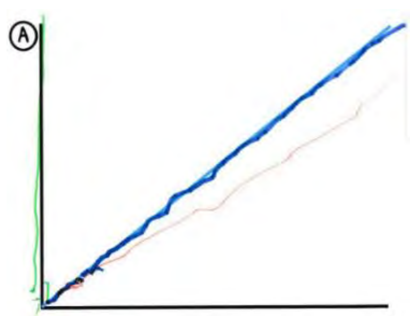

Figure 6: Eri and Robinson's Three Graph A Traces:
The *y*-Axis (green), The First Attempt (orange), and The Second Attempt (dark blue)

The students' actions and reflections as they enacted their three traces of Graph A (Figure 6) show their process of collaborative instrumentation. As the pair negotiated how to use the Graph Tracer and attended to details of paper and marker speed in their tracing actions, the graph and Graph Tracer became an instrument with which they intersubjectively reasoned covariationally about height and time. Both their successful trace and their demonstration of the marker's motion as a change in height over time show how they had connected their enacted tracing of the graph with its covariational meaning. The completion of this trace and the students' articulations of their activity are evidence of the first major step the pair took towards enacting a shared understanding of how marker speed affects graph shape when using the Graph Tracer.

As the pair continued to enact traces of other graphs, they refined their collaborative scheme for creating smooth traces as they reflected on how their individual actions influenced their collaborative traces in different ways. For instance, when asked to compare and contrast Graphs G, I, and J by ordering them in increasing speeds of the marker motions required to trace them, Eri and Robinson initially disagreed. Robinson's intuition was that faster motion of the marker would make steeper graphs, which we interpret as an *emergent* (Moore & Thompson, 2015) view of the graph as a trace of the marker's motion. However, Eri based her reasoning on how long her subjective experience of drawing each graph had felt and the maximum height a graph reached, which we interpret as a *static* view of the graph based on its visual features.

The disagreement was resolved as they experimented by drawing three different lines at three different speeds on the same blank graph and then comparing their speeds and the steepness of those lines (Figure 7, left). This analysis convinced Eri to change her mind as she came to Robinson's way of thinking. We interpret that she did so by considering Robinson's movement of the paper in addition to the time she felt as she drew the graph. Thus, the slope of the graph seemed to have become a multiplicative object for Eri, composed of both embodied actions. As the episode continued and the pair began to develop collaborative schemes for creating and interpreting their own height/time graphs, Eri's initial static reasoning gave way to more emergent reasoning about the graph as a trace of the marker's motion over time.

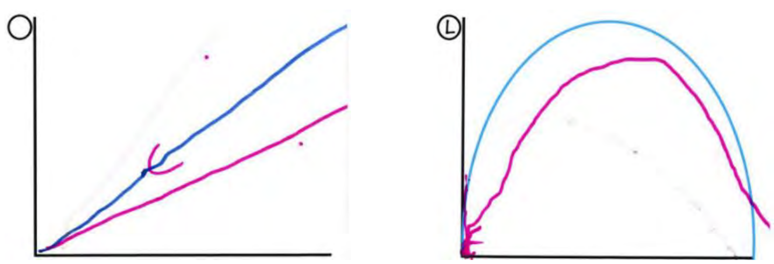

Figure 7: Eri's Marker Speed Experiment (left) and Eri's Trace of Graph L (right)

Although Robinson grew tired of the activity and eventually left the interview, Eri remained and took some time to consider Graph L. She used the Graph Tracer (with the PR's help) to attempt to trace the curve of Graph L and produced an imperfect but structurally similar result (Figure 7, right). She then expressed emergent shape thinking as she explained what she had done: She moved the marker the fastest at the ends of the curve and slowest along the top. Although Robinson's departure put an end to the pair's collaboratively instrumented activity, Eri's continued solo instrumentation via this activity seemed to support her new awareness of how the marker's speed impacted the shape of the resulting trace. This completed her process of enacting her new understanding of that relationship and showed further evidence of her emergent reasoning about the graphs she had created with the Graph Tracer.

Concluding Discussion

Using our analytic lens of collaborative instrumentation, the findings presented in this paper show how Eri and Robinson were able to move together from complete unfamiliarity with height/time graphs and the Graph Tracer tool towards a more fluent and collaborative stage in their instrumented use of the Graph Tracer and in the shared meanings they made of graphs given to or constructed by them. The Graph Tracer's requirement for simultaneous embodiment (e.g., Lakoff & Johnson, 2000; Núñez, et al., 1999; Wilson, 2002) of both the covariational situation and the creation of the corresponding graph also provided the students with a rich opportunity to reason about how these two acts are meaningfully related. Through their joint activities and their discussion of the relationship between marker speed and graph shape, both students worked together to enact their growing transformation of those artifacts into instruments they could use to reason emergently (Moore & Thompson, 2015) about height/time graphs. Eri also displayed a more sophisticated understanding of how marker speed influenced the steepness of the graph, thus beginning to interact with the idea of slope, an important graphing concept.

To continue this design experiment, we are interested in refining the design of both the Graph Tracer tool as well as the task, traceable graphs, and questioning used in this iteration. Eri and Robinson encountered physical difficulties in bracing the Graph Tracer and sliding the paper smoothly. A solution as simple as working on a smoother surface might mitigate the issue, but this solution places the burden on the user rather than the designer. Instead, the addition of a tray to brace the Graph Tracer and make the paper easier to slide could be considered. Alternately, it might be worth laminating the traceable graphs and using dry erase markers. Furthermore, modifications to the physical dimensions of the Graph Tracer like narrowing its width might improve students' ability to see their trace as they work, but this would need to be tested to determine the effects on durability and stability during use. Future iterations might also refine the questioning in order to elicit deeper and more elaborate descriptions of students' reasoning as they work. Possible directions that could benefit from deeper questioning include what students feel they are struggling with and why they choose certain actions as they use the Graph Tracer.

One limitation of the study is the messiness of the interview setting. The online setting presented barriers to conducting an effective interview, including difficulties seeing each other and the students' work as well as the challenge of two researchers conducting an interview together remotely. However, from our analysis, we conclude that the current design of the Graph Tracer has strong potential for use in the learning of covariation and graphing, thereby challenging the status quo of how these topics are traditionally taught. Future work might include refining the design of the Graph Tracer as well as gathering more data and performing further analysis to examine students' collaborative use of the Graph Tracer to reason about slope. We would also like to develop new tasks and gather new data to explore how students might use the Graph Tracer to reason about other graphing and function concepts such as rate of change, concavity, and points of inflection. Implementation of this design in a classroom setting could also support an investigation into how the Graph Tracer might be used as part of the regular middle school curriculum. Finally, it would be interesting to explore other designs that could also support the simultaneous embodiment of both covariation and covariational graphs and to further assess the analytic value of the collaborative instrumentation concept.

Acknowledgments

Chapter 17:

Working Groups and Colloquia

FUTURE DIRECTIONS FOR STATISTICS EDUCATION

Travis Weiland
University of Houston
tweiland@uh.edu

Christopher Engledowl
New Mexico State university
chriseng@nmsu.edu

In continuing from past working groups on statistics education, this working group met for PME-NA 43 to present new findings in the field and to make new connections, as well as work toward future directions. Each day of the working group was based on a different theme including measurement, issues of equity and social justice, and data science. Each day included short presentations of a few projects in line with the theme, followed by discussions of the theme in statistics education, and ended with discussions of future directions related to the theme.

Keywords: Data Analysis and Statistics, Measurement, Equity, Inclusion, and Diversity

The recent data science revolution in K-12 curriculum as well as the pandemic laying bare issues with the statistical literacy of the citizenry have made statistics education gain traction and attention in educational research. The pandemic has brought data and data-based arguments front and center in the media and people are increasingly able to openly access data for themselves (Ancker, 2020). Data science has also found a new hold in the K-12 mathematics curriculum. This can be seen in added focus on data science in the new GAISE II report (Bargagliotti et al., 2020) and based on curriculum reforms in California that seem to be reinvigorating the old math wars. The goal of this working group is aimed at continuing discussions begun at previous meetings, and to create space for new work and collaborations. In an effort to create an open environment but also focus on specific elements of the field, the working group was be structured around three themes. The working group consisted of the leaders (authors) as well as approximately 6-10 participants each day of the conference. We had the largest number of returning participant this year of any of the three years we have done this working group, which was exciting. Furthermore, the group had participants from a wide range of expertise including university faculty, doctoral students, and researchers, which allowed for rich and diverse conversations during the conference. One of the greatest challenges in statistics education is creating community and growing the field and those are exactly what this group aims to do. Our primary product each year is increased connections between researchers, faculty, and doctoral students and creating new spaces for collaboration and discussion. In this post conference report, we focus on highlighting some of the major ideas and topics that came up in our discussions during the working group.

Discussion in Relation to Themes

The working group was structured around three main themes: measurement, issues of equity and social justice, and data science. The structure allowed people to freely flow in and out of the group based on interests from day to day. The themes also helped us to focus our discussions and create an environment for considering tangible future directions.

Measurement

Recently, there have been calls for increased focus on not only the need for developing instruments backed by strong validity arguments, but also for examination of validity evidence for existing instruments and closer attention to instruments being used for research purposes (Lavery et al., 2019). The NSF-funded Validity in Measurement in Mathematics Education

Statistics Education synthesis group has spent the past two years documenting instruments used in statistics education research, as well as the types of validity evidence that accompany them. In this theme, we discussed findings and implications of the ongoing project, and broadly discussed issues of validity in measurement. A big question that came up from people participating in the discussion on this day was, *how do people in the field help others know what instruments are available and what they measure and for what populations*? The VMED project is working towards a solution to this issue, but it will continue to be an issue of advertising beyond people in just statistics or mathematics education as other disciplines continue to research the teaching and learning of mathematics. This is particularly true in the case of the growing data science movement that is transdisciplinary.

During our discussions one of the questions we centered around was, *what instruments does statistics education need?* We present here some of the main discussion points that came up in hopes to spark future discussion and work in these directions:

- There seems to be a need for statistics education measurements at the K-12 grade levels including measures of statistical knowledge and practice as well as measures around identity, beliefs, affect, and dispositions.
- As the importance of preparing teachers to teach important understandings from statistics and data science continues to increase it will be important for researchers and teacher educators to have measures of those understandings to develop and measure the effectiveness of teacher preparation and education programs and experiences.
- Observation protocols are needed for researching the practice of teaching statistics. Such protocols could be useful for preparing teachers of statistics in teacher preparation programs at universities and for site supervisors there to focus on important aspects of teaching statistics particularly those that are potentially different than teaching mathematics as Cobb and Moore (1997) discuss. Furthermore, such protocols would be helpful in teacher education for use in lesson studies and other professional development experiences. They could also be useful for teachers who use research-based teaching practices to defend their practices that may seem out of line with administrators visions of teaching statistics
- How do we work with other disciplines to develop measures that support multiple disciplines? In particular, disciplines like computer science, civics, and science. This need for interdisciplinary work is increasingly important given the current data science revolution.

Another issue that came up in conversations around the use of measures was, *who do we want using these measures?* As researchers, our main focus is on measures for educational research. However, when a measure is made public it is open for anyone's use. Do we want measurements for policy makers and administrators to use in schools? A measure created for the best of intentions and used in ethical ways by researchers can easily be used in ways they were not designed or intended for. A particular worry is policy makers attempting to use such measures to evaluate teachers and make personnel decisions based on their results, which we have seen with Value-Added Models (VAMs), to the consternation of those that created them (American Statistical Association, 2014). Measurement will continue to be an ongoing area of much needed research in statistics education particularly as what it means to do statistics and data science continues to evolve rapidly with developments in technology.

Issues of Equity and Social Justice

The centrality of context to statistical practice makes the discipline well positioned to interrogate issues of equity and social justice and creates spaces in the often neutrally positioned mathematics curriculum for interrogating such issues. Thought there are several decades of past work in relation to the topic of equity and social justice in statistics education (Frankenstein, 1994; Lesser, 2007; Rubel et al., 2016) it is an area that has not received wide attention in the field. This however seems to be shifting. For example, in our working group every doctoral student that attended showed some level of interest in this theme and most were studying issues relate to this theme in their dissertation work. In searching recent National Science Foundation funding awards, we also notice a notable presence of funded work in this theme particularly over the past three years. That said what was really notable was it's presence at all. Another thing we noticed in our search is a significant influence of data science on these projects with several focusing explicitly on data science. We discussed the fruitful connections we see possible in interdisciplinary work leveraging affordances from mathematics education, statistics education, and data science education to creating meaningful opportunities for students to engage in investigations of issues of equity and social justice in school mathematics classrooms (see Table 1 for details).

Table 1: Affordances each field offers for engaging in investigations of issues of equity and social justice in statistics and data science education in school mathematics classrooms.

Mathematics Education	Statistics Education	Data Science Education
• Strong location in the school curriculum • Growing sociopolitical turn • Developed frameworks around equity • Decades of work on critical mathematics education (CME) and Teaching Mathematics for Social Justice (TMfSJ)	• Strong basis in mathematics curriculum • Simulation-based approaches to inference • Literature base around teaching and learning • Educational models • Context is central throughout • Centered around investigations driven by questions • Inductive approach • Focus on variability (diversity) • Methodological discipline	• Focus on cleaning, managing and structuring data commonly needed in publicly available datasets • Focus on use of open-source technology • Focus on data visualization • Data stories

There are also interesting shifts in the world of methodologies that relate to this theme. For example, in the past decade there have been discussions about critical quantitative methods (Stage & Wells, 2014). More recently there has been a strong push in educational research to look at using quantitative methodologies using critical race theory lenses under the moniker of QuantCrit (Garcia et al., 2018; Sablan, 2019). There are even research institutes focused on rethinking quantitative methods and methodologies all together to create new quantitative ways of knowing the world such as the Institute for Critical Quantitative, Computation, and Mixed Methodologies, whose mission it is to, “to advance the presence of scholars of color among those using data science methodologies, and challenge researchers to use those methods in ways that can dismantle the structural barriers to enable human flourishing for underrepresented communities, professionals, and young people” (https://www.icqcm.org/). We are encouraged by the growing body of work in this area. However, there is still much work to be done. Addressing issues of equity and social justice in statistics education is still predominantly being done by a small subset of the field. Furthermore, such considerations have not yet made there way into the recommendation of major policy documents such as the Statistical Education of Teachers (Franklin et al., 2015 or the GAISE II report (Bargagliotti et al., 2020).

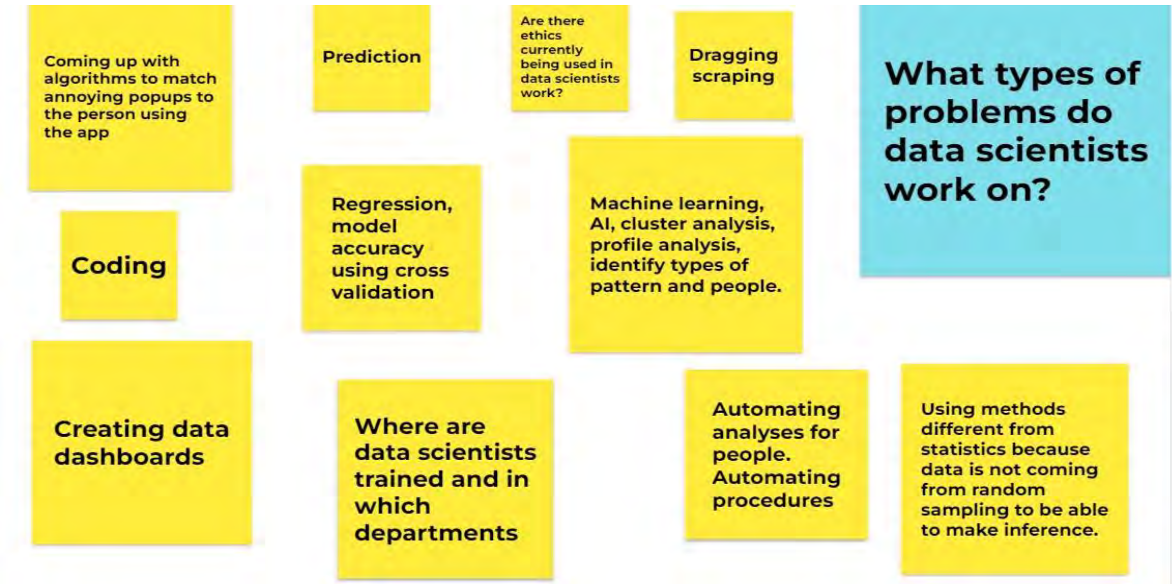
Data Science

Data Science is increasingly gaining traction and attention in the K-12 curriculum. California in particular has been making huge strides at the policy level to create spaces for data science in the mathematics curriculum. Yet we have little research in data science education relative to what are the epistemic practices are that students should learn, how students learn those practices, or how to prepare teachers to teach data science. Furthermore, data science itself is an ill-defined field that does not yet have a clear identity or community itself. Questions for us to consider then are *how do mathematics and statistics education relate to data science education?* Also, *what could be fruitful points of collaboration?*

In some ways it seems like data science is sucking the air out of the room in new initiatives in the K-12 mathematics curriculum. Big name scholars like Jo Boaler are actively working to create significant space for data science in the high school mathematics curriculum in California as part of recent policy changes in the mathematics curriculum in that state that has sparked a reinvigoration of the old math wars. However, this work is moving very quickly and there is little research in data science education currently to guide curricular reforms. Data science itself is still rather ill-defined as a field making it difficult to then state what students should learn or understand from the field. In our working group, one of our main conversations in this theme was, *what is data science?* We found a wide range of models and definitions during our discussion and search, but little common grounding other than it involves interdisciplinary work drawing from computer science and statistics and that data wrangling and visualization are central aspects of data science work. In thinking about data science, we brainstormed from our collective understanding of what data science is, to reflect on the question: *What types of problems do data scientists work on?* You can see the main points of our discussion on the Jamboard we used to organize our thoughts shown in Figure 1.

We ended our discussion of data science much as we started in being unsure of what it was and how it should unfold in the school mathematics curriculum. We have more questions than answers, but we hope that as interest in and demand for data science in the school curriculum increases more scholars will actively investigate issues in this theme to help guide the rapid development of curriculum.

Figure 1: Jamboard of thoughts around the question of What types of problems do data scientists work on?



Author 1 encourages scholars to also be cautious in reflecting on what is data science for and who is it serving in the curriculum when working on scholarship in this area. Data science education initiatives are being well funded by tech companies and the common rationale for the need for data science relies on the common neoliberal claims of work force needs. In reflecting upon Labaree's (1997) discussion of the American struggle over educational goals we must consider is the goal of education to serve the workforce needs of private corporations or is it to nourish democratic equality and citizenship? What does data science education look like with the goal of nourishing democratic equality and citizenship? I think this is an important connection and one not being considered widely.

Concluding Thoughts

Each year we end the working group feeling exhausted and excited. We are exhausted from the rigor of planning three days of engaging 90-minute sessions that are highly flexible and from engaging in 90 minutes of intense and invigorating conversations. It is those very conversations that excite us too. It is exciting to be in community with people that are deeply interested in the things we are interested in. We continue to carry on this working group because of that, because of the community that is developed and the interactions that nourishes us from being together. Statistics educators that do rigorous educational work in spaces around K-12 teaching and learning are a very small group who are spread across many organizations, institutions, disciplines, and locations. In mathematics education spaces, we miss out on conversations around the content we love. In statistics spaces, we miss out on the conversations about how people learn and teach. In statistics education spaces, it is not uncommon for much of the focus to be on post-secondary statistics education. This working group at PME-NA is a rare opportunity for those of us that transverse all of those spaces, educational research, mathematics education, statistics education, and statistics. We hope that the highlights we present here help to spark more conversations around statistics education in K-12 settings and that more people come join in those conversations next year.

cannon_so@mercer.edu

With a renewed focus on data investigation and its relationship to issues of equity and justice, we build on past statistics education working groups to co-develop a syncretic space in which new knowledge can emerge while embracing the tension between critical and dominant views. To do so, we invite a wide range of discussions and collaborations within the domain of statistics and data science education. The primary goal of this working group is to initiate cross-institutional collaborative subgroups based on overlapping research interests. The first two sessions will focus on identifying mutual interests among participants, and the third session will be devoted to planning for collaborative activities over the coming year.

Keywords: Data Science, Statistics, Equity, Social Justice, Measurement

Data science has begun to appear in the K-12 mathematics curriculum in various locations (Bargagliotti et al., 2020). Moreover, discourse around data science has become a political hot potato in curriculum reform in certain regions in the world (e.g., Fortin, 2021), resembling that of the earlier Math Wars (Schoenfeld, 2004). Against this backdrop, this working group aims to spark multiple research collaborations with a focus on *teaching and learning with data investigation*. Our word choice of data investigation is intentional; we invite wider perspectives on teaching and learning with real-world data, such as growing literature on data science education, while building on the continuing development of curriculum and research in statistics education. Teaching with data investigation requires a drastic shift toward identifying heuristic solutions for real-world problems *in context*; this contrasts with teaching mathematics, which often focuses on generalization and abstraction (Lee et al., in press; Wild & Pfannkuch, 1999). The ongoing pandemic has also brought meaning-making with data to the fore of determining everyday practices like wearing a mask and getting vaccines. Developing data-enabled citizenry with awareness of ethical implications of data use is a key concern to promote democratic social processes. However, it is well-documented that teaching and learning with data investigations is marginalized in the mathematics curriculum (Lovett & Lee, 2017), and teachers often do not feel prepared to teach statistics and data science in K-12 classrooms (Banilower et al., 2018).

PME-NA has been an international space to examine issues about statistics and data science education from a wide range of perspectives. For example, Morgado and Sánchez (2021) presented a use of Geogebra to support students' statistical covariational reasoning, and Rubel et al. (2021) applied a critical lens to examine the GAISE II report (Bargagliotti et al., 2020). These contributions reflect that statistics and data science cross both disciplinary and theoretical boundaries (Ben-Zvi et al., 2018). This working group will deepen discussions begun at previous meetings, and also germinate seeds for new collaborations. In an effort to create a syncretic environment that can also focus on specific elements within the domain, the working group is structured to develop sub-groups based on research interests and to engage in dialogic processes across the sub-groups.

Emerging Interests from the Past Working Group

The discussions in the past working group suggest some broad themes of interests that participants may bring. We briefly discuss these themes and propose this working group to deepen these discussions and form collaborative sub-groups.

Issues of Equity and Social Justice

The centrality of context to data investigation makes statistics and data science education an optimal space to examine social issues and participate in democratic social processes. The past working group has identified important affordances of mathematics, statistics, and data science education in terms of centering equity and social justice in students' learning experiences. Discussions may include applying the current understanding of teaching mathematics for social justice to bring data investigation to the fore of political participation. Discussions may also include the role of data science education in widening students' access to public datasets and communicating their findings with multiple stakeholders.

Data Science Education in K-12 Settings

Teaching and learning data science in a K-12 setting poses both promises and challenges. It is an opportunity to lower the boundaries among the subject areas that are often siloed in art, language, mathematics, science, and social studies. For example, students may investigate US census data to identify important trends in the US demographics. This kind of interdisciplinary study brings together domain content knowledge in social studies and data investigation practices and allows students to question and understand important sociopolitical issues. One of the associated challenges is offering resources and professional development opportunities that are needed to integrate data investigation across multiple disciplinary learning settings.

Measurement

There have been recent calls for careful examinations of kinds of validity evidence and arguments for the research instruments that are used to advance the field of mathematics education (Lavery et al., 2019). The interdisciplinary nature of teaching and learning with data investigation adds complexity to this foundational work. This working group will discuss these issues and how they present different challenges in various research contexts related to teaching and learning with data investigation.

Structure of Sessions

Through sessions, participants will gradually form sub-groups with shared research foci. We purposefully structured whole group discussions to facilitate inter-group dialogues.

WORKING THROUGH DISSONANCE: ADDRESSING TENSIONS THAT ARISE WHEN STUDYING MATHEMATICS TEACHER PREPARATION USING AN EQUITY LENS

Dr. Jennifer B. Chauvot
University of Houston
jchauvot@uh.edu

Dr. Jeannette D. Alarcón
University of Houston
Jdalarcon2@uh.edu

We view critical dissonance as key for equity work. As such, this working group session focuses on developing appropriate methodological approaches for a systematic study of phenomena related to the intersection of equity work and mathematics teaching and learning in university-based teacher preparation; we call this approach equity-focused research. We will create a collegial, scholarly space for unpacking and addressing persistent issues that arise when research design in mathematics education research is driven from an equity perspective. The goal is to engage with fellow researchers to discuss and/or develop appropriate methods and designs for studying the ways that preservice teachers understand, implement, and/or resist culturally responsive/sustaining teaching practices after learning about them in their mathematics methods coursework.

The main topic of this session is tensions that arise when designing research using an equity lens. It is imperative that research integrate an equity focus in all aspects of study design, but this can be particularly challenging when working with large sets of numerical data that can be available within teacher preparation programs. In keeping with the spirit of the conference call for proposals, this working group session will use facilitated "critical reflection and conversation" to engage participants across the three sessions.

Our work is situated as critical education research. As such we draw from scholarship that raises critical consciousness in understanding and addressing persistent social issues such as racism in education (Banks, 1993; Gay, 2000; Ladson-Billings, 1995; Nieto, 2004; Villegas and Lucas, 2002). Building from the concept of critical pedagogy we understand dialogue as the key to building critical consciousness about content and systems (Darder, et al, 2003). We draw from Hernandez et al. (2013) model of five thematic categories that can be useful for framing research in mathematics teaching and learning using an equity lens. They are (1) content integration, (2) facilitating knowledge construction, (3) prejudice reduction, (4) social justice, and (5) academic development to guide curriculum development. Given time constraints for the working group session and the urgency for equity work, categories three and four will be highlighted as a framework for the session.

Category 3, prejudice reduction, must be included in curriculum design and implementation for mathematics teacher preparation because mathematics, as a subject area in school, has long been cast in a gate-keeping role. As such, many pre-service teachers enter their programs believing that certain types of people are better at mathematics than others. Despite durable attempts to frame this idea as a byproduct of personal preference for school subjects, the reality is that positioning mathematics in this way is and has always been racially motivated. In the working group, we will explore ideas for disrupting this notion via mathematics teacher preparation coursework and experiences. Category 4, social justice, is an often-misused concept in education. Because social justice has its beginnings in the labor rights movement, we believe that the mathematics curriculum could be a lesser tapped space for helping students use mathematics to uncover root causes for pressing social issues such as patterns of economic disparity, especially along racial lines.

The session structure and expected outcomes are as follows:

- Working Group Structure
    - Session One: Establish the working group environment with an emphasis on collaboration and building community
    - Session Two: Engaged action planning
    - Session Three: Wrapping up and planning for the next steps.
- Time structure for 3 90-minute sessions
    - Opening work (10 minutes)
    - Planned presentation (15 to 20 minutes)
    - Work time (45 to 50 minutes)
    - Closing work (10 minutes)
- Planned presentations
    - Day one: brief presentation to define the notion of interdisciplinary, collegial work and situate it as relevant for the working group (Alarcón et al, 2021).

In this work, we share our approach to teacher educator professional development exploring problems of practice together, and how collaborative planning for the teacher preparation coursework played an integral role in helping us, as teacher educators, understand culturally responsive teaching as a pathway to actualizing equity and justice in education.

- Day two: brief presentation of an exemplar study to situate our conversation about the tensions that can arise when using large datasets to explore equity pedagogy in teacher preparation (Alarcón & Chauvot, under review).
- Day three: presentation of artifacts and other work products (all participants)

- Collaboration activities and preliminary ideas for artifacts

    - Asset Mapping; Community Commitments; Community Check-in; Closing Circle activities are all structured, facilitated activities; they will result in artifacts that will serve as organizing documents for the group
    - The work time segment will utilize principles of cooperative learning with an emphasis on group sense-making and consensus-building. Artifacts produced could include a research statement for conducting equity-focused research; an action plan for revising an existing project with an equity focus; and/or an action plan for future collaboration among working group members.

Argumentation, justification, and proof are conceptualized in many ways in extant mathematics education literature. At times, the descriptions of these objects and processes are compatible or complementary; at other times, they are inconsistent and even contradictory. Regardless of the descriptions of these processes, however, given the importance of argumentation, justification, and proof to the discipline of mathematics, as well as their valued roles as learning practices, it is critical to query the relationship between engaging students in such processes and the promotion of equitable learning spaces and outcomes. The Argumentation, Justification, and Proof Working Group met for the sixth time at PME-NA 43 in 2021 in Philadelphia, PA. The goal of the 2021 sessions was to facilitate discussions and collaborations among researchers to advance our collective understanding of argumentation, justification and proof through an equity and inclusion lens. A concluding discussion that looked across the sessions occurred on Day 3.

Keywords: Reasoning and Proof; Advanced Mathematical Thinking; Equity, Inclusion, and Diversity

History of the Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group (AJP-WG) met for the first time at PME-NA 37 in 2015 (Cirillo et al., 2015). The group then met for three additional years in 2016, 2017, and 2018 (Staples et al., 2016; Conner et al., 2017; Conner et al., 2018). Topics covered across the four years included: definitions and concept images of argumentation, justification, and proof (AJP), research implications of using different definitions to study the constructs, positionality of researchers studying AJP, how definitions and descriptions are used by researchers and practitioners within particular contexts and applications, and how issues of equity, social justice, and marginalized populations intersect with the teaching and learning of AJP. The AJP-WG sessions were well-attended each year, and the group has been active between meetings. Following the 2018 meeting, AJP-WG members began work on an edited book (i.e., Bieda et al., 2022). Across the authoring teams of the AJP-WG conference papers, the book, and the white papers (i.e., Cirillo et al., 2016; Staples et al., 2017), dozens of scholars have been involved in the group's work, including many graduate students. A Research Colloquium, where the team shared analyses from the book, was facilitated at the 2020 conference (Cirillo & Bieda, 2020). In 2021, we returned to the Working Group format with a focus on AJP through an equity and inclusion lens.

Working Group 2021: Goals and Focus

This sixth meeting of the working group focused on the degree to which AJP may or may not promote equity and inclusion in mathematics classrooms. To explore this idea, we engaged participants in explorations of classroom artifacts and data focused on the interrelationship between each construct of AJP and specific aspects of equity and inclusion. Day 1 began with introductions of the leadership team and the participants in the room and on Zoom (i.e., the conference was hybrid due to the COVID-19 pandemic). M. Staples and C. N. Gomez Marchant then introduced our theoretical framing for the session. Specifically, the team focused on the constructs of *access* and *agency* as we analyzed classroom artifacts to consider how justification can support access and agency for students, and thus potentially more equitable outcomes. We then explored how justification can be an *equity practice* in classrooms (in addition to a mathematical and learning practice). Day 2 began with a presentation by K. Kosko of elementary classroom data and an interactive discussion regarding the role of relational and cultural factors in promoting (or hindering) mathematical argumentation and concluded with time for networking among participants. On Day 3 we shifted the focus to proof. Two classroom video clips were shared by M. Cirillo to consider the ways in which proof may or may not promote equity and inclusion in mathematics classrooms. The Day 3 session concluded with interactive activities wherein participants reflected on the three days of WG activities and engaged in discussions aimed at making connections across the WG themes.

Theoretical Background

Given that argumentation, justification and proof (AJP) are important both to the discipline of mathematics and to supporting student sensemaking and understanding, it is critical to investigate potential relationships between engaging students in such processes and promoting equitable and inclusive learning spaces and outcomes. Access and agency are constructs that are potentially crucial for examining the role of argumentation, justification, and proof in creating more equitable outcomes (Gutiérrez, 2002), because these practices can provide students with access to powerful mathematics and opportunities to understand themselves as knowers and doers of mathematics, as well as having their voices matter and influence the classroom. As we seek to promote strong mathematics learning and rehumanize mathematics classrooms, we need to further examine and theorize potential relationships between equitable engagement and the constructs of AJP. We assert this against a backdrop where mathematics, and its ways of knowledge development, have a history of exclusion that not only impacts participation in mathematics education (Louie, 2017) but also in the discipline more broadly. For example, proof has been positioned as a high-status process and thus can be positioned as exclusionary (see, e.g., Knuth, 2002; Otten et al., 2020).

In framing equity for the working group, we followed Unterhalter's (2009) definition of equity as "equality turned into an action" (p. 416). This means we have to consider the consequences of our actions in the learning and teaching of mathematics as working towards the construction of equitable mathematics learning spaces or perpetuating current myths about who can and cannot do mathematics. Equity, therefore, is about who has power in the classroom, in the community, and in our global society (Gutiérrez, 2009). For our goals and purposes in guiding conversation about the role of equity within AJP research, we used Gutiérrez's four dimensions of equity to encourage conversation about differing elements of an equitable classroom (see Figure 1). Access reflects the opportunity students have to learn. Achievement focuses on tangible measures like standardized test scores, enrollment in Advanced Placement courses, and participation in courses. These two elements, which make up the dominant axis, are needed to be seen as successful in our capitalistic society. On the other axis, the identity dimension focuses on teachers' concentration on capital and resources students bring into the mathematics classroom; while the power dimension "takes up issues of social transformation" (Gutiérrez, 2009, p. 6). The identity and power dimensions make up the critical axis. The critical elements work to change society while the dominant ones will only maintain the larger systems in place.

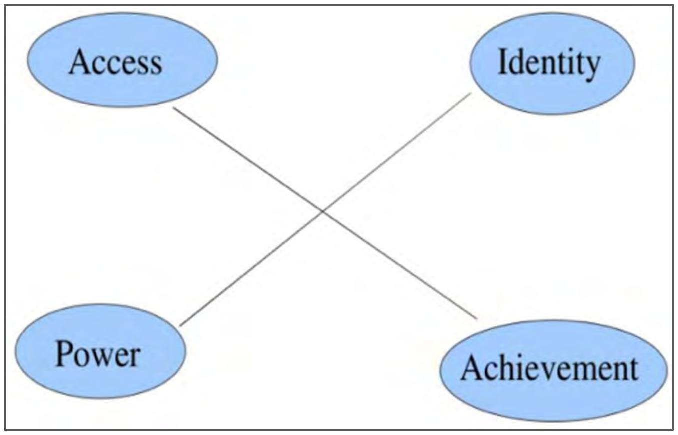

Figure 1: Dimensions of Equity (Gutiérrez, 2009)

Another important construct that motivated our conversations about equity in AJP was *agency*. Agency was defined as, "The ability to influence and make decisions about how and what is learned in order to expand capabilities" (Adair & Colegrove, 2021, p. 8). Agency is related to the racial and social identities of learners because agency influences how people position themselves in relation to micro and macro systems of power. While a broad definition of agency involves the notion of a willingness to act, we also drew on the work of González-Howard and McNeill (2020) who specify the construct of *epistemic agency*, which encompasses how students are positioned, participate, and shape the knowledge construction process in the classroom.

Working Group 2021 Sessions

In the sections that follow, we report on the activities of each of the three days of the working group. We conclude this section with a summary of the reflective discussion that took place on Day 3, where we looked across the activities of the three sessions.

Day 1 – Introductions and Justification through an Equity and Inclusion Lens

We began Day 1 by leveraging a google slide template to have people introduce themselves to the group and facilitate connections (see materials in AJP, 2022). Our goal was to help people get to know others "in the room," particularly as we were spread across in-person and online spaces. After providing context for the group's past work and activities, we turned to the 2021 WG focus by sharing a quotation from our proposal:

> Given the importance of argumentation, justification and proof to the discipline of mathematics, as well as their valued roles in supporting student sense making and understanding, it is critical to query the relationship between engaging students in such processes and the promotion of equitable and inclusive learning spaces and outcomes. (Cirillo et al., 2021, p. 1922)

This launched our work, considering the relationship between argumentation, justification, and/or proof and equity. Participants did a turn-and-talk to share their initial thoughts on this. In the share back, many issues were raised, from who determines acceptable reasons, to classroom interactions and how AJP might serve to either distribute authority - when used to elicit students' ideas and thinking or monopolize it (power) - for example, if a teacher concentrates the authority to determine what counts as a proof or not.

C. N. Gomez Marchant then described the framing of equity we wanted to begin with to guide our work, as described above. Our group proceeded to consider *justification* as an *equity practice.* We offered the following as a definition of justification: "Mathematical justification is the process of supporting your mathematical claims and choices when solving problems or explaining why your claim or answer makes sense" (Bieda & Staples, 2020, p. 103).

Leveraging some of the constructs from the discussion of equity and an equity lens, we posed the following question, highlighting the constructs of *access* and *agency:* "How does justification create opportunities to access important mathematical ideas and highlight students' capacities as thinkers and doers of mathematics (agency)?" To the degree that it promotes access and agency, we can consider justification as a potentially equity-promoting practice and explore how it might promote equity outcomes. In small groups, participants then had the opportunity to review two transcripts - one from a middle school and one from a high school classroom. Participants were asked to look for instances of justification and discussed whether justification, in those instances, was serving to promote equity and inclusion.

In the follow-up discussion, it seemed clear to participants that justification was a practice teachers could (and should!) organize in their classrooms and that it could serve to promote equity goals. It was noted that widespread or regular engagement in justification by students is dependent on norms and a particular environment that would center students' ways of thinking and position students as mathematical thinkers. Classrooms with such norms that had lots of student contributions *but did not include justification activity* would likely not be as equitable in terms of promoting access to mathematics and agency, particularly epistemic agency. Students' contributions to knowledge development were seen as a crucial element.

A question that was prompted, and not resolved, was: Is it the act of justification that makes [justification] an equity-promoting practice (the practice itself) or is it the pedagogical work that makes it part of the classroom that makes it an equity-promoting practice? In considering justification itself, we might further consider the unique nature of the practice (as compared to other practices like modeling, problem solving, and conjecturing) that allows for authority to be taken up by any individual, which may allow it to play a different role in how equitable outcomes are supported.

Day 2 – Argumentation through an Equity and Inclusion Lens

Day two of the working group focused on exploration of argumentation through an equity and inclusion lens. After facilitating participant sign-ins, attention was drawn to the focal question: "In what ways are students positioned to access important mathematical ideas and highlight their capacities as thinkers and doers of mathematics?"

A. Conner, C. N. Gomez Marchant, and K. Kosko asked WG members to consider this focal question through the lens of mathematical argument and argumentation as they engaged with artifacts from an elementary classroom. After illustrating how students' own conceptions of argument may vary (see Figure 2 which contains the teacher prompt: "It is rude to argue"), the working group was introduced to a 360-video of an informal activity focusing on the Commutative Property of Multiplication in a third-grade classroom (see Kosko et al., 2022). The recorded students had just completed an initial task where they were asked to cover a 3cm by 4cm array with Cuisenaire rods (length-based concrete manipulatives where each color of rod represents a specific length). The video (Extended Reality Initiative, 2022) began after this initial task, with the teacher asking students to cover a new array (7cm by 8cm) with exactly one color of rod (i.e., one set length of rod). After students engaged in the task, there was a class discussion about why commutativity works.

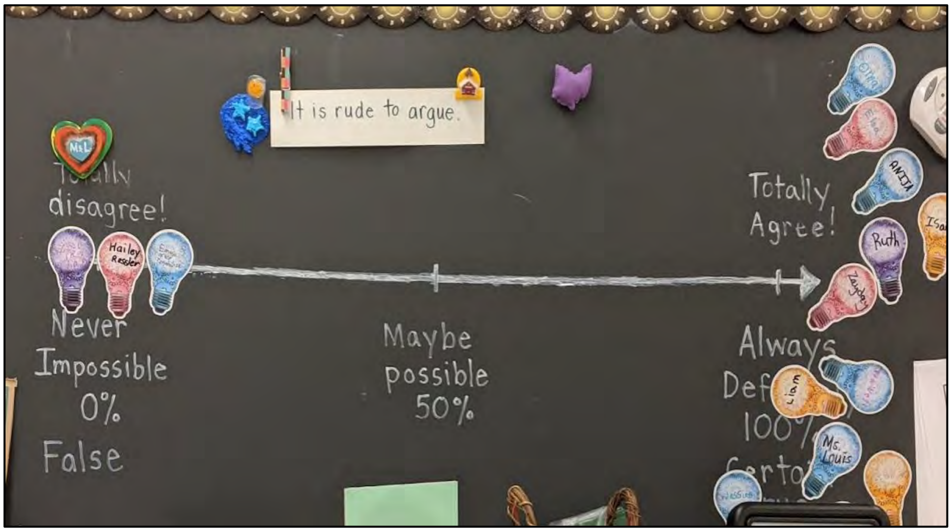

Figure 2: Example of elementary students' initial reaction to whether "It is rude to argue."

Working group participants watched the video to familiarize themselves with the situation and then were asked to view it again while considering two questions: How are students positioned to access important mathematical ideas? How are their capacities for being thinkers/doers of mathematics highlighted (or not)? In the subsequent discussion, a common theme emerged both from the online (Zoom) and face-to-face discussions among the WG participants. There seemed to be a tension between supporting access and agency to students as they were thinking through the mathematics while also attending to specific learning goals. For example, within the online conversation, one working group member noted that by asking students in the front-right side of the classroom to keep the strategies they had come up with to share with the whole class, the teacher effectively "shut down the conversation in the group." However, another member noted that "if you have specific learning goals you want to give all [students] access to…" then such decisions may need to occur. As reflection and discussion of the 360-degree video continued, M. Staples summarized the theme of the discussion by stating that "as we're trying to provide access for mathematical ideas, we have to shape the environment" but then left the group to ponder the question of what mathematical trade-offs occur in such cases.

Following WG members' reflections on access to mathematics in the 360 video, A. Conner shifted the group's attention to data related to how preservice teachers (PSTs) engaged with the same video (see slides 9-10 of Day 2 in AJP, 2022). Participants noticed that a PST who described students' mathematics was more focused on students than the PST who focused on the classroom teacher. Participants also noted that this method of examining preservice teachers' point of view while watching a 360 video seems promising for accessing PSTs' beliefs or current views of teaching and learning. One participant reflected that these two videos and reflections demonstrated that the classroom teacher can attempt to *give* agency to students, or they might *allow* students to have such agency. Extending this point, an online participant commented that one PST may be attempting to "make [agency] happen" versus "making a moment" to allow for students' agency. After this discussion, WG members were provided with opportunities to network during the time that remained in the session.

Day 3 – Proof through an Equity and Inclusion Lens

The primary activities for Day 3 were: (1) considering proof through an equity, inclusion, and access lens and (2) looking across the three WG sessions (described in the next section of this paper). M. Cirillo began Day 3 reminding participants of the access and agency aspects of the WG's equity and inclusion framework (described earlier in this paper). Cirillo then introduced Bass's (2015) Cycle of Inquiry and Justification by sharing a representation she developed to capture these ideas (see Figure 3). In this framework, the "reasoning of inquiry," which could be characterized as inductive reasoning, includes Exploration, Discovery, and Conjecture; while the "reasoning of justification," which could be characterized as deductive reasoning, includes Proof and Verification. Cirillo contrasted the Cycle of Inquiry and Justification with the notion of Proof as Show-and-Tell (see Cirillo et al., 2017). She then posed the following question: How do we create opportunities for student agency within the process of proving?

