
Data Analysis

To analyze the quantitative data from Phase 1, we hoped to perform an ordinal logistic regression of the five-point scaled Likert items – comparing students' majors and their classifications. Unfortunately, the data did not meet the assumptions for this regression approach, particularly we failed the proportional odds assumption ($p < 0.001$). Additionally, in looking at the raw scores for students, many students responded similarly to one another with little deviation (i.e., most students responded with somewhat or strongly agree on all Likert items) – indicating that there was little to no difference in how students responded based on major or classification. As such, we will focus predominately on the qualitative data analysis for this project as it provides a richer description of students' voices.

To analyze the qualitative data (in both Phase 1 and Phase 2), we did open coding and thematic analysis (Braun & Clarke, 2006). As the crucial component of our study was to lift students' voices and reflections about their teacher preparation programs, we did our initial coding in vivo. Two researchers individually coded all the data. They then discussed disagreements on coding to continue to refine the codebook. Then all three researchers coded the data with the refined codebook. All three met to discuss changes that needed to occur to have an agreed upon codebook.

Results

Recall our research question was: *What do preservice and inservice teachers believe about how their program is preparing them to be teachers or has prepared them to be teachers?* We conducted a two-phase exploratory convergent parallel design study to answer this question. Three central themes emerged regarding students' experiences in our programs in the Phase 1 analysis. These were 1) connections to content they will teach, 2) what is good pedagogy, and 3) classroom management. We then sent a follow up survey to get more information specifically relating to these three themes. The results presented below combine results by theme, but clearly indicate which phase they were from.

Connections to Content They Will Teach

In the Phase 1 survey, many former students made connections between how their mathematics courses tied directly to what and how they are now teaching their students.

Specifically, there were 15 comments from former students that mentioned seeing this connection. Several comments focused on direct content connections. For example,

> My courses gave me a good background to the knowledge I already had, which allows me to more easily break down the content for students. The best example I have is the geometry course I took. We delved further into geometry proofs than normal high school curriculum goes, but that knowledge has helped me create a foundation of learning for my sophomore geometry students.

Likewise, another former student said,

> I felt like the courses I took at University X were very helpful in preparing me for teaching mathematics. I learned a lot about how connected the various parts of mathematics were which helps me to use those connections with my students currently.

Additionally, several former students discussed not only the connection between what they learned but how the classes were taught. "[I] developed a better understanding of the 'why' behind the mathematics, an understanding of how secondary concepts are used in post-secondary mathematics, and learned concepts that I now teach that I did not learn in school." And some students referenced certain classes.

> The problem solving class was THE most effective class for teaching me how to teach math, and it wasn't even a teaching class directly. It made me realize how students struggle and what makes a difficult problem fun, and I strive to recreate or use problems from that class in my own classroom. I also really think the class with [professor] helped with explicitly integrating math practices and finding research based (even multi-disciplinary) inquiry activities to do with students.

From these comments, we are encouraged that these respondents are taking their experiences in college level mathematics classes and connecting them to their practice as teachers. However, not all participants on the first survey mentioned similar experiences. Some former, as well as current students, commented on not seeing the connection between their mathematics courses and what they teach or will be teaching (i.e., Horizon Content Knowledge (Ball et al., 2008)). Specifically, there were 12 related comments. These comments often centered on the idea that the content that was taught in their undergraduate mathematics classes was beyond the content that they teach their middle or high school students. For example, one respondent said "There was not a lot of information targeted at helping us teach mathematics to students. For example, what are common misconceptions high school students have about math and how can we counteract that in the classroom." Another said, "Although I enjoyed all the mathematics courses required, the higher level classes are just not that applicable."

Additionally, several comments stated that the undergraduate mathematics classes should have discussed the aforementioned middle and high school content. "I would have appreciated more of an in-depth look at the content I'm currently teaching my students. While we covered some parts of the content, there was much that I am now teaching that I didn't see … in college."

Perhaps, the comment that summarizes these student experiences best addresses both mathematics and education classes simultaneously.

> Creation of content is one area that I wish I would have been given more of a chance to practice. [Education classes] taught me to teach lessons, and the mathematics [classes] taught me to understand the math. However, I did not have a chance to really marry the two skills. It

would have been helpful to have a course solely dedicated to creating content (test items, quizzes, activities) that checked for higher-order thinking questions and rigorous task creation.

On the Phase 2 survey, we directly asked how respondents perceived how the content they were taught connects (or does not) to the connect they teach. Nine respondents indicated that the classes they took were helpful, but not all respondents discussed the connection of content. Of those that did five said that the mathematics content they were taught was directly connected. For example, one respondent said, “the math I have been teaching is at a lower level than I was taught at the college level and has me prepared to go beyond and answer questions students may ask.” Interestingly, another respondent had a similar response but a different implication. “The math courses I took, while I found interesting, really didn’t help prepare me for teaching. The content taught is above the levels I teach.” Three respondents had similar comments that the content was not connected to what they teach. In these two comparing responses we see that both students knew that the content in college level mathematics class is beyond what they will be teaching their future middle or high school students. However, one respondent perceived this as a positive because it led them to be able to answer questions beyond the content, and the other respondent did not see this similar value.

A take-away from this finding is that students currently in our program and those who have completed it, vary in terms of what they expected certain courses to give them. The mathematics courses in our program are designed to be college-level mathematics classes that are taught in student-centered ways focusing on conceptual understanding, and then that conceptual understanding connects to the content they will teach. As this was not consistent across participants, this indicates potential programmatic clarity issues (e.g., transparently explaining to our students the purpose of the program design and specific classes).

What is Good Pedagogy?

Another theme that emerged from our data was the idea of what good pedagogy is and where students see it. Preservice teachers experience pedagogy, from a learner’s point of view, in their own classes or in their field experiences. In Phase 1, 12 participants discussed, from their point of view, how their mathematics classes were taught. For instance, one participant said, “Many of the mathematics courses within the Middle Grades mathematics degree were designed as inquiry based courses themselves. As such, they served as a good model of how to teach math using this method.” While another said, “all of the Middle Grades mathematics courses I had challenged me to think about the ‘why’ for each math skill and operation, not just the how. This deeper understanding helps me identify student misconceptions.”

There were a few instances of former students saying that courses they took were not student centered, but they often referenced specific courses (e.g., Abstract Algebra) which Secondary Mathematics majors take and are not taught by mathematics education faculty within the department. Importantly, when participants referenced good pedagogy, it most often focused on student-centered instruction. Yet, when we asked former students to describe their teaching style, 16 were coded as all or leaning student-centered, 15 were coded as all or leaning teacher-centered, and 14 were coded as a mix between the two. Notice the even split. Further, some participants who identified as leaning teacher-centered were also the same participants that mentioned the disconnects in the previous theme.

Regarding education classes, the comments on what is good pedagogy often focused on how those classes focused on inquiry-based learning but especially focused on experiences in the field. There were 18 comments from current and former students addressing the importance of field experiences. For instance, one participant said, “I believe getting to actually teach students early in [Program Name], gave me confidence in classroom management. While teaching real students, I began creating my teacher personality.”

In Phase 2, we focused on asking the participants to define good mathematics pedagogy for themselves and then state if their teaching does or does not espouse this definition of good mathematics pedagogy. Three respondents said that direct instruction works best for them and their students. One said, “a clear concise instruction of the topic that at least addresses where it can be relevant outside of the math classroom.” All respondents who said their teaching was teacher-centered said that they do achieve this style of teaching all or most of the time. Most respondents said that they teach in student-centered ways. “Good mathematics pedagogy is allowing students to construct understanding for themselves while guiding them toward that understanding.” Similarly, some respondents discussed the importance of conceptual understanding. “Good mathematics pedagogy is being able to understand math on a conceptual level, understanding how I got my answer, and why it makes sense.” Most respondents said that most of the time they can achieve this teaching style. However, two participants the hardships with this. One said,

> I take pride in my classroom and I love my students. As a result, I believe my teaching lives up to my mathematics pedagogy daily. In the current state we are in with challenges from the COVID situation, I do believe I am currently challenged more daily to live up to my expectations for my classroom experiences for my students.

Another said,

> My teaching does not live up to this definition as often as I would like due to time constraints. I cannot give students the amount of time they need to discover and construct their own understanding within the confines of my class times and the amount of content they need to see each year. I am able to do this about once every other week for an entire class, and other classes I try to build in smaller amounts of time for discussion and discovery, just not on a large scale.

This is often a very common reason that teachers do not implement active learning as often as they wish: time constraints. Similarly, the COVID-19 pandemic has impeded their ability to teach in the way they believe to be most successful for their students.

Classroom Management

Overwhelmingly, 23 participants in Phase 1 expressed a wish for more learning in their program on classroom management. One participant said, “I felt unprepared to deal with a class of 30 students when the time came.” Whereas another participant mentioned classroom management but acknowledged the importance of being in the K-12 classroom to learn about that. “I am not sure if there is a way to prepare for classroom management without having your own classroom, but that is the one skill I wish I could have gotten more experience in.”

Respondents from Phase 2 elaborated on the specifics they wished they knew about in regards to classroom management from their preparation programs. Six respondents have had issues with behavior management and disruptive students. Two respondents were not prepared to deal with students having cell phones in class and the disruption it causes. Two respondents mentioned not being prepared for students with mental health issues (exacerbated by the pandemic). Respondents also mentioned struggles with apathetic students, unsupportive parents, and a lack of administrative support. One respondent specifically discussed their role in classroom management.

> A specific issue was realizing I CAN affect and shape student behavior/misbehavior. In [education] classes, I was taught to accept all answers and let students control/lead classroom discussion. This caused me to not properly address student misbehavior and for general confusion and frustration in the classroom. For example, when doing PBI [project based instruction], students and groups would not participate in the learning, but distract students and the class.

This comment addresses a connection between teachers' desired teaching styles and learning goals and how classroom management can distract from those learning goals. These respondents overwhelmingly discussed a need for support in managing their classes; and continued support even after their teacher preparation programs.

Discussion and Conclusion

We aimed to understand what future teachers experience when they go through a mathematics teacher preparation program. Our findings are heavily tied to our institutional context as a UTeach replication site and that in particular we have several mathematics education faculty housed in the mathematics department. Thus, our findings not only inform practically how we can improve our program, but they illuminate overarching gaps between how we design our programs and what students experience when they go through them (or what they expect to get out of a program).

From our data we found three overarching themes about students' experiences in teacher preparation programs. We then followed up with additional questions regarding these three themes. First, there was a split between participants in terms of ones that experienced the connections to content they will teach when in their undergraduate mathematics classes to ones who did not see that connection. Moreover, the fact that college mathematics courses covered content beyond middle and high school content was sometimes a benefit and sometimes not for respondents. Second, what is good pedagogy was discussed in the context of both how we as mathematics education faculty teach our courses and their experiences in the field. Further, most of the time, teachers are able to live up to their definition of good pedagogy, but if they are not, it is often due to time constraints or issues related to the pandemic. Third, classroom management was something that a large majority of participants wished was a focus of their learning. Specifically, teachers have issues with behavior management, disruptive students, cell phones, unsupportive parents, and more, and these are all topics they wish were discussed in their teacher education programs.

Together, these three themes highlight an important take-away for the field of mathematics teacher education. That is, what is the purpose of a program in mathematics teacher education (and the courses within it)? Often in academia, program design is shrouded behind administrative procedures that students never need to know about (Fielding, 2001). They are at a university to get a degree. Those degrees vary by state and university. However, our findings indicate that if we want students to get the best possible experience out of their teacher education program (as they often are designed based on research or community standards (e.g., AMTE, 2017)), then an important component of that is to include students in program-level discussions and be transparent about what they should get out of an education. We acknowledge that our findings are very specific to our institutional context, however, according to Chan (2016), "student expectations and purposes for completing undergraduate education tend to be instrumental and personal, while institutional aims and purposes of undergraduate education tend to be highly ideal (i.e., life- and society-changing consequences)" (p. 19). We believe this is a larger concern in teacher preparation.

This work provides initial steps in building program reform that is rooted in students' voices and experiences of their program. Moreover, implications from this work will inform the teacher preparation research community about perspectives on their education which can be used to understanding, from a student point of view, if programs are achieving their goals. Further research is needed to ascertain if these disconnects have long lasting effects on effective teaching or on the retention of teachers in the field.

We examined transitions in secondary math pre-service teachers (PSTs)' professional identities as they engaged in online practice-based, virtual simulations designed to support the development of their skills to facilitate argumentation-focused discussions. Using a single item measure, we captured a snapshot of the PSTs' identity at two time points and observed notable shifts over time. Findings indicated that identity development was related to PSTs' opportunities to practice teaching in the simulations. For some PSTs, their math teacher identity became more central during the semester, while for others it foregrounded other sub-identities.

Keywords: Preservice Teacher Education, Identity, Instructional Activities and Practices, Professional Development

Teacher identity can be defined as "teachers' understandings of themselves as teachers, which has been shaped through ongoing processes of interpretation and re-interpretation of personal and professional experiences embedded in multilayered social [historical] contexts" (Schutz et al., 2020, p. 208). Teacher identity is dynamic, develops over time, and continuously evolves (Watson, 2006). Identity is thought to be relational (Day et al., 2006); thus, it is formed and reshaped as we negotiate and internalize our interactions within our environment. This relational component undergirds the notion that no one claims an identity by themselves (Carlone & Johnson, 2007). Thus, identifying as a teacher involves how one sees themselves and how that image of self is affirmed or disaffirmed by others (Schutz et al., 2020). Additionally, identity tends to be multidimensional, meaning being a teacher is only one aspect of who teachers are. Our sub-identities (e.g., sister, Muslim) develop through experiences in different contexts which we harmonize over time (Beijaard et al., 2004).

Research on teacher identity in math education has gained traction within the last two decades (Brown & McNamara, 2011; Kaasila, 2007; Lutovac & Kaasila, 2011). This increased attention came through acknowledgement that professional identity is "a key influencing factor on teachers' sense of purpose, self-efficacy, motivation, commitment, job satisfaction" and is thus an "essential" aspect of "teacher work" (Day et al., 2006, p. 601). Not developing a robust teacher identity can manifest in actions that are destructive to career goals and choices and run contrary to teachers' desired ways of being. In more extreme cases, it can lead to early burnout and attrition (Nghia et al., 2017). As such, teacher educators have put greater emphasis on designing learning experiences for their pre-service teachers (PSTs) to support the development of positive professional identities (Izadinia, 2013; Walkington, 2005). We know that engaging in the work and lifestyles of teachers (including field experiences or internships) support identity development, so being intentional about designing enriching experiences for PSTs bode well for them developing relevant teaching competencies and a realistic, rather than idealistic, idea of the profession (Hong, 2010).

One alternative approach to developing professional identity worth exploring more closely is the use of virtual simulations. Simulations, unlike naturalistic settings such as field experiences, can eliminate the potentially limiting effect of working in one school with one mentor teacher and allow for carefully crafted experiences to practice aspects of ambitious instruction that is central to the work of teachers. This may help in supporting identity development by allowing the simulation designer to ensure engagement in the work of teaching in ways that are known to be meaningful. Magen-Nagar and Steinberger (2022) and Carrington and Pereira (2011), for example, found that PSTs had a clearer image of themselves as teachers following engagement in simulations that were integrated into their teacher education courses. In this study, we examined how participation in a suite of practice-based simulations designed to support PSTs in developing the skills to facilitate discussions focused on argumentation influenced secondary math teachers' professional identity.

Study Context

This study was a part of a larger project focused on understanding secondary PSTs' participation in a suite of three increasingly complex practice-based simulations – *Eliciting Learner Knowledge (ELK), Teacher Moments (TM),* and *Avatar-based Simulation (ABS)* - collectively called the Online Practice Suite (OPS). OPS was designed to address some of the current limitations within teacher education programs through providing PSTs support in advancing their skills around a single teaching practice, the facilitation of argumentation-focused discussions. The OPS leverages the technical aspects of online simulation platforms to decompose complex practice and provide PSTs opportunities to engage in repeated practice of different aspects of teaching. Within ELK, a pair of PSTs alternatively role play a student or a teacher using a text-based chat, with a goal that the PST playing the teacher might elicit the student's understanding of the topic. Within TM, PSTs reviewed written work from two students and planned an argumentation-based discussion based on the students' ideas. In ABS, PSTs practiced facilitating a small-group, argumentation-focused discussion about a mathematical idea with five student avatars in an online simulated classroom.

Dotger and Smith (2009) suggested teachers develop their professional identity by gradually learning the practices and expectations of a profession. Thus, participation in OPS created opportunities for PSTs to engage in three online simulations and practice their discussion facilitation skills, which created a context where professional identity could flourish. We were interested in understanding how participation in the OPS would influence pre-service mathematics teachers' professional identity development. Specifically, our research questions were: *1) How do secondary pre-service teachers identify in relation to teaching math prior to and after participation in a suite of online practice-based simulations? 2) How do these identities change over time? 3) What reasons do secondary pre-service teachers provide for their existing mathematics teacher identity?*

Participants, Data Sources and Analyses

Participants included twenty-five PSTs enrolled in secondary mathematics teacher education programs at two institutions in the U.S. To track the PSTs' identity development, we adapted McDonald et al. (2019)'s single item measure to capture a "snapshot" of the teacher's identity at a particular moment (p. 4) (Figure 1). This item was embedded at two time points. First, PSTs responded as part of an online background questionnaire (BIQ) including items about their personal characteristics and professional background, administered at the semester start. Second, they responded as part of an online survey administered after completing the final (ABS) simulation. Participants were given the following prompt, "Select the picture that best describes the current overlap of the image you have of yourself and your image of what a math teacher is." They selected among a set of seven overlapping circles varying in the degree of overlap: 1 = no overlap (do not identify as a math teacher) and 7 = near complete overlap (closely identify as a math teacher) (see Figure 1). In addition, PSTs explained why this picture best described the image of themselves as a math teacher. All PSTs completed the pre-measure; 19 completed the post-measure.

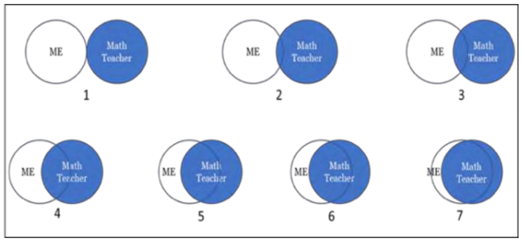

Figure 1: Single Item Measure (adapted from McDonald et al., 2019)

Participants' image selections were tabulated and the sum of the responses for each image number on the pre and post measures were included in Table 1. The reasons provided by participants who selected a particular image were grouped together by number, then read to identify common themes.

Findings and Discussion

Table 1 shows the PSTs' image selection and the total PSTs who selected each image on the pre and post measure.

Table 1: PSTs' Selection of Image from the Teacher Professional Identity Overlap Measure

	Number of PSTs Selecting Image	
Image Number	BIQ (pre-measure) (*n* =25)	Post ABS Survey (post-measure) (*n* = 19)
1 (no overlap)	0	0
2	0	2
3	7	1
4 (50% overlap)	7	3
5	10	4
6	1	7
7 (more than 90% overlap)	0	1

Results showed that prior to OPS, a majority of the PSTs (24/25) selected images with medium overlap (Images 3-5) between their current image of self (indicated as ME in the overlapping circles) and their image of a mathematics teacher. However, there was one PST who indicated strong overlap (Image 6) showing that this PST strongly identified as a mathematics teacher. We noticed how PSTs' professional identity shifted towards the end of participation in the OPS. Of the 19 participants who completed the post measure, eight selected images with maximum overlap (Images 6-7) indicating that they strongly identified as mathematics teachers suggesting that PSTs' experiences in the OPS may have supported their identity development as mathematics teachers.

We also closely examined the shifts in PSTs' image selections from pre- to post-administration and made some interesting observations. We only used data from the 19 participants who completed the post-measure in this analysis. First, the range of image numbers changed from 3 to 5 showing greater variability in the degree to which PSTs identified as mathematics teachers. For the pre-measure, PSTs selected images between 3 and 6, however, on post-measure they selected images between 2 and 7. Second, PSTs shifts were multi-directional; 12 PSTs identified more strongly as math teachers (moving from a lower image number to a higher image number), three showed no change (same image number), and four responses moved from a higher to a lower image number.

We examined PSTs' reasons for their image selections to better understand influences on the PSTs' identity development. Two factors stood out on responses at the mid-level (Images 3 and 4) for either pre or post response or both. One, responses indicated an awareness that their math teacher identity was one of multiple identities they held. As Garry noted, *"While math teacher is a part of me, it does not define me as a person"*. The second factor was related to how strongly they connected being a math teacher with having actual teaching experience; thus, for those who had none prior to OPS, they did not see themselves as math teachers. Hannah captured this well "*Since I* *have not had a lot of in-person experience teaching math, I do not fully picture myself as a 'real' math teacher yet, but it is still something that I have been studying a lot."* For those PSTs who selected Images 6 and 7 during post-administration, they indicated that their experiences within the OPS activities provided them an opportunity to practice teaching, which made them feel more confident to engage in the work of a math teacher. This underscores the connection between identity and efficacy in that individuals tend to identify more closely with a role for which they feel more confident performing (Schutz et al., 2020; Kelchtermans, 2009). We noted a subtle distinction between the responses associated with Image 6 and Image 7 with respect to feelings of preparedness and levels of comfort. More specifically, Ellie who selected Image 7, commented, *"I feel super prepared after everything this semester to be a teacher!".* Responses associated with Image 6 also reflected a sense of being better prepared, but coupled this with noting they still had more to learn. This is reflected in the response by Nancy who stated, *"I feel really comfortable teaching in my placement, but there is still so much to learn!"* PSTs who selected Images 6 and 7 in the post explicitly stated that participation in the OPS helped them to perform aspects of a challenging teaching practice, which would support them in their role as a math teacher.

We were also interested in understanding how identity could change through participation in OPS, so we took a closer look at Sharon who selected Image 6 on pre and Image 4 on the post. Sharon described the reason Image 6 reflected their profession identity stating,

> I have often been told that I am the embodiment of a math teacher. People say that I am logical…and have expertise in math. I have a love for math that exists outside of my classes and teaching experiences... However, there are dimensions of me that are separate from my identity as a math teacher, such as my hobbies and personality.

They identified strongly as a math teacher because they were recognized as such by others, had a love for the discipline and had a connection with math beyond their academic life. We note here that they mentioned that there were still aspects of self (i.e., hobbies and personality) that are distinct from being a mathematics teacher. Interestingly, at the end of participation in the OPS, Sharon selected Image 4 and stated the reason, "*I have many interests separate from math education, but my career embodies who I am in terms of my love for children, math, and learning*". By the end of their participation in the OPS, it appeared that other interests were more central to their identity widening the gap between their current self and their mathematics teacher identity.

Conclusion

In the OPS, mathematics teacher identity development took multiple pathways. Participation appeared to strengthen and make teacher identity more central for some PSTs, while for others it foregrounded other sub-identities. These findings showed the dynamic nature of identity and that how identity changes and develops is related to individuals' personal interpretations of these experiences. Aligned with existing literature, we also observed interconnectedness of mathematics teacher identity and teacher efficacy (c.f. Marschall, 2021), that recognition by others (e.g., Sharon) (Carlone & Johnson, 2007) and opportunities to engage in the work of teaching (e.g., Ellie, Nancy) (Hong, 2010) engendered a stronger mathematics teacher identity (Images 6 and 7). In this regard, online practice-based simulations are a valuable resource as they provide opportunities for PSTs to practice teaching without some of the drawbacks of field experiences, which bodes well for developing a robust mathematics teacher identity. We also noted that the PSTs who indicated having stronger professional identities on the post attributed it to participation in OPS. Given that OPS comprise researcher-designed simulations, these experiences may not be considered akin to the realistic experiences advocated for PSTs (Hong, 2010). However, this may be related to the degree of authenticity the PSTs themselves ascribe to the simulation. This is an area for further exploration.

DESIGNING SIMULATIONS OF STUDENT THINKING FOR PRESERVICE SECONDARY TEACHER EDUCATION

Duane Graysay

Hillary Bermudez
Syracuse University
hbermude@syr.edu

Mathematics teacher educators need pedagogical strategies to orchestrate opportunities for prospective secondary mathematics teachers (PSMTs) to develop their capacities to elicit and build on student thinking. We share preliminary results of an ongoing project to design protocols for clinical simulations that will create such opportunities and that will press PSMTs to act on those opportunities in ways that elicit and build on student thinking.

Keywords: Preservice Teacher Education

Over the past few decades, researcher have documented the positive impact of teaching that elicits and builds on student thinking on students' achievement in mathematics across K-16 (e.g., Carpenter & Fennema, 1992; Laursen et al., 2014). Scholars focused on issues of equity in mathematics education suggest that eliciting and using evidence of student thinking is a necessary component of equity-oriented teaching that positions students as active agents in constructing mathematical knowledge (Chao, Murray, & Gutiérrez, 2014; Seda & Brown, 2021). For these reasons, among others, the Association of Mathematics Teacher Educators (AMTE, 2014) and the National Council of Teachers of Mathematics (NCTM, 2014) describe the practice of eliciting and using evidence of student thinking as a core practice for mathematics teachers. Because the practice is a complex activity (Van Zoest et al., 2017), prospective secondary mathematics teachers (PSMTs) need support in their professional education for learning how to engage in eliciting and building on evidence of student thinking.

However, though research and recommendations support teaching that incorporates tasks that promote student thinking and that elicits and builds on that thinking, teachers face a number of barriers related to socioeconomic status of communities, school or district policies that constrain their authority, demands related to high-stakes testing, and other factors, each of which can limit the extent to which teachers are able to act on those recommendations (Serrano Corkin et al., 2019). In the face of those barriers, many mathematics teachers choose (or are constrained) to teach in ways that emphasize memorization, drill, and practice with limited opportunities for students to think independently or creatively (Banilower et al. 2006; Weiss & Pasley, 2004). So, while PSMTs need opportunities to engage in eliciting and responding to student thinking as part of their professional education (Didis et al., 2016), we cannot rely solely on clinical field experiences to provide those opportunities. We face a fundamental challenge in mathematics teacher education to complement clinical experiences with other experiences designed to create opportunities for PSMTs to engage in eliciting and building on student thinking.

In this brief report, we describe initial stages of our work to investigate the design of clinical simulations of student thinking as a pedagogy for orchestrating opportunities for PSMTs to observe, elicit, and build on student thinking.

Designing Clinical Simulations

We ground the project in the *pedagogies of practice* model (Grossman et al., 2009), positing that effective teacher education requires close connections between content that teachers learn in professional coursework and practical skills developed in clinical experience. The perspective has been influential for designing coursework for teacher education (e.g., Core Practices Consortium, 2017). Our work bridges the development of knowledge and skill by orchestrating "iterative and interactive relationship[s] between teachers' development of principles for teaching and practical tools [for teaching]" (Grossman et al., 2009, p. 278). Further, according to principles of situated cognition (Brown, Collins, Duguid, 1989), learning to teach requires participation in the kinds of environments in which that teaching will occur.

Our design builds on others' uses of clinical simulations to engage prospective teachers with problems of practice (e.g. Dotger & Smith, 2009; Dotger et al., 2017). Our design aligns with the use of approximations of practice to engage prospective mathematics teachers in developing high-leverage instructional practices (Arbaugh et al., 2019, 2020; Campbell & Elliott, 2015; Graysay & Freeburn, 2018; Graysay & Masingila, 2021; Lampert et al., 2010; McDonald, Kazemi, & Kavanagh, 2013).

We based designs on two guiding principles. First, simulation must create opportunities for a PSMT to observe realistic depictions of behaviors that students exhibit while engaged in mathematical thinking. Second, to engage PSMTs in eliciting and building on student thinking, simulation must allow aspects of student thinking to remain opaque unless elicited by the PSMT. We designed three protocols to guide actors in taking actions that represent realistic depictions of student thinking and that serve as *triggers* (Dotger & Smith, 2009) to communicate information about the student's approach. We designed simulations around a task from Rivera (2007). Rivera reported, based on extensive study of ninth-grade Algebra students' responses to this task, two types of strategies that students use: *figural* strategies focus on spatial relationships among Patterns and *numerical* strategies focus on quantities derived from each pattern. Rivera reported that many students were able to extend the pattern iteratively yet struggled to express an explicit generalized expression for the number of tiles needed for an arbitrary figure. Our designs are based on simulating student responses that represent those findings.

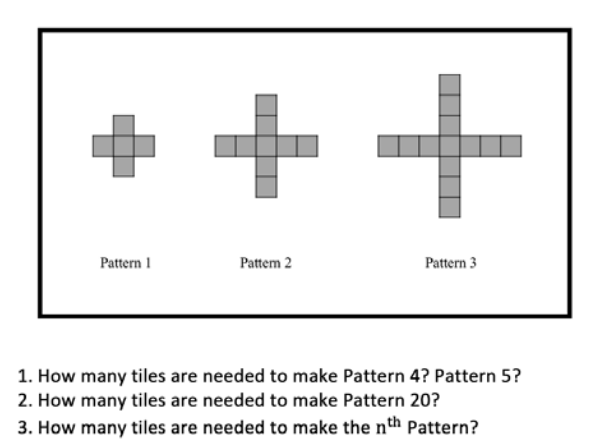

Figure 1. The Tiling Task (Rivera, 2007)

Each protocol includes an initiating trigger in which the student shows a table that she has constructed showing the number of tiles in the first three Patterns and asks for an opportunity to talk through the task with a teacher. The protocols then diverge, each presenting a different simulated figural or numerical strategy to extend the table and an initial, albeit imperfect, expression of her generalization. In the Nell McNally simulation, Nell skip-counts by four to find the number of tiles for the 20^{th} figure and proposes $n+4$ as her generalization. In the Suzy Greenberg simulation, Suzy perceives Pattern 2 as Pattern 1 plus a group of four additional tiles, Pattern 3 as Pattern 1 plus two groups of four and proposes *5+n*4* as a generalization. In the Michelle Gordon simulation, Michelle perceived each pattern as two overlapping rows of tiles with a shared tile at the center and proposes *n*2-1* as a generalization. We instructed actors to respond to questions from the teacher and to allow the teacher to help them revise their generalization. We trained actors in one-hour sessions outlining each role and the triggers that they should present during the simulations. To address proof of concept we chose actors who self-reported ambivalence about their mathematical ability, no prior training as actors, and no teaching experience. In this report we refer to protocols with female names, but in practice we asked actors to self-select a gendered name consistent with their identity.

Our goal in this stage of the project was to determine the effectiveness of the designs for creating conditions in which PSMTs would have opportunities to engage in eliciting and responding to student thinking. We sought to answer the following:

1. Are the protocols and training sufficient for guiding the actors in portraying their role?
2. In what ways, if any, do the simulations provoke PSMTs to elicit and build on student thinking?

Data Collection and Analysis

We collected data in two events separated by several days. Prior to the first event we provided four participating PSMTs (Emily, Fiona, Gabriella, and Heather (pseudonyms)) in their final year of an undergraduate teacher education program with copies of the task. We asked them to generate multiple possible approaches to the task. We explained the nature of the simulation experience. We provided no information about approaches that Nell, Suzy, or Michelle would represent. In the first data collection event each PSMT met individually with an actor portraying Michelle. In the second event each PSMT participated in one conversation with an actor portraying Nell and one conversation with an actor portraying Suzy. We recorded conversations to capture the presentation of triggers and the responses from PSMTs.

We coded PSMTs' responses using the Teacher Response Coding Scheme (TRC) (Van Zoest et al., 2021). The TRC is a multidimensional framework based on the idea that for each mathematical idea that a student expresses, a teacher's response invites some Actor (*teacher* or *student*) to make some Move to advance the conversation. Responses vary in the extent to which the student would recognize their own idea in the response (*explicitly, implicitly*, or *not at all*), and in terms of how the student's idea anchors the Move (*core, peripheral, other*, or *not at all*). Space precludes including the fifteen possible Moves included in the TRC; examples include *Dismissing, Clarifying*, or *Justifying* the idea, *Collecting* a new idea, and *Checking In* for understanding. We added Move codes for responses that we could not clearly identify with an existing code from the TRC. For student statements we created a separate code set: An *Intended Trigger* is a statement that is explicitly provided in training, an *Unplanned Trigger* is consistent with the role but not explicitly provided in training, and an *Off-Protocol* statement is an improvisation by the actor in response to a PSMT question that the training did not anticipate. We divided transcripts into two sets of six, each coded the transcripts in one set, then reviewed the other's coding and resolved differences of opinion to arrive at consensus coding for the twelve transcripts. As we coded we noted patterns in response within each simulation, within each PSMTs' set of simulations, and across the simulations for each role (Nell, Suzy, or Michelle).

Preliminary Findings

Effectiveness of Protocols

We found the protocols moderately effective at guiding actors' portrayals of Nell, Suzy, or Michelle. In each simulation, actors presented intended triggers, though the timing of triggers varied depending on how each PSMT responded. For example, in response to Nell's extension of her table of values by skip counting to find the number of tiles for Pattern 4 and Pattern 5, Emily quickly interjected to guide Nell away from writing out the table to get to the 20th pattern and began introducing and developing a different approach. In contrast, after Nell presented the same skip-counting trigger, Gabriella encouraged Nell to follow her approach, allowing Nell to write out the table up to Pattern 20.

Our goal was to create conditions that would press the PSMTs to elicit and build on student thinking. We found the protocols not very effective at helping the actor deflect the introduction of alternative approaches by PSMTs. We had asked actors to portray Nell, Suzy, and Michelle as insistent on following their own approach by including a deflection trigger, a paraphrasing of "I want to do it my way first." However, we noted that in multiple simulations PSMTs were able to introduce and pursue an alternative approach that the protocol did not prepare the actor for, suggesting that the deflection triggers and actor training were not sufficient to ensure that the simulation followed our intended student approach.

Opportunities to Elicit and Build on Student Thinking

Given that we found evidence in each simulation of actors presenting the intended triggers, we find that simulations were effective at creating opportunities for PSMTs to elicit and build on student thinking. However, simulations were not universally effective at pressing PSMTs to act on those opportunities. In each simulation, PSMTs made some inquiries into how the student had arrived at their initial extension of the table, which allowed the actor to present a trigger representing their numerical approach (Nell) or their way of conceptualizing the structure of the Patterns (Suzy and Michelle). Some PSMTs responded, as Gabriella did, by asking the student to develop the student's idea, eventually helping the student revise her generalization in a way that was consistent with her approach. However, as described in the preceding illustrative anecdote, others responded -- as Emily did -- by replacing the student's idea with a different approach and then working to develop the new approach instead of building on the student's thinking.

Discussion

We provide early, preliminary results of an ongoing project to design simulations that create conditions in which PSMTs are pressed to engage in eliciting and building on student thinking. Our findings suggest, first, that we can create protocols that will effectively guide actors to make statements and take actions that simulate authentic ways that students respond to a given task, regardless of the actor's self-reported mathematical confidence, prior training as an actor, or experience as a teacher or teacher educator. However, the current designs were not effective at creating conditions in which PSMTs are pressed to respect student thinking and build on that thinking rather than replacing students' approaches with the teacher's preferred alternative. Our next step in this ongoing project is to incorporate triggers that actors can present to deflect attempts by PSMTs to guide them away from one approach in favor of the PSMTs' preferred alternative.

MATHEMATICAL MAKING IN TEACHER PREPARATION: RESEARCH AT THE INTERSECTIONS OF KNOWLEDGE, IDENTITY, PEDAGOGY, AND DESIGN

Denish Akuom	Steven Greenstein	Eileen Fernández
Montclair State University	Montclair State University	Montclair State University
akuomd1@montclair.edu	greensteins@montclair.edu	fernandeze@montclair.edu

In this proposal, we share research that explores the potential benefits of a novel Making experience within mathematics teacher preparation that we hypothesized would inform the pedagogical and curricular thinking of prospective teachers of elementary mathematics (PMTs). That experience had PMTs exploring at the intersection of content, pedagogy, and design to digitally design, 3D print, and share an original manipulative with a child to promote their mathematical thinking. We share several vignettes of our research that aim to discern some of the potential benefits the experience might offer PMTs. These take a variety of theoretical and methodological approaches at the intersections of teacher knowledge, identity, pedagogy, and design. Implications of our findings for teacher preparation and professional learning are provided throughout the paper and in its conclusion.

Keywords: Teacher Knowledge, Technology, Problem-Based Learning, Integrated STEM/STEAM

Prospective elementary teachers (PMTs) have been characterized as coming to teacher preparation with limited conceptions of mathematics (AMTE, 2013) and a model of mathematics teaching that appeals mostly to rules and procedures (Ball, 1990; Ma, 1999). Consequently, teacher preparation must offer opportunities that challenge this model, and provide pathways to meaningful interactions and deepened understanding of both content and pedagogy. Connecting with a body of research that conceives of Making in education as the creative practice of designing, building, and innovating with analog and digital tools and materials (Halverson & Sheridan, 2014), we present one such opportunity that we centered in a novel Making experience within mathematics teacher preparation. That experience tasks PMTs with digitally designing, 3D printing, and sharing an original manipulative with a child to engage and advance their mathematical understanding. In seeking to determine what this experience might offer PMTs as they prepare to teach mathematics, our work has taken a number of theoretical and methodological approaches to address research questions at the intersections of teacher knowledge, identity, pedagogy, and design. These questions address the project's broader agenda, which is framed by the following question: *What are the potential benefits of a Making experience within mathematics teacher preparation*?