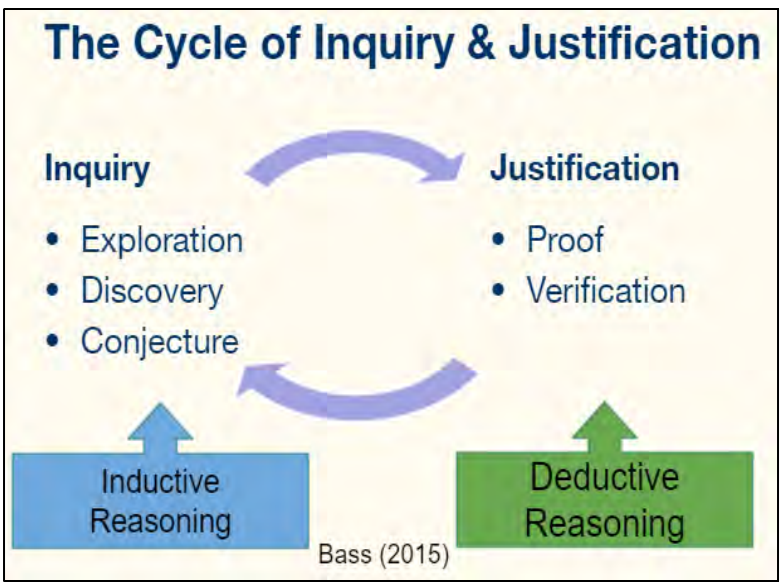

Figure 3: Bass's (2015) Cycle of Inquiry and Justification as represented by M. Cirillo

To explore these ideas, Cirillo shared two videos from her *Proof in Secondary Classrooms* study (Cirillo, 2015-2020) and posed a focal question inspired by Bieda and Staples' (2020) paper: In what ways are students positioned to access important mathematical ideas and highlight their capacities as thinkers and doers of mathematics? In Video 1, a secondary student shared a proof that she had written during groupwork with her class. In the video we can see the students' classmates applauding her work and directing their comments about the proof directly to her. In Video 2, two secondary students are interviewed about their choices and rationales for choosing to work on proofs in different formats (e.g., two-column or flow proof). Participants and WG leaders reflected on when and where they noticed student access and agency in the videos. Herbst and Chazan's (2012) notion of (competing) professional obligations was cited in a discussion about tensions between honoring the students' agency and honoring the obligation to the mathematics. C. N. Gomez Marchant offered some commentary about the videos, which touched on the lack of constraint in students' communication of their mathematical ideas and their agency with respect to making choices about how to represent their work (e.g., in a proof format that aligns with their preferences rather than one dictated by the teacher). Last, Cirillo raised questions about who, in school mathematics, has opportunities to engage in proof?

Day 3 - Looking Across the Three Days

In a synthesizing activity on Day 3, we asked participants to engage with the following question via a Jamboard activity (see AJP, 2022): "Over the past few days, what questions have come up for you with respect to AJP through an equity and inclusion lens?" Themes related to conceptual framings, classroom practice, disciplinary conceptions of rigor and what is valued, and the voices present in these conversations emerged across the question posed.

Several participants asked questions about the framework used for exploring the equity considerations and implications of AJP. Referencing the choice of Gutiérrez's (2002) access and achievement constructs, one participant asked, "While I understand the importance of helping students play the game, how are we empowering them to change the game? How are we changing the game ourselves?" Another participant wondered about other potential framings, asking "What are good ways to examine equity issues in relation to AJP? We used access and agency. What other approaches could be helpful?"

Many participants posed questions about teachers and students enacting AJP as an equity practice in K-12 mathematics classrooms, asking, for example: (a) " How can teachers incorporate Equitable Mathematics Teaching Practices (proposed by NCTM) in teaching mathematical argumentation, justification, or proof?" (b) "Across middle and high school mathematics, is there a trajectory of sorts for AJP?" (c) "How do we transition from researcher-implemented interventions to equipping class[room] teachers broadly to implement these practices in their own classes?" and (d) "Can we see each of A, J, and P as related to equity as practices or is it really more related to how the teacher engages students in the process?"

Participants also shared their wonderings about important disciplinary tensions related to what counts as rigor and what is important and valued in AJP. In particular, the following questions were posed: (a) "I'm continuing to think more about the tension between students producing complete "airtight" proofs and honoring students' ideas and where they currently are in their proof understanding. Do all class proofs need to be airtight, especially at the beginning?" (b) "Does an emphasis on formal proof foreground the math discipline and therefore lead teachers (and students) to think that proof is only for those going into math fields?" (c) "Do we need to question the definitions of rigor and proof as well as attending to the things that we've been attending to the last few days? (d) "While I see the importance of A & J... Aside from (as Nico says) helping students get through the "mathematics" gateway, what other reasons do we have to enculturate students into rigorous proofs? Can enculturation happen without oppression of some sort (and hence implicit gatekeeping)?" (e) "How can students be both well prepared for university work related to AJP while simultaneously respecting their thinking and sensemaking?"

Finally, questions were raised about the limited voices in current conversations about AJP research and practice. For example, one participant inquired: "In what ways are we open to and inviting of diverse voices to the discussion of AJP in research?" Another participant asked a related, but more specific question, "How can we ensure value for teacher and student voices in our AJP research? How can we respectfully conduct research with teachers?"

Conclusion

Across the three days of the AJP-WG, we considered separately—justification, argumentation, and then proof —through an access, equity, and inclusion lens. During the last portion of Day 3, the group had the opportunity to reflect on the discussions that took place over the course of the three sessions. Through participants' contributions to the Jamboard and the subsequent discussion, questions and comments related to conceptual framings, classroom practice, the role of the teacher in AJP, disciplinary conceptions of rigor, and so forth, surfaced. These discussions gave the AJP-WG and its leadership team much to ponder and consider for AJP-WG discussions at future PME-NA meetings.

Building on our previous work, if accepted, the 2022 AJP-WG will consider questions surrounding how research on argumentation, justification, and proof uses differing frameworks and tools to investigate these constructs (see Bieda et al., 2022). We will question if the frameworks and methods currently in use allow us to investigate the problems of practice related to AJP in today's classrooms, and, attending to questions raised at the end of the 2021 working group session, we will consider what is needed in frameworks and methods that will facilitate the investigation of AJP in meaningful and inclusive ways.

Acknowledgement

The AJP team would like to thank all WG participants for their thoughtful participation in the 2021 sessions (see participant list in the Day 1 "Welcome" slide links in AJP, 2022). The research reported in this paper was supported with funding from the National Science Foundation (DRK12 #1453493, PI: Michelle Cirillo; DRK12 #1908159, PI: Karl Kosko). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Argumentation, justification, and proof are essential constructs in the field of mathematics and teaching and learning in mathematics classrooms. Research involving these constructs draws on a variety of definitions and analytic frameworks that include discursive, social, and content factors. This year, we examine frameworks used in research involving these constructs and engage working group participants in critical conversations about how these have been used, with what impact, as well as considering future directions for addressing new questions and making further progress on long-standing ones.

Keywords: Reasoning and Proof; Advanced Mathematical Thinking

History of Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group (AJP-WG) met for the first time during the 37th Annual Meeting of the North American Chapter of the Psychology of Mathematics Education (PME-NA) in 2015 (Cirillo et al., 2015). The group met from 2016 to 2018 (Staples et al., 2016; Conner et al., 2017; Conner et al., 2018). AJP-WG sessions were well-attended each year, involving over 50 scholars, including many graduate students. In addition, the group has been active between meetings. Following the 2018 meeting, AJP-WG members began work on an edited book, published in 2022 (Bieda et al., 2022). A Research Colloquium, where we shared analyses from the book, was facilitated at the 2020 conference (Cirillo & Bieda, 2020). Across authoring teams of the AJP-WG conference papers, the book, and white papers (i.e., Cirillo et al., 2016; Staples et al., 2017), many scholars have contributed to the work. The working group was re-convened at the 2021 Annual Meeting of PME-NA, with a focus on AJP through an equity and inclusion lens.

Topic and Goal

In the concluding chapter of *Conceptions and Consequences of Mathematical Argumentation, Justification, and Proof*, Kosko and Bieda (2022) relate the results of asking authors to carefully consider the consequences of definitions in their analyses of given data related to argumentation, justification, and proof (A, J, and P). They conclude that both definitions and analytic frameworks are essential components in understanding how researchers interpret data. Furthermore, these definitions and frameworks are essential determinants of what data are collected and examined within research studies and how these studies are interpreted into classroom practice. Kosko and Bieda highlight a question from an earlier iteration of this working group that continues to influence our conversations: How does analyzing an artifact (e.g., classroom episode, interview response) from a particular lens (e.g., A, J, or P) influence what we say about it?

In 2022, our working group builds upon this earlier question by examining the influence, efficacy, and usefulness of existing frameworks for research on AJP and considers needed improvements to frameworks that examine both the products and processes of AJP. Current and future questions, including those discussed during the 2021 working group (see Cirillo et al., this volume), suggest a need to critically examine frameworks in use and potentially revise currently used frameworks, adapt frameworks from other areas of mathematics education, or theorize and construct new frameworks for examining processes and products of AJP in classrooms.

Theoretical Background

Argumentation, justification, and proof are considered central to the discipline of mathematics and, as such, have been part of research in mathematics education for decades (see, e.g., Harel & Sowder, 2007; Stylianides et al, 2017; Tall, 1992). However, while proof has been explicitly named and examined in reviews of research, argumentation and justification have been slower to be acknowledged as explicit areas of research (see Stylianides et al.'s (2016) review of PME research on proof and argumentation). Despite their ubiquitous presence in mathematics classrooms, mathematics education researchers have defined these constructs in numerous ways (see, e.g., Cirillo et al., 2016), and have used a wide range of theoretical and analytic constructs to frame their work. In the book that originated in this working group, the editors asked authors to engage in a thought experiment by using a given definition of a construct within their analysis of data across grade levels. Authors were free to supplement the definition with a compatible analytic framework. Within the 12 chapters explicitly focused on specific constructs, authors used frameworks focused on discursive analysis, social factors, and content or task analysis. For instance, all of the argumentation and one of the justification chapters used discursive frameworks; at least one chapter addressing each construct brought social factors into their analysis, including several explicitly addressing the role of the teacher; and five chapters (at least one for each construct) included an analysis of the task related to AJP.

Plan for the Working Group

In the 2022 Working Group sessions, we provide time for presentations related to commonly-used frameworks for research on AJP, presentations that raise questions about frameworks used across A, J, and P (or that could be extended to do so), group discussions that brainstorm the kinds of frameworks that are needed for new questions and new perspectives on AJP. Questions that will frame our sessions include (1) What frameworks for AJP have been used, how have they been used, and what have those frameworks allowed us to accomplish in past research? (2) How does analyzing an artifact (e.g., classroom episode or interview response) from the lens of argumentation, justification, or proof through a particular framework influence claims we can make? (3) What frameworks for analyzing AJP are still needed to help move the field forward with respect to teaching and learning AJP, classroom research, fostering reasoning and sensemaking, promoting equitable participation, classroom practice, and other aspects of researching AJP? Concerning session activities, Day 1 will focus on current frameworks used in AJP, with focused discussion surrounding discursive analysis (i.e., Toulmin's Scheme) and content or task analysis. Day 2 will continue this thread with attention to analytic frameworks illuminating social factors (i.e., sociomathematical norms). Although time on Days 1 and 2 will be devoted to needed or novel analytical frameworks, Day 3 will focus explicitly on this topic and developing action items for the working group and the field as a whole. We will also intersperse time for networking during the sessions.

This report summarizes the work and conversations of the first meeting of the working group on Mathematics Curriculum Recommendations for Elementary Teacher Preparation at the PME-NA 2021 conference. We share a theoretical framework that proved especially salient to our discussions and synthesize the outcomes of small group conversations that we facilitated. We will also share our plans for the continuation of this working group at the AMTE 2022 conference and our proposed next steps for designing research to address questions that arose.

The organizers of the working group on Mathematics Curriculum Recommendations for Elementary Teacher Preparation had several goals for our initial meeting. First, we wanted to bring together a community of researchers interested in improving how future elementary teachers are prepared to teach mathematics. Second, we wanted to better understand the current state of teacher preparation programs. In particular, we wanted to know what participants perceived to be obstacles to the effective preparation of elementary teachers of mathematics, specifically in regards to following the recommendations from the Conference Board of the Mathematical Sciences (2012) and the Association of Mathematics Teacher Educators [AMTE] (2017) for PSTs to receive twelve credit hours of instruction in elementary mathematics. Such discussions also resulted in gathering preliminary data about the number and sequencing of elementary mathematics content and methods courses in participants' programs. Finally, we wanted to initiate a discussion about what researchers thought were the most important topics, practices, and ideas to be included in such courses. Since the PME-NA 2021 conference, the organizers of the working group have met to debrief and think about our next steps for continuing this work. In this report, we will first share the content of our conversations and work at the PME-NA 2021 conference, and then we will discuss our planned next steps for continuing this work at the PME-NA 2022 conference and beyond.

What We Learned at the PME-NA 2021 Conference

Prior Research

On the first day of the conference, we shared some research results to situate the need for this working group. First, we discussed results from Corven et al. (accepted) regarding the relationship between the number of instructional minutes on mathematics topics in teacher preparation and the specialized content knowledge (SCK; Ball et al., 2008) program graduates demonstrated for those topics. An important additional result shared was that incorporating other potential sources of learning about the topics (e.g., professional development, experience teaching the topic) did not change the strength of the relationship and appeared to be additive to prior instruction for the purpose of predicting SCK demonstrated (Corven et al., accepted). Participants later stated that these results increased their comfort with the idea of not including every elementary mathematics topic in their courses; however, other obstacles to making such a change (e.g., the need for PSTs to pass licensure exams) emerged. Next, we shared curriculum design principles from the Elementary Mathematics Project (EMP; Chapin et al., 2021), a curriculum that also chooses to focus on high-leverage mathematics topics and instructional practices. Several participants were excited to learn about the availability of the curriculum materials and the built-in professional development opportunities for mathematics teacher educators (MTEs), such as videos of expert instructors enacting the lessons with pre-service teachers (PSTs). One of the results of research on this curriculum that was shared related to the importance of wanting PSTs to engage in math communities and reimagine their relationship with mathematics (Gibbons et al., 2018). The EMP curriculum emphasizes using mathematical discussions in small groups and MTEs modeling how to facilitate whole-class discussions using student thinking (Chapin et al., 2021).

A Guiding Theoretical Framework

Although there are many similarities between the two programs that we discussed during the conference, the research presented on them exhibited a key theoretical framework that helped guide the remainder of our discussions. This framework was the knowledge-oriented vs. thinking-oriented approaches to teacher preparation proposed by Li and Howe (2021). Knowledge-oriented approaches emphasize teaching mathematical understandings (i.e., content) that PSTs will need to know to teach mathematics effectively, whereas thinking-oriented approaches emphasize PSTs learning to reason about, explain, and make sense of the mathematics they will teach. Thinking-oriented approaches do not treat mathematical knowledge as a fixed product that is given to students, and they often help teachers build skills for analyzing student thinking. The research from Corven et al. (accepted) looked at outcomes that are more knowledge-oriented, whereas the published research shared on EMP looked primarily at thinking-oriented outcomes. However, there is research on both programs to look at other outcomes. For example, Corven (2021) considered how PSTs in the first program understood student solutions to a division story problem, and Starks (2021) explored PSTs' knowledge of decimals within programs using the EMP curriculum. Thus, although Li and Howe's framework relates to the design of teacher preparation programs, we recognized that the distinction in the framework is not binary, and teacher preparation programs generate outcomes that are aligned with both teacher knowledge and teacher thinking.

Obstacles to Ensuring PSTs are Well-Prepared to Teach Elementary Mathematics

In our initial discussions on the first meeting of the working group, we generated a list of obstacles that participants identified as perceived barriers to the effective preparation of elementary teachers in mathematics. Some of these potential obstacles are listed below.

- Assumption that PSTs already know elementary mathematics content
- Lack of consistency between instructors of the same course
- Lack of guidance or support for new instructors of the course (especially for adjunct faculty and graduate students)
- Lack of cohesion or coherence across courses (especially when courses can be taken in any sequence)
- Too few courses/credit hours, especially in particular program structures (e.g., a one-year Master's degree program)
- Too many topics or grade bands to cover, particularly when PSTs need to pass licensure exams

- Lack of cooperation and collaboration between mathematics and education department faculty

Although the number of obstacles identified was disheartening (and we note that the above list is not complete), we observed that creating documents with specific recommendations for elementary teacher preparation courses could provide a first step towards addressing several of these obstacles. Specifically, recommendation documents could improve consistency between instructors in terms of which topics to teach and how much time to spend on each topic and, at the same time, support instructors new to teaching the course. Additionally, if we can obtain further research support to justify teaching fewer topics, then more institutions would likely feel comfortable promoting courses that feature deeper engagement on fewer mathematical topics. Although this change might have an impact on PSTs' performance on content-based licensure exams, there could be other ways to address such an obstacle (e.g., a one-credit supplemental course that covers additional material specific to such an exam). However, such decisions would need to be made on an institution-by-institution basis. We also believe that producing these documents would support MTEs in advocating for additional courses at institutions that currently allot fewer than twelve credit hours to elementary mathematics coursework.

Preliminary Ideas for Course Designs

On the second day of the working group meeting, we broke into three small groups to brainstorm ideas for outlines of elementary content courses. Two of the small groups met in person, and one met virtually over Zoom. After working for about an hour, we came back together to share what we had come up with in small groups.

Two of the groups developed similar topic outlines for two elementary mathematics content courses. Both groups developed a first course that focused on number and operations with whole numbers and decimals (i.e., in base 10), and a second course that focused on fractions and rational numbers. One group also elected to include measurement within this second course to link these critical topics. Another similarity is that both groups discussed ideas to bring in some thinking-oriented approaches within a course intended to promote content knowledge. Two specific ideas mentioned were (1) activities about sorting or categorizing student work and connecting students' strategies to developmental progressions and (2) using number talks as a pedagogical technique to build PSTs' number sense and help PSTs think about different strategies students may use for various operations. One group brought up an important question about wanting evidence that certain topics were easier or harder for PSTs to learn or were worth skipping in teacher preparation programs. Such research would help inform decisions about how much time to spend on each topic, or whether the topic should even be included at all. This idea was a key element of our debriefing conversation on the final day of the working group.

The third group took a different tack by thinking about broader goals for PSTs' mathematical experiences and considering thinking-oriented approaches to course design recommendations. As an example, this group supported using deep, whole-class discussions to deepen PSTs' SCK and allow the instructor to understand PSTs' current reasoning. They also called for explorations that allow PSTs to reconsider what it means to be "smart" in mathematics and to broaden their view of mathematics. Furthermore, they suggested designing tasks to engage PSTs in the Common Core Standards for Mathematical Practice to give them models for what they could do in their future classrooms. Like the first two groups, this group also mentioned the importance of moving away from the goals of covering lots of material and "exposing" PSTs to concepts (i.e., introducing them to PSTs without promoting mastery of them). One advantage of this group's approach is that the activities they developed could be implemented across many different mathematical topics. Additionally, this group wanted to connect the course content to what is currently being taught in elementary schools, specifically by using activities from reform-oriented elementary mathematics textbooks. After discussion among the members of the working group, participants agreed that the different approaches the small groups took was valuable. Recommendation documents could include both a list of mathematical topics and suggested timeframes alongside pedagogical approaches instructors should consider when teaching the courses, allowing teacher preparation courses to attend to both knowledge- and thinking-oriented outcomes simultaneously.

Next Steps

As part of the debriefing conversation on the final day of the working group, we discussed potential next steps. As a preliminary note, three of the organizers of this working group will be running a working group session at the AMTE 2022 conference using some of the same activities we engaged in at PME-NA. Our goal is to get a broader perspective on these issues from practicing MTEs who may have a different perspective on or level of involvement with the mathematics education research community. Additionally, we will be encouraging attendees at that session to bring ideas generated from our conversations back to meetings of their local AMTE affiliates. We hope that such continuations of our work will help working group members gain a better understanding of MTEs' needs for the documents we hope to produce. Two of the organizers have already conducted a discussion session at a local AMTE affiliate meeting (Long & Corven, 2021); one idea that arose from that conversation (more discussion of pedagogy and teaching methods within content courses) aligns with integrating knowledge- and thinking-oriented approaches. However, we anticipate that other ideas could emerge from these conversations to complement the discussions we had last year. For example, the idea of following PSTs into the field post-graduation was not explicitly brought up in our discussions at the PME-NA 2021 conference. MTEs at regional institutions who may be members of AMTE (and/or a local affiliate), but not PME-NA, may have relationships with local schools at which their graduates teach that afford increased access to conduct such research. We see extensions to local AMTE affiliates as an opportunity to grow the membership of this working group, the mathematics education research community, and the PME-NA organization.

As a working group, we developed some broad ideas for what types of research we would need to conduct to move forward. For example, additional research on the effect of eliminating a particular topic from teacher preparation coursework might be needed to convince institutions that removal is warranted. Thus, our goals for the PME-NA 2022 conference will be not only to continue with the drafting of recommendations documents, but also to spend an equal amount of time on designing specific research studies that we could conduct at our own institutions to inform this work. We also hope to engage in studies that are collaborative across institutions to examine the effects of different teacher preparation program structures, while accounting for potential differences in PST population. Alternatively, some participants may wish to conduct action research, for example, by teaching two sections of the same course with different emphases on topics and comparing outcomes. Our discussions at the PME-NA 2022 conference would focus on refining participants' ideas for designing and conducting such studies. Additionally, the organizers of the working group have had preliminary discussions about applying for NSF grant funding to support collaborative research to meet the working group's goals. Obviously, designing such studies, writing a grant proposal, and applying for such funding would take time, but we see the continuation of this working group as a resource to engage more individuals in such a proposal.

Additionally, at future meetings of the working group, we wish to engage more diverse and international (across North America) perspectives on the curriculum and development of elementary teacher preparation programs. We invite colleagues from all nations and institutions with an interest in this research area to participate in this working group and provide additional perspectives on the questions this working group is addressing. Furthermore, we have received interest from additional researchers in joining the organization team for this working group; we affirm that we enthusiastically support new members to join this working group in either a participant or leadership role. Our meeting at the PME-NA 2021 conference was an excellent first step towards addressing the questions we are focused on, and we look forward to applying the lessons we learned to our future meetings over the next several years.

In our first year of work at the PME-NA and AMTE conferences, we explored the current state of elementary teacher preparation programs and generated questions about how to create a viable recommendations document for the mathematics curriculum of elementary teacher preparation. Our current goal is to build upon this work by designing research studies to generate data and answer questions that underlie our future recommendations for elementary teacher preparation.

Keywords: Preservice Teacher Education, Teacher Educators, Mathematical Knowledge for Teaching, Elementary School Education

Teacher preparation programs vary substantially in what mathematics elementary pre-service teachers (PSTs) learn and to what degree across Canada (NCEE, 2016), Mexico (Hrusa et al., 2020), and the United States (Malzahn, 2020). We confirmed these findings at the 2021 PME-NA conference (see Corven et al., this volume, for details); many participants' programs fell short of the recommended 12 credit hours in elementary mathematics (Conference Board of the Mathematical Sciences, 2012). The organizers of this working group believe experiences during teacher preparation affect how teachers teach elementary mathematics; thus, more guidance on how to effectively prepare elementary PSTs to teach mathematics may reduce undesirable variation between preparation programs and improve the average quality of graduates' teaching. To reach these goals, we need to generate recommendations for the (re)design of elementary teacher preparation in mathematics that are concrete, actionable, and based on research.

Limiting the number of mathematics topics covered in elementary teacher preparation may be both desirable and necessary. Corven et al. (in press) conclude the amount of instructional time PSTs receive on mathematics topics is strongly and positively associated with specialized content knowledge (SCK; Ball et al., 2008) novice teachers demonstrate for those topics. Further, since the amount of instructional time required to generate an appreciable increase in an average PST's SCK for a topic seems to be substantial, attempting to cover every topic in elementary mathematics during teacher preparation is not feasible (Corven et al., in press). There has been some movement towards limiting the number of topics taught in elementary teacher preparation programs. One example is the Elementary Mathematics Project (Chapin et al., 2021), which also invites PSTs to build a new relationship with mathematics as members of dual communities of mathematics learners and future mathematics teachers (Gibbons et al., 2018). At our previous meeting, members of the working group wanted to know if research existed that addressed whether certain mathematical topics were more or less important for PSTs to know and/or were easier or harder for PSTs to learn. Without answering such questions, content recommendations would only reflect individuals' opinions, and therefore might be disregarded.

At this working group's meeting at the 2022 Association of Mathematics Teacher Educators conference, not only did some of the same questions arise, but participants shared different ideas for how to craft recommendations for teacher preparation programs based on local constraints. The organizers drew upon these conversations to revise a long-term plan for the working group, which we will enact this year. We see our meetings this past year as comprising Phase I of the working group; our goals were to get a sense of the landscape of elementary teacher preparation programs and to think about obstacles to creating program recommendations. This year, we move into Phase II, which consists of designing research to inform our future recommendations.

Organization and Presentation Plan

The first session will re-orient members to the work that has already been done so as not to be duplicative; however, members will have opportunities to ask questions about and make additions to the previously generated list of concerns about elementary teacher preparation. We will also review frameworks that inform our work, such as knowledge- vs. thinking-oriented approaches to teacher preparation (Li & Howe, 2021). We will then brainstorm research questions that would be important to answer to make informed recommendations for teacher preparation programs. We anticipate members asking research questions concerning the impact of inclusion and/or omission of certain mathematical topics in content courses, the perceptions of novice elementary teachers regarding their preparation to teach mathematics topics, and mathematics professional development opportunities for novice elementary teachers.

In the second session, participants will work in groups to design small-scale research studies that they could conduct in their own contexts to generate data that will help answer one of the research questions from the previous day. We would encourage participants to consider methods like action research and survey research that can be conducted with minimal financial support and within each participant's capacity. Additionally, participants may decide to collaborate on a multi-site study to compare or contrast outcomes from different approaches to teacher preparation or examine impacts of contextual factors. We expect participants to provide each other with feedback on the research plans and to help each other develop appropriate instruments (e.g., interview protocols, survey questions) for the collection of relevant data. We will ask participants to document their ideas in a shared Google Drive folder.

During the final session, we will ask participants to share their proposed studies and receive additional feedback and ideas from the group. Ideally, participants could support each other in data collection efforts to allow for collaboration on specific research questions. Regardless, all study plan documents will be kept in the shared Google Drive to facilitate submission to local Institutional Review Boards. We expect this meeting of the working group will lead to ongoing productive collaborations among working group members prior to our next meeting.

The New Long-Term Plan

In Phase III, members will conduct the research designed in Phase II, and the working group will support each other in synthesizing the results of the studies and writing research reports for future PME-NA conferences. Thus, we expect Phase III to take two years to complete. In Phase IV, we will organize a conference to draft and refine the recommendations based on the Phase III research results. We will also disseminate the recommendations and the research supporting them via an edited book. Through this plan, we intend to support PME-NA members in the conduct of research to improve elementary teacher preparation throughout North America.

For the third time in four years, the Mathematical Play Working Group met to discuss the state of research into the role that play can have in mathematics education research. This meeting provided an opportunity for members within the group to share recent progress in their respective areas of focus. The group also continued theoretical discussions regarding areas of focus for new research and productive framings and perspectives for addressing mathematical play. Additionally, the working group dedicated a portion of the meeting to collaborating with the Embodied Mathematical Imagination and Cognition [EMIC] *Working Group.*

Keywords: Instructional activities and practices; Affect, emotion, beliefs & attitudes; Informal education

For the past four years, the Mathematical Play working group has convened to investigate and advance the field's understanding of mathematical play. Our collaborative work has been characterized by: 1) experiencing mathematical play together, 2) identifying the features and affordances of mathematical play for learning and doing mathematics, 3) and discussing implications for designing mathematical play learning experiences across ages and contexts. Broadly, our work has spanned both theoretical and practical worlds; for example, we seek to understand what aspects of mathematical activity might allow it to be characterized as "play" while simultaneously considering the extent to which mathematical play is possible and productive in classrooms. Our explorations have ranged in context from early childhood preschool classrooms to university mathematics courses, and have examined the use of block play, videogames, partner activities, simulations, board games, and making/tinkering activities.

Summary of 2021 Meeting

Our goal for the 2021 working group meeting was to examine mathematical play along two dimensions - activity grounded in instruction and activity grounded in play - with specific exploration of activities that might support shifts along these dimensions in two specific ways (Figure 1). On the first day, we explored how traditional mathematical instructional tasks might be altered to afford greater opportunity for play. On the second day, we investigated ways play-based activities might be adapted to better support meaningful learning toward specific conceptual outcomes. Working group sessions engaged participants in conceptualizing these two shifts through sharing and explorations of existing projects and discussions of perspectives to support such shifts. Finally, we spent the third day of the meeting collaborating with the Embodied Mathematical Imagination and Cognition [EMIC] Working Group.

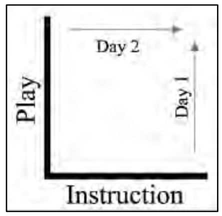

Figure 1: Organization of two shifts we will explore – increasing the playfulness of high instructional tasks (Day 1) and increasing the instructional utility of high play tasks (Day 2)

Day 1: Adapting Mathematical Tasks to Increase Opportunities for Play

On the first day of the 2021 working group, Ellis and Plaxco each presented examples from their respective projects demonstrating efforts to shift existing activities grounded in instruction toward more playful settings. Ellis presented a new (as of the conference) project in which her research team is modifying existing tasks designed to support covariational reasoning about linear and quadratic relationships for play activities. This new area is based on Ellis' extensive work supporting students' sensemaking regarding rates of change and accumulating growth (e.g., Ellis, Ely, Singleton, & Tasova, 2020). In her group's attempt to play-ify existing tasks, Ellis described scenarios in which players (with experience creating accumulation graphs from a given growing shape) would build accumulation graphs and for other players who were then tasked with reconstructing the growing shape. Working group attendees participated in a paired activity to play this game with each other.

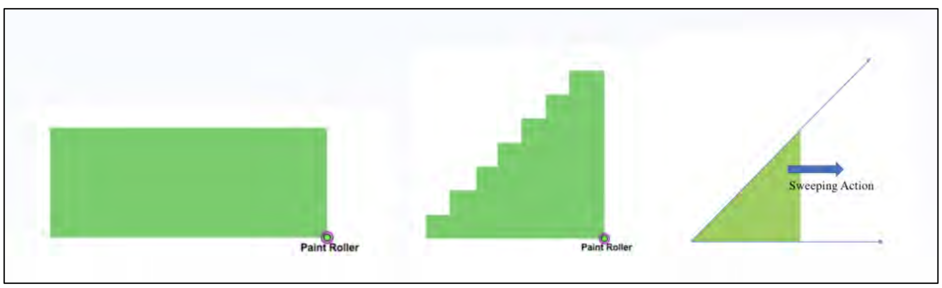

Figure 2: Screenshots of growing figures from Ellis' presentation

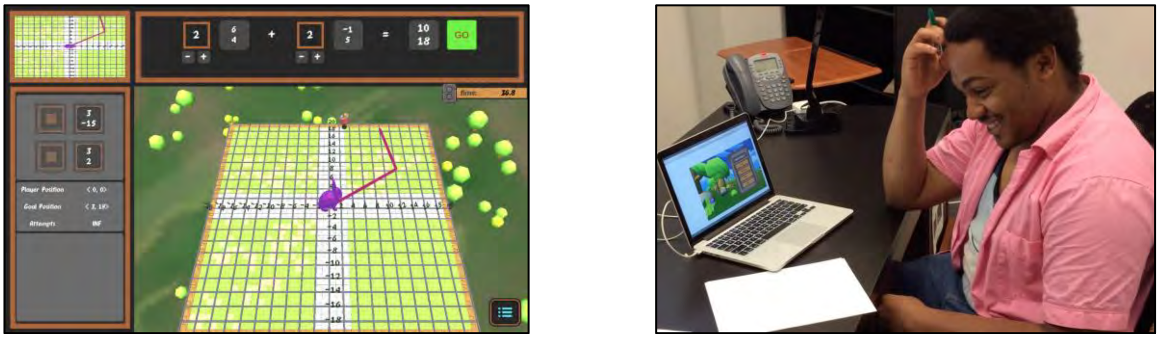
Following this, Ellis had group participants share and discuss and then shared out their experiences among the whole group. Ellis then presented brief examples of student data that exemplified some of the phenomena that the group had experienced. Following this presentation, Ellis outlined her team's working definition for playful math as instances in which students engage in activity with (a) agency in exploration, (b) self-selection of goals, (c) self-direction in how to accomplish the goals. The ensuing discussion addressed several topics, notably the importance of focusing on student agency and the role it plays in authentic play as well as the tension between structure (toward an intended learning goal) and autonomy (the natural progression of the player's activity).

Plaxco then presented examples from his research collaboration in designing and creating the videogame *Vector Unknown* (Figure 3a; Mauntel, Levine, Plaxco, & Zandieh, 2021) for supporting students' Linear Algebra understanding that is based on the existing Inquiry-Oriented Linear Algebra curriculum [IOLA; Wawro, Zandieh, Rasmussen, & Andrews-Larson, 2013]. In his presentation, Plaxco provided an additional instance of the importance of layer agency by describing a player (Lance, Figure 3b) deciding to play what Lance described as a "meta" game of achieving an *additional* goal beyond the goal of the game intended by the design team. The resulting discussion connected Ellis' presentation with Plaxco's, specifically focusing on the role that level design can have in shifting players' focus toward more authentic activities that can also tend to lead to richer mathematical discussions.

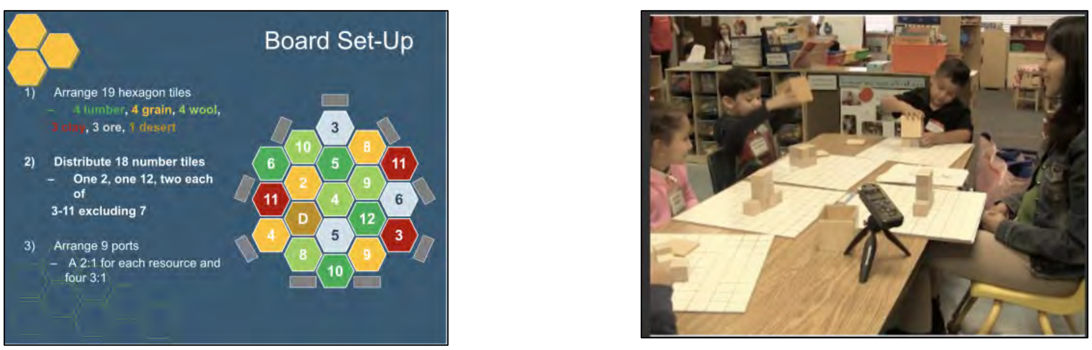


(a) (b)

Figure 3: A screenshot of the *Vector Unknown* (a) and photo of Lance deciding to play a "meta" game within the videogame (b)

Day 2: Adapting Play Activities to Support Mathematics Learning

On the second day, Molitoris-Miller, Reimer, and Simpson presented playful contexts that provide opportunities for mathematical thinking and learning. Molitoris-Miller suggested ways undergraduates encountered moments of mathematical play through explorations with the board game Catan (Austin, Kronenthal, & Miller, 2021). In particular, discussions focused on how board and game setup, players' strategies and solution methods, and students' mathematical arguments traversed the traditional boundaries of play and mathematics.



(a) (b)

Figure 4: Molitoris-Miller's described board setup for the game Catan (a) and Reimer shared analysis of guided play episodes in preschool classrooms (b).

Reimer then presented his research conducted in preschool classrooms to explore how young children and teachers engaged in spatial reasoning through play (Reimer, 2021). Reimer described guided play episodes that encouraged children to explore a variety of contexts and materials. In particular, discussion focused on ways teachers and children participated in play together, with specific attention to the agency and authorship afforded to children through co-participation in play.

Finally, Simpson engaged the working group in a tinkering task (Simpson, Zhong, & Maltese, 2022) using common materials to design a delivery mechanism for sharing objects with a friend next door. The group used popsicle sticks, elastic bands, straws, and other materials to construct their mechanisms. Simpson guided discussions around the potential of low-notation, playful environments to provide opportunities for youth to experience, express, and build upon mathematical practices in a context that is not bounded by standardized tests and textbooks.

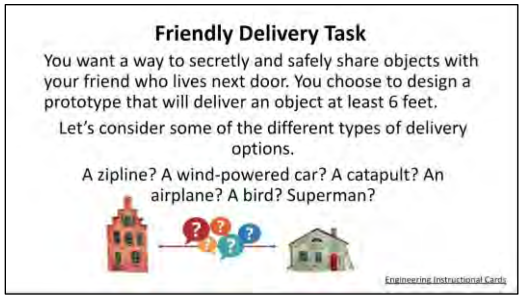


Figure 5: Simpson's engineering task offered opportunities to legitimize informal ways of thinking about mathematics.

Day 3: Intra-working-group Discussion with EMIC

The final day, the Mathematical Play and EMIC working groups met together for a session focused on exploring areas of overlapping interest. In particular, the two working groups converged to explore play as an embodied approach to mathematical learning, and embodied activities as opportunities for mathematical play. EMIC group members, led by Hortensia Soto, guided participants through an activity focused on supporting an embodied sense of the geometric properties of triangles, specifically, the fact that the interior angles of any triangle sum to 180° and external angles of any polygon sum to 360° (Soto, 2021). The groups also discussed how this activity might be generalized for any closed polygon. The following discussion centered around the importance of embodied activities for mathematical learning and discussed potential commonalities between the play, embodied mathematics, and creativity.

Ongoing and Future Work

Since the conference, several subsets of attendees have continued collaborations and intend to develop these into extensive projects. For example, co-author Ellis and meeting attendee Rob Ely have secured internal grants at each of their universities, have continued to analyze their play data, and have developed analytical framings for mathematical play, which they intend to present at the next PME-NA conference. Co-authors Reimer, Williams-Pierce, and Simpson have continued collaborations, meeting to develop their focus on failure and feedback in free-play environments. Co-authors Plaxco, Zandieh, and Mauntel have continued development of a 3-dimensional version of *Vector Unknown* and are collecting data with that version of the game during Spring 2022. In reflecting on the Working Group, co-authors Plaxco, Reimer, Williams-Pierce, and Ellis identified agency as a critical aspect of mathematical play that warrants further development. This aspect of players' experiences emerged across every discussion and presentation during the working group session as a critical component for not only successful play, but also deeper mathematical meaning to emerge during play. In light of this, we have chosen this as the central focus of the next Working Group, which we intend to shift in format from years' past. Specifically, with our next Working Group, we intend to spend the time collaboratively developing theoretical framings related to Mathematical Play. The primary goal of this work is to develop a collective touchstone for: (1) defining mathematical play in a way that situates all of the group members' work within the field, (2) identifying and characterizing the role of agency in mathematical play, and (3) identifying meaningful structural connections between mathematical practices and playful disposition.

PLAYFUL MATHEMATICS AND LEARNING

Coordinators: Robert Ely, University of Idaho, ely@uidaho.edu; Amy Ellis, University of Georgia, amyellis@uga.edu

In this colloquium we build on findings established in the working group *Mathematical Play: Across Ages, Context, and Content*, which met in 2018, 2019, and 2021 (e.g., Plaxco et al., 2021). In those meetings, the working group developed definitions and criteria for characterizing mathematical play and for exploring multiple contexts in which mathematical play occurs. The work presented in this *playful mathematics and learning* colloquium extends these characterizations to examine relationships between play and classroom-based learning.

Playifying classroom mathematics offers opportunities to center student voices, particularly those voices that may be underrepresented in traditional classroom settings. It also offers spaces for challenging status-quo classroom norms, which can increase student agency and autonomy (Gresalfi et al., 2018). At the same time, there is a tension between the open-ended nature of play and the highly directed nature of typical classroom instruction. We explore this tension by identifying design principles for infusing play into classroom spaces, and by discussing theoretical and methodological constructs for characterizing the mathematical play that can arise both in and out of classroom spaces. In doing so, we explore mathematical play phenomena across ages (pre-kindergarten through college), contexts (informal and classroom settings), and domains (early number, algebra, geometry, probability, and calculus).

Session 1: Playifying Mathematics in the Classroom

The bulk of research on mathematical play investigates the mathematics that emerges in children's natural play or in informal spaces. We instead introduce the construct of "playful math", exploring a set of four design principles to playify classroom-based activities: (a) allow for free exploration within constraints; (b) allow the student to act as both designer and player; (c) engender task-based anticipation; and (d) enable task-based feedback. We share results from two related projects that enacted these principles in middle-school, high-school, and undergraduate settings in algebra, geometry, and probability. We found that the design principles were successful in eliciting playful engagement, which corresponded to increases in student agency, goal selection, and sustained engagement.

Amy Ellis, Anna Bloodworth, & Dru Horne (30 mins): We share the results of two small-group teaching experiments and one whole-classroom teaching experiment investigating rates of change through a task called *Guess My Shape*. In shifting from typical covariation activities to a game in which students became shape designers, we found that students introduced novel shapes and graphs that represented more challenging mathematical ideas than what had occurred in prior non-play versions of the tasks. We discuss the resulting mathematics that emerged and discuss implications for task design and student engagement.

Rob Ely & Annelise Nielsen (30 mins): We present findings from a set of classroom activities in which undergraduates played the *Double Spin* probability game and a *Fold-and-Cut* geometry activity. We share characteristics of a form of novel engagement during playful math, the Explore-Strategize Cycle, in which exploration of phenomena in the task environment gave rise to strategic goal-directed activity, the outcome of which changed the space of potential phenomena explored next, and so forth in a cyclical manner. Such cycles were not present in

Lischka, A. E., Dyer, E. B., Jones, R. S., Lovett, J. N., Strayer, J., & Drown, S. (2022). Proceedings of the forty-fourth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Middle Tennessee State University.

non-play activity. We present on Explore-Strategize Cycle and discuss resulting task design strategies.

Discussion (30 mins): Participants will discuss in groups (a) the relationship between design principles for playifying tasks and the resulting student play, and (b) the relationship between student play and mathematical learning goals and outcomes.

Session 2: Drawing Classroom Mathematics from Play

Janet Walkoe & Mari Levin (30 mins): We claim that the insights children gain when playing create a rich body of experiences that are potential resources for later algebraic reasoning. Drawing on a systems approach of learning, we theorize movement toward expertise as a reorganization of sub-conceptual knowledge elements children gain as they interact with their world. We call these elements *seeds of algebraic thinking* (Walkoe & Levin, 2020). Here we provide examples of seeds and illustrate how they can be taken up in a range of experiences. We elaborate how our perspective highlights the relationship between children's early play and their engagement in formal algebra instruction.

Anita Wager, Candice Love, Madison Knowe, Melissa Gresalfi, & Amy Noelle Parks (30 mins): In the *Playful Learning Project*, kindergarten teachers are engaging in professional development around integrating play in mathematics teaching. This involves recognizing the mathematical content embedded in spontaneous play and the possibilities for designing mathematical engagement that embody a spirit of playfulness. We discuss how the PD design elements supported teachers to: (a) recognize and elicit early number and geometric concepts in free play and design playful lessons to allow children to explore these concepts; (b) identify the key classroom mathematical routines and their emotional and mathematical heartbeats (e.g., free play, center-based play, choral counting, problem-solving); and, (c) identify structures in adopted curricula that support playful, exploratory mathematics and structures (and structures that do not).

Discussion (30 mins): The discussion will address theoretical principles for recognizing and fertilizing the mathematical seeds found in children's informal play.

Session 3: Play and Intellectual Need

Aaron Weinberg (30 mins): When a student encounters a problem they cannot solve using their current knowledge, they experience a need for a concept or tool to resolve it. Harel (2013) called this an intellectual need, and proposed that such a need is required for students to learn a concept or tool. We can design problematic situations that we hope will engender students' intellectual need for particular concepts and tools we want them to learn. Yet, sometimes students respond with confusion rather than curiosity when faced with such problematic situations. Playifying mathematics tasks could help with this. I describe a theoretical framework for designing and enacting tasks that can provoke intellectual need, and I discuss ways in which playful math might help students persist in their mathematical exploration to experience intellectual need.

Discussion: We include a full hour of discussion in order to integrate ideas across all three sessions of the colloquium. We will first coordinate small-group discussions to conceptualize and resolve the tension between the open-ended nature of play and the directed nature of classroom learning (30 minutes). We will then convene a whole-group discussion to identify principles for capitalizing on findings from informal and formal mathematical play in order to playify classroom spaces.

This working group was a continuation of a 2019 PME-NA working group focused on the challenges and opportunities of using simulations of teaching practice as an educative tool for preservice teachers. Initially, we shared our diverse experiences designing and implementing simulations before and during the COVID-19 school closures. This discussion inspired us to consider the various dimensions of simulations and the continuums of choices along each dimension. We aim to meet again at PME-NA 2022 to refine our definitions of the dimensions of simulations, discuss research collaborations, and develop an NSF grant proposal to continue our work.

Keywords: Simulation, Preservice Teacher Education, Online and Distance Education, Technology, Classroom Discourse.

During their professional preparation preservice teachers (PTs) must obtain authentic practice-based experiences (Ball & Forzani, 2009; Forzani, 2014). According to Grossman, Hammerness, and McDonald (2009) approximations of practice are one of the three key components of professional practice and they provide “opportunities to rehearse and enact discrete components of complex practice in settings of reduced complexity” (Grossman et al., 2009, p. 283). Through approximations of practice PTs obtain opportunities to learn from their mistakes, try different instructional approaches, and improve their pedagogy (Girod & Girod, 2008). PTs have the opportunity to enhance their skills in a safe environment and have a minimal chance to negatively impact actual students’ learning. A plethora of professions, such as medicine, aviation, and the military have expanded their use of simulations. Several researchers have investigated the impact of simulations on teacher professional learning (e.g., Bondurant & Amidon, 2021; Howell & Mikeska, 2021; Lee et al., 2021; Mikesa et al., 2021; Straub et al., 2014). An endorsement from the American Association of Colleges for Teacher Education ([AACTE], 2020) and the COVID-19 pandemic, the use of digital simulations has expanded. We see the expanded use of digital simulations as an opportunity to learn from our experiences and develop best practices.

Focus of Work

We entered the working group with a set of guiding questions oriented around how our collective work, thinking, or use cases might have been affected by COVID-19, both in the short-term in contrast to prior use of simulations, and in the longer term thinking about what parts of those changes are likely to persist in a post-pandemic world. In contrast to the 2019 working group that focused on the theory and design of simulations themselves, this 2021 session was focused more directly on the contextualization of simulation use, particularly the contrast case provided by the context of working within COVID-19 inducted constraints. Our guiding questions, described in the main proceedings document, were as follows:

1. What affordances and/or challenges in using, adapting, and integrating digital simulations existed before the pandemic?
2. How and why did the affordances and/or challenges change during the pandemic?
3. What affordances and/or challenges do you see in using, adapting, and integrating digital simulations after the pandemic?

Organization for Active Participant Engagement

We began, as we had proposed, by grounding the discussion in the results of the prior working group. This was, in part, to orient the group as some presenters and participants had attended in 2019 while others had not. It also served to establish a common vocabulary, drawing on a provisional list of dimensions of authenticity that had been the core of the 2019 group's discussion. We then went on to describe each of our own experiences before and after COVID-19, beginning with the working group organizers and then inviting the participants to share similarly. While originally conceptualized as a one to one mapping of session dates to experiences with simulations before, during, and after COVID-19, we found that beginning with the contrast of prior experience to current experience was a more productive orientation for most participants, which ended up bridging both sessions 1 and 2.

Subsequently, we discussed the commonalities among our work and attempted to determine the key design decisions or dimensions of simulations. Finally, we closed by deciding that we wish to meet again at PME-NA 2022 to refine our definitions of the dimensions of simulations, discuss research collaborations, and develop an NSF grant proposal to continue our work.

Building on Prior Work

Initially, the 2019 PME-NA organizers, Heather, Yvonne, and Carrie, shared the takeaways from their working group. The 2019 organizers discovered that it would be helpful to develop a common vocabulary and identify design characteristics of simulations. They identified the following dimensions of simulations: boundedness of set-up, complexity of intended response, role of feedback, extemporaneity, linearity of time, individuality, and elaboration of student character(s). They discussed how the researcher's goals impact their design decisions. A key distinction the organizers uncovered among their work was whether the effectiveness of the simulations was the primary focus of the research.

Contrasting Simulation Use Cases

Next, each participant shared their work using simulations, beginning with the five 2021 organizers. The first four shared their experiences within their own courses and the final organizer shared her experiences across multiple sites. New participants to the group were then invited to share their work using simulations. The aim was to only share how they used simulations before COVD-19. However, many of the organizers' work continued or expanded during COVID-19. Therefore, the organizers shared their experiences and takeaways before and during COVID-19. These presentations inspired discussions that lasted into the second session.

Liza studied elementary and secondary PTs' use of equitable teaching practices in virtual simulations. Her takeaways were that overall PTs found the virtual simulations very authentic and beneficial to their pedagogical content knowledge and skills. She also explored the PTs' implicit biases, perceptions of the student avatars, and quantity and quality of the opportunities that the PTs' provided students of different social markers (gender, race) to participate. She found that unless a random method was deliberately used, PTs did not call on students equitably. She also found that PTs typically asked closed questions that were not cognitively demanding. Finally, Liza noticed that the student avatars' behaviors and words often reinforced stereotypes.

Minsung studied elementary PTs' experiences in non-digital simulations and digital-simulations. In using simulations during the pandemic, Minsung noticed how PTs sequenced student work differently, how PTs provided examples/counterexamples to address errors and misconceptions, whether PTs asked students to critique each other's work, and the quantity and quality of PTs' interactions with the students. Minsung also noticed the interactor effect (referred to as the interviewer effect in survey research). She noticed that each avatar's dispositions varied depending who the interactor was. In the simulation facilitated by the female interactor, avatars shared that they were so excited with math. Minsung found that the affordances of using digital simulations include exploring some key pedagogical practices, analyzing student work samples in a shared work space, less nerve-wracking but feeling more real, conferencing their teaching performances with peers in a public space by reducing variability across different field placement settings/contexts, receiving content-specific feedbacks from the instructor, identifying their strengths and areas of improvement on the targeted teaching practices, and recording/assessing/researching teaching in a safe environment.

Yvonne explored secondary PTs' written and video-recorded responses to samples of students' work in math content courses as a part of the Mathematics Of Doing Understanding Learning and Educating for Secondary Schools (MODULES[2]) project. She examined differences in Foundation and Contingency skills across 27 pairs of video and written simulations of practice (SoPs). Foundation was defined as whether or not math knowledge is harnessed productively in teaching and contingency was defined as responding to potentially unexpected student contributions (Rowland, 2013). She found 7 pairs with higher Foundation in the video SoP and zero pairs with higher Foundation in the written SoP.

Carrie investigated elementary PTs' facilitation of number talks in peer-to-peer rehearsals and virtual simulations. Carrie noticed that the foci of peer-to-peer feedback varied from understanding of properties to personal solution strategies. Virtual rehearsal simulation (VRS) feedback centered on positioning of students, understanding student solution strategies, and pressing for connections between strategies. In addition to variation in feedback foci, the development of elicitation strategies was studied. By coding different elicitation prompts, analysis of teaching episodes found that PTs who rehearsed in virtual simulations increased in their use of more closed-ended prompts during rehearsals, as compared to PTs who rehearsed with peers. However, when comparing change in elicitation strategies when teaching in classroom settings, PTs that rehearsed with virtual simulations increased in their use of more open-ended prompts while PTs that rehearsed with peers decreased in their use of more open-ended prompts (Lee et al., 2021). The study of how PTs develop in their use of elicitation prompts during rehearsals seeks to better understand how to support stronger discourse practices.

Heather's perspective is a bit different as her work has been as a researcher studying elementary PTs' facilitation of classroom discussions in virtual simulations across multiple sites, giving her a broad perspective on simulation use across very different contexts but a less intimate one as she has not been working with her own students. The focus across her projects has largely been on formative assessment, relying on a theory of action that supposes that some learning is produced by engagement alone, but that the primary learning mechanism is reflecting and receiving feedback and support. Her more recent work has focused on scaffolding across simulation types.

Heather reported several high level noticings from her experiences with math teacher educators (MTEs) and PTs. Heather's first noticing was that before the pandemic people were hesitant and cautious about using simulations. While some of the caution may have been well-founded, she suspected that some were also fear of the new. Heather has always acknowledged the affordances, but also that simulations have a place among other activities and are neither designed as nor well-used as replacements for interactions with real children. Heather noticed that the field has swung toward simulations with enthusiasm as a result of the COVID-19 school closures, which increased both their popularity and the number of cases in which they were, of necessity, used as replacements for field work rather than complements to it. While the enthusiasm is encouraging, she noted this loss of hesitance as potentially problematic, as it might produce more acceptance of off-label use of simulation in the future, which might be appropriate but, like any off-label use, merits careful consideration of unintended consequences.

Heather also observed that using simulations in online courses was easy and seamless. She conjectured that we may be more likely to accept interactions through a screen as legitimate human interactions after the abundance of online classes and meetings that we participated in during COVID-19. Like all online classes, simulations opened up access to PTs whose lives were less complicated with the removal of long distance commutes, but it limited access in other ways, exacerbating inequality for PTs with inadequate technology access. None of this is particular to simulations per-se, as distance learning forced all of us to consider more closely the affordance of distance-learning in ameliorating some sources of inequity while amplifying others, but the processor-intensive requirements of simulation certainly brought it into sharp focus in this context.

Heather also reflected on PTs' feedback on surveys that raised questions about transfer to classroom practice, in some cases related to simulation but in some cases more broadly. Many PTs commented that teaching five students in a small group on a screen was very like teaching in a zoom breakout room with real students. Some complained that it seemed unnatural in the simulation to see only the students' faces and not themselves on video, and that not seeing themselves on screen made it difficult to regulate their facial expressions. While raised in the context of the simulation, this critique only makes sense in contrast to zoom teaching, as both Mursion simulation and real-life do not afford visual feedback of this kind. And it points to a larger set of competencies that PTs training during COVID-19 might struggle with, having spend most of their formative practice in an environment where facial regulation, body language, and even the ability to 'hide' by turning the camera off for a moment may have encouraged teaching practices that are unavailable in real life. Many PTs reported simulations as more relevant to PTs who will eventually teach online. However, Heather considers connecting through a screen to be a surface feature of the experience. PTs also reported that the simulation helped them facilitate either a small group or a whole-class discussion, depending on the design of the simulation.

Heather noticed that across the studies it was clear to her that intensity of use led to more PT learning. Heather conjectured that there may be a threshold of use to reach a minimum comfort level, and wondered how to normalize the experience for PTs so their first experience was not focused solely on getting acclimated to the environment. PTs knowledge of and skills with leading argumentative discussions improved when they had more simulation experiences. PTs with less experience reported a desire to be better prepared for the simulation, because they were unable to support unpredictable student responses. Heather observed that the amount of learning available also varied by context and degree of support available from the MTEs, with those who were able to provide more structure for preparation and reflection eliciting more learning. She was not surprised by this, as MTEs always mediate learning from experience. However, Heather pointed out that this finding hints at an affordance of simulation in allowing this direct mediation, which is not always available in traditional field work.

Lastly, Heather noticed that MTEs paid most attention to what they had available to pay attention to. When ETS staff scored the videos and provided written feedback and scores, few MTEs viewed their PTs' videos. When ETS staff only provided the videos, most MTEs watched the videos despite the time commitment required to do so. These MTEs uniformly reported that they needed to watch the videos to understand their PTs' strengths and weaknesses. The videos also provided the MTE insight about the degree to which their own instruction had been successful, both with respect to personally defined goals and overall. Finally, most of the MTEs owned what they saw, attributing their PTs' performance to their own actions as teachers, and using it to reflect on how to grow professionally.

Next, the working group participants were given the opportunity to share their experiences. The participants included: Kyle Turner, a graduate student from the University of Texas at Arlington, Bima Sapkota, a graduate student from Purdue University, Zeynep Arslan, a graduate student from Trabzon University, and Neet Priya Bajwa, from Illinois State University. Kyle, Bima, and Zeynep chose to share their experiences.

Before the pandemic Kyle participated in the Mathematics Association of America (MAA) META Math research project. The goals of the META Math project were to "increase faculty capacity to guide undergraduate pre-service teachers in making explicit connections between undergraduate mathematics and secondary school mathematics, and developing deep, sophisticated understanding of mathematics taught in grades 7-12" (META Math). The investigators and assistants developed lessons, a year-long faculty development program to train faculty on how to use of the lessons, researched PT learning that resulted from the use of these lessons, and evaluated the effectiveness of the faculty development program. The in person simulations in this project involved PTs analyzing hypothetical student work samples that contained common misconceptions. PTs were asked to identify and using guiding questions to help the hypothetical student better understand the material.

As an instructor of an elementary mathematics methods course, Bima used simulations during COVID as an alternative to field experiences. Using online conferencing, PTs rehearsed teaching elementary math lessons with their peers. PTs also video-recorded their peer-teaching sessions. Moreover, Bima is using the approximations of practice framework as her guiding framework for her ongoing dissertation study. In particular, Bima is investigating how teacher educators could assess secondary PTs' Mathematical Knowledge for Teaching when they engage in approximations of practice, including lesson plan, implementation, and reflections on teaching. The focus of Bima's dissertation research is on how to best support the PTs' discipline-specific practices, including posing purposeful questions and selecting mathematical tasks for students.

Zeynep used both in person and virtual simulation with PTs. She found the simulations beneficial to the PTs content knowledge (of solving equations) and instructional practices.

Looking to the Future

Finally, we discussed the components of simulation experiences that are worth preserving after the pandemic and our future collaborations. The participants agreed that although the research using simulations is growing, the results have been promising, and there are many unresolved questions. All participants plan to continue to use simulations and expressed interest in meeting again for a working group at PME-NA 2022. Liza expressed a desire to develop an agreed upon framework that captures the dimensions of simulations. She would like to solidify the design decisions that exist as well as best practices (when to do what, with whom, and why). Heather suggested continuing to use simulations as formative assessments (for PTs and MTEs) and as a 'boundary condition' to facilitate conversations. Heather expressed a need for a broader infrastructure, more vendors, and more equity of access. Yvonne expressed interest in working on a research commentary. Heather also suggested developing an NSF grant proposal to support a conference, noting that an affordance of the PME working group format is allowing a group of scholars to work toward such a goal over time and to allow graduate student members access to this type of collaborative experience. All attendees expressed interest in these future endeavors.

CONCEPTUALIZING ETHICS, AUTHENTICITY, AND EFFICACY OF SIMULATIONS IN TEACHER EDUCATION

Carrie Lee Wilkerson East Carolina University leecarr16@ecu.edu	Liza Bondurant Delta State University lbondurant@deltastate.edu	Yvonne Lai University of Neb.-Lincoln yvonnexlai@unl.edu
Heather Howell ETS hhowell@ets.org	Bima Sapkota Purdue University bsapkota@purdue.edu	Minsung Kwon Cal. St. Univ, Northridge minsung.kwon@csun.edu

This working group explores the ethics of simulations of practice in teacher education. As the pedagogy of simulations of practice becomes increasingly popular in content and methods courses, we step back and ask: How are we equipping preservice teachers to engage with students and content in equitable ways? How are K-12 students portrayed and perceived in simulations? How may the need for efficiency run up against ethics? The working group expands on the work of a 2019 and 2021 PME-NA working group with a goal of disseminating conversations around the ethics of simulations of practice. We have reached out to different publishers with the goal of collaboratively editing a book. Working group participants will be invited to contribute book chapters. During our time together we will construct common themes with participants and develop an action plan for the completion of the book.

Keywords: Simulation of Practice, Preservice Teacher Education, Online and Distance Education, Technology, Classroom Discourse

Preservice teachers (PSTs) need ways to connect their content preparation to their future teaching practice. To do so, they need environments where they can experiment with teaching moves–including those that involve attending to power dynamics and handling student conceptions–prior to entering the field (Association of Mathematics Teacher Educators [AMTE], 2017; Ball & Forzani, 2009; McDonald, Kazemi, & Kavanagh, 2013). One common approach to providing PSTs with these environments are *simulations of practice;* opportunities for PSTs to engage in practices that are proximal to actual teaching (cf. Grossman, 2009). For instance, in a simulation of orchestrating a discussion, a PST may lead a discussion with students acted by avatars with particular characteristics (e.g., Bondurant & Amidon, 2021); with fellow PSTs acting as students; or PSTs may be provided student work ahead of time and asked to describe different potential strategies for connecting student contributions. Simulations provide a variety of opportunities for teachers to develop their teaching knowledge and practices (Girod & Girod, 2008).

During COVID-19, the use of digital simulations, which are particularly amenable to online and hybrid applications, came into the mainstream and received both positive and negative attention at a broader scale than ever before. The American Association of Colleges for Teacher Education ([AACTE], 2020) endorsed digital simulation and collaborated with a technology provider, Mursion™; the first time a professional organization had provided such a strong endorsement. At the same time, Mursion™ received negative press attention around the practice of having a single actor represent characters with a different race or ethnicity than their own (Baker-White, 2021).

In short, digital simulations seem to be entering a new phase in teacher education; one in which their potential is beginning to be realized at scale, supported by educational theory and research, but with much work remaining to be done to design simulations that are ethical, authentic, and useful. Furthermore, more attention is needed to the ways in which digital and non-digital approaches are complementary, overlapping, and mutually informative (Mikeska et. al 2021) and how attending simultaneously to the interactive and non-interactive working of teaching can help in the development of broader design principles and approaches, as we have argued for through this series of working groups.

More generally, especially in the current climate, where pandemic-related school closures may have impacted mathematics learning (Kuhfeld & Tarasawa, 2020), and school closures may exacerbate already widening achievement gaps (Dorn, Hancock, Sarakatsannis, & Viruleg, 2020), PSTs need experiences where they can attend to students and content in equitable ways. Teacher educators need ways to notice and provide feedback for such practices, as well as evaluate the explicit and implicit ethics informing the design of simulations, whether or not the simulations are digital. This working group seeks to expand this conversation in the field.

Focus of the Work

This working group seeks to explore the following questions: What common ethical concerns emerge from our work in the space of designing, implementing, and assessing authentic simulations in teacher development? What are design principles for digital and non-digital simulations that promote equitable teaching? How can we disseminate our collective work in the space of simulations in teacher development?

Organization and Plan for Active Engagement

This continuing group will expand the conversation around simulations by critically examining the ethics, authenticity, and efficacy of our collective work in simulations with the goal of dissemination. Prior to convening in Nashville, we will inquire into different dissemination opportunities and select the best avenue to present to our members (edited volume or special journal issue).

The working group will consist of three sessions during the conference followed by virtual meetings through the following year. Sessions will focus on creating a collective vision for the dissemination of work and formulating groups and a timeline.

Session 1. Collective Understanding: Conceptualization and Common Language

In this session, we will begin by briefly sharing the takeaways from our 2019 and 2021 PME-NA sessions with a focus on ethical concerns, authenticity, and efficacy of simulation work. We will also engage new participants by asking them to share their experiences. From this brief review we will break into groups to further conceptualize issues around ethics and design principles. Within group discussions, a common discourse will be negotiated as a group. This common discourse will ground our approach to dissemination of work.

Session 2. Identifying Key Topics for Dissemination

From conceptualization and common discourse, we will then converge on key topics for a special call or edited volume on simulations in teacher education. It is anticipated this work will involve negotiations and exploration of essential investigators in each of the spaces identified.

Session 3. Timeline

Finally, we aim to design a call for chapter proposals and construct a feasible timeline for the writing and editing process. The organizers will brainstorm outlets for sharing the call for chapters. Additionally, they will compile a list of roles and responsibilities and delegate them to individuals. They will also add meeting dates and zoom links to their calendars to ensure the plan is effectively executed.

The Complex Connections: Reimagining Units Construction and Coordination working group began at PMENA 2018, with the aim of facilitating collaboration amongst researchers and educators sharing Steffe's (2017) concerns about units construction and coordination for all learners. This working group made dramatic progress in their ability to conceptualize their work and impact the mathematics education field in the form of publications and task development.

Keywords: Learning Theory, Learning Trajectories and Progressions, Mathematical Knowledge for Teaching, Number Concepts and Operations

The Complex Connections: Reimagining Units Construction and Coordination working group began at PMENA 2018, with the aim of facilitating collaboration amongst researchers and educators sharing Steffe's (2017) concerns about units construction and coordination for all learners. The main goals of the working group were to extend research around units construction and units coordination to new grade levels and to facilitate collaborations with researchers with different backgrounds and experiences. In this report, we describe how the goals of the working group have evolved, including progress and products up through the working group meetings at PMENA 2021.

Past Two Years of Progress

Given that this Working Group has been formed over the past four years, we thought it might be helpful to provide context to the progress made in this working group thus far. When this working group was formed in 2018, we had five leaders and a skeletal webpage. Our goals were two-fold: (1) Extending Units Coordination, and (2) Widening Units Coordination. Essentially, this meant considering how units coordination could frame mathematics education research in grade levels not examined (i.e., prekindergarten and secondary education). By widening the frame used for Units Coordination, we envisioned carrying this frame into mathematics education intersections (i.e., special education and cognitive psychology) not yet explored in mathematics education research.

Since switching to a two-page proposal, our group has not provided context for progress made. So, we wanted to provide a brief discussion of the progress made in the past two years. By doing so, we hope to illustrate how many goals have been met and how our group continues to examine innovative approaches to examine nuances in individual's units coordination development, as well as scale-up this work to examine broad trends in individual's units coordination in a variety of contexts and for a variety of purposes.

Progress Made in 2019

In 2019, our leadership team changed to include one new leader and our attendance grew dramatically (see Figure 1). Given this growth, we began examining Units Coordination in more depth, allowing for tasks to be created intentionally for online course designs (used for both research and teaching), how covariational reasoning contexts explain students' reasoning through their units coordination, and details surrounding the intersection between mathematics education and special education. Our webpage (https://unitscoordination.wordpress.com/) began including a robust member list and tasks used in teaching experiments, interviews, and high education course designs.

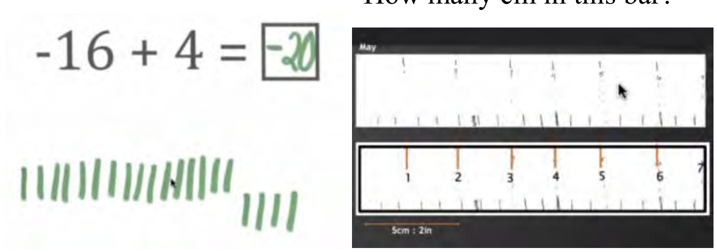
Figure 1: Attendees at the 2019 Complex Connections Working Group

This group began to create a connected group of scholars, students, and teachers. Intellectual outcomes included 10+ publications bridging from prekindergarten to Calculus students. Moreover, unique modalities and online formats for engaging pre-service teachers began to emerge in this group's work, setting the stage for important and innovative pedagogical tools for an unimagined world-wide pandemic. This group spent much of their time examining tasks that many were using in their research and teaching and often revisiting the question, "what constitutes as a unit?" and "what does it mean to coordinate units in these new contexts and with these new tools?". These reflective questions seemed quite broad but allowed the group to refine and adjust their language and task development while designing new courses and research studies. In short, in 2019 this working group was better positioned to extend and widen the Units Coordination frame to more areas and with unique contexts. Outcomes included publications, and intellectual cohesiveness in the mathematics education field.

Progress Made in 2020 (June 2021)

In June of 2021, our leadership lost one leader to the PME-NA Steering Committee and gained one new leader. Due to COVID19, our working group moved to a hybrid format wherein many participants were in an online synchronous format. Considering the reduced attendance and engagement during this conference, our working group continued to grow in members by making innovative accommodations for non-English speakers. In total, we had 17 participants with six of these serving also as group leaders. Outcomes from this working group included refined foci in how units and units coordination are used/defined in areas such as, integer reasoning, combinatorial reasoning, covariational reasoning, pre-service teachers' fraction reasoning, and algebraic reasoning. The term "unit" was now considered to encompass several types of units: (1) discrete units, (2) continuous units, (3) static units, and (4) dynamic units. This allowed the group to again reflect on, "what constitutes as a 'unit'?", and "how can these new units be coordinated in such novel contexts?". This group also examined novel contexts and tasks being developed for research and teaching purposes. Some of these tasks (see Figure 2) were not designed with units coordination frameworks, promoting the discussion around the question, "how might these tasks be helpful or limiting in their design and enactment?". By refining how foci and questions, our groups' intellectual growth continued to progress in a cohesive manner.

How many cm in this bar?



Consider the following statements.

A. I travel 12 meters in 5 seconds.
B. I travel at a constant rate of 12 meters per 5 seconds.
C. I travel at a constant rate of 12/5 meters per second.
D. It takes me 5/12 seconds to travel 1 meter.

Pick a pair of statements that **don't mean exactly the same thing**. Write a statement that would convince anyone else in the class that those two statements don't mean exactly the same thing.

Pick a pair of statements that **mean exactly the same thing**. Write a statement that would convince anyone else in the class that those two statements do mean exactly the same thing.

Figure 2: Examples of some tasks discussed that broached novel ways to frame Mathematics Education with Units Coordination Learning Theories.

In short, in June 2021 this working group was better positioned to extend and widen the Units Coordination frame to particular areas and with more refined language and tasks. Outcomes included five new publications, two new software apps designed to measure individuals' units coordination, and a more comprehensive set of language around what constitutes as a unit and how units can be coordinated in several novel contexts.

Progress Made Throughout the October 2021 Working Group

In the fall of 2021, the PME-NA conference held a second hybrid conference, allowing attendees to participate via online synchronously and/or in-person. The difference in this conference is that many more participants attended in-person. This only increased our participation from June of 2021. In particular, we had a total of 19 attendees and seven of these served as leaders. Many of these attendees were ones who participated in the Complex Connections Working Group each year they attended PME-NA. However, three of these 19 participants were new participants and joined our group to both learn and contribute in unique ways. In the subsequent sections, we will elaborate on progress made during each day of the working group, explaining details of this group's intellectual growth and associated outcomes.

Day One Progress and Outcomes

The first day of the working group began by using language from past working groups to define and characterize a unit, units coordination, and contexts participants used or envisioned using units coordination in their research and teaching. We divided into two in-person groups and one online group, capturing ideas in three separate Google documents. Participants also recorded several questions they still had in their discussion. By the end of this day's working group, we were positioned to examine tasks from one research group and make note of tasks and apps we could examine in subsequent working groups.

The group had a wide variety of ways to characterize units (see Figure 3). For example, one participant wrote that a unit is defined differently dependent upon the type of unit one is constructing (i.e., perceptual, figurative, abstract) whereas another participant implicitly suggests an individual's formation of collections, suggesting discrete, static units. These variations suggested how often researchers and teachers use this term differently and why the progress this group has made in reflecting on these variations is important.

- "things" like angle degree measure
- a "thing" that can be iterated
- what is a unit depends...is distinguished between perceptual / figurative units. Forming collections versus not. Abstract unit.
- unit for me: constructed via the unitizing operation
  discrete 1s and measurement units

Figure 3: Participant notes characterizing what constitutes as a unit

The group described units coordination in one broad manner, providing a more coherent characterization of this frame. For instance, one participant connected the units variation discussion to units coordination by stating that units coordination refers to, "how units change over time and how the relations and actions with units change in different situations." Moreover, this group added that, "You have to at least distribute the elements of one composite unit across another composite unit." This statement was echoed in each small group, providing a coherent frame of reference for the remainder of the time in the working group.

The group members also described the contexts they used units coordination. This variation included variety in age of person (prekindergarten to college level) and variety of units in varying contexts (e.g., fractional units, whole number units, algebraic units, measurement units, covariational units). This wide variety explained the variation in how units were characterized but also provided means to coherently synthesize units coordination in a more in-depth and comprehensive manner.

Finally, the groups explicated many questions they still had regarding their own work and this framework (see Figure 4). These questions served as the basis for the remainder of day one's work and the basis for progress we would make in day two, day three, and beyond.

- what do we each mean by "quantity" in relation to "units?" - Drew from Thompson's explanation of how "units" are specific types of quantities.
- can a unit be within a measurement model?
- what does a situation mean? Is this a recognition template?
- what about division of fractions? How would different color help with recognizing the units? Jerry says "use word "disembedding" quite a bit. Perhaps color theory would be helpful?
- do you see overlap with Units Coordination and proportional reasoning?
- does units coordination have layers or levels?

Figure 4: Examples of questions participants had in small group discussions

Many of these questions pressed participants to reflect on their language and the underlying scheme theory used to explain how units coordination develops and changes over time.

Moreover, some participants were examining characteristics of tasks that they found leveraged students' mathematical development but had been developed for only practical purposes.
To examine units, units coordination, and to help participants answer some of these questions, we explored fraction tasks (designed for pre-service teachers - PST) and their responses. We discussed the limitations many of these tasks inherently had in their design and enactment.
In short, progress from day one, allowed the working group to further refine their definitions and characterizations for units and units coordination. Novel contexts and questions surrounding tasks fundamentally provided more nuanced progress on task development, task enactment, participants' responses, and analyses of these responses.

Day Two Progress and Outcomes

The second day of the working group continued the examination and discussion of written assessment items. Both the in-person and remote participants analyzed the work of pre-service teachers (PSTs) on static fractions tasks, discussing the following prompts in small groups:

- Is there indication that the PST coordinated units?
- Is there counter-indication that the PST coordinated units?
- What are the obstacles to overcome in assessing units coordination with this item?
- What are the ways that you have assessed units coordination?

One of the takeaways from the following discussion was the difficulty with making an assessment of an adult's units coordination with fractions solely from their responses to written items. Participants discussed myriad ways that a student might make marks and representations on the paper to determine a normative size or number without coordinating fractional units. We discussed how such assessments, though useful for making inferences of children's reasoning, may not be sensitive enough to assess adults' fraction schemes. Yet, they may be useful in other ways. For instance, we shared a PST's response to a task that was intended to evoke their use of l (see Figure 5). After project leaders shared this response, the members discussed how the PST's converting the fraction 9/6 to a mixed number was not necessarily a counter-indication of their construction of an iterative fraction scheme. In fact, the members discussed that it might indicate a PST's tendency to focus on part-whole relationships when developing appropriate pedagogical content knowledge for elementary school instruction.

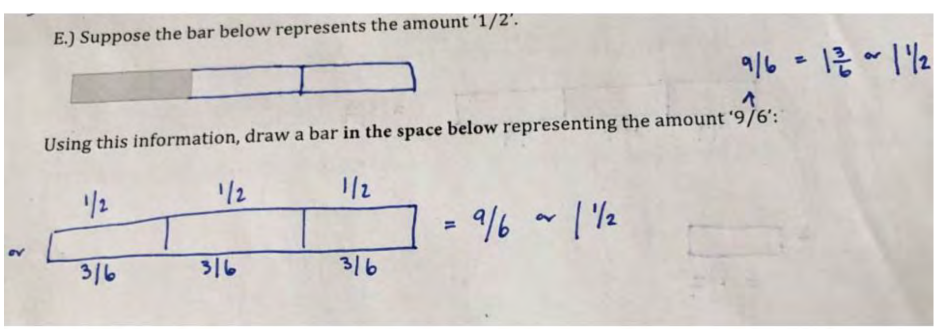


Figure 5: Screenshot of PST fraction task response shared by Working Group leaders

The second half of the Working Group was led by Dr. Teruni Lamberg, who participated in-person. Dr. Lamberg shared a sequence of fractions tasks she had used with in-service elementary and middle grades teachers' professional development. We continued Day 1 discussions regarding relationships between fractions understandings, such as part-whole schemes versus iterative or partitive schemes, and their constitutive operations. Dr. Lamberg's tasks were not designed to assess units coordination, rather, they were designed to assess fractions understandings as described in the Common Core State Standards. Thus, consideration of these tasks provided opportunities to make connections between units coordination and fractions curricula. Of particular import was the discussion of the disembedding operation. Disembedding is a hallmark of coordination of two levels of units. It involves mentally "removing" an item or amount from a whole extent or collection, without modifying the size or numeracy of the extent or collection. We discussed Dr. Lamberg's idea that intentionally varying color may be helpful in fostering students' disembedding composite units, particularly in the context of fraction division.

Day Three Progress and Outcomes

The third day of the working group focused on how units coordination is assessed. The in-person attendance, of six, was lower than the previous days, which is typical for the last working group day due to early flights. There were eight individuals who participated remotely. The first half of the session the discussion was led by Dr. Amy Hackenberg, who streamed a video of a teaching experiment session with a sixth-grade student as well as a written task (and rubric) that she had used in a clinical interview setting. Dr. Hackenberg explained how the contrasts in the student's responses to the tasks in the video were useful for understanding the distinction between a student not coordinating units and a student coordinating units "in activity". We discussed the details of the rubric for the interview task she shared, and several participants noted that this level of detail in the types of expected responses for students at different stages of units coordination could be an area of improvement in assessments with PSTs.

One important benefit of this Working Group is to provide a space for discussion about units coordination research presented elsewhere in the program. In addition to Dr. Hackenberg's discussion of her research, two participants in the working group from James Madison University elaborated on their research report investigating the validity of written instruments for assessing PSTs' units coordination. Their research team presented their report at a session earlier that morning, and they attended the Working Group meeting to elaborate on their findings and to discuss potential collaborations. Several of the members of the Working Group who have been focused on PSTs' fractions understandings expressed interest in collaborating with the design of methods to validate and improve upon written assessments.

Two additional Working Group members shared applets that they have designed. As shown in Figure 6, Sarah Kerrigan created a Geogebra version of the Bars Tasks (https://www.geogebra.org/m/zhgajwzp).

Figure 6: Screenshot of applet shared by Sarah Kerrigan

Although this applet was created out of necessity, due to the need to assess students' reasoning remotely because of the COVID19 pandemic, several participants noted its potential benefits over traditional paper and pencil assessments. We discussed the potential for students to complete the assessment via Geogebra and screen-record their activities, improving inferences of their process for solving the tasks. The Bars Tasks were originally validated with sixth-grade students by comparing researchers' inferences based solely on the paper with other researchers' inferences based on watching video-recordings of the students' solving the task (Norton et al., 2015). Kerrigan's applet could potentially be used to either validate the written assessment with older students, such as with PSTs, or to replace the written assessment for use with other groups of students.

Unlike Sarah Kerrigan's applet, the applet that Dr. Cameron Byerley shared was not designed specifically to assess units coordination. She discussed an applet (see Figure 7) that was designed to help individuals construct proportional reasoning related to the risk of contracting, being hospitalized, or dying from COVID19. Units coordination is involved throughout students' mathematical development, and one of the goals of the Working Group is to extend our understanding of its roles and its relationships with quantitative, covariational, and probabilistic reasoning. Dr. Byerley discussed how her knowledge of units coordination informed and influenced applet design decisions, such as the use of horizontal, left-aligned rectangular bars to represent and compare the size of COVID risks with everyday probabilities such as getting in a car accident or winning the lottery. Her discussion of interviews with citizens on their use of the applet was heartening, in that some of the participants expressed a deepened understanding of the risks they faced with not getting vaccinated, but disappointing in that others expressed either skepticism of the statistics or a disconnect between the sizes of the bars and the relative sizes of the risks.

Figure 7: Screenshot from applet shared by Working Group Leader Cameron Byerley

Progress Made Following the October 2021 Working Group

Since the members of the working group met, work has been done to develop a Special Issue, reflection of tasks relative to the granular size of studies and modalities, and updates of the working group website. The website (https://unitscoordination.wordpress.com/) now features new members, tasks, rubrics and publications. Thus, the working group has connected new resources, for different purposes, and connected scholars, so as to form new research questions and research foci. It is our hope to leverage the energy from these connections for more actionable work on a Special Issue in the fall of 2022.

Conclusion

Throughout the past four years, this working group has refined and housed publications, tasks, discussions, and virtual tools to examine units construction and coordination. In the past year, this work has become more refined and intentional, prompting members to conceptualize their work with this frame in a more precise manner. Moreover, the working group website (now the second search item in a Google search for "units coordination") has developed dramatically, bridging scholarship across grade levels, within the intersections of special education, mathematics education, early childhood education, and research in undergraduate mathematics education. Evidence of engagement with these tools is allowing scholars and teachers to develop rubrics, allowing more coherent foci with this frame across the nation. Thus, we measure progress through the conceptual development of the working group and aim to evidence this with a special issue in the next two years.

A powerful aspect of using neo-Piagetian frames to examine students' construction and coordination of units is their potential to apply across mathematical domains. This working group aims to facilitate collaborations between scholars of algebraic and covariational reasoning, with the particular aim of extending research on units coordination and construction across these contexts. An ultimate goal of this working group will be to develop a Special Issue.

Keywords: Algebra and Algebraic Thinking, Learning Theory, Number Concepts and Operations, Learning Trajectories and Progressions

Background

This Complex Connections working group, focusing on units construction and coordination learning theories, will provide collaborative discussions for participants examining, assessing, and teaching students' algebraic and covariational reasoning. Thus, this paper delineates findings from these two constructs, set in units construction and coordination learning theories.

A connection between middle-grades students' units construction and coordination and their algebraic reasoning is emerging in the research. Notably, Hackenberg and her colleagues (Hackenberg et al., 2017) have determined that to meaningfully reason about unknowns relies cognitively on students' operations on composite units. This suggests that construction of assimilatory composite units is a consequential prerequisite to much of the algebraic reasoning that is typical in middle-grades curricula. Additionally, Olive and Çaglayan (2008) demonstrated ways that assimilating with three levels of units supported middle-grades students' solutions to a word problem that could be modeled algebraically. In their investigation, assimilating with three levels of units supported students to utilize a substitution method for solving the system of equations because they could anticipate an equation as a three-level unit structure and operate on that structure in mental activity. Additional connections have been drawn between students' units construction and coordination and their algebraic reasoning as it relates to generalizing figural linear patterns (Hackenberg, 2013; Zwanch, 2022b), their equation writing (Hackenberg, 2013; Hackenberg & Lee, 2015; Hackenberg et al., 2021; Zwanch, 2019), and their guess and check strategies to solving algebraic equations (Zwanch, 2022a).

Similar to connections being drawn between units construction and coordination with algebraic reasoning, researchers have started to investigate connections between units coordination and covariational reasoning. Carlson and colleagues (Carlson et al., 2002) built a framework for capturing covariational reasoning and defined it as "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). Johnson (2015), directly built on Carlson and colleagues' framework in her investigations of secondary students' quantification of rate and ratio. Although these frameworks provide a way to categorize students' covariational reasoning, there has been little work investigating connections between construction and coordination of units and levels of covariational reasoning in these frameworks. Given these advances in this field, members of the working group will discuss points of collaboration.

Session 1: Extending to Algebraic Reasoning

<u>Goal: Discuss connections between algebraic reasoning and units construction/coordination</u>

Activities: In a large group, participants will solve algebraic reasoning tasks and analyze their solutions, focusing on the potential solution strategies of students. Participants will form small groups based on their own interests in (1) early and middle-grades algebra, (2) elementary algebra reasoning, and (3) secondary grades of algebraic reasoning. Within these small groups, participants will view and analyze videos, transcript excerpts, and written work taken from empirical studies. Participants will discuss theoretical and pragmatic connections between the students' units construction and coordination and aspects of their solution strategies.

Session 2: Extending to Covariational Reasoning

<u>Goal: Discuss connections between covariational reasoning and units construction/coordination</u>

Activities: In a large group discuss the theoretical connections between the two bodies of research before engaging in some covariational tasks. In small groups, participants will solve covariational tasks and analyze their solutions to identify what units constructions and coordination emerged in their work. After coming back together to share our ideas, we will break into groups again based on own interests (1) middle-grades covariational reasoning, (2) secondary-grades covariational reasoning, and (3) undergraduate covariational reasoning. Participants will have the opportunity to analyze student data from clinical interviews, discuss task design and assessment, and theoretical and teaching applications.

Session 3: Extending to Algebraic and Covariational Reasoning

<u>Goal: Discuss connections between algebraic and covariational reasoning, and units construction/coordination</u>

Activities: In a large group, participants will solve algebraic reasoning and covariational reasoning tasks and analyze their solutions, utilizing units construction and coordination to orient to the potential students' strategies. Participants will form small groups based on their own interests in algebra and covariational reasoning (1) early and middle-grades, (2) elementary grades (3) secondary grades. Within these small groups, participants will view and analyze videos, transcript excerpts, and written work taken from clinical interviews and teaching experiments. Participants will discuss theoretical and pragmatic connections between the students' units construction and coordination, and aspects of their solution strategies. We will wrap this session up with a review of our drafted call for a Special Issue proposal. We plan to explore journal possibilities and language in the call. The details for this Special Issue will be advertised widely with our listserv and on our units coordination webpage (https://unitscoordination.wordpress.com/). Future work will be discussed to allow for opportunities for future collaboration. Additional information will be added to the group's webpage, allowing for current research and resources to be made available.

The Embodied Mathematical Imagination and Cognition (EMIC) Working Group was established in 2015 at the annual PME-NA conference. As an interdisciplinary group of researchers, teachers, students, and practitioners, EMIC has strived to advance our understanding of how our physical experiences and body-based resources impact the ways we learn mathematics. Over the past several years, EMIC's founding members have collaborated on initiatives to a) expand this area of research through grants, workshops, and publications, b) share these findings with teachers and practitioners, and c) grow the community through new members and opportunities for participation. This progress report highlights the progress and accomplishments of EMIC and its members.

Keywords: Technology; Cognition; Informal Education; Learning Theory.

A Brief History and Motivation of the EMIC Working Group

The first meeting of the EMIC working group took place in East Lansing, MI during PME-NA 2015. It has a somewhat longer origin, however, growing out of several earlier collaborative efforts to review the existing literature, document embodied behaviors, and design theoretically motivated interventions. One early event was the organization of the 2007 AERA symposium, "Mathematics Learning and Embodied Cognition." This and other gatherings led to a funded NSF "catalyst" grant to explore a Science of Learning Center, which was to involve scholars from multiple institutions and countries. Though unfunded, those SLC efforts shaped a subsequent 6-year NSF-REESE grant, "Tangibility for the Teaching, Learning, and Communicating of Mathematics," starting in 2008. Interest from the International PME community in this topic grew and led to special issues of *Educational Studies in Mathematics* (2009), *The Journal of the Learning Sciences* (2012), and an NCTM 2013 research pre-session keynote panel, "Embodied cognition: What it means to know and do mathematics," along with a series of academic presentations, book chapters, and journal articles, as well as several masters' theses and doctoral dissertations. By now, several research programs have formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards, Ferrara, & Moore-Russo, 2014; Lakoff & Núñez, 2000; Radford 2009), demonstrating a "critical mass" of projects, findings, senior and junior investigators, and conceptual frameworks to support an on-going community of like-minded scholars within the mathematics education research community.

It was within this historical context that approximately 22 members of PME-NA 2015 came together for three 90-min sessions of semi-structured activities. On **Day 1,** the organizers engaged attendees in some of the body-based math activities used in their research on proportional reasoning and geometry. One activity (Figure 1b) engaged participants in a projection activity using Alberti's Window, which helped experience the role of body perspective on form and representation. We discussed how embodied theories are advancing our understanding of mathematical thinking, and how these ideas are shaping a new class of educational interventions. During **Day 2**, we used hands-on activities to expand our own understanding of topology. We then built on the emerging rapport among the group to hold a facilitated discussion of the potential intellectual benefits of forming a self-sustaining Working Group on embodied cognition, along with the necessary infrastructure it would need to maintain. Several concrete proposals led to the list of Future Steps on **Day 3**. However, before we tackled those matters, participants began the session doing math games and activities in small groups, including Spirograph, Set, Rush Hour, Tangrams, and Mastermind. We reflected on how some games and activities draw people into rich mathematical thinking and actions, and how we naturally engage in math through these activities. Day 3 culminated in an organized list of Future Steps, with some working group members assigned to specific tasks. We have convened annually since.