In this proposal we share some of the findings of our research along with their implications for teacher preparation and professional learning. Because the theoretical framings and methodological approaches we've taken are specific to each of these projects, this proposal is not organized in the conventional manner. Instead, we begin with the broader rationale for this project and then we present three vignettes of our research, each situated within their own literature, framings, and approaches. We conclude by looking across these and other projects to offer some reflections on the potential value of STEAM-integrated curricular experiences in teacher preparation.

Rationale

Schad and Jones's (2019) review of the research on the Maker movement in K12 education finds that students' learning through Making dominates that literature, with foci that include the improvement of STEM learning outcomes, increasing motivation and interest in STEM, and increasing equity by broadening notions of what counts as Making in STEM education. The extent to which this review mentions research on what *teachers* learn through Making is through studies of how they learn to design makerspaces and integrate maker-centered learning strategies (Clapp et al., 2016) into existing curriculum. Thus, there is almost no research on supporting teacher learning through Making. Our work (Akuom & Greenstein, 2021; Greenstein et al., 2017, 2018, 2019, 2020, 2021, 2021, under review) is situated within that gap in the research.

This work connects with a body of literature that frames *teachers as designers* (e.g., Brown, 2009; Maher, 1987) of learning experiences and of the material resources that mediate them. We conceive of design quite broadly to include the "intentional activity of transforming ideas and knowledge" (Carvalho et al., 2019, p. 79) into "tangible, meaningful artifacts" (Koehler & Mishra, 2005, p. 135). Our purpose in doing so is to introduce a pedagogically genuine, open-ended, and iterative design experience into mathematics teacher preparation that is centered on the Making of an original physical manipulative for mathematics teaching and learning. We hypothesized that the experience would afford unique pathways of diversified engagement that could promote epistemic and pedagogical shifts toward inquiry-oriented creative and participatory practices that support teaching and learning mathematics with joy and understanding. Accordingly, we view this Making experience as a *Learning by Design* (Koehler & Mishra, 2005) approach that honors the proposition that it is productive to develop teacher knowledge within a context that recognizes the interactions and connections among its constituent domains of knowledge. We also view the experience from a constructionist perspective (Harel & Papert, 1991), which argues that meaningful learning happens through the designing and sharing of digital or physical artifacts "that learners care about and have some degree of agency over" (Schad & Jones, 2019, p. 2). Indeed, when teachers take agency over the design of their own curriculum materials, they may challenge the *dissonance* that often arises at being tasked with implementing curriculum they neither chose nor endorsed. A *harmony* occurs, as a result, as these teachers come to see themselves as agents of curricular and pedagogical reform (Leander & Osborne, 2008; Priestley et al., 2012).

The Curricular Context and Experience

The study took place over three semesters in a specialized mathematics content course for PMTs at a mid-sized public university in the northeastern United States. Situated in an instructional context in which the teacher educators of those courses modeled an inquiry-oriented pedagogy, the course engaged students in a Making experience defined by the following task: "The purpose of this project is for you to 3D design and print an original physical tool (or 'manipulative') that can be used to teach a mathematical idea, along with corresponding tasks to be completed by a learner using the tool." The data corpus was comprised of video recordings of the in-class design sessions, the design of the tool, and these four written project components: 1) a "Math Autobiography," 2) an "Initial Idea Assignment," 3) a "Project Rationale," and 4) a "Final Paper/Reflection" that presents the findings from problem-solving interviews conducted by the PMTs with their tool and an elementary-age target learner.

The PMTs learned to use the Tinkercad (Autodesk, Inc., 2020; see Figure 1, left) digital modeling platform to design their manipulatives. They worked on their designs in in-class design sessions during three or four of the weekly class meetings. These sessions were held in a design lab (Figure 1, right), that we deliberately chose as we imagined that the PMTs' design activity would be more inspired in an environment intentionally configured to accommodate the kind of immersive, collaborative social space that nourishes it.

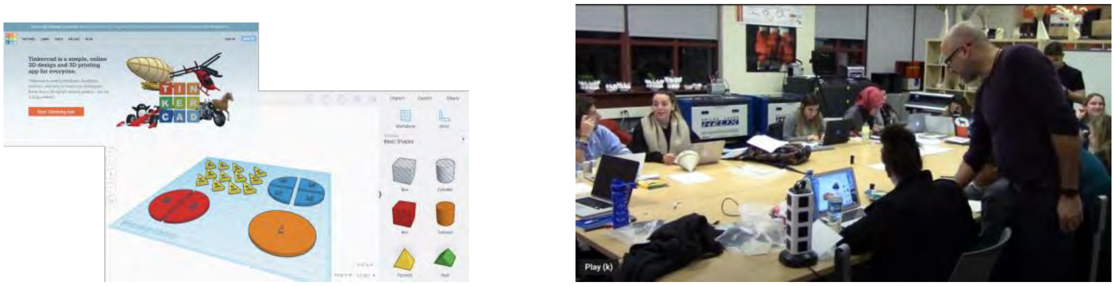

Figure 1: The Tinkercad design environment (left) and the design setting (right).

The first implementation of the Making experience occurred in the context of a pilot study (Greenstein, et al., 2019). Findings from exploratory and revelatory case studies (Yin, 2009) revealed that as the PMTs designed their manipulatives, they leveraged an appreciably rich and mature repertoire of teacher knowledge domains that we are not typically afforded opportunities to see. This finding betrays essentializing characterizations of elementary teachers as lacking in knowledge for teaching mathematics (AMTE, 2013) and suggests the promise of the Making experience. Accordingly, our pilot work became the launching point on a trajectory of further research.

Three Vignettes

In the findings that follow, we present three vignettes of research we've undertaken on that trajectory. Should this proposal be accepted, we will share the findings of these and other projects in our presentation. We propose that this body of work offers evidence of the broadly formative value of a making-oriented, learning by design experience in mathematics teacher preparation.

The Interplay of Discourses of Identity, Mathematics, Pedagogy, and Design in Mathematical Making

Here we took a commognitive perspective on learning (Sfard, 2007, 2008) in order to explore the premise that learning to teach mathematics can be seen as changes in discursive activities that include narratives about mathematics and identity (Heyd-Metzuyanim & Sfard, 2012). We adopted this perspective by foregrounding the identities (Sfard & Prusak, 2005) of teachers as learners in order to recognize what affective, interpersonal, and social matters can bring to this conversation. The following question guided the inquiry: *As prospective teachers of elementary mathematics Make new manipulatives to support the teaching and learning of mathematics, what might their discourses reveal about the epistemology of learning to teach mathematics?*

Methods. We addressed the question through a revelatory case study (Yin, 2009) of a prospective elementary teacher named "Moira" and by framing mathematics learning as the interplay between discourses about mathematical objects (*mathematizing*), participants of the discourse (*identifying*), teaching and learning (*pedagogy*), and design activity (*designing*). This framework provided us with a lens through which to study how the process of making a manipulative can provoke the four discourse activities and make visible the intertwined nature of a teacher's learning. We chose Moira because her initial design was a tool intended to simulate the "keep-change-flip" algorithm for fraction division. However, when the course's teacher educator pushed back on the idea because it did not meet the expectations for a tool that would support a students' conceptual learning, she tried to make sense of the algorithm but could not. Eventually she abandoned the idea altogether. We sought to understand this change through the lenses of the four discourses.

Findings. In this section, we present just one of the central results, which came from a follow-up interview we conducted with Moira in order to understand her rationale for the change in her design idea. It concerns our analysis of this change through the discourses of Mathematizing [*M*], Pedagogy [*P*], Designing [*D*], and Identifying [*I*]. Moira explained, "I wanted to make something that could be interpreted in many different ways [*M/P/D*] ..." As she considered her initial "keep-change-flip" tool, she explained how she realized that, "flipping the fraction upside down in my initial tool... it was just not useful [*M/P/D*] ... Then I came up with this [fraction comparison tool]" [*M/D/I*].

These reflections revealed how Moira's decision to abandon her initial design in light of the *dissonance* she wrestled with as she contemplated its purpose was not just about mathematizing, it was also about identifying. As a teacher, it was important to her that her students have the opportunity to develop their own ways of thinking about fractions with a tool that can be used in a variety of personally meaningful ways. Moira acknowledged that the pedagogy promoted in the course was also part of her decision to change her design: "Well, [the change of design] was because we were talking and you [the teacher educator] said, 'you're just teaching them how to – you're just giving them a way to solve the problem.' And I realized, you're right ..." [*M/P/D/I*]. By switching to a design for comparing fractions, Moira found *harmony* in the realization that she could participate in the discourse endorsed in the course and honor the teacher she wanted to be [*P/I*].

Implications. As in a woven tapestry, learning to teach mathematics weaves together four threads – or discourses – that are unique to a PMT's discursive experiences and particular to a learning community where an inquiry pedagogy is promoted. In this sense, to characterize Moira's learning to teach mathematics as a complex structure of discursive activities interwoven in dialectical unity is to illuminate the brilliance of a tapestry threaded by what she wants to teach (mathematizing), how she wants to teach it (pedagogy), decisions about what resources to make available (designing), and the kind of teacher she wants to be (identifying). This finding of the intertwined nature of the four discursive activities establishes that identity is as central to learning to teach mathematics as is the learning of mathematics, pedagogy, and design. And its implications speak to the formative potential of interdisciplinary project-based experiences as venues for the cultivation of prospective teachers' identities as *teachers becoming* (Greenstein et al., under review).

Designed Manipulatives as Anchors for Teacher Knowledge

This next vignette presents research that explores the 'life' of teachers as designers (e.g., Brown, 2009) of their own curricular materials, tracing their design activities from *tool-design* to *tool-use*. The aim is to explore how a PMT's designed manipulative can mediate the perennial gap (Ünver, 2014) that exists between teacher preparation and practice. The project proceeded in two phases. We began by examining the conceptual, pedagogical, social, and material resources that PMTs bring to their design decisions, their rationales for their uses of those resources, and how these intersect to mediate those design decisions. This phase is depicted in the inner ring of Figure 2. We then extended our inquiry to explore whether the designed tool could possibly be some sort of anchor for their conceptual/pedagogical visions in practice (see the outer ring of Figure 2). The following questions guided the inquiry: *As prospective teachers Make new* *manipulatives for mathematics teaching and learning, what are the resources and rationales they bring to their design decisions? Can connections be made between the resources for their design decisions and how their designs mediate the pedagogical moves they make in practice?*

Methods. To convey just one of many "images of the possible" (Shulman, 2004, p. 147), we present some of the findings of a revelatory case study (Yin, 2009) with "Anyango," a PMT whose written work explicitly expressed a wealth of design decisions and whose problem-solving interview demonstrated how her embeddings of pedagogical and conceptual knowledge in her designs served as anchors for that knowledge in practice.

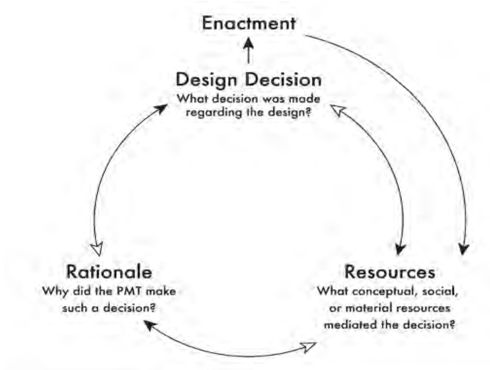

Figure 2: The 3 elements of a design decision (inner ring); Mediating resources may also be evoked in enactment (outer ring).

As the PMTs designed their manipulatives, it was their intention (Malafouris, 2013) to provide their designs with particular affordances (Gibson, 1977) for utilization schemes (Verillon & Rabardel, 1995) that they hypothesized would enable the child to abstract, through their sensorimotor manipulations, the perceptual elements that are the basis of the target concepts. Schön's (1992) notion of "knowing in action" (p. 2) directed our attention as our *Learning by Design* approach (Koehler & Mishra, 2005) enabled us to characterize the interplay between the PMTs' knowledge, experiences, intentions, and other resources that mediated their design decisions as they were invoked and made visible during the iterative design of their tool. In addition, we used the analytic concept of an *embedding* to connote a design element that embeds a PMT's pedagogical and/or conceptual knowledge in their tool. We referred to instances in which the tool served the PMT as a resource for (i.e., a reminder of) knowledge they embedded in the tool as an *anchoring* phenomenon.

Results. Anyango conceived of her design idea in response to the needs of a child she had worked with during problem-solving interviews earlier in the course. She wanted "to help… students visualize and deepen their understanding as they explore fraction relationships." Her design is "a 3D version of fraction strips (Figure 3). Each strip was made to be a rectangular/square piece that slides into individual pegs… [the] blocks stack vertically... to indicate height as value and amount." With several fractions mounted on a single "platform with the 1 (whole) always being visible… the student could begin to grasp how all the smaller parts can equate and compare to the whole." Technological knowledge, the mathematics of fractions, and a responsive pedagogy (e.g., Smith et al., 2016) mediated these and other design decisions that embed fraction values and concepts into the tool.

Anyango posed the following task in her problem-solving interview with the child: *Jack and his two friends each had the same size pizzas for lunch. Jack ate 5/8 of his pizza. Judy ate 2/3 of* *her pizza. And Sam ate 3/6 of his pizza. Who ate the most pizza? Who ate the least?* The child responded by stacking five one-eighth pieces, two one-third pieces, and three one-sixth pieces,

Figure 3: Anyango’s fraction tool

each on their own pedestal with their labels facing her (Figure 3, right). Anyango’s intention was for the child to compare “heights as amount” and identify the tallest as the one “who ate the most,” and shortest as the one “who ate the least.” When she asked the child, “Who ate the most?” the child attended exclusively to the symbolic representations engraved on each of the pegs and concluded that “It’s Jack” (represented by the 5/8 piece). She went on to say that, “5 out of 8 is the biggest of all of them… 2 out of 3 is smaller and 3 out of 6 is… kind of small.” Then, when Anyango asked the child to justify her answer, the child explained, “The top is two and the bottom is three.” We inferred from this response that the child was basing her comparisons on interpretations of fractions as two separate whole numbers. According to this way of thinking, 5/8 is greater than 2/3.

We interpret Anyango’s next move as a noticing one (Sherin et al., 2011) as she leveraged her pedagogical knowledge about the efficacy of interpreting and attending to students’ thinking:

> Anyango: If I turn this [pedestal] around [Figure 2, left, such that the child’s gaze can no longer be restricted to the fraction labels on the pieces], who ate the most?
> Child: <*Pointing to Judy’s stack of two one-third pieces:*> This one.
> Anyango: Who has the least?
> Child: <*Pointing to Sam’s stack of three sixth-pieces:*> This one.

In this excerpt, an unintentional design affordance enabled Anyango’s “flipping” move and served as an anchor for her pedagogical knowledge in action. In a similar anchoring move soon thereafter, Anyango returned the tool to its initial, label-facing orientation so that the child could connect the physical representation of the amount to the symbolic one.

Implications. The diversity of design decisions made by Anyango and other PMTs, as well as the breadth of resources they leveraged and embedded within their designs, speaks to the generative power of the Making experience in terms of the agency PMTs enacted through their design activity and the wealth of conceptual resources that mediated it. In addition, the identification of anchoring phenomena in practice suggests that the Making experience yielded material epistemic scaffolding (in physical manipulative form) that supported PMTs and their commitments to the models of knowing and learning they construct in teacher preparation.

Dare to Care: A Case Study of a Caring Pedagogy on Mathematical Making, Teaching, and Learning

The mathematics and Maker cultures can be interpreted as exclusionary (Stinson, 2004; Gutiérrez, 2017; Barton et al., 2017), thereby suggesting opportunities for broadening learning opportunities to these spaces through *caring* and *Maker* pedagogies. We selected three participants for a revelatory case study (Yin, 2009), each with accompanying “outsider” traits to the project. The teacher educator (TE) and PMT (“David”) brought caring pedagogies to their work but viewed themselves as interlopers to the Making culture. David’s kindergarten student, “Vincent,” is a student with disabilities (SWD) on the autism spectrum whose embodied acts of learning are not typically embraced in traditional mathematics classrooms. By focusing on *caring-centered relationships*, we illustrate how *together*, the participants redefined values associated with Making, traditional mathematics, and what can get celebrated as learning.

Hackenberg's (2010) *mathematical caring relations* (MCR) honor the mathematical and affective dimensions of learning. To navigate an MCR, a teacher must *decenter* "from his or her own perspectives… to help students realize and expand their ideas and worlds" (p. 239). In our project, we honor the open-ended nature of designing and Making a mathematics manipulative, the sometimes uneasy navigation through emergent mathematical "unknowns," the child's unique needs and experiences, and the tensions that are negotiated by carers (Noddings, 2012) in balancing these considerations. We therefore asked: *How does enacting a caring pedagogy during a Making-centered experience impact and broaden opportunities for meaningful mathematics learning? How does this challenge traditional notions of who can Make or participate in mathematics, and who cannot?*

Methods. We utilized purposeful sampling (Creswell, 2007) to focus this case study on our three participants. MCRs were analyzed and revealed through participants' verbal utterances and intonations, body language, actions, and mutual positionings (Simmt, 2000). The possibility of intersecting caring and Making theories called for a grounded theory approach (Glaser & Strauss, 1967) to analyzing and cross-referencing our data sources.

Results. David's Making experience began with an easy "answer" to the project task by designing an already-existing manipulative with a classmate. However, when the TE noticed the warm interactions between David and Vincent in a video recording of an earlier interview, she invited David to design a manipulative that was responsive to these interactions. When David articulated his trepidation in undertaking this more open-ended task, the TE promised to support him. We recognized this moment as the TE accepting responsibility for supporting David in caring for Vincent, and in navigating the discomfort and tensions (Noddings, 2012) that accompany this pedagogical decision. David, in turn, accepts responsibility for Vincent's care by sharing and utilizing Vincent's knowledge and love of shapes. After a few sessions with Vincent, David opts to design triangular, square, and hexagonal prisms with holes and corresponding inserts intended to create a one-to-one matching task.

During a design session, David noticed that some printed inserts did not fit into their intended holes. The TE utilized this moment of struggle to support David through his technological anxieties, and recommended including the "mis-shapes" in the matching task. David reflected on this being a "teachable moment" because his "mis-shapes" became usable for his and Vincent's learning. In another teachable moment, Vincent showed David how every shape and insert need not "match" to fill the holes (e.g., Vincent drops hexagonal inserts into the square hole). These uninhibited moments of insight suggested a transition in Vincent's attention from a shape's sides to its genus—a driving force underlying the concept of topological equivalence. These explorations culminated in Vincent aligning the hexagonal and square prisms with unlike holes to peer through them, and David receptively arranging the pieces between them to form a telescope (see Figure 4)! Together, they locked eyes and exchanged laughter and words of affirmation in an MCR where David decentered from the intended activity to *literally see his child's point of view* (Hackenberg, 2005).

Implications. Our focus on Making something *for* and *with* a specific student enabled a TE and PMT to leverage caring-centered pedagogies, and speaks to the inclusivity that caring brings to learning. As a member of the SWD community, Vincent's inclusive participation enabled him to learn with his characteristic, embodied enthusiasm in ways that defy the exclusionary notion that SWDs are not expected to participate in problem solving. The TE and David's caring-

Figure 4: Vincent sees similarities in different-shaped holes.

centered pedagogies embraced David's "mistakes" as an important part of his learning in addition to Vincent's inclination to know and learn with his body. By providing a platform "to demonstrate care for individual students and for the subject matter itself" (Bartell, 2011, p. 54), this case demonstrates how Making can create a novel opportunity to honor and invite the participation of supposed outsiders to the mathematics and Maker cultures and embrace the mathematical struggle, surprise, and discovery of all learners.

Conclusion

In addressing the question, *What are the potential benefits of a Making experience within mathematics teacher preparation?*, our research has revealed a number of positive outcomes. We shared these findings and their implications for teacher learning at the conclusion of each of the vignettes we presented above. With the conference theme of critical dissonance and resonant harmony in mind, we now provide a summary overview of the findings reported here and of other projects associated with this research.

Over and over, our findings demonstrate that immersing prospective teachers in a communal design environment and tasking them with a pedagogically genuine design experience generates opportunities for them to *harmonize emerging dissonances*. Moira's shift to a design for a conceptually promising learning tool harmonized the dissonance she faced as she confronted the rote understandings associated with her initial design idea. Anyango reconciled the dissonance that arose in her interaction with a learner by enacting a harmonizing pedagogy for the child's sound learning using a novel use of her tool. And the dissonances David felt in his interactions with a teacher and learner were harmonized as he navigated a caring pedagogy that gave rise to unforeseen and innovative perspectives on his tool for that child's learning. In addition, in projects not reported here, we observed two learners harmonize the dissonance they experienced in making sense of fraction division through embodied actions (e.g., Abrahamson, & Lindgren, 2014) with a physical "Fraction Orange" manipulative (Greenstein et al., 2021). We also observed the dissonance one PMT felt as she hesitated to leverage her cultural funds of knowledge (Moll et al., 1992) being harmonized as another PMT encouraged her to leverage it in their design of a tool for counting (Akuom & Greenstein, 2021).

These findings contribute to bodies of research on a "teacher's becoming" (Vågan, 2011; Greenstein et al., under review). They also generate new opportunities for research that moves the field forward regarding the potential value of constructionist, STEAM-integrated curricular experiences in teacher preparation. Future research could more closely explore the design of these environments in teacher preparation, the teacher educator's role in designing and facilitating these experiences, and the subsequent in-service instruction of teachers who participated in these experiences during teacher preparation.

A PROSPECTIVE TEACHER'S SHIFTING VIEWS IN HOW MATHEMATICAL AUTHORITY OPERATES IN THE CLASSROOM

Michael Hamilton
University of Georgia
mwhamilton@uga.edu

This case study investigated how one prospective teacher's views of how mathematical authority operates in the classroom were influenced by her student teaching practicum by comparing mathematical authority diagrams produced prior to and after student teaching. I found there were similarities across the diagrams, but many differences in the diagrams resulted directly from her student teaching experience(s). The most noticeable difference was in her views of students as mathematical authorities. Practical implications, particularly for mathematics teacher educators, are discussed.

Keywords: Preservice Teacher Education, Teachers' Perspectives

Introduction

Many discussions of effective instructional strategies in mathematics classrooms have implications for how authority should operate in the classroom. For instance, many strategies and recommendations made in *Principles to Actions* (NCTM, 2014) require teachers to leverage and build upon *students'* ideas, *students'* solution strategies, and *students'* experiences as means for students to develop their own conceptions of mathematics. Following these recommendations, teachers who enact productive instructional strategies consistently position students as authorities in the classroom particularly when it comes to the mathematics that is reasoned with, discussed, and presented. However, consistently positioning students as authorities in the mathematics classroom can be challenging for mathematics teachers (Amit & Fried, 2005; Hamm & Perry, 2002; Wilson & Lloyd, 2000). One reason it can be challenging for teachers to frequently and consistently positions students as authorities is that multiple sources of authority, other than the teacher and students, may be operating within the mathematics classroom (Wagner & Herbel-Eisenmann, 2014). Because enacting instructional strategies that consistently position students as mathematical authorities is challenging and complex, the purpose of this study is to investigate a prospective teacher's views of how mathematical authority operates in classrooms and how those views were influenced by their student teaching experience(s).

Literature Review and Theoretical Framing

Mathematical authority in classrooms is a relatively new line of inquiry in mathematics education research. Consequently, few conceptions of mathematical authority exist and many scholars provide descriptions of mathematical authority rather than defining the construct (see Gresalfi & Cobb, 2006; Stein et al., 2008; Wilson & Lloyd, 2000). Moreover, many descriptions of mathematical authority describe only the teacher and students as potential authorities and leave out other individuals or objects outside of the immediate classroom content. Gresalfi and Cobb, for instance, described mathematical authority as "the degree to which students are given opportunities to be involved in decision making and whether they have a say in establishing priorities in task completion, method, or pace of learning" (p. 51). However, Wagner and Herbel-Eisenmann's (2014) study suggests individuals and objects, in addition to teachers and students, can be positioned as mathematical authorities in the classroom. Hence, I contend that a new definition of mathematical authority that allows for a variety of potential sources of mathematical authority is needed to further our understanding of mathematical authority relations in classrooms.

To develop my conception of mathematical authority, I draw from tenets of Gresalfi and Cobb's (2006) description of mathematical authority along with Weber's (1947) conception of authority. Weber perceived authority as a relationship in which one individual chooses to follow the orders of another. Furthermore, Weber claimed that when an authority relation exists, the individual chooses to follow the orders of the other when the other is seen to have a valid claim to legitimacy by the individual. Amit and Fried (2005) summarized Weber's conception of an authority relation well when they wrote an authority relation "has as much to do with those who obey it as it does with those who command it: a relationship of authority is a quasi-reciprocal one" (p. 147). The primary tenets of Weber's conception of authority that I draw on are authority being described as a *relationship* and one that hinges of the *legitimacy* of the individual who is viewed as an authority. Tying those tenets of authority together with Gresalfi and Cobb's description of mathematical authority, I define mathematical authority as a relationship in which at least one individual views another subject (i.e. person, community, object) as a legitimate source of mathematical knowledge or mathematical reasoning and, thus, able to make meaningful mathematical contributions.

Methods

This study was a particularistic and descriptive case study (Merriam, 1998) of one prospective teacher's views of mathematical authority in the classroom and how those views were influenced by their student teaching practicum. As part of a larger study, Grace was a student in the secondary mathematics education program at a large public university in the southeastern United States and completed her student teaching practicum in a high school classroom during the Fall 2021 semester. Grace took part in three interviews prior to student teaching, one interview during student teaching, and three interviews after student teaching. Grace also developed two diagrams representing how she thought mathematical authority operated in the classroom (see Figures 1 and 2). The purpose of the diagrams was to provide Grace a medium in which she could explore and explicate aspects of her experiences and thoughts related to mathematical authority in the classroom (Black & Halliwell, 2000; Wagner & Herbel-Eisenmann, 2014). Grace developed her initial diagram during the second interview. Prior to the sixth interview, Grace developed the second diagram and recorded a video explanation of her diagram. During the sixth interview, Grace was asked to further describe aspects of her second diagram and compare her second diagram with her first diagram side-by-side. Grace was chosen for this case study because of the influence student teaching had on her views of mathematical authority in the classroom, particularly when it came to students positioned as mathematical authorities.

The data from the interviews and the video describing the second diagram were transcribed. These transcripts were then coded with broad codes such as *teacher as authority*, *students as authority*, and *objects as authority*. Within each code I then determined emergent themes and created subcodes describing those themes (Strauss & Corbin, 1998). With the new subcodes I re-coded the transcripts again and asked if new codes needed to be included. This process continued until no new codes emerged. Both diagrams were analyzed in tandem with the coded transcripts. Specifically, aspects of the diagrams that were not discussed in the interviews were analyzed based on Grace's descriptions of the diagram, particularly how she described relationships between sources of authority in the diagram (e.g. via arrows between sources).

Results

Prior to student teaching Grace viewed all students as mathematical authorities and some students were viewed as more of a mathematical authority in relation to their peers. Moreover, the legitimacy by which students were positioned as mathematical authorities was primarily rooted in their mathematical conceptions. To represent mathematical authority operating among students and the teacher in her first diagram, Grace drew bidirectional arrows between all the students, represented by squares, and between the teacher and the students (see Figure 1). Grace explained that students viewed their peers as mathematical authorities due to their peers' knowledge of a certain mathematical topic or because they can "find value in how they're thinking about the math." As she described the teacher positioning students as mathematical authorities, Grace claimed, "there are always ways to either look at problems or solve problems that I would never think of that my students would think of." Furthermore, a student could be viewed as more of a mathematical authority by both their peers and the teacher if they consistently contributed productive mathematical insights and/or ideas in class discussions. Consistent in Grace's descriptions of what made a student a mathematical authority was their mathematical thinking or insights. In addition to the teacher and students, Grace included other sources of mathematical authority in her first diagram that were divided into those positioned by the teacher as authorities (such as Department Heads) and those positioned by students as authorities (such as Tutors).

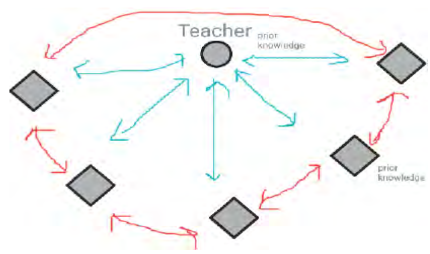

Figure 1: Students and teacher represented as mathematical authorities in first diagram

When asked to compare diagrams, Grace noted there was much more detail in her second diagram. Grace's second diagram did not include many new sources of mathematical authority, but some sources that were once viewed as sources for the teacher were now viewed as sources for both students and teachers. For instance, in the first diagram Grace included *fellow teachers* as a source that the teacher might view as a mathematical authority when it comes to increasing content knowledge and how to best teach certain mathematical concepts. In the second diagram Grace espoused a similar view of how teachers might position other teachers as mathematical authorities, but she also described how students might view other teachers as mathematical authorities. What is notable in her description of this shift is it is grounded in her experiences as a student teacher. During student teaching, Grace saw students go to their previous teachers for help on math homework which she indicated influenced differences in how she developed her second diagram. While describing her second diagram, and as she compared the two diagrams, Grace consistently attributed changes in her views of how mathematical authority operates in the classroom to her student teaching experience(s).

The most salient change in Grace's views about mathematical authority was related to students and their position as mathematical authorities. From the teacher's perspective, Grace continued to view all students as mathematical authorities in the classroom, however her view of students positioning their peers as mathematical authorities shifted. When discussing her second diagram, Grace claimed, "after finishing my student teaching there's no denying that some students have more mathematical authority than others". In isolation this claim may seem no different than Grace's claim prior to student teaching that some students could be viewed as more of a mathematical authority in relation to their peers. Yet, the primary reasons Grace held this view after student teaching were the differences she noticed in students' personalities and/or dispositions. For instance, Grace viewed some students being positioned as more of a mathematical authority than others due to differences in their confidence, willingness to participate, and abilities to clearly communicate their ideas. These views are shown in her second diagram (see Figure 2) by representing students with various sized rectangles and with unidirectional arrows going between students. When elaborating on why she represented students this way, Grace said, "there could also be students that don't have any arrows going to them at all," meaning some students may not be viewed as a mathematical authority by their peers. Influenced by her student teaching experience(s), Grace no longer held the view of students positioning all their peers as mathematical authorities. Moreover, what is notable in this shift is that students' personalities and/or dispositions were the primary factors that led to them being positioned as mathematical authorities by their peers, not necessarily the validity of their mathematical ideas or conceptions. In other words, the legitimacy by which students were primarily positioned as mathematical authorities shifted from their mathematical ideas and insights to their personalities and/or dispositions.

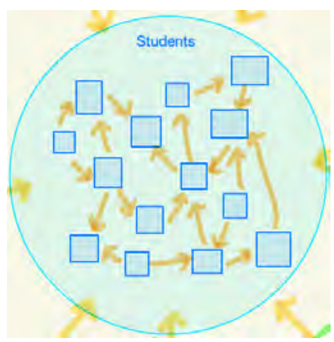

Figure 2: Students as mathematical authorities to other students in second diagram

Discussion and Implications

Although this study focuses on just one student teacher's shifting views of how mathematical authority operates in the mathematics classroom, Grace's story is notable due to the change in her view of students as mathematical authorities as well as what influenced those changes. Britzman (2003) claimed learning to teach is an active and interactive endeavor in which "one's past, present, and future are set in dynamic tension" (p. 31). Because student teachers experience this dynamic tension it would be reasonable to assume their student teaching experience(s) lead to changes in their beliefs, conceptions, and perspectives, as was the case with Grace. Given the complex nature of student teaching, student teachers like Grace may need support from mathematics teacher educators (MTEs) navigating and reflecting upon their shifting views and the implications of those shifts on their instructional practice. Additionally, and echoing a suggestion made by Wagner & Herbel-Eisenmann (2014), mathematical authority diagrams may be a powerful tool to engage teachers in such reflection on their instructional practices. Through this support and reflection, novice teachers may be better prepared to enact instructional strategies that consistently position students as mathematical authorities and, as a result, support students in developing their own meaningful conceptions of mathematics.

Typically, mentor teachers (MTs) help teacher candidates (TCs) learn by supporting them before and after lessons and observing TCs' practice. This design research study reimagines the MT-TC relationship to be one of co-learning and tests a provisional theory and design of a Collaborative Learning Structure (CLS) tool to support MT-TC co-learning equity-oriented teaching. We draw from a case in which a pair of educators used an early iteration of the CLS. Our analysis demonstrates that rather than asking teachers to plan to confer in 'curious or uncertain' moments, it may be more beneficial to confer in 'decision-making moments' while teaching. We discuss implications of our theory of co-learning equity-oriented teaching.

Keywords: Preservice Teacher Education, Equity, Inclusion, and Diversity, Mentor Teachers,

Teachers engage in learning while teaching as they navigate in relation to students and subject matter, a process Lampert (2009) calls "learning teaching." Shulman (2005), like Lampert characterizes teaching as necessarily entailing a "pedagogy of uncertainty." The relational and improvisational nature of the work constantly presents a necessity for teachers of all levels to make new decisions about "how to act under conditions where knowledge is limited but actions must be taken" (Shulman 2005, p.20).

Teacher education programs routinely place teacher candidates (TCs) in field experiences, primarily designed to give them opportunities to practice teaching and learn from mentor teachers (MTs). Mentors typically offer support before and after teaching and position themselves as observers, rarely engaging with novices "inside the action of teaching" (Schwille, 2008). This arrangement assumes teaching is an individual act and leaves teachers alone to "grapple independently with the complexities that may arise" (Ghousseini, 2021, p.1). Drawing on concepts from theater studies, Ghousseini et al. (2021) liken these norms of noninterference to the "fourth wall" that separates actors from the audience. They argue that this "entrenched wall" separates "teachers who gather to improve their practice and the practice itself" (Ghousseini, 2021, p.1). That mentors and novices are typically positioned as spectators of one another's teaching has implications for the learning opportunities available in field experiences. Our study seeks to design learning opportunities for *both* MTs and TCs supported by tools which break through the fourth wall, thereby opening up practice to collaboration, experimentation, inquiry.

Purposes and Research Questions

We are in early stages of a four-year NSF funded project to reimagine the MT-TC as *co-learners* (i.e., Thompson et al., 2015) of *equity-oriented teaching* (e.g., Aguirre, et al., 2013). Using design research methodology (English, 2003), we are creating tools that we term Collaborative Learning Structures (CLSs) which create opportunities for mentors and novices to co-learn in the context of field experiences. The CLS, in focus here, works to make more explicit the implicit work of teaching, which occurs during instruction, in an effort to support teachers in learning about equity-oriented teaching together. Striving for equitable teaching and learning in a mathematics classroom is an ongoing process (NCTM/TODOS, 2016) characterized by an orientation to teaching centered on the needs and assets of traditionally marginalized students and is, therefore deeply relevant and urgent for all educators including MTs and TCs alike (Gutierrez, 2018; Shah & Crespo, 2018). Teachers must be on a daily quest for understanding the dissonance felt by traditionally underserved students in their math classrooms and act in ways that elicit, draw on, value, and validate students' perspectives, strengths, knowledge, and skills.

Methods

We started our project with a provisional theory of co-learning between MTs and TCs and, over the next several years, intend to revise it as we iteratively study MT-TC dyads' use of CLSs, and revise the CLSs accordingly (Cobb et al., 2003; English 2003). Our current CLS tool prompts mentor-novice pairs to focus on equity in students' participation patterns during a lesson. Before the lesson, the MT-TC dyad are asked to confer about the upcoming lesson (either person may be teaching) and to anticipate moments to confer *during* the lesson when the person teaching might "feel curious or uncertain" regarding their noticings of students' mathematical understandings and/or participation patterns. The intent is for the MT-TC dyad during the lesson to "co-notice" students' participation, confer at least one time to discuss an uncertain moment, and deliberate about what to do next with students. After the lesson, the MT and TC are asked to reflect on noticing either made during the lesson, any instructional decisions jointly made, and identify new goals for co-learning. Due to logistical reasons related to the global pandemic, we were unable to collect data using a CLS with MTs and TCs. However, we were able to study a coaching cycle between a teacher and a coach as they engage using parts of our initial CLS tool. While the case focuses on co-learning between in-service professionals (rather than MT-TC dyads), our analysis supported a revision of a key aspect of our theory of co-learning and the CLS. The case below exemplifies how our team is relating a teacher's in-the-moment decision-making to opportunities for MT-TC co-learning. Our analysis highlights how we are thinking about the design of tools to support MT-TC dyads co-learning equity-oriented teaching.