Figure 1: A small selection of embodied activities created by EMIC organizers and experienced by EMIC participants. *Clockwise from top left*: experiencing geometric transformations, acting out geometry conjectures, constructing icosahedra first as small, then at human scale, and enacting topological relations.

Founding Members

The EMIC community has welcomed several new members since its inception in 2015 and the leaders of our working group at PME-NA have shifted each year to reflect the focus of each annual meeting. Below are the founding members of EMIC who have led the charge for many of this group's collaborations within and between PME-NA convenings.

- Candace Walkington, Southern Methodist University
- Caro Williams-Pierce, University at Albany, SUNY / University of Maryland
- David Landy, Indiana University / Netflix
- Dor Abrahamson, University of California, Berkeley
- Erin Ottmar, Worcester Polytechnic Institute
- Martha W. Alibali, University of Wisconsin-Madison
- Mitchell J. Nathan, University of Wisconsin-Madison
- Ricardo Nemirovsky, San Diego State University
- Rogers Hall, Vanderbilt University

Collective Efforts and Accomplishments

Beyond PME-NA, EMIC members have actively collaborated over the past several years to continue advancing this field of research, bridging the gap between research and classroom practice, and expanding the EMIC community. Below, we provide overviews of the progress and accomplishments shared by members of our group (see Figures 1 and 2).

Table 1: Events Organized by the EMIC Community Since PME-NA 2015

2019	(May) NSF-funded EMIC I Workshop.
2020	(May). EMIC Virtual Panel #1. Hosted by embodiedmathematics.com.
2020	(October). EMIC Virtual Panel #2. Hosted by embodiedmathematics.com.
2021	(June; postponed from June 2020). EMIC Virtual Working Group at **PME-NA 42**. Theme: How Embodied Mathematics Can Bridge Cultural Divides. Topics included varieties of cultural and linguistic ways of expressing mathematical ideas.
2021	(October; postponed from June 2020). NSF-funded EMIC II Workshop.
2021	(October). EMIC Research Colloquium at **PME-NA 43**. Theme: Promoting Inclusive Mathematics Education Research and Practices. Topics included exploring varieties of physical inclusivity in different virtual stations and immersive technology.

Highlights: Funded Grant Proposals and Projects

1. Creation and maintenance of the website https://www.embodiedmathematics.com/. This is a portal for resources, events (including workshops and webinars), and announcements.

2. NSF EMIC I. A successful proposal to host a three-day NSF Synthesis and Design workshop, May 20-22, 2019, hosted by University of Wisconsin-Madison. The theme was "The Future of Embodied Design for Mathematical Imagination and Cognition" with 8 members serving as organizers. There were 50 attendees, comprised of international researchers, educational practitioners, and graduate students. All attendees presented. Keynotes from Dr. Brian Bottge and Dr. Maxine McKinney de Royston. This resulted in a white paper (Nathan et al., 2021) and an open access journal article (Abrahamson et al., 2020).
    a. Follow-up collaboration between a WG faculty member (Abrahamson) and workshop participant (Danny Luecke), a Secondary Math Education Developer/Instructor at Turtle Mountain Community College, North Dakota, to create pre-/in- service teacher courses, Ojibwe Math I, II, and III, as well as a course titled Math In Context.
3. NSF EMIC II. A successful proposal to host a second NSF three-day Workshop in 2020 (delayed to Sept. 25-26, 2021), hosted by Colorado State University. The theme was: "EMIC: Professional Development for Undergraduate Mathematics Instructors" with 7 member organizers. Keynotes from Dr. Nathalie Sinclair, Dr. Brooke Ernest, Dr. Francisco Ortega, & Dr. Molly Kelton.
4. Several grants awarded by IES CASL program to study embodied cognition, including: the role of action in pre-college proof performance in geometry (Funded 2016-2020 for Nathan & Walkington); the use of perceptual learning technology to study algebra learning (Ottmar & Landy, 2018), and use of augmented and virtual reality (AR/VR) to foster collaborative embodiment in immersive learning environments (Walkington & Nathan, 2020).

Products and Dissemination

1. Invitation by Springer to produce an edited book on our collective work on Embodied Mathematical Imagination and Cognition for the *Research in Mathematics Education* Series (Jinfa Cai, series editor).
2. Exhibit presented by Abrahamson and Rosenbaum at an NSF-funded WG meeting (EMIC I, Madison, WI) has led to a research project (Palatnik, WG faculty), a journal paper (Benally, Kimiko, Palatnik, Abrahamson, in press), and a Spencer proposal (item).
3. A joint symposium on Embodied Cognition with 6 members at the 2018 APA Technology, Mind & Society Conference (Harrison et al., 2018)
4. Publication of Nathan (2021), a textbook on embodied cognition for education.

Community Engagement/Broadening Participation

1. Expanding a group website using the Google Sites platform to connect scholars, support ongoing interactions throughout the year, and regularly adding additional resources/activities https://sites.google.com/site/emicpmena/home
2. Several members creating and teaching Embodied Cognition and Gesture seminars at their institutions.
3. Extending the embodied-design agenda into special education in dialogue with Universal Design for Learning (Abrahamson, Flood, Miele, & Siu, in press)
4. Some senior members joining junior members' grant proposals as Co-PIs and advisors.
5. Interest from Head of Education R&D (Dr. Ilona łowiecka-Tańska) of the largest STEM museum in Europe (the Copernicus Hall of Science in Warsaw, Poland) to incorporate

exhibits that had been developed for/at an NSF-funded WG meeting (EMIC I, Madison, WI) by Abrahamson and Rosenbaum.

6. EMIC Virtual Workshop #1, May 19, 2020. Theme: “Instructional Gestures for Classrooms and On-Line Mathematics Learning.” Designed for an audience of K-16 teachers, parents, and mathematics education researchers. Panelists: Dr. Mitchell J. Nathan, Dr. Martha Alibali, & Dr. Rebecca Boncoddo. Discussant: Dr. Hortensia Soto. Moderator: Dr. Caro Williams-Pierce. Hosted by embodiedmathematics.com.
7. EMIC Virtual Workshop #1, October 12, 2020. Theme: “Reading Group: The Future of Embodied Design for Mathematics Teaching and Learning.” Convener: Dr. Dor Abrahamson, with a panel of authors from the (Abrahamson et al., 2020) paper.

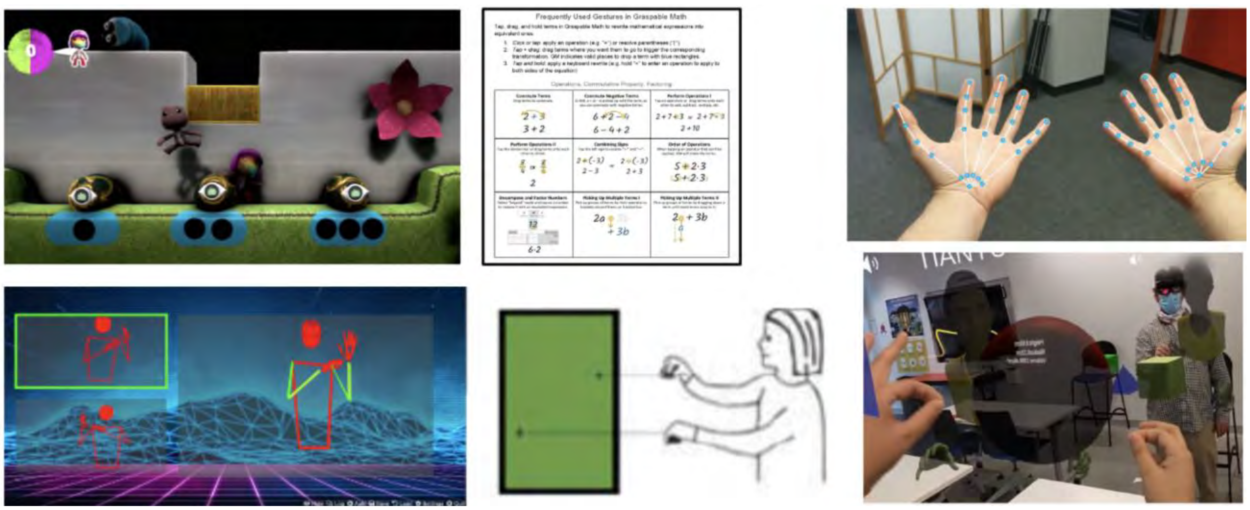

Figure 2: Embodied technologies designed by EMIC members that engage body based processes in support of mathematical reasoning. Clockwise from top left: The collaborative video game, Rolly’s Adventure; Graspable Math; hand joints and holographic math objects in the augmented reality/virtual reality (AR/VR) shAR Geometry environment; Mathematical Imagery Trainer for Proportion (MIT-P); The Hidden Village-Online.

Conclusions and Looking Ahead

Embodied accounts of reasoning, learning, and instruction are proving to be highly generative frameworks for understanding and cultivating mathematics learning and teaching, and for informing a new generation of designs for interactive technologies, curricula, and assessments. The true potential for these ideas and practices to lead to transformational mathematics education depends on a thriving, informed, interactive community of scholars and practitioners who engage with these approaches, evaluate their impacts, and improve theory and practice. Thus, we see predictably recurrent events such as the PME-NA working groups and research colloquia as a cornerstone for maintaining a highly educated and engaged core community. We will continue to offer outreach events and pursue external funding for specialized workshops when the resources are available. Future research colloquium topics that offer particular promise to the mathematics education community are: Broadening participation in mathematics and STEM through embodied design for learning, teaching, and assessment; the growing access to augmented and immersive technology, such as AR and VR, as a means to transform learners’ collaborative interactions with mathematical objects and phenomena

(Walkington et al., 2021); and the potential for multimodal learning analytics that use machine learning methods to integrate complex data streams that include channels of speech, gesture, eye gaze, facial expressions, mouse clicks, and so on, to support more sophisticated descriptions of learners' behaviors that can lead to real-time formative assessment and predictive models of educationally important student outcomes (Abrahamson et al., 2021; Closser, 2021).

Acknowledgments

We wish to acknowledge the scholars and educators who have been the backbone of these interactive working groups, workshops, and panels by providing the stimulating intellectual environment for these ideas to take root and blossom. We also wish to acknowledge the generous funding from NSF-DCL Grant #1824662 and NSF-DUE Grant #1835409.

The Embodied Mathematical Imagination and Cognition (EMIC) Research Colloquium offers hands-on individual and collaborative mathematics activities; technological, curricular, and pedagogical demonstrations; and open spaces for exploration and discussion regarding the embodied nature of mathematics education. At PME-NA 44 we will use the conference theme of "critical dissonance and resonant harmony" to invite the community to directly experience some of the many ways embodied perspectives challenge the status quo through expanded notions of mathematical activity and assessment, and to explore some current contributions, future potential, and challenges for more inclusive educational experiences for learners and teachers.

Keywords: Cognition; Learning Theory; Social Justice; Systemic Change; Technology

Theoretical Background

It is increasingly apparent that effective mathematics education systems need to address the embodied needs of learners by designing educational experiences that: 1) are grounded in people's natural propensities for movement, sensation, perception, and collaborative interactions with cultural and scientific tools; 2) support "multiple linguistic repertoires," (McKinney de Royston et al., 2020, p. 10) including verbal, nonverbal, and multimodal ways of knowing, communicating, and assessment; and 3) facilitate learners' participation in systems that support the distributed nature of knowledge and reasoning (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards et al., 2014; Radford 2009; Walkington et al., 2021). Evidence-based design principles are informing innovations in material-based curricula and digital technologies that support embodied mathematical imagination and cognition (EMIC) using platforms such as physical and video games, skits and virtual reality, craft making and tactile computing, motion capture, and participatory simulations (e.g., Abrahamson et al., 2020).

A Brief History and Motivation of the EMIC Working Group

The EMIC working group officially started in East Lansing, MI during PME-NA 2015. However, it emerged from a variety of earlier initiatives, including a 2007 AERA symposium, "Mathematics Learning and Embodied Cognition," a 6-year NSF-REESE grant (Nemirovsky et al., 2008), special issues of *Educational Studies in Mathematics* (2009), *The Journal of the Learning Sciences* (2012), and an NCTM 2013 research pre-session keynote panel, "Embodied cognition: What it means to know and do mathematics." A group of PME-NA members recognized a “critical mass” of investigators involved in related projects, and contributed findings and conceptual frameworks to form a stable and growing mathematics education research community to discuss, explore, and advance this scholarly program. We have convened annually at PME-NA ever since, organizing events that investigate the embodied nature of mathematics through physical and digital games, art and craft, individual and collaborative dance and movement, language, perception, immersive experiences, and more. EMIC members have continued to explore new technologies (e.g., Harrison et al., 2018; Walkington et al., 2021) and research methods (e.g., Abrahamson et al., 2021; Closser et al., 2021). They go beyond scholarly publications and presentations to offer: novel embodied technologies, including some that have gone to scale, for classroom use, special education, and emerging bilinguals; teacher learning programs for instructional uses of gestures; and webinars for teachers and parents. We are redesigning our website so it can continue to serve as a portal for resources, events (including workshops and webinars), teaching materials (e.g., syllabi), and announcements.

EMIC 2022: Critical Dissonance and Resonant Harmony

The organizers (including the authors; plus Dr. Janet Walkoe, U. MD and coordinator M. Nathan) have several years of experience co-designing and facilitating the PME-NA sessions. In 2022, we will organize hands-on activities and group discussions around the central questions that frame this year’s conference theme. On **Day 1**, we will use these prompts in small-group interactions to guide design activities with participants around (a) developmentally appropriate math topics (e.g., number, operations & algebra; geometry & measurement; probability & data analysis; functions & calculus; etc.); (b) research questions and designs for exploring embodiment of that topic; and (c) considerations of embodiment (vs. traditional) approaches to lesson design, instruction, and assessment. The first day will explore “How does this approach challenge a settled mathematics learning status quo?” As one example, an EMIC perspective might reframe high school geometry proofs from static two-column schemas to a deductive process grounded in movement- and object-based transformations. At least one organizer will join each small group. Day 1 will also include open-ended Q&A on the nature of embodiment theory, research methods, and design principles.

On **Day 2**, participant-groups (membership can be fluid) will explore “How does this approach help to create more socially just contexts for learning and teaching mathematics?” and “Whose voice does your work center in the mathematics learning process?” We will start this off by sharing findings and videos from the EMIC community demonstrating examples of support for emerging bilingual students and students with physical disabilities. An example is describing expansive forms of assessment practices that include ways students exhibit nonverbal (e.g., gesture-based) and distributed ways of knowing. **Day 3** reconfigures the small groups around common themes that arose in topic-specific groups on Days 1 & 2. We will invite these groups to reflect on who math education experiences are designed for, who is systematically marginalized, and what is gained in a truly inclusive approach. We then shift to a facilitated whole-group discussion, inviting members of each group to share ways an embodied framework can improve learning conditions for every mathematics learner, and benefit society more broadly.

Conclusions and Looking Ahead

Embodied approaches to design, instruction, and assessment show promise for fostering systemic change and harmony in mathematics education for amplifying inclusion of historically marginalized communities. There is much more to do to understand these impacts and realize their potential. An engaged community is vital for such transformative work to occur.

This Working Group was occasioned by a convergence of concerns over the widespread de facto acceptance of notions of objectivity in the field of mathematics education. Because the ideologies of the field continue to be based largely in elements of scientism, we propose that the mathematics education arena familiar to researchers must shift and take up the work of philosophy and critique for the field to remain relevant in current and future times. This scientism structures, for example, the common belief in the usefulness of mathematics and the subjectivity of the soft science research in which we engage (e.g., using inter-rater reliability). This working group provides participants the opportunity to engage in active learning experiences and critical discussions about the ways in which objectivity infiltrates aspects of our field, and to expose oneself to new viewpoints about the philosophy of mathematics education.

Keywords: Doctoral Education, Research Methods, Systemic Change.

Dialectically engaging with the idea of objectivity, the nature of knowledge in mathematics education, and the philosophy of mathematics education research is a task that is long overdue, particularly in the U.S. context. This Working Group captures this urgency whilst also capturing the anxiety of the present historical moment apropos politics, global health crises, and new ways of popularly understanding "facts." Indeed, engaging with this issue at this particular point in the history of our field is an ethical imperative, which many mathematics education researchers continue to disavow by focusing instead on the production of qualified labor power in students (see Baldino & Cabral, 2013, 2015) as the implicit, neoliberal goal of mathematics education.

This Working Group will examine various myths of objectivity in mathematics and mathematics education research, problematizing ideas that are taken for granted and often are glossed over. However, we first and foremost approach this Working Group with the guiding question, "Is our field prepared to ask and engage with these questions?" Myths are stories we tell ourselves and tell others, and as such, they have their own agency. A myth performs or creates an effect, such as trying to say that something is the "truth" of the world. In that sense, myths are "real," but they do not necessarily preclude alternative myths from existing or being mutually exclusive with other myths. Conventional notions of objectivity, however, seek to kill alternative myths, and as such, strive to delineate a clear line between what is objective and what is not. As a consequence, the act of leaving myths of objectivity unrecognized is an exercise in hegemony and the reproduction of dominant epistemologies—what are sometimes called "common sense." An example of the ways in which myths of objectivity infiltrate mathematics education research is the work of Piaget (1970), whose *Structuralism* can be read as a resolution of the (ostensible) duality of objectivity and subjectivity into pure objectivity, claiming that differences in psychological structures should be simultaneously considered infinite in variability yet deterministic in universality. Another example can be seen in "equity" research that does not, in fact, achieve its espoused goal of equity but rather results in a meritocratic fetish of mathematics success and failure that implicates the primacy of school credit system even within research that claims to dismantle it (Baldino & Cabral, 2013, 2015; Bullock, 2013; Gutiérrez, 2008; Martin, 2003; Moore & Johnson, under review; Pais, 2012; Straehler-Pohl & Pais, 2014). Another is the unquestioned understanding of dominant mathematics as necessary to be a "successful" member of society or as the only path towards solving present crises. In particular, even as there is more research that embraces students' subjectivities, the mathematics that is taught—one that emerges from a dominating culture—is still framed as universal while the overlooked historical and material interests driving it continue to reinforce oppressive practices and structures (Bullock, 2018; Fasheh, 2012; Gutiérrez, 2017). As Martin et al. (2010) ask, whose mathematics are we teaching? "For whom? and for what purposes" (p. 14)? We do not posit that objectivity is a false narrative, but rather we posit that objectivity is *a narrative* into which the field has largely fallen whilst simultaneously assigning it ultimate epistemic authority. To be clear, we do not wish to throw objectivity out of researchers' discourse, but we desire to shift participants' discourse towards a dialectical engagement with objectivity and subjectivity.

To the above ends, we organize this working group in a way that: (1) is welcoming to newcomers to the constituent perspectives surfaced while simultaneously digging deeply within and across in a manner that will push the thinking of veterans, (2) explicitly surfaces and honors a diversity of perspectives, (3) takes seriously the possibility of improving mathematics education practice in the face of the irreconcilable dialectic of objectivity and subjectivity that exists across the wholistic fabric of our work, and (4) honors and employs research-based and anti-hierarchical pedagogy. Thus, each day is comprised of a series of task- and inquiry-based explorations and discussions. Each task is designed and implemented by a different subset of contributors, rooted in our own humanity and experiences with/against uncritical notions of objectivity. We—the facilitators—are ourselves varied in terms of race, gender, sexuality, dis/ability, and career stage, as well as in terms of our particular areas of specialized expertise (including activism, art, media and critical discursive analysis, philosophy, and psychoanalysis), all of which contribute to a rich collection of tasks and discussions.

The sequence of discussions is designed to give attention to as many aspects of our practice as possible. On Day 1, our two key areas of focus are *Disciplinary Knowledge* (e.g., Mathematics) and *Research Design*. On Day 2, our two key areas of focus are *The Publication/Outreach Process* and *Final Products of Research*. We conclude on Day 3 with an *Overarching Conversation* reaching across these interrelated areas as well as time spent *Looking Ahead* to implications for our own work as well as to possibilities for subsequent working groups, collaborations, and articles. Tasks vary substantively across the Working Group, including time spent: doing/reflecting on mathematics, critically examining unstated or uninterrogated assumptions in research design, examining research products through etic frames such as art, and examining our work towards meaningful social/educational change through etic frames such as activism. Each task gives rise to open-ended opportunities for discussion within and across topics of, for example, unearthing values, questioning reality and existence, examining what we mean by "knowing," and surfacing tacit aspects of practice.

In this report, we describe the goals, organization, and outcomes of the Gender and Sexuality Working Group at the 2021 PME-NA annual meeting. We discuss the general organization and format of the group meetings and provide summaries of the papers, commentaries, and discussions that occurred. We then describe the ongoing projects and plans that have resulted from collaborations formed through the working group.

Progress Made at the 2021 PME-NA Conference

During the 2021 PME-NA conference, the Gender and Sexuality Working Group convened to discuss emerging conceptual and theoretical frameworks currently being utilized by scholars to explore topics related to gender and sexuality in mathematics education. The journal *Mathematics Education Research Journal* (MERJ) recently published a special issue on the topic of innovations within this area, and members of this working group contributed four of the seven articles published in this special issue. Authors of these four papers presented brief summaries of their work and another member of the working group provided a short commentary guided by the following two questions: (a) How does this article relate to your own work? (b) How do the theories and/or methodologies stimulate and/or “push” your own thinking? These presentations sparked lively discussions regarding the proposed conceptual and theoretical frameworks. This format allowed all members of the working group to become familiar with the emerging and developing perspectives, and to consider how these perspectives may inform their own research.

We begin with Hall’s overview of the MERJ special issue. Then, the remaining structure of this report follows the structure of the presentations as they occurred: *paper presentation* followed by a *commentary*.

Mathematics Education Research Journal Special Issue Overview

Jennifer Hall provided an overview of the recent Special Issue of the *Mathematics Education Research Journal*, entitled Innovations in ‘Gender Issues’ Research in Mathematics Education, which she co-edited with Eva Norén (Stockholm University). Jennifer and Eva were the Co-Convenors of the International Organization of Women and Mathematics Education (IOWME) from 2016 to 2021, and they aimed to lead a project that would have a meaningful impact on the field.

Recently, there has been a resurgence of interest in 'gender issues' research, with scholars pushing the field in various ways. Hence, the Special Issue was an outlet for such researchers to share their work. Papers with the following foci were sought: (a) Non-binary/non-homogenous conceptions of gender; (b) Feminist and/or queer theory frameworks; (c) Transgender, non-binary, and other gender minority participants, and (d) Gender-sensitive research designs.

The call for abstract submissions was made from September to November of 2019 on channels such as the IOWME Facebook group and the Mathematics Education Research Group of Australasia mailing list. In total, 14 abstracts were received from authors from nine countries, and seven abstracts from authors in two countries were accepted and developed into papers.

Each paper was reviewed by one of the co-editors of the Special Issue, an author of another article in the Special Issue, and an external reviewer, and went through the usual process for revision. The resulting papers comprised two short communications (up to 3,000 words) and five full-length articles (up to 9,000 words). The short communications were both position papers, whereas two of the full-length articles were theoretically-focused papers and three were empirically-focused papers. The published papers can be accessed at https://link.springer.com/journal/13394/volumes-and-issues/33-4.

Many authors drew on feminist, queer, and/or poststructural theories in their work. When empirical research was discussed, qualitative methodologies and methods, such as narrative inquiry, interviews, and observations, were commonly used and/or recommended. Overall, there was an acknowledgement by the authors and co-editors of the Special Issue of the complexity of gender as a construct and the ever-changing nature of 'gender issues' research. Recommendations were made to look to other fields for inspiration and for examples of innovative research, as well as to increase awareness and focus on intersectionality in 'gender issues' research. Furthermore, researchers—both those focused on gender and those for whom gender is just one 'variable' in their research—were cautioned to clearly operationalize the term *gender* in their work and to use consistent terminology. It is hoped that the Special Issue will serve as a valuable resource for researchers in the coming years.

Paper Presentation by Przybyla-Kuchek

In alignment with our goals as a working group to share emerging theories and methodologies in gender and sexuality in mathematics education, Przybyla-Kuchek (2021) suggested Baxter's (2003) Feminist Poststructural Discourse Analysis (FPDA) as a possible methodological approach to researching gender and its intersections with other social identities in mathematics classrooms. Although significant work on gender and sexuality in mathematics education takes identity into consideration, researchers commonly use methodological approaches that tend to focus on analysis of interviews with participants. Much has been learned from speaking to girls and women about their mathematical experiences, and this work continues to be important, but researchers should also consider how identities are experienced, enacted, or performed as they are being created. Researchers taking up poststructural theory and feminism together theorize gender as performative, and thus gives space to consider how identity is performed in and outside of classrooms.

Przybyla-Kuchek highlighted the transcript of a seventh-grade mathematics classroom interaction that appears in her MERJ article, shared the video clip of the interaction, and briefly summarized the gendered discourses that could be producing the interaction. The interaction is of a spontaneously formed small group of students. Two White male students attempted to "help" Georgia, a White female student, answer a question on a worksheet. Gendered and racialized discourses played out in the interaction as the complex subject position of "damsel in distress" was performed by two participants. One female student voluntarily took up a subject position in a more powerful way to distract one of the boys from "helping" Georgia. The boys' subject positions as "super smart" were consistent and solidified in the interaction. Although the interaction was complex and multiple discourses were working to position the participants in relation to mathematics, Przybyla-Kuchek identified the interaction as a moment of resistance, a speech event in which gendered discourses were disrupted and participants created new and powerful subject positions.

With such analyses, researchers can consider how powerful discourses (re)produce gendered subject positions for girls in mathematics classrooms. More importantly, using this approach, researchers and participants could identify the everyday, local ways in which powerful and even harmful discourses that produce girls as less capable in mathematics are disrupted. FPDA uncovers the significant work that participants are already doing to tear holes the fabric of discourses that constitute who can do mathematics and what it means to do mathematics. Furthermore, Przybyla-Kuchek considers how research is conducted and written to produce truths about girls and mathematics, and challenges mathematics educators to be self-reflexive across the entirety of the research process, including the writing and publication process.

Commentary by Piatek-Jimenez

Piatek-Jimenez' commentary surrounded the main themes that were discussed during a virtual meeting with Przybyla-Kuchek. In her paper, Przybyla-Kuchek (2021) discussed arguments by Walkerdine (1998) and Parks (2009) who suggested that the "gender gap" in mathematics is only as real as we have made it, through our designs of educational practices. In other words, it is not that the researchers are discovering an underlying truth, but that a "truth" is being created through the process. This idea resonated with arguments made by Piatek-Jimenez and Dias (2021), related to large-scale assessments, where the authors analyzed recent TIMSS, PISA, and NAEP data, and noted that whether one can claim a gender achievement gap exists depends on how one chooses to analyze the data and interpret the results. This point also related to the plenary address presented by Dr. Toya Frank during the first night of the PME-NA 2021 Conference, when she discussed conducting quantitative research. During her presentation, Dr. Frank noted "Numbers are not objective, but are socially constructed as well." Piatek-Jimenez argued that such a lens is important when conducting gender and sexuality research, as it is important to remember that the work that we do is affected by socially constructed perceptions and there is no "truth" that we are "discovering."

In addition to the lenses that are used while conducting research, the formats used to present the work influence how scholars in the field interact with and interpret the results. Przybyla-Kuchek (2021) discussed two innovative ways to present results, both of which disrupt the traditional structures used within mathematics education research. For example, Walshaw (2005) used a "split-text format," where the entire transcript of an interview and Walshaw's own writing and analysis were shown simultaneously on the page. Utilizing this format restructures the relationship between the author and the reader. It also allows the reader to conduct their own analysis of the text, removing "truth" from the analysis of the author. Such a format is not only unusual in our field, but Piatek-Jimenez argued that it is discouraged. For instance, Piatek-Jimenez recalled being told by a mentor that the entirety of transcripts should never be made public. As such, Walshaw's usage of split-text formatting is one way of interrupting common epistemological and research traditions.

Additionally, Przybyla-Kuchek (2021) interrupted such norms by sharing a portion of one transcript prior to sharing the gender and racial/ethnic background of the participants. Based on pseudonyms that the participants chose for themselves, one might make assumptions about the participants prior to learning their actual gender/racial/ethnic identities. By presenting the results using this format, Przybyla-Kuchek forced the reader to check their own assumptions and reread the interview transcript with alternate lenses. This method of presenting data provides the reader with a deeper understanding of the results of the study and how the reader's own biases may influence their interaction with the article itself.

Paper Presentation by Kersey

Kersey presented the methods from two studies reported in a single article in the MERJ special issue. In the article, Kersey and Voight (2021) focused on the experiences of queer and/or transgender postsecondary students in science, technology, engineering, and mathematics (STEM) fields. Based on the paucity of research within and outside of mathematics education on this population, Kersey & Voigt inferred that STEM fields may be less welcoming than the humanities and social sciences and investigated this possibility through their studies. In the first study, narrative inquiry was employed with postsecondary transgender students, whereas the second study employed a grounded theory narrative study with undergraduate queer students. The authors reported that transgender students who had transitioned indicated that they were subjected to lower expectations when presenting as female. Transgender women experienced this change as a net positive, since their treatment by others was no longer accompanied by gender dysphoria. Queer students experienced mathematics and other STEM fields as objective and independent of identity, yet simultaneously exclusionary of their queer identities. Many of the queer students in these studies found strength and resilience in queer communities, but there were some transgender women who did not view being queer as a central facet of their identity and did not feel the same sense of community. In general, participants who were more gender-nonconforming felt a greater need for community with other queer people. Kersey presented a tool used in their data collection that helped to draw connections between gender category oppression and gender transgression oppression.

Commentary by Jackson

Jackson commented on the article and presentation by remarking on three aspects: the use of queer theory, theory, and methods. Regarding queer theory, Jackson highlighted his appreciation for the way that queer theory was employed throughout the research project and article. For instance, in the methodology the authors "avoided placing boundaries around STEM, queer, or transgender." The researcher did not themself decide who was a STEM student. Jackson encouraged the working group to pause and to think about how, in our own research, what counts as in/outside of "math ed" and to what extent this is in conflict with some foundations of queer theory is defined by researchers. In the studies discussed in the article, the authors allowed the participants to identify with STEM, queer, transgender, or any other affiliation. There is a tension because this also brought forward some issues related to the construct of identity that the working group has been exploring and discussing. Throughout the article, the authors returned to the notion of identities and the way that identities are able to shift: Identities do not have to be stable, or have an interior expression. Jackson reflected on the notion that identity, in some regard, is about a claim to an affiliation; one can claim, but the claim isn't always "settled" as there is always the contingency that another person can accept/reject that affiliation. This brought forward the notion of *identity work*, for whom we perform identities, and/or how we mobilize our identities.

Methodologically, Jackson discussed the use of narrative inquiry and narrative analysis. Jackson highlighted the distinction between a narrat*ed* event and a narrat*ive* event. The analysis in the paper was focused on narrated events, those from the past. Whereas narrative events could also be analyzed to highlight the way that discourses are used in the telling of events itself. Jackson discussed how this distinction challenged him to think about methodologies that would tighten the time frame between the narrated event and the narrative event. Jackson noted that at times the participants' stories that were represented in the article seemed vague in the relationship to STEM contexts specifically, and that it seemed the participants themselves were analyzing/generalizing their own experiences. Jackson wondered about the insights that might be available through methods in which participants journaled immediately after each class to describe "unsettling" events or things that made them more or less comfortable.

Jackson also commented that participants in the study used word such as masculine and feminine. Jackson wondered what methods would help us to accurately capture what is perceived as masculine or feminine since these meanings change in space and time. Furthermore, Jackson discussed the language of privilege and oppression used in the paper and how careful researchers have to be to use such terms. Jackson highlighted how the authors noted that some participants may not have been comfortable in naming an experience, or their set of experiences as oppressive. Hence, researchers need to capture rich details of experiences.

Paper Presentation by Wiest

The purpose of this paper was to call for research on sexual identity in mathematics education, which is starkly absent (Dubbs, 2016; Fischer, 2013). Wiest discussed that the little research that has been done has shown differences in academic outcomes based on sexual orientation in spatial skills (Xu et al., 2020) and mathematics and science grades and course taking (Pearson & Wilkinson, 2017). Individuals in academic STEM (science, technology, engineering, and mathematics) pursuits tend to report uncomfortable and unsupportive environments that take a toll on psychological well-being, career satisfaction, productivity, and persistence (e.g., Barres et al., 2017; Institute of Physics, Royal Astronomical Society, and Royal Society of Chemistry, 2019; Mattheis et al., 2019; Stout & Wright, 2016). Wiest argued that targeted research is needed on mathematics education and sexual identity. Wiest suggested research questions might be formulated within these broader questions:

- What academic and social experiences and outcomes do lesbian, Gay, Bisexual, plus (LGB+) students have in general and in relation to individual and intersecting identities? How might these experiences and outcomes differ by age/grade level and academic setting? Which factors favorably and unfavorably influence student performance, dispositions, and success? How might these experiences and outcomes differ by specific fields and subfields of study, as well as by individuals' degree of disclosure of LGB+ identities, and why?
- What might "queer" curriculum and pedagogy look like? How might instruction be inclusive of LGB+ students and LGB+-headed families? How can the effectiveness of these instructional approaches and programs be evaluated?
- What are the workplace experiences and roles of LGB+ school staff, including teachers, administrators, and counsellors? What are the roles of non-LGB+ staff?
- How can education efforts best succeed within the broader sociopolitical climate, which can vary widely in relation to LGB+ acceptance? How might the field serve an advocacy role in that regard?

Commentary by Dias

Dias highlighted that the purpose of Wiest's (2021) paper is to call for research on sexual identity in mathematics education, summarize the existing research on sexual identity in STEM/mathematics education, and propose research questions that would advance the work in this area. Dias reflected on the absence of attention to sexual minorities in mathematics education research and calls for equity.

Dias related the paper and presentation to her own work by discussing the following points. First, Weist (2021) highlighted that sexual identity affects learning in the mathematics classrooms, as do many other aspects of students' subjectivities. These identities are important for educators, who are called upon to teach mathematics equitably to all students. Wiest wrote that teacher educators must prepare teachers with pedagogies that are inclusive of sexual minorities and humanize minoritized sexualities in their classrooms and in schools in general. Dias stated that this argument is consistent with her own arguments which has been criticized as being mathematics education without mathematics. Dias affirmed that her goal is that teachers are prepared to humanize LGB+ students, as well as students who don't conform to the gender binary, and learn how to work with parents of LGB+ students for the sake of the students' well-being, when families are not supportive of their sexual identities.

Second, Dias commented that Wiest uses LGB+ to indicate sexual orientations that include lesbian, gay, bisexual, and beyond (e.g., asexual, pansexual), essentially, all sexual orientations that are not strictly heterosexual.

Third, Dias reflected on the point in Wiest's paper regarding students' challenges and resilience. Although some students exhibit resilience in response to challenges, many LGB+ students are negatively affected by their experiences both in and out of school (e.g., by physical and verbal victimization, by exclusion from school curricular materials and classroom discussions) that can result in a number of self-harmful outcomes, including poorer psychological well-being and lower educational engagement, performance, and aspirations. Dias noted the important contribution of this paper to call for more research that can inform teaching practices and school policies to help protect and support sexual minorities.

Lastly, Dias noted the importance of disseminating research that shows that positive school support (and other factors such as openly gay teachers, gay-straight alliances, and participation in queer youth centers) are important for LGB+ students to feel comfortable in school. This idea encouraged a project that Dias is a part of in which spaces and moments for LGB+ student populations in campuses in the state of Sao Paulo, Brazil are being investigated. Weist mapped a variety of questions that can advance the field. We must call on journals and publishers to print this work. Dias stated that she will take the questions to her students and research group. In conclusion, Dias argued that Wiest's publication is very important in that it calls attention of the mathematics education community to the need of research in this area clearly, comprehensively, and in a nuanced manner.

Paper Presentation by Moore

In his presentation, Moore centered on the implications of sexuality for mathematics education researchers. Moore's motivation to write the paper was to synthesize a theoretical basis for queer research in mathematics education—as one did not seem to have existed before. These implications can be summarized in three points:

First, theory is important. Theory in our field is too often seen as a methodological tool, a setting that we must choose to best fit the situation and our insights. In this way, theory becomes a slave to context. The trouble with this approach is that if the contextual basis that we consider mathematics education to be is always the same, then the theoretical impositions we make as researchers will always turn out in the same ways.

Second, we must make our thinking, understandings and discourses about queerness in mathematics education as complicated as possible. This recommendation is not meant to be obtuse. It is rather to see that queerness is not only about identity and subjective positions but is rather about our research and the ways in which we go about doing it. The queer project rejects a suspiciously understandable approach to recognizing our subjects. Our recognitions of each other are always-already failed recognitions. So then why would we be so naïve as to think that the goal of research is to be as organized and scientific as possible? On the contrary, the goal is to make research as complicated as possible. Only then might we approximate the inherent failures that we have committed in attempting to recognize anything in our data.

Third, we must take seriously the ways in which mathematics implicates and is implicated by gender and sexuality. Mathematics education cannot escape the anxieties, the identifications, the questions, and the desires that are produced by sexuality, and therefore also by gender as a sexual construct. Taking up the task of queer research in mathematics education means recognizing our enterprise as one of radical subjectivity.

A queer understanding of our field leads us to understand the critical importance that Moore calls for in the paper: if we are to ask questions about identity, subjectivity, gender, and sexuality, then the queer project in mathematics education is precisely the project of making life livable—even for the heterosexual and cisgender. The queer project is expansive in this way, just as the Queer Identity Intersection (a diagram that Moore introduced in the paper) gives possibilities for emergent, reconstructive centers that do not exist now. To briefly recapitulate: If we are engaged in "gender and sexuality" research, then we must queer what we think about those terms, and see that in order to engage in such research means to be as complicated as possible, imaginative and philosophical with our approach to theory, creating new understandings that are not extensions of existing "classic" knowledge that we have inherited over the last 50 years, and seeing ourselves as engaged in a process of humanizing not only the research that we perform, but also the field of mathematics education, and the mathematics itself.

Commentary by Pinheiro

Moore's (2021) review of theoretical literature provides lenses to understand the ways that research frameworks can contribute to our understanding of the intersection between mathematical and queer identities. In his article, Moore reviewed the theoretical framework of 28 articles in which queer identities in mathematics education were discussed. Through the literature review, Moore proposed the framework, The Queer Identity Intersection (QII) of Mathematics Education. Such a framework is composed of two roads in which one can get situated and analyze through perspectives where you are in the roads and what you need to get to the intersection. Moore's intentions with the QII framework were to provide researchers with an analytical tool that provides inciteful ideas for researchers' conceptualizations of what they need to have a strong theoretical framework that can analyze queer students mathematical and queer identities at the intersections. For Moore, queer identities and mathematical identities are situated in the borderlands, a place that he suggests is uncomfortable because of the multitude of realities (e.g., queer identity reality and mathematical identity reality). Moore argues that both queer and mathematical identities, when enacted, contribute to the conceptualization of the learning processes of one's understanding of becoming part of a community of practice. Therefore, one's mathematical identity is constantly affected by one's queer identity, which influences students' experiences with learning and knowing mathematics, and being part of the community of practice that encompasses mathematics. Keeping in mind that queer identities are marginalized in schools, and that mathematical identities can be marginalizing forces that limit who is capable of learning and doing mathematics (Reinholz & Shah, 2018), Moore concludes that "to fully understand notion of queer identity in mathematics education, [he] suggests [the] intersection of queer identity and mathematical identity" (p. 18), since in the intersection, we are trying to understand the experience of the individual itself, not looking specifically at one or the other identity, but at the "element of identity that […] becomes the unit of analysis" (p. 18). Moore implicitly suggests that mathematics for social justice lessons must be implemented by considering students' experiences in the mathematics classroom, considering the intersection between students' queer identities and mathematical identities.

After pointing to these important highlights, Pinheiro discussed how Moore's (2021) article relates and contributes to his own research. Pinheiro also uses intersectionality theory to explore the ways that gender, sexuality, and mathematics play a role in queer high school students' experiences with the teaching of mathematics for social justice. Pinheiro stated that the major push of Moore's article to his understanding of issues of gender and sexuality intersected with mathematics comes from Moore's idea that mathematical identity is also a social identity. Therefore, intersectionality, as a theory of social identities, applies directly to our understanding of how at the intersections, one's experience in the mathematics classroom is defined and shaped specifically by the individual's sexual, gender, and mathematical identities.

Ongoing Projects

After the conference concluded, the authors created a WhatsApp group with the intent of having an efficient channel for continuing our conversations. Everyone whose contact information was on the sign-up sheet created during the conference was given a choice to join the group. In the WhatsApp group we have identified common research interests and concrete projects upon which we are establishing new collaborations. As a result of this newly formed social media group, three members of the Working Group (Pinheiro, Dias and Moore) are planning to analyze data collected by Pinheiro on women's experiences in an undergraduate mathematics program. Two other members of the group (Piatek-Jimenez and Hall) are also working on a research collaboration and are currently preparing a Spencer Foundation grant application to fund their work.

Future Directions

The working group participants during the 2021 PME-NA expressed a desire to explore applications of these emerging theoretical and methodological perspectives. Particularly, there was interest in the application of different theories to data analysis, and what that application of methods might reveal and how it might impact students, teachers, and classrooms. To move forward in the 2022 PME-NA, we plan to share interview and classroom data with participants, and as a group we will analyze the data through various theoretical and methodological perspectives as a way to consider what researchers might conclude from the data using different theoretical approaches. Our hope is that the discussions will make space for participants to compare what different methods with various theoretical lenses are able to capture or limit in their own research in gender and sexuality in mathematics education.

Gender research in mathematics education continues to be important work for gender equity in mathematics, as well as in STEM fields more broadly. Additionally, authors recently called for research on sexuality, identified a dearth of research in this area, and a need to theorize and operationalize such research (Dubbs, 2016; Moore, 2021; Wiest, 2021). Building upon working group discussions of emerging theories and methodologies during PME-NA 2021, in the 2022 working group sessions, we will apply these theories and methods to interview and classroom data to explore concrete ways of studying gender and sexuality in mathematics education that utilize different perspectives. Our goals are to (a) explore how gender and sexuality may be "seen" through different methods of data collection, focusing on how different meanings of gender and sexuality, as they are described and performed, may lead to new insights; and (b) produce a list of research questions and potential projects to consider for future research.

Keywords: Gender; Equity, Inclusion, and Diversity; LGBTQIA+

Throughout the progression of gender research from achievement and participation to broader systemic, cultural, and societal barriers, researchers have identified a plethora of barriers for girls and women in mathematics (Leyva, 2017; Lubienski & Ganley, 2017). They have also demonstrated the importance of mathematics education research to gender equity in mathematics, as well as in STEM more broadly. Despite a lull of gender research, in the past 5 years there has been renewed interest in gender research with the emergence of new research paradigms (e.g., queer theory and postmodernism), and the consideration of intersectionality (Leyva, 2017; Lubienski & Ganley, 2017; Lubienski & Ataide Pinheiro, 2020; Stinson & Walshaw, 2017). For example, one important shift has been for researchers to move beyond male/female, men/women, and boys/girls binaries in terminology usage and throughout gender research methodology. Additionally, authors have recently called for research on sexuality in mathematics education, identified a shortage of research in this area and argued a need to theorize and operationalize such research (Dubbs, 2016; Moore, 2021; Wiest, 2021). For example, one area of continued interest is expanding notions of identity. Building upon the decades of gender research and expanding sexuality research in mathematics education, our working group continues to explore new approaches to gender and sexuality studies and identify paths for progress towards gender equity in the many ways it can be defined.