Participants

The focal participant in this study is Sally, a white middle school math teacher with 19 years of teaching experience, with the last 10 years as a 6th grade math teacher at this school. Sally's school serves approximately 1000 students, nearly 40% of whom are students of color, the majority of whom are Latinx. Nearly half of the students at the school qualify for free/reduced lunch. Four years ago, Sally and a colleague successfully initiated efforts to de-track mathematics in their school, which is now in its second year of being de-tracked.

Context, Data Collection, and Analysis

We gathered data on use of some of the CLS tool prompts in a coaching cycle, including planning, teaching, and debriefing, between the district math coach and Sally. A project researcher audio recorded, observed, and took field notes throughout the cycle, including during the 70-minute math class. This coaching cycle occurred after a professional development session featuring "worked examples" (Renki, 2017). Sally and the coach planned a lesson using worked examples that Sally intended to use during three class periods the next day. The goal for Sally's lesson was for students to identify the origin and represent five teams participating in a race on a straight line divided into equal intervals with this information: Team A is in the lead; Team B is 4 miles behind Team C; Team C is 2 miles behind Team A and 8 miles ahead of Team D; and Team E is 5 miles ahead of Team B. Students were to note the position of each team relative to others and be able to explain how they knew. Sally expected students to use positive and negative numbers to express spatial relationships. She and the coach discussed advantages of using worked examples to explore and compare multiple solutions. During the lesson the math coach and project researcher joined in co-noticing and conferred with Sally about what they noticed. Sally made a number of changes to the original lesson plan in-the-moment but her pedagogical reasoning remained invisible to them.

We analyzed excerpts from the lesson debriefing in service of further refinement of the CLS tool and the theory of co-learning underlying its design. Our analytic questions included: What was uncertain for Sally while teaching? What did she notice during the lesson about students who were currently experiencing low status? What decisions did she make that related to elevating those students and on what basis did she make the decisions? How might what we learn from analyzing Sally's reflections on her in-the-moment decisions and the reasoning behind them inform refinement of the CLS tool for both novices and experienced teachers?

Results

The following two excerpts from a transcript during the lesson debriefing session make visible a sample of many decisions Sally made while teaching and her reasons for making these decisions (Ball, 2018). The numbers in Table 1 and Table 2 indicate Sally's reasons verbatim from the transcript. Our analysis references Sally's reasoning with these numbers. Sally changed her plans from using worked examples and, instead, selected and sequenced her students' work (Smith & Sherin, 2019) The coach asked her to explain her reasoning around this decision.

Table 1: Excerpt 1 from Sally's Lesson Debrief with Coach and Researcher

Sally's Reasoning from the Debrief *indicates reasons known ahead of the lesson ** indicates reasons unknown ahead of the lesson	**Analysis**
1. One of the reasons I made the shift is I could see the waning attention span of this group.** **2.** And I was looking at the time, and I needed to make sure that they could understand the relationship of pieces together. So, I decided to table this [worked examples] for now.** **3.** That, and the fact that we had 3 kids who pulled up numbers to show the distance between. That seemed more authentic than doing this [worked examples]. ** **4.** The last thing as to why I did make the shift is…which of the kids who responded today were my IEP kids? Which of my kids, whose journals went up on the overhead, were my IEP kids? And which four voices came out that haven't contributed anything all year? So, I took it as a win.*	Sally entered class knowing that some students have shorter attention spans than others and because of this she watches how much time she spends on activities (**1**, **2**). She also noticed several students' work and voices she wanted to elevate (**4**) do work on the math problem in ways that offered her ideas to share that would benefit other students (**3**).

Table 1 offers insight in Sally's deep knowledge of students that prompted in-the-moment decision changes to her lesson plans. Table 2 represents Sally's pedagogical reasoning when she was asked by project researcher to elaborate on her decisions who she called on and why.

Table 2: Excerpt 2 from Sally's Lesson Debrief with Coach and Researcher

Sally's Reasoning from the Debrief	Analysis
5. And the two IEP kids, one of them had the numbering system I wanted.** **6.** Not Will, but this was the kid that showed the numbers…** **7.** James needs to have his status raised with other students. James knows what he's doing. He knows why he's doing it. He's not comfortable giving his ideas out to kids who claim to have math status.* So, I wanted his status to be raised for those people to see Jonathon as a mathematician.** **8.** Mike doesn't participate a lot. *And, so, when I saw the numbers on his paper and that we could connect to Will…I wanted his ideas to come up because he never shares. And because this was a deep thought to share about the exact relationship between things …** **9.** Brandon just needs all the status he can get. He's a copier. He's very good at it.* And, so, the fact that he had something different from his group, and they were arguing about it, because his was in a separate spot than everybody else's, and the two girls [in his group] have really high math status in the classroom.**	James and Brandon are students with IEPs who Sally knows are seen by others and themselves as having lower status and she noticed they both had ideas that she knew could be useful to other students (5). She could see that James knew how to solve the problem (5, 7). Brandon usually copies others but this time he had not copied and his group was arguing about his ideas and the ideas of two girls with high status in his group (5, 9). Will was not someone who needed his status elevated (6) but he had math ideas that Sally thought would allow her to connect Mike's (8) deep thinking with Will's idea (8).

What Sally learned about how to attend to students' participation patterns and status *while* teaching are things she could not have known earlier. These improvised moments represent Sally's efforts to be responsive to who her students are outside and inside the math class, what they know, and what they need to feel engaged, seen, and successful. However, despite the math coach and project researcher's attempts to engage with Sally while she was teaching, most of the rich pedagogical reasoning which she engaged in during the lesson remained invisible to them. This analysis leads us to refine the CLS tool to shift from conferring during the lesson in moments that feel 'curious or uncertain,' to "decision-making moments" in teaching. We aim to position MTs and TCs as co-learners in shared enactments of equity-oriented teaching and create routines supportive of co-learners in predicting when these moments are about to occur and pausing for collaborative sharing of co-noticing and decision-making. We will test a revised theory of co-learning that centers moments of decision-making, specifically regarding how to center traditionally marginalized students' mathematical sensemaking.

EXPLORING THE USE OF ONLINE MODULES FOR SUPPORTING MATHEMATICS FOR TEACHING

Jennifer Holm
Wilfrid Laurier University
jholm@wlu.ca

This research examines the use of online modules in supporting the development of mathematics for teaching in pre-service teachers. This paper focuses on a single participant in the research study to provide some overarching themes that were presented in the work. Although the results were mixed on even improving mathematics content knowledge, the case provides evidence for considering how to improve an online platform in supporting future teachers.

Keywords: Mathematical Knowledge for Teaching; Preservice Teacher Education; Online and Distance Education

This research is based in Ontario in a Bachelor of Education program, where individuals would attend the program after a four-year degree. Since the program itself is a two-year program, there are limitations in the number of hours provided to mathematics. In the studied university, there are two required mathematics methods courses (one in each year of the program), but these courses explore pedagogical methods for teaching mathematics in combination with mathematics for teaching. Since previous research has pointed to concerns about the level of mathematics for teaching in pre-service teachers (e.g., Kajander, 2010), the creation of an online portal provided extra time for pre-service teachers to focus on mathematics knowledge for teaching. In this research, a single participant from the piloted study is examined in detail to provide some preliminary questions and starting points for expanding the online platform.

Literature and Theoretical Framework

The research is framed by the discussion of mathematics for teaching presented in the research literature. Mathematics for teaching has been identified as an understanding of mathematics content which "bridges content knowledge and the practice of teaching" (Ball et al., 2008, p. 389). In creating the modules, the focus was on an understanding of models, manipulatives, and alternative algorithms that would be needed by a teacher, but not necessarily someone studying mathematics (Baumert et al., 2010; Hill, 2010; Ma, 1999). The mathematics for teaching knowledge needed by teachers also differs from the knowledge a mathematics student would need or gain during a classroom learning experience (Chamberlin et al., 2008; Davis & Simmt, 2006; Kajander, 2010). In particular, the lens used in analyzing the participant responses focused on the notion that merely stating a procedure or procedural steps would not be enough to show mathematical reasoning and support a claim when teaching (Ball & Bass, 2000). In evaluating the responses, the responses were coded to examine whether they followed a procedure or used an alternative method for solving the question.

More research, especially during the pandemic, has been conducted on using online technology as a platform to teach without specifically considering video-interventions. For example, Mulenga and Marbán (2020) examined pre-service teachers and their engagement during an online mathematics course and noted that the ability to personalize the program supported development, although attitude related to mathematics and technology impacted performance. Although there is much that can be learned from the research about online teaching in mathematics, since this research focused on the use of video-interventions, the literature discussed focuses on this area. The majority of research on video-based interventions with pre-service teachers focuses on the use of classroom observation videos for prompting discussion of teaching and learning practices (e.g., Borko et al., 2008). In these interventions, teachers are often shown short videos of active classrooms and asked to observe teacher practices and student behaviours. Barth-Cohen et al. (2018) used video analysis with the intent of increasing the reflective practices of the pre-service teacher. This study also points to how video is an underused and understudied form of professional development. Johnson et al. (2019) examined the use of virtual teaching playgrounds with a video component in supporting pre-service and in-service teachers and determined no difference between the in person and virtual learning outcomes. The study presented in this paper adds to this existing literature by focusing on an intervention to support mathematics knowledge for teaching through video-based interventions.

Methods

The participants in the research study were pre-service teachers enrolled in the Bachelor of Education program. Since the online modules were an addition to the program, pre-service teachers self-selected if they wished to participate. The platform for the program was housed within the university system limiting the possible participants to those who had enrolled in the program. The modules in the platform were completed and adjusted in an iterative process, with participants being enrolled and allowed to work, then additional information or modules were created. At the time of the research, three modules were completed: measurement, algebra, and fractions. Each of the modules contains sub-modules related to different areas of the content strand based on complexity determined by the Ontario curriculum up to and including grade 8 (Ontario Ministry of Education, 2020). For example, the algebra module contains sub-modules related to repeating patterns, linear patterns, and non-linear patterns. The number of sub-modules varied between the different content modules.

Each of the sub-modules followed an identical pattern to allow familiarity with the course content, as well the initial platform had a linear layout, so this prevented overly complicating the platform. Each sub-module began with an initial mathematics problem that was then submitted to the site. Upon submission of their work, participants would be able to view videos of different ways to solve the problem, as well as see an answer to the initial mathematics problem. Next, participants would be invited to complete and submit a solution to a second, similar problem. A survey was also provided to ask participants about their experience in the sub-module. Figure 1 shows the first and second question in the measurement sub-module on area. Data collected for the entire project consists of the solutions to both sets of problems and the information provided in the survey.

A gardener has a 1.5 m^2 garden where she will plant flowers. She decides to plant bluebells on an area that is 0.6 of the total garden. One how many total square meters can she plant bluebells?

A gardener has a 2.2 m^2 garden where she will plant vegetables. She decides to plant squash on an area that is one-quarter of the total garden. On how many total square meters will she plant squash?

Figure 1. Questions from area sub-module

Note. Question 1 is on the top. This question would appear before the video intervention. Question 2 is on the bottom.

The videos and questions in the program were designed to be completed on the participants' own time and are elective, so participants chose which problems to do and to what extent they wished to complete them. At time of writing, 19 participants volunteered to be part of the project; however, only 9 had completed any work within the platform. The data collection is ongoing, and the number of questions that the participants have completed varies between the participants. Data was collected through the online learning management system of the university, and ethics was obtained through the university Research Ethics Board. The participant in this summary was one of two participants to complete all sub-modules in the measurement section, and the only individual to complete any sub-modules in the algebra module. For the data analysis, descriptive statistics were first collected on the number of correct and incorrect solutions both before the video intervention and after it. Solution methods were then analyzed to see if there was evidence of mathematics for teaching and if the solution method differed from the start to the finish.

Results

For the purposes of this discussion, I will use the pseudonym of Terry. Since gender was not a question in the data collection, the pronoun "they/them" will be used throughout when discussing Terry's solutions. Table 1 provides a summary of the questions answered correctly and incorrectly before the intervention and after watching the videos. The number of questions that were answered correctly increased for the second question that was attempted.

Table 1: Summary of Data

Question	Correct	Incorrect
Question #1 (pre-intervention)	9 (36%)	16 (64%)
Question #2 (post-intervention)	16 (64%)	9 (36%)

In exploring the survey results, Terry rated the majority of the questions as "easy" both before and after the intervention. There were questions that Terry got correct before the intervention that they got incorrect after, so there was no consistency in the application of correct procedures after intervention. As well, there were questions that Terry got incorrect both before and after intervention, such as the volume of rectangular prisms sub-module.

In the second part of the analysis, the individual solutions of the individual were examined. This data led to some interesting results where only one solution method changed from the pre-intervention question to the post-intervention question. Even with the change in method, Terry still gave an incorrect answer. The solutions Terry submitted can be found in Figure 2. The question was found in the irregular shapes sub-module, where participants were asked to find the area and perimeter of an irregular shape in question 1, and then a different irregular shape in question 2. In one sub-module, Terry did not show a solution method in the second question, but the answer was incorrect both before and after the video.

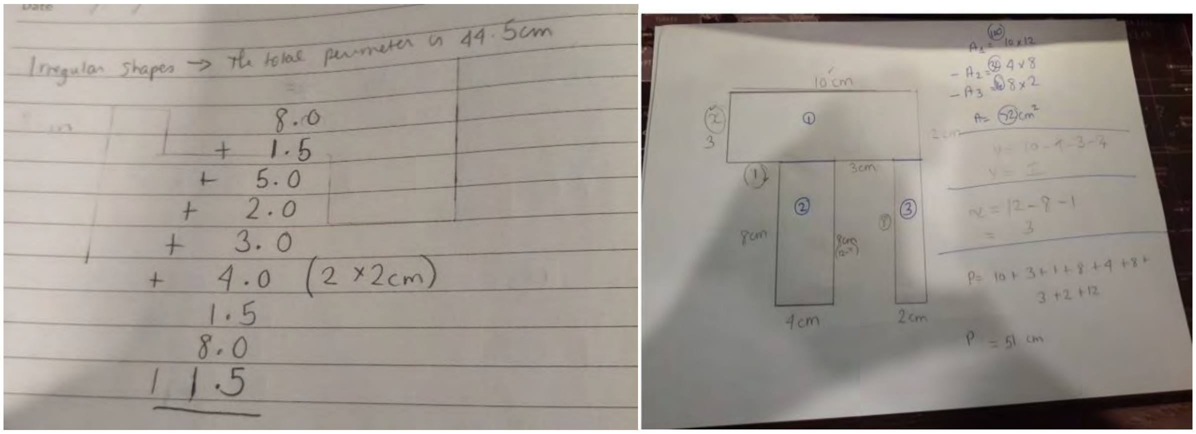

Figure 1. Solutions to a question related to finding the area and perimeter of an irregular shape. The solution on the left was the first question.

Discussion and Conclusion

This single participant provided some interesting initial results related to the use of the online modules. A limitation of the study was the fact that Terry mainly completed the modules within a three-day period right at the beginning of their participation in the study. At the time of the data collection, the province of Ontario had instituted a mandatory mathematics exam for licensing (Ontario College of Teachers, 2019), so this likely also led to some of the focus on simply solving questions instead of focusing on mathematics for teaching since the goal of the Test was to solve mathematics questions correctly and in a set time frame (Education Quality and Accountability Office, 2020). Terry did show gains in mathematics knowledge between the two questions; however, there was no evidence that the interventions had an impact on their mathematics knowledge for teaching.

In conclusion, the project has added to the discussion of video-based interventions for learning mathematics for teaching but has also raised some suggestions about how to create a better platform for implementation. In examining the results for strictly increasing mathematics knowledge, there is evidence that it does help. In considering mathematics for teaching, the results were not as promising. With the implementation of the exam, it could be that Terry was simply focused on increasing mathematics content knowledge and did not believe that there was a need for anything different. In reflecting on the platform used in the study, clearly more needs to be done to point participants towards considering the importance of mathematics for teaching, which may change future results. At present, this was only a pilot study exploring the platform to learn more about changes that could be made to support learners. Creating a new platform while considering the need to highlight mathematics for teaching would open possibilities for a revised project that could support adding extra mathematics-focused hours to a teacher education program.

A PRELIMINARY LOOK AT PROSPECTIVE MATHEMATICS TEACHERS' PRODUCTIVE STRUGGLE

Nitchada Kamlue
Western Michigan University
nitchada.kamlue@wmich.edu

Laura R. Van Zoest
Western Michigan University
laura.vanzoest@wmich.edu

This exploratory study aims to describe what productive struggle looks like when prospective mathematics teachers in a middle school mathematics methods course engage with a challenging mathematics task. We hypothesize that a productive struggle consists of different types of struggles—goal struggle, strategy struggle, and sub-strategy struggle—that can coexist simultaneously. We provide insight into the complexity of prospective teacher productive struggle and how it differs from that of middle school students. This information is useful for teacher educators who want to capitalize on the opportunity productive struggle offers for prospective teacher learning.

Keywords: Instructional Activities and Practices, Preservice Teacher Education

In general, people perceive struggles as things they should avoid. However, the National Council of Teachers of Mathematics (NCTM; 2014) views students' mathematical struggles as "opportunities for delving more deeply into understanding the mathematical structure of problems and relationships among mathematical ideas, instead of simply seeking correct solutions" (p. 48). Several researchers have worked to better understand those opportunities by studying school students' (e.g., Warshauer, 2015) and prospective teachers' (e.g., Zeybek, 2016) efforts to make sense of mathematics when engaging with challenging mathematical activities. Despite these gains, we lack research that reveals how and when learning occurs during the time that learners are engaged in a productive struggle. This information would help mathematics teacher educators to recognize and leverage their PTs' productive struggle and thus better support those PTs to be able to *support productive struggle in learning mathematics* (NCTM, 2014) in their future K-12 classes. Thus, this study explores the inner workings of PTs' productive struggle to investigate how and when those learning moments arise.

Literature Review

Productive struggle is a growing area of research that has encompassed three major themes: (a) types of struggles (e.g., DuCloux et al., 2018; Warshauer, 2015), (b) factors that foster productive struggle in classes (e.g., Roble, 2017; Russo et al., 2021), and (c) ways to help PTs to support productive struggle in their future classes (e.g., El-ahwal & Shahin, 2020; Warshauer et al., 2021). Since our work focuses on PTs' productive struggle, we elaborate on the first theme. Warshauer (2015) investigated 327 middle school students' struggles and developed a productive struggle framework that included four dimensions: (a) Task, (b) Student Struggle, (c) Teacher Response, and (d) Outcome. Within the Student Struggle dimension, she identified four kinds of student struggles: (a) *get started*, (b) *carry out a process*, (c) *give mathematical explanation*, and (d) *express misconception and errors* (Warshauer, 2015). These identified kinds of struggles have served as the foundation for other research in this theme. Sayster and Mhakure (2020) used Warshauer's kinds of student struggles to discuss 28 high school students' struggles with simplification of rational algebraic expressions. Their results aligned with Warshauer's kinds of student struggles. Other researchers have investigated PTs' struggles. Zeybek (2016) used Warshauer's kinds of student struggles to document the struggles of 48 pre-service middle grade teachers when engaging in non-routine tasks in a geometry course. Zeybek's findings aligned well with the results of Warshauer's study, thus she concluded that "struggle types are similar in all classrooms regardless of grade level or participants as long as participants are engaged in a high level task" (p. 411). DuCloux et al. (2018) used Warshauer's kinds of student struggles as a guide to analyze the perceptions of 32 prospective elementary, middle, and secondary teachers about their struggles. Their participants identified perseverance and struggling together with their peers as important aspects of their productive struggles. Although these studies provide us some information about PTs' productive struggles, they stop short of investigating the inner workings of productive struggle. Hence, our study aims to build on the existing research by exploring this research question: *What do PTs' productive struggles look like when they are engaged in a challenging mathematics task in a middle school mathematics methods course?*

Theoretical Framework

We ground our work in Warshauer's (2015) productive struggle framework mentioned above, with our adaptations shown in Figure 1. Rather than looking at tasks with a variety of cognitive demands, we used a *doing math* task (Box 1; Stein et al., 1996). Similarly, rather than looking at all possible outcomes, we looked only at interactions that led to a productive outcome (Box 4). To operationalize a productive outcome, we defined a *productive struggle* as an interaction that begins with some expression of struggle, verbal (e.g., "I'm confused", "I don't know", or long pause), or physical (e.g., deep sigh, putting hands in head) that provides the opportunity to better understand a well-specified statement of a mathematical truth—what we call a mathematical point (MP; Van Zoest et al., 2016)—and ends when some sense has been made of the MP and the focus of the interaction changes. Our work is situated in Boxes 2 and 3.

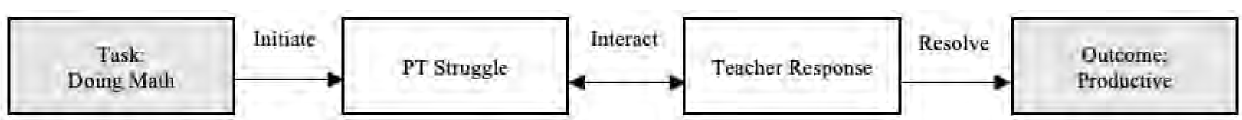

Figure 1: PT Productive Struggle Framework (Developed from Warshauer, 2015)

Methodology

This exploratory study is part of a larger ongoing project that investigates the teaching and learning that occurs in a middle school mathematics methods course (e.g., Ochieng, 2018; Van Zoest & Levin, 2021). The current study took place with the 18 PTs in the Fall 2021 course during the first two 90-minute class sessions. The PTs were engaged in the Frog Problem (see Figure 2), which met the criteria for a *doing math* task (Stein et al., 1996). (For more details about the Frog Problem, see Andrews (2000) and Dixon and Watkinson (1998).)

Figure 2: The Frog Problem Prompt and Representation of Two Frog Teams of Size Three

Data collection included videos and audio recordings of both class sessions, which were primarily whole-class discussion on the first day and small-group discussions on the second-day. We also gathered electronic copies of all PT written work and reflections from both days to help us better understand what a productive struggle looks like in detail. We first identified interactions that met our definition of productive struggle (see above). These interactions—

referred to as "productive struggles"—served as our primary data set for the study, with the other data sources referred to as needed to help us make sense of each productive struggle. Our analysis of these productive struggles was supported by coding the answers to these questions: (a) Who is struggling?, (b) What are they struggling with?, and (c) Why is it a productive struggle? In our broader analysis we looked at the role of the teacher response, but here we narrow the discussion of our results to what we found out about the Student Struggle dimension of Warshauer's (2015) framework, identified as PT Struggle in Box 2 of Figure 1.

Results & Discussion

Based on our preliminary analyses, we hypothesize that a productive struggle consists of different types of struggles that can coexist simultaneously. We identified three types of struggles: *goal struggle*, *strategy struggle*, and *sub-strategy struggle*. We use an illustrative productive struggle (IPS) to elaborate on these types and to provide insight into the inner workings of PTs' productive struggles and how they may differ from school students' struggles (Warshauer, 2015). This particular productive struggle took place during a small-group discussion among four PTs (PT1, PT2, PT3, and PT4) that occurred on the second day of the classes' engagement with the Frog Problem. At this point in the discussion, the group knew the actual numbers for frog teams of size 1, 2, 3, and 4. PT3 suggested an arithmetic sequence [$a_n = a_1 + (n - 1)d$] as a template for finding an equation that represents the fewest number of moves for any size team of frogs and the other PTs agreed. (Note that the difference of the fewest moves from each consecutive case is not constant, thus an arithmetic sequence does not apply to this situation.) The IPS began with the following exchange:

PT1: So wait, what would *d* be then?
PT3: That's what I'm trying to figure out because the difference increases so [*d*]'s not consistent. So I don't know that it's technically arithmetic because the, an arithmetic sequence is consistent.
PT1: That's true.
PT3: So I don't know if I can change the *d* to be something like that.

This exchange initiated a productive struggle because it provided the PTs the opportunity to better understand this MP: *d is a constant that represents a common difference between each consecutive term in an arithmetic sequence.* The IPS ended approximately ten minutes later when the group made sense of that MP and agreed on a plan for a different approach (discussed in more detail below).

After the transcript excerpt above, the other PTs joined PT3 in her struggle by attempting to find *d* even though they recognized that the *d* in an arithmetic sequence needs to be constant. We noticed that their struggle was related to *express misconception and errors*, one kind of student struggle from Warshauer's (2015) study. However, the result from our study is slightly different, since the PTs realized the misconception of using *d* as a common difference in arithmetic sequence when the differences in their data are not constant. We hypothesize that the PTs additional experience in learning mathematics may be responsible for their ability to recognize their misconception, leading to a more sophisticated version of this kind of struggle than that seen in Warshauer's study with middle school students.

The PTs were struggling with making sense of *d* in an arithmetic sequence. However, while struggling with this specific concept, they also had been struggling with how to use an arithmetic sequence as a template to find the equation that represents their solution to the task. This is an example of what we call a *strategy struggle*. Hence, struggling with finding *d* became a *sub-*

strategy struggle since it represents small steps or elements in the proposed strategy. While engaged in both of these types of struggles, they also had been struggling with how to find an equation to represent the fewest number of moves for any size team of frogs. This struggle is defined as a *goal struggle* since the goal of this task is to generalize their obtained data to any size frog team. Since struggling with this sub-strategy struggle—making sense of *d* in an arithmetic sequence—brought an opportunity for the PTs to better understand the stated MP (see above), we hypothesize that with *doing math* tasks, resolving sub-struggle strategies may be where PTs' learning—their coming to better understand an MP—occurs. To describe more about how that learning occurs, we need to take into consideration context outside the IPS. From our broader analysis, the challenging mathematical task—the Frog Problem—initiated the PTs' goal struggle. Then, the PTs' goal struggle initiated the PTs' strategy struggle, followed by the PTs' sub-strategy struggle that led them to further their learning of the MP of this IPS. Thus although in this case there were three struggles going on simultaneously that were moving the PTs towards the goal of the lesson, it was the sub-strategy struggle that made this particular interaction productive in the sense of learning mathematics.

Towards the end of the 10-minute IPS, making a decision to change to a different focus after making sense of the *sub-strategy struggle* provided evidence that learning had occurred. Below is when the PTs realized they could not use the current approach and proposed a next strategy for the group to consider.

PT2: So instead of making it *d*, could almost like put a variable that was like the last variable I'm gonna add two then in place of d like that's what it would represent there?

PT1: So what do you mean?

PT2: Like, Ok so [PT3: I know what you're saying] Yeah, Like if you have like when you [PT3: But then we will have two variables] use the last one. Yeah that's the only thing is that there'd be a lot of variables.

PT4: Like and now we can do some substitution or elimination to figure out the other variable

PT1: So I feel like the total moves for the first four groups we can plug that in and maybe solve for a variable.

PT2: Yeah

Making these decisions as a group provided evidence that they were all engaged in making sense of the MP and had benefited from the learning opportunity.

Conclusion

The results of this exploratory study revealed the complexity of the inner workings of PTs' productive struggle. We hypothesize that a productive struggle can consist of different types of struggles—*goal struggle*, *strategy struggle*, and *sub-strategy struggle*—that may coexist simultaneously. These types of struggles expand our knowledge about struggle by adding detail about the nature of struggles to the already existing information about kinds of struggles (e.g., Warshauer, 2015; Zeybek, 2016). These findings highlight the importance of mathematics teacher educators recognizing the mathematical opportunities that may be present in their PTs' struggles and provide some insight into how mathematics teacher educators might leverage their PTs' productive struggles to better prepare those PTs to support their future students' productive struggles.

RECRUITING AND RETAINING MINORITIZED PRESERVICE TEACHERS: CRITICAL RESISTORS

Nick Kim
The University of Tennessee
nkim2@utk.edu

Lynn Hodge
The University of Tennessee
lhodge4@utk.edu

Shande King
Trevecca Nazarene University
nking2@trevecca.edu

The primary purpose of this research was to provide insight into the narratives and experiences of minoritized (based on race) preservice teachers (PST) interested in teaching mathematics and how those experiences impact recruitment and retention of those minoritized teachers. Narrative inquiry framed through equity and identity lenses were chosen as the methodology for gathering and analyzing data from one-on-one, structured interviews as well as a focus group interview. A finding from the data analysis resulted in one specific resonant thread, Critical Individuals: Resistors. In summary, the PSTs' minoritized identities clearly impacted their decisions to pursue and remain in mathematics teacher education. All participants could recall "aha moments" when dealing with important people in their lives who either supported or attempted to resist their journeys to pursue teacher education.

Keywords: Preservice Teacher Education, Teacher Educators, High School Education

Teacher shortages across the United States in elementary, intermediate, and secondary schools are a recognized concern and can be credited to the difficulties in recruiting and retaining highly qualified teachers. The American Association for Employment in Education (AAEE, 2016) found data signifying a substantial teacher shortage in the Southeast United States. More specifically in Tennessee, forecasts designate that half of the more than 65,000 teachers in the state will leave or retire in the next decade (Aldrich, 2017). Teacher preparation programs, policymakers, and administrators are particularly familiar with said difficulties in that they are continuously tasked with the challenge of finding highly qualified teachers in response to a reduction in enrollment for teacher educator programs (TEP) (Flannery, 2016; Westervelt, 2015), a high rate of teachers leaving the profession only after a few years, and a high proportion of veteran teachers retiring.

Shortages of specifically minoritized teachers coupled with the growth of minoritized students attending schools raise additional challenges. According to McFarland et al. (2018) and National Center for Educational Statistics (NCES, 2019), minoritized students made up approximately 52% of public-school students in 2015-2016. By contrast, however, minoritized teachers made up approximately 20% of U.S. public school teachers during the same timeframe – constituting a mere 4% growth since 1999-2000 (McFarland et al., 2018; NCES, 2019). These statistics evidence the unlikelihood of many minoritized students seeing a proportional number of teachers representing their own communities. This is significant in that minoritized teachers are more likely to honor and support the cultures and interests of minoritized students, and according to research, such exemplification has been found to be a source of motivation for some minoritized students (Guarino et al., 2006).

Issues and Problem Statement

Research has addressed issues of teacher shortages and recruitment in general as well as more specific issues of teacher shortages among disciplines including science, technology, engineering, and mathematics (STEM). Fisher and Royster (2016) found that secondary level core subject teachers such as mathematics and science teachers as well as special education teachers are most likely to leave the teaching profession. Fisher and Royster (2016) take a look at multiple studies that offer different accounts as to why mathematics teachers leave the profession including: not enough preparation in the mathematics content, stressful situations from poor student behavior and lack of administrative support, and pressure from high-stakes testing. Fisher and Royster (2016) also offer resolutions to reduce teacher stress levels and ease the teacher retention problem by offering recommendations for stronger professional development, more effective mentoring for new teachers, and more productive peer collaboration.

In spite of these studies, we still know little about how to recruit and retain mathematics educators in practical ways. Therefore, we are forced to look for new and innovative ways to recruit more teachers, especially mathematics teachers, in practical ways that do not require extensive budget reforms that are unlikely to be implemented. This study addressed the broader issues of diversifying the teacher workforce and teacher shortages, particularly in the area of mathematics education. In doing so, the study shined light on the effective recruitment and retention strategies by identifying common stories amongst minoritized participants. The primary research question addressed in this study: How do minoritized preservice teachers' experiences (identity) contribute to their decision to pursue mathematics education? The sub question addressed in this study: How does an identity as a minoritized individual based on race and ethnicity affects one's pursuit of mathematics education? In this study, experiences are defined as life events that impacted the individuals' identity as a minoritized individual.

Theoretical Framework

The notion of identity informs the design of this study. An individual's identity is created as one participates in the social and cultural practices within a community of practice (Lave & Wenger, 1991). In this instance, concentrating on the involvement in social experiences also indicates a clear emphasis on the individual as a participant of the sociocultural community (Lave & Wenger, 1991). This situated perspective of identity comprises in what ways individuals see themselves, how society views them, and how they interpret these views in relation to their positions within communities of practice (Matheny, 2016). In addition, Hodges and Hodge (2017), drawing on Wenger (1998), described identity as a "constant becoming" where identities evolve based on their experiences within communities of practice.

More specifically and making identity more concrete, Gresalfi and Cobb (2011) and Hodges and Hodge (2017) identify one's "personal identity" as formed when one comes to associate with certain practices valued within a community. "The idea of personal identity provides structure to a narrative approach by focusing our attention on the normative ways of acting and valuations of these norms from a participant's perspective (Hodges & Hodge, 2017, p. 104)." In this way, the notion of personal identity informs the design of this study by focusing attention on whether or not and to what extent PSTs experiences as minoritized individuals influenced their decisions to pursue mathematics teacher education. In addition, this identity lens emphasizes the resources, including other individuals and interactions, that contribute to or delimit the participants' identities.

Narrative Inquiry

Clandinin and Connelly (2000) refined the narrative research approach to a narrative inquiry methodology that commences and concludes "in the midst of living and telling, reliving and retelling, the stories of the experiences that made up people's lives, both individual and social" (p. 20). Narrative inquiry is mutual as the researcher and the participants "reach a joint intersubjective understanding of the narratives that occur during the research process" (Moen, 2006). The cooperative association between participants and researcher is also expressed in the re-storying of their experiences. Human beings give meaning to experience by situating it in time, place, and relationship to others (Connelly & Clandinin, 2006). This is the reason why the study is situated in Tennessee as the participants and researcher have collaborated in various learning environments prior to the study.

Data Analysis

This study consisted of seven participants of varying races, genders, and status as a university undergraduate student. During this study, preliminary and primary data analysis occurred concerning both the individual narrative interviews as well as the focus group interview. Preliminary data analysis during both interview types assisted in providing structure and quality-checking of participant responses. In addition, this process provided an opportunity to start initial analysis for possible implications and overall recurrent themes. The researcher continued to use the research journal during this preliminary analysis process to keep note of themes, irregularities, and noteworthy findings. Patterns and findings from the preliminary analysis portion of the individual narrative interviews influenced modifications in the questions and process of conducting the focus group interview. The analysis of the data collected in the research journal was then transferred to a spreadsheet with each individual participant's quotes and initial codes. This was the beginning process of the primary data analysis.

Primary data analysis of the transcriptions from the audio from both interviews served as the primary source of data in this study. In addition, video recordings of the Zoom Video Conferencing interviews allowed the researcher to focus not only on the words chosen by the participant but also their body language, facial expressions, changes in tone, and verbal emphases while answering personal questions about their experiences. The experiences and narratives collected were then coded *in vivo* through continuous coding cycles with constant comparisons (Saldaña, 2013). In the opening round of coding, each individual interview was evaluated separately through multiple readings of the transcript while examining the notes on body language and facial expressions to be for significant findings to address the research questions. These codes were created from concrete experiences contributing to participants' journey to become a minoritized mathematics teacher and recorded in the spreadsheets mentioned above.

Results

Resonant Narrative Threads

Clandinin defined resonant threads as "threads that echoed and reverberated across the accounts" (Clandinin et. al., 2012, p.14). Therefore, similar themes and significant differences were identified across the narratives. The next section will describe how the participants' interactions with critical individuals in their lives resisted their journey to become a mathematics teacher.

Critical Individuals: The Resistors

Critical individuals resisted the participants' intentions to pursue mathematics teaching. The major reason for resisting becoming a mathematics teacher came from their families concern about the adequacy of teacher salaries. Sydney, Tiana, Peter, and Il-seong's families all wanted them to "earn higher than average salaries" since they were in lucrative fields of mathematics or engineering in Peter's case. The rationale was due to financial stability. All participants questioned and revisited their decisions to pursue mathematics teacher education because of the concerns expressed by their families, but ultimately the participants decided that a high salary was not the major factor in their decisions to become a teacher. This theme is made clear in Sydney's (a Black, female) comments about her decision to continue pursuing becoming a mathematics teacher. As she notes:

> My grandparents, they were like, Sydney, if you're going to school for math, don't be a teacher. And they kind of skewed my viewpoint a bit. And I was like, should I do something else? Because they made me feel like I was settling... They were like, you're smart, so why are you going to pursue a math degree, then just going settle on being a teacher? And I was like, I guess, yeah, you're right. I mean, why am I just going to settle on being a teacher, but then I realized that I wasn't settling on being a teacher. They wanted me to go and work and get money, which is fine. Money is great, don't get me wrong, but I was like, I was not going to be happy with that. Man, of course, I'd be happy, but was I going to be genuinely happy? And I realized I wasn't going to be genuinely happy with that, so I went back to teaching.

For most of the participants, becoming a teacher serves more than just earning a salary; it is about making a difference in students' lives, similarly how other teachers have changed their lives.