History and Goals

The Gender and Sexuality Working Group has convened for the past 4 years. In the past two conferences, we focused largely on establishing shared theoretical backgrounds, conceptualizing identity, and exploring methods for engaging in gender and sexuality research. During the PME-NA 2021 working group sessions, we explored emerging theories and methodologies through presentations and commentaries on articles in the Special Issue of *Mathematics Education*

Research Journal titled: Innovations in 'Gender Issues' Research in Mathematics Education. Authors of four of the seven articles in the issue presented brief overviews of their ideas, highlighting new insights on gender and sexuality theories, methods, and trends. Emerging theories discussed included queer theory and feminist poststructural theory. Furthermore, as an editor of the issue and working group member, Hall provided insights on gender and sexuality research internationally, reflecting on Special Issue submissions.

The working group participants during the PME-NA 2021 sessions expressed a desire to explore applications of these emerging theoretical and methodological perspectives. Particularly, there was interest in applying different theories to data analysis, what that application of methods might reveal, and how such research might impact students, teachers, and classrooms. To move forward, at PME-NA 2022, we plan to share interview and classroom data with participants. As a group, we will analyze data through various theoretical and methodological perspectives as a way to consider what researchers might conclude about gender and sexuality from the data. We expect to use these discussions to make space for participants to better understand how taking up different methods with various theoretical lenses can capture or limit their own research in gender and sexuality in mathematics education. Hence, our goals are to (a) explore how gender and sexuality may be "seen" through different methods of data collection, focusing on how different meanings of gender and sexuality, as they are described and performed, may lead to new insights; and (b) produce a list of research questions and potential projects to consider in our own future research.

Working Group Structure

Broadly, the working group structure will progress from jointly analyzing post-secondary interview data to analyzing K–12 classroom data. The sessions will culminate in group discussions about how participants operationalize gender and sexuality based on the types of data we collect and which theoretical perspectives we bring to the data.

Session 1

In the first session, participants will analyze a more familiar form of data for researchers studying gender and sexuality in mathematics education: interviews. The organizers will share several transcripts and audio/video from individual and focus group interviews with post-secondary participants. The interviews focused on participants mathematical experiences and were collected as part of ongoing projects conducted by members of the working group.

Session 2

Building from discussions about the analysis of interview data from the first day, the organizers will share whole-class and small-group video data from K–12 mathematics classrooms. Participants will discuss, as a group, what they noticed relating to gender and sexuality in the data and generate research questions to pose to the group. There will be a focus on what meanings gender and sexuality take and how gender and sexuality are understood in analyzing the data, considering small-group and whole-class settings.

Session 3

On the last day of the working group, participants will reflect on the analysis done in the two previous sessions. Discussions will focus on how we might approach data from various perspectives including how interview data (i.e., how a participant discusses their experiences) highlights or even requires different theoretical orientations or understanding of gender and sexuality compared to classroom data (i.e., performances of gender and sexuality in the moment). Participants will identify potential new research questions to pose to the field of mathematics education and potential projects that could seek to answer such research questions.

AESTHETIC AND AFFECTIVE DIMENSIONS OF MATHEMATICS LEARNING

V. Rani Satyam

meghan.riling@vanderbilt.edu

Students' aesthetic and affective responses are interrelated and both central to mathematics learning. This new working group will bring together researchers as a community to explore the connection between affect and aesthetic, and how this connection can help to understand how students experience mathematics. The goals of this working group are to evaluate the state of the field, build shared terms, and identify research questions for further inquiry.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Curriculum; Instructional Activities and Practices

Theoretical Background

The role of affect in mathematical experiences and learning has become abundantly clear over time (e.g., Cheeseman & Mornane, 2014; DeBellis & Goldin, 2006; Malmivuori, 2001). *Affect* has been defined as all aspects of experience that involve feeling (McLeod, 1988); this ranges from deeply held, long duration constructs such as beliefs, attitudes, math anxiety, and motivation, to shorter-term and in-the-moment feelings such as emotions and engagement (Grootenboer & Marshman, 2016; McLeod, 1992; Middleton et al., 2017). In math, where success versus failure is starkly visible, students' affective responses can be quite strong (Boaler, 2015) and impactful (Grootenboer & Marshman, 2016; Op 't Eynde et al., 2006).

Yet, similar to how we would also examine a piece of art for explanations for an individual's gasp in a museum, we argue that researchers also need to attend to the nature of the mathematical experience for explanations for how it potentially impacted its students (e.g., inspiring a question). We refer to the way a lesson supports the felt impulses that compel (or impede) a student to continue to progress (or not) through an experience as its *aesthetic dimensions* (Dietiker, 2015). Some researchers have recently begun to study the aesthetic potential of mathematical learning environments (e.g., Dietiker, 2016; Sinclair, 2001), learning for example how the design of technological tools can offer surprise and appeal (Sinclair et al., 2009). While still emerging, the field is learning how to design and enact what Sinclair (2001) calls "aesthetically-rich" mathematical experiences, which she describes as those that "enable children to wonder, to notice, to imagine alternatives, to appreciate contingencies and to experience pleasure and pride" (p. 26).

This working group will explore the linkage between affect and aesthetic to tackle multiple dimensions of one of the most significant dilemmas facing mathematics classroom practice today: poor student experiences with mathematics that fuel negative student dispositions. Through our working group design, we plan to bring together graduate students, early career and senior faculty together, to solidify the current state of the field and help form informal and formal connections for future research endeavors.

Working Group Goals and Strategies

The goals of this working group are threefold: (a) we seek to bring together researchers in order to evaluate the state of the field in regards to aesthetic and affective issues, (b) we aim to build community, through structured but also informal conversation and sharing each other's work, and (c) we will build shared terms (given the various constructs for similar ideas) and articulate common research questions, to push for inquiry in these areas.

This is a new working group to address the continued need for focus on students' mathematical dispositions, and the potential enabled by identifying the shared interests in aesthetics and affect. Our aim is to enable new solutions to a persistent problem that can become possible by bringing together these two domains. We plan to continue this working group next year, expanding our focus to useful tools and methodologies.

Session Organization

Prior to the conference, we will survey our participants to gather information on their research interests specific to aesthetics and affect, student age group (elementary, secondary, postsecondary), and whether they are already doing work in this area or interested in it as a new topic. We will welcome participants to bring an artifact they would like to work on with the group for feedback, e.g., a task they wish to refine, to improve the aesthetic or affective response.

Day 1: We will start by having participants introduce themselves and share their research interests (15 min). We will give two short interactive presentations, one on aesthetics and one on affect, with whole-group discussion on the linkages for 60 minutes. We'll end with an overview of the goals of this working group and will ask participants to bring an item they are working on or would like to work on, to share for the next session (15 min).

Day 2: We will form mixed subgroups based on the research foci shared on Day 1. These groups will analyze artifacts shared by participants to answer the question: *How do these two perspectives (affect and aesthetic) inform what we know about this artifact?* (45 min) Within each subgroup, we allot 45 minutes for participants to share an item they've been working on or their research interests and goals. To enable participants to meet each other, learn each other's interests, bond informally, we will then have a jigsaw (reforming new groups) to share what was learned by considering multiple perspectives. An underlying goal is for participants to notice the common ideas across researchers, via differently named constructs.

Day 3: Having shared our interests in the previous session, this day will focus on forming directions for the future. For the first 30 min, we will again form subgroups where participants brainstorm important research questions and potential future directions for this collective group. Each group will type into a shared Google Doc, for easy sharing with the whole group (40 min). We will maintain a Google Drive folder, where the Google Docs will be kept as a record after the conference. There will also be a folder for participants to share their published work with the group to facilitate spread of ideas–especially from new scholars. We will provide space for participants to list their names and contact information next to any research questions/directions they'd like to pursue. In the last 20 minutes, we will present our plans for the future of the working group, to focus on tools, instruments, methodologies, etc. helpful for studying the affective and aesthetic dimensions of mathematical learning.

This working group, which is a continuation of a regular working group space dedicated to goals of equity at PME-NA since 2009, invites scholars actively engaged in antiracist research and teaching practices to come together to strategize around how to respond to choques and dissonance to work towards harmony. This year, the aim is to dismantle or deconstruct instances of dissonance and harmony that have emerged from a choque, or a confrontation within our field.

Keywords: Systemic Change, Equity, Inclusion, and Diversity

> Choques represent both moments of contestation and creative production. (Torre & Ayala, 2009, p. 390)

Our work in this session aims to provide a space for discussing a choque, an instance when we crash into something in our field and have to find new ways to think, act, and be. Choques could include revisions on a paper, moments in the classroom, interactions within a department or with colleagues, hitting a research wall, or recent events affecting your work because of the pandemic. We are also opening up a space for sharing moments of joy, especially those arising after a choque; those moments that help you find equilibrium.

This working group is designed as a space for any who attend to engage in reciprocal practices and relationship building. There is an explicit expectation that all those who attend this working group will come prepared to share artifacts of their current efforts and also learn from and through the efforts of other attendees. To be explicit, the outcome is not to produce a product but to make the space for the building of relationships, strategic knowledge, and awareness of those looking to sustain this work. Moving from dissonance to harmony requires collectivity and relationality--you cannot form a harmony with only one voice. As such, relationships are central to the formation and sustainability of research collectives engaging in antiracist research and teaching that seeks to make systemic change.

Within a context that includes the never-ending COVID-19 pandemic, our ability to plan and to go about things as usual seems more and more absurd. Yet, we also watched society quietly step back from the reckonings of Spring 2020 in the face of an ongoing white backlash (Gomez et al., 2022; Anderson, 2016). In other words, in the face of growing recognition that we cannot go on in this way, rather than leading to harmony, some *choques* lead us right back to a status quo of dissonance. This reflects the need for us to embrace *choques*, to challenge ourselves to push through dissonance and discomfort with intention, commitment, and actions towards something new.

History of the Working Group

Originally created as a space to bring attention to issues of equity and diversity to mathematics teaching and learning (Foote et al., 2009), this working group has evolved as the field of mathematics education has changed over the past 13 years. Part of the evolution, as well as the continued need to hold a space at yearly PME-NA conferences, is evident in the shared leadership of this group since its initial meeting in Atlanta in 2009. After one year of interruption in 2020, the work of building space to discuss making change and working towards justice in mathematics education was renewed at PME-NA 43. Presently, the scholars involved in this group have emphasized a focus on bringing together PME-NA attendees committed to antiracism.

Organization of the Working Group

The organization of the working group embraces *choques* through pivots between harmony and dissonance. Each session will build on each other with the following format:

- Session 1-Artifact Unpacking: The goal of this session is to share and learn from artifacts of *choques*, either those resulting in present dissonance, or those that eventually led to a sense of harmony. Participants are expected to bring an artifact (e.g., an example of a *choque* that they either are or have been working through). Through structured collaboration, participants will share the artifact, describing the *choque* and where it has led them. In this session, we hope to help participants work towards initiating their goal (i.e., write an article addressing an equity issue, build a collaborative mentorship team to address social justice issues; discuss an article to gain and share knowledge) Finally, questions of interest will be collected, organized, and posted for use during the following sessions of the working group.
- Session 2-Interconnectedness & Common Ground: Using participant-generated goals emerging from their artifacts, participants will be organized into small groups to engage, share knowledge and practices, and imagine new possibilities. Small groups will engage in structured activities to help synthesize thinking around their artifacts towards productive collaborations and plans of action.
- Session 3-Encouragement & Action: The final day of the working group will be a space for working group participants to continue the work of session two and more open-ended conversation and dialog on areas of interest. Participants will be encouraged to talk about next steps, with the emphasis being this is only the start of the conversation, but the connections made extend beyond the limits of any conference and organization

REPORT ON: This working group is a consistent space for equipping, informing, and challenging mathematics education researchers to "frame equity as a continually evolving process of growth". Since its inception this working group has continued to productively orient, inspire, and organize mathematics education researchers to move toward outcomes in our field that prioritize anti-racist mathematics education as a mechanism for change. The challenge of this working group remains one of moving from collective reflections around issues of equity and diversity in mathematics education to actions that become catalysts for change. We acknowledge that this year's call for "productive struggle" is necessary, however it needs people and community to support such efforts.

Keywords: Equity, Inclusion, and Diversity, & Social Justice

"Healing is a process that we navigate for a lifetime." (Ginwright, 2018, p. 6)

This working group is a consistent space for equipping, informing, and challenging mathematics education researchers to "frame equity as a continually evolving process of growth". Since its inception, this working group has continued to productively orient, inspire, and organize mathematics education researchers to move toward outcomes in our field that prioritize anti-racist mathematics education as a mechanism for change. The challenge of this working group remains one of moving from collective reflections around issues of equity and diversity in mathematics education to actions that become catalysts for change. The challenge of equity work is that it is contextual and complex. More so, the solutions are rarely simple and require sustained commitment to collective action.

The Equity Working group seeks to push back on traditional views of measuring equity. Insofar to say that no one outcome can ever lead to equity. We are not defined by the products we create but instead we create change by being in community with each other. Equity becomes a reality for all through collective action. The Equity Working Groups is needed each year because each year the participants are different and the issues of inequity present in both mathematics education and in the greater North American context is always in flux. As the opening quote to this report states "healing is a process that we navigate for a lifetime" (Ginwright, 2018, p. 6) and this working groups is one way we can consistently navigate challenging and changing inequities in the field. This report will restate a brief history of the working group followed by an overview of the previous three years. Additionally, will point to the future of the Equity Working Group.

A History of the PMENA Equity Working Group

This Working Group originates from the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME scholars graduated from one of three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA) that comprised the DiME Center. The Center was dedicated to creating a community of scholars poised to address critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).The DiME Group (as well as subsets of that group) has engaged in important scholarly activities, including the publication of a chapter in the *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007), a one-day AERA Professional Development session examining equity and diversity issues in mathematics education (2008), a book on research of professional development that attends to both equity and mathematics issues with chapters by many DiME members and other scholars (Foote, 2010), and a book on teaching mathematics for social justice (Wager & Stinson, 2012) that also included contributions from several DiME members. In addition, several DiME members have published manuscripts in a myriad of leading mathematics education journals on equity in mathematics education. This working group provides a space for continued collaboration among DiME members and other colleagues interested in addressing the critical problems facing mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Over time, the Working Group has encouraged building on and featuring senior scholars' work, including Jo Boaler (Boaler, 2002), Walter Secada (Secada, 1992), Marta Civil (Civil, 2007; Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Eric Gutstein (Gutstein, 2003, 2006; Gutstein & Peterson, 2013), Jacqueline Leonard (Leonard, 2007; Leonard & Martin, 2013), Danny Martin (Martin, 2000, 2009, 2013), Judit Moschkovitch (Moschkovich, 2002), Rochelle Gutiérrez (2002, 2003, 2008, 2012, 2013) and Na'ilah Nasir (Nasir, 2002, 2011, 2013; Nasir, Hand & Taylor, 2008; Nasir & Shah, 2011). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), Megan Franke (Kazemi & Franke, 2004), and Anita Wager, (Wager & Stinson, 2012) as well as many others outside of the field of mathematics education.

PMENA 2019: Heal, Connect, Advance

During the 2019 PMENA working group we began by sharing three words; Heal, Connect, and Advance. These three words became the underpinnings of our activities. During the first session we asked participates to brainstorm what additional words are missing from the three we shared. We then had participants discuss the following question:

> What are some examples, movements, policies, or directions that have occurred in mathematics education that some may have intended as expansion, displacement, or growth that have actually served to privilege some and marginalize others?

Both questions were used to pull generative themes from those attending the working group. Generative themes were used the second day to help groups identify the root cause(s) of the themes they identified. The activity allowed participants to co-construct knowledge together making it easier for them to connect with each other and provide outlets to advance their work related to equity. Figure 1 provides two examples of work done during the conference.

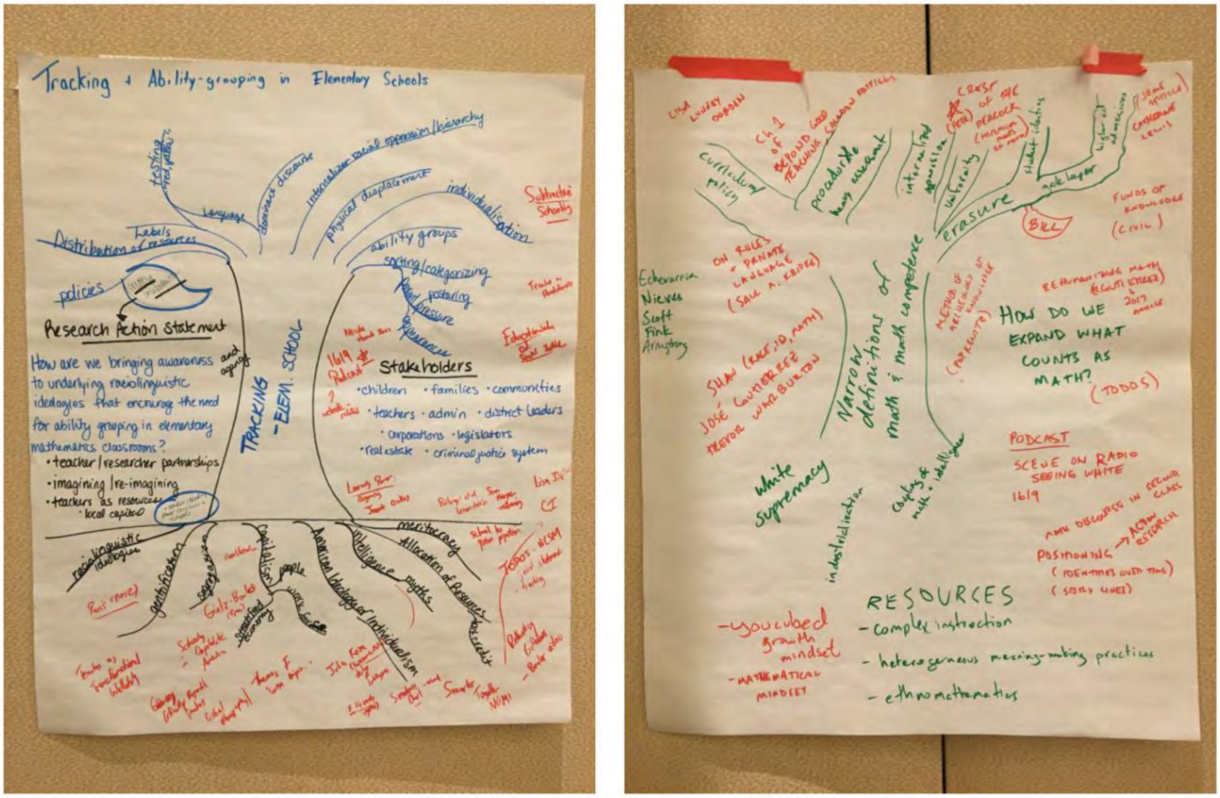

Figure 1: PMENA 2019 Problem Trees]

PMENA 2021: Joy as a Form of Resistance

Building on the work of PMENA 2019, we wanted to continue to advance an ecology of healing by centering Joy as a catalyst for action. We began the first day by asking participants to share what brings them joy because as Desmond Tutu and the Dalai Lama explain in The Book of Joy, “being joyful is not just about having more fun. We’re talking about a more empathetic, more empowered, even more spiritual state of mind that is totally engaged with the world” (2016, p. 63). For those engaged in challenging inequities in academia, moments of resistance are examples of experienced joy. On the second day of the working group, we focused on how the theories we use in mathematics education can and should align to what we value. Multiple theories, traditionally not seen in mathematics education were shared with participants as they were left with these questions:

- What might that have to do with our work as researchers?
- What does it mean for us as researchers to respect ourselves and recognize our power, as well as respect those who choose to work with us?
- What does giving AND receiving mean in our roles and in our work? Who gets to determine that?
- Our research is historically situated, as are we--what work are we continuing? Whose work are we continuing? Why? To what end?
- If resilience is collective, shared between us and others, what does that look like when we are acting as researchers? When we are working with teachers and pre-service teachers?

PMENA 202X: A Sustained Movement

Build on the previous year it is evident that the equity working group (and all working groups) should embrace a virtual component. We seek to continue to provide both a virtual and physical space for people to engage in cognitive dissonance around understanding equity in mathematics education. Harmony begins when multiple voices come together to challenged and ultimately change issues of inequity. The Equity Working Groups seeks to sustain itself by continuing the working done at PMENA, for PMENA members.

This is a report on the working group aimed at providing a structure for Mathematics Teacher Educators (MTEs) to engage in Continuous Improvement Lesson Study (CILS), a process of MTE professional development that involves working collaboratively to design a lesson, improve preservice teacher (PST) learning, and MTE practice.

Background

The CILS process integrates lesson study (Lewis & Hurd, 2011) and the Continuous Improvement process (Berk & Hiebert, 2009). Lesson study is a collaborative process of investigating instruction with the goal of improving student learning through a single lesson. This teacher-driven professional development focuses on analyzing student learning and leads to enhanced instructor knowledge (e.g. Watanabe, 2004; Demir et al., 2013). Hiebert and colleagues at the University of Delaware developed a model "continuous improvement" for MTEs to reflect through a process of "planning, enactment, analysis, and revision" (Berk & Hiebert, 2009, p. 339). We have integrated these two methods of researching and improving instruction and student outcomes, lesson study and continuous improvement to inform an integrated process that we call Continuous Improvement Lesson Study (CILS) and is shown in Figure 1.

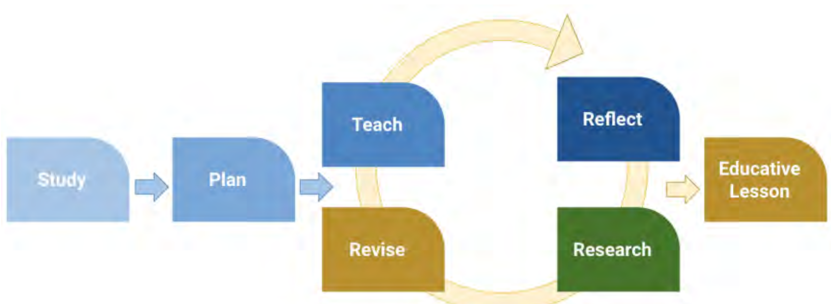

Figure 1: The Continuous Improvement Lesson Study (CILS) Process

Working Group Summary

We began the working group by discussing the CILS along with how we as MTEs improved our own practice while engaging in the process. Because CILS serves as professional development for MTEs, we had participants complete a Jamboard noting challenges they face in teaching preservice teachers (Figure 2) and used the responses when discussing the CILS process to illustrate how CILS helped us address these challenges in our own classroom.

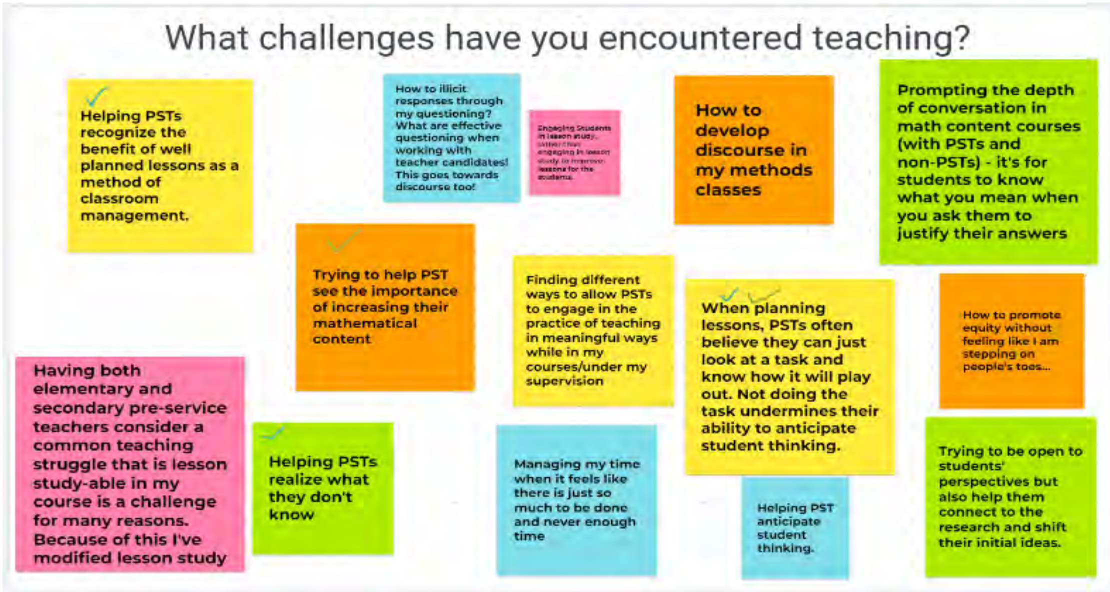

Figure 2: Brainstorming from Participants on the first day of the Working group

The expressed goal of the working group was to have mathematics teacher educators form CILS teams to study a research-based lesson MTEs taught to preservice teachers within their methods or content courses. While the participants were interested in our work and asked insightful questions about the process, it quickly became evident that most of the participants who attended the working group were interested in having their preservice teachers (PSTs) act as teachers while engaging with a lesson study with children and not in using CILS as a means to support their own professional development.

Because of the diverse interests related to lesson study, we invited the working group participants to share how their work intersects with lesson study more broadly. We had good conversations about lesson study, the various ways lesson study has been adapted in higher education, and let the participants know our goal was still to work on CILS in preservice teacher coursework. For the second day, only one participant interested in working with CILS returned to the working group. Our team had conversations with the participant about their work but did not form a CILS team with the participant since the participant was not attending the third day of the conference.

Challenges

Due to the Covid-19 pandemic, our working group members chose to present virtually but with the option of having conference participants join virtually or participate in person while at the conference. We believe that presenting online was one of the main reasons for the limited participation within the working group. When people walked by the working group room, there were no presenters standing at the front or outside the room to share more about the aims of the session and we were not physically at the conference which greatly decreased networking we had hoped to do to share more about our working group. Thus unfortunately, we were unable to achieve the set goals of the working group.

New Modifications Proposed

We propose two modifications moving forward for a refocused working group proposal for PME-NA 44 in Nashville, 1) partner with other researchers who engage in lesson study and 2) broaden the theme of the working group to be around lesson study adaptations, including those that support equity. New collaborators that have expressed interest in the newly adapted working group include Dr. Catherine Lewis, Professor at Mills College and President of the World Association of Lesson Study (WALS), and a leading U.S. expert in lesson study; Dr. Susie Hakansson, Mathematics Education Consultant and member of The California Action Network for Mathematics Excellence and Equity (CANMEE), and other members of the CANMEE network. CANMEE uses lesson study to improve mathematics learning, instruction, and the lesson study process with an equity lens.

The adaptations are meant to address the wide variety of lesson study participants from different levels, such as PSTs and in-service teachers conducting lesson study with children, to mathematics teacher educators engaging in lesson study with other higher education faculty members as a form of professional development (Appelgate et al., 2020; Soto et al., 2019). Some specific adaptations specific to equity that will be discussed include the addition of an equity commentator role in lesson study as well as selecting focal students to monitor and assess student learning, teaching mathematics through problem-solving, and developing and revising lessons focused on teaching mathematics for social justice and analyzing student and teacher learning.

This working group is a follow-up initiative that will allow the mathematics education community to engage with adaptations of lesson study designed to address equity in the mathematics classroom. This year we will examine four adaptations (Teaching Through Problem-solving, Focal Students and Equity Commentator from the California Action Network for Mathematics Excellence and Equity (CANMEE), Rights of the Learner, and Continuous Improvement Lesson Study (CILS)), identifying impacts on equitable teaching practices (i.e, practices that involve all students in cognitively demanding mathematics). Participants will view a video-recorded research lesson that grounds the discussion of the adaptations. The group aims to publish an edited volume on equity-focused lesson study, with a broader goal of supporting participants to develop lesson study that integrates equity across different contexts (e.g. K-12 teachers, preservice teachers, graduate students, and mathematics teacher educators).

Keywords: Equity, Inclusion, and Diversity, Teacher Educators, Professional Development

Lesson Study

Lesson study (LS) is a collaborative process of investigating instruction that serves as a teacher-driven professional development that focuses on analyzing student learning and leads to enhanced instructor knowledge (Watanabe, 2018). LS traditionally consists of four phases: 1) study the curriculum and formulate goals, 2) plan the lesson, 3) teach the researched lesson, and 4) reflect on learning (Lewis & Hurd, 2011) and has been used both in K-12 and post-secondary classrooms. In the introduction to their 2019 book on LS in mathematics, Huang et al. (2019) noted that the field has not yet published "how to use LS as a tool to address equity of student learning opportunity" and called for this focus (p. 10). This working group will examine the following four equity-focused LS adaptations.

Teaching Through Problem-solving

In Teaching Through Problem-solving, widely used in Japan, *students* develop each new mathematical concept and procedure in the curriculum, by solving a problem that requires the new concept/procedure (Takahashi, 2021). Student reflective mathematics journals, organized board use and student-led discussion routines make student thinking visible and actionable during instruction, allowing students to take agency as authors (not simply consumers) of mathematics (LSGAMC, 2022). School-wide LS joined with Teaching Through Problem-solving has shown a strong positive impact on the mathematics achievement and perseverance of historically underserved learners (Lewis et al., 2022a,b).

California Action Network for Mathematics Excellence and Equity (CANMEE)

CANMEE incorporates equity into the lesson study process by including focal students and equity commentators. Selecting, interviewing, and writing assets-based descriptions of focal students allows teachers to learn about and know their students. Attending to focal students operationalizes equity in the classroom by increasing students' mathematical agency and identity, transforming teachers' beliefs and perceptions of focal students, shifting teachers' instructional practices (Bartell et al., 2017) that impact all students, and creating a culture of professionalism. Equity commentators bring new knowledge to the team, connect theory and practice, make claims about teaching and learning, and model reflection on teaching and learning. They focus on focal students' access to high cognitively demanding grade level mathematics. Emerging evidence suggests impact on both students and teachers.

Rights of the Learner (RotL) Framework

Rights of the learner framework is based on the premise of students engaging in democratic sharing of ideas (Kalinec-Craig, 2017; Torres, 2020). The four Torres's RotL are: "1) the right to be confused; 2) the right to claim a mistake and revise the thinking, 3) the right to speak, listen, and be heard; and 4) the right to write, do and represent what makes sense to them" (Kalinec-Craig, 2017, p. 1). By focusing on the rights of the learner during LS, a teacher provides a more equitable classroom environment where students feel comfortable engaging in the content through their own unique understanding lens.

The Continuous Improvement Lesson Study (CILS) Process

The CILS (Dick et al., 2022) process integrates LS (Lewis & Hurd, 2011) and the Continuous Improvement process (Berk & Hiebert, 2009) to support equitable teaching practices of mathematics teacher educators (MTEs). The incorporation of continuous improvement within LS focuses on both preservice teacher learning and lesson revision as a lesson is taught multiple times by each participating MTE. We found that engaging in the CILS process supports MTEs to develop an educative curriculum and collaborative environment that supports equitable teaching.

Working group Organization

This working group is an extension of a previous working group, with additional lesson study researchers and a structure that enables participants to engage with various lesson study adaptations related to equitable teaching practices. Table 1 contains the structure of the working group. The plan is to continue meeting at future PME-NAs to conceptualize and test equity-focused adaptations and share challenges/learnings with the goal of understanding/improving these adaptations and sharing them in an edited volume.

Table 1: Overview of the Proposed Working group Session

	Activities	Take-Aways
Session One	1. Introductions and Agenda 2. History of Lesson Study (LS) with Four Adaptations 3. Questions and Small Group Discussions Regarding Equitable Teaching Practices	1. Resources regarding the four adaptations. 2. Homework (HW): Watch public lesson video
Session Two	1. Debrief videoed public lesson and unpack lesson through the four equity-focused LS adaptations 2. Small group discussions, on chosen adaptation(s)	1. Debrief lesson 2. HW: Draft LS plan with equity-focused adaptation
Session Three	1. Share draft plans for testing equity-focused adaptations through LS implementation 2. Subgroup work time for refinement of plans 3. Subgroup brief share-out 4. Final reflections, future work plan	1. Continue planning for LS implementation 2. Future plans for collaboration and sharing

In 2021 we met at PME-NA Mexico and Philadelphia. At PME-NA Mexico, the working group met virtually. Facilitators introduced central tenets of the self-based methodologies (SBMs) and relationships between SBMs and MTEs' work (Chapman, 2020). SBMs are useful in describing MTEs' living awareness, living contradictions, empathetic relations, growing relationships, practical knowledge, and change in self and practice (Chapman et al., 2020). Working group facilitators narrated their methodological decisions and provided examples of SBM studies in video form with captions to accommodate English and Spanish speakers. Attendees asked questions about the similarities and differences among SBMs. To close the working group, proposals for PME-NA 43 and the Association of Mathematics Teacher Educators (AMTE) 2022 conference were discussed.

At PME-NA Philadelphia, the working group met in person and virtually. Two facilitators attended in person with the remainder attending virtually. The hybrid modality allowed MTEs attending the conference to meet virtually as needed alongside MTEs who were attending the conference in person. Facilitators shared the history of our working group and our collaborative project to create a special issue for the *Philosophy of Mathematics Education Journal*. The primary goal of the special issue is to create views of MTE work, their practices and from their unique perspectives, while the editors will focus on ways to encourage discussion about the philosophical underpinnings of the MTEs' stories, narratives, and empirical studies. Researchers using SBMs study their lived experiences by writing stories (i.e., using narrative inquiry), identifying a practice they want to improve (i.e., using self-study), or unpacking the influence of the socio-cultural and political contexts in their work (i.e., using autoethnography). We hypothesize that SBMs emphasize self-understanding, self-exploration, and contribute to understanding, conceptualizing, and improving MTE practices. SBM research processes produce empirical research about MTE practices while supporting MTE professional learning and unearthing how MTE knowledge, instructional approaches, beliefs, and identity inform their relationships with mathematics, pedagogy and practice.

In preparation for the 2021 working group, we reviewed empirical studies using SBMs published between 2014 and 2021 to identify themes in findings. Findings from the SBM studies included two themes: “exploring MTEs’ work in different career stages” and “MTEs incorporating new practices” (Suazo-Flores et al., 2022, under review). These themes documented how MTEs’ knowledge is constituted and informed by experiences, and is therefore dynamic, constantly evolving according to the situation and time.

As a research group, we have been using conference spaces, such as PME-NA and AMTE, to build a critical mass of scholars using SBMs and to invite others to explore the possibilities of SBMs for their inquiry. Drawing from a review of the use of SBMs (Chapman et al., 2020), the working group is identifying how findings from the use of SBMs inform the field of mathematics teacher education. Our goal is to unpack how the use of SBMs benefits MTEs' development and contributes knowledge to the field of mathematics teacher education.

Early reports on MTE practice (Chauvot, 2009; Tzur, 2001) described what MTEs know and how they develop their knowledge. Yet, *how* MTEs know in their interactions with teachers is less studied. In 2008, Jaworski stated that "co-learning between teachers and educators can be seen as the way ahead for developing mathematics teacher education practice" (p. 11). Within this context, we portray MTEs as learners of teaching about teaching mathematics. In conducting studies using SBMs, MTEs document interactions with teachers that yield new practices and intellectual growth, contributing knowledge to mathematics teacher education. When conducting such studies, MTEs draw from either implicit or explicit philosophical considerations (Stinson, 2020). Our task at PME-NA Philadelphia was to invite MTEs to describe their ways of knowing in interactions to enable the facilitators of the working group to hypothesize about MTEs' philosophical positions.

At PME-NA Philadelphia, attendees analyzed data from one facilitator's study. The goal of the activity was to identify evidence of ways of acting and being with a teacher candidate. Working group members' analysis of the data resulted in an awareness of MTE's ways of knowing, i.e., how her knowledge of mathematics teacher education and her identity informed her interactions with the teacher candidate. Building from the discussion of the data, attendees shared preliminary topics and data that might be of interest to the working group and for the special issue. Finally, the group closed the meeting with plans for future meetings. In 2022 we will meet at the AMTE conference. Since most PME-NA 43 attendees were interested in contributing articles for the special issue at the *Philosophy of Mathematics Education Journal,* facilitators created writing groups to meet bi-monthly, virtually between the PME-NA 43 meeting and the AMTE 2022 meeting. In addition, facilitators have been meeting weekly to develop a timeline and plan for the special issue.

PHILOSOPHICAL UNDERPINNINGS OF MATHEMATICS TEACHER EDUCATORS' WORK

Elizabeth Suazo-Flores
Purdue University
esuazo@purdue.edu

Signe E. Kastberg
Purdue University
skastber@purdue.edu

Melva R. Grant

Calgary University
chapman@ucalgary.ca

Mathematics teacher educators (MTEs) are turning research lens on themselves to explore their knowledge and practices and with that contribute knowledge to the field of mathematics teacher education. In this working group we build from our exploration of MTEs' work. MTEs will describe their work and their views of knowledge and being in their work as MTEs. We invite MTEs to join our working group and assert that MTEs' discussions of their work will provide opportunities for professional learning that reveals how their knowledge and identity inform their practice.

Keywords: Mathematics Teacher Educators, Philosophy, Practice, Qualitative Research.

Qualitative methodologies employed in the study of mathematics teacher education have empowered mathematics teacher educators (MTEs) to turn the research lens on themselves and gain nuanced perspectives. The goals of self-based methodology ([SBM], Chapman et al., 2020) include improving one's own practice, fueling ideas for others' practices and contributing to dialogues about the complex work of MTEs. Published findings from inquiry into MTE practice have illustrated how studies of self can complement findings from explorations of instructional activities and their impacts on mathematics teachers, leaders and learners as well as their environments and contexts (e.g., Grant, 2019; Grant & Ferguson, 2021; Kastberg et al., 2020). Mathematics education as a field benefits when the complexity of the work of MTEs is laid bare.

We aim to continue creating spaces at mathematics education conferences to support MTEs in the writing of articles of SBM studies (Suazo-Flores et al., 2018, 2019, 2020, 2021, 2022). Our focus at PME-NA 44 is the edition of a special issue for the *Philosophy of Mathematics Education Journal*. We learned that MTEs engaged in scholarly inquiry of their practices communicate their diverse ways of knowing, their views of what is real, and their perceptions of others' knowledge, such as the ways they discover or construct knowledge (Guba, 1990; Paul & Marfo, 2001; Stinson, 2020). Moreover, MTEs research pursuits may be constrained by disciplinary cultural norms, research training and/or editorial preferences. Such inquiry makes explicit MTE's role in conducting and reporting research (Guilfoyle et al., 2004), which creates trustworthiness in their reports (Grant & Lincoln, 2021).

The working group at PME-NA 44 will include the work of authors studying MTEs' lived experiences empirically, theoretically, and philosophically informed using SBM or some other intimate approach (Hamilton et al., 2016). This work contributes to the recognition and understanding of the complexity of mathematics teacher education. These papers delve into the "particularities and intricacies" of MTE's work as informed by emotional, social, relational, and organizational contexts (Hamilton et al., 2016). We want to use this working time as a meeting space to continue supporting each other in the writing of such articles.

Session Information

We have regularly met to continue creating professional development spaces to engage more MTEs in writing about their practice from their perspective (Suazo-Flores et al., 2018, 2019, 2020, 2021, 2022). At PME-NA 44, MTEs are invited to join our working group to learn about the philosophical underpinnings of SBM studies (Chapman et al., 2020). Working group activities will include on Day 1, engaging the audience in thinking about philosophical underpinnings involved when conducting research studies that focus on the self. On Day 2, we will invite MTEs to present their studies and to identify philosophy and trustworthiness/authenticity (Grant & Lincoln, 2021). On Day 3, we will develop action items and discuss new projects such as writing a proposal for ICME-15.

"Taking up space as a disabled person is always revolutionary" (Ho, 2020, p. 115). We are mathematics education researchers and practitioners demanding radical changes within and beyond our field to center issues of/with/by the disabled. Our working group draws upon critical theories such as Disability Studies in Education, Critical Race Theory, and DisCrit in order to offer a justice-oriented vision of mathematics education based on conceptualizations of disability and ableism as it relates to other forms of oppression and identities (e.g., race, class, gender, queerness, citizenship, carcerality, material precarity, etc). Traditionally, research on mathematics and disabilities has been conducted within a special education paradigm. Under this paradigm, research often, implicitly or explicitly adopts a deficit and dehumanizing approach which locates the "problem" within the individual student rather than in the social, discursive, political, and structural context of education and other systemic dynamics of racialization (Meghji, 2022) and ableism (Goodley et al., 2019). We resist the continued dehumanization of and harms inflicted on disabled communities. We demand that mathematics education researchers and practitioners address this critical dissonance by taking up equity-oriented approaches to understanding disability and its intersections through Black Feminists and Disability Justice methodologies. Likewise, we call for more resonant harmony frameworks such as Multiple Mathematics Knowledge Bases and Culturally Responsive and Sustaining Practices that honor the voice, agency, and leadership of those most impacted. The purpose of this working group is to build upon our previous working group and to take up and move forward towards solidarity, interdependence, and collective action with the disabled community in our research agenda.

Struggle Toward Disability Justice

Consisting of faculty, graduate students, disability activists, and classroom teachers, this PME-NA working group met from 2016 to 2018,. Some of the major accomplishments of this working group include (a) establishing and maintaining an email list-serv, (b) co-editing a special issue in the journal *Investigations in Mathematical Learning* (Lambert et al., 2018), and (c) publishing an NCTM book titled *Humanizing Disability in Mathematics Education: Forging New Paths* (Tan et al., 2019).

Moving forward, we center Disability Justice, a theoretical framework developed through the grassroots efforts of disabled queer activists and disabled people of color (Sins Invalid, 2019). It focuses on the relationship between ableism and other interlocking systems of oppression, such as racism, sexism, imperialism, settler colonialism, and capitalism. We specifically draw upon the 10 principles for disability justice created by Patty Berne and others from Sins Invalid: intersectionality, leadership of the most impacted, anti-capitalist politics, cross-movement solidarity, recognizing wholeness, sustainability, cross-disability solidarity, interdependence, collective access, and collective liberation. Given the legacy of harm done to disabled communities, Disability Justice, its centralization of the needs and experiences of folx experiencing intersectional oppression, allows researchers to recognize the intersecting legacies of white supremacy, colonial capitalism, gender oppression, and ableism to understand how people's bodies and minds are labeled "deviant", "unproductive" and/or invalid. (Sins Invalid, 2019). Traditionally, researchers determine the questions asked, the methods of data collection, and the meaning made of the data, with no input from the disabled individuals of color. Acknowledging disabled students and communities of color have gifts (Annamma & Morrison, 2018) such as unique mathematical ideas and perspectives and solutions to challenge current structures of ableism (Tan & Kastberg, 2017) and bringing them into the research process to shift power and decolonialize the research process. For example, members of the working group have published an emancipatory research study (Lewis & Lynn, 2018) where Lewis (disabled researcher) was positioned as the inquirer and Lynn (student with dyscalculia) as the expert. We aim to build out theories of intersectional disability justice in and through mathematics education.

Plan for Resistance and Co-conspiring

Session 1: Community, Caring, & Co-learning - Introductions and community building (40min), and discussing an agenda for the group for the upcoming year (50min); Session 2: Generating, Struggling, & Planning - Identify potential collaborative endeavors (30min), break up into subgroups based on areas of interest (40min), and regroup as a large to share out (20min); Session 3: Planning for Next Steps - Subgroup work (40min), large group share out and conversations (20min), and closing and identifying concrete next steps (30min)**.**

MATHEMATICS, MATHEMATICS EDUCATION, AND CITIZENSHIP: CONCEPTIONS, PROFESSIONAL PRACTICE VIEWS, AND FIGURED WORLDS

Amy Brass
Pennsylvania State University
aqb6161@psu.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Preservice Teacher Education; Teacher Educators

The United States was recently categorized a "backsliding democracy" (International Institute for Democracy and Electoral Assistance, 2021), and commitment to citizen development in American schools has been inconsistent (Torney-Purta & Lopez, 2006). Citizenship scholars believe that one way to foster civic practices is through interdisciplinary connections and scholarship (Lee et al., 2021). This interest in interdisciplinarity is consistent with recent suggestions by mathematics education organizations, such as the National Council of Teachers of Mathematics (NCTM) (2018, 2020) which encourages students to investigate civic and social issues through mathematics in ways that foster their development as informed and engaged citizens. Additionally, the Association of Mathematics Teacher Educators (AMTE) (2017) also supports this interdisciplinarity by calling for mathematics teacher education programs to "uncover [teacher] candidates' passion for and commitment to mathematics as a discipline and an essential component of an effective citizenry" (p. 42).

Yet, extant research centered on relationships across mathematics, mathematics education, and citizenship is scarce. The purpose of this study is to explore conceptions held by mathematics teacher educators (MTEs) and by middle-level preservice teachers (PSTs) regarding the relationships across mathematics, mathematics education, and citizenship. The goal is to learn how these conceptions relate to MTEs' and PSTs' views on teaching, including how their conceptions do and do not align with current calls for developing democratic citizens, so that educational stakeholders can respond to K-12 schools' and the university's role in sustaining democracy. These research questions guide the study: (1) How do MTEs and middle-level PSTs conceptualize the relationships across mathematics, mathematics education, and citizenship? (2) What relationships exist between the connections MTEs and PSTs make across mathematics, mathematics education, and citizenship and their views of their professional practice?

Conceptual and Theoretical Framings

Drawing on citizenship literature (e.g., Castro, 2013; Westheimer & Kahne, 2004), four multifaceted, overlapping conceptions were created to frame participants' views on citizenship. *Conforming citizens* value consensus, established community norms, and patriotism; *cognizant citizens* are aware and informed of civic issues; *contributing citizens* participate in their communities; and *critical citizens* act as agents of change and focus on societal structures causing and perpetuating injustices. All of these citizens draw on specific intellectual and participatory civic skills (e.g., Patrick, 2002) and civic dispositions (e.g., Stitzlein, 2021). In relation to mathematics, these civic skills and dispositions connect to NCTM's (2000) Process Standards: communication, connections, representations, reasoning and proof, and problem solving. Together, these citizenship conceptions, civic skills and dispositions, and NCTM's Process Standards will serve as a framework for exploring the relationships across mathematics, mathematics education, and citizenship in the study.

The theoretical framework for this study draws on sociocultural theory, specifically the notion that people and their social, historical, and cultural contexts are inseparable (Rogoff, 2003) and the use of figured worlds (Holland et al., 1998). A figured world is "a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., p. 52). The cultural context of the figured world becomes a means for interpreting the members, activities, discourse, and artifacts of that world. It is through these aspects of a figured world that the positioning and identities of the members of that world emerge. The figured worlds that PSTs create about their identities as classroom citizens in a mathematics methods course will be explored through this study, and these figured worlds will be compared and contrasted with PSTs' citizenship in other contexts.

Methods

This study consists of two phases. Phase 1 of the study focuses on views held by MTEs; Phase 2 of the study focuses on the views of PSTs. Methods for each phase are described below.

Phase 1

Phase 1 utilizes an open-ended Qualtrics survey with responses from 90 MTEs and semi-structured interviews with 20 MTEs. Both the survey protocol and the interview protocol consist of prompts to elicit participants' views of citizenship, views of mathematics and mathematics education for citizenship, and connections to views of their professional practice. Qualitative data analysis will involve a mixture of deductive and inductive coding techniques (Miles et al., 2014). Deductive codes represent different citizenship conceptions, civic skills, civic dispositions, and NCTM's (2000) Process Standards. Inductive analysis will be utilized (Bhattacharya, 2017) to identify inductive codes, categories, and themes related to MTEs' views of mathematics, mathematics education, and citizenship.

Phase 2

Phase 2 utilizes an ethnographically-informed case study (de Freitas et al., 2017) that focuses on 22 middle-level PSTs; their conceptions of the relationships across mathematics, mathematics education, and citizenship; and how those conceptions relate to their views of teaching. Data collection methods include observations of PSTs in their educational methods courses; course artifacts, surveys, and video-recording class sessions when PSTs engage in mathematics-related tasks focused on civic issues; and interviews. Like the Phase 1, qualitative data analysis in this phase will use a mixture of deductive and inductive coding techniques (Miles et al., 2014). Connections across emerging codes, categories, and themes that reflect the main elements of figured worlds – artifacts, discourse, and identity – will help me identify the figured worlds at play related to the PSTs' identities, participation, and positioning as classroom citizens in the mathematics methods course and how those worlds relate to their citizenship in other areas.

Anticipated Contributions

Anticipated contributions of this study include strengthening interdisciplinary scholarship between mathematics education and citizenship. This scholarship has the potential to engage student citizens in civic issues and the potential to explore how mathematics can be used to foster the development of informed and engaged citizens. Further, by recognizing how MTEs and PSTs view mathematics and mathematics education for citizenship, efforts can be made to explore ways in which educational stakeholders can respond to K-12 schools' and the university's role in advancing the preservation of democracy.

EXAMINING CRITICAL FACTORS IN PARENT-CHILD MATH ENGAGEMENT

Anastasia Betts
University at Buffalo SUNY
albetts@buffalo.edu

Parent-child engagement in shared math activities has a significant positive impact on children's mathematics achievement, yet studies of parent motivations and decision-making related to shared math activity with their children are largely absent from the research literature (Betts & Son, Accepted for Presentation). Furthermore, many students arrive at school unready to take full advantage of mathematics learning in school, quite often due to low prior knowledge borne of insufficient exposure to early math concepts and skills in the home prior to beginning kindergarten (Betts, Thai, Jacobs, & Li, 2020; Duncan et al., 2007; Nguyen et al., 2016). Parents are children's first teachers and are often the most well-positioned in terms of proximity (both physical and relational) to provide children with the modeling, scaffolding, and expectations that lead to learning and success (Bandura, 1977; Bloom, 1984; Bronfenbrenner, 1992; Marjoribanks, 1976; Mowder, 2005; Vygotsky, 1986). Parents are also one of the biggest influences in the home learning environment prior to the onset of formal schooling (Blevins-Knabe, 2016; Cankaya & LeFevre, 2016).

Dissertation Study Goals

The purpose of the proposed study is to examine the factors that influence parents' cognitions and decision-making around shared math-activity with their young children by exploring how parents' perceptions of their role, expectations for their child, personal math skills, self-efficacy, and perceptions of time and energy influence and interact with one another. These factors of Role, Expectations, Skills, Efficacy, and Time have been assembled into the RESET Framework, which was then used to create the RESET survey instrument. A further section of the survey was developed to examine the self-reports of Math Activity Participation of Parents (MAPP). This study provides an opportunity to develop tools and approaches for studying the home numeracy environment (i.e., the RESET Framework, the RESET-MAPP survey instrument), which may inform the design of better parent-engagement programs that can increase parent-child math activity and better outcomes for children. Research questions include: (1) To what extent are parents' mathematical parenting beliefs and perceptions represented by the RESET framework? (2) What relationships exist between parents' mathematical parenting beliefs and perceptions, and their self-reports of mathematical parenting behaviors? and (3) What mathematical parenting beliefs, perceptions, and behaviors characterize different groups of parents?

Theoretical Framework

No current literature exists for specifically understanding the interaction of factors that influence the motivations and decision-making of parents with respect to the mathematics education of their children (Mowder, 2005). However, Hoover-Dempsey and Sandler's (1997) parent education involvement model, Bandura (1977), Marjoribanks (1976), and Vygotsky's (1986) social theories of learning, as well as Bronfenbrenner's (1992) Ecological Systems Theory of Learning, and Mowder's (2005) Parental Development Theory provide a rich conceptual framework upon which the present study was grounded. The domains of the RESET Framework were derived from the work of Hoover-Dempsey and Sandler (1995, 1997; Walker et al., 2005; Walker et al., 2010) as well as Mowder (2005) and others. Additionally, Bandura, Marjoribanks, and Vygotsky in their individual work describe the critical importance of the parent/caregiver in the role of the child's development through providing models, establishing expectations, and acting as more knowledgeable others who both guide and "draw forth" the child's development and learning. Lastly, Bronfenbrenner's Ecological Systems Theory of Learning informs the RESET Framework by describing how parents formulate their perceptions along the RESET domains, through proximal influences in the micro- and meso-systems (e.g., family, parent groups, community groups, etc.) and distal influences in the exo-system (e.g., economics, politics, education), and macrosystem (e.g., cultural values, attitudes, beliefs, and ideologies, etc.).

Methodology

This exploratory parallel mixed-methods study proposes to use the RESET framework to examine parents' mathematics parenting cognitions and behaviors using the digital RESET-MAPP survey and follow-up interviews. The sample (n = 829) for the study includes parents of 4- and 5-year-old children who have not yet begun kindergarten. The sample was provided by a commercial sample provider, Innovate MR, which creates samples of participants from their nationwide database of hundreds of thousands of individuals (Innovate MR, n.d.). Samples are created using a blend of diverse sources including using online and offline strategies, large-scale advertising networks, specialty websites that cater to specific demographics (e.g., different ethnicities, cultural backgrounds, interests, educational levels, etc.), as well as using mail and TV advertisement strategies. The sample drawn for this study was diverse in terms of geography (e.g., participants will be drawn from a national database of research participants), ethnicity/cultural background, socio-economic status, education level, marital and employment statuses, age, and gender, etc. Purposive sampling will be used to create the secondary sample ($n \geq 18$) for the follow-up interviews, drawn from the population of survey participants, and selected based on their ability to provide additional depth or elaboration to phenomena that emerge from the survey data. Qualitative and quantitative data collected from the digital survey and qualitative data collected from the follow up interviews will be analyzed for insights into the specific research questions (noted earlier). Quantitative analysis will include descriptive statistics (e.g., measures of frequency, central tendency, dispersion/variation), as well as other tests to identify relationships and correlations. Qualitative analysis measures will include discourse analysis through coding frequency analysis. Analytical coding strategies, including a priori coding using the RESET framework, as well as other methods of inductive and deductive coding will be used. Qualitative data will be transformed into quantitative data as appropriate, and then triangulated with the existing quantitative data for means of deriving insights, drawing conclusions, and answering the specific research questions guiding this study.

Significance of this Study

The development of the RESET Framework is theoretically significant, as it has the potential to fill a gap in the research corpus by establishing a clear and useful conceptual framework for examining factors that influence parent involvement in their child's mathematics education. Understanding parents' beliefs, attitudes, and practices across the RESET domains provides practical significance through empowering the design of better parent engagement programs that that may increase parent-child interactions and improve child early mathematics knowledge. Lastly, this study will provide detailed information about the ways in which parents most need support that can empower them to better support their children.

LEARNERS' COLLABORATIVE USE OF HUMAN-SCALE SPATIAL DIAGRAMS

Camden Bock
The University of Maine
camden.bock@maine.edu

Freudenthal (1971) describes a vision for a didactical exploration of geometry that is "tied to lived reality with strong bonds," where lived reality is a material, spatial world that our bodies "live in," "move in," and "analyze" (pp. 418-419). Fruedenthal (1971) advocates for learners to explore phenomena from their lived reality with a rich mathematical lens. In geometry, diagrams provide an opportunity to connect learners' embodied experiences of the material world to exploration of mathematical phenomena. Gestures can realize "virtual mathematical objects or mathematical relationships" in diagrams — linking the motion of learners' bodies to the inscription — through multimodal, embodied discourse (Chen & Herbst, 2013, p. 302). However, diagrams are commonly inscribed on plane surfaces (*e.g.,* blackboards, paper) at scales smaller than the learners who inscribe them (*e.g.,* Greiffenhagen, 2014; de Freitas, 2012).

Technologies have long existed to bring geometry out of the plane and into the learners' material world (*e.g.,* clay sculpture, wood joinery). However, the time it takes to modify the inscription of a material diagram is typically much greater than their planar counterparts (*e.g., stylus, chalk*). The recent commercial availability of 3D filament pens and immersive virtual, augmented, and extended realities offer new ways to quickly construct and modify diagrams in space (Ng & Sinclair, 2018; Dimmel et al., 2020). Digitally rendered spatial diagrams offer opportunities to bridge the digital affordances of dynamic geometry environments with material affordances that emulate learners' interactions with their lived reality. I ask: How does the scale of a human-scale spatial diagram shape learners' collaborative discourse?

Background

Dynamic geometry environments can connect the movements of learners' bodies to continuous transformations of a digitally rendered figure. Multitouch tablets offer a surface where these maps can be made by the body itself, with the dragging of fingers (Ng & Sinclair, 2015), rather than mediating these interactions through keyboard or mouse input systems. Touch screen tablets thus provide a portal that links the digital worlds of dynamic diagrams directly to movements of learners' bodies. Digitally rendered spatial diagrams can extend this connection between movement and diagramming by allowing learners to pinch and drag components of a figure as they might grasp an object in the real world. The dragging or pinching of fingers to manipulate digitally rendered diagrams on multitouch tablets or digitally rendered spatial diagrams links the movement of the learners' body to smooth transformations of a diagram, which can support students in descriptions of geometric transformations as "continuous and temporal processes" (Ng & Sinclair, 2015, p. 85; Bock & Dimmel, 2021a; 2021b).

Spatial diagrams also offer learners novel ways to relate their body to a diagram. Learners might stand beside, look from above, or step inside a diagram (Dimmel & Bock, 2019; Bock & Dimmel, 2021a; Cangas et al., 2019). In human-scale and larger spatial diagrams, learners might put their head inside, kneel under, reach around, or reach through a diagram (Dimmel et al., 2021; Palatnik & Abrahamson, 2022). Other human-scale embodiments of diagrams have been explored in walking-scale geometry, where learners use their bodies to become vertices or to trace lengths of segments (Ma, 2017). Human-scale spatial diagrams — digitally rendered or physically realized — offer opportunities for networks of learners' bodies to interact with a diagram. Within and among such collaborative, body-based diagrammatic interaction has the potential for *creative mathematical* acts (Sinclair et al., 2013) — moments when learners realize virtual objects and relationships in unscripted ways.

Creative Acts

Creative acts "bring forth" something that "was not present before" in a way that does not "align with current habits and norms" for mathematical behavior, to "change the way language and other signs are used and alter meanings that circulate in a situation" (Sinclair et al., 2013, p. 241). For example, a learner might use a gesture to realize the altitude of a triangle that was not inscribed on a diagram. This could be a creative act if the altitude shaped the learners' mathematical discourse, and if using a gesture to realize the altitude of a triangle was unusual for their mathematical practice. The study of creative acts helps to understand how agency can be distributed in novel and mathematically meaningful interactions among learners, their bodies, and the potentials embedded in the milieu. The lens of creative acts can be applied to investigate the affordances (*e.g.,* scale) of technologies that support creative acts (Sinclair et al., 2013).

To understand the affordance of *scale* in human-scale spatial diagrams, it is important to understand learners' discourse as multimodal (*i.e.,* composed of speech, intonation, rhythm, gesture, body position, and body movement) and in relation with other learners and the spatial inscriptions composing a spatial diagram. The creative acts lens draws attention to the distribution of agency between learners, their bodies', and diagrams. With human scale diagrams, learners' can not only realize virtual mathematical objects and relationships with language, gesturing (above, in front of the diagram) and direct manipulation, but also by moving their body to vary their perspective, by gesturing (around, inside, outside and through the diagram), by starting and stopping their movement, and by directing their gaze.

Research Question, Methods, Design

I will conduct a series of semi-structured interviews where participants collaboratively explore a set of spatial diagrams. Interviewers will ask participants to repeat or clarify statements or actions they make during their exploration. Multimodal archives of participants' exploration of the diagram will be collected, including video of their first person (virtual) perspective of the spatial diagram, video of their bodies in the 'real' world, and audio of the conversation between participants. Within each interview, episodes will be identified where learners relate their bodies to the spatial diagrams in new ways (*e.g., stepping inside)*. Transcripts of verbal elements of discourse will be developed and embedded as subtitles in a composite video archive. Participants' gestures and bodily relationships with the diagram will be spatially annotated on the video archives. Analysis will include a characterization of creative acts within the episode and coding of the relationships between learners' bodies and the scale of the diagram.

This study seeks to describe some of the ways that learners' bodies can relate to human-scale spatial diagrams, which are uncommon in school settings. I am inspired by Benally et al.'s (2022) investigation of the collaborative construction of human-scale physical spatial diagrams and the asymmetric embodied relationships to a diagram. This study will contribute an understanding of what is possible with learners' collaborative explorations of spatial diagrams. More specifically, this study will explore the ways that learners realize the potentials of diagrams by reconfiguring their embodied relationships with a human-scale or larger diagram. This work extends understandings of learners' use of perspective in digital (Bock & Dimmel, 2021a, 2021b; Dimmel et al., 2020) and physical (Benally et al., 2022) spatial diagrams, the inscription of diagrams in space (Ng & Sinclair, 2018; Cangas et al., 2019), and the embodied relationships between learners and diagrams (Sinclair et al., 2013; de Freitas & Sinclair, 2014).

DEVELOPING COMBINATORIAL MEANING FOR ALGEBRAIC STRUCTURE: LESSONS FROM A DESIGN-RESEARCH CYCLE

Lori J. Burch
Indiana University
ljburch@iu.edu

Keywords: Algebra & Algebraic Thinking, Design Experiments, High School Education

Goals of Research

The broad goal of my dissertation study is supporting mathematical thinkers (students and teachers alike) to develop mathematical meanings as personally powerful and to leverage such meanings in the teaching and learning of algebra (Silverman & Thompson, 2008). Correspondingly, the following research questions have guided the design and implementation of this work. First, what affordances does developing algebraic structure as a generalization of one's own reasoning hold for mathematical thinkers? Second, how can teachers, in whole-class instruction, support students to develop personally powerful mathematical meanings related to algebraic structure? Through my dissertation, I report on two studies within a design-research cycle: a teaching experiment with two secondary algebra teachers (as participants) and a subsequent classroom study at the secondary level. Both interventions aimed to investigate the development of mathematical meanings as participants: (a) generalized quantitative relationships out of a combinatorics task (i.e., a counting problem) and (b) reasoned about their generalization in the context of symbolic tasks typical of secondary algebra curricula (Kaput, 2008/2017).

Theoretical Framework

I follow Thompson and colleagues' definition of mathematical meanings as "the space of implications that the current understanding mobilizes" (2014, p. 13). Elsewhere (Burch, under review), I contrasted two potential mathematical meanings for the cubic identity for binomial expansion, i.e., $(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$, which is the mathematical focus of my dissertation studies. Here, I briefly describe these two meanings—computational and combinatorial—before situating the combinatorial meaning within a theoretical model of combinatorial thinking (Lockwood, 2013). First, mathematical thinkers operating from a *computational meaning* credit equivalence between $(a+b)^3$ and $a^3 + 3a^2b + 3ab^2 + b^3$ to the result of algebraic computation, i.e., sequential two-factor application of the distributive property. This meaning's space of implications often implies a uni-directional nature that allows a thinker to determine an expansion from binomials but does not imply structural relationships that would allow the thinker to use the same kind of reasoning to determine binomial factors given an expanded polynomial (Tillema & Burch, 2021). By contrast, the *combinatorial meaning* emphasizing combinatorial and quantitative relationships (Tillema & Gatza, 2016) can mobilize a bi-directional understanding of the identity. That is, $(a+b)^3$ can be interpreted as three independent events, $(a+b)$ and $(a+b)$ and $(a+b)$, where *a* and *b* each represent a number of possibilities for two categories of outcomes that are available on each event. The expansion, $a^3 + 3a^2b + 3ab^2 + b^3$, represents a case breakdown of all possible three-event outcomes, where cases are organized according to the number of *a*-possibilities selected (Tillema & Burch, in press). A thinker's space of implications when operating from a combinatorial meaning includes opportunities to leverage structural relationships to multiply and factor any three binomials (beyond cubing) and to anticipate structural relationships in any degree of expansion.

Given hypothesized differences in the space of implications, the combinatorial meaning for the cubic identity has the greater potential of being personally powerful. Thus, it is this meaning that I aimed for study participants to develop. To that end, I find useful Lockwood's (2013) model of combinatorial thinking (MCT) in guiding the development of this study. The MCT consists of three aspects on which a person might focus when solving a combinatorics (or counting) problem: a set of outcomes, a counting process, and a formula/expression. When approaching the cubic identity from a combinatorial perspective, a thinker could consider the following question related to the symbolic problem $(a+b)^3$: What are all possible partial products when cubing the binomial $(a+b)$? The *set of outcomes* is the set of all possible partial products, where each partial product (i.e., outcome) contains one factor from each binomial. The *counting process* describes the method the thinker uses to produce (or organize) a set of outcomes (e.g., a case breakdown). Lockwood defined the *formula/expression* as determining the cardinality of the set of outcomes. In this example, $2^3 = 1 + 3 + 3 + 1$ represents the number of partial products in a way that reflects the set's organization. When emphasizing the combinatorial nature of algebraic structure, the formula/expression can represent the identity itself as $(a+b)^3 = 1a^3 + 3a^2b + 3ab^2 + 1b^3$. Thinkers with a personally powerful combinatorial meaning operate from an expectation of connectedness between the three MCT components. That is, the *counting process* should be represented consistently in both the *set of outcomes* and the *formula/expression* used to symbolize them. Such a connectedness allows a thinker to mobilize their meaning toward answering broader questions related to relationships between the coefficients of a polynomial and its roots (Viète's formulas). It is this connectedness in combinatorial reasoning that I aimed to support participants across both studies to develop.

Methods

In my dissertation, I report on two studies as part of a design-research program (Cobb et al., 2017). In both studies, I acted as teacher-researcher with a mathematics education researcher collaborating as witness-researcher. The first study, a teaching experiment (Steffe & Thompson, 2000), included two veteran secondary mathematics teachers who participated in six, 90- to 150-minute, teaching episodes over four days. The second study was a classroom study (Cobb et al.), including 18 secondary students in a dual-credit Finite Mathematics course. All students participated in a curricular unit over 10 days of instruction. Four acted as focus students, which included real-time recording of classwork and clinical interviews before and after the classroom intervention. All interviews and classroom instruction were recorded with multiple video cameras capturing student work and researcher/student interaction. Videos have been mixed into single files for use in multiple iterations of retrospective data analysis (e.g., transcription, coding, making conjectures and interpretations) (Steffe & Thompson). Both interventions were anchored by the Card Problem (Tillema & Gatza, 2016) which provided a quantitative and combinatorial context from which to generalize the cubic identity for binomial expansion (Burch et al., 2021).

Preliminary Findings & Anticipated Contributions

Responses to my research questions will contribute to the integration of combinatorics in secondary curricula (Lockwood et al., 2020) in a way that (a) addresses shortcomings of current teaching methods (e.g., Mason, 2017) and (b) supports the development of coherent meanings related to algebraic structure (Warren et al., 2016). The findings from my first study show important differences in teachers' combinatorial meanings that can inform teacher education and research efforts (Burch, under review). My second study will contribute empirically to the MCT literature by applying the MCT framework (Lockwood, 2013) as a model for algebra *instruction*.

ACCESS TO COGNITIVELY DEMANDING MATHEMATICAL LEARNING OPPORTUNITIES IN CO-TAUGHT ELEMENTARY MATHEMATICS

Laurel Dias
University of Utah
laurel.dias@utah.edu

Keywords: Elementary School Education, Instructional Activities and Practices

In elementary school classrooms, teachers are expected to deliver instruction to a wide range of learners with diverse backgrounds and prior knowledge. The broad scope of student needs challenges teachers to provide all students with mathematical learning opportunities (MLOs) that are both accessible and cognitively demanding. Although rigorous MLOs are essential to develop students' conceptual understanding, many learners do not have access to the same cognitively demanding MLOs as their peers (Hiebert & Grouw, 2007; Lynch et al., 2018). The success of all learners in mathematics, including those who struggle, requires that teachers work together to provide instruction, support, and interventions that go beyond explaining the content and enable students to become expert learners and doers of mathematics (Hiebert & Grouw, 2007; Lambert, 2020, 2021). Co-teaching is an instructional model that draws on the expertise of more than one teacher as they deliver joint instruction and consider the needs of every learner in the classroom (Cook & Friend, 2010). Research has identified five commonly used co-teaching models; however, we know little about the nuances of these co-teaching models in elementary mathematics and their relationship with the cognitive demand and accessibility of MLOs. The research question that guides this study is what is the relationship between different co-teaching models and the cognitive demand and accessibility of MLOs offered to students? Answering this question is critical to understanding how co-teaching can enrich learning opportunities for all elementary students in mathematics.

Theoretical Framework

The cognitive demand, or level of thinking, required to solve a task is meaningfully connected to students' development of conceptual understanding (Huinker & Bill, 2017). More cognitively demanding tasks allow students to struggle to make sense of mathematics and engage in more conceptual learning (Hiebert & Grouws, 2007; Lambert & Stylianou, 2013; Silver & Stein, 1996). A Task Analysis Guide for determining the cognitive demand required to solve a mathematical task was created using research on characteristics of academic tasks, high-level thinking skills, Professional Standards for Teaching Mathematics, and the examination and categorization of hundreds of tasks used in QUASAR classrooms (Smith & Stein, 1998, p. 348). In addition to the potential cognitive demand of tasks, it is important to consider the implementation of the task. Teachers have control to alter the cognitive demand of tasks both when they set up and when they implement the task (Stein et al., 2009).

Universal Design for Learning (UDL) is a philosophical approach to instruction grounded in the learning sciences and neuroscience, in which teachers redesign curriculum and instruction with student experiences and variability in mind (Meyer, Rose, and Gordon, 2014). UDL Math is a mathematical version of UDL created to support teachers in designing instruction that centers all students as problem-solvers capable of engaging in cognitively demanding mathematical tasks (Lambert, 2021). The six design elements of the UDL Math framework delineate criteria for how the design of MLOs can develop students into mathematical learners (Lambert, 2021).

It's crucial to study the instructional design of co-taught lessons because co-teaching models are not all enacted the same way and may support teachers in enhancing student access to MLOs differently. The lenses of cognitive demand and UDL Math will be applied to co-taught lessons to determine how MLOs are influenced by each co-teaching model teachers enact in this study.

Methods

Data Gathering

The participants in this study are a pair of elementary teachers who designed and enacted co-taught math instruction for twenty students in a 2nd-grade class. I selected the teachers through purposeful sampling of pilot survey data (Patton, 2002). This study consisted of two data collection cycles during the 2021-22 school year at a diverse urban elementary school. Each cycle consisted of 45-minute video-recorded lesson observations 2-3 times a week. The first cycle lasted four weeks and provided the teacher pair time to develop their co-teaching relationship in math and gain familiarity with different co-teaching structures. During the second cycle, teachers delivered grade-level mathematics instruction using various co-teaching models. Instructional artifacts were collected and documented throughout the observations. Additionally, the teacher pair participated in reflective interviews and surveys throughout the data collection process to involve them as sense-makers of their instruction (Savin-Baden & Major, 2013).

Data Analysis

The analysis aims to understand the affordances of each co-teaching model for students' MLOs in elementary mathematics. After determining the co-teaching model used for each co-taught lesson, I will analyze lessons for two criteria. First, I will code the students' access to MLOs with a coding scheme I developed based on evidence of UDL Math design elements in the lesson (Lambert, 2021). Second, the cognitive demand of MLOs during lessons will be analyzed using the Instructional Quality Assessment Rubrics (Boston, 2012). Interrater reliability will be calculated for both coding schemes applied to the data set. Considering both access and cognitive demand will give a rich picture of the affordances of each co-teaching model for student MLOs.

Contributions

Through this research, I seek to better understand how co-teaching structures impact students' access to cognitively demanding mathematics. The need to understand how the cognitive demand of MLOs can be maintained while designing accessible instruction is an essential topic in the field of education today. In today's classrooms, students have unique learning needs that must be considered when designing MLOs. The COVID-19 pandemic has further exacerbated the wide range of student differences in mathematical understanding. This study will produce an empirically grounded understanding of how co-teaching can support elementary mathematics instruction that is cognitively demanding and accessible to all students. In addition, this study is situated in actual classroom practice, allowing for important insights into how co-teaching can be used to plan and enact inclusive mathematics lessons. These findings will also benefit teacher professional learning by providing guidance on the design and enactment of co-taught mathematics instruction.

MULTILINGUAL INTERNATIONAL STUDENTS' MATHEMATICS IDENTITIES IN PROOF-BASED COLLEGIATE MATHEMATICS COURSES: USING NARRATIVE INQUIRY

Jihye Hwang
Michigan State University
hwangji7@msu.edu

Keywords: Language, Diversity, Equity, and Inclusion, Undergraduate mathematics

Mathematics is not language-free. Researchers have claimed that mathematics has its discourse (Barwell et al., 2007), which includes both linguistic non-linguistic parts, and each language system has different mathematics discourses (Barwell, 2018; Halliday, 1978). The stereotype that "mathematics is language-free" is not only toxic in diminishing roles of language in mathematics but can also make multilingual international students hidden from people's attention and care in their mathematics classrooms. In this study, I refer to multilingual people as those who use one language in some situations and another in other situations (Planas & Setati, 2009). According to this definition, I include people who are traditionally called "English as Second Language," "English as Another Language," or "non-native English speakers" as multilingual.

I believe that multilingual international students' experiences in proof-based mathematics classrooms should be investigated. The following is a summary of my reasoning for the claim: 1) language is a part of one's identity; 2) many multilingual international students experience a transition in their language of instruction (LOI) as they moved to the U.S from their home country, which influences their experiences and identities; 3) transitions from computation-based mathematics to proof-based mathematics courses will influence their identities in mathematics courses; hence, 4) multilingual international students face a two-fold transitions, one linguistic and one mathematical, that influence their mathematics identity in proof-based mathematics courses. Thus, this study tries to answer the following research question and sub-questions: What are multilingual international students' mathematics identities in various linguistic and mathematical contexts?

1. How do multilingual international students leverage their first and/or other languages when the LOI in proof-based mathematics courses is different from their first and/or languages?
2. What kinds of lived experiences do multilingual international students report to have affected their mathematics identities?

In this study, mathematics identity is defined as one's understanding of their relationship to mathematics, experiences that constructed this relationship across time and space, and one's vision for their mathematical possibilities for the future, which I adapted from Norton's (1997) definition of identity. Further, I view language as sources of meaning (Barwell, 2018), which expands the notion that language is a resource that students bring to the mathematics classroom (Moschkovich, 2002), by acknowledging that language is not neutral but stratifying and stratified.

Researcher Positionality

I am a multilingual international student who is a Korean woman and has studied and taught mathematics in the U.S. in my second language, English. Throughout my experiences, I faced a lot of challenges communicating mathematics in English and sometimes felt I was not valued by the community, and in turn, that led me to take some passive positions. I do not think that language is not the only component that intersects with my experiences, but I think it has been an important factor, especially related to my confidence. I tended to attribute the reasons for my challenging experiences solely to my lack of proficiency in speaking English, however, I believe there are a lot of external influences that shaped my view of my experience. This view is enhancing a deficit narrative about multilingual international students, whereas I adopt an anti-deficit perspective toward multilingual international students' experiences as it can be found in my research question and how I view language.

Method

For this study, I use narrative inquiry as a research method. Narrative inquiry is a research method that focuses on understanding human's lived stories (Connelly & Clandinin, 1990). People's experiences are in their stories as well as their beliefs, attitudes, and values, and their experiences are represented in a story as a whole rather than listed facts or figures (Foote & Bartell, 2011). According to the perspective, to understand students' experiences during their education, it is required to listen to people's stories of their education. By studying their stories, researchers can have a powerful tool to communicate, evoke emotions, empathize, and reflect on the experiences as well as provide insights into the factors of such experiences (Foote & Bartell, 2011; Martinie et al., 2016). Narrative inquiry is a useful tool to study anyone's experiences, but in the educational field, it has been more used to study marginalized populations' experiences to invite readers to revisit their own views and experiences in the educational field (Kim, 2012; Martinie et al., 2016).

The study participants will consist of five to six multilingual international undergraduate and graduate students in a large public university in the Midwestern U.S. The collected data will be their mathematics autobiography titled "Me and Math: my relationship with mathematics up to now" (Di Martino & Zan, 2010), one semi-structured synchronous interview based on their autobiography, and a series of email interviews that can provide multilingual international students with sufficient time to reflect and think about their experiences without worrying about a time constraint. Then the data will be analyzed to build a narrative because narratives can communicate who the participants have been in mathematics classrooms and what are their experiences as a mathematics doer better than the patterns of their behaviors.

Anticipated Contributions

In K-16 mathematics education, especially in higher education mathematics education, not much of multilingual international students' experiences and how they view themselves in mathematics is studied even though it is important. Hence, this study will be one addition to a set of studies, as well as a calling for more research on this population to serve them in a better and more equitable way. Moreover, this study will contribute to challenging the deficit narratives about multilingual international students and focus on what they are bringing into the classroom by viewing language as sources of meaning (Barwell, 2018). Narratives of multilingual international students in their mathematics learning and doing that will appear as a result of this study will hopefully provide an opportunity for readers to empathize with their experiences, reflect and challenge their own perspectives toward multilingual international students, and further consider these students' experiences in their teaching and research.

PROMOVIENDO EL RAZONAMIENTO PROPORCIONAL CON APOYO DE LA TECNOLOGÍA DIGITAL

Erasmo Islas
Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional (Cinvestav)
erasmo.islas@cinvestav.mx

Los conceptos asociados al razonamiento proporcional, tales como fracción, razón y proporción son clave en la educación matemática en los niveles básicos, ya que son pilares de las matemáticas superiores y su aplicación es transversal a otras ciencias, tales como física, química, economía, entre otras disciplinas (Lamon, 2007; Lobato et al., 2010). Más allá de servir de fundamento, el razonamiento proporcional es crucial en el ámbito cotidiano de las personas.

Dada la relevancia del tema, un sinnúmero de investigaciones ha reportado la problemática en la educación matemática alrededor del razonamiento proporcional; en nuestro estudio, resumimos tales problemáticas en cuatro categorías: 1) La carencia de sentido en el tratamiento de situaciones proporcionales debida a una excesiva aritmetización (Hart, 1988; Lamon, 1994, 2007, 2020; Adjiage y Pluvinage, 2007). 2) Una pobreza en el desarrollo de habilidades proporcionales de los estudiantes al no tener la oportunidad para resolver problemas en contextos que les permitan explorar las múltiples representaciones de la proporcionalidad (Obando et al., 2014; Mutaquin et al., 2017; Weiland et al., 2020). 3) Los estudiantes avanzan en su educación matemática con un concepto de razón vago o inexistente, lo cual conlleva a que la proporcionalidad no se vincule con las funciones lineales (Streefland, 1984; Harel et al., 1994). 4) Incapacidad de los estudiantes para distinguir las relaciones lineales de las relaciones no lineales, provocando la tendencia a aplicar el modelo de la proporcionalidad directa en contextos donde no es aplicable (De Bock et al., 2002, 2007; Fernández y Llinares, 2012).

Tomando en cuenta la problemática planteada, el problema al que se enfrenta la comunidad es cómo enseñar a los estudiantes a razonar proporcionalmente. El acercamiento escolar más frecuente hacia la proporcionalidad se da desde una perspectiva aritmética, separándola de sus vínculos con las relaciones funcionales y sus múltiples representaciones. En nuestra propuesta ponemos a prueba un diseño de enseñanza en el que consideramos que el tránsito entre múltiples representaciones, apoyado en simulaciones digitales, propicia mejoras en las habilidades de razonamiento proporcional en estudiantes de secundaria.

Preguntas de Investigación y Marco Teórico

Una vez planteada la problemática, en este estudio buscamos dar respuesta a las siguientes preguntas de investigación: 1) ¿Cómo diseñar una secuencia didáctica, mediada por la tecnología, que ayude a los estudiantes a promover sus habilidades de razonamiento proporcional y les permita aplicar el conocimiento adquirido en otros contextos? 2) ¿Qué ventajas (o desventajas) se pueden apreciar en el razonamiento proporcional de estudiantes de secundaria, cuando se les plantean tareas de proporcionalidad con múltiples representaciones y enfocadas a la distinción entre situaciones lineales y no lineales?

Respecto al objeto de estudio, el razonamiento proporcional de los estudiantes de secundaria, tomamos como referencia la base teórica construida por Karplus et al. (1983), Lesh et al. (1988) y Lamon (1994). También, aceptamos como valido el modelo de razonamiento proporcional propuesto por Modestou y Gagatsis (2010), quienes consideran a la distinción entre situaciones lineales y no lineales un aspecto clave del razonamiento proporcional. En este sentido, son fundamentales los estudios sobre la sobregeneralización de la linealidad de De Bock et al. (2002, 2007). Nuestro diseño de tareas busca que los estudiantes desarrollen las habilidades de razonamiento proporcional establecidas por Weiland et al. (2020) y Lobato et al. (2010), las cuales incluyen: 1) Atender y coordinar dos cantidades que varían dependientemente, 2) Distinguir las situaciones lineales de las no lineales, 3) Reconocer y utilizar las estructuras de las situaciones proporcionales (por ejemplo, razón unitaria, constante de proporcionalidad, linealidad), 3) Reconocer el invariante en una proporción, 4) Comprender la proporcionalidad desde múltiples representaciones, 5) Distinguir entre razones y fracciones. Consideramos a estas cinco habilidades como clave para nuestro estudio y son las que invocamos con el término habilidades proporcionales.

Enfoque Metodológico

El proyecto se enmarca en un enfoque de investigación basada en diseño (IBD), según la tradición de Gravemeijer y Cobb (2006), y Bakker (2018). La propuesta de enseñanza consiste en un enfoque socioconstructivista, de acuerdo con Cobb et al. (1992) y Simon (1995). En armonía con el enfoque epistemológico descrito, para la secuencia de actividades de enseñanza utilizamos una trayectoria hipotética de aprendizaje (Simon, 1995). A su vez, el diseño de actividades se basa en los principios de la didáctica de Cuevas y Pluvinage (2003). Acorde con el enfoque de diseño, se pretende innovar mediante la simulación de situaciones reales con tecnología digital.

En el análisis retrospectivo del diseño (análisis de datos) se evalúa la adquisición de habilidades con los niveles de razonamiento proporcional propuestos por Langrall y Swaford (2000), asimismo se buscará incrementar la teoría en esa dirección en función de los hallazgos.

Resultados Preliminares

El primer ciclo se realizó mediante una intervención didáctica presencial en dos grupos de una Escuela Secundaria en México. Participaron en el estudio 35 estudiantes (14-15 años) en el invierno de 2021. La instrucción se dividió en tres sesiones de 90 minutos en un salón de cómputo de la escuela. Cada estudiante contaba con una computadora personal que tenía precargados entornos didácticos virtuales interactivos (EDVI's), en Geogebra. A la par de los EDVI´s cada estudiante contaba con hojas de actividades. Durante las sesiones se promovió un aprendizaje colaborativo y se discutieron las actividades de forma grupal. Nuestro primer ciclo de IBD reveló cuestiones sobre la eficacia de las tareas diseñadas y dio pautas para su rediseño. En general, los estudiantes lograron transitar en las múltiples representaciones de la proporcionalidad y aplicaron habilidades desarrolladas en problemas de aplicación; sin embargo, la evidencia fue insuficiente para hacer afirmaciones contundentes sobre la adquisición de habilidades. Por otro lado, debido a la diversidad de contextos se profundizó poco en la generalización de los modelos matemáticos a los que llegaban los estudiantes.

En cuanto a la influencia de la tecnología en el estudio, es claro que su uso permite simular situaciones cotidianas susceptibles de problematizarse, además de brindar ventajas pragmáticas y epistémicas. El uso de entornos didácticos virtuales interactivos (EDVIS) permitió: presentar al estudiante datos aleatorios, interactuar con los contextos de forma dinámica, mostrar los objetos matemáticos en distintas representaciones y validar los resultados. Los datos sobre la experiencia de los estudiantes con los EDVI's permitieron detectar concepciones erróneas que, probablemente en formas de enseñanza tradicionales, pasarían inadvertidas. Por otro lado, el interactuar con los EDVI´s provocó en los estudiantes un interés que iba más allá del contexto matemático planteado, involucrándose con problemas que se derivaban de las tareas.

THE ROLE OF STUDENTS' GESTURES IN OFFLOADING COGNITIVE DEMANDS ON WORKING MEMORY IN PROVING ACTIVITIES

Vladislav Kokushkin
Virginia Tech
vladkok@vt.edu

The role of individual cognitive differences in doing mathematics has become a significant area of research within the psychology of mathematics education (e.g., Bull & Lee, 2014; De Smedt et al., 2009; Ping & Goldin-Meadow, 2010). Prior literature revealed the importance of working memory (WM) – a mental workspace used by individuals to simultaneously maintain and actively manipulate relevant information when they are engaged in a cognitive task (Baddeley & Hitch, 1974; Daneman & Carpenter, 1980; Ma et al., 2014). WM modulates the number of pieces of information (chunks) an individual can operate on. If the task requires managing too many chunks simultaneously, a learner's WM becomes overloaded and they tend to seek ways to offload some of the information onto the environment (Risko & Gilbert, 2016).

A typical example of cognitive offloading is hand gesturing. Several studies investigated the role of students' gestures in lightening the cognitive load on their WM in the context of elementary mathematics (Alibali & DiRusso, 1999; Cook et al., 2012; Goldin-Meadow et al., 2001; Ping & Goldin-Meadow, 2010; Wagner et al., 2004). However, little is known about the effect of gesturing on students' WM when they are engaged in high-level mathematical activities, proving activities in particular.

Research literature shows that novice undergraduate students work with proofs in different ways than experienced mathematicians. Weber and Mejía-Ramos (2011) observed that, when reading a proof, mathematicians tend to skim the proof and grasp its overall framework before attending to the details. In contrast, novice readers may not have enough expertise to decide what is important to read first and tend to check everything, line by line (Selden & Selden, 2003).

The goal of my dissertation research is to investigate how undergraduate students navigate cognitive challenges in working with proofs. In line with previous research findings, I hypothesize that various strategies in reading, constructing, and presenting proofs pose different cognitive load on a prover's WM (Inglis & Mejía-Ramos, 2021; Selden & Selden, 1999). The requirement to simultaneously store and manipulate a growing amount of information contained in proofs will place a considerable burden on an individual's WM. Therefore, a student will need to find available mechanisms for cognitive offloading. Without being allowed to write or draw, hand gesturing should become the primary way to offload the information onto the environment. Thus, the central research question guiding my study is *how do undergraduate students use gestures to offload cognitive demands on WM when they are engaged in various proving activities, such as reading, constructing, and presenting mathematical proofs?*

Theoretical Framework

In addressing this research question, I adopt an embodied (Barsalou, 2008; Lakoff & Johnson, 1999; Lakoff & Nuñez, 2000; Roth & Thom, 2009; Shapiro, 2007; Varela et al., 1991; Wilson 2002) and Piagetian (Piaget, 1970, 1972) perspective.