Reflecting one significant difference, Gabriel's (a Latino, male) resistor came in the form of an eighth-grade mathematics teacher. His teacher was a White, female who recommended Gabriel take below grade-level mathematics coursework during his freshman year of high school. Gabriel has always been confused about why he was placed into such a low performing class. Instead of harboring negative feelings, Gabriel used the actions of the teacher as motivation to pursue high- level mathematics in high school. As the participants' journeys make clear, they decided to carve their own paths in spite of resistance from some critical individuals in their personal lives. It seemed that these tough life decisions created critical decisions in which the participants chose to listen to their own voice rather than the voice of their resistors. However, the resistors did play significant roles in motivating participants in some cases, such as Gabriel's. These critical individuals, these resistors, often play a role in what I call aha moments when individuals decide to pursue teaching.

Conclusion

Minoritized PSTs have experiences with critical individuals in their journey to pursue a mathematics teacher license. These individuals can often be resistors not just supporters. This research examined the critical individuals who resisted PSTs decision to pursue mathematics education through various ways. The resistance came from family members as well as teachers. The first recommendation based on this research is to inform PSTs with all of the financial issues with becoming a teacher. Starting with low salary- presenting the statistics that show teacher salaries combined with benefits such as retirement and step raises actually are competitive with many other professions. In addition, identifying the teach grants or federal teacher loan forgiveness programs that can ease some of the financial burden.

Another recommendation based on the research is to allow current secondary teachers, as well as community college or university instructors, to actively search for potential mathematics teachers by explicitly providing opportunities for minoritized students to teach or tutor or by explicitly recommending them to consider mathematics teaching. In contrast, current teachers should be made aware of their decisions on how they track their students and the long-term impact those decisions have on their potential students' potential career choices.

MAESTROS, ESTUDIANTES, LENGUAJE Y MATEMÁTICAS: PRÁCTICAS PEDAGÓGICAS PARA UNA FORMACIÓN CON VISIÓN GLOBAL

TEACHERS, STUDENTS, LANGUAGE, AND MATHEMATICS: PEDAGOGICAL PRACTICES FOR PRE-SERVICE TEACHERS WITH A GLOBAL VISION

Gladys Krause	Adriana Ávila	Elgar Gualdrón
William & Mary	Universidad Autónoma de Bucaramanga	Universidad de Pamplona
ghkrause@wm.edu	aavila2@unab.edu.co	egualdron@unipamplona.edu.co

Describimos la segunda fase de una investigación en curso que se pregunta sobre la manera en que los maestros en formación asumen sus prácticas pedagógicas en un contexto global donde el lenguaje y las matemáticas se conjugan. Tal intención obedece al propósito de formar maestros que respondan a los retos educativos actuales. Uno de estos retos es el uso del inglés como lengua global. Se presenta una experiencia de trabajo conjunto entre estudiantes y docentes de dos cursos de enseñanza de métodos y didáctica de las matemáticas, uno en Estados Unidos y otro en Colombia. Esto implicó el diseño de actividades para la enseñanza de las matemáticas usando como referencia cuentos infantiles. Dentro de los resultados se identifica que las actividades fueron influenciadas más por el uso del lenguaje que por el contenido matemático que se quería enseñar.

Palabras clave: Teacher Educators, Preservice Teacher Educators, Elementary School Education

Este artículo presenta resultados preliminares de una investigación en curso que tiene como centro la formación de docentes de la escuela primaria y preescolar en el área de las matemáticas. Además, nuestra investigación intenta identificar cómo esta formación contribuye a el desarrollo de docentes globales (Krause et al., 2021).

El uso de la palabra "globalización" explotó en los años noventa porque capturó la naturaleza cada vez más interdependiente de la vida social en nuestro planeta (Steger, 2013). Esta interdependencia ha llevado a grandes cambios sociales, políticos, y económicos a nivel mundial, que han influenciado los sistemas educativos locales. Esta interdependencia ha establecido procesos de estandarización en el campo educativo enfatizando en exámenes que miden y posicionan a los estudiantes, a los maestros y a los sistemas educativos de acuerdo con un ranking establecido por agentes económicos (por ejemplo, la Organización para la Cooperación y el Desarrollo Económico - OCDE), que al mismo tiempo se encargan de patrocinar dichos exámenes (por ejemplo, las pruebas PISA) (Meyer & Benavot, 2013). Como consecuencia, el aula escolar en el mundo está cambiando y este cambio, necesariamente, nos obliga a hablar sobre la formación de maestros. Como formadores de maestros estamos obligados a preparar maestros que puedan asumir los retos que traen estos cambios en los sistemas educativos. Los tres autores de este artículo nos dimos en esta tarea hace dos años. En 2020 iniciamos nuestro trabajo colaborativo enfocándonos en entender cómo se están formando los maestros desde nuestros contextos locales, específicamente desde los cursos relacionados con los métodos y didáctica de las matemáticas. Resultados preliminares de la primera fase fueron publicados y presentados en esta misma conferencia el año anterior (Krause, et al., 2021). En dicha publicación documentamos la planeación, desarrollo e implementación inicial de retos matemáticos en dos clases: una de métodos de enseñanza de las matemáticas en Estados Unidos y la otra de didáctica de las matemáticas en Colombia. En este estudio encontramos cuatro aspectos en común en los dos contextos; los maestros en formación (MEF): (1) usaron diferentes estrategias para solucionar los problemas matemáticos, (2) reflexionaron sobre los posibles efectos negativos de la memorización de fórmulas sin entender conceptos, (3) se dieron cuenta de que entienden más matemáticas que lo que realmente creían, (4) reportaron el disfrutar el trabajo de los retos matemáticos (Krause, et al., 2021). Otros aspectos que identificamos se refieren a que los MEF en el contexto colombiano mostraron características de trabajo colaborativo, mientras que en el contexto de Estados Unidos los MEF expresaron tendencias más individualistas. Adicionalmente, en el contexto de Estados Unidos los MEF estuvieron más atentos al uso del tiempo mientras que en Colombia consideraciones de tiempo para la solución de problemas no fueron notorias. A partir de estos resultados pasamos a una segunda fase de nuestro estudio en la que, informados por los resultados anteriores, decidimos integrar los dos contextos en una actividad conjunta.

En esta fase le pedimos a los MEF que diseñaran y enseñaran actividades matemáticas para los MEF en el otro país. Esta integración tomó varios meses de planeación principalmente porque debíamos establecer puentes de comunicación entre dos contextos monolingües, uno en inglés y otro en español. En este artículo documentamos la experiencia de diseño, integración y resultados preliminares que han emergido al analizar este trabajo. En este artículo nos centramos en contestar la siguiente pregunta de investigación: *¿de qué manera asumen los maestros en formación sus prácticas pedagógicas en un contexto donde el lenguaje y las matemáticas se conjugan*?

En las siguientes secciones describimos la actividad pedagógica que desarrollamos para integrar las dos clases, cómo se implementó, y las decisiones de instrucción que tomamos informados en la literatura. Por último, presentamos un resumen de lo que aprendimos y los pasos a seguir en el futuro.

Antecedentes y Marco Teórico

Nuestro estudio parte del principio que las matemáticas deben estar en el centro de las discusiones de equidad en la sociedad y por ende en el salón de clase (Moses & Cobb, 2002; Gutierrez, 2013). Este principio rige el marco teórico de nuestras prácticas pedagógicas. En el contexto estadounidense la clase de métodos de enseñanza de las matemáticas se enfoca en proveer oportunidades que fomentan el extender y expresar ideas matemáticas. Un aspecto para resaltar en esta clase es el enfoque que tiene en fomentar la participación de estudiantes multilingües. En particular un pilar importante de esta clase es el promover las discusiones matemáticas especialmente aquellas que mantienen el lenguaje y la identidad cultural de los estudiantes (Krause, et al., 2021; Krause & Colegrove, 2020). En el contexto colombiano, la clase Didáctica de las Matemáticas centra su interés en proveer a los futuros licenciados de estrategias y recursos que les permitan integrar la formación matemática en la educación infantil (Murcia & Henao, 2015).

Cuando estudiamos la globalización en el contexto educativo es muy común encontrar artículos y estudios que hacen referencia a los “ciudadanos globales” (por citar algunos (Spring, 1998; Steger, 2013; Subedi, 2013; Triandis, 2001)). En muchos casos, estos ciudadanos globales son aquellos ejecutivos que se mueven fluidamente entre continentes y estudiantes internacionales que en muchas ocasiones gozan de los mismos privilegios económicos. Sin embargo, muy poco se dice sobre otros ciudadanos globales que también se mueven entre países y culturas, pero con menos ventajas económicas. Este contraste lo describe claramente Doerr (2020), quien hace un paralelo mostrando cómo los diferentes estatus que proveen la raza, el nivel socioeconómico y el nivel educativo de algunos ciudadanos globales contrastan con otros ciudadanos globales que cruzan fronteras en busca de seguridad, educación y empleo. En las escuelas públicas de los Estados Unidos, estos ciudadanos globales son un número bastante grande. La pobreza es una de las razones más comunes descrita por ellos como el motivo principal para dejar su país (Bigelow, 2006). Particularmente en Centro y Latino América, los Estados Unidos ha jugado un papel importante en contribuir a este estado de pobreza. El acuerdo *North American Free Trade Agreement* (NAFTA) es quizá una de las razones más mencionadas y estudiadas en las aulas de clase como una consecuencia directa del incremento en las migraciones masivas de Centro América a los Estados Unidos. Sólo en México, 10 años después de la firma de este acuerdo, el salario mínimo declinó 50%, las exportaciones de maíz de Estados Unidos a México incrementaron 14% y el precio del maíz mexicano bajo 45% entre los años 2001 y 2005. Según reportes económicos en esa misma década 3 millones de empleos que dependían de la agricultura mexicana desaparecieron (Bigelow, 2006).

Otro aspecto que se menciona comúnmente al hablar de globalización es el uso del inglés como lengua global (Melitz, 2016). Al hablar de la globalización como un proceso de interconexión, el lenguaje se convierte en un medio casi obligatorio para esta interconexión, sirviendo como herramienta en los procesos de estandarización que mencionábamos anteriormente. En el contexto colombiano, bajo el argumento de la necesidad de un país más competitivo en tiempos de la globalización, el gobierno central aprobó una serie de reformas educativas en el año 2005 en las cuales el aprendizaje y enseñanza del inglés adquiere un papel prioritario en el sistema escolar nacional (Usma, 2009).

Identificados estos dos grandes aspectos de la globalización, influenciando cada uno de los contextos donde trabajamos, nos dimos a la tarea de diseñar la actividad en común.

Descripción y justificación de la actividad

La orientación del ejercicio propuesto para nuestros MEF (tanto estadounidenses como colombianos) fue diseñar una actividad para enseñar un concepto o desarrollar un pensamiento matemático a partir de cuentos para niños. La actividad debía además ser enseñada a sus pares del otro país. Esta decisión la tomamos informados por la literatura. Sabemos que frecuentemente los educadores de matemáticas usan los ensayos pedagógicos como medio para modificar sus prácticas de instrucción (Webb & Wilson, 2022). Estos ensayos son herramientas que permiten a los MEF imaginar nuevas posibilidades de enseñanza y aprendizaje. Además, estos ensayos proveen la oportunidad al MEF de reflexionar en *cómo y por qué* actuamos de la manera que lo hacemos desde el punto de vista del maestro y del estudiante (Webb & Wilson, 2022). De esta manera, los ensayos pedagógicos abren la puerta para reflexionar en nuevas formas de aprender y en por qué respondemos de la manera que lo hacemos en el mismo momento de la instrucción. Además, la reflexión colectiva contribuye a alinear nuestras prácticas de instrucción a través de la observación y discusión (Webb & Wilson, 2022).

En preparación de la actividad cada pareja de Estados Unidos y de Colombia tuvo la posibilidad de escoger un cuento y tener 6 semanas para diseñar la actividad de enseñanza. La actividad debía trabajar algún concepto o pensamiento matemático. Los MEF tenían la libertad de escoger el concepto matemático que ellos consideraran adecuado. Luego, dispusimos diferentes espacios en línea para que los MEF de los dos países se pusieran en contacto y se enseñaran la actividad.

La idea de usar los cuentos surge con la intención de proveer a los estudiantes con un punto de partida en común. Tal intención obedece a la diferencia de idiomas que se manejan en los dos contextos, por tanto, de cada cuento se tenía su versión en inglés y en español. El uso de cuentos para enseñar matemáticas ha sido empleado por los investigadores en sus clases. Por ejemplo, en la clase de Estados Unidos el primer autor ha diseñado una actividad donde los MEF crean una figura geométrica usando las letras de su nombre. Como preámbulo de esta actividad el primer autor trae varios cuentos que hacen referencia a los nombres. Uno de estos cuentos es Crisantemo (y su versión en inglés Chrysanthemum) (Henkes, 2008), *The Name Jar* (Yangsook, 2003), *Marisol McDonald Does not Match* (Brown, 2011), entre otros. Durante la clase hay un espacio para que los estudiantes lean los cuentos, vean las imágenes, y compartan sus apreciaciones del libro con sus compañeros. Luego, los discutimos como clase. La discusión del cuento se centra en varios aspectos de pertenencia e identidad y la relevancia que estos tienen en el aprendizaje de las matemáticas. Al mismo tiempo, esta actividad abre un espacio en la clase para hablar sobre cómo hacer conexiones en clase de matemáticas con la lectura. Además del uso de libros que incluyen diferentes representaciones culturales y lingüísticas en el salón de clase. Luego, los MEF pasan a realizar una actividad matemática que requiere reemplazar y despejar variables usando valores asignados a cada letra del nombre de cada uno. Así se generan pares ordenados que luego se ubican en el plano cartesiano. De esta manera se generan figuras geométricas usando sus nombres. En esta actividad el cuento es una herramienta para ayudarnos a discutir el tema de pertenencia e identidad, es el preámbulo de la clase. La actividad matemática se conecta con este preámbulo y el cuento nos ayuda a unir los nombres con la matemática. En preparación a nuestra actividad colaborativa, Colombia adoptó esta actividad también. Teniendo en cuenta que el monolingüismo en cada uno de nuestros contextos locales podría generar una barrera de comunicación, decidimos ubicar cuentos que estuvieran disponibles en inglés y español, o que no tuvieran palabras, solo imágenes. También necesitábamos que los MEF pudieran tener acceso a los libros de forma digital. Aquí nos apoyamos en los recursos de las bibliotecas en cada una de nuestras instituciones. Siguiendo estos parámetros tomamos como base cinco cuentos infantiles: *Un Charco Azul* (Amaco, 2007); *Cómo Atrapar Una Estrella* (Jeffers, 2010); *Crisantemo* (Henkes, 2008); *Mi León* (Mandana, 2006); estos cuatro dispuestos en inglés y en español y *Journey* (Becker, 2013) que contiene sólo imágenes.

Las pautas para la actividad fueron las siguientes: (1) trabajar en grupos de dos. Cada grupo fue asignado a otro par en el contexto de la otra clase y fueron presentados con 6 semanas de anterioridad a la ejecución de la actividad. Basados en nuestras experiencias pedagógicas sabemos que el trabajo en parejas proveería un poco más de seguridad para que los estudiantes en cada contexto se sintieran apoyados en el diseño y ejecución de la actividad. Esto era importante para nosotros, dado que era la primera vez que estábamos realizando la actividad y además sabíamos que los estudiantes en los dos contextos se sentían un poco atemorizados de afrontar este reto, dado las diferencias en el lenguaje. (2) Diseñar una actividad matemática a partir de uno de los cinco cuentos seleccionados. (3) Cada grupo debía enseñar la actividad al otro grupo asignado de la otra clase. Es decir, un grupo de Colombia debía diseñar una actividad y luego enseñarla a un grupo asignado en Estados Unidos y, de la misma manera, un grupo de Estados Unidos debía diseñar una actividad y luego enseñarla a un grupo de Colombia. De esta manera cada grupo asumiría el papel de maestros y de estudiantes. Estas dos parejas tenían en común el mismo cuento. (4) El "intercambio" académico se hizo a través de la plataforma Zoom y pedimos que se grabara esta interacción. Esto lo hicimos con el fin de tener acceso a cada momento de instrucción de los grupos y así poder estudiar el desarrollo de la actividad. El tiempo que se destinó para que cada pareja ejecutara su actividad fueron 15 minutos. Así, en total, cada grupo debía tomar 30 minutos para el intercambio. (5) Finalmente, cada estudiante debió escribir una reflexión sobre la experiencia y sus aprendizajes. La reflexión la usamos para conocer las apreciaciones individuales de cada estudiante. Al mismo tiempo, la usamos para aprender sobre el impacto que tuvo en los dos grupos. La reflexión tenía 7 puntos específicos donde pedíamos a los MEF describir desde el diseño de la actividad hasta su experiencia enseñándola y participando como estudiantes de la actividad del otro grupo. También, preguntamos por sus sugerencias sobre cómo hacer este intercambio más significativo para su formación como maestros y una descripción de lo que aprendieron sobre cómo enseñar matemáticas, el lenguaje y, en general, de toda la actividad.

Métodos

Datos

Los datos que analizamos para nuestro estudio se conforman de las actividades diseñadas por cada grupo, las reflexiones individuales, y los videos donde los maestros en formación participaron del intercambio de actividades en los dos roles: maestros y estudiantes. En total tuvimos 13 parejas en cada contexto, es decir 26 grupos en total. Este trabajo produjo 26 actividades de matemáticas, 52 reflexiones, y 13 videos. El análisis de los datos se hizo siguiendo el modelo hermenéutico dialéctico (Martínez, 2013), con el cual revisamos los datos desde diferentes dimensiones como la enseñanza, el aprendizaje, la comunicación y la didáctica misma de la experiencia, a fin de descubrir significados y aprender de ellos.

Cada uno de los instructores leyó las reflexiones e identificó aspectos diferenciadores en cada reflexión y aspectos que fueron comunes. Al mismo tiempo, cada instructor vio cada uno de los videos y marcó episodios donde aspectos de uso del lenguaje sobresalieran en referencia a cómo se comunicaban conceptos matemáticos, tanto en el papel de maestro o de estudiante. Luego, a través de diferentes sesiones de trabajo, los investigadores discutieron cada uno de estos episodios y aspectos emergentes de las reflexiones y seleccionaron aquellos que encontraron en común. De este análisis salieron los resultados que describimos a continuación.

Resultados

En este primer análisis, cuatro ideas sobresalieron: (1) los cuentos infantiles no fueron ese punto de partida de lenguaje común que consideramos. El cuento fue usado por algunos MEF como el medio de instrucción. Es decir, no tuvieron en cuenta que los compañeros del otro país ya conocían el cuento, en cambio optaron por leerlo y usar esta lectura como medio para la enseñanza de las matemáticas. Por ejemplo, el grupo 1 usó el cuento *Un Charco Azul* (Amaco, 2007). En este grupo la pareja de Estados Unidos leyó el libro en español a su pareja colombiana. A medida que leían el libro pausaban y hacían preguntas sobre las imágenes del libro, por ejemplo, preguntaron "¿cuántas golondrinas estaban tomando agua?" "¿Cuántos animales han visto en total hasta este punto?" Aún sabiendo que su pareja colombiana tenía el libro en español. Algo similar sucedió en Colombia, aun sabiendo que la pareja en Estados Unidos tenía el libro en inglés, los estudiantes decidieron leerlo en inglés al grupo de Estados Unidos. (2) Los temas matemáticos cubiertos se centraron en su mayoría en contar e identificar figuras geométricas y patrones porque, según la explicación de algunos estudiantes, son temas que no requieren un mayor uso del lenguaje. Un estudiante escribió en su reflexión:

> "… we chose our topic because we felt that shapes and patterns required little knowledge of English/Spanish words in order to comprehend or explain." [… escogimos este tema porque sentimos que las figuras y los patrones requieren poco conocimiento de palabras de inglés/español para entender o explicar las ideas."].

(3) La experiencia fue diferente para cada estudiante dependiendo del papel que asumieron. Este resultado es quizá el que muestra con mayor claridad indicaciones del impacto que tuvo la

actividad en los MEF y que sirve como punto de partida para expandir esta investigación. Cuando los MEF reflexionaron sobre su papel como maestros, ellos hablaron sobre el número de veces que practicaron, los recursos que usaron para asegurarse de traducir las palabras correctas, los materiales que decidieron usar, y de cómo sus habilidades docentes fueron puestas a prueba. Sin embargo, cuando asumieron el otro papel, el de estudiantes, la experiencia fue un poco diferente. En ese momento ellos tenían que responder sin aviso previo o preparación para lo que debían contestar. Por ejemplo, un estudiante de Estados Unidos escribió en su reflexión:

> I was expecting to be more nervous as an instructor than the student, but the opposite
>
> happened for me. I knew exactly what I was going to say and teach for my own lesson, but I was nervous about doing the activities for the other group correctly. I got nervous when I did not understand the directions because I wasn't sure how to ask, but we eventually got it and it was really fun!
>
> [Esperaba estar más nervioso como instructor que como estudiante, pero al contrario sucedió para mí. Sabía exactamente lo que iba a decir y enseñar para mi propia lección, pero estaba nervioso por hacer correctamente las actividades para el otro grupo. ¡Me puse nervioso cuando no entendía las instrucciones porque no estaba seguro de cómo preguntar, pero finalmente lo conseguí y fue muy divertido!]

En Colombia una estudiante escribió:

> Me sentí muy bien, como volviendo a ser niña de nuevo, aunque un poco ansiosa ya que nos estaban observando y esperando nuestra respuesta, pero aun así fue satisfactorio ya que se pudo realizar la actividad y nos entendieron al momento de dar nuestras respuestas.

Acá cabe anotar también que, en las reflexiones, fue claro que cada MEF trabajó y dedicó tiempo para diseñar las actividades, sin embargo, este esfuerzo no incluyó tiempo para conocerse un poco más entre ellos o comunicarse con alguna frecuencia antes de la actividad, a pesar de que los canales de comunicación estuvieron dispuestos con bastantes semanas de anterioridad.

Adicionalmente otras ideas emergieron del análisis. Por ejemplo, los MEF concluyeron que pueden usar diferentes métodos de comunicación y que el no ser bilingües en realidad no fue una barrera tan grande como la que inicialmente temían al momento de presentarles la asignación. Esto es algo que queremos seguir estudiando y analizando, ya que pueden surgir alternativas pedagógicas importantes para la formación de maestros. También encontramos que el uso de recursos (por ejemplo, herramientas de traducción, materiales, imágenes, etc.) fue bastante usado por los diferentes grupos. Este es un tema bastante relevante para nuestra investigación. Por ejemplo, preguntas como ¿cuáles recursos son los más eficientes? ¿por qué se usan o por qué no? ¿quién tiene acceso a estos recursos? Están entre algunas de las ideas que aún seguimos explorando.

Discusión y Conclusiones

Iniciamos este trabajo con la intención de identificar de qué manera los MEF asumían los retos que pudieran presentarse al diseñar e implementar una actividad de matemáticas en un contexto donde dos idiomas y la matemática convergían. Los resultados preliminares de nuestro estudio nos dirigieron a dos puntos esenciales que informan y contribuyen al trabajo de formadores de maestros. Uno es la diferencia entre la preparación y el tiempo que dedicaron los futuros maestros en nuestro estudio para asumir los papeles de maestros y de alumnos. En las reflexiones de los MEF encontramos que ellos dedicaron bastante tiempo a preparar la actividad y a ensayar cómo presentar la actividad. Sin embargo, este esfuerzo se enfocó sólo en eso, en su preparación. No hubo ningún registro de comunicaciones previas para conocer un poco más de quienes asumirían el papel del estudiante. No hubo registro de comunicaciones para conocerse un poco más. Ninguno de los grupos intentó reunirse con anterioridad para familiarizarse un poco más y establecer estrategias para comunicarse. En las indicaciones de la actividad intencionalmente dejamos por fuera el "requerir" que se comunicaran con anterioridad, sin embargo, los presentamos con 6 semanas antes porque queríamos ver si ellos sentían la motivación o necesidad de hacerlo en preparación a la actividad. El encontrar que esta parte estuvo ausente en todos los grupos, nos lleva a concluir que es necesario enfatizar prácticas pedagógicas que guíen al maestro en formación para que trabaje y aprenda a conocer más de cerca a sus estudiantes. En el contexto de los Estados Unidos, particularmente este resultado fue bastante sorprendente. Uno de los pilares de la clase de métodos de la enseñanza de las matemáticas del primer autor (en Estados Unidos) es el formar a los futuros maestros para que aprendan a conocer más a fondo a cada uno de sus estudiantes y usar este conocimiento para informar sus prácticas pedagógicas. Específicamente, los MEF en esta clase desarrollan una tarea donde cada uno de ellos debe entrevistar a un estudiante focal en sus salones de práctica. Esta tarea tiene varios propósitos. Una es averiguar más sobre el estudiante, incluyendo sus intereses y las actividades que realiza fuera de la escuela. Otro propósito es averiguar más acerca de las ideas del estudiante, actitudes y disposiciones hacia las matemáticas. De esta manera, los maestros en formación tienen una base para empezar a trabajar en el diseño de problemas de matemáticas y otras actividades que se desarrollan en la clase (Krause & Colegrove, 2020). Esta tarea es una las primeras que realizan los MEF en el semestre. Por lo tanto, ya para el momento que realizaron este intercambio entre Colombia y Estados Unidos, los MEF en la clase de Estados Unidos habían realizado esta entrevista. Este resultado es bastante diciente ya que los MEF particularmente en el contexto de Estados Unidos van a estar trabajando en escuelas con una diversidad cultural y lingüística amplia. El conocer los fondos de conocimiento que traen los estudiantes al salón de clase es esencial en cómo los futuros maestros asumen sus prácticas pedagógicas (Civil et al., 2005). Al mismo tiempo, este resultado aclara un poco por qué los MEF no usaron los cuentos como lenguaje común. Su enfoque se centró tanto en ellos mismos que no permitió ver los recursos que ya aquellos, asumiendo el papel de estudiantes, tenían como presaberes. Como mencionamos anteriormente, el ignorar este recurso hizo que cada actividad consumiera más tiempo del que en realidad necesitaba. Lo que puede ser una razón para justificar la superficialidad del contenido matemático que se enseñó. Este sólo punto de enfocarse en ellos mismos prácticamente desencadenó un efecto dominó al momento de enseñar la actividad. De igual manera para la clase de Didáctica de las Matemáticas en el contexto colombiano, sorprende que los MEF no se interesaran por conocer a sus estudiantes de manera previa. Esto riñe con lo que de manera permanente se trabaja en su formación para ser maestros en educación infantil. En este nivel es particularmente importante reconocer quiénes son los alumnos, cuál es su contexto, qué les gusta, qué saben. Las respuestas a tales preguntas fundamentan las bases del constructivismo y el aprendizaje significativo (Ministerio de Educación Nacional, 2014) que se espera alcancen los niños y las niñas.

El otro punto esencial que nos muestran los resultados es el contenido matemático escogido para las actividades. Todavía es necesario estudiar este punto con detenimiento, pero por los resultados preliminares conjeturamos que el lenguaje sí jugó un papel importante en la decisión del contenido matemático que se enseñó. En varias de las reflexiones los maestros en formación explícitamente dijeron que usaron patrones y figuras geométricas porque así no tendrían que usar tantas palabras. El debate existente en la enseñanza de las matemáticas en contextos bilingües es común en los Estados Unidos. Existen grupos avocando por educación bilingüe que incluya instrucción de matemáticas en la lengua materna de los estudiantes y al mismo tiempo existen grupos avocando por instrucción bilingüe, pero excluyendo la matemática (Jacobs, 2016). Independientemente de este debate, los resultados de esta investigación revelan un aspecto del uso del lenguaje que poco se menciona en estos debates. La calidad de la instrucción de las matemáticas (Jacobs, 2016). En este trabajo los resultados mostraron que los MEF, en los dos contextos, se prepararon para usar el lenguaje de sus estudiantes y que además el uso del lenguaje fue lo que condicionó la decisión de qué enseñar. Algo que esperábamos que surgiera de la interacción previa (que no ocurrió) era que entre los grupos hablaran y compartieran un poco sobre sus experiencias en las prácticas escolares que son parte de su formación como maestros y que tomaran de ahí las ideas sobre el contenido matemático. Este aspecto particular del uso del lenguaje nos hace pensar en la idea de la estandarización de prácticas educativas como consecuencia de la globalización y el uso del inglés como lengua de la globalización. Particularmente estos dos aspectos del lenguaje se conectan con la creciente población de estudiantes inmigrantes en las escuelas de Estado Unidos. ¿Qué pasa con la calidad de la educación que reciben estos estudiantes mientras adquieren un nivel de inglés adecuado para comunicarse con sus maestros que, en la gran mayoría, son monolingües? Esto es una pregunta que todavía no se contesta en nuestro campo de educación de matemáticas bilingüe y que tampoco hemos visto en la literatura sobre la globalización y la educación.

El intercambio pedagógico que nos atrevimos a diseñar resultó ser una herramienta eficaz para apoyar la formación de los maestros en formación. Al mismo tiempo, abrió la puerta para continuar caminos de investigación que claramente se necesitan para fortalecer la formación de maestros para que enseñen matemáticas.

TEACHERS, STUDENTS, LANGUAGE, AND MATHEMATICS: PEDAGOGICAL PRACTICES FOR PRE-SERVICE TEACHERS WITH A GLOBAL VISION

We describe the second phase of an ongoing investigation that asks about the way in which pre-service teachers assume their pedagogical practices in a global context where language and mathematics are combined. Such a focus supports the goal of preparing teachers who can respond to current educational challenges. One of these challenges is the use of English as a global language. We present an experience from collaborative work between students and professors of two courses teaching methods and didactics of mathematics, one in the United States and the other in Colombia. This included the design of activities for the teaching of mathematics using children's books as a reference. Among the results we noted that the activities were influenced more by the use of language than by the mathematical content to be taught.

PRESERVICE AND BEGINNING TEACHERS' PERSPECTIVES ON EQUITY

Abstract: This report is part of a larger, longitudinal study focusing on the development of equity-related knowledge, beliefs, and practice across 68 individuals and five teacher preparation programs. In this brief report, we seek to unpack the ways five preservice and beginning mathematics teachers think about equity, especially as it relates to their current and future teacher practice. Analysis of interview data from these participants suggest as many as twelve different aspects of equity reflected in their thinking, as well as multiple actions teachers could take to promote equity including raising expectations, rejecting deficit views, and using complex instruction.

This material is based upon work supported by the National Science Foundation under Grant No. 1758401.

Keywords: Preservice Teacher Education, Equity, Inclusion, and Diversity

In this brief report, we describe preliminary analysis of data from an ongoing, longitudinal study of middle/high school mathematics teacher education and beginning teacher practice in the U.S. as it relates to equity. Our goal is to understand how teachers develop and use their knowledge of equity - how they think, what they think, and how they apply their knowledge. We are guided in this work by ideas from culturally responsive teaching (Gay, 2002; 2010; 2015) and equity literacy (Gorski 2014, Gorski & Swalwell, 2015), as well as from work by experts in the field of educational equity in mathematics (e.g., Aguirre, Mayfield-Ingram, & Martin, 2013; Bartell et al., 2017; Gutierrez, 2009; Moschkovich, 2013; Ramirez & Celedon-Pattichis, 2012). We adopt Aguirre, Mayfield-Ingram, and Martin's (2013, p. 45-48) categories of access and advancement, the use of cultural and linguistic resources, and the development of identity and agency to structure our thinking about teacher knowledge and its development. Further, we incorporate self-determination theory (Ryan & Deci, 2000) into our conceptual framework as a lens through which to consider teacher agency and perceived constraints to increasing equity.

Using a combination of data sources including interviews, work samples, surveys, written reflections, and videos of instruction, our research group is constructing data sets for each of 67 preservice or beginning teachers (PT/BT) across five teacher education programs in the U.S. Each PT/BT participates in the research project for four years, encompassing the final two years in their education program and the first two years of their post-program classroom teaching. Most study participants are/were enrolled in undergraduate programs at their institutions, but some are/were enrolled in a graduate certification program while teaching concurrently. For this brief report, we examine the knowledge and beliefs of five PT/BTs, which was a convenience sample but also spanned four of the five programs. We present our preliminary analysis of the end-of-program, structured interviews, and focus on the following research question: *How do*

PT/BTs think about equity in relation to their teacher education programs and their emerging teaching practice?

The interview protocol for each PT/BT included the following questions: (1) Since you began your teacher education program at [institution], what experiences have particularly impacted how you think about teaching mathematics? (2) What are some of the most important things you have learned about teaching and about students in your teacher education program? (3) What, if any, instruction or experiences related to equity have you had in your teacher education program? (Note: a definition of equity was <u>not</u> provided) (4) What have you learned about equity through your teacher education program? (5) How do you feel personally about equity? (6) What actions should math teachers take to promote equity in opportunities to learn, participation in learning, and learning outcomes? (7) What do you wonder about, or what questions do you have, about equity and mathematics teaching? We used an open-coding process (Strauss & Corbin, 1990) involving four interviews and two coders which resulted in six codes. Next, three researchers coded one common interview independently using the six codes and met to discuss differences, refine coding categories, and add new codes as appropriate. Finally, three researchers independently coded three interviews each using the refined coding scheme and met again. The final coding scheme we established accounted for the sections of data we interpreted as equity-related, with some sections of text receiving two or more codes.

Using the process described above, we achieved kappas of 0.9^+ across coders for these six codes: **personal meanings** - personal meanings, experiences or definitions of equity; **understanding/sense-making** - productive struggle, mathematical reasoning, cognitive demand, creativity, learning from mistakes, critical thinking and problem solving; **building relationships with students** - includes relationships with individual students or groups, attending to social/emotional needs, listening to students and sharing with them beyond the mathematics at hand, knowing about students' homes, knowing who needs what to help them learn; **connecting the math/classroom to the real world** - building math instruction upon students' interests and lives, bringing current events/issues into the classroom, attending to social (in)justices, connecting to lived experiences outside the classroom; **inequities in education and actions to take** - includes expressions of awareness of educational issues such as bias, deficit views, and privilege (from a personal or systemic perspective), descriptions of inequities in general or specific terms, as well as strategies for addressing inequity; and **constraints to increasing equity** - focus on barriers identified by PT/BTs that they believe will materially limit their ability to create more equitable classrooms, or barriers for the world to be more equitable, also includes expressions of lack of knowledge about how to achieve a vision of equity. For this paper, we focus on initial analysis of the "personal meanings" code and responses to the questions "How do you feel personally about equity?" and "What actions should math teachers take to promote equity in opportunities to learn, participation in learning, and learning outcomes?"

A constant-comparative analysis of the five PT/BT interview transcripts resulted in 12 "equity associations" demonstrating the many ways these five PT/BTs connected the notion of equity to themselves and to their emerging teacher practice.

Equity as Accommodation - "equality is everyone gets the same resources, but equity is where you, um, accommodate for those who would need the additional resources to be able to perform at the same level as everyone else around them"

Equity as Productive Struggle - "I know that sounds evil, and almost inequitable, but um, I mean, there's this idea of a constructive, I think, constructive struggle that students need to go through so that they've reached an understanding themselves"

Equity as Asset-Based Teaching - “it's very, very easy to prioritize and . . . spend a lot of time on boost up the students who are also good students . . . I think that it's so easy to just fall into like this compare and contrast. I think you like you at first do it in your own head. . . . you start thinking all these negative things and then like it starts coming out in your actions and your words . . . it’s just something you have to be really conscious of.”

Equity as Accessibility and Choice - “it'll make math more accessible to all students because you, you know, as long as you follow like some certain basic rules, like you can solve, like coming, coming up with a new way to solve a problem is, is actually a better thing.”

Equity as Assigning Competence - “giving them that public specific praise in class to raise their status of not only of themselves, but also how other students view them.”

Equity as Differentiation - “supporting those students who might need extra support . . . challenging all of your students to just go above and beyond and push past your expectations.”

Equity as Personal Experience - “and just being like a female in a math class was you could tell, as soon as I walked in the room, they didn't even look at me twice.”

Equity as Culturally Responsive Teaching - “so for me, it's like the culturally responsive teaching. . . . you have to know who your students are to be able to meet their needs best.”

Equity as Social Justice - “it's sort of the responsibility of an educator to address these systems of oppression and inequity that are looming around us and making our students aware”

Equity as Empowerment - “maybe have a focus on empowering students . . . explaining to them the reality of the world and then working with them to break down the barriers.”

Equity as Personal Transformation - “a lot of the time, I thought, well, why don't people just work harder if they're not doing as well?. . . . [the program] made me realize that there are barriers that other people have had to fight through systemically that I've never faced.”

Equity as a Systemic Issue - “issues with the system is how we should be viewing it rather than how that idea kind of portrays it as issues with the person. . . . dismantling hierarchies of status in class trying to almost like level the playing field.”

Although we can imagine other associations that PT/BTs might make that we did not find in the interviews of these five individuals, for example, equity as racial justice or collective liberation, initial analysis suggests that PT/BTs are able to connect the idea of equity to their own lives and their emerging teacher practice in many different and potentially powerful ways. Going forward, we are interested in determining whether/how different ways of thinking about equity cluster together within and across individuals and teacher preparation programs, and whether/how particular associations are expressed in the classroom.

Regarding actions that mathematics teachers could take to promote equity in opportunities to learn, participation in learning, and learning outcomes, all five PT/BTs noted that teachers should engage students in problem solving that draws on contexts that are familiar or interesting to students and related to their experiences. One PT/BT, Frank, believed the experience would help students understand that mathematics could be useful in navigating their world.

> I think math teachers have to take the opportunity to use real world issues in the class. Not just like word problems, but actually bringing about, in the right way, in the right context, issues that face their students in a very real way […]. Saying, okay, we can use math to help solve this issue or we can use math to at least analyze this issue that many of you are facing or dealing with. And that can be one way for maybe students who haven't dealt with that issue before in my class to kind of open their eyes to it. (Frank, PT/BT)

Three PT/BTs suggested that teachers should differentiate their instruction to meet students where they are and build on their existing knowledge. The PT/BTs noted that engaging students in problem solving could be challenging. Two PT/BTs suggested that it was important that teachers have non-deficit views about the students and their capabilities. Teachers should believe their students can engage in challenging mathematics with scaffolding. One of the PT/BTs discussed the importance of allowing students to engage with productive struggle for learning.

> In regard to overall instruction, I think learning to allow your students to struggle. And I know that sounds evil, and almost inequitable. I mean, there's this idea of a constructive struggle that students need to go through so that they've reached an understanding themselves, rather than the instructor providing the answer for them. (Colin, PT/BT)

In addition to believing that students are capable of handling challenging work, three PT/BTs stated that the teachers need to develop a supportive classroom environment to encourage student discourse. They pointed out the importance of classroom discussions among the students, and the students and the teacher, and they highlighted the work that the teachers need to do to make the classroom into a discussion-rich space.

> I really think teachers ought to use this idea of complex instruction. Whether it be exactly that or some sort of form of it, it's just what I've been able to see in the classroom. There have been students who have been so quiet at the beginning of the year, but to see their growth using this, this kind of teaching, this group work building on students' strengths and giving them that public specific praise in class to raise their status of not only of themselves, but also how other students view them in class. I think, is it just, it does a lot for when it comes to equitable participation in class, you see students grow, you see them finally feeling like they have a voice. I would say using that strategy is definitely a big teacher move (Frank PT/BT)

Discussion

In this paper, we focus on ways of thinking about equity as expressed by five PT/BTs who were interviewed near the completion of their respective teacher education programs. As we move forward in our research, we are interested in considering how frameworks for thinking about equity, such as that proposed by Gutierrez (2009), could be useful in characterizing this data. For example, comparing the 12 “equity associations” made by the five PT/BTs with the axes of access, identity, power, and achievement (Gutierrez, 2009), we notice that they attended collectively to all four axes, but with differing emphases. With regard to the categories and framework developed by Aguirre, Mayfield-Ingram and Martin (2013), these PTs expressed ways of thinking about equity falling into all three categories - access and advancement, the use of cultural and linguistic resources, and the development of identity and agency. One component of equity literacy (Gorski 2014, Gorski & Swalwell, 2015) we did not find in the data for these five PT/BTs is empowering students to collectively take action to create meaningful changes inside or outside their schools. This is not to suggest that the PT/BTs do not think in this way, but rather that this idea was not evoked during the interview.

With respect to influences on PT/BTs’ knowledge, both Colin and Frank pointed to university courses and their instructors as they described the importance of productive struggle and complex instruction, respectively. In fact, we found an emerging theme in the data thus far as the PT/BTs repeatedly return to the importance of maintaining non-deficit views of students and allowing them to engage in problem-solving and productive struggle. Going forward, we will investigate how these ways of thinking about equity may serve as “launch pads” for designing increasingly equitable classrooms, and how they may constitute “comfort zones” allowing teachers to maintain the status quo.

ANALYSIS OF PRE-SERVICE TEACHERS' VIRTUAL NUMBER TALKS PRACTICE: IMPLICATIONS FOR THE PREPARATION OF FACILITATING MATHEMATICS DISCUSSIONS

Audrey Meador	Nicole Fletcher
West Texas A&M University	Fairfield University
ameador@wtamu.edu	nfletcher@fairfield.edu

Efforts within mathematics teacher education have recognized and attended to the importance of developing pre-service teachers' skills for leading mathematical discussions. Number Talks have been utilized in teacher preparation programs to create opportunities to practice discussion facilitation moves. A virtual Number Talk field experience was enacted to provide pre-service teachers the experience of facilitating Number Talks while navigating technology. Two purposefully selected pre-service teachers' experiences conducting virtual Number Talks were analyzed using a formative assessment that decomposed the discussion practice. As a mode of using research to inform teacher educator practice, results of the analysis provide implications for assisting pre-service teachers in orchestrating productive mathematics discussions using technology in order to move from critical dissonance to resonant harmony in praxis.

Keywords: pre-service teacher education, technology, classroom discourse, teacher knowledge

Facilitating meaningful mathematics discourse is recognized as an essential element of effective mathematics teaching practice (NCTM, 2014). To orchestrate productive mathematical discussions, teachers must attend to discussion components in the moment and possess an understanding of mathematics content, student thinking about content, and pedagogical practices to develop students' mathematical understanding (Smith & Stein, 2018). Recent efforts within mathematics teacher preparation programs have attended to pre-service teachers' (PSTs) skills in leading discussions that support students' development of conceptual understanding (Shaughnessy et al., 2021). Number Talks have been utilized in this regard to build fundamental knowledge and skills for leading productive mathematical discussions (Woods, 2021).

In Fall 2020, we implemented a Number Talks-based, virtual field experience to allow PSTs to practice and refine skills in conducting a productive mathematics discussion (Fletcher & Meador, 2022). The virtual Number Talk teacher learning cycle (VNT TLC) was our response to creating field experiences for students when access to schools was unavailable (Joswick et al., 2021). While this modification served a purpose, it also created a critical dissonance in PST practice. Not only were PSTs required to juggle the demands of conducting a mathematical discussion, but they had to do so in a virtual space. Conducting a productive mathematical discussion requires attention to the areas of *framing, orchestrating,* and *recording/representing content* (Shaughnessy et al., 2021) in real time. When enacting a mathematical discussion in a virtual classroom, consideration must also be given to the use of technology in these areas. We analyzed PSTs' skills in facilitating mathematical discussions, demonstrated in their virtual Number Talks videos, to move our own practice as teacher educators from critical dissonance to resonant harmony. The following research questions guided our analysis: (1) Which areas of work in a mathematics discussion (*framing, orchestrating, recording/ representing content*) are revised through participation in a teacher learning cycle focused on virtual Number Talks? (2) Which areas of work in a mathematics discussion do PSTs attend to, or not attend to, when developing a virtual Number Talk practice? As we respond to these research questions, we focus on the voice of the PST as a formative assessment of our own teaching practice. We use our analysis of PSTs' experiences implementing virtual Number Talks to inform our teaching on facilitating meaningful mathematics discussions, using technology to achieve pedagogical goals, and attending to equitable opportunities for student voice in the mathematics classroom.

Theoretical Framework

Facilitating a meaningful mathematics discussion requires the building of shared understanding "of mathematical ideas by analyzing and comparing student approaches and arguments" (NCTM, 2014, p. 35). By implementing mathematics discussions, teachers also engage in several effective mathematics teaching practices (Smith & Stein, 2018), such as using and connecting mathematical representations. Teachers must also identify a mathematical concept to guide the discussion so that the flow of the conversation is directed to this point (Shaughnessy et al., 2021; Sleep, 2012) and ensures that the sharing of ideas involves discourse and not merely a "show and tell" of ideas (Kazemi & Stipek, 2001; Smith & Stein, 2018). We utilized a decomposition of the facilitation of mathematics discussions in a formative assessment framework developed by Shaughnessy et al. (2021) as our theoretical frame. Shaughnessy and colleagues (2021) created a checklist of skills for leading mathematics discussions centered on the decomposition of three main areas of work, *framing, orchestrating,* and *recording and representing content*, along with associated teacher moves (see Table 1).

Table 1: Mathematics Discussion Skills Assessment Checklist (Shaughnessy et al., 2021)

Areas of Work	**Teacher Moves**	
Area of Work: Framing	Launching	Efficiently engages students in the mathematical work
		Directs attention towards the mathematics intended for the discussion
	Concluding	Makes a closing statement that indicates the conclusion of the discussion.
		Supports students in remembering or making sense of at least one key mathematical topic or practice
Area of Work: Orchestrating	Eliciting contributions	Elicits multiple solutions, strategies, or ideas
		Elicits a range of student understanding or methods
		Engages several students in sharing their thinking
	Probing students' thinking in relation to the mathematical goals	Poses questions to get students to explain their thinking about processes
		Poses questions to get students to explain their understanding of key mathematical ideas
		Follows up on responses to make more student thinking about the mathematics available
		Provides support for students to complete their contribution or clarify their thinking
	Orienting students to the contributions of peers	Ensures that the class can hear others' ideas
		Poses questions to students about others' ideas and contributions, including asking students to comment on, add to, or restate another student's idea
		Supports the listening of the class through the use of moves that require all students to respond to others' work
		Encourages students to attend, listen, and respond to peers' contributions in order to maintain productive and focused interaction
	Making contributions	Uses moves such as redirecting, revoicing, and highlighting to keep the discussion on track
		Ensures that substantive and relevant analysis is part of the discussion
		Makes mathematical contributions which enrich the core ideas of the discussion and keep the discussion focused on the learning targets

Area of Work: Recording and Representing Content	Keeping accurate records	Records student ideas in ways that are true to the students' contributions
		Attends to the accuracy of records and representations
	Choosing and using appropriate representations to convey key mathematical ideas.	Records in ways that are clear, organized, and visible to the class
		Uses recordings which support student understanding and participation

This frame was also selected for analysis to capture the technology component of the virtual Number Talks. After study of the framework and initial assessment of PSTs' virtual Number Talk videos, we found that technology could be addressed in the *orchestrating* and *recording/representing content* areas of the assessment. We also considered the use of the teacher learning cycle and the ability of the framework to highlight areas of work PSTs enacted throughout the cycle. Additionally, the assessment checklist provided exemplar decomposition move descriptions (Shaughnessy et al., 2021) that provided guidance and clarity of recognition when evaluating the virtual Number Talks videos for evidence of these moves.

Methods

As part of a larger study, we considered a purposeful sample of two teachers' Number Talk videos for qualitative analysis using the assessment framework. These teachers were deliberately chosen for two main reasons. The first selection criteria for analysis included PSTs who demonstrated development of a variety moves in each of the three main areas of the checklist as they progressed through our learning cycle. The final selection criteria included PSTs with a range of prior teaching experience, while also taking into consideration their respective field placements. As a result, two teachers were chosen as cases for this study. Institutional review board approval was obtained and for anonymity of participants, pseudonyms are being used.

Setting and Participants

A virtual field experience based on Number Talks was implemented in Fall 2020 in an elementary mathematics methods course required for an elementary education master's program at a university in the northeastern United States. 29 students were enrolled in the course, with 23 consenting to having their course assignments analyzed for research purposes.

Dakota was in their second year of the elementary education master's program and was enrolled in the course in the fall semester prior to student teaching. Dakota was working for a third semester as an intern at a suburban public K-4 school and had no other prior teaching experience. Dakota's school was implementing a hybrid model but did not permit videotaping, so Dakota completed the VNT TLC field experience (Fletcher & Meador, 2022) with three third grade students recruited with the help of the instructor. The students did not know one another or Dakota prior. Dakota had not heard of the phrase "Number Talks" before the project but had seen the practice while observing classes during their internship.

Emerson was in their graduate year of a five-year integrated Bachelor's/Master's program in elementary education and was enrolled in the course prior to student teaching. Emerson was in their first semester of working as an intern in a suburban public school for grades 3-5. Emerson had prior experience working as a paraprofessional in a summer school program for grades 9-12. Emerson's school implemented a hybrid cohort model at the start of the semester and later shifted to primarily in-person instruction with some students learning remotely. Emerson completed their Virtual Number Talks field experience with three third grade students from their internship. Emerson was unfamiliar with Number Talks prior to the project.

Data Sources

Sources of data consisted of two complete virtual Number Talks videos submitted by each participant as part of the VNT TLC (Fletcher & Meador, 2022). At the start of the cycle, the PSTs learned about Number Talks through readings, videos, discussions, and demonstrations. Next, the PSTs planned their first Number Talk by identifying the mathematical focus of the Number Talk, selecting a set of problems from a provided list [most of these problem sets were taken from Parrish's (2010) *Number Talks* book], anticipating student responses and strategies along with follow-up questions (Smith & Stein, 2018), selecting technological tools, and considering participation norms. The instructor provided feedback on the plans, and then PSTs rehearsed their Number Talk with peers from the course, reflected on the experience, and made any necessary modifications to their plan based on feedback. The PSTs then implemented and video recorded their Number Talk with K-6 students and reflected on the experience. Following the first Number Talk, PSTs engaged in further learning and planning for a second Number Talk, using the knowledge and skills developed during their first to inform their planning for the second. They facilitated and video recorded a second Number Talk and then completed a final reflection as part of the learning cycle. Figure 1 details an iteration of the VNT-TLC cycle.

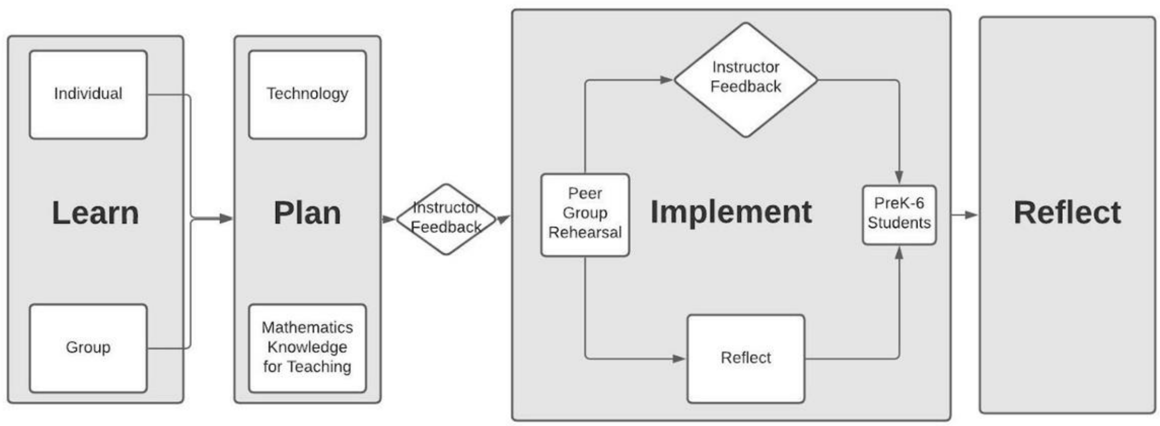

Figure 1: One Iteration of the VNT-TLC Cycle (Fletcher & Meador, 2022)

Data Analysis

The analysis of the data sources was conducted in three phases. The first phase began by individually evaluating the first and then the second virtual Number Talk videos for each of the purposefully selected participants using the assessment checklist. Each video was broken into one-minute segments for unit analysis and each minute was evaluated for evidence of the decomposed teacher move areas of the checklist. A code of 1 was recorded if the participant demonstrated proficient use of the teacher move, a 0 if the participant demonstrated developing use of the teacher move, and an X if the move was not applicable or not observed. Through rounds of watching and coding participants' Number Talks videos, a consensus of proficient and developing practice was achieved inductively to develop a common definition and description for analysis using the skills checklist. Notes were also recorded to provide rationale for assignment of codes. The second phase of data analysis consisted of the comparison of codes assigned to each Number Talk video by going through each unit of analysis in an open coding format (Strauss & Corbin, 1990; Vollstedt & Rezat, 2019). Discrepancies of code assignment were discussed, notes were compared, and videos were revisited at the unit under consideration before a consensus on the code was determined. The final phase of data analysis consisted of constant comparison analysis (Glaser & Strauss, 1967; Leech & Onwuegbuzie, 2007) of the *framing*, *orchestrating*, and *representing/recording data* decomposition areas coded for each participant between the first and second Number Talk.

Results

The results are presented by participant and are organized by the three areas of work in leading a mathematics discussion developed by Shaughnessy et al. (2021): *framing*, *orchestrating*, and *recording and representing content*. Because the checklist was intended to be used with videos of mathematical discussions rather than transcripts of this data source (Shaughnessy et al., 2021), we describe the occurrence of moves from the checklist observed in the Number Talk videos. The number of occurrences of each move was documented during data analysis, but because the number of moves is affected by the number and complexity of the problems presented, we instead report whether or not the moves were attempted.

Dakota's Areas of Work

Dakota's *framing* of the mathematical discussions through launching of both Number Talks included prompts that "efficiently engaged the class in the mathematical work." Dakota did not "direct attention towards the mathematics intended for the discussion" in the launch of their first Number Talk, but this was observed in their second. In concluding both discussions, Dakota "made statements to indicate the conclusion of the discussion." Dakota also attempted to "support students in remembering or making sense of at least one key mathematical topic or practice" in both Number Talks, though they executed this move more effectively in the second.

During the *orchestration* of the mathematical discussions in both Number Talks, Dakota elicited contributions by "eliciting multiple solutions, strategies, or ideas" and "engaging several students in sharing their thinking." Dakota was not observed "eliciting a range of student understanding or methods" during their first Number Talk, but this did occur during their second. However, this could be due to the task, as Dakota was facilitating dot arrangement Number Talks, and less of a range of understanding would be expected with this task. Dakota probed student thinking frequently by "posing questions to get students to explain their thinking about processes" during both Number Talks, a key component of the routine structure. "Posing questions to get students to explain their understanding of key mathematical ideas" was observed in both of Dakota's Number Talks, but the use of this question type was far more limited than questions to get students to explain their thinking. Dakota did not "follow up on responses to make more student thinking about the mathematics available" in either Number Talk. "Providing support for students to complete their contribution or clarify their thinking" was not observed in their first Number Talk but was observed in their second.

The orienting students to the contributions of peers' component of *orchestrating* a mathematical discussion was used less frequently than other moves during Dakota's Number Talks. Dakota did not "pose questions to students about others' ideas and contributions, including asking students to comment on, add to, or restate another student's ideas" during their first Number Talk but did use this move during their second Number Talk. Similarly, "encouraging students to attend to, listen, and respond to peers' contributions in order to maintain productive and focused interaction" was observed only in Dakota's second Number Talk. Dakota did not "support the listening of the class through the use of moves that require all students to respond to others' work" during either Number Talk. Dakota also did not use any moves to "ensure that the class can hear others' ideas," but this was not needed during either of Dakota's small group virtual Number Talks as all students could be heard clearly.

Dakota showed significant improvement in the making contributions component of *orchestrating* a mathematical discussion. In their first Number Talk, Dakota did not use moves such as “redirecting, revoicing, and highlighting to keep the discussion on track” or “make mathematical contributions which enrich the core ideas of the discussion and keep the discussion focused on the learning targets.” Yet they did use the move “ensure that substantive and relevant analysis is part of the discussion” once during the first Number Talk. However, in their second Number Talk, Dakota employed all three of these types of moves throughout the discussion. Dakota’s second Number Talk was double the length of their first Number Talk, even though the problem type (dot arrangements), number of problems, and the number of students all remained the same from the first to the second Number Talk. The increased length was due to Dakota’s use of the making contributions moves frequently throughout, which extended and deepened the discussion of each problem.

Dakota’s *recording and representing content* also improved significantly between their first and second Number Talk. Dakota did not record student thinking during their first Number Talk. When a teacher facilitates a dot arrangement Number Talk in-person, they may record student thinking, or they may use gestures to demonstrate student thinking about groupings and number decomposition. Because Dakota’s Number Talk was virtual, they were not able to gesture towards the dot arrangement image on the screen as a teacher could gesture towards an image on the board or a large hand-held card (Dakota did not use the Zoom function of using a slide as a virtual background). In the virtual setting, recording would be necessary to make student thinking available to others, but this move was not used. In their second Number Talk, Dakota “recorded student ideas in ways that are true to the students’ contributions,” “attended to the accuracy of records and representations,” “recorded in ways that are clear, organized, and visible to the class,” and “used recordings which support student understanding and participation.” Throughout the Number Talk, Dakota recorded students’ thinking by circling dot groupings and recording equations along with branches to demonstrate number decomposition.

Emerson’s Areas of Work

Emerson *framed* the mathematical discussions by launching with moves that “efficiently engaged the class in the mathematical work” and “directed attention towards the mathematics intended for the discussion” in both Number Talks. Emerson concluded the discussions by “making statements to indicate the conclusion of the discussion” in both Number Talks and by “supporting students in remembering or making sense of at least one key mathematical topic or practice” in their second Number Talk. Emerson elicited contributions during their *orchestration* of the mathematical discussions by “eliciting multiple solutions, strategies, or ideas” and “engaging several students in sharing their thinking” in both Number Talks. “Eliciting a range of student understanding or methods” was observed in Emerson’s first Number Talk but not in their second. This is potentially explained by Emerson’s choice of tasks–Emerson used dot arrangements for their first Number Talk and a sequence of double-digit addition problems for the second. Facilitating a Number Talk focused on double digit addition may require further developed Mathematical Knowledge for Teaching (Ball et al., 2008) than is necessary for a discussion of dot arrangements, making “eliciting a range of student understanding or methods” more challenging with this type of task.

To probe student thinking as part of the *orchestrating* area of work, Emerson “posed questions to get students to explain their thinking about processes” in both Number Talks. Emerson “posed questions to get students to explain their understanding of key mathematical ideas” in their first but not second Number Talk, which again could be explained by task complexity. “Follow up on responses to make more student thinking about the mathematics available” was not observed in either Number Talk. Emerson did not use moves to “provide support for students to complete their contribution or clarify their thinking” in their first Number Talk but did so in their second. Emerson employed some moves to orient students to the contributions of peers more than others. Emerson “encouraged students to attend to, listen, and respond to peers’ contributions in order to maintain productive and focused interaction” in both Number Talks, and their frequency in the use of this move increased from the first to the second. “Posing questions to students about others’ ideas and contributions, including asking students to comment on, add to, or restate another student’s ideas” was not observed in Emerson’s first Number Talk and was observed once in their second. Emerson did not “support the listening of the class through the use of moves that require all students to respond to others’ work” in either Number Talk. Due to a student’s internet issues during the first Number Talk, Emerson “ensured that the class can hear others’ ideas,” but this move was not needed in the second Number Talk.

Emerson demonstrated some variation in the making contributions component of *orchestrating* a mathematical discussion. Emerson “used moves such as redirecting, revoicing, and highlighting to keep the discussion on track” during both Number Talks. “Making mathematical contributions which enrich the core ideas of the discussion and keep the discussion focused on the learning targets” was not observed in Emerson’s first Number Talk but was observed in their second. Emerson used moves to “ensure that substantive and relevant analysis is part of the discussion” in their first Number Talk but did not use this type of move in their second. Again, the increase in task complexity may have been a contributing factor.

Emerson showed a marked improvement in their *recording and representing content*. Interestingly, this improvement occurred midway through their second Number Talk. During the first Number Talk and first half of the second, Emerson recorded student thinking by typing students’ contributions verbatim. Emerson “recorded student ideas in ways that are true to the students’ contributions” but did not “record in ways that are clear, organized, and visible to the class” due to font size and use of small virtual sticky notes on a blank whiteboard. This method of recording did not allow Emerson to “attend to the accuracy of records and representations” or to “use recordings which support student understanding and participation” as a student’s explanation for adding a two-digit number that demonstrated understanding of place value was recorded verbatim. Midway through the second Number Talk, Emerson switched from typing to recording equations using the pen tool. Emerson’s clear and accurate recording with equations highlighted the place value understanding inherent in the student’s partial sums strategy, supporting other student’s comprehension of the strategy.

Discussion and Conclusion

Analyzing Dakota and Emerson’s virtual Number Talks using the formative assessment checklist for prospective teachers’ skills in leading mathematics discussions (Shaughnessy et al., 2021) revealed both proficiencies and areas in need of further development–critical dissonance and resonant harmonies. Both Dakota and Emerson demonstrated skills in *framing* their Number Talks during both the launch and conclusion. Both PSTs elicited multiple solutions and strategies throughout both number talks and “accepted, respected, and considered” all answers, a key component of Number Talks (Parrish, 2010, p. 19). Dakota and Emerson also made efforts to engage all students during both Number Talks, although tendencies to call on certain students were first observed. An implication for future practice is moving beyond involving multiple students in the discussion, to ensuring more equitable opportunities for student engagement.

Most PSTs conducted their Number Talks with small groups of students. Though small group size was used for flexibility of implementation during COVID, a benefit of this was that it allowed for a focus on mathematical content, technological tools, and discussion facilitation rather than classroom management. Although the small group size shifted the focus to the important work of discussion facilitation, our analysis revealed that positioning students to make sense of or attend to the contributions of others during discussion *orchestration* was observed less frequently. Prior research has identified positioning students to interact with the ideas of their peers as a challenge for teachers due to the cognitive demand of productively utilizing student solutions and strategies (Smith & Stein, 2018). Even teachers aware of the benefits of incorporating student thinking into their instruction can be apprehensive about responding to student thinking “on the fly” (Smith & Stein, 2018, p. 9). The move of orienting students to the contributions of peers presented an area of critical dissonance in need of resolution. When discussion facilitation does not encourage students' to consider the contributions of peers, it brings about the question of whose voice in particular is being centered. While both PSTs were developing in terms of this move, lack of effective moves to orient students to strategies suggested by their peers minimizes the opportunity for discourse as the conversation proceeds in a “show and tell” format that does not highlight or illustrate important mathematical ideas (Smith & Stein, 2018, p. 6). To achieve resonant harmony, we need to further emphasize the importance of this practice and support PSTs in learning to implement this move.

Recording and representing content was an area of dissonance that shifted to harmony for both PSTs. Representing and recording students' thinking is a challenging but vital way to support students' development of conceptual understanding by connecting language, notation, and visual representations during mathematics discussions (Garcia et al., 2021). Within the cycle, teacher participants were provided with various technologies for *recording and representing content* when facilitating a Number Talk virtually (Dimas, 2020). Both PSTs demonstrated growth from their first to their second Number Talk in using technology for pedagogical goals. Representations corresponded more accurately to students’ thinking and were more effective in supporting other students’ understanding of shared ideas as teachers became more familiar with the virtual space. We hypothesize that the effectiveness of PSTs' recording of student thinking may vary based on task selection, depending on PSTs' depth of knowledge and comfort level with the operations, relevant concepts, strategies, and representations relevant to selected tasks. Still, facilitating Number Talks virtually afforded PSTs the opportunity to use technology tools as they developed skills needed to effectively record and represent mathematics for instruction.

Analyzing pre-service teachers' work in the areas of *framing, orchestrating*, and *recording and representing content* during virtual number talks provided a formative assessment of the strengths PSTs bring to classroom discussions as well as the knowledge and skills needing further attention in future iterations of the VNT TLC and course. Research of this type allows for an awareness of the areas where teacher education experiences may create a critical dissonance in praxis and provides an opportunity for dissension resolution to achieve resonant harmony. Moreover, and in agreement with Shaughnessy et al. (2021), we acknowledge that assessment of mathematical discussion practice with this framework is a dynamic process. We are also cognizant that the framework can be tailored to serve various purposes, such as learning about supports for noticing and areas that are important but not addressed in the checklist framework (Shaughnessy et al., 2021). Regardless, engagement with decompositions of mathematical discussions and analyses of experiences created by teacher educators to develop this practice elaborate the field’s understanding of this instructional component for teaching and learning.

SUBVERTING DOMINANT SCRIPTS OF MATHEMATICS TEACHING: EXPLORING PROSPECTIVE ELEMENTARY TEACHERS' (RE)IMAGININGS OF A CLASS DISCUSSION

Sheila Orr
Michigan State University
smorr11@msu.edu

Sandra Crespo
Michigan State University
crespo@msu.edu

Recent calls to (re)humanize mathematics education require a clearer articulation of how equity-oriented pedagogy can be taught to and learned by teacher candidates. In this article we propose and theorize "flipped scripts" as a research and pedagogical construct that can help identify prospective teachers' (PTs) potential to (re)imagine mathematics classrooms as inclusive and equitable spaces for learning. We use examples of PTs' imagined representations of a mathematics class discussion to examine explicit and hidden messages they communicate about students as capable or struggling learners of mathematics. We conclude by offering implications and affordances of studying PTs' generated "flipped scripts" as indicators of their potential to take up and enact humanizing mathematics pedagogical approaches.

Keywords: Classroom Discourse, Elementary School Education, Preservice Teacher Education, Culturally Relevant Pedagogy

Efforts to conceptualize equity-oriented pedagogies in our field have been ongoing and have taken multiple forms such as teaching mathematics for social justice (Gutstein, 2006), culturally relevant mathematics teaching (Tate, 1995), and most recently the call to (re)humanized mathematics classrooms (Gutiérrez, 2017). Despite past and present efforts to conceptualize equity-oriented pedagogies, teachers of all experience levels find it challenging to stray away from dominant forms of mathematics instruction which set up classrooms as hierarchical and exclusionary spaces for learning (Louie, 2017). This challenge is compounded for those at the initial stages of teacher preparation and for mathematics teacher educators (MTEs) interested in supporting prospective teachers (PTs) to reimagine mathematics classrooms as loving and nurturing spaces for learning. In this study we seek to understand PTs' potential for subverting dominant scripts for mathematics teaching. We conceptualize dominant instructional scripts as representations of practice that center intellectual authority solely on the teacher and that set up classrooms as exclusionary spaces for learning. We explore PTs' capacity for generating "*flipped scripts*" which we conceptualize as representations of instructional practice that counter exclusionary and dominant forms of mathematics teaching practice.

Theoretical Framework

We enter the conversation of reimagining mathematics classrooms as humanizing spaces for learning by building on previous studies focusing on culturally relevant mathematics teaching (Leonard et al., 2010; Parker et al., 2017), teaching mathematics for social justice (Kokka, 2015; Gutstein, 2006) and (re)humanizing mathematics (Goffney & Gutiérrez, 2018). These previous studies have highlighted the instructional practices of teachers who have challenged dominant forms of mathematics instruction and align with the conceptualization of humanizing pedagogy as described by critical scholars outside of mathematics education (del Carmen Salazar, 2013; hooks, 1994; Freire, 1993). To be clear, humanizing pedagogical practices are not new to mathematics education but rather have been a topic of continued interest and scholarship. Bartell and colleagues (2019) share their exploration into working with prospective teachers to draw on students' funds of knowledge (Moll et al., 1992) to build connections between their lived experiences and the content in the classroom. Additionally, Yeh and colleagues (2020) explore how (re)humanizing classrooms become a place where students are free of deficit narratives and challenge the way students with dis/abilities are excluded from traditional mathematics classrooms. Humanizing pedagogies disrupt familiar dominant scripts of mathematics classrooms that position teachers in control of the content and form of the classroom discourse.

Louie (2017) describes the dominant script of mathematics classrooms as embedding a culture of exclusion and describes it as “the restrictive and hierarchical culture that has historically dominated American mathematics education” (p. 489). A culture of exclusion sorts students into those who know and do not know while creating only narrow forms of participation in the classroom. Cultures of exclusion are characterized by dominant instructional scripts in the classroom that set the stage for competitive student behaviors that are unproductive and potentially harmful. Running counter to this culture of exclusion is an inclusive mathematics classroom. Inclusive classrooms encourage multiple solution paths and forms of participation, and it also encourages students to engage in collaborative learning practices. An inclusive classroom, as described by Louie, is a classroom working to (re)humanize mathematics.

Our study also draws from studies of *lesson plays* and of *lesson scripts* of mathematics classrooms which are used as artifacts that make visible the imagined instructional practice of practicing and prospective teachers (Zazkis et al., 2009; Zazkis & Herbst, 2017). We use a collection of classroom dialogues generated by prospective teachers to explore the extent to which they reproduced dominant (exclusionary) instructional scripts and/or produced what we are calling *flipped* (inclusive) instructional scripts. We use Louie’s framework of exclusionary and inclusive mathematics classroom culture to identify and unpack salient characteristics of *dominant* and *flipped* classroom scripts that the PTs in this study generated. We argue that flipped classroom scripts may be good indicators of PTs’ readiness and potential for enacting humanizing pedagogy in their future mathematics classrooms.

Research Methods

This is an exploratory study that uses a small portion of data collected for a larger study of PTs’ generated representations of mathematics teaching practice (Crespo, 2006). This data consisted of 17 imagined classroom dialogues generated by PTs who were at the end of their senior year elementary mathematics methods courses, prior to their yearlong internship. This study uses one of the project’s teaching scenario prompts that features *The Coins Problem* as the mathematical object for a potential class discussion with third graders (Ball & Bass, 2003; Stylianides, 2007). The teaching scenario prompt (Figure 1) was designed to elicit PTs’ representations of their emerging mathematics teaching practice by asking them to write teacher questions they might use with the given task and by generating a classroom dialogue that illustrated a possible class discussion a teacher and their students could have around this mathematics problem.

Imagine you have given your students the following problem to work on.

The Coins Problem

You have a bunch of coins in your pocket, and you know that there are some of each—Pennies, Nickels, and Dimes. Suppose you take out two coins. How much money could you pull out?

. Write 3 questions you want to make sure you ask the students about this problem. Say a little bit about what your goal is for asking these questions.

a. Imagine students have spent some time working on the coins problem, you call everyone’s attention to begin the class discussion about the problem. What can you imagine students will say and do in return? Write out as much of your imaginary class discussion as you can in the following format:

Class Exchange	Explanation
T: *Let's have a discussion about the coin problem, is everyone ready?* *Ss: Yes* *T:*	*Getting everyone's attention and make sure everyone is ready to share and listen*

Figure 1: Generate a Classroom Dialogue (Two-Coins Problem) Task

We drew on Louie's (2017) exclusion/inclusion framework to characterize the PTs' generated classroom dialogues as following or not following dominant scripts of math class discussions. As seen in Table 1, scripts classified as flipped (inclusive) set the stage for a collaborative classroom culture and include teacher questions that create openings for diverse solutions and answers communicating the message that all answers (including mistakes) and forms of participation are valued. In contrast, scripts classified as dominant (exclusionary) set the stage for a competitive classroom culture and include teacher questions that have a narrow set of possible solutions and answers creating a sorting mechanism for those who do and do not know the answer. Through the data analysis a third category emerged where the dialogues were a mixture of both flipped and dominant scripts.

Table 1: Examples of Flipped and Dominant Scripts

Script Type	Class Exchange	Explanation
Flipped Script	T: Can 3 students come up and share their solutions and how they got them Ss with different solutions and methods come up and put their work on the board	
	T: Why are these so different? Are they all correct? S: They are all correct but people picked different coins. The coins have different amounts so you will get different totals.	To show a problem can have many solutions
	T: What happens when you add a 3rd coin? Ss: we get even more different answers	Compare different situations
	T: Why? Ss: Because we had more choices	Justification
	T: What does that mean? S: The more choices there are the less chance there is of getting the same thing.	Finding a solution/rule
Dominant Script	T: What are the values of the coins? S: one cent, 5 cents, 10 cents T: if there are 2 of each coin in his pocket, how many different combinations could you make? S: 6 T: how did you get that? S: 3x2 Ss: No there has to be more than 6 T: Why did you say that?	Speak up to get class attention, once all eyes are on you and all talking has stopped you can start your discussion with an intriguing question.

To unpack the distinctions between dominant and flipped scripts we examined: (1) PTs' questions in both parts (a) and (b) of the task and the extent to which these questions set the stage for exclusionary and inclusive classroom discussion, (2) how students are represented in terms of being active/passive participants and competent/not competent, (3) PTs' explanations for their teaching moves. Each of these domains highlighted a different aspect of how the prospective teachers were imagining their class discussions. We then re-read the scripts with a focus on coding each of these three areas as either adhering to or subverting the dominant scripts of mathematics instruction.

Findings

Of the 17 responses to the coins problem task, we categorized 5 of them (29%) as meeting the criteria of dominant scripts, 3 of them (18%) met our criteria of "flipped script", and the remaining 9 (53%) were a mixture of both, dominant and flipped scripts. Although it may seem discouraging that only 3 (18%) of the dialogues were classified as flipped scripts, we see the latter types of mixed scripts as also suggestive of PTs' potential for learning and taking up (re)humanizing mathematics pedagogy.

Our analysis of the questions the PTs generated in the flipped and mixed scripts found an important difference between the questions the PTs generated in part (a) and (b) of the teaching scenario prompt that we interpreted as PTs' willingness to go "off-script" as another feature of their potential to subvert dominant scripts. The questions PTs had generated in the part (a) of the task focused exclusively on the mathematics of the coins problem task, whereas when they then attempted to enact those questions within the class discussion those initial questions were left out and instead the questions used were more dialogical and had a dual focus on the mathematics and the students' participation. In doing so, they represented the classroom as a more humanizing space where students could be more active (rather than passive) participants. Instead of representing students as answer givers to factual questions asked by the teacher, the students in the flipped scripts were represented as generating and constructing ideas collaboratively. Flipped scripts also (re)imagined teachers as inviting students into the space by asking questions to generate discussion and pressing students to explain their reasoning once an answer was shared.