Specifically, consistent with the Gesture as Simulated Action framework (Holster & Alibali, 2008), I consider gestures as a unique type of action that plays an important role in students' organization of thought and manifest the embodied nature of mathematical cognition (Alibali & Nathan, 2012). Next, I conceptualize the notion of mathematical proof through Harel and

Sowder's (2005, 2007) transformational proof schemes, according to which the prover is actively involved in operating upon mathematical objects, observing the result, and building upon the proof. Hand gestures allow learners to "act on" abstract objects by simulating motion-based transformations as if these objects were physically present (e.g., Nathan et al., 2021; Williams-Pierce et al., 2017). Finally, I use Pascual-Leone's (1970) neo-Piagetian model of WM. Pascual-Leone asserts that human cognitive performances are products of coordinated sensory-motor activity, and depend on the activation of a set of task-relevant mental schemes. WM capacity is then defined as the number of mental schemes one can activate at a time. The centrality of action in the proposed framework will help to explain the beneficial effect that gestures have on proving mathematical conjectures – by offloading cognitive demands on students' WM.

Data and Methods

I recruited ten undergraduate students enrolled in Introduction to Proofs. Each of them participated in two WM screening assessments: Figural Intersection Task (Pascual-Leone & Baillargeon, 1994) and Direct Following Task (Pascual-Leone & Johnson, 2005, 2010). Based on the results of the assessments, the participants were divided into groups with low (three students; scores 5.5 and lower), medium, and high (three students; 6.75 and higher) WM capacity. Students with low and high WM capacities were invited to participate in five more interviews: three proof-based interviews, a stimulated recall interview, and a post-interview assessment of fundamental number theory concepts and proof techniques.

During the three proof-based interviews, the participants were engaged in reading for comprehension, reading for validation, presenting, and constructing mathematical proofs. The participants were not given calculators, pens, scratch paper, or other figurative materials. Each interview consisted of a number-theoretic and a "geometry-based" task (a conjecture involving mathematical objects, the properties of which can be naturally represented via hand gesturing).

The complexity of each task was conceptualized in terms of its M-demand – the number of schemes it requires to be activated (Case, 1978; Pascual-Leone & Goodman, 1979). I conducted a line-by-line analysis of the M-demands of the tasks based on the hypothetical sequence of mental actions that needed to be carried out to complete the proof. In doing that, I first broke the proof into lines, containing 1-2 mathematical statements. For each line, I counted the number of previous lines involved to make sense of the current line, and the number of contextual schemes that a prover may or may not need to activate when working with the proof. The need to activate these schemes places additional cognitive pressure on the participants' WM. The participants' mastery of these schemes was measured separately in a post-interview assessment.

The described methodology allowed me to identify the places of proofs, in which the experienced M-demand exceeded an individual's WM capacity. If the participant produced a hand gesture (or a sequence of gestures) when working on the target places of proofs, the gesture was labeled as having an offloading purpose. The nature of offloading gestures was then discussed with the participants during the stimulated recall interviews. The intra- and inter-subject analysis of students' gestures is being conducted at the current moment.

Anticipated Contributions

In summary, the most significant contribution of my study is closing the gap in understanding the effect of students' hand gesturing on WM in proving activities. Understanding mechanisms underlying the phenomenon of cognitive offloading will inform undergraduate instruction and help to improve learning conditions for students in advanced mathematics classrooms, which addresses one of the major goals of research in mathematics education.

Keywords: Undergraduate Education; Equity, Inclusion, and Diversity; Systemic Change

Background and Significance

Over the last few decades, the field of higher education has been concerned with the retention of underrepresented students of Color in the science, technology, engineering, and math (STEM fields). STEM identity development has emerged as a useful analytic framework in this research, as students with stronger STEM identities—students who recognize themselves and are recognized by others as "STEM people"—are more likely to persist in the STEM fields (Carlone & Johnson, 2007; Chemers et al., 2011; Malone & Barabino, 2009). STEM identity develops through the process of socialization, in which *agents of socialization* set and maintain the norms, culture, and values that newcomers in the STEM fields should emulate. At institutions of higher education, instructors act as primary agents of socialization (Garibay, 2018) both implicitly and explicitly signaling who "belongs" in the STEM fields, and who doesn't, with Black, Latinx, and Indigenous students often falling into the latter category (Haynes & Patton, 2019; Johnson, 2007; McGee, 2016).

Although mathematics is a gateway into the broader STEM fields (Adiredja & Andrews-Larson, 2017; Leyva et al., 2021), there is a dearth of literature that focuses on undergraduate *mathematics* socialization. Yet, mathematics courses are places where many underrepresented students of Color may experience socialization from their instructors that leads them to decide that they aren't "math people", and thus, are not "STEM people"—leading to their attrition from the STEM fields. Moreover, the role of graduate teaching assistants (GTAs) as agents of mathematics socialization remains unexamined, despite the large role they play in teaching these lower-level undergraduate mathematics courses that are gateway courses into the broader STEM fields (Ellis, 2014; Speer et al., 2005).

Research Question and Guiding Concepts

Given this background and dearth of research on the socializing influence of GTAs in mathematics departments, the primary question that guides this dissertation study is: ***How do GTAs perceive their role as agents of mathematics socialization for underrepresented undergraduate students of Color*?** At the heart of my research question is how GTAs might serve as *gatekeepers* into the culture of the mathematics community at their institution. How do GTAs define the shared values, beliefs, and practices of this culture? How do they identify the ways that these values and beliefs show up in their teaching practices and interactions with underrepresented undergraduate students of Color? How do they articulate and understand their roles as agents of mathematics socialization, and the power and opportunities they have to help underrepresented undergraduate students of Color feel a sense of belonging in undergraduate spaces? What constraints do they face in doing so?

Besides GTAs' individual beliefs, values, and descriptions of their teaching practices, this study also focuses on how race and power operate at a structural level to influence these beliefs, values, and practices, and how these beliefs, values, and practices may be exclusionary to undergraduate students of Color—despite GTAs' intentions. This focus on structurally-amplified effects—rather than individuals' intentions—reflects the study's grounding in Critical Race Theory (e.g. Bell, 1998; Davis, 2019; Delgado & Stefancic, 2017) and Critical Whiteness studies (e.g. Battey & Leyva, 2016; Leonardo, 2004; Matias et al., 2014), which also influence my choice to study GTAs at a historically white institution of higher education (HWI). With these foundational assumptions in mind, this study also draws on both Martin's (2000) framework on mathematics identity and socialization, and Liu's (2017) framework on power governors and privileged spaces to conceptualize mathematics identity as *membership* into mathematics communities as HWIs, and position GTAs as *gatekeepers* into the culture of this community.

Study Design

Due to the focus on values, beliefs, practices, and culture, this critical qualitative study borrows heavily from critical ethnographic methods (Madison, 2020). This study utilized purposeful sampling (Patton, 2014) to recruit ten mathematics GTAs from a large public flagship university that is a historical white institution. Data collection consisted of: (1) initial fieldwork in the mathematics department at the study site, (2) narrative individual interviews with each of the participants, and (3) six weekly focus groups with all ten participants. The initial fieldwork consisted of informational interviews, document analyses, and observations of the physical space of the study site, in order to help build the historical and current context of where participants teach, study, and work. The interviews and focus groups largely centered on how participants view the norms, culture, and values of mathematics, how they have come to these beliefs through their own socialization processes, and how they may perpetuate or seek to disrupt these norms and beliefs as agents of mathematics socialization for undergraduate students of Color. Data analysis will consist of open coding to look for line-by-line emerging themes to create initial codes. Codes will then be refined by looking for patterns and connections among the themes in order to create a codebook (Glesne, 2016). The codebook, as well as the guiding concepts, will be used to conduct "codeweaving" (Saldaña, 2009) in order to interpret and make sense of the findings through the lens of the guiding concepts.

Preliminary Findings and Significance

While data analysis is still ongoing, preliminary themes include (1) a lack of institutional support and disconnect from faculty values (2) colorblind and power-evasive discourse (Bonilla-Silva, 2018) (3) dissonance between intention and practice, and (4) differentiation by race and nationality in opportunities and willingness to learn about and articulate structural racism in mathematics education. As analysis continues, it is important to note that while this dissertation study alone will not fully answer *how* GTAs act as agents of mathematics socialization for undergraduate students of Color, the findings will provide an important foundation to understand the influences that GTAs may have on undergraduate underrepresented students of Color, the opportunities they may have to enact change in mathematics departments, and how they might be supported in doing so. Ultimately, the goal of this study—and the goal of all of my scholarly work— is to build on the current body of critical mathematics education research that seeks to transform mathematics education spaces to be more inclusive and welcoming of underrepresented students of Color. More specifically, this line of research seeks to illuminate how to disrupt the ways in which mathematics socialization might uphold whiteness and perpetuate racism, so that we might better retain, support, and serve underrepresented students of Color in mathematics and the STEM fields, and work towards furthering racial equity and justice in higher education as a whole.

BEYOND PREDETERMINED ANSWERS: WHAT EXPERIENCES AND ENGAGEMENT DO OPEN-ENDED MATHEMATICS TASKS ELICIT FOR PRESERVICE ELEMENTARY TEACHERS?

Emily A. Mainzer
Pennsylvania State University
ead202@psu.edu

Keywords: Preservice Teacher Education; Instructional Activities and Practices; Affect, Emotions, Beliefs, and Attitudes

This dissertation study seeks to qualitatively describe the experiences and engagement of elementary preservice teachers (PSTs) during open-ended tasks. Ball (1990) identified a need to intervene in elementary PSTs' "knowledge, assumptions, and feelings about mathematics and about themselves in relation to mathematics" (p. 13). Open-ended mathematics tasks have the potential to play a role in provoking this break with prior experience. While many tasks in mathematics education have encouraged students to share their own approaches to getting an answer (e.g. Humphreys & Parker, 2015; Parrish, 2014), recently developed open-ended tasks (e.g. Danielson, 2016, 2018; Ray-Riek, 2013) are different in that no set answer exists.

Background and Theoretical Framework

The open-ended mathematics tasks that are the focus of this research include "Which One Doesn't Belong?" (Danielson, 2016), "Notice and Wonder" (Ray-Riek, 2013) and "How Many?" (Danielson, 2018). Practitioner resources have shared anecdotal evidence that these tasks may elicit engagement that is both broader in terms of which students engage and in terms of how they engage (Danielson; Illustrative Mathematics, 2021; Newell & Orton, 2019; Ray-Riek; Rumack & Huinker, 2019). These tasks may elicit similar engagement in PSTs, as it offers them the opportunity to become the "arbiter" (e.g. Dewey, 1934, p. 68) of their own mathematical experience rather than having the outcome set for them from the beginning.

Despite these tasks' popularity in practitioner circles, research into the tasks' impacts is lacking. The use of these tasks meets the criteria for what Matney et. al (2020) called a black hole of research: "an instructional practice for which there is a scarcity of blind-peer-reviewed research evidence supporting its efficacy, yet has attained critical gravity in the teaching field" (p. 247). Existing in a 'black hole' does not mean that an instructional practice or activity has no value; rather, it means that there is a critical mass of something that intuitively attracts practitioners, but research has yet to thoroughly and systematically shed light on it.

Because the use of open-ended tasks have not been thoroughly researched, identifying theory relevant to their potential requires reviewing theoretical and empirical literature regarding phenomena with similar characteristics. This review identifies three theories that provide insight into why these tasks may provoke more frequent and deeper engagement: positioning, aesthetic engagement, and self-determination theory (SDT).

Sociocultural positioning theory posits that at any moment, each member of the classroom (teachers and students alike) is positioning others and being positioned by others (Hand & Gresalfi, 2015; Langer-Osuna & Esmonde, 2017). The teacher's acts of positioning—which includes selection and implementation of tasks—can make certain identities available to students and not others. In other words, "what someone does in a particular activity is always done in relation to what one has opportunities to do" (Hand & Gresalfi, 2015, p. 191).

While positioning helps to explain the opportunities for engagement made possible by open-ended tasks, aesthetic engagement and SDT suggest innate human characteristics with which these opportunities connect. For Dewey (1934), aesthetic engagement was both a universal human need and something which the environment must support in order for it to occur. As Sinclair (2001) noted, "these dual facets—of perception and of action—permit children to become absorbed in and identify themselves with some object or idea" (p. 26). This perspective expands engagement as not only a taking up of, but being "caught up in" (Wong, 2007, p. 209).

The robust empirical basis for SDT (Ryan & Deci, 2017, 2020) strengthens the assertion that there are universal human characteristics and that environmental factors can support the expression of these characteristics. SDT asserts that humans, in addition to having physical needs, have basic psychological needs. When in an environment that supports these needs, "people's curiosity, creativity, productivity, and compassion are most robustly expressed" (Ryan & Deci, 2017, p. 5) The need most relevant to open-ended tasks is autonomy, or the extent to which a person feels regulation over their own experiences and behavior (Ryan & Deci, 2017).

Methodology and Methods

This study seeks to formally research the impacts of a pre-existing phenomenon for which there are already anecdotally reported benefits. As such, it makes sense to not be tied to one methodology, but rather to choose a pragmatic selection (e.g., Coyle, 2010; Frost & Nolas, 2011; Frost et al., 2010; Morgan, 2007) of methodologies and associated methods that are most likely to provide the information needed to address the research question. Drawing upon multiple methodologies—particularly those of ethnography, case study, and grounded theory—allows for seeking participants' perspective of the phenomenon, defining the phenomenon clearly, and providing space to not only understand the phenomenon through the lens of existing constructs but also for new insights to arise.

This study consists of four data collection methods conducted in three sections of an undergraduate elementary math methods course: collection of PSTs' introductory assignments regarding their relationship with math, in-person video-recorded observation of four open task sessions, an open-ended questionnaire, and semi-structured interviews. The instructor for the class will facilitate the PSTs' completion and discussion of the tasks while the researcher observes. After each task implementation, participants will respond to the brief questionnaire. The researcher will interview willing participants to further understand specific instances of their engagement (including video-stimulated recall) as well as their responses to the questionnaire.

Video-recordings, transcripts, and responses to semi-structured questionnaires and interviews will be coded according to existing engagement-related constructs (individual: behavioral, affective, and cognitive; collective engagement; expressions of autonomy; and aesthetic experience). The researcher will also code these items inductively for any new insights that arise. The introductory assignment will be used to provide further background for understanding PSTs' responses on the questionnaire and in interviews.

Importance of Research

This study will have important implications for elementary mathematics teacher education and mathematics education research. It addresses a 'black hole" of research by formally exploring the impacts of an instructional practice lauded by practitioners. In doing so, the study offers a potential opportunity for PSTs to experience mathematics in a different and more holistic way than what they likely experienced in their own K-12 education. Preliminary results suggest that open-ended tasks provoke many PSTs to think and feel about mathematics in a way they have not previously experienced. The openness of the tasks seems to be a significant factor in positioning PSTs in a way that makes these experiences possible.

THE BLACK WOMAN'S TOOLKIT: STORIES OF PERSISTENCE IN UNDERGRADUATE MATHEMATICS COURSES.

Olanrewaju T. Oriowo
University of North Carolina at Charlotte
ooriowo@uncc.edu

Keywords: Equity, Inclusion, and Diversity, Gender, Preservice Teacher Education

This study is an asset-based approach to exploring the experiences of Black women, who are pursuing secondary mathematics licensure, as mathematics learners. The most recent American Community Survey shows that although Black women are making great strides in undergraduate degree attainment, very few were in the field of education and fewer still in mathematics and statistics. Black women accounted for 6.24% of bachelor's degrees in 2020 (NCES, 2022) which is actually about two thirds of the undergraduate degrees awarded to Black students. However, only 3.24% of the degrees awarded to Black women were in the field of education and 0.4% in the field of mathematics and science (NCES, 2022). Since data that drills down to the specific licensure areas for the education degrees is unavailable, we can assume that secondary mathematics education was not a popular choice, implying that the actual percentage of secondary mathematics education degrees might be closer to the proportion of mathematics and statistics degrees.

Research supports the belief that having a teacher or role model who is of the same race or ethnicity has positive implications on students' dispositions, motivation, and achievement (e.g. NCES, 2019; Young et al., 2020). To put this in perspective, 15% of students enrolled in US public elementary and secondary schools are Black or African American (NCES, 2022), 7.5% of public school teachers are assigned to secondary mathematics, and 6.7% of teachers are Black. If we were to assume the proportion of secondary mathematics teachers applies to distributions by race, then we can expect about 0.5% of secondary mathematics teachers to be Black. At this rate, a fraction of a percentage of these students can hope to have a black, female, mathematics teacher over the course of their educational journey.

Young et al. 's (2020) study revealed a discontinuity between the ability of Black girls compared to their participation patterns in Advanced Placement (AP) courses, noting that the mentorship of Black educators can provide the "aspirational role model to emulate" (p. 215). The purpose of this study, therefore, is to 1) contribute to literature that focuses on the successes and persistence of Black women, specifically future secondary mathematics educators, who engage in the study of mathematics at the collegiate level, 2) elucidate the knowledge, skills, and resources that these women leverage in order to find that success, and 3) gain insight into ways that teacher preparation programs can recruit more Black women into mathematics education programs and create learning environments that are inclusive and that support the development of a robust mathematics identity.

I focus on the experience of the first, credit-bearing, undergraduate mathematics course in this study because mathematics courses are very important gatekeepers to continued participation in STEM and, by extension, other mathematics-related programs (such as secondary mathematics education) in many universities (Ellis et al., 2014; Tao & Gloria, 2018) and therefore an important site to examine for critical experiences that help or hinder the uptake of secondary mathematics education as a course of study. I define persistence as continuing the journey to degree attainment as a secondary mathematics education major (or minor, depending on the institutional program structure).

The two overarching research questions guiding this study are as follows:

1. When sharing stories of persistence and success in the first undergraduate mathematics course, which cultural capital do Black girls who are Secondary Mathematics Education majors, believe was instrumental in that success?
2. How do the counternarratives of the participants compare and contrast in terms of their capital?

Using a counternarrative research design, I propose to engage narrators in the reflective telling of mathematics learning experiences before, during, and after a particular event: the first, credit-bearing mathematics course taken at their current 4-yr institution as a requirement for their major. I chose Counternarrative Inquiry, not only because it allows attention to the ways in which marginalized peoples are resisting derogatory dominant narratives (Mertens, 2020), but because it also preserves the voice of the participants, which is vital for this study and is aligned to the theoretical framework. I will use Yosso's (2005) Community Cultural Wealth (CCW) as the analytical framework, applying it through a lens of Critical Race Theory (Bell, 1995; Delgado & Stefancic, 2017) and Black Feminist Thought (Collins, 2015; Combahee River Collective, 1977), to draw attention to what is revealed in the stories told by the narrators.

Preliminary findings from a pilot study reveals that aspirational capital, defined as the "the ability to maintain hopes and dreams for the future, even in the face of real and perceived barriers…this resilience is evidenced in those who allow themselves…to dream of possibilities beyond their present circumstances" (Yosso, 2005, p. 77-78), is a fundamental anchor is the persistence of the two Black women participants. Social capital, which is derived from networks of peers and the community that provide emotional and instrumental support (Yosso, 2005), is notable in its limited use towards success. It is especially evident when participants tell stories about classroom experiences, stories that highlight an isolation and loneliness that has been reported in several research studies (e.g., King & Pringle, 2018; Marra et al., 2009, etc.).

Where there have been several studies documenting the underrepresentation of Black women in undergraduate and graduate STEM and STEM-related disciplines (Alexander & Hermann, 2016; Ellington & Frederick, 2010; Haynes et al., 2016), asset-based studies that attend to the experiences and barriers that begin to offer insight as to sociopolitical and cultural factors that surround how Black women experience mathematics are relatively few (King & Pringle, 2018; Lim, 2008; Young et al., 2018). Per Young et al.'s (2020) recommendation, this study will contribute to the body of research that attends to sociocultural hurdles that Black girls and women overcome en route to success.

INTEGRATING SPATIAL REASONING INTO EARLY CHILDHOOD CLASSROOMS: AN INTRAPRENEURIAL APPROACH TO SPATIALIZING THE CURRICULUM

Robyn K. Pinilla
Southern Methodist University
rpinilla@smu.edu

Keywords: Geometry and Spatial Reasoning, Early Childhood Education, Instructional Activities and Practices, and Curriculum

Spatial reasoning comprises a vital set of skills for development in science, technology, engineering, arts, and mathematics (STEAM) domains (Lord & Rupert, 1995; Wai et al., 2009) that support mathematical and academic achievement (Duncan et al., 2007) but is rarely taught in early childhood classrooms (Clements & Sarama, 2011; Moss et al., 2015). Many factors may influence teachers enacting spatial reasoning instructional practices, including the professional learning opportunities they have experienced (Horn & Garner, 2022; Putnam & Borko, 2000), the tools to which they have access (Kazemi & Hubbard, 2008; Lave & Wenger, 1991), and their knowledge of and beliefs about teaching spatial reasoning (Ball et al., 2008; Batista et al., 1982; Skott, 2013). This study seeks to address the problem that we do not have a clear picture of how, or if, early childhood teachers enact spatial reasoning instructional practices by considering how professional development (PD), tools, and teachers' knowledge and beliefs interact with teaching practice to develop ways of supporting teachers' situated learning for teaching spatial reasoning.

This research aims to develop a local theory of situated teacher learning specific to learning and enacting spatial reasoning instructional practices (see Figure 1; Cobb et al., 2003) and a suite of pedagogical tools (Putnam & Borko, 2000) to support those enactments. The proposed situated teacher learning and practice model is adapted from Clarke & Hollingsworth's (2002) model of teacher growth. It specifies conjectured domains contributing to teacher learning and practice, and will undergo iterative refinement using design-based research methods (Cobb et al., 2003; Sandoval, 2014) as responsive to the research context. Simultaneously, tools related to enacting spatial reasoning teaching practices will be developed in context as pedagogical tools (Putnam & Borko, 2000). By developing this local theory and tools to support teacher learning, I aim to answer the question: How can we support early childhood educators in enacting spatial reasoning teaching practices?

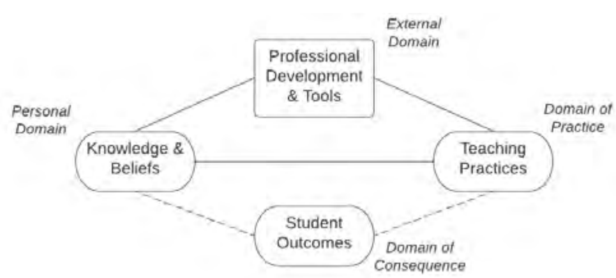

Figure 1: Proposed Model of Situated Teacher Learning & Practice

Methods

This study is conducted at a local STEM-focused elementary school and employs design-based research methods (Cobb et al., 2003; Sandoval, 2014) within a descriptive case study (Merriam, 1998; Yin, 2009). The case will be bounded by grade levels within the school, specifically kindergarten and first-grade, and design iterations will focus on leveraging an open-source curriculum aligned with state and national standards for teaching spatial reasoning. Kindergarten and first-grade teachers will be new to the building in fall 2022, which, combined with the school's inquiry learning framework and adoption of an open-source mathematics curriculum, offers a unique opportunity to spatialize a standards-aligned curriculum by offering a companion guide to typical mathematics instruction. Data collection will occur concurrently with summer and fall semester professional learning opportunities for situated teacher learning about spatial reasoning in which they will collaboratively construct pedagogical tools to enact spatial reasoning teaching practices (Horn & Garner, 2022; Moss et al., 2015). Given the school calendar and professional learning session structures, I anticipate three opportunities for group professional learning with individualized coaching occurring more frequently.

Using semi-structured interviews (Merriam, 1998), I will collect data on in-service teachers' background knowledge and beliefs about teaching spatial reasoning and their experiences with professional development that could support their enactment of spatial reasoning teaching practices. These interviews inform two learning components within the proposed model of situated teacher learning (i.e., the external and personal domains; see Figure 1). I am also creating a companion guide for the kindergarten and first-grade mathematics curriculum with representations and extensions. Pending school district approval, I will observe teachers enacting spatial reasoning instruction within typical mathematics instruction. I will also conduct debrief interviews to elicit feedback after teachers enact recommended practices in the classroom for personal reflections that will be used to triangulate findings and support internal validity and trustworthiness of findings (Merriam, 1998). Data collection and analysis will occur recursively to inform revisions to the research design and suite of tools as I learn how to better support teachers' spatial reasoning instructional practices.

Data Analysis

I will use iterative rounds of qualitative data analysis to explore how researchers can support early childhood teachers in enacting spatial reasoning teaching practices. I will apply a priori provisional codes based on learning components in the proposed bidirectional model of situated teacher learning while reading sources and recording preliminary jottings (Saldaña, 2016). I conjecture that data might inform multiple components and will therefore employ simultaneous coding (Miles et al., 2014) of passages that align with inclusion into multiple a priori descriptive codes. I will then engage in open coding to locate emergent themes using methods most appropriate for each data source type. Interviews will be coded using In Vivo coding methods (Saldaña, 2016) to develop codes and themes that can then be supported by descriptive statistics emerging from survey data of teachers' perceptions about enacting spatial reasoning instruction. Between iterative coding rounds, member checking will ensure accurate capture of teachers' perspectives and provide opportunities to integrate revisions (Merriam, 1998).

Results and Implications

This in-progress research contextualizes Horn and Garner's (2022) work on teacher learning using a sociocultural approach to create a local theory for early childhood teachers' enactment of spatial reasoning instruction. Given that current educational standards minimally mandate spatial reasoning skills instruction (National Research Council, 2006), we must understand how spatial reasoning aligns with our current curricular requirements to provide opportunities for teachers and students to learn these critical skills (Clements & Sarama, 2011). The proposed theoretical framework could guide future research to design professional learning opportunities and tools for teachers' use to leverage their knowledge and beliefs to teach spatial reasoning.

DESCRIBING THE MATHEMATICAL MODELS UNDERGRADUATE STEM MAJORS CONSTRUCT DURING MODELING TASKS.

Elizabeth Roan
Texas State University
Eaw109@txstate.edu

Keywords: Modelling, Undergraduate Education, Mathematical Representations

Mathematizing (the process of transforming a real-world situation into a mathematical model) receives a lot of attention in modelling literature because it is difficult for students. (Galbraith & Stillman, 2006; Jankvist & Niss, 2020). Many existing studies further our understanding of participants' difficulties with mathematizing by characterizing the "blockages" that occur (Brahmia, 2014; Stillman & Brown, 2014). While these studies adequately describe the blockages in terms of student knowledge, the field would benefit from a study of the mental processes that may be important for participants to productively engage in while mathematizing. Such mental processes would include quantitative reasoning and associated theories such as covariational/multivariational reasoning. Framing *mathematizing* this way is appropriate because previous studies focused on quantitative reasoning have indicated that quantitative reasoning promotes mathematization (Ellis, 2007; Ellis, Ozgur, Kulow, Williams, & Amidon, 2012; Mkhatshwa, 2020). Additionally, researchers have suggested that quantitative reasoning is a lens with which to understand participants' mathematical reasoning about real world scenarios (Carlson, Larsen, & Lesh, 2003; Czocher & Hardison, 2021; Larson, 2013). In order to provide theoretical structure for and empirical evidence of the cognitive sources of students' blockages, as well as give consideration to how facilitators could help students overcome them, I will be analyzing STEM undergraduates' mathematization in terms of mental processes rather than actions and behaviors. Thus, the goal of this study is to answer the research question: "How do the mathematical models undergraduate STEM majors construct during mathematization arise from their quantitative, covariational, and multivariational reasoning?" The study will extend the field's understanding of quantitative, covariational, and multivariational reasoning by applying those theories in a novel demographic doing modeling tasks. Additionally, it will extend findings on STEM undergraduates' understandings of differential equations (Arslan, 2010; Rowland & Jovanoski, 2004) by stating a participant's meaning for the differential equation they constructed and its terms. Finally, the results will inform development of instructional materials based on participants' already-existing ways of thinking rather than promoting specific behaviors.

Theoretical Framework

My theoretical framework synthesizes five interrelated constructs/theories: quantitative reasoning, covariational reasoning, multivariational reasoning, schema of action (SoA), and mathematical modeling. Quantitative reasoning is "the analysis of a situation into a quantitative structure- a network of quantities and quantitative relationships" (Thompson, 1993), where a quantity is a triple consisting of an object, attribute, and quantification. Covariational reasoning is defined as "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (Carlson et al., 2002, p. 354). Multivariational reasoning is the extension of covariational reasoning to two or more varying quantities (Jones, 2018). An SoA is defined as an organized pattern of thoughts or behaviors that can be applied to different cognitive objects in different situations (Nunes & Bryant, 2021). Lastly, a mathematical model is a conceptual system consisting of elements, the relationships among elements, operations, and rules of governing interactions. Because a mathematical model is a conceptual system, it is held, at least partially, internally and is expressed into the world through different representations, which are dictated by a participant's use of any external notation systems (Lesh & Doerr, 2003). Synthesizing these theories: (1) The elements of a mathematical model can be characterized by the quantities participants construct/impose onto the task scenario. (2) The rules governing the relationships and interactions between elements can be characterized by an individual's quantitative, covariational, and multivariational reasoning. (3) The operations on the quantities are determined by the SoA's employed by the STEM undergraduates to justify those operations.

Methods

The data collection for this study is part of a larger study of facilitator scaffolding moves that improve participants' mathematical modeling competencies. The data come from task-based interviews designed to evoke complex thought processes where the interviewer's role is to elicit complete coherent reasons the participants give for their own activities (Goldin, 2000). In the larger study, participants will be given at least six tasks over ten sessions. I will curate data from the sessions corresponding to three different dynamics scenarios common to differential equations (Cats & Birds (lotka-volterra predator-prey model), Tropical Fish (net rate inflow-outflow), and Ebola (SIR disease transmission model)). I choose these tasks because they invite different ways of constructing quantities and uses of quantitative operations. Additionally, dynamic tasks elicit dynamic reasoning, which is connected with quantitative reasoning and covariational reasoning (Keene, 2007). Probing questions like "What does <quantity> mean to you?", and "Why did you choose to <add/subtract/multiply/divide> <quantity> and <quantity>?" will bring out the participants' rationales for associating specific elements of the scenarios with the arithmetic operations they choose (that is, mathematization).

In the initial phase of analysis, I will go through the transcripts and written work to identify instances where participants: discuss their conception of a quantity, justify the usage of arithmetic operations, or reason about a quantity's values co-varying/multi-varying with other quantities. For each instance, I will identify the quantities participants construct/impose onto each task scenario by noting the object, attribute, and documenting evidence of quantification using the quantification criteria developed by Czocher and Hardison (2021). I will then document levels of covariational reasoning (Thompson & Carlson, 2017) and types of multivariational reasoning (Jones, 2018; Kuster & Jones, 2019; Panorkou & Germia, 2020) used with the quantities. I will then examine moments when a participant uses an arithmetic operation $(+, -, \cdot, \div)$ and its associated SoA. In some cases, the participant may give an explicit reason for using the operation and in others I may need to infer it based on data from previous tasks. I will use the SoA's documented in Thompson (2011), and Nunes and Bryant (2021) and extend those lists as needed. Each model a participant develops will be characterized by the quantities present in the model, including how each quantity was derived, the covariational/multivariational reasoning used with each quantity, and the SoA the participant used when using arithmetic operations with the quantities they deem relevant to the scenario. This will yield descriptions of how participants transform the quantities they impose onto a situation into mathematical representations via participants' quantitative, covariational, and multivariational reasoning. By performing this analysis across tasks and across participants, I will be able to provide evidence of the mental processes participants engage in while mathematizing different dynamic scenarios.

Acknowledgments

Research that will be reported in this paper is supported by National Science Foundation Grant No. 1750813 with Dr. Jennifer Czocher as principal investigator.

FOSTERING A GROWTH MINDSET IN MATHEMATICS: FACULTY AND STUDENT EXPERIENCES

Yolanda G. Rush
Illinois State University
ygrush@ilstu.edu

Tami S. Martin
Illinois State University
tsmartin@ilstu.edu

Keywords: Affect, Attitude, and Beliefs.

A major hurdle for students at two-year institutions is to complete developmental (remedial) or transfer-level (credit-earning) mathematics courses with a grade of C or better. A national study revealed that about 68% of students at two-year institutions take remedial courses (Chen, 2016). Some students take two or three remedial courses consecutively and only about 11% of those students pass their transfer level “gateway” course (Jaggars & Stacey, 2014). As the name implies, gateway courses are used as a prerequisite to enter many majors. College algebra is one such gateway course (Giang-Nguyen, 2015; Tunstall, 2018) and nearly 1/3 of the college algebra enrollments occur at two-year institutions (Bressoud, 2021). However, college algebra has only about a 50% pass rate (C or better) (Giang-Nguyen, 2015; Okello, 2010). Further, many college algebra students fear mathematics and have their performance influenced by prior experiences in mathematics (Herriot, 2006).

Affective factors—in particular, mindset and self-efficacy—may play a vital role in the success of students at two-year institutions (Center for Community College Student Engagement (CCCSE), 2019). Specifically, researchers have found that mindset interventions can influence students to seek help (Shively & Ryan, 2013), increase perseverance, and lead to lower failure rates in mathematics (Lewis, 2019). In addition, Auten (2013) found that mindsets of students and teachers play a vital role in students’ academic success at community colleges. Although previous work has examined student achievement after mindset interventions (Aronson et al., 2001; Blackwell et al., 2007; Steele, 2007), few studies have documented the experiences of two-year college students and their instructors while they are enrolled in courses that attempt to foster growth mindsets. Knowing more about college students’ experiences, personal views, motivations, attitudes regarding mathematics (Mesa, 2017), and faculty members’ perceptions as they work to implement strategies aimed at fostering growth mindsets in their students would provide evidence about which factors contribute to the effectiveness of mindset interventions. Rather than focusing on the outcome of mindset intervention, I seek to understand the process of attempting to positively affect students mindsets and self-efficacy beliefs.

Thus, my research questions are: (1) How does each instructor approach and implement growth mindset components into their courses? (2) What do two-year college instructors report about their experiences during the process of developing and implementing strategies for fostering growth mindset in their developmental courses and how do they perceive the effects of their approaches on students? (3) What do two-year college students report about their experiences and effects on mindset and self-efficacy beliefs as they engage with their instructors’ who are attempting to foster a growth mindset in their developmental courses?

This will be a qualitative study with a conceptual framework based on a constructivist paradigm and mindset theory. The constructivist paradigm—the belief that learners (students and teachers) will construct their own understanding through experiencing and reflecting on experiences (Lerman, 1989)—will be used as a lens through which to investigate how students and teachers construct their own understanding of growth mindset beliefs as they interact in mathematics classrooms geared toward fostering growth mindset beliefs.

Mindset theory is based on the idea that people hold different beliefs about whether certain attributes (e.g., intelligence and personality) are malleable. People form implicit theories based on their goals and how they interpret the outcomes of their efforts (Bernecker & Job, 2019; Dweck, 2006). A growth mindset (incremental theory) is based on the belief that intelligence is malleable and can be grown through effort and guidance, while a fixed mindset (entity theory) is based on the belief that each person has only a certain amount of talent or intelligence (Dweck, 2006). In learning and performance, people with growth mindsets are open to change; they see failure or adversity as the need to put forth more effort (Bernecker & Job, 2019); and compared to people without growth mindsets, their goals are more aimed at improvement (Dweck, 2006). In this work, mindset theory will serve as a lens through which to view students' and teachers' perspectives about their experiences, as teachers attempt to foster growth mindset beliefs in their students over the course of one semester.

Self-efficacy beliefs can play a major role in the actions of students. Self-efficacy is the belief in one's capability of "organizing and executing" a plan to reach a certain goal (Bandura, 1997, p. 3). This belief can influence one's effort, the amount of time they are willing to spend on a task, and how long they are willing to persist when faced with failure or obstacles (Bandura, 1997). My goal is to determine whether students' self-efficacy beliefs were influenced as they engaged in a classroom that fostered growth mindset beliefs.

In this case study, I will focus on one to three two-year college instructors who are teaching a developmental mathematics course and some of their students. The developmental mathematics course is specifically designed for students whose next mathematics course is college algebra. I will work with the participating instructors to develop approaches for promoting growth mindsets in their students. I will document the instructor collaboration process from my own perspective and instructors will keep weekly journals to document their experiences. Before and after the semester, I will interview the instructors and some of their students, regarding their perceptions about the course, their prior experiences, and their mindsets related to mathematics. For the students only, I will also ask about their mathematical self-efficacies. I will use surveys to assess mindsets of instructors, and mindset and self-efficacy beliefs of students before and after the semester. The survey questions I intend to use are designed to measure mathematical mindsets and mathematical self-efficacy beliefs on a 5-point Likert scale (Rothrock, 2019; Williams, 2015). Student responses will be used to determine if there were shifts in mindset and self-efficacy beliefs during the semester.

This research is important because it builds on past work that has investigated student mindset and self-efficacy at the collegiate level and additional work on effectiveness of growth mindset interventions. In particular, this study will fill a gap in existing research by examining the process of fostering growth mindset beliefs in the mathematics classroom from both instructor and student perspectives. Most community colleges have not implemented the much-needed direct efforts to influence mindset and self-efficacy (CCCSE, 2019), and it is important to learn more about two-year college students' experiences and personal views within the mathematics classroom, and faculty members' strategies (Mesa, 2017). Therefore, my study will capture how instructors experience their work attempting to foster growth mindsets in their students, and how students perceive the effects of those efforts. This study will add to the literature about mindset studies in mathematics at community colleges by documenting the perceptions and experiences of students and instructors in their work on mathematical mindsets.

A CASE STUDY APPROACH TO INCONGRUOUS MATHEMATICS SELF-EFFICACY IN UNDERGRADUATES: A SUMMARY OF DISSERTATION RESEARCH

Bridgette E. Russell
Central Michigan University
buse1b@cmich.edu

Christine M. Phelps-Gregory
Central Michigan University
phelp1cm@cmich.edu

We have all encountered students who seem over- or under-confident in their skills. For example, the student who is confident they will do well but fails every exam. Or the student who repeatedly worries of failing yet gets 100% on every exam. These students have incongruous mathematics self-efficacy. Mathematics self-efficacy (MSE) is a person's beliefs about their ability to succeed in mathematical activities. Incongruous math self-efficacy (IMSE) is when a person's MSE and their abilities do not match to a significant extent.

Background and Theoretical Framework

Self-efficacy is defined as a person's beliefs about their ability to complete a particular task (ranging from a problem to a full course) (Bandura, 1986). Much research has been done on self-efficacy and its predictive power in student success (e.g., Bandura, 1986; Hackett & Betz, 1982; MacPhee et al., 2013; Zeldin et al., 2008). This research suggests that a student's self-efficacy is directly correlated to their success in mathematics, their career choices, and their success within their career (e.g., Buschor et al. 2014; Hackett, 1985; Hackett & Betz, 1989; Pajares & Miller, 1994). Research suggests, however, that some students are overconfident, and some are underconfident; that is, some students have IMSE, also called "feeling-of- knowing accuracy" or calibration (Schraw, 1995; Pajares & Miller, 1994). These terms have been used to describe a disconnect between a person's self-efficacy beliefs about a topic and their abilities as measured through assessments (e.g., Stolp & Zabrucky, 2009; Sheldrake, 2016)

More research is needed on IMSE; in particular, qualitative work with undergraduate students is often lacking in the literature. Much of the current literature is quantitative in nature (Labuhn et al., 2010). In addition, much of the work on IMSE is much focused on K – 12 students, as well as teachers (e.g., Chen, 2006; Dassa & Nichols, 2019; Labuhn et al., 2010). When looking at the population of undergraduate students there is even less focused on IMSE (Morán-Soto & Benson, 2018), even though undergraduates differ in significant ways from K – 12 students, particularly in their need for self-motivation.

My dissertation study will focus on undergraduate students in an intermediate algebra course. The following research questions will guide the study. **Research question 1:** What are the global and problem focused mathematics self-efficacy beliefs of undergraduate students in an intermediate algebra course? **Research question 2:** For these students, what is the relationship between problem focused self-efficacy beliefs and performance on a given set of problems? **Research question 3:** For these students, what is the relationship between global mathematics self-efficacy beliefs and performance on an exam in their course? **Research question 4:** For these students, what changes occur in the global and problem focused mathematics self-efficacy beliefs before and after a mastery experience (exam/problems)?

Methods

Using the pilot study as a foundation, students from intermediate algebra will be selected based on an initial survey assessing their MSE beliefs and mathematics history. Fifteen participants will be selected based on their MSE scores, selecting for variation in MSE. They will then be interviewed before their exam. The first interview will follow a semi-structured in-depth format and ask for a more detailed mathematics history focusing on MSE beliefs in the participants' own words. During interview 1 there will also be a problem focused section where the participants will be asked their MSE for three problems from their course work and then be asked to solve the problems. A second survey will be administered after the participants have taken their first exam, but before their grades are returned. This survey will ask participants how they feel about the exam, and their predicted results. After their grades are returned, a second interview will be conducted to assess the participants' predicted results compared to their actual results, and any changes to their MSE beliefs.

Preliminary Findings and Anticipated Results

The purpose of this study is to identify students who display the characteristics of IMSE and to examine their understanding of this misalignment. In doing so, I hope to uncover more about the MSE beliefs of undergraduate students in an intermediate algebra course.

In terms of research question one, in my pilot study I found a range of MSE beliefs, both global and problem focused. Out of the five participants, four expressed moderate to high global MSE beliefs. Across the three problems participants solved in interview one, participants seemed to have more confidence with computational problems, versus word problems, and there was evidence of IMSE in the problem focused self-efficacy ratings, with participants being confident in their answers and getting them wrong, as well as not being confident in their answers, and getting them correct. In my larger dissertation study, I anticipate a broader range of MSE beliefs, as well as more instances of IMSE beliefs. I am also interested in a potential connection between participants' global MSE beliefs and their problem focused MSE beliefs.

In terms of research question two, in my pilot study students' global MSE aligned with their problem performance. There were, however, instances of problem focused IMSE identified in all participants who completed the study. For one participant in particular, Gabrielle, she expressed high confidence on the more difficult computational problem but was incorrect in her solution; she then expressed low confidence in the word problem and was the only participant to get it correct. In my dissertation study, I anticipate finding more cases like Gabrielle.

In terms of research question three, in my pilot study, participants overestimated their performance on the exam. No participant passed the exam; however, all but one participant thought that they would pass. Participants did tend to hedge their predictions. In my dissertation study, I expect to find more instances of IMSE and hope to examine the relationship between global MSE beliefs of students and final course grade. I also hope to find students who underestimate their performance and see how their data compares.

In terms of research question four, in my pilot study there was little to no change in students' global MSE or course grade predictions before and after the exam. There was, however, change in the participants' problem focused MSE especially related to the easier computational problem and the word problem. Before solving these problems, students would rate them as very difficult, but then after solving would rate them as less difficult. In my dissertation study, I anticipate finding similar results. I hope to find more instances of global MSE changes based on exam performance, and how this might be related to final course grade performance.

Implications

This work has important implications for research and practice. In particular, we hope to expand the current understanding of the relationship between performance and MSE by providing qualitative case studies of instances of IMSE. In addition, there are practical implications from having an improved understanding of these relationships, particularly for helping students better judge their own expected performance and their need for additional study.