Reading the scripts with a focus on teacher-student interaction and student-peer interaction we also found PTs' flipped scripts represented class discussions that break off from the dominant Initiation-Response-Evaluation (IRE) pattern of classroom discourse and instead represented the teacher pressing for explanations with multiple back and forth between the teacher and student(s). However, it is important to note that the student responses in the flipped scripts were not as clearly specified as the answers represented in the dominant scripts. There was typically a sentence or two included about students sharing answers or collaboratively generating a list. We interpret this difference as suggesting that PTs may have a general vision of what inclusive mathematics class discussions might look like but are not yet able to produce specific teaching moves that align with their vision.

Discussion & Implications

We offer the construct of "flipped scripts" as an indicator of PTs' potential to take up and enact humanizing mathematics pedagogical approaches. We offer it as a useful analytical lens to analyze PTs' generated representations of mathematics teaching at different stages of development of (re)imagining mathematics instruction as equitable and humanizing. PTs generated classroom dialogues with mixed scripts can provide MTEs with the opportunity to see the initial attempts of PTs to create humanizing pedagogical approaches. In identifying ways PTs attempt to flip the script from exclusionary to inclusive forms of mathematics instruction, MTEs can build on the assets PTs bring to the teacher education classroom.

PRESERVICE MATHEMATICS TEACHER BELIEFS REGARDING PROCEDURAL VERSUS CONCEPTUAL TEACHING BEFORE AND AFTER METHODS COURSES

Derek Pope
Stony Brook University
derek.pope@stonybrook.edu

Angela Kelly
Stony Brook University
angela.kelly@stonybrook.edu

After a two-semester graduate mathematics pedagogy sequence, nine preservice mathematics teachers showed significant changes in their beliefs away from mathematics as a set of rules and procedures and towards mathematics as a process of enquiry. Interviews corroborated quantitative findings and pointed towards practical conceptually-focused strategies in the courses as a driving factor in affecting students' beliefs. Implications for preservice mathematics teacher education are discussed.

Keywords: Teacher Beliefs; Preservice Teacher Education

Teaching mathematics with a focus on developing conceptual understanding, and not merely procedural fluency, is called for in the *Common Core Mathematics Standards* (National Governors Association, 2010). The link between teachers' conceptual views of mathematics and the achievement of their students is well documented (e.g., Staub & Stern, 2002; Tchoshanov, 2011). However, in a recent study of U.S. mathematics teachers, only 61% of high school teachers and 49% of middle school teachers considered themselves very well prepared to develop students' conceptual understanding (Banilower et al., 2018). In a study of preservice mathematics teachers, only 24.1% of teachers proposed instructional strategies that promoted conceptual understanding and qualitative reasoning (Cankoy, 2010).

Why might there be dissonance between the benefit of teaching students conceptually and teachers' beliefs that mathematics should be taught this way? This study sought to understand preservice teachers' beliefs about how mathematics should be taught before and after two content pedagogy (methods) courses, and to identify programmatic or other factors that contributed to changes in beliefs. The following research questions guided the collection and analysis of data: (1) What is the nature of secondary mathematics preservice teachers' beliefs about the nature of mathematics (as a more conceptual or procedural discipline) before and after their methods courses? (2) Which aspects of students' preservice teacher preparation program impacted their beliefs about how mathematics should be taught?

The conceptual framework for the present study is derived from research that suggests that teachers' pedagogical beliefs are precursors to their enacted pedagogy (Pajares, 1992). This study also drew inspiration from Conney et al.'s (1998) and Gomez and Conner's (2020) belief structures to help explain why teachers changed their beliefs.

Methods

This was a convergent parallel study that explored the beliefs of a group of nine preservice mathematics teachers. Although a preliminary analysis, this study was significant in its examination of secondary preservice teachers specifically, its mixed methods approach, and its emphasis on understanding not just how beliefs changed but why (Gomez & Conner, 2020).

The research sample consisted of a subset of a cohort of preservice teachers in a secondary mathematics teacher preparation program at a large public research university. Of the 19 students enrolled in *Introduction to Methods of Teaching Mathematics* (Methods 1) and *Advanced Methods of Teaching Mathematics* (Methods 2) in Fall 2020 and Spring 2021, nine students volunteered to participate in the study. Two were undergraduates, five were graduates in the Master of Arts in Teaching program, and two were in a five-year combined program. All but one student were women. The primary researcher was also the course instructor.

The Intervention: Methods 1 and Methods 2

Methods 1 and 2 were both three-credit courses which met for 160 minutes per week for 14 weeks. Both courses were taught synchronously online due to the COVID-19 pandemic. Course activities in Methods 1 centered around exploring how students learn mathematics and creating mathematical tasks that foster conceptual understanding. The instructor shared many examples of learning activities from his own experience as a high school mathematics teacher. Two important components of Methods 1 were observations of secondary mathematics classrooms and practice planning, implementing, and reflecting on two lessons which students taught to their peers. Methods 2 built upon this foundation and focused on sequencing lessons into coherent unit plans as well as assessment of student learning. Students also had their third opportunity to plan, implement, and reflect upon a lesson to their peers.

Data Sources

Data sources included: (1) a survey taken in the beginning of Methods 1 and again after Methods 2; (2) a VoiceThread assignment completed in the beginning of Methods 1; and (3) a 45-minute semi-structured interview over Zoom after Methods 2.

The validated survey consisted of 33 six-point Likert-scale items that measured participants' beliefs about mathematics and how it should be taught (Tatto et al., 2012). The first six survey statements related to beliefs about mathematics as a set of rules and procedures and the next six to beliefs about mathematics as a process of enquiry. Composite scores were calculated for the two categories, indicating participants' preferences toward statements about mathematics as a process of enquiry as opposed to mathematics as a set of rules and procedures.

At the same two points during participants' teacher preparation program, interviews were conducted to provide further detail on survey choices and to attempt to understand factors that had influenced any belief changes. The first interview was conducted virtually using VoiceThread. After the completion of the two-semester methods sequence, participants sat for a 45-minute semi-structured interview over Zoom. Interview guides were developed based on prior research to provide different ways for participants to demonstrate their beliefs about mathematics and how it should be taught. To triangulate results, multiple types of questions were used, including open-ended questions, reactions to student work, and reactions to a video of a very procedural approach towards teaching the fact that $x^0 = 1$ for $x \neq 0$.

Data Analysis

Quantitative analysis involved performing a paired-samples *t*-test to identify significant differences in participants' composite scores before and after the Methods sequence. A power analysis performed using SPSS v28 indicated that the sample size of nine was adequate for >80% power and a large effect size.

Qualitative analysis involved an iterative coding process. The project team coded interview transcripts line-by-line using a priori provisional coding (Miles & Huberman, 1994), grouped thematically into axial codes, with elements of grounded theory (Saldaña, 2009).

Results

Quantitative Results

Figure 1 shows how students' preference toward mathematics as a process of enquiry over mathematics as a set of rules and procedures changed from before Methods 1 (first bar) to after Methods 2 (second bar).

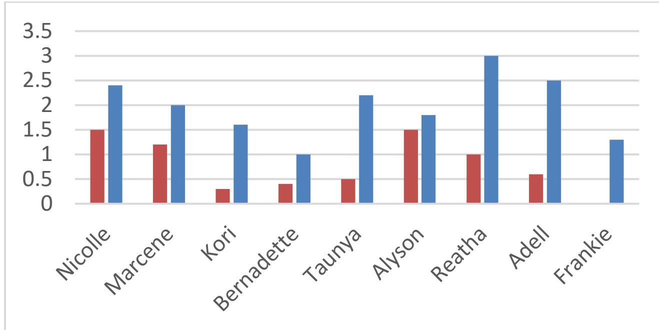

Figure 1: Pre-Methods 1 and Post-Methods 2 Survey Responses

The fact that all values were nonnegative for the pre-Methods survey indicated that all students came into their Methods courses preferring statements towards mathematics as a process of enquiry, with one student showing no preference. All values increased from the beginning of Methods 1 (M = 0.78, SD = 0.54) to after Methods 2 (M = 1.98, SD = 0.63), indicating that students developed significantly stronger preferences towards mathematics as a process of enquiry, $t(8) = 6.063$, $p < .001$, with a large effect size, Cohen's $d = 2.02$.

Qualitative Results: What Changed?

Interview transcripts corroborated students' positive shifts towards mathematics as a process of enquiry over mathematics as a set of rules and procedures, with implications for how the preservice teachers planned to teach mathematics in the future. When asked if her views had shifted on how to teach students rules such as $x^0 = 1$, Adell said:

> Absolutely. And I think it's really just because of the Methods courses. I think those were definitely the most powerful courses that I was able to take. I don't ever want to just spit out facts to my students, or rules… I would still make everything as conceptual as possible, use different methods, use manipulatives, use technology like Desmos, GeoGebra. It would feel wrong if I just gave them out as rules.

Changes in beliefs were particularly notable given that many students affirmed that they were taught mathematics in very procedural, teacher-centered ways, and that they had planned to teach this way until their participation in the teacher preparation program. For example, in reaction to a procedural video about $x^0 = 1$, Bernadette stated that "before [Methods] I would probably teach it like that… I don't think I would have much of a problem with just giving students a rule like $x^0 = 1$. But after the program definitely I would teach them to understand why."

Qualitative Results: Why Were There Changes?

Interview transcripts also gave insight into why changes occurred after the Methods sequence. Adell, who showed one of the greatest changes in her preference toward mathematics as a process of enquiry, expressed her desire to have a classroom full of technology, manipulatives, and group work, saying that the Methods classes gave her pedagogical tools that she had not previously possessed which she could use to develop students' conceptual understanding. Adell expressed how her changed beliefs influenced her actions as a tutor and as a mathematics student:

> I think the Methods classes even just changed the way I thought, like I could see even how I was tutoring changed completely, just based on the Methods classes. The way that I felt about my other math classes definitely changed. I was so happy in my algebra class

> when I saw a pattern myself, in the textbook, and then I noticed that it was just given to me as a rule… It was just so nice to finally see a pattern myself.

In reference to teaching a rule such as $x^0 = 1$, Adell said that she did not understand why it worked until it was discussed in her Methods class. She recalled writing the number two to various descending powers and noticing a pattern and planned to teach it the same way in the future. Adell was an example of a reflective connectionist who was able to formulate a coherent philosophy of teaching that connected new information with her experience (Cooney et al., 1998). Another student, Allyson, also said that although she always wanted a collaborative mathematics classroom (as evidenced by her relatively high score on the pre-Methods 1 survey), during Methods she learned many strategies for actualizing the type of classroom she wanted.

Reatha, another student who showed a large increase in her score pre- to post-Methods, said that in Methods she was introduced to the importance of groupwork, self-exploration, and developing mathematical ideas with teacher assistance, rather than lecturing. She also mentioned her belief that students should be presented problems before learning the procedures, as opposed to learning a procedure first and then simply repeating it. Reatha even said that after the class discussion on why $x^0 = 1$, she contacted her friend to teach her why the rule worked, giving evidence that an activity in the Methods class had a direct and immediate impact on her pedagogical practice.

Based on interview transcripts, course elements that appeared to have positive effects on students' productive beliefs about mathematics and its teaching included: (1) use of interactive technology (e.g., Desmos and GeoGebra); (2) use of physical and virtual manipulatives (e.g., Algebra Tiles); (3) use of collaborative groups; (4) practice writing exams that assessed both conceptual understanding and procedural fluency; (5) learning about why mathematical rules work; (6) reading the book *Mathematical Mindsets* (Boaler, 2016), with its emphasis on teaching mathematics creatively instead of through memorization; (7) use of topic-specific examples of teaching for conceptual understanding; (8) realizing through discussion and readings that many students are not successful learning mathematics in procedural ways; (9) observing secondary lessons taught conceptually; and (10) reflecting on their personal experiences learning mathematics procedurally in light of alternative methods.

Conclusion

A sequence of Methods courses purposefully designed to convince preservice teachers of the merits of teaching mathematics for conceptual understanding, and the detriments of teaching mathematics for merely procedural competency, significantly affected their beliefs about the nature of mathematics towards mathematics as a process of enquiry. The findings presented here imply that beliefs can change when preservice teachers are provided opportunities to learn various strategies for teaching mathematics conceptually, practice using these strategies with their peers, and reflect on their experiences learning and teaching mathematics this way. Preservice teacher programs should be structured in ways that support these changes in beliefs and practice through a variety of strategies, so that students have both the motivation to change their beliefs and the pedagogical toolkit to modify their practice accordingly. Future research could explore how other aspects of secondary mathematics preservice programs, such as clinical experience, work in tandem with Methods courses to influence preservice teachers' beliefs and practices.

PTS' EXPERIENCE DEVELOPING CULTURALLY RESPONSIVE MATHEMATICS LESSONS IN A MIDDLE SCHOOL MATHEMATICS METHODS COURSE

Zareen G. Rahman
James Madison University
rahmanzx@jmu.edu

The proposed presentation describes 20 prospective teachers' (PTs) experience developing culturally responsive mathematics lessons in their middle school mathematics methods course. One mathematics teacher educator guided the PTs in developing and implementing lessons as they engaged in micro-teaching episodes. During Spring 2020, Fall 2020 and Spring 2021 semesters, the PTs engaged in micro-teaching guided by the lesson analysis tool developed by Aguirre and Zavalla (2013) to make culturally responsive mathematics teaching (CRMT) explicit. Engagement in the activity allowed the PTs to learn about developing and implementing lessons that are mathematically rigorous as well as sensitive to social justice issues. The proposed presentation aims to deconstruct how micro-teaching guided by the CRMT tool was employed and to describe the opportunities for PTs' learning.

Keywords: Culturally Relevant Pedagogy, Equity, Inclusion, and Diversity, Social Justice and Preservice Teacher Education.

Incorporating culturally responsive pedagogy (CRP) in mathematical context is challenging (Nasir, Hand, & Taylor, 2008). PTs in their methods courses must experience ways to weave CRP with the content they teach (Cochran-Smith, Davis, & Fries, 2004). For example, using students' funds of knowledge (FoK) to teach mathematics (Moll & Gonzalez, 2004). The research on FoK encourages teachers to incorporate students' wider experiences into teaching mathematics. However, this doesn't necessarily include issues of equity and social justice (Aguirre & Zavala, 2013). CRMT includes knowledge, beliefs, and teaching practices that highlight mathematical thinking, culture, language, as well as issues of social justice (Aguirre & Zavalla, 2013; Aguirre, 2009; Gay, 2009; Gutiérrez, 2009; Kitchen, 2005; Leonard, Napp, & Adeleke, 2009; Turner et al., 2012). It includes 8 dimensions that incorporate elements of pedagogical content knowledge (PCK) and CRP to guide equitable mathematics teaching.

Mathematics education research with a focus on social justice views mathematics as a tool to analyze social justice issues locally or globally (Aguirre, 2009; Christiansen, 2008; Gutiérrez, 2009; Gutstein, 2006; Mukhopadhyay & Greer, 2008; Tate, 1994; Turner & Strawhun, 2007; Gutstein, 2006; Mukhopadhyay & Greer, 2008; Peterson, 2005; Varley-Gutierrez, 2011; Kitchen & Lear, 2000). When teaching mathematics for social justice, teachers provide opportunities for students to use mathematics to challenge and understand existing structures of power.

According to Aguirre and Zavala (2013) developing culturally responsive mathematics teachers requires that they become aware of the larger context within which they teach mathematics. They must conceptualize their role as a teacher to prepare their students to become engaged members of a larger social, cultural or political context. Teachers must recognize that teaching mathematics is a political activity, it is not the neutral subject it's often perceived to be. This means becoming aware of inequities in mathematics education and the role of mathematics as a gatekeeper to advance courses and careers. To this end, the specific research question guiding this study is: *How did engagement in a micro-teaching activity guided by the CRMT tool provide opportunities for PTs' learning?*

Methodology

Action research methodology was employed to investigate how micro-teaching guided by the CRMT tool provided opportunities for PTs' learning over three semesters (Johnson, 2005; Kemmis & McTaggart, 2000; Mills, 2003; O'Brien, 2001; Willis & Edwards, 2014). Micro-teaching activity included PTs developing lesson plans and video recording a short 5-10 minute teaching episode from that lesson. The Mathematics teacher educator (MTE) and peers provided feedback on the video followed by the PTs reflecting on their experience.

The study took place at a public university in the mid-Atlantic region of United States (US). Data sources include student lesson plans, video lessons, student reflections, and peer feedback provided by the PTs during Spring 2020, Fall 2020 and Spring 2021 semesters. Qualitative research methods, specifically thematic analysis (Braun & Clarke, 2019) was employed to systematically code the data and look for emergent themes. Data was organized into 8 CRMT dimensions when analyzing the lessons. Dimensions 1 through 5 guided the analysis on how the lessons attended to students' mathematical thinking. (1-intellectual support, 2-depth of student knowledge and understanding, 3-mathematical analysis, 4-mathematical discourse & 5-communication and student engagement). Dimensions 6a and 6b provided information about students' language (6a-academic language support for ELL & 6b-use of ESL scaffolding strategies). While dimensions 7 and 8 guided the lesson analysis on culture and social justice components (7-funds of knowledge/culture/community Support & 8-social justice).

Findings

Analysis of data collected over three semesters unearthed PTs' perceptions about CRMT and their challenges. During Spring 2020 semester PTs' understanding of CRMT ranged from 'using mathematics to solve real-life problems' to 'developing a math lesson superficially using context from another (non-US) culture'. Most PTs sprinkled some context over mathematics. Such lessons pointed towards the need to improve my PTs' perceptions about CRMT. I planned to help them see connections between CRP, social justice and teaching mathematics. During the next two semesters I devoted more time to unpacking CRMT and introduced it earlier on in the semester. Using existing resources (Berry, Conway, Lawler, & Staley, 2020) I highlighted how CRMT dimensions could form the foundation of a math lesson. PTs examined a social justice based mathematics lesson in class guided by the CRMT tool and developed their own ideas about CRMT. PTs appreciated seeing a math lesson where math and social justice were given equal importance. I also provided a list of social justice standards (Teaching Tolerance, 2016) to be used in the lesson plans along with mathematics standards. The resulting student work from Fall 2020 and Spring 2021 semesters showed marked improvement in students' lesson plans.

Description of two Lessons from Fall 2020 and Spring 2021

During Fall 2020 one PT developed a lesson on linear equations and gender wage gap. The guiding question for the lesson was, How do functions represent the relationship between two variables? The PT stated the following mathematics standard and social justice goals: "The student will investigate and analyze linear and quadratic function families and their characteristics both algebraically and graphically, including connections between and among multiple representations of functions using verbal descriptions, tables, equations, and graphs.", "Students will be able to recognize inequality in the world around them and discuss the issues critically." and "Students will be able to do their own research on inequalities and voice their biggest concerns in that area." During this semester the MTE did not ask the PTs to include social justice goals into their lesson however this PT included them. Among other activities in the lesson, the PT planned to have the students engage in a Desmos activity comparing graphs of two linear functions depicting the wages of two different people. Later in the lesson, the PT planned for the students to react to an image depicting gender wage gap data through Jamboard. The lesson presented a balance between a focus on mathematics and the social justice issue being considered. The lesson did not touch upon the needs of students whose first language is not English. A deep connection to students funds of knowledge and their culture was also missing.

In another example of a lesson from Spring 2021, a PT aimed to engage students in discussions about digital activism while learning about histograms, stem-and-leaf plots and dot plots. The PT stated the following mathematics and social justice goals: "The student, given data in a practical situation, will (a) represent data in a histogram; (b) make observations and inferences about data represented in a histogram; and (c) compare histograms with the same data represented in stem-and-leaf plots, and line (dot) plots" and "I take responsibility for standing up to exclusion, prejudice and injustice" The PT planned to collect data on the number of letters in student names and make a histogram from this data. The PT also planned to ask the students questions like, "What could happen to our histogram if we asked this same question in another country? A different era in history? Another culture?" Such questions could potentially lead to a discussion about similarities and differences in naming conventions of different cultures. While this lesson also included social justice standards, the inclusion of social justice standards did not lead to a deep connection between mathematics and social justice. This semester the students were explicitly asked by the MTE to include social justice standards so inclusion may have been a response to that requirement. The lesson did have the potential to connect to students' home cultures but did not attend to learning needs of students whose first language was not English.

These lessons showed a shift away from superficial use of context. The inclusion of social justice standards may have encouraged the PTs to choose contexts that justified their selection of social justice standards. Their intentional goal selection for both mathematics and social justice may have allowed the PTs to think of both these factors as important in their planning. Overall the analysis of PTs' lessons over three semesters showed a decrease in the use of contexts such as, "ice cream activity" or "graphing flowers" and an increase in contexts such as, "planning a community garden", "using American sign language" or " learning about affordable housing".

Challenges and Growth during Spring 2020, Fall 2020 and Spring 2021

Engagement in the micro-teaching activity itself provided the PTs with the opportunity to learn about CRMT, become aware of their challenges, and experience excitement in connecting issues they feel passionate about to mathematics. The PTs shared similar concerns and patterns of growth over the three semesters. I describe these findings below.

Finding a context was challenging. Some of the PTs' concerns were general in nature because of the novelty of CRMT, for example, "When I saw that we had to come up with a culturally relevant lesson, I got nervous. I had never been forced to come up with a lesson that wasn't all about math. This assignment pushed me out of my comfort zone and forced me to consider other people and their perspectives on the world." (Spring, 2020) PTs shared specific concerns as well, and their biggest challenge was deciding on a context. As one PT shared, "It was also more difficult coming up with an idea to do my lesson on and incorporating the culture I wanted to." (Spring, 2020) The specific challenge was to first find a connection between mathematics and a real world situation that was also culturally relevant.

CRMT was perceived as beneficial for students. Despite their challenges, the PTs found that connecting mathematics to a context was beneficial for their students. Some were motivated to overcome this challenge. One PT shared, "I learned that CRMT is not always going to be the easiest method of teaching, but it is something I am going to have to work on getting used to and trying to implement in my classroom whenever possible." (Spring, 2021) Another PT explained their thinking by saying, "Prior to this course I hadn't had much experience thinking about students' funds of knowledge can be implemented into a math lesson. I have learned that it is extremely important to make content relevant for students so that they feel connected to it and thus more interested in it." (Spring, 2021) The PTs found the idea of CRMT useful for their students. In addition, PTs' initial concerns were allayed with support from MTE as well as their peers. Through peer and professor feedback, cycles of revision and many discussions, the PTs became less apprehensive about CRMT. One PT shared, "Developing lessons based on culturally relevant pedagogy is extremely important, because it allows all students to feel valued and represented." (Spring, 2020)

CRMT was perceived as meaningful for the PTs. In addition to being beneficial for their students many PTs shared finding the process of incorporating context into mathematics lessons exciting. For example one PT shared, "I really liked doing this lesson. It was cool to incorporate something that is a big part of my own homelife culture into a lesson … I got feedback saying that they thought the sign language was a cool touch."(Spring, 2020) Even though the goal was to learn about their students and find contexts relevant to their fictional students, the PTs found it rewarding to connect their own passion to mathematics. A PT commented, "This topic is very close to me and I wish I could have focused more on mental health in teenagers." (Fall, 2020) The PTs started thinking about what contexts were important to them as well as their students.

Discussion and Implications

The experience with the micro-teaching activity allowed the PTs to broaden their perception of teaching and learning of mathematics. It was the first time each PT had heard about culturally responsive mathematics teaching. The experience of learning ways to develop culturally responsive mathematics lesson plans allowed them to unpack their own beliefs about being a mathematics teacher. Many of the PTs were uncomfortable with the idea of social justice in a mathematics classrooms and needed support to unpack how the two were connected. Using the CRMT tool to examine existing lesson plans in class, class discussions, peer feedback on lesson plans and having access to social justice standards all proved to be sources of support.

Through this ongoing action research project I am learning about the actionable steps MTEs can take to develop supports for their PTs. In particular MTEs can help their PTs consider ways of incorporating social justice contexts into teaching and learning mathematics. Allowing PTs to express their concerns about discussing difficult issues in a mathematics classroom can be a first step in allaying those concerns. MTEs must provide tools and examples to show how PTs can develop CRMT but more importantly MTEs must support their PTs. It's a challenging task to help PTs change their perception about mathematics as more than just a stand-alone subject that is devoid of context. This work requires the MTEs to have patience with PTs in order to support their growth.

Conclusion

Findings indicate that MTEs need to be intentional in their course design to highlight the connections between mathematics and social justice. With guidance, future teachers can begin to see how to design classroom experiences to support mathematical knowledge that underpins social issues. This work addresses the need to develop effective mathematics teachers for diverse learners (Civil, 2007; Leonard, 2008; Civil, 2002; González et al. 2001).

THE SELF AS NOTICER: SUPPORTING PRESERVICE TEACHERS' DEVELOPING AWARENESS

Ethan Rubin
ebrubin@uci.edu

Elizabeth A. van Es
evanes@uci.edu

Gaining insight into how one's noticing shapes decision making can enable a teacher to reflect on how they frame, interpret, and respond to classroom activity and disrupt the influence of dominant ideologies. Working in the context of teacher education, we conjectured that systematically analyzing and reflecting on their own noticing can enable preservice teachers (PSTs) in mathematics to develop more equitable practices. Using data from summative assignments in a course on advancing equitable teaching, we investigate how PSTs use lenses of equitable teaching to make sense of their noticing and develop conceptions of equity. Analysis reveals that PSTs engaged in meaningful reflection and adopted terms from the course but avoided discussing the sociopolitical dimensions of instruction. These findings have implications for course design and facilitation in the context of developing PSTs' noticing for equity.

Keywords: Preservice teacher education, instructional vision, social justice

Objectives of the study

Teacher noticing, which encompasses how teachers attend to and interpret details of classroom activity, has been recognized as an important construct for equitable teaching practice (Schack et al, 2017; Scheiner, 2021). How teachers notice interactions is situated within dominant narratives from the history of mathematics education as a field (Sherin et al, 2011). Especially in Western education, mathematics has been characterized as an objective subject without social or political implications, despite a complex legacy of racialized, gendered, and otherwise biased structures and institutions (Gutierrez, 2018). Through that framing, math education continues to be a site for reproducing dominant narratives about what counts as "smart," who is capable of mathematics, and related ideologies that undermine efforts toward equitable education (Louie, 2017). One approach to disrupting those ideologies is for teachers to develop an awareness of how their noticing is shaped by broader sociopolitical systems and their personal histories within those systems. As the influence of dominant narratives becomes more visible, teachers are able to recognize biases and blind spots in their noticing, empowering them to reframe their conceptions of classroom activity and cultivate instructional practices that support equity (Mendoza et al, 2021). Gaining insight into oneself as a noticer and understanding how noticing shapes moment-by-moment decision making can therefore enable a teacher to reflect on how they frame, interpret, and respond to classroom activity and disrupt the influence of dominant ideologies (Louie et al., 2021; Patterson Williams et al, 2020).

Working in the context of teacher education, we conjectured that developing insight into oneself as a noticer can enable preservice teachers (PSTs) to develop more equitable practices. We enter this conversation by investigating pedagogies for supporting preservice teachers in the process of gaining insight into their noticing practices. In response to the constraints imposed on education by the COVID-19 pandemic, we adapted a course for PSTs focused on learning to systematically notice and analyze teaching practice (see Sherin et al, 2009). The course centered on developing "lenses" for noticing and advancing equitable teaching, including attending to student thinking, discourse, positioning, and identity. We structured the course around a series of noticing tasks that entailed using those lenses to analyze how noticing, instruction, and commitments come to life in moment-to-moment interactions. As a summative assignment, the PSTs reflected on and analyzed those noticing tasks in order to represent their noticing as a system informed by the lenses the course had introduced. In this study, we ask: how do preservice teachers use lenses of equitable teaching to make sense of their noticing practices? What do their self-analyses reveal about their emerging conceptions of equitable instruction?

Theoretical framework

Noticing is especially central to teaching for equity, as noticing is shaped and constrained by ideologies that frame what teachers deem worthy of attention and how they interpret those details (Louie, 2017). Noticing occurs continuously as an active and subjective process, whether or not the teacher in question is conscious of attending to certain phenomena over others or interpreting details in particular ways. Becoming aware of one's noticing, however, enables a teacher to understand, question, broaden, and disrupt their noticing practices (Erickson, 2011; Mason, 2009). Similarly, ideologies are shaping noticing whether a teacher is aware of them or not; awareness helps one see what ideologies are shaping noticing and how, i.e. are they supports or barriers to advancing equity in teaching.

The concept of frames is of particular importance for unpacking the relationship between ideologies and noticing. Hand (2012) describes frames as structures that establish "expectations for how the emerging activity should unfold and for the roles that different individuals will take within it" (p. 251). Louie (2021) builds on this understanding, characterizing frames as narratives that shape both *what* and *how* we notice, and which "take on authority as they are told and retold [to] influence their tellers' and others' subsequent framing" (p. 3). Frames are both internal structures that teachers rely on to make sense of classroom activity *and* modes of representation and communication with students about the content and context of learning in the discipline. Frames that are based in dominant ideologies, e.g., white racial knowledge or race denialism ("colorblindness"), can perpetuate those ideologies (Reisman et al, 2020; Bonilla-Silva, 2006). On the other hand, frames based in challenging inequitable systems and rehumanizing learning can disrupt dominant ideologies (Gutierrez, 2018; Louie, 2017; McKinney de Royston et al, 2021).

The relationships between ideologies, frames, and noticing have prompted attention to how teachers' self-awareness in noticing develops. For instance, Patterson Williams et al (2020) offer a model of teacher noticing that centers on cultivating an "inner witness" by attending to how equity unfolds in "micro-moments within fleeting classroom discourse" (p. 505). Mason (2009) parses the development of teacher awareness into phases of preparation (e.g. structuring and planning), paration (the enactment of teaching), and postparation (e.g., reflection and interpretation). Postparation practices then provide the basis for preparation in continuing instruction. Philip (2019) describes practices for gaining insight into one's teaching through narrating, re-narrating, and re-envisioning episodes of teaching. Across these frameworks, authors highlight the importance of reflecting on past practice to improve future practice in iterative cycles. In the context of teacher education, this insight indicates pedagogies for supporting the development of self-awareness with pre-service teachers. In the course design that led to this study, we drew on these frameworks to engage PSTs in representing, reviewing, and reinterpreting their noticing as the manifestation of commitments, beliefs, and ideologies they consciously and unconsciously hold.

Research methods

Study context

This study was situated in a required course for a combined Master of Arts in Teaching and teaching credential program that took place in the fall of 2020. The course, titled "Learning to Learn from Teaching," engaged preservice teachers in analyzing representations of teaching practice (e.g., videos and transcripts) to develop their noticing practices and their *awareness* of their noticing. Through course readings, discussions, and assignments, we provided PSTs with multiple lenses that together constitute a model of responsive and equitable teaching. PSTs were directed to use the lenses to analyze and reflect on representations of teaching in a series of noticing tasks assigned throughout the course. Their observations and reflections were recorded in a noticing journal, which documented PSTs' noticing in a form they could review and reference. Examples of lenses and associated readings are listed in Table 1.

Table 1: Lenses and readings from the course

Lens	Summary	Readings
Understanding students' identities	Knowing, doing, and being are intertwined aspects of learning. Students' identities, practices, and knowledge are all continuously expressed and developing in the classroom.	Herrenkohl & Mertl, 2010
Student thinking (strengths-based perspective)	"Smartness" in math has been narrowly defined in terms of speed, accuracy, and "right" answers. Teachers can challenge this ideology by focusing on students' strengths instead of deficits and moving beyond the right/wrong binary to understand and appreciate student thinking.	Louie, 2017; Jilk, 2016
Discourse and accountable talk	Classroom discussions can be understood through three forms of accountability: to knowledge, to standards of reasoning, and to the learning community. Rich classroom discourse involves students collaborating to navigate the process of sensemaking and guide discussion through questioning, reasoning, and mutual support.	Hufferd-Ackles et al, 2004; Michaels et al, 2008

Prior iterations of the course culminated in PSTs planning, enacting, recording, and analyzing a lesson in their student teaching placements. Due to the COVID-19 pandemic, however, PSTs were not in classrooms and therefore could not produce and analyze representations of their own teaching. As an alternative, we engaged PSTs in a method of self-analysis using their interpretations of videos and transcripts in the noticing journals as data. In prior work, we developed an analytic method to characterize the relationship between teachers' commitments, noticing practices, and instructional practices (see Authors, 2022), which we refer to as a system of noticing. We conjectured that the process of constructing a personal system of noticing through reflection and analysis of noticing tasks would support PSTs developing the kind of awareness that would support equitable practice in teaching.

Developing a system of noticing first required PSTs to review their responses to noticing tasks and make distinctions between their observations and their inferences. PSTs identified patterns in what they tend to notice (observations) and how they interpreted those details (inferences). They then grouped their patterns of observations and the associated inferences into clusters that shared a noticing lens. Figure 1 provides an example of a cluster of observations and inferences around a noticing lens.

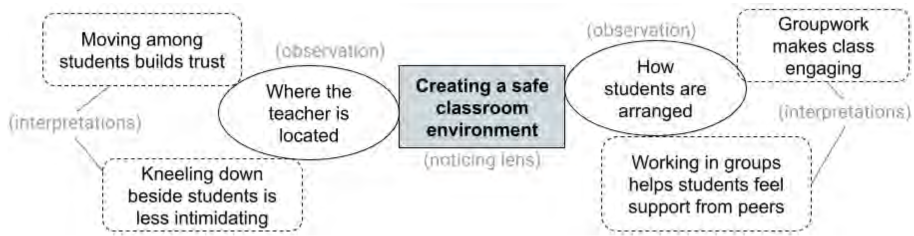

Figure 1. Example of a system of noticing

Through this process, we conjectured that PSTs would develop the ability to distinguish between an objective observation and an interpretation, thereby revealing the influence of commitments, ideologies, and dominant narratives on how they interpret what they see. Grouping the observations and inferences and naming that cluster as a lens then helps preservice teachers identify the specific narratives, ideologies, and commitments at play. By making these aspects of noticing visible, we intended to position preservice teachers to consider how their noticing may or may not support equity and determine aspects of their noticing they want to refine, expand, or disrupt. In addition to creating a visual representation of their system of noticing, the preservice teachers wrote a paper explaining how they developed and interpreted their system of noticing using their noticing task responses and the literature from the class. The paper consisted of three parts: 1, explain the noticing lenses using evidence from the noticing tasks; 2, analyze the lenses using the course readings; and 3, identify areas of noticing to expand or disrupt and describe a plan for doing so.

Data analysis

Of the 11 mathematics candidates enrolled in the course, five consented to participate in this study. Data consists of their summative system of noticing assignments, which include a visual representation of the system of noticing and a reflection paper explaining the data from their noticing tasks and the concepts from course readings that they used to develop that representation. We employed iterative qualitative methods (Miles & Huberman, 1994) to examine the ways that PSTs took up lenses of equitable and responsive teaching and the conceptions of equitable teaching their work revealed. First, both authors read through, made margin comments, and wrote memos about each paper. The authors then discussed their comments and memos, identifying categories and themes that stood out across their impressions. These themes concerned which lenses were raised by the PSTs, what kinds of explanations they provided to justify prioritizing those lenses, and how their explanations related to the course materials and goals. Following these discussions, the authors returned to the data to conduct rounds of focused coding (Saldaña, 2011) around three areas: how terms were used (e.g. definitions and examples), critical statements (e.g. “students often feel vulnerable”, “math is seen as irrelevant,”) and normative or values statements (e.g. “teachers should do X”, “I want to create a classroom that is Y”). Finally, the authors reviewed the readings that PSTs cited most to consider how student definitions aligned with the definitions of concepts in the course materials and the extent to which their critical and normative stances were consistent with the aims of the course.

Results

Analysis revealed two main findings. First, PSTs appear to have taken up the fundamental aims and practices of the course by trying on lenses to re-envision and re-imagine schooling in light of their commitments. Second, PSTs applied language from the course readings and discussions, but often defined those terms in partial or adapted forms that were more compatible with their pre-existing frames. These redefinitions showed a tendency to avoid the broader systemic issues and ideologies that influence classroom activity.

Finding 1: Interpreting noticing through beliefs and commitments

Although this portion of the assignment asked PSTs to describe what they noticed and inferred in the noticing tasks, all five PSTs in this study consistently made normative or aspirational statements about teaching. Student 1, for instance, made the arguments that "students should develop ideas, have authority in the classroom, and be responsible for their knowledge" and "it is crucial to create a safe, supporting, and inclusive place…students should have the opportunity to practice their identity, individuality, and whom they are." Student 2 stated that "we need to value students for who they are and acknowledge their differences" and Student 5 made claims like "students should lead the direction of the discussion" and "teachers need to learn how to really listen to their students." In a similar vein, Student 4 linked their understandings of key concepts to value statements: "Tools are shared through communicating with one another, thus, communication is a practice that must be developed to promote learning"; "Students develop their identity through interactions, thus participation is key in providing students with an opportunity to develop their identity"; "Knowing, doing, and being are all intertwined, hence it is important to study all aspects." These claims about the purposes of teaching indicate that these PSTs were articulating their beliefs and commitments about how teaching *should* be and understanding those commitments as the basis for their noticing.

In several cases, PSTs expressed normative or aspirational claims by pairing critiques of schooling with alternatives. Student 1 articulated these dyads in each section of their paper, starting with: "in many cases, the teacher is considered as the only authority in the classroom…I believe in a student centered classroom." In their next argument, they state, "students cannot see the connection between what they learn as mathematics and how it is used…students must become aware of…the applications of the subject." Finally, they point out that "all students come from different backgrounds and stories and we should not expect them to adjust their identities to the dominant culture. Students should be appreciated as individuals with unique thoughts, beliefs, values, and identities." Student 4 used the same format, at one point unpacking a specific observation by explaining that "this student might have felt left out…teachers must not turn away different representations of participation because it may hinder students' opportunities to learn. Thus, students must not only be encouraged to participate but more importantly must be offered assistance to participate." Later in their paper, Student 4 presses on assumptions about the nature of doing mathematics, noting that "students have been conditioned to believe that if they are fast and accurate, then they are smart. However, my noticing lens disrupts this narrative because my… noticing lenses value participation and use participation to redefine smartness."

Students 2, 3, and 5 reverse these dyads, with Student 2 saying, "I look at the positive interactions or ideas…teachers may focus too much on what students are doing wrong," and Student 3 expressing that they pay more attention to student-led discussions because they have observed classrooms in which "there is not a lot of room for discussion, just lectures and note taking." Student 3 also provides a more personal example, saying, "I remember being in the classroom and not wanting to provide my opinions because I was afraid of being wrong and other students judging me for it. So, when I observe students, I look to make sure that everyone feels comfortable being wrong and learning from it." Student 5 makes a broader claim about their beliefs on the nature of learning: "students should be given the opportunity to construct knowledge for themselves. If students are constantly spoon-fed knowledge without a chance to build it for themselves, we position them as incompetent learners that need someone to build it for them." Across these examples, we see PSTs using their normative commitments as frames to interpret classroom activity. Instructional practices they observed, interpersonal dynamics, and messages implied by teacher actions were interpreted in relation to beliefs about what is valuable in teaching and learning, which in turn pointed PSTs to alternatives they conceptualized as solutions to persistent issues in schooling.

Finding 2: Redefining terms from the course to fit with pre-existing frames

PSTs used terms from the course, but often adapted them to fit with their pre-existing frames. This was most visible when PSTs explicitly provided definitions and illustrations that were partial or selective versions of the concepts introduced in class. Student 2, for instance, begins their paper by defining "noticing" as "a critical and analytical tool that…pertains to student attainment, cognition, and thinking, as well as the educational environments where such facets take place." The framing emphasized in the course, however, sought to define noticing as a typically unconscious manifestation of a teacher's identity, their personal and social history, and the systems in which they work, rather than as an analytical tool that teachers can choose to aim at students. Student 2's focus on attainment and cognition appears again when they use the term "accountability" to mean "where students are held accountable in understanding certain content material…[and] held accountable in finding answers, persevering if struggling." This conception of accountability indicates a partial understanding of "accountable talk" from the course readings, as it omits Michaels et al's (2008) emphasis on the social dimension of accountability to a learning community. The idea of "perseverance through struggle", on the other hand, does *not* appear in the course materials. Student 3 applied a similar partial understanding to interpret a video shown during class, writing that "during the discussion, some students were right while others were wrong, but there was never any judgment in the room." In the course, however, the rationale for showing that video was to demonstrate a teacher rejecting the frame of the "right/wrong binary", valuing student sensemaking *instead* of thinking in terms of students being right or wrong.

The tendency toward partial or selective understanding is further illustrated by what PSTs did *not* talk about when explaining or analyzing a given concept. For instance, four of the five PSTs cited Philip et al (2016) as evidence that they attended to power and positioning. The reading, whose title refers to "becoming racially literate" and "racial-ideological micro-contestations" (p. 361), unpacks a classroom interaction in terms of the teacher's avoidance of talk about race, which tacitly enables racial antagonism between students and excludes a Black student by delegitimizing his insights about content that involves Black communities. Student 5 argued that the problems in that situation arose because the teacher "positioned himself as the authority figure in the room by acting as the 'gatekeeper of knowledge'", in accord with a claim that asking the question "was the teacher acting as the 'gatekeeper of knowledge'...allows us to analyze who has the power in the classroom." While questions of authority and gatekeeping are relevant to this example, the absence of race, identity, and power dynamics beyond the interpersonal scale in this account is conspicuous. Likewise, Student 3 diagnosed the problems in the Philip et al reading as "[the student] being disregarded so much and constantly defending his opinion to the point where he just stopped." Again, this analysis brings up relevant points, but there is scant mention of race despite the authors' insistence that race, and particularly the teacher's refusal or inability to *discuss* race, is crucial to understanding the example. Student 1, in contrast, did mention race in the context of this example, but they interpreted it in colorblind terms: "we ostracize an individual due to simply the color of their skin, but at the end of the day, we are all human, so why do these discrepancies exist?" This response conflicts with the authors' argument that a student's race entails legitimate differences in experience and perspective, which can afford insights that should be recognized.

With regard to Philip et al (2016) and several other examples, PSTs showed a tendency to omit the sociopolitical aspects of a concept or situation by choosing to focus on smaller scale interpersonal perspectives. All five PSTs prioritized some version of students feeling safe, welcome, and included, and four made claims about attending to positioning. In their explanations and examples, they focused primarily on how teachers' actions affected students. Student 4, for example, stated that "teachers can create an inclusive classroom by asking students questions and inviting students to participate." Student 5 claims, "I very much focus on how students are positioned in the classroom. For example…where the knowledge is coming from contributes to the power dynamic between teacher and student." Their understanding of positioning related to how students were positioned *within* the classroom through interactions, without engaging with how students were already positioned *coming into* the classroom based on their identities and histories. Likewise, PSTs' accounts of students feeling safe/unsafe or welcome/unwelcome focused on how teachers' actions could *cause* a student to feel that way, rather than considering how certain students may not feel safe or welcome within school institutions even before a teacher acts.

Discussion

Findings suggest that PSTs took up the *practices* of developing self-awareness that were facilitated by the course design, although their responses did not necessarily capture the details of the content. Even when PSTs brought up different ideas than were discussed in the course, their practices of surfacing assumptions and interpretations, critiquing the status quo, and reimagining instruction were consistent with the course aims. The prevalence of normative and aspirational statements indicates that PSTs were examining their noticing in the context of their beliefs and commitments, which complements the course focus on revealing the power of ideologies and frames. Through reflection and analysis of representations of their own practices, PSTs were beginning to see the connections between a teacher's ideologies and commitments, what they notice, and the actions they can take to embody a vision of responsive and equitable teaching. This is consistent with other research on developing PSTs awareness (e.g., Philip, 2019). While the conceptions they applied within those practices were at times partial or misaligned with the course content, it is important to recall that these were *emerging* conceptions; many of the ideas and frameworks in the course were entirely new for the PSTs. Research on developing frames for equitable teaching speaks to the difficulty of changing frames, even with experienced educators who participate in extended professional development (Louie, 2017; Reisman et al, 2020). For PSTs, this process is additionally complicated because they lack the frame of reference on which experienced teachers rely. Without their own experiences of the classroom context to draw on, pre-service teachers often struggle with what details are noteworthy in a case and how to interpret those details (Darling-Hammond & Hammerness, 2002; van Es et al, 2017). Given the novelty of the course material, the fact that PSTs were applying relevant practices in efforts to make sense of their noticing in terms of their commitments indicates they began to adopt the perspectives intended by the course.

It is noteworthy, however, that the areas in which PSTs' responses departed most from the course aims revolved around sociopolitical awareness. Despite efforts throughout the course to center and unpack the effects of social histories and systems on instruction, the PSTs rarely mentioned the sociopolitical dimension. As a counterpoint, McKinney de Royston et al (2021) consider how Black educators enact frames of care and protection towards Black students and find that their frames are characterized by "clarity about the historical and political landscape" that illuminates "racialized disparities and experiences in schools…as by-products of systemic racism" (p. 73). This clarity is expressed in "politicized caring", which motivates and empowers the teachers and school leaders to disrupt harmful narratives and structures in the name of making students feel safe and cared for. By contrast, the PSTs here bring in a frame of *apolitical* caring. In these reflections, PSTs emphasize creating a sense of safety and students feeling welcome or at home, but without addressing the broader social and systemic issues that affect students' experiences of schooling. This pattern was visible even in PSTs' responses to representations of explicitly racialized situations, as in the Philip et al (2016) example. This fits with a more generalized tendency to view the classroom as a neutral space until it is shaped by teacher actions. Treating the classroom as a neutral space (rather than one inherently pre-shaped by sociopolitical factors) frames creating a sense of student safety as a question of *not* doing things to make them feel *unsafe* as individuals within classroom interactions, rather than disrupting or counteracting broader sociopolitical narratives. The absence of a sociopolitical frame, even under the guise of neutrality or valuing interpersonal relationships, ultimately reproduces a colorblind ideology that perpetuates harmful narratives and delegitimizes the experiences of students from historically non-dominant communities (Bonilla-Silva, 2016). These findings therefore raise questions regarding what kinds of pedagogies, artifacts, and supports are needed for PSTs to cultivate systemic *and* interpersonal perspectives as compatible and complementary frames (Weis & Fine, 2012).

Limitations and future research

The systems of noticing that PSTs developed and the reflections they analyzed to do so were produced by engaging with a set of artifacts, representations, and readings that were selected by the authors. As teacher educators, we were not neutral or objective in the selection of these materials. Rather, we attempted to curate a set of materials that support a vision of equitable noticing and instruction that we hoped to cultivate with this group of PSTs. It is likely that engaging with different representations or being informed by different literature would reveal other tendencies in PSTs' noticing, ideologies, and commitments. The study is also limited by its small size, both in terms of the number of PSTs involved and by virtue of being a single instance of the course. This study represents only one iteration of guiding this process of development, and findings reveal both areas of success and possibilities for improvement. Further research is needed to consider the implications of these findings for course design and facilitation in the context of developing noticing for equity and social justice. Moreover, a single course is clearly insufficient for deep and lasting change given the complexity of noticing and the persistent nature of dominant ideologies and narratives. Future research will also address how this process can be supported and sustained in other PST courses and in professional development for early career teachers.

This paper examines the possibilities of designing a formative assessment that gathers information about novice elementary teachers' skills with modeling content and makes sense of such information. A decomposition of the practice of modeling content was developed and used to design the assessment. Participants included ten first-year teachers who graduated from a range of different teacher education programs. The findings reveal that our formative assessment works to gather information about teachers' capabilities with modeling content and that the associated tools support making sense of the information gathered.

Keywords: Assessment; Instructional Activities and Practices; Preservice Teacher Education

Ms. Hazard is a third-grade teacher who is currently teaching her students how to name shaded parts of areas as fractions using the definition of a fraction in the Common Core State Standards (CCSSO, 2010). She knows that it is crucial that students grapple with the importance of making equal parts, naming one of the equal-sized parts, and then counting the number of shaded parts to name the fractions. In her initial lesson, she presents students with the task shown in Figure 1. There is disagreement about the fraction of the rectangle that is shaded, with students suggesting 1/3, ¼, and 1/2. She holds a rich discussion where children share their thinking and consider the thinking of others, including asking questions of their classmates. The class talks about how some students arrived at ½ because they used part of the rectangle as the whole and other students, who arrived at 1/3 or ¼, used the whole rectangle. They further talk about how some students noticed that one of the parts was bigger and that they added a line to make the parts the same sizes and that this is how some people arrived at 1/3 and others arrived at ¼. At the end of the discussion, it seems that a convincing argument for ¼ has been shared and that the class is tentatively in agreement that the shaded area is ¼ of the large rectangle. Ms. Hazard recognizes that the class needs to consolidate the core ideas shared.

What fraction of the rectangle is shaded gray?

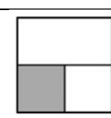

Figure 1: Third Grade Fractions Task

Ms. Hazard concludes by saying to the class, "We had such an important discussion today and I want you to listen carefully as I share how I think about naming this fraction because it connects to lots of ideas that were shared today and can help us think about other fraction problems." Ms. Hazard goes on, "The first thing I ask myself is, 'What is the whole?', and I outline the whole. Our whole is the big rectangle." As she says this, Ms. Hazard outlines the big rectangle with a whiteboard marker. "Then, I ask myself, 'Is the whole divided into equal parts?' Let's look, here the parts in the whole are different sizes. See this part [pointing to the rectangle on top] is bigger than these parts [pointing to the parts on the bottom]. So, I need to make the parts the same size, so I can divide this part [pointing to the rectangle on top] in half to make the parts the same size." Ms. Hazard uses her red marker to split the part in half. Ms. Hazard goes on, "Now I ask myself, 'how many equal parts does it take to make the whole?' I can count one, two, three, four." As Ms. Hazard counts, she points to each part and labels them one, two, three, four. Ms. Hazard goes on, "Then, I ask myself, 'What do you call one of the parts?' We call one of the parts, one out of the number of equal parts. We have four equal parts so we can call one of our equal parts, one-fourth. We have one equal part shaded in our rectangle, so one-fourth of the rectangle is shaded." Ms. Hazard labels the shaded part as one-fourth on the board. Ms. Hazard concludes, "We will continue to work with fractions and it is really important that we ask ourselves four questions. What is the whole? Trace around the whole [while tracing]. Is the whole divided into equal parts? If not, make the parts the same size [traces line with finger]. How many equal parts does it take to make the whole? What do we call one of the equal parts? We can call it one-fourth." Ms. Hazard records these questions on the board as she says them.

Ms. Hazard first engaged students in grappling with mathematical ideas related to naming a shaded part of area as a fraction and concluding that ¼ of the rectangle is shaded. She then provided access to thinking by naming, highlighting, and scaffolding important ideas surfaced by students in ways that support the whole class in doing complex mathematics. Ms. Hazard named the core ideas and provided scaffolding questions that support students in learning what to ask themselves as they approach such mathematical work.

In recent decades, there has been increased attention to several instructional practices that teachers can use to support students in constructing understanding of mathematics, including selecting rich mathematical tasks (i.e., Smith & Stein, 1998) and facilitating discussions of students' work on such tasks, either in small group or whole class (Chapin, O'Connor, & Anderson, 2013; Smith & Stein, 2011; Kazemi & Hintz, 2014). But we argue that these instructional practices are, by themselves, insufficient to enable every student to be successful with complex mathematical work and to experience of joy of mathematics as they can often leave core mathematical ideas "in the ether" rather than supporting students to synthesize and generalize the ideas they have developed individually and collectively.

Fundamentally, modeling content is about intentionally and thoughtfully providing access to content that may otherwise remain hidden to some students. Modeling, which requires the teacher to think aloud while demonstrating a skill, makes visible those practices and processes that happen internally and often remain invisible to learners if not explicitly named, explained, and shared. As we saw in the vignette from Ms. Hazard's classroom, when modeling, a teacher names, highlights and scaffolds the topics and practices in ways that support students in doing complex mathematics without taking over the work for them or compromising students' agency and their opportunity to engage in complex mathematical work.

The concept of "explicitness" in modeling is distinct from "direct instruction," which is a teacher-centered approach for delivery of content instruction (Archer & Hughes, 2011). Explicitness in modeling is not meant to reinforce or recreate the patterns of telling that are often seen in U.S. mathematics classrooms (Stein, Smith, Silver, & Henningsen, 2000), but rather it is aimed at making "access" a reality rather than a goal of collaborative development of mathematical ideas. But this sort of explicitness has often had an uncomfortable place in mathematics education. We argue both that this sort of explicitness is important and that the consideration of when to make content explicit through modeling is crucial for ensuring that all students have opportunities to engage with complex mathematical ideas. The key here is what is made explicit and what is left for students to figure out, and what "making explicit" means for the role of the teachers and students. Yet, partly due to concerns that focusing on modeling content might result in direct instruction, mathematics teacher educators have often backgrounded the work of making complex mathematics accessible through modeling. Further, this practice is complex and difficult and there is much to learn about how to support new teachers in learning to model content in productive ways (Charalambous et al., 2011).

We believe that formative assessment could make a substantial contribution to preparing new teachers to model content to support children's mathematical learning. By formative assessment, we mean assessments used to formulate subsequent learning opportunities (Cizek, 2010). Formative assessment enhances learning by revealing the current state of learners' knowledge, skills, and dispositions and ensuing action that facilitates growth (Black & Wiliam, 1998; Hattie & Timperley, 2007; Shute, 2008). We use the term skills to describe teacher candidates' (TCs) abilities to carry out specific aspects of the work of teaching at a particular moment in time, fully recognizing that TCs' capabilities will grow and change over time. Studies of the development of expertise have found that practice opportunities alone do not sufficiently support TCs to improve. Practice opportunities need to be coupled with structured directive coaching (Ericsson & Pool, 2016), which formative assessment can provide. Thus, formative assessment is a critical component in teacher preparation (AMTE, 2017; Darling-Hammond et al., 2005) and we need additional tools to assess TCs' skills with particular practices and components of teaching (Boerst et al., 2020; Shaughnessy & Boerst, 2018; Shaughnessy, Boerst, & Farmer, 2019; Shaughnessy et al., 2021). We argue that if we develop and refine formative assessments of teaching practice and tools that support teacher educators in providing timely feedback to TCs on their skills, then TCs will develop more robust skills with these teaching practices, impacting student learning. Thus, we sought to investigate whether it would be feasible to design a formative assessment focused on modeling content for use with elementary TCs. Specifically, we investigated whether such an assessment could elicit and reveal detailed aspects of TCs' skills with modeling content.

The Teaching Practice: Modeling Content

Modeling Content

Although the field of mathematics education does not yet have a shared conceptualization or common language for decomposing modeling content, a number of scholars have worked to specify and define instruction related to modeling content in ways that support our conceptualization of this instructional practice, which is distinct from behavioral modeling (demonstrating how to complete a task or behavior). The work of Collins, Brown, and Newman (1989) and Collins, Brown, and Holum (1991) in their development of the cognitive apprenticeship as a way to make thinking visible to students, name modeling as the work of performing a task while making internal processes external. Leinhardt's seminal research on instructional explanations (e.g., Leinhardt, 2010; Leinhardt et al., 1991; Leinhardt & Steele, 2005) has illustrated the complexities of explanations that are accountable to both the discipline of mathematics and pedagogical purposes. They also suggest criteria for such explanations.

Other scholars have worked to decompose the work of modeling content by examining specific types of teacher moves related to explicitness. Selling (2016) offered a decomposition of eight types of teacher moves that made different aspects of mathematical practices explicit in middle and high school mathematics discussions. This included moves like highlighting and naming when students were engaged in particular practices. Furthermore, Selling highlighted how the work of making aspects of mathematics explicit often happens at the end or in the middle of lessons, rather than at the beginning, which is also supported by other empirical research (e.g., Schwartz & Bransford, 1998; Schwartz & Martin, 2004). Further, teachers' choice and use of particular mathematical examples can support, constrain, or even obscure the mathematics that is available for students to learn within a particular domain (Ball et al., 2005; Rowland, 2008) and the choices teachers make about particular mathematical representations influence the nature of students' learning opportunities (Ball, 1993).

Overall, the mathematics education research base supports our conceptualization of modeling content and suggests that this practice is related to student learning (Cohen, 2018). The research also supports our conception of modeling as being appropriate and effective after students have had an opportunity to grapple with the mathematical ideas themselves (Schwartz & Martin, 2004). We recognize that the way that this practice is often enacted does not align with our view of this practice. When Cohen summarized her study of explicit instructional strategies (modeling & strategy instruction) in elementary ELA and mathematics lessons, she reflected, "explicitness need not be directive or prescriptive, though the instruction in this study suggests that it often is" (Cohen, 2018, p. 322). This suggests that, given the tendency for directiveness and prescriptiveness in classrooms, it is crucial that we support teachers in learning how to make context explicit in productive ways that are not directive or prescriptive.

Decomposing the Teaching Practice

To assess teachers' capabilities in modeling content, we drew upon Grossman et al.'s (2009) notion of parsing teaching practice into specific areas of work to create a "decomposition" of the practice. Because we were interested in using decomposition in teacher preparation, we attended to the importance of decomposing in ways that the practice can be taught and learned by TCs (Boerst et al., 2011). We drew upon prior research on the importance of modeling content for student learning and research on moves that teachers make when demonstrating, explaining, and modeling content to develop an unpacking of the work of modeling content, a "decomposition" of the teaching practice. We identified different aspects of what teachers have to do to model content. We acknowledge that a decomposition is a living document (Jacobs & Spangler, 2017; Shaughnessy, Ghousseini, et al., 2019; Shaughnessy et al., 2021). One challenge of decompositions is that while they are meant to provide details about the work of carrying out the practice, they cannot name the complete set of knowledge and skills required to carry out the practice or they will be unwieldy. While we recognize that teaching practice is dependent on mathematical knowledge for teaching and teachers' views of mathematics and children's ideas, the decomposition is focused squarely on teachers' enactment of the teaching practice.

Our decomposition deliberately foregrounds certain aspects of the work of modeling content with students—specifically those that we consider crucial for entry-level teaching. We further considered the aspects of modeling content that are most likely to be accessible to and learnable by novices. We began by identifying specific aspects of leading modeling content and what teachers of any level of experience and expertise do to try to accomplish those. For example, in modeling content, one important goal is to make thinking visible that might otherwise be invisible. This entails specific techniques such as annotating, which refers to adding in ideas necessary to support students' understanding, including clearly articulating what you are doing and why you are doing it. These moves are also foundational for the more complex work experienced teachers do in modeling content. We organize our decomposition for modeling content into six areas of work: (1) planning to model, (3) framing, (3) doing content area work, (5) highlighting core ideas, and (6) making thinking visible by emphasizing thinking and key elements, and (6) using language and representations carefully (see TeachingWorks, 2019 for a list of moves associated with each area of work).

Assessing Teacher Candidates' Skills with Modeling and Explaining Core Content

The design of the assessment was influenced by our view of teaching as interactive and situated in contexts (Cohen et al., 2003; Lampert, 2001). We aimed to design an assessment focused squarely on TCs' ability to model content in real time. Three considerations led us to design a standardized assessment in which TCs video recorded themselves modeling content in response to a prompt without children present. First, skillful modeling is responsive to the ideas and resources that students bring and learning goals for students. A standardized assessment enabled us to design a scenario in which we could specify the prior work that children had done and the learning goals for students. Second, modeling content can be done by the teacher, students, or co-constructed by teachers and students. These approaches differ in how much can be seen about a teacher's skills with modeling. Our standardized assessment created an instance in which we could see TCs doing all of the work rather than handing some of it off to students. Third, because the selection of content matters and we wanted a design that would enable us to see patterns in performances across TCs, a standardized assessment allowed us to standardize the content being modeled and the example and representations used. We purposefully selected content that is core to the upper elementary curriculum (comparing fractions) and focused on the use of a particular representation (the number line) to see how all TCs could model content in this situation. Specifically, we asked TCs to model comparing the fractions 5/4 and 5/6 using the number line. Figure 2 contains the "class background" and instructions. Aware that TCs might have different ideas about the practice of modeling, we included a definition of the work of modeling in the full instructions and student learning goals.

Class Background
Your fourth grade students have been working on identifying and ordering fractions. They are familiar with number lines and understand the importance of creating segments of equal length when partitioning the whole into segments of equal length. Students have worked with common fractions such as halves, thirds, fourths, sixths and eighths. They are comfortable with the relationship between halves, fourths, and eighths. Students in general know that if you divide a unit interval into n equal segments that n/n is one whole.
Instructions
You will model how to use a number line, or two number lines, to accurately place and compare two fractions. You can choose any number line representation(s) that you think best communicates these ideas to fourth grade students. • Begin with unmarked line(s) and model placing the necessary whole numbers. It is recommended that you place the whole numbers far enough apart that you can easily partition the intervals into fourths and sixths. • Show how you determine, with precision, where each of the fractions falls on the line. Specifically, remind students how to partition the unit interval(s) and use that information to locate the fractions on the line. • Explain how to determine which fraction is greater using the number line. You should model the process of using this technique as you would for a group of fourth graders. The goal is to make explicit the process for placing and comparing the fractions 5/4 and 5/6 on the number line.

Figure 2: Assessment Task

We used the decomposition to develop a checklist that would support us in noticing the skills with modeling content demonstrated by the TCs. We focused on five areas of work: *framing*, *doing the content area work*, *highlighting core ideas, making thinking visible by emphasizing thinking and key elements,* and *using language and representations carefully*. We excluded *planning* because we identified the content to be modeled and the example and representations for the TCs. Our checklist focuses on the teacher's use of specific techniques within our decomposition. In other words, techniques are what we look for to see if the practice happens. We could look directly for most of the techniques. However, in some cases, we had to further unpack ideas. For example, within *highlighting core ideas*, we had to identify the core ideas.

Present Study

We used the tool we had developed to investigate whether an assessment could elicit and reveal details in teachers' skills in modeling content. While the assessment was designed to be used with TCs enrolled in a teacher education program, we studied the practice of first-year teachers from a range of teacher education programs because this enabled us to study the use of the assessment in ways that were not constrained to one teacher preparation program.

Methods

The ten participants, all in their first year of teaching, spanned grades 1–5. All of the teachers were teaching in the midwestern USA. Contexts varied across urban, suburban, and rural schools. We recruited a diverse sample of teachers with respect to grade level, school district, and teacher preparation program. This sample was not intended to be representative of all first-year teachers. All teacher names used in subsequent sections are pseudonyms.

Data sources include a video record of each participant modeling in response to the provided prompt. We met with each teacher individually in their classroom after school hours or during a prep period. We gave teachers the assessment instructions and allowed 20 minutes of preparation time. Teachers were aware that we were studying their skills in modeling content. Teachers were told that they had up to 10 minutes to complete the modeling.

Data analysis proceeded in two phases. First, members of the research team independently watched each video and used the checklist to capture attributes of the performance. Second, the team discussed cases where there were differences in observations on the checklist, referencing and refining a codebook as needed to reach consensus.

Findings

Framing

Framing included both launching and closing the modeling. For launching, we found that eight of the 10 teachers made an opening statement that *named what was about to be modeled*. Two teachers *explained the purpose* of what was being modeled. Three teachers *connected the modeling to students' prior learning*, future learning, or background and/or experience. None of the teachers *closed the modeling* by summarizing or revisiting core ideas and results.

Doing Content Area Work

The content area work included four components. Six of the 10 teachers marked whole units (intervals) on the number line. To place the first fraction on the number line, six teachers marked the number line and labeled the fraction. To place the second fraction, eight teachers marked the number line and labeled the fraction. Seven teachers stated which fraction is greater.

Highlighting Core Ideas

With respect to *backgrounding* ideas, we found that only two of the 10 teachers avoided highlighting aspects of the content or task that are distracting or may lead to misconceptions.

This means that eight teachers highlighted aspects of the content or task that were confusing or might lead to misconceptions. For example, Mr. Houston highlighted that he was using 24 cm as the unit length because it was divisible by both 6 and 4.

Three of the teachers *foregrounded* mathematical ideas by using explicit verbal and non-verbal markers to draw students' attention to important aspects of the content. Ms. Wheeler used gestures to emphasize that the value of a fraction on a number line represents a distance from zero by motioning from the zero on the number line to the point representing the fractional value.

Teachers varied in *marking ideas*. We focused on five core mathematical ideas. Two of the 10 teachers elaborated the whole unit before partitioning, five teachers highlighted the meaning of the denominator (with respect to one or both of the fractions), three teachers explained the partitioning using the language of equal parts (or same-sized parts), nine teachers showed how to use the numerator and the parts that had been marked to locate the fractions (with respect to one or both fractions), and five teachers stated how to use the representation to determine the comparison. There was variation in how many ideas each teacher marked. Further, we examined the *sequencing of teachers' marking of the core ideas* and found that only three teachers compared the fractions on a number line in a logical manner.

Making Thinking Visible by Emphasizing Thinking and Key Elements

We examined whether teachers made use of three different sorts of techniques for making thinking visible by emphasizing thinking and key elements: annotating, marking metacognition, and thinking aloud. Two of the ten teachers engaged in *annotating*, adding ideas necessary to support students' understanding, including clearly articulating what you are doing and why you are doing it. For example, Ms. Wheeler emphasized why she was drawing two (stacked) number lines and the importance of lining up the number lines to later support the comparison. One teacher, again Ms. Wheeler, engaged in *thinking aloud* as a means to make thinking visible for students. After Ms. Wheeler marked both fractions on the number line, she engaged in a think aloud about how to compare the fractions. None of the teachers *marked metacognition* by using verbal, tone, or visual markers to indicate to students when thinking was being made visible.

Using Language and Representations Carefully

When looking at teachers' use of language, we found that nine of the 10 teachers consistently *used language economically*. All 10 teachers consistently *used language which was grade level appropriate*. However, only two of the teachers consistently *used language which was mathematically accurate and precise*. The mathematical language used by teachers that was not accurate and/or precise included referring to numbers as higher and/or lower, and saying fours and sixes rather than fourths and sixths. When we looked at teachers' use of representations, we found that only four teachers *drew number lines in accurate ways* (e.g., having arrows on both ends of the number line, marking 0, and making equal parts). Nine of the teachers *produced writing and representations that were legible and visible*. Only four teachers *organized the board in a way that supported understanding* how to use a number line to compare two fractions.

Discussion

Having access to detailed information about TCs' developing proficiencies with teaching practices is crucial for quality teacher education. Moreover, teacher educators must be able to use the data gathered from such assessments to focus efforts to support TCs' development. This study sought to examine the utility of using an assessment to assess teachers' skills with modeling content for formative purposes. The findings reveal details about skills with modeling content displayed by each of the teachers in the study.

We identify four key limitations of the design and use of the assessment and checklist. One limitation concerns the use of a checklist, yielding information primarily about the presence or absence of each technique rather than the use of a rubric, distinguishing the quality or quantity of teachers' enactments above the threshold. However, checklists allow for in-the-moment scoring, whereas a rubric requires that a teacher educator watch the entire performance and often rewatch it before making a judgment. Further, the checklist addressed our goal of capturing whether a TC could enact a particular technique. A second challenge is the potential interaction of mathematical knowledge for teaching (MKT) and modeling content. Even with the focus on content that matters for teaching mathematics, and supports built into the materials (e.g., student learning goals), there were instances in which MKT appeared to be a factor in the enactment. This is unsurprising as MKT is clearly intertwined throughout the work. In these cases, it was unclear whether we were accurately capturing a teacher's skill with modeling content or whether their use of MKT prevented them from demonstrating their modeling skill. This is an inherent problem in examining teaching practice. A third limitation is that we do not know whether the teachers in this study would perform differently if they modeled content in a different context. The context could be interpreted along multiple dimensions, including, but not limited to, the mathematics task used, the grade level of the students, or even engaging in the modeling work with actual children rather than through a simulation. This is an inherent problem; however, because we are not making claims about teachers' skills more broadly, we argue the assessment reveals important information about teachers' skills with modeling that can be used for formative purposes. A fourth limitation is that our study does not provide evidence of whether these teachers could decide what and when to model in their own teaching. We call out this point because, as we stated in the introduction, the goal of a teacher modeling in math class is to expand access to opportunities to engage in cognitively-demanding mathematical work. The aim is not to increase access by lowering the cognitive demand and spoon-feeding content to students. Instead, modeling is a means to consolidate ideas that students have explored. Thus, it is crucial that other sorts of information be gathered to determine (and, if necessary, intervene on) TCs' beliefs about what, when, and why to model.

Despite these limitations, our findings suggest that a standardized assessment of modeling content can reveal important information about TCs' skills. As we did not intend to make claims about this sample of teachers or a larger population of TCs, the small sample was appropriate for our goals. However, the variations in performance that are used to illustrate the capabilities of the assessment and tool cannot be interpreted as representing the skills of a larger population of TCs. This standardized assessment accomplished many of our design goals. Its ability to capture a range of skills could make the assessment and scoring tool useful in teacher education. Teacher educators and programs could use such assessments to track TCs' growth over time and to identify areas of strength and weakness with respect to the practice, which would allow for targeted support and program-level curriculum design.

We close by noting two questions that arose from this study. First, we might explore how this assessment could fit into a trajectory of assessments for assessing TCs' skills with modeling content. Second, in light of the questions that arose in this study about the role of content knowledge, we need to investigate further how we can reliably assess teaching practice in ways that account for the role of content knowledge for teaching.

MATHEMATICAL ARGUMENTATION: ALIGNMENT OF TASK GOALS WITH PRESERVICE TEACHERS' ENACTMENTS IN A SIMULATED CLASSROOM

Mathematical argumentation is a practice in which K-12 students should be engaging but supporting preservice teachers (PSTs) in learning to facilitate argumentation among students is challenging. The tasks used to support PSTs' learning in this area should be as carefully selected as the tasks that K-12 classroom teachers choose for their students. In this study, we examine a performance task that was designed for PSTs to practice facilitating an argumentation-focused mathematics discussion in a simulated classroom environment. Findings showed that most PSTs both articulated and enacted at least one feature of argumentation that was embedded in the performance task's student learning goal. However, evidence of PSTs' attention to critique in both the learning goal and the enacted discussion was limited. This suggests that careful consideration of alignment between a specific discursive practice and the design features of a performance task could yield better learning opportunities for PSTs when using online simulations.

Keywords: Classroom discourse; preservice teacher education; teacher educators; task design; mathematical argumentation

Introduction

Mathematical discussions have been a focus in mathematics teacher education for decades with a great deal of attention paid to supporting teacher learning (Boerst et al., 2011; Ghousseini, 2008; Stein, et al., 2008). Related research has been widely covered in mathematics education literature and has included examining cognitively-oriented math tasks that can support K-12 students' engagement in discussions (Stein & Lane, 1996), exploring how to effectively launch and implement those tasks to support students in having productive discussions (Jackson et al., 2012), and developing frameworks for orchestrating productive discussions (Stein et al., 2008). While justification and proof have always been critical components of mathematics, the advent of the Standards for Mathematical Practice (National Governors Association, 2010) made the term argumentation prominent in the mathematics education world. Since then, several scholars have published on how to support PSTs in learning how to facilitate mathematical argumentation with their students (Conner & Singletary, 2021; Rumsey & Langrall, 2016; Stylianou & Blanton, 2018). Learning how to engage students in productive mathematical argumentation requires targeted learning opportunities, especially for PSTs who have limited experience with this practice. While some research has examined the tasks used by teachers to engage K-12 students in mathematical argumentation, more limited research has been conducted to examine the performance tasks used by teacher educators to support PSTs as they learn how to engage in this aspect of the work of teaching mathematics. This study is directly designed to address this gap by examining how PSTs perceived and used one performance task that was designed to support them in learning how to facilitate argumentation-focused discussions.

Theoretical Framework

One promising approach for helping PSTs learn how to engage in novel teaching practices, such as facilitating argumentation-focused discussions, is the use of approximations of practice where PSTs can try out and refine an instructional skill in settings of reduced complexity (Grossman, Compton et al., 2009). Approximations of practice are one type of pedagogy of practice advocated for in a theory of practice-based teacher education. This theory hypothesizes that teacher learning is supported by opportunities for them to learn in and from their practice. This stance suggests that teachers, especially PSTs, need to have opportunities to practice discrete components of the work of teaching mathematics, ideally in settings of reduced complexity and with opportunities for feedback, reflection, and repeated practice.

Peer teaching has been one kind of approximation used in practice-based teacher education and involves a PST playing the role of teacher while their peers act as students (Kazemi et al., 2016). A newer technology that is being used to engage PSTs in approximations of practice to support their learning is simulated classrooms (Howell & Mikeska, 2021). Simulated classrooms readily allow for repeated practice, interactions with students without having to find classroom placements and reflection through video recorded practice sessions (Gibson et al., 2011). From a research perspective, these practice spaces support analyses of PST learning opportunities. Because they are designed spaces, researchers can also pay close attention to the functioning of the practice spaces themselves and optimize them over multiple iterations of study.

Within both simulated and real-life learning environments, the kinds of tasks teachers use in their classrooms to engage students can impact their learning opportunities (Hiebert et al., 1997; National Research Council, 2001; Stein et al., 2000). While much work has focused on cognitively-oriented task choice in the K-12 setting, an area less explored is performance-based task choice for PST learning. As educators we hypothesized that similar logic applies here, i.e., the nature of the tasks used to support PST learning likely relates to the quality of learning opportunities they experience. How those tasks are interpreted can also impact what students and/or teachers learn from and interact with them (Watson & Ohtani, 2015). Part of interpreting a task is deciding what the learning goal is for a given instructional sequence and then making choices about how to engage students around the task to reach the learning goal (Hiebert & Grouws, 2007; Sleep, 2012).