ASSESSING PRESCHOOL TEACHERS' SELF-EFFICACY AND ATTITUDES TOWARD STEM THROUGH A PROFESSIONAL DEVELOPMENT PROGRAM

Hannah Smith
Worcester Polytechnic Institute
hsmith2@wpi.edu

Background of the Project

The importance of integrating STEM education into preschool classrooms has been echoed across contexts (National Research Council, 2011; Chesloff, 2013). However, teachers' low confidence and negative attitudes toward STEM, combined with few opportunities for professional development (PD), have resulted in an avoidance of STEM teaching (Timur, 2012). Effective PD programs provide opportunities to improve teachers' confidence and attitudes toward STEM and are crucial to the success of preschool programs (Hamre et al., 2017). Prior studies have shown that effective PD includes developmentally appropriate instruction, individual coaching (Bowman, 2001), group-focused interventions (Ginsburg et al., 2006), and modeling instruction (Wasik et al., 2006). However, PD workshops may provide only one of the aspects mentioned above which is inadequate and may not be high quality (Gomez et al., 2015). Further, common PD programs for preschool teachers lack research-based practices and are not monitored for content and effectiveness (Gomez et al., 2015).

Goals of the Research

The goal of the current project is to assess the effectiveness of a PD program exposing Head Start preschool teachers to STEM. This program uses research-based practices and combines the use of developmentally appropriate activities, group sessions, individualized coaching, and modeling instructional practices. Further the program is comprehensive and long term, which allows for greater growth among our teacher participants and connection with teachers. Through the program, I aim to increase teachers' attitudes and self-efficacy towards STEM teaching, increase their ability to recognize STEM activities in their teaching, and expand current curriculum to incorporate more STEM activities. As part of a research fellowship with the AIMS (Activities Integrating Math and Science) Center that focuses on increasing STEM in classrooms through PD, I am working with a team to design and implement a six-month PD program with preschool teachers focused on increasing STEM activities in their classrooms. For my dissertation, I am leading the research behind the PD program to investigate the following research questions: 1) How do teachers' self-efficacy and attitudes toward STEM change after participating in the PD? 2) In what ways do teachers expand and implement activities presented in the PD? 3) What aspects of the PD lead to the greatest growth in teachers' use of STEM activities in their classrooms?

Methodology

The current project will provide STEM PD for a Head Start preschool site. Participants include 26 California Head Start preschool teachers who teach 131 children in 8 classrooms with each classroom having 2-4 teachers. This PD program will take place over 6 months, beginning in January 2022, with each month covering a different module and focus: patterns, spatial communication, movement, board games, robots, and coding. Each module will follow the same format and consist of a 2-hour professional learning (PL) session, classroom integration of what was learned in the PL session with follow up individualized coaching, and a family engagement section with take home kits for each child around the module's topic. I will be focusing on studying the program, as well as the PL sessions. To study the implementation of the program, I will analyze survey and interview responses. I will also review participants' responses and interactions during the PL sessions, as well as researcher field notes of the sessions. Prior to the beginning, and after completion of the 6-month PD program, teachers will complete a 5-point Likert scale survey to uncover their attitudes and self-efficacy around teaching STEM. This survey was created by combining the Early Childhood Teacher's Attitudes toward Science Teaching Scale (Cho, 2003) and two sections of the Teacher Efficacy and Attitudes Toward STEM (T-STEM) Survey (Friday Institute for Educational Innovation, 2012). Additionally, teachers will fill out a 4-question open-ended reflection worksheet at the end of each PL session asking: what they enjoyed about the session, what was difficult and challenging about the session, how researchers could more effectively lead the session in the future, and a final question specific to each module. For example, the question for the pattern module is: "What patterns are you now noticing in your daily life? Personal experience? Community?" A subset of 10 teachers will also participate in 20-minute exit interviews asking about their overall experience with the program, classroom implementation, expansion of activities, and growth as a preschool teacher of STEM. PL worksheets, interviews and researcher field notes during the sessions will be qualitatively coded to find common themes. I will also include measures of fidelity of the program including number of PL sessions attended, coaching sessions attended, and completion of worksheets. Analyzing these data sources will help us determine the effectiveness of the program. Specifically analyzing the survey responses before and after completing the program will allow us to assess teacher growth in self-efficacy and attitudes toward STEM teaching. By examining the worksheets, interviews and field notes I will be able to detect common themes around how teacher's ability to recognize STEM improved as the program continued and whether they felt as if they had improved in this competency. I will also be able to analyze how teachers were able to implement the activities from the sessions into their classroom and expand on these activities.

Preliminary or Expected Findings

I expect to see increases in teacher attitude and self-efficacy toward STEM as measured by the Early Childhood Teacher's Attitudes toward Science Teaching Scale and the T-STEM Survey. I will run repeated measures t-tests to assess growth in these surveys. To assess whether a teacher's abilities to recognize STEM in their teaching as well as expand their current curriculum to include STEM, the worksheet responses, exit interview responses and field notes will be examined. I also expect to see teachers develop an increased awareness of the ways children learn and experience STEM in the preschool classroom.

Expected Contributions

This dissertation work will have direct contributions to the teachers and their students who participated in this professional development program. As a research practice partnership study, one of the main goals is to provide impact to educators and their students. In addition, this work will examine the effectiveness of this program and provide recommendations for future preschool professional development programs. This will also provide further insights into how we can best increase STEM in preschool classrooms and increase teachers' attitudes and self-efficacy towards STEM.

SECONDARY MATHEMATICS TEACHERS' DECISION-MAKING WITH ONLINE SOCIAL JUSTICE-ORIENTED CURRICULAR MATERIALS

Anita Sundrani
University of Houston
asundrani@UH.edu

Keywords: Curriculum; Equity, Inclusion, and Diversity; Social Justice; Technology

Introduction

As culturally responsive frameworks and anti-bias resources become more commonplace, mathematics teachers across the United States are increasingly seeking content from the internet as they plan their lessons (Gewertz, 2015; Timberlake et al., 2017). However, there is mounting evidence that resources from online spaces may not be standards-aligned, developmentally appropriate, equity-based, or even accurate (Gallagher et al., 2019; Greene, 2016). Still there are teachers who are able to discern high quality and social justice-oriented resources embedded in critical pedagogy that lead to positive student academic, cultural, and affective outcomes. To date, there has been little investigation into secondary mathematics teachers' decision-making processes when selecting which materials to use from online spaces and even less about choosing critical content centered around teaching mathematics for social justice. Therefore, the goal of this project is to explore mathematics teachers' decision-making processes when planning and enacting social justice-oriented mathematics lessons from online spaces.

Background & Theoretical Perspective

Previous studies have investigated how in-service and pre-service mathematics teachers design, implement, and revise lessons centered around social justice (Harper et al., 2021; Myers, 2019). While these studies referenced sources linked to online spaces, they did not interrogate the decision-making processes of the participants as they navigated these spaces.

This study draws from the theoretical frameworks of teacher decision-making and critical mathematics education to investigate how secondary mathematics teachers engage with these spaces, make decisions to use certain materials, and enact these instructional resources in the classroom. Remillard and Heck's (2014) model of the curriculum enactment process provides insight into what factors influence teachers' decisions when using curriculum. A focus on critical mathematics provides a lens into how educators who teach mathematics for social justice approach curricular content from online spaces when planning and enacting their lessons.

Critical Mathematics Educators' Decision-Making

Over the past decade, researchers have begun to explore the decision-making processes of social justice and critical educators. King and Nomikou (2018) linked the ideas of decision-making and teacher agency by suggesting that educators are more apt to take risks in their decision-making if they feel they have more autonomy and agency over their work. MacPherson (2010) investigated eight different decision-making orientations that pre-service teachers take up when teaching culturally and linguistically diverse learners. In her study, Bartell's (2013) participants felt that one of the challenges of TMSJ was making the decision of how to balance social justice with mathematics content. These previous findings suggest that research on decision-making throughout the curriculum enactment process in critical mathematics education still needs to be explored.

Methods

The following research questions will guide my exploration.

1. How do secondary mathematics teachers engage with online spaces when searching for critical mathematics content?
2. What are secondary mathematics teachers' decision-making processes when choosing online materials to teach and/or supplement their curriculum in critical ways?
3. How do secondary mathematics teachers enact critical mathematics content found from online spaces in their classrooms?

Research Design & Data Collection

A sample of secondary mathematics teachers will be recruited from across the United States based on recommendations from critical mathematics education scholars to take part in a multiple-case study (Yin, 2009). As part of phase I of study activities, the participants will be given a demographics survey, asked to provide three social justice-oriented mathematics lesson plans, and interviewed about their interactions with online spaces during lesson planning. During phase II, teachers will be asked to keep a journal as they plan for one social justice-oriented lesson. A semi-structured interview will take place prior to enacting this lesson in the classroom. For phase III, I will visit the participants' schools to observe the lesson plan that was discussed via Microsoft Teams to see how the lesson is enacted in the classroom. At the end of the school day, the teacher will be interviewed to learn how the lesson plan was enacted in the classroom and understand the teacher's in-the-moment decisions.

Data Analysis

To answer RQ1 and RQ2, I will provide a summary of the participants' demographics, including the school characteristics, teacher characteristics, and course information. I will also provide response-level excerpts open coded using an In Vivo approach (Saldaña, 2013) from all interviews and the planning journals. These codes will be analyzed using Remillard and Heck's (2014) model of curriculum enactment and categorized by common characteristics of critical mathematics teachers based on literature (Gutiérrez, 2012; Gutstein, 2006; Ladson-Billings, 1995). Additionally, data gathered from all lesson plans provided will be analyzed using an appropriate lesson plan analysis protocol selected through relevant literature (Hu et al., 2019).

To answer RQ3, I will first open code the data gathered from the lesson planning observations based on teacher actions and verbal communication. I will then categorize this data by in-the-moment decisions identified through a comparison of the intended and enacted lesson plans. I will analyze these moments using a critical framework protocol that has been used with teachers previously to identify strengths with cultural competence and critical consciousness or adapt a critical framework that already exists, as necessary (Brown & Crippen, 2016; Hu et al., 2019).

Anticipated Contributions

Anticipated findings include insights into how social justice topics are embedded in secondary mathematics curriculum. I also hope to understand these educators' rationales for decisions they make when they plan and enact their critical mathematics lessons. This research may also set the stage for further research into critical mathematics educators' decision-making processes. Lastly, findings may be used to inform mathematics methods course content for pre-service teachers and professional development opportunities for in-service mathematics teachers to learn how to critically navigate online spaces when planning for instruction.

Background and Significance

Although mathematics education research is designed to improve mathematics education for *all* students, some scholars may have positioned Black learners of mathematics as historically and systematically inferior to their counterparts thereby furthering the perception that Black learners have deficits (Bullock, 2019; Gardner-Neblett et al., 2021; Gutiérrez, 2008; Martin, 2019). Mathematics education has not fully addressed how racism is related to its teaching, and consequently, the published quantitative research reflects colorblind narratives that fail to consider mathematics as a racialized and gendered space (Battey & Leyva, 2016; Gutiérrez, 2008; Parks & Schmeichel, 2012; Ridgeway & McGee, 2018). Hence there is a dire need for scholars who conduct quantitative mathematics education research to challenge the dominant deficit discourses about Black learners and teachers in mathematics education. To this end, critical scholars in mathematics education have recently put forth calls to advance mathematics education research, policy, and practice toward liberation for Black learners. That is, researchers must attend to the sociohistorical and sociopolitical dimensions of education, including the manifestations of structural racism and antiblackness, especially in posing research questions posed and data collection and interpretations.

Given this background and the urgency for quantitative mathematics education scholars to use research to create, foster, and sustain mathematics spaces as sites of resistance against antiblackness and white supremacy, the primary question that guides this dissertation is: *How can quantitative mathematics education researchers use critical racial research to support and create liberatory mathematics education, particularly for Black learners, teachers, and researchers of mathematics?* I use two theories: Quantitative Critical Theory (QuantCrit; Gillborn et al., 2018) and Black Critical Theory (BlackCrit; Dumas & ross, 2016), and apply them to quantitative education research to illuminate, critique, and dismantle anti-black discourse and practices. This manuscript-style dissertation is motivated by three distinct but interrelated lines of inquiry that explore the possibilities of critical racial research in transforming mathematics education research and education more broadly. Each area of inquiry is reflected in a paper, and each paper represents parts of a complete statement of the need for QuantCrit and BlackCrit practices in mathematics education research.

Research Questions & Design of Studies

Specifically, in my dissertation, I seek to identify the problems of antiblackness in mathematics education research, the possibilities of using critical racial research theories and methodologies in rupturing antiblackness, and how Black mathematics education researchers could learn to use QuantCrit and BlackCrit to expose, critique, and dismantle antiblackness in mathematics education. In Paper 1, I provide a primer on why and how QuantCrit and BlackCrit could be applied to mathematics education research. In Paper 1, I will address the following research question: *Using a Black Critical Theory (BlackCrit) lens, what contributions does*

QuantCrit provide to larger critical conversations centering race and racism in mathematics education? Paper 1 is a conceptual paper that attends to why QuantCrit and BlackCrit are necessary theoretical and methodological frames in quantitative mathematics education research and how QuantCrit could be applied to mathematics education scholarship and praxis.

Critical quantitative education scholars increasingly use secondary data to disrupt deficit discourses about Communities of Color (e.g., Covarrubias, 2011; Gillborn, 2010; Morris & Perry, 2017; Pérez Huber et al., 2018; Young & Cunningham, 2021). In Paper 2, using secondary data analysis of Black New York City Mathematics Teaching fellows' dispositions towards teaching racially and culturally diverse students, I provide an empirical example of BlackCrit and QuantCrit. In Paper 2, I explore *What might a BlackCrit QuantCrit lens uncover about Black mathematics teachers' dispositions towards teaching racially and culturally diverse students?* I will analyze the subset of 42 questions that attend to the participants' dispositions towards teaching racially and culturally diverse students in mathematics classrooms. Undergirding the tenets of QuantCrit, I will be analyzing the data in a three-step process: 1) perform a K-means cluster of the 74 participants who self-selected Black as their racial/ethnic group, 2) use the clusters to create typologies of the participant's dispositions, 3) compare the distinct typologies to interrogate the dispositions of Black NYMTF.

Paper 3 is based on a critical ethnographic study of a six-session collaborative research workshop developed by the researcher that centers on how Black Graduate Students in Mathematics Education Research (BGMER) conceptualize and apply QuantCrit and BlackCrit to their own scholarship. Paper 3 answers the following research questions: *1) What supports do Black emerging mathematics education scholars need to become critical racial researchers who use QuantCrit and BlackCrit in their research? And 2) How do Black graduate mathematics education researchers use QuantCrit and BlackCrit to attend to the specificity of antiblackness in a collaborative research workshop focused on QuantCrit and BlackCrit?*

I aim to not only know *what* critical literacies BGMERs employ and share in the workshops but also *how* BGMERs apply BlackCrit and QuantCrit to their research projects. I will collect field notes, transcribed audio and video from the workshops, and artifacts (such as participants' annotations or notes on the pre-engagement reading materials and participants workshopped research projects), and keep a research journal to reflect on my research processes, as well as, engage in member checking to study the cultural practices and norms of six sessions of the workshop over a period of three months and analyze the data using a constant comparison analysis, allowing me to use the direct experiences and perspectives of the critical scholars to develop a theory on the phenomenon.

Background and Significance

The three studies contribute to the literature by informing how mathematics education researchers can use QuantCrit and BlackCrit in mathematics education research. Specifically, I seek to identify the problems of antiblackness in quantitative mathematics education research, the possibilities of using critical racial research theories and methodologies in rupturing antiblackness, and how Black mathematics education researchers could learn to use QuantCrit and BlackCrit to expose, critique, and dismantle antiblackness in mathematics education. QuantCrit and BlackCrit are relatively new frameworks in education; there is little research specific to mathematics education on how QuantCrit and BlackCrit can be applied to research in mathematics education. The findings from the three studies will lay the groundwork for future research into the possible kinds of questions that researchers need to start asking to dismantle antiblackness and how we execute the inquiry.

INVESTIGATING STUDENT-CONSTRUCTED THEMES ACROSS THE MATHEMATICS CURRICULUM USING EVERYDAY AESTHETICS

Brady A. Tyburski
Michigan State University
tybursk2@msu.edu

Keywords: Curriculum; Affect, Emotion, Beliefs, and Attitudes; Undergraduate Education

Background and Theoretical Framework

In mathematics curricular documents (e.g., National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; Zorn, 2015), it is common practice to outline cognitive goals, habits of mind, and standards of practice that are intended to organize students' curricular experiences. Correspondingly, there is extensive research on the degree to which students engage with and understand these pre-determined, cross-curricular themes, such as function, equivalence, and abstraction (e.g., Warren & Cooper, 2009; Zandieh et al., 2017). However, we do not often ask students directly about the themes *they* construct based on their experiences within the mathematics curriculum. In mathematics courses, too, we do not tend to provide students with opportunities to engage in thematic reflection. A natural question arises: *How are mathematics students organizing their experiences across the mathematics curriculum?* In other words, which experiences are salient? Which experiences are viewed as (dis)connected? In what ways do students find meaning and continuity across their mathematical experiences?

To address this question, I conceptualize organizing one's experience as an *artistic act*. Such acts are governed in part by cognitive, rational thinking processes; however, they are equally impacted by extra-rational forces, such as emotions, beliefs about (school) mathematics, and one's many identities. To attend holistically to both the rational and extra-rational dimensions of organizing experience, I use the theory of everyday aesthetics (Saito, 2010). This modern branch of aesthetics is grounded in non-Western aesthetic traditions and the classic work of John Dewey (1934/2005). Dewey argued that aesthetics should not be restricted to just evaluations of finished "museum art". Rather, he situated the aesthetic in moment-to-moment experience:

> in order to *understand* the esthetic in its ultimate and approved forms, one must begin with it in the raw; in the events and scenes that hold the attentive eye and ear of man, arousing his interest and affording him enjoyment as he looks and listens. (p. 3, emphasis in original)

Aesthetics in this sense describe impactful experiences that combine emotion, the senses, satisfaction, and understanding. As Sinclair (2009) put it, "Dewey looks for integration with the human being in interaction with the world" (p. 50). By attending to the everyday aesthetics involved in organizing and making sense of one's experiences, then, we gain a holistic and humanistic view on the ways of being and thinking students bring into our mathematics classes.

Although the use of everyday aesthetics to study education is only just emerging (e.g., Marini, 2021; Marini & Merchán, 2021; Sinclair, 2009), aesthetics in general has been a lens used by mathematics education researchers to make sense of important extra-rational dimensions in learning (Dirkx, 2008). In particular, Sinclair (2001, 2008, 2018) has written extensively about the powerful role of aesthetics in mathematical learning and inquiry. Attention to the role of aesthetics in mathematical thinking and sense-making may not be a common topic, but it is one that has appeared in both classic and modern research (e.g., Dreyfus & Eisenberg, 1986; Jasien & Horn, 2022) that continues to shine a light on humanistic aspects of doing mathematics.

Research Questions and Methods

I focus on undergraduate mathematics students—as they have had years to organize and make sense of their K-16 mathematics experiences—and consider two research questions: (1) What are themes students construct across the undergraduate mathematics curriculum? (2) What ways do students organize and make sense of their experiences across the undergraduate mathematics curriculum?

To study these questions, I will recruit ~5 students with at least two semesters of undergraduate mathematics courses completed. Participants will then be invited to reflect on their mathematics experiences by individually creating art that responds to the following prompt: *Consider your journey as an undergraduate mathematics student. This includes your experiences, emotions, people you've interacted with, highs and lows, mathematical content, etc. What are some patterns and themes that you have noticed? Feel free to use any of the artistic resources provided to you to organize and make sense of your experiences. You can also reflect in writing using a story, a poem, or a song, if you wish.* This arts-based approach allows students to reflect individually in a holistic, multimodal, and multisensory way (Bagnoli, 2009; Papoi, 2017). Consistent with the theory of everyday aesthetics, it also provides students the opportunity for reflection on the connective and cohesive forces (Clark & Rossiter, 2008; Sinclair, 2009) they consider to be present across their everyday mathematical experiences.

In line with my goal to learn how *students* organize their experiences, analysis of these artistic artifacts will be carried out via a (video-recorded) discussion led by *students* and governed by their interests and curiosities. To begin, each participant will share their artistic artifact and what it means to them. Follow-up discussion will then concern themes that students identify across each of their artifacts and experiences.

I conceptualize this discussion as a "book club" where the "text" of interest is the mathematics curriculum. Like a book club, the goal of this discussion is for a community of learners to come together to reflect on their opinions, interpretations of, and feelings about a text (e.g., its themes), while being open to the possibility that their views may be transformed and enhanced by other participants' views of the text (Kerka, 1996). In fact, productive book clubs encourage the sharing of alternative (and potentially contradictory) perspectives of the text to facilitate further exploration and discussion of themes (Beach & Yussen, 2011). As the facilitator of this book club, my role is primarily to allow the discussion to be driven by participants, but I will also point out occasional observations and offer suggestions for new topics to consider.

Implications

We know from studies with pre-service teachers that undergraduate mathematics students do not always develop the connections between mathematics content areas we may have expected (e.g., Wasserman, 2018). Research akin to this proposed study has the potential to help us understand the themes students actually come away with on not only a course-by-course basis but also across sequences of courses and the entire mathematics curriculum. It also builds on the calls of researchers (Melhuish et al., 2020; Zandieh et al., 2017) for further study into the extent to which students develop understandings of key themes, such as function, across the undergraduate curriculum. Research of this nature has the potential to offer suggestions for how we might modify the curricula of courses and course sequences to build on patterns, themes, and connections that we know students are likely to construct. In other words, it allows us to integrate a realistic, asset-based view of learners' capabilities (Peck, 2020) into our curricula, a piece of the puzzle essential to improved curriculum design (Lattuca & Stark, 2009).

SYNERGIES AND TAKE-UP WHEN PRACTICE-BASED PROFESSIONAL DEVELOPMENT AND COLLABORATIVE LESSON DESIGN ARE USED TOGETHER

Jennifer Valerio
University of Pennsylvania
valerioj@upenn.edu

Background and Framing Concepts

Designing professional development (PD) that helps teachers enact more ambitious instruction responsive to emergent student thinking is challenging work. Two approaches to this sort of PD, practice-based professional development (PBPD) and lesson study (LS), have different mechanisms for fostering change and different focus points. Although there is substantial research support for each approach (e.g., Grossman et al., 2018; Huang & Shimizu, 2016; Kavanagh et al., 2020; Lewis, 2016), each has limitations that can be characterized as "problems of enactment" (Kennedy, 1999) when used alone.

LS focuses on changing teaching via teacher-led, structured inquiry into problems of practice and by improving the planning process and instructional resources teachers use to enact lessons (Hiebert & Morris, 2012). Inherent within LS's focus on developing knowledge *for* and *of* action is a focus on student learning and the scrutiny and refinement of instructional materials (Watanabe et al., 2008). Lewis's (2016) research on LS over the course of two decades identifies four types of outcomes: changes in teachers' knowledge, beliefs, professional community, and curriculum resources. Missing from this list is a change in teachers' actual teaching practices--what they do when they are teaching. LS, therefore, faces the possibility that without structured opportunities to develop a new set of pedagogical skills, teachers may face the "problem of enactment" described by Kennedy (1999), i.e., vision change without the necessary pedagogical skills to enact the new vision, making teachers unable to execute the lesson plans as intended.

PBPD, by contrast, emphasizes knowledge *in* action, and prioritizes changing teaching through pedagogical training in enacting core teaching practices, i.e., specific instructional skills such as launching problems and facilitating discussions (Ball & Forzani, 2009; Grossman, Hammerness, et al., 2009; Grossman et al., 2018). This model employs pedagogies of enactment, including representation, decomposition, and approximation, (Grossman, Compton, et al., 2009) which require teachers to rehearse teaching practices in situations of increasing complexity in order to develop adaptive expertise (Kavanagh et al., 2020). Challenges arise, however, in the transfer of pedagogical skills to specific educational contexts (Zeichner, 2012; Philip et al, 2018). A parallel "problem of enactment," then, may arise if vision and practice changes occur without the necessary resources to support enactment in teachers' specific learning contexts.

Because the two PD approaches involve different processes, pedagogies, and expertise, they are seldom used together in ways that give equal weight to each approach. Yet, when used in tandem, LS and PBPD could prove complementary in ways that help teachers surmount the "problems of enactment" that can otherwise undermine translation of vision into practice when each approach is used alone.

During the 2020-2021 school year, the Responsive Math Teaching (RMT) Project at Penn Graduate School of Education devoted equal time and resources to both approaches to professional development with the same group of K-8 teachers in a large, urban school district, providing an opportunity to study how the two approaches might work together to foster changes in teaching. This study draws on both constructivist (Piaget, 1973) and socio-cultural (Vygotsky,

1978) frameworks in order to trace individual teachers' learning across time within the context of an inquiry community.

Goals and Research Questions

This study explores how RMT's Collaborative Lesson Design (CLD), a modification of lesson study, and PBPD might have valuable *synergies*, i.e., ways in which they are mutually supportive such that the affordances of one approach complement the challenges of the other. In addition to looking for evidence of synergy between the two approaches, this study also endeavors to better understand and describe whether and how *take-up* occurs as teachers and tools move between the two PD forms. Here, I define *take-up* as the acceptance, adoption, and incorporation of ideas into one's own classroom practice. I have intentionally used the term *take-up* to incorporate both vision and practice changes.

The research questions that follow examine the interplay between PBPD and CLD and the teacher take-up that occurs therein:

1. To what extent does individual teachers' take-up of responsive teaching evolve over the course of the year across both forms of PD and what does this evolution look like?
2. What evidence is there that participation in CLD supports classroom enactment of the practices learned in PBPD?
3. What evidence is there that participation in PBPD supports the enactment of lessons planned in CLD?

Methods

This study focuses on eight purposefully selected participants and employs a qualitative, interpretive, case study approach (Creswell & Poth, 2018), working from the assumption that doing so provides a deeper, more contextualized understanding of the interplay between PBPD and CLD and of individual teacher take-up than a broader, decontextualized look across a larger number of participants. Cases are defined as individual teachers from a large, under-resourced urban school district participating in both forms of professional development during the 2020-2021 school year (Miles, Huberman, & Saldana, 2020; Ravitch & Carl, 2016).

Preliminary Findings

Although it is early in the data analysis process, some tentative findings have emerged. Across participants, the take-up of responsive teaching practices involves an iterative process of building knowledge, deploying that knowledge during enactment, encountering struggles during enactment, and then returning to knowledge-building with a focus on addressing the specific struggles that have emerged. I anticipate that my findings will ultimately include take-up mappings (Valerio, 2021) for illustrative cases, a description of the types of struggles teachers encountered, and a description of the supports that helped teachers overcome these struggles.

Additionally, preliminary data indicate that CLD supports the enactment of practices addressed in PBPD by giving teachers the opportunity to adapt the practices for their specific context and students, to design and adapt high leverage math tasks suitable to their context, and to tap into the expertise of colleagues for advice about a variety implementation challenges. PBPD supports the enactment of lessons developed through CLD by providing space for teachers to decompose and rehearse ways to address enactment challenges that arise and to further hone both their teaching practices and their emergent vision of responsive instruction. Further data analysis will more fully flesh out these findings.

USING VIDEO TAGGING TOOLS TO UNDERSTAND FACILITATOR NOTICING

Margaret Walton
University of Maryland
mwalton@umd.edu

Background & Significance

Much of the math education research community has emphasized the importance of teachers *noticing*, or attending to and flexibly responding to student thinking (e.g. Carpenter et al., 1989; Empson & Jacobs, 2008). Like other teaching practices, noticing is a skill that teachers often need to develop (van Es, 2011).

Video clubs (VCs) are a type of professional development (PD) that can help teachers learn to notice (Sherin & Han, 2004; Luna & Sherin 2017; Sherin & van Es, 2005). A VC is a small group of teachers who meet to watch a short video clip of classroom instruction. They then participate in a discussion about aspects of student thinking in the video, which is usually led by a facilitator. The facilitator guides teachers to focus on students and reason about student ideas (van Es et al., 2014; Borko, Jacobs et al., 2014).

A number of researchers argue that facilitators are key to teachers learning to notice (Castro Superfine et al., 2019; van Es, 2011; Goldsmith & Seago, 2008). However, few studies examine how teacher educators learn to facilitate a VC. Studies about facilitator learning have found that facilitators often have difficulty leading teacher discussions about student thinking (Borko, Koellner et al., 2014; Elliott et al., 2009; Jackson et al., 2015). This difficulty might be because facilitators need to develop their own noticing abilities (Amador, 2016; 2020).

The purpose of this study is to support facilitators in learning to lead VC discussions that help teachers learn to notice. I plan to design a facilitator PD (F-PD) that employs a video tagging tool that supports facilitators' own noticing development. I will implement the F-PD with mathematics education graduate students who instruct pre-service teachers (PSTs). My research questions are:

- How can a video-based F-PD support facilitators in learning to lead PSTs in a VC?
    - In what ways can a video-tagging tool support facilitators in noticing student thinking while *participating* in a VC?
    - In what ways can a video-tagging tool support facilitators noticing teacher thinking while *leading* VC discussion?

Background and Theoretical Framing

The processes involved in teacher noticing generally include: (1) attending to important moments of student mathematical thinking, (2) interpreting that thinking using knowledge of content, pedagogy, and students, and (3) determining how to respond (Jacobs et al., 2010; Sherin & van Es, 2009). As teachers' noticing skills develop, they can learn to focus more on the relationship between students' thinking and instruction, and often seek to understand students' mathematical thoughts (van Es, 2011). VCs can support this development (Sherin, 2007).

Facilitators can be key to supporting teachers' noticing learning in PD like VCs, but to do so they may need to develop their own noticing abilities (Amador, 2016; 2021). Noticing is more complex for facilitators than for teachers because they need to notice both student *and* teacher thinking (Amador 2021; Kazemi et al., 2011). Specifically, a facilitator needs to understand how a teacher reasons about instances of student thinking in relation to their classroom instruction. A facilitator must consider several aspects of teacher thinking at once, including: (1) the way teachers understand the math content (Lesseig et al., 2017), (2) the way teachers make sense of student thinking, and (3) how teachers relate content and student ideas to learning goals (Borko, Jacobs et al., 2014).

I intend to develop a series of VCs and VC planning activities to help facilitators with noticing student *and* teacher thinking. One of the features that will make my F-PD different from traditional video clubs is that I will employ a video tagging tool, which allows users to annotate video directly on the screen. This tool could scaffold facilitators' noticing development in several ways, which I explain in the Research Plan.

Research Plan

My dissertation employs design research methods (Cobb et al., 2003; The Design-Based Research Collective 2003; Gravemeijer & Van Eerde, 2009). Consequently, the F-PD design described here is the first iteration of what could be many as I refine and re-implement the design, based on my findings of how facilitators learn to notice.

The F-PD includes five group meetings and two independent work sessions with six math education graduate students called facilitator participants (FPs). These FPs aim to build careers in teacher education. In Part 1 of the F-PD, FPs engage in virtual VCs via Zoom (www.zoom.us) so that they can focus on noticing *student thinking*. During these VCs, FPs annotate the videos that they watch, which could help them identify, reason about, and remember interesting moments of student thinking that they can then discuss with other FPs. Part 2 of the F-PD shifts focus to noticing of *teacher thinking*. Here, FPs use video annotations in a different way. They first analyze example VC annotations by PSTs (Walton & Walkoe, in press) to understand how PSTs think about student thinking. FPs use this analysis to write hypothetical discussion protocols that they could use for VC discussion.

Data collection will include video recordings of the virtual sessions, FPs' video annotations from Part 1, and FPs' video discussion protocols from Part 2. I will code the Part 1 data using similar methods to other research in noticing (Sherin & van Es, 2009) to understand how FPs noticing of student thinking developed. I will focus on noticing of teacher thinking as I examine the data from Part Two. I will analyze FPs' discussion protocol assignments using deductive codes based on a framework I developed that outlines facilitator noticing of teacher thinking.

Impact

Teacher noticing of student thinking has been shown to enhance K-12 learning of mathematics (Carpenter et al., 1989; Empson & Jacobs, 2008). In order for teachers to learn to notice, they need access to high quality PD led by well-prepared facilitators.

I plan to widely disseminate my F-PD design for use with other facilitators. The demand for video-based PD continues to rise (van Es & Sherin, 2017) and my design could create a greater number of experienced facilitators, giving more teachers access to noticing PD.

This project will help researchers further understand and describe the cognitive processes related to noticing, especially from the facilitator perspective. In particular, the exploration of video tagging will help determine how scaffolds can support noticing development. More broadly, the project will also contribute to the conceptualization of facilitator learning, which is an understudied field in education research (Elliott et al., 2009; Tekkumru-Kisa & Stein, 2017), but one that is imperative for developing facilitators who can provide high quality learning experiences to teachers.

INVESTIGATING SECONDARY PRE-SERVICE TEACHERS' MATHEMATICAL CREATIVITY

Anne Waswa
University of Georgia
anw04326@uga.edu

Mathematical creativity (MC) is important in school and outside school (Chamberlin & Moon, 2005; Panaoura & Panaoura, 2014), it is one of the aims of mathematics (Mann, 2006), and of mathematics education (Andrade & Pasia, 2020; Levenson, 2013). Encouraging creativity in learning has potential to increase student rigor in learning, challenge students to learn more, and promote student engagement in learning (Garfinkel & Albrecht, 2018). On the other hand, lack of support for creativity can result in a decline in learned variability, can hinder radical breakthrough solutions, and restrict academic achievement to narrow sets (Kim, 2016). Unfortunately, research on MC has not been foregrounded (Haavold, 2018; Haylock, 1987; Leikin, 2009, 2011). Among the important areas of research is teachers' MC because as Sheffield (2013) argued, we cannot separate teachers from the development of MC. However, there is less research that focuses on the conceptions of MC of pre-service teachers (PSTs) and the MC of PSTs as they actively engage in problem solving. Therefore, my research seeks to address the following research questions: (1) What is secondary PSTs' mathematical creativity when they engage in problem solving? (2) What are PSTs' conceptions of mathematical creativity in the teaching and learning of mathematics?

Theoretical Frameworks

Radical Constructivism

The theory of knowing and learning that inform my study is radical constructivism (von Glasersfeld's, 1995), whose fundamental principles are also informed by Piaget's constructivist theory of knowing. I will draw from this theory, not to explain PSTSs' MC, but to drive and form the kinds of descriptions that I can provide regarding PSTs' MC. The fundamental principles of radical constructivism include that, "knowledge is not passively received either through the senses or by way of communication; knowledge is actively built up by the cognizing subject" and that "the function of cognition is adaptive, in the biological sense of the term, tending towards fit or viability; cognition serves the subject's organization of the experiential world, not the discovery of an objective ontological reality" (von Glasersfeld, 1995, p. 51). The first principle informs my assumptions of PSTs as actively constructing their knowledge as they engaged in PS. The second fundamental principle speaks to the acquisition of knowledge through mental mechanisms. The notion of fit and viability speaks to the construction of knowledge that works for the cognizing subject, as opposed to the construction of knowledge being some movement toward or approximation of reality and truth. It follows that the models I develop in my study are merely viable models, meaning that I cannot develop with certainty models of PSTs' mathematics and MC that provide a true picture of their knowledge.

Framework for MC

I adopt Lithner's (2008) research framework for creative and imitative reasoning. In particular, I use Lithner's framework to define the qualities that characterizes reasoning as creative, and what differentiates creative mathematically founded reasoning (CMR) from general creative reasoning. Lithner (2008) defines reasoning as "the line of thought adopted to produce assertions and reach conclusions in task solving" (p. 257). According to Lithner (2008), CMR should be novel, plausible, and mathematically founded. Other characteristics that I focus on that are indicative of creative thinking include fluency and flexibility (see Lithner, 2008).

Methods

The study is qualitative in nature, with a teaching experiment (TE) (Steffe & Thompson, 2000) and clinical interviews (Ginsburg, 1997) serving as the main methods of data collection. Participants will be six secondary mathematics PSTs.

Teaching Experiment

The main aim of using a teaching experiment (TE) "is for the researcher to experience, firsthand, students' mathematical learning and reasoning" (Steffe & Thompson, 2000, p.267). From this experience a goal of teaching experiment includes "[constructing] models of students' mathematics" (p. 268), and this aligns with my goal of understanding and developing PSTs' viable models of mathematics in relation to their MC. I plan to conduct tentatively eight one-hour sessions with my participants together with a witness, potentially a graduate student. All sessions will be video-taped using two cameras. One camera will capture PSTs' written work from overhead and their explanations while the other camera will capture their facial expressions, explanations, gestures, and the surrounding environment. Witnesses' notes during the episodes and together with my notes, and participants' scanned written work, will be additional sources of data. The tasks will focus on quadratic growth and linear growth, and I will leverage literature from researcher that focuses on these topics (e.g., Ellis 2011a; 2011b; Fonger et al., 2020; Graf et al., 2018; Lobato et al., 2012). I also leverage literature from quantitative reasoning and/or covariation reasoning (e.g., Carlson et al., 2002; Ellis, 2007; Ellis et al., 2020; Moore, 2013; Moore et al., 2014; Moore & Thompson, 2015; Saldanha & Thompson,1998; Thompson, 2011; Thompson & Carlson, 2017).

Clinical Interview

My goal in conducting clinical interviews is to offer ground for open and reflective thinking and sharing with PSTs, in order to understand PSTs' conceptions of MC. I plan to conduct two clinical interviews with each PST, one before the TE and another after the TE to track and compare their conceptions of MC before and after conducting the TE. I will use an interview protocol as a guide. The protocol contains open-ended questions that focus on PSTs' experiences with MC outside school, in school, and in their teacher preparation program.

Data Analysis

I will use MAXQDA software to organize and analyze my data. My approach to data analysis will entail ongoing and retrospective analysis (Simon, 2019; Steffe & Thompson, 2000) and conceptual analysis (Thompson, 2008).

Anticipated Contributions

My research extends existing research on conceptions of MC by using a different approach of investigating PSTs' conceptions of MC in the context of problem solving. The novelty in this contribution is that PSTs reflect on their own MC after engaging in PS when describing their conceptions of MC. In addition, my research goes beyond identifying characteristics of MC to making connections between PSTs' mathematical meanings and their MC. This a methodological contribution to the field in terms of providing a different approach to studying MC. The findings of these research will potentially inform teacher preparation in terms of contributing ideas on understanding and supporting PSTs' MC and their teaching with and for MC from the developed models of PSTs' mathematical meanings and their MC.

PROSPECTIVE MATHEMATICS TEACHERS' TECHNOLOGICAL PEDAGOGICAL CONTENT KNOWLEDGE IN PIECES

Nicholas Witt
Western Michigan University
nicholas.e.witt@wmich.edu

Keywords: Technology, Pre-Service Teacher Education, Mathematical Knowledge for Teaching

The nature and form of knowledge that teachers utilize while creating technology-infused curriculum materials is of great importance due to the abundance of technology that is accessible and sometimes necessary for teachers to engage with during their day-to-day tasks. Many teachers still rely on textbooks to guide their instruction (Banilower et al, 2018), but recent research has shown that textbooks seldomly suggest using technology in ways that fully leverage its affordances (Sherman et al, 2020). Thus, it would be of great importance to the mathematics education community to better understand what knowledge is needed for teachers to be able to adapt their curricular materials to better integrate technology.

One framework for thinking about this type of knowledge is the Technological Pedagogical Content Knowledge (TPACK) (Mishra & Koehler, 2006) framework, but many questions remain with respect to theorizing the nature and form of this knowledge (Angeli, Valanides, & Christodoulou, 2016). Attempts at theorizing this type of knowledge in the moment of planning have been conducted (Bibi & Khan, 2017) with university instructors, but how this knowledge is utilized in relative novice mathematics teachers will be a new contribution to the field. Furthermore, while fine-grained analyses of conceptual change have mostly focused on disciplines such as mathematics (Izsak, 2005; Levin, 2018) or physics (diSessa, 1993), studies involving harder to define concepts such as ideology (Philip, 2011) and pedagogical knowledge (Markauskaite & Goodyear, 2014) have also been approached from a Knowledge in Pieces (KiP) (diSessa, 1993) epistemological perspective. However, examining mathematics teachers' knowledge in use during the act of lesson planning with mathematical action technology (MAT) (Dick & Hollebrands, 2011) has not been explored and may provide some guidance to mathematics teacher educators on how they may structure interventions to develop such knowledge.

Theoretical Framework

Given that this line of research is centered around understanding what resources (broadly speaking) are drawn upon by Prospective Mathematics Teachers (PMTs) at a fine-grained level of analysis, I will bring a KiP epistemological framing to better understand the knowledge resources that PMTs utilize when designing technology-infused curriculum materials for middle school students. Much of the data will be analyzed through the lens of the TPACK framework, but I acknowledge that this may need to be extended to better suit the context of my study. The TPACK framework extends Shulman's (1987) Pedagogical Content Knowledge (PCK) to include technological knowledge and has many connections to Mathematical Knowledge for Teaching (MKT) (Hill, Ball, and Schilling 2008), but connecting KiP to TPACK may help to clarify how TPACK may apply in this context.

Methods

Stemming from some earlier projects that focused on analyzing the PMT-designed or PMT-adapted curriculum, I am now focusing on understanding and describing the nature of what the process of designing MAT-infused curriculum looks like in the moment of planning. With a focus on the knowledge that PMTs demonstrate in the moment of planning lessons that incorporate MAT, I am planning to conduct a Microgenetic Learning Analysis (MLA) (Parnafes & diSessa, 2013). In utilizing MLA, I will engage in many of the same techniques that are utilized in grounded theory (Strauss & Corbin, 1990), but my focus is on knowledge with the goal being to gain insight into the ways in which different knowledge systems interact with each other while the PMTs are working on creating technology-infused lesson materials.

At this point, I have collected data from four interviews with five participants. Each participant is enrolled in a course on incorporating technology into middle school mathematics classes. It is composed of both prospective elementary and secondary teachers. The first interview was focused on reflecting on their first lesson plan that was created for the course. The second interview was a task-based interview involving mathematics content that is relevant to their final lesson plan. This interview was conveyed through the same digital platform that they utilized in their final lesson construction. The third interview was a two-hour long interview where they were in the process of creating their final lesson plan. The fourth interview was a reflection on their experience in the course and their final lesson construction.

The interviews were semi-structured with the exception of the third interview where they were free to create their lesson in a manner that they typically worked. During this interview I asked questions about why they made the curricular decisions that I observed and what they were thinking about. I plan to conduct one more round of interviews to serve as a *member-check* (Creswell & Poth, 2016) interview once some initial data analysis has been completed. In addition to the interview video and audio data, I asked each participant to share their computer screen which I also have recorded. Throughout the semester, I observed every class meeting except for one and recorded observation notes of moments in the class session when the participants were speaking about something that may be relevant to how they may think about constructing a lesson involving technology.

For the analysis, I am beginning to do this with an open consideration of the data where I am “tagging” moments in the video of my interviews where I see knowledge related to Technology, Pedagogy, and Content. From here, I plan to look for themes across the four rounds of interviews and then try to construct a model of how each participant’s knowledge changed over the course of the semester. I hope to be able to construct models of how their thinking changed over as it pertains to constructing lessons with technology.

Contributions of the Study

As technology has become more and more omnipresent in mathematics classrooms there is a need to better understand how PMTs and in-service teachers learn how to effectively integrate technology into their curriculum. Methodologically, few mathematics education studies that examine the in-the-moment knowledge that teachers exhibit as they create lesson materials and furthermore even fewer studies do so with the added complexity of integrating technology. It is my hope that this study provides some guidance for future studies on how teachers develop their knowledge of creating lessons that integrate mathematical action technology. Finally, as the knowledge in pieces epistemological frame has typically been utilized in studies of mathematics content knowledge or science content knowledge, this study will be an attempt at expanding the reach of this perspective to teacher knowledge involved in creating curriculum.