Study Purpose

In this study, we examined the features of a performance task designed to engage PSTs in an approximation of practice where they practiced one ambitious mathematical teaching practice: facilitating discussions that engage students in mathematical argumentation. We explored how the PSTs interpreted the task's goal and examined how they subsequently engaged in the simulated discussion. We set out to answer the following research questions: *RQ1. How do PSTs articulate the goal of a discussion task focused on argumentation?; RQ2. To what extent do PSTs engage student avatars in mathematical argumentation that targets the task's goal in the simulated classroom?*

We made design choices in the performance task development phase that led us to hypothesize that this task provided opportunities for PSTs to practice engaging the student avatars in three key features of mathematical argumentation: (a) explaining or justifying their work, (b) comparing different approaches to solving the problem, and (c) critiquing one another's work. Specifically, we anticipated the PSTs would do so, respectively, by providing the students with opportunities to discuss the choice and utility of rates used in the solution (pounds per day versus days per pound) and/or justify the approaches used; note similarities and differences in the approaches used; and consider the efficiency and utility of different solution approaches.

Methods

Study Context

This study was part of a larger research project examining teacher educators' use of and PSTs' learning within an online suite of simulated teaching experiences, one of which is an Avatar-Based Simulation (ABS) (Mikeska et al., 2022). This study reports on the task design phase when we used the task with PSTs to gauge its success and inform subsequent updates. In this study, we were piloting a mathematics performance task that we developed to see how PSTs interpreted the task materials and how they engaged in facilitating the argumentation-focused discussion in the simulated classroom. This task was developed for the middle school level but was designed along the same structure as used in our prior work for the elementary level (Howell & Mikeska, 2021).

Mathematical Task

The content focus of the mathematical task, *Hungry Hungry Huskies,* is proportional reasoning, and the specific problem the student avatars (hereafter referred to as students) engage with is a story problem in which two dogs consume dog food at different rates. The students are asked to use the rates of consumption to predict how long it would take to consume a given quantity. We designed the story line of the task as if the five middle school students worked on the problem in two groups, with one group using a pictorial representation and the second using a table. Similarities and differences across the two solution approaches were deliberately constructed to provide opportunities to compare different ways of solving the same math task, with the intention that these will also open avenues to support argumentation. For example, both groups reached a correct answer, a design feature intended to help the PST focus on methods over answers. While both approaches are successful in this case, neither is optimal in general. This aspect of the task design was intentional so instead of the PST favoring one approach over the other, they would be encouraged to identify affordances in each. Each approach also relied on a form of visual inspection to draw conclusions, leaving the possibility that the approaches might not extend effortlessly with less friendly numbers (i.e., if the amount of dog food they were looking for did not appear in the table). This was an intentional task feature to provide PSTs a space to press on the limitations of the visual approach. One group uses unit rates and the other does not, providing a point of contrast and a place the PST might press to find out why unit rates were used and what they afford. In addition, one group represents the ratio as pounds per day where the other represents it as days per pound, creating an opportunity for the PST to think about the significance of 'per unit' while working on proportional reasoning tasks.

Study Design

Seven PSTs enrolled in secondary mathematics teacher education programs across the U.S. participated in this study. For data collection, each PST completed: (a) an online background questionnaire about their personal characteristics and professional background; (b) a 20-minute discussion in the simulated classroom using the *Hungry Hungry Huskies* mathematics task; (c) an online task survey to provide information about their discussion preparation and their perceptions on the task components and their discussion performance; and (d) a semi-structured interview where they answered questions about the discussion goal, the task materials and their discussion performance. Each discussion was video recorded and then later transcribed for analysis purposes.

Before the PSTs engaged in their ABS session, they were given a task packet to prepare to facilitate a 20-minute argumentation-focused discussion among five students around the students' work on the mathematics problem. The task packet included the students' work, the learning goal, the mathematics problem that they solved, tips about engaging the students in argumentation, and other information about what to expect in the simulated classroom. PSTs facilitated this discussion with the students from their computers.

Analysis

Analysis included multiple approaches. First, we conducted qualitative content analysis to identify patterns in the PSTs' open-ended responses from the interview and survey about the goal of the discussion. We looked for alignment between PSTs' articulations of the goal of the discussion and these three features of an argumentation-focused discussion: students explaining/justifying their work; students comparing their approaches; and students evaluating and/or critiquing each other's work. Using hypotheses described above that emerged from the task design phase of development, we looked for PST alignment with these features in their responses to questions about the goal of the task. Second, we reviewed video records from each ABS session to determine whether there was evidence that each PST provided the students with opportunities to engage in the specific features of mathematical argumentation embedded in the task design as articulated above.

Findings

In terms of PSTs' articulations of the task's goal (RQ 1), one of the PSTs reported all three of the features of argumentation-focused discussions that we were looking for (justification, comparison, critiquing). Three of the PSTs articulated two of the three (justification and comparison). Two PSTs each reported on one feature of the discussion: one each for justification and critique. There was one PST who did not articulate any of the features that we expected when asked what the goal of the task was. Instead, she stated that she "wanted students to explore each other's methods and think about their own method." While relevant, her response was not detailed enough to determine whether she was addressing any of the key features that we anticipated. Table 1 summarizes findings across the 7 PSTs.

Table 1
PSTs' Articulations of Features of Argumentation in the Task Goal

PST (pseudonyms)	Justification/ Explanation	Comparing Approaches	Critiquing Each Other's Work
Taylor	X	X	X
Addy			X
Mo	X	X	
Saylor	X		
Molly			
Lynn	X	X	
Caleb	X	X	

One of the PSTs, Taylor, included all three features, stating:

> "(1) All students will present and explain their ideas; (2) All students will listen to the justifications of others and respond appropriately to further understanding; (3) All students will interact with each other to have a meaningful math discussion; (4) Students will analyze others' work in order to compare and contrast ways to solve the problem; (5) Students will be engaged and feel involved throughout the entire discussion."

In Taylor's response, she noted that there would be justifications and that students would compare and contrast the ways of solving the problem. Taylor was alluding to critique in stating that the students would "respond appropriately to further understanding" and in her comment about contrasting the approaches to the problem. Another PST, Lynn, said

> "The overall goal of the discussion I wanted them to be able to compare and contrast the strategies, that was a big one, …to justify their work and say how their procedure connected to their answer."

Here, Lynn was highlighting two of the features: justification and comparing approaches to the problem. She went a step further to state that the students should connect their work to their answer. Critique, however, was not evident in her response.

The fact that a majority of PSTs (n = 6) provided evidence of understanding at least one component of the goal that we considered to be a key feature underscores that most PSTs in our study were pedagogically aware of one or more of the key features of mathematical argumentation they should aim for when facilitating their discussion. However, the lack of PSTs' attention to critique in the learning goal suggests it did not stand out as part of the goal.

Our analyses addressing the extent to which the PSTs engaged the students in argumentation (RQ 2) suggest that most PSTs did support the students to justify their work in the discussion (n=7) and to compare their approaches (n=6). This evidence points to alignment between how PSTs articulated the goal and engaged the students in the discussion. All PSTs supported the students to justify their work by typically asking the students to share their solutions or to talk about how they came to their answer. Caleb did so by stating, "You were asked to come up with an answer that the group agreed on, along with evidence to support your answer. So what group would like to [share] first?" Here, Caleb was reminding the students that they were to justify their solution with some sort of evidence. A typical way that PSTs engaged the students in comparison was by asking them to identify similarities and differences in their solutions. In her discussion, Taylor said,

> "So now we're going to do a little bit more of an advanced skill. Now that you've both solved the problem, I'm happy to tell you that both groups got the answer right. So we're just going to compare and contrast. So that means we're going to point out similarities and differences between the two ways to solve the problem."

Taylor let the students know, now that they shared their work, it was time to compare approaches. One of the students, Ethan, indicated that a difference was that his group used a drawing and the other group used a table. Another student, Dev, said that his group used unit rates in the solution but the other group did not. The groups were considering each other's work and comparing it to their own.

While the PSTs engaged the students in justification/explanation and comparing approaches quite a bit, critique was less evident. Only 3 of the 7 PSTs engaged the students in critique. When evident, critique was usually around the limited utility of a given approach. For example, when using a table to solve rate problems, very large numbers could become difficult to represent in a table. Molly encouraged her students to think in this direction by stating,

> "Do you guys want to talk about maybe what do you like best about this method and then maybe where Savannah identified maybe an area of concern, like if this would work for other problems...identify something you liked about this method and then something you didn't like about this method."

Molly encouraged a critical lens by asking the students to identify a part of the solution that they disliked, but also clued them in on thinking about other problems. Addy, who both described critique as part of the learning goal and enacted her discussion with evidence of critique, encouraged a critical lens in a different way. To set the students up to critique, she had them complete a "See, Think and Wonder" chart while observing each group's written work. More explicitly, she also told the students "We are mathematicians and we're going to act like great mathematicians, evaluating and critiquing each other." A little later on, one of the students, Savannah, asked a group if they thought their picture would work to solve other problems.

Discussion

To date we have analyzed how PSTs articulated the goal of the discussion they facilitated and found that most PSTs (n=6) articulated and enacted at least one of the key features of argumentation that we intended in the task design phase. This evidence suggests that PSTs were interpreting the performance task's associated learning goal as intended. Just as the PSTs articulated more justification and comparison in the task's goal, they also engaged in more of that dialogue in their simulated discussions. While this finding suggests that the task's learning goal needs to better support PSTs to engage their students in critique, it also demonstrates that the PSTs' enactments, at least in part, aligned with their understanding of the goal in the simulated environment. An open question, then, is whether including ideas around critique in the learning goal will support PSTs to engage the students in more of it.

In this study, we were able to examine the alignment between the performance task's goal and the PSTs' enacted practices in the simulated discussion, but we did not consider the quality of the argumentation that occurred. That is, we identified where it occurred, but not how or what the mathematical content of the argumentation was. Future work will need to analyze the quality and content of argumentation in the simulated discussions.

The literature supports the conclusion that facilitation of argumentation is difficult, and novice teachers often struggle with this practice, an issue the larger study seeks to address. The affordance of this analysis is in allowing us to draw conclusions about where the designed task might be improved in ways that increase PST opportunity to learn to engage students in critique, justification and comparison. With the understanding that tasks influence opportunities to learn, these findings prompted our team to re-design the task and its affiliated learning goal around which PSTs facilitated the simulated discussion to better support them with learning opportunities to practice engaging the students in the full set of argumentation features when facilitating the mathematics discussion. Future work will examine how PSTs make use of the revised task in the simulated discussions, including addressing the mathematical point of the argumentation that is evident (Sleep, 2012).

The purpose of this study is to investigate how preservice elementary teachers view mathematics lesson coherence. It is often reported that how lessons are less coherent in U.S. mathematics classrooms compared to high-achieving countries. Stigler and Hiebert (2009) urged the importance of teacher' conception and their learning to achieve coherent lessons. In this study we examined 18 preservice teachers' views of lesson coherence. We developed theoretical framework by extensively reviewing previous studies. By crosschecking preservice teachers' responses across our survey questions using the framework, we illustrate what knowledge of lesson coherence the preservice teachers have and have not, and thus suggest how teacher educators help preservice teachers to develop and analyze lessons to be more coherent.

Keywords: Lesson coherence, Preservice teachers, Teacher beliefs

Lesson coherence is important predictors that contribute to teachers' high quality of mathematic teaching and classroom practice (Hiebert et al., 2003; Stigler & Perry, 1990; Stigler & Stevenson, 2005). When lesson coherence is achieved, students have more chances to conceptually understand mathematics better. Lesson coherence is in close relation not only to teachers' effective mathematics instruction but also to students' learning. Accordingly, lesson coherence has gained significant attention to address how U.S. teachers did in their everyday classroom (Jacobs & Morita, 2002; Stigler & Perry, 1990; Stigler & Stevenson, 2005; Wang & Murphy, 2004). It has been reported that lesson coherence can be established when topics, activities, and teachers' discourse moves are structurally and contextually connected each other (Sekiguchi, 2006; Stigler & Stevenson, 2005). The purpose of this study is to investigate how preservice elementary teachers (PSTs) view mathematics lesson coherence. Despite the important relationship between teacher view and instructional practices, there is relatively a few research studies on teacher view of mathematical lesson coherence (e.g., Cai, Ding, Wang, 2014; Sekiguchi, 2006; Stigler & Perry, 1990; Stigler & Stevenson, 2005; Wang & Murphy, 2004). Considerable amounts of research have dealt with teacher lesson coherence, but far less research has dealt with in-service and preservice teachers' view of this topic in the US context. The research questions that guided the study are: How do preservice elementary teachers view mathematics lesson coherence?

Theoretical framework

Figure 1 shows our conceptualization of lesson coherence drawn from prior research studies (e.g., Hiebert et al., 2003a; 2003b; Newmann et al., 2001; Wang, Cai, & Wang, 2015; Wang & Murphy, 2004). Coherence often relates to connectedness and interrelations to mathematics content and instructional activities (Wang, Cai, & Wang, 2015; Wang & Murphy, 2004). In particular, lesson coherence refers to 1) connectedness of lesson structures and events within and across lessons (Cai et al., 2014), 2) goal-oriented and content-focused classroom activities to achieve learning outcomes (Liang, 2013), 3) “how well lessons follow a logical and structured sequence of events and how well lessons focus on one or related topics and proceed from simple to complex situations in the process of concept development” (Chen & Li, 2009, p.713), 4) relations among themes or topics in the lesson (Sekiguchi, 2006), and 5) “coherence was defined by the group as the (implicit and explicit) interrelation of all mathematical components of the lesson… a lesson with a central theme that progressed saliently through the whole lesson” (Hiebert et al., 2003a, p. 196). Hiebert et al. (2005) argue that it is not enough to simply include all components but individual components work together to achieve lesson coherence.

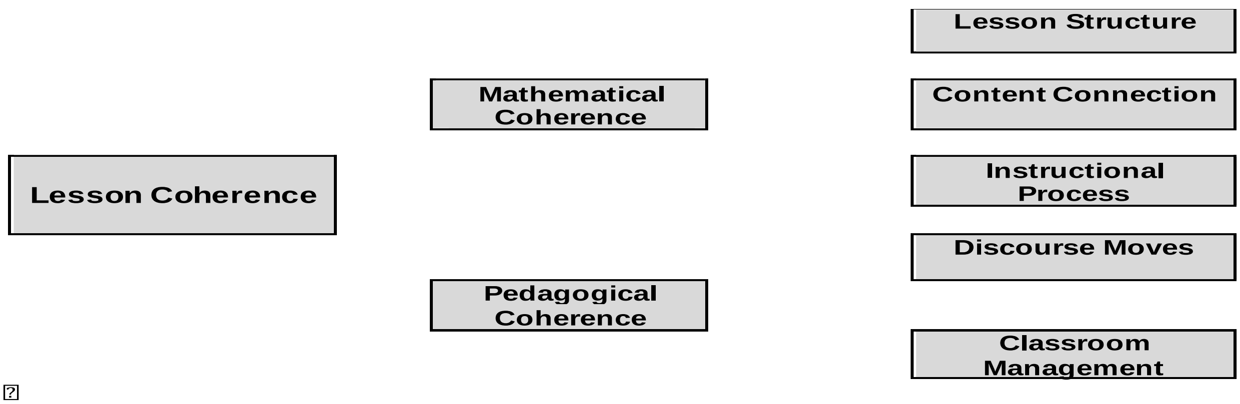

Figure 1. Theoretical framework for our study

Methods

Participants A total of 18 PSTs participated in the study from two elementary mathematics methods classes at a large Northeastern university of teacher preparation in the United States that offers a five-year teacher preparation program. As part of the undergraduate major in elementary education, students complete a core sequence of educational psychology courses and two mathematics content courses before taking a three credit-hour methods course in their senior year. Participants were recruited from their second methods course during their internship year. Their ages ranged from 22 to 35 years, with 54 females and 4 males.

Instruments Since the purpose of this study is to explore PSTs’ views and perceptions, we employed open-ended survey questions. Open-ended survey method allows respondents to include more information, attitudes, and understanding of a particular subject by responding to the questions with their own wording directly (Reja, Manfreda, Hlebec, & Vehovor, 2003). At the beginning of the semester, the PSTs were asked to answer three questions that were adapted from Cai et al. (2014). The questions include: 1) When people say a lesson is very coherent, what does the word “coherent” mean to you? What are the characteristics of a coherent lesson?; 2) If you mentor a new teacher, how would you guide the new teacher to achieve coherence in her or his teaching?; 3) Some people say that a coherent lesson can foster students’ learning. Do you agree with this statement? Why?

Data analysis We used an inductive content analysis approach (Grbich, 2007) for the written response. We initially organized raw data into a spreadsheet, read all of the responses, and created codes based on the raw data. More specifically, data analysis involved these four processes: (a) an initial reading of each PST’s response, (b) identifying the subcategories under each analytical aspect according to the framework shown in Table 1, (c) coding the categories and subcategories, and (d) interpreting the data quantitatively and qualitatively (Creswell, 1988).

In order to answer the research question examining PSTs' view of lesson cohere, PSTs' responses were categorized based on the themes that emerged as researchers read multiple cases.

Summary of Results

Figure 2 presents our finalized categories that describe PSTs' conception of lesson cohere. When PSTs were asked to describe their conception on lesson coherence, two additional categories emerged in addition to two categories drawn from previous studies: student learning opportunities and what teachers need to know and do. Of the 18 PSTs, 17 defined mathematics lesson coherence with respect to mathematical coherence, and 3 PSTs viewed it from pedagogical coherence. Ten PSTs additionally stated student learning opportunities resulted from coherent lessons, and five PSTs additionally mentioned what teachers need to know and do in order to create a coherent lesson.

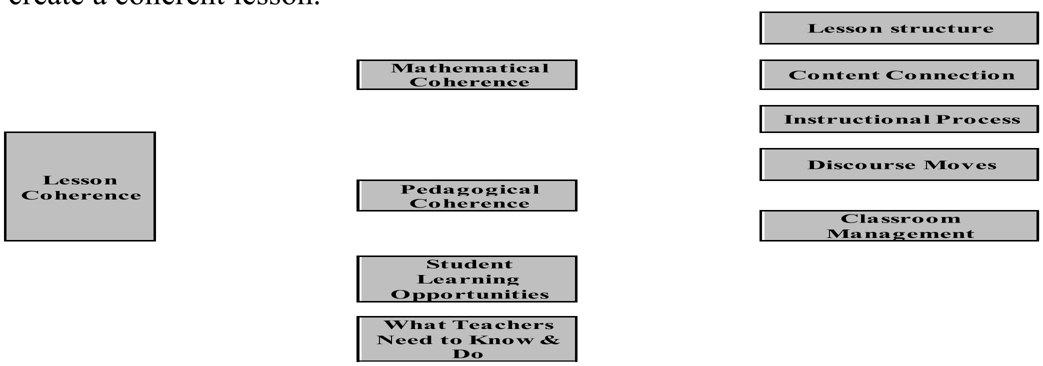

Figure 2. A framework that describes PSTs' conception of lesson coherence.

Mathematical coherence

When the PSTs defined lesson coherence from mathematical coherence, they displayed similar distributions among three subcategories: the lesson structure (10 PSTS), content connection (9 PSTs), and instructional process (11 PSTs) (**Figure 3**). Nine PSTs discussed across two characteristics, either lesson structure and content connection, lesson structure and instructional process, or content connection and instructional process. Our PSTs showed clear attention to mathematical coherence with reference to lesson coherence. However, the responses of PSTs were mostly broad and did not include narrowed topics and a several activities that need to be arranged for understanding of the topics the previous studies emphasized (e.g., Sekiguchi, 2006; Stigler & Perry, 1990). The PSTs displayed a lack of attention to pedagogical coherence. As pedagogical coherence, particularly teachers' intentional discourse moves help students to obtain mathematical knowledge (e.g., Chen & Li, 2009), PSTs need support to develop content rich discourse throughout their lesson.

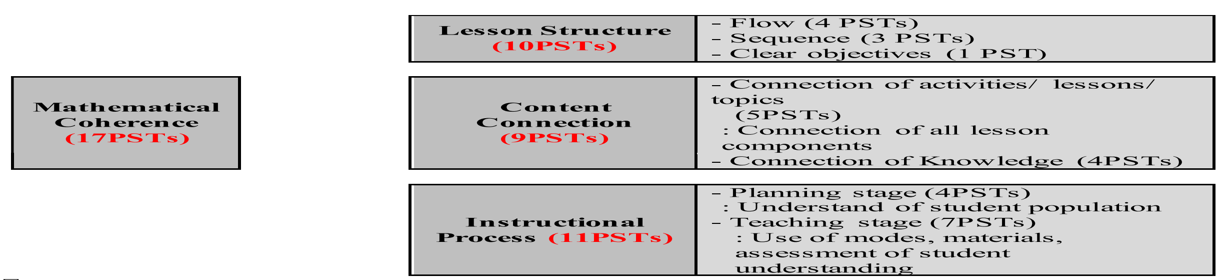

Figure 3. Distribution of PSTs' view on mathematical lesson coherence

Specifically, ten PSTs described lesson structure as an important characteristic of a coherent lesson. Among them, four PSTs emphasized flow, stating that “A coherent lesson is broken up into parts, [so] it flows nicely” (PST #4). Three PSTs mentioned the sequence of the lessons, stating that “A coherent lesson should be structured as beginning, middle, and end”. Among them, PST #17 stated, “A coherent lesson includes a general introduction of the topic, some problems that include that topic and methods in going about solving that problem.” Only one PST (PST #4), emphasized clear and focused lesson objectives in the lesson structure.

Interestingly, none of the PSTs mentioned mathematic problem complexity to create a coherent lesson, such as organizing mathematical problems to proceed from simple to complex. In general, our PSTs tended to focus on the lesson structure, using a broad concept of ‘flow’ and ‘sequence’ rather than how activities are systematically and logically organized in a lesson.

Discussion and Conclusions

This study contributes to the current literature on teacher view on lesson coherence and the knowledge base of teacher education. This study has implication for teacher educators working to design mathematics education courses for PSTs, as well as for researchers interested in furthering understanding of teachers’ knowledge and beliefs on lesson coherence. Very few PSTs had such complex understanding regarding lesson coherence. The findings of this study suggest that teacher educators need to find a better way to help PSTs perceive lesson coherence differently. Future studies need to be done with different research tools and in multiple contexts, possibly using interviews or observations to provide more detailed explanations for preservice teachers’ responses.

AMBITIOUS MATHEMATICS INSTRUCTION FROM TEACHER PREPARATION TO ELEMENTARY CLASSROOMS: AN EXAMINATION ACROSS CASE STUDIES

Casedy Ann Thomas

Faith.Peddie@gmail.com

This study cross analyzes the results of two multiple case studies that focus on ambitious mathematics instruction within two institutions. The first study examines how three elementary mathematics methods instructors in the same teacher education program (TEP) provide their teacher candidates with learning opportunities. The second study examines how two elementary teachers who graduated from that TEP enact mathematics instruction. Findings suggest that teacher beliefs influence both the content that students have the opportunities to learn (OTL) and the nature of the learning opportunities. The results describe how instructors and teachers perceive the purpose of elementary mathematics instruction and how their beliefs align with the enactment of ambitious mathematics instruction with learners.

Keywords: Elementary School Education, Preservice Teacher Education, Teacher Beliefs, and Instructional Activities and Practices

Purpose

Mathematics education research has yet to reach a consensus on the construct of ambitious mathematics instruction (Kazemi et al., 2009; Newmann & Associates, 1996; Windschitl et al., 2018). This has implications for TEPs that aim to support teachers in enacting such instruction and for novice teachers (i.e., those with zero to three years of experience) who attempt to draw upon their pre-service teacher experiences as practicing teachers. In this study, the researchers conceptualize ambitious instruction as comprised of a set of teaching practices that foster students' deep, conceptual understanding of standards-based mathematics concepts (Newmann & Associates, 1996). The National Research Council (NRC; 2001) defines conceptual understanding as "an integrated and functional grasp of mathematical ideas" (p. 18).

In an effort to further operationalize ambitious instruction, the researchers examine the complexity of enacting such instruction within three methods courses at one TEP and in two novice teachers' classrooms who graduated from that program. By focusing on the enactment of ambitious instruction at various stages, this study acknowledges the complexities that novices face in enacting such instruction. By doing so, we argue that a shared vision of ambitious mathematics instruction within a TEP could have positive implications for the ways that novices transfer these opportunities and experiences into their own teaching practices.

The purpose of the study is to examine what perceptions of ambitious instruction from a TEP carry over into novice teachers' beliefs while remaining conscious of the many factors that influence their beliefs and instruction. Various factors impact novice teachers' instruction, yet in order for us to develop a shared vision of what ambitious instruction means and looks like in the classroom, we seek to examine the trajectory of these beliefs from a TEP into elementary schools. To do so, this study cross-analyzes the results of two multiple case studies that were nested within a larger longitudinal study; one study was bounded within a University's TEP and focused on three instructors who taught elementary mathematics methods courses (Thomas, 2021); the other study was bounded within a school and focused on two graduates of the University's TEP.

Theoretical & Conceptual Frameworks

Theoretical Framework: Activity Theory

Both studies drew upon activity theory in order to examine teachers' interactions with the socio-material context in which they develop mathematics teaching practices and create learning opportunities for their students. Activity theory emerged from the Vygotskian theory of cognition, examining cognitive activity from a socio-cultural lens (Peddie, 2019; Chahine, 2013). As Pai, Adler, and Shadiow (2006) explain, "There is no escaping the fact that education is a sociocultural process," or an artifact-mediated activity (p. 6). Therefore, activity theory is useful for understanding how teachers and educators may be influenced, and how their teaching practices provide opportunities to learn for students. Within the framework for activity theory, a subject is influenced by mediating artifacts both conceptual and material to reach, develop, or create some object. In the first study, elementary mathematics methods instructors (subjects) engaged with artifacts to create learning opportunities for teacher candidates (objects). In the second study, novice teachers (subjects) were influenced by numerous factors (artifacts) as they planned for and enacted instruction with elementary students (objects). Although tools were conceptualized differently in each study, both researchers examined tools as mediated artifacts as they relate to pedagogies of practice (Grossman et al., 2000).

Activity theory was instrumental in both studies and informs the comparative analysis across studies as it relates to OTL and beliefs about and the enactment of ambitious elementary mathematics instruction. Activity theory provides a lens for examining how and why methods instructors provide particular OTL for teacher candidates and how such OTL seem to translate into novice teachers' beliefs and instructional activities with elementary students within an artifact-mediated activity system.

Conceptual Frameworks

Opportunity to learn. The first study (Thomas, 2021) draws upon Schmidt and colleagues' (2011) framework for OTL, defining it as "the content to which future teachers are exposed as part of their teacher preparation programs" (p. 140). The second study defines OTL as the "the set of experiences that schools organize to help students acquire the knowledge, skills, and abilities specified in those official standards (Schmidt & McKnight, 2012, p.13). Although there is variability within these definitions of OTL, as it relates to the contexts and learners, both studies focus on OTL ambitious elementary mathematics in pedagogy and practice.

Influence of beliefs on practice. We take the position that *beliefs* are more cognitively ingrained and harder to change than *perceptions* (Philipp, 2007). Likewise, teachers may believe that it is important for students to grapple with cognitively demanding tasks, but if the psychological strength of this belief is not strong, then they may not follow through to create such opportunities; further, just because a belief has strength in one context does not mean that it will have as much strength in another (Cooney et al., 1998; Thomas, 2021). When examining how teacher educators' and novice teachers' beliefs impact mathematics instruction, both studies take into consideration the teachers' beliefs and their actions in the classroom; reporting upon beliefs that were considered psychologically strong, supported with evidence, and demonstrated consistently within the actions of the participants. Hence, we take the position that, "Teachers' beliefs influence the decisions that they make about the manner in which they teach mathematics" (NCTM, 2014, p. 10).

Research Questions

1) How do methods instructors and novice teachers perceive the purpose of elementary mathematics instruction?
2) How do the methods instructors' and novice teachers' beliefs of teaching mathematics align with the enactment of ambitious mathematics instruction?

Methods

Sample

Two researchers implemented multiple case studies to examine teachers’ perceptions of elementary mathematics instruction. Both studies were nested within the same longitudinal mixed-methods study that focused on the ways that five TEPs support novices' development of ambitious instruction. The first researcher's study took place at one TEP in a southeastern state, called Robin University (pseudonym). During that time, there were three total elementary mathematics methods instructors at Robin University and each participated in the study. The second researcher's study took place the following school year within two elementary classrooms in the same southeastern state at McCaskey Elementary School (MES). The teachers taught at the same school and both attended Robin University.

Data Collection

In the first study, the researcher observed each instructor two to three times for a duration of two and a half hours each, for a total of 20 hours of observation. The researcher took fieldnotes alongside each observation. Additionally, each instructor participated in two rounds of interviews that lasted between 45 and 60 minutes each. The first interview was structured to better understand the methods instructors’ perceptions of their instructional strategies (prior to observations) and the second interview was semi-structured and took place after observations to further examine emerging findings. In the second study, the researcher observed and recorded three one-hour mathematics lessons for each teacher for a total of nine hours of observation. In addition, the teachers participated in one structured interview that focused on topics related to classroom expectations, curricular resources, and beliefs of teaching mathematics. The study also featured three semi-structured interviews with each teacher that took place after each lesson and focused on the ways that teachers planned and enacted their mathematics instruction. The interviews lasted approximately 30 minutes each. Finally, each teacher provided supporting artifacts such as lesson plans and lesson handouts.

Analytical Strategies

Each researcher drew upon an instrument called the Mathematics Scan (M-Scan; Berry et al., 2017) to analyze their observation data. M-Scan represents a schema of instruction that can be used to measure teachers’ implementation of standards-based teaching practices. The instrument is useful in research that focuses on ambitious mathematics instruction because it captures differences between teaching for conceptual understanding versus teaching for acquisition of procedural knowledge (Berry et al., 2017). M-Scan has nine dimensions that measure teaching practices in four domains: task selection and enactment, the use of representations, the use of mathematical discourse, and lesson coherence.

The researchers captured fieldnotes from each lesson observation and transcribed their own interviews. Analytic logs were developed alongside each set of field notes and transcriptions. The researchers independently analyzed each of their data sets. Additionally, each used inductive and deductive coding to develop emerging themes that incorporated Erickson's (1986) model of analytic induction and constant comparison (Miles, Huberman, & Saldaña, 2014) respectively. The themes were triangulated across each of the data sources to support assertions in each research study. Both researchers compared confirming evidence and disconfirming evidence for each of their emerging assertions and continued to adjust the assertions until all evidence was accounted for.

For the purposes of this study, the researchers cross-analyzed the archival interview transcriptions from both studies, examining the similarities and differences in perceptions of ambitious instruction, and they simultaneously engaged in deductive coding. Based upon emerging themes from this data analysis, the researchers triangulated video recordings and field notes from observed lessons and analytic memos to further explore OTL provided to students and how these compared to each individual's stated perceptions and beliefs.

Results

Across studies, assertions suggested that both instructors' and teachers' perceptions of teaching elementary mathematics seemed to be associated with their enactment of ambitious mathematics instruction. The results also feature examples of OTL that instructors provided to students at Robin University in addition to experiences that the novice teachers seemed to draw upon from their pre-service experience to enact such instruction. For example, a teacher at MES described the importance of encouraging students to use various strategies when solving mathematics tasks. In turn, it was common for the teacher to provide students the opportunity to represent content using words, pictures, and symbols. This teacher described how the experiences at Robin University allowed her to practice doing mathematics as a child would, which helped her conceptualize how the use of various strategies could strengthen students' understanding of mathematical concepts. The findings from the first study confirm that the methods instructors at Robin were providing OTL that emphasized the importance of providing multiple mathematical representations inclusive of mathematical tools and engaging in problem solving that incorporated multiple strategies.

Furthermore, the results describe counter-examples that focus on various mediating artifacts that seemed to be associated with novices' enactment of ambitious mathematics instruction. This was witnessed in the first study when novices felt pressured within the context of their field placements to conform to cooperating teacher norms. Later, teachers complied with the school-wide expectations at MES in order to develop their mathematics lessons. The teachers also had relationships with their grade-level colleagues that seemed to influence the ways that they selected and enacted mathematics tasks. Grade-level colleagues with more teaching experience provided materials and lesson implementation ideas to teachers that they then enacted in their own classrooms. There was also a relationship between Robin University and MES such that the teachers were provided professional development opportunities by the University.

Discussion & Significance

Math education is making strides in studying the development of ambitious mathematics instruction at the pre-service level (Cavanna et al., 2017; Kazemi et al., 2009). However, more work needs to be done focusing on the capabilities of novice teachers in enacting ambitious mathematics instruction (Jong, 2016). This study is significant in that it focuses on OTL across methods instructors and classrooms. We also focus on the various perceptions of instructors and novices as there is still more to be understood about the ways that beliefs seem to influence the enactment of ambitious mathematics instruction. This study highlights significant ideas that seemed to have transferred from one university to novice teachers' classroom settings while using activity theory as a lens to examine the complexities of defining ambitious mathematics instruction. Future research could benefit from examining the impact of a shared vision at different levels as well as the continued study of various mediating artifacts that seem to be associated with the enactment of ambitious mathematics instruction.

This study is focused on different lenses that may be used to make quality determinations with respect to prospective elementary teachers' instructional decisions. Using a professional noticing framework, we analyze individuals' deciding responses within a video-anchored case to explore the varying ways that quality of such decisions might be determined. Specifically, we examine how quality may be ascribed to decisions via holistic and analytic lenses. Our findings suggest key differences and tensions in quality determinations when using analytic and holistic lenses to make quality determinations with respect to instructional decisions.

Keywords: Teacher Noticing; Instructional Activities and Practices; Preservice Teacher Education

Purpose

The purpose of this preliminary study is to explore the variations of quality with respect to instructional decisions via a professional noticing framework. Specifically, we focus on *how different rating lenses may be used to evaluate the quality of prospective elementary teachers' (PSETs') decision making skills within their professional noticing of children's mathematical thinking.* This study was conducted as part of a larger funded venture focused on development of PSETs' professional noticing capabilities with respect to dimensions of equity.

Professional Noticing and Deciding

Focus on teacher noticing and variants thereof has been sustained for some time (Schack, Fisher, & Wilhelm, 2017); Sherin, Jacobs & Philipp, 2011a) and, as such, is increasingly shaping practitioner guidance in a variety of ways including noticing along mathematical progressions (Thomas, et al., 2014) and noticing via equity lenses (Jackson, Taylor, & Buchheister, 2018). While some portrayals of noticing focus primarily on attending and interpreting (i.e., sense-making) (Sherin, Jacobs & Philipp, 2011b), Jacobs, Lamb & Philipp (2010), describe a third, interrelated component process, *deciding*, which connotes intended activity resulting from the interpretation of a mathematical moment stemming from one's attending to certain features of that moment. As such, the component process of deciding represents the bridge between an individual's cognitive processing of a mathematical moment (attending, interpreting) and intended action in response to that moment.

We focus this investigation on the deciding component and the different ways in which the quality of such decisions may be examined. Historically, decision quality has been considered through a lens of routine. Different types of decisions were categorized with little attention to the perceptive and interpretive activity that guided such actions (Leinhardt, Weidman, & Hammond, 1987). However, professional noticing frameworks recast decisions as resultant of perception and interpretation allowing for more expansive applications of lenses with respect to quality. For example, quality determinations might be a function of alignment with a particular mathematical learning progression (Schack, et al., 2013). From this perspective, for example, a task aimed at helping a student move from constructing perceptual unit items to figural unit items was determined as higher in quality in that it matches well with typical mathematical development along a learning progression. This lens for evaluating decisions is predicated on detecting subtle details of mathematical activity, interpreting them through a developmental lens, and responding to create productive space for mathematical construction. Another lens to determine decision quality might foreground the extent to which a particular decision addresses multiple and varied critical incidences or perspectives within a mathematical moment (Fisher, Thomas, Jong, Schack, & Dueber, 2018). For example, in a whole class discussion, a decision that connects with and furthers the mathematical reasoning of multiple, varied student perspectives might be deemed more productive than a decision that merely focuses on a single individual. Stockero et al. (2017) describe the distinction between these two lenses as *noticing within* and *noticing among.* Lastly, researchers may evaluate decisions more holistically via considerations of context to determine the extent to which a proposed decision is centered on student reasoning and has the potential to bend that moment toward conceptual growth and/or productive activity. From this perspective scoring processes such as rubrics or flowcharts (Fisher et al, 2018; Schack et al., 2013) may recede or be used with increased flexibility to enhance interpretive space for raters. Further, more holistic, contextualized and interpretive lenses render distinctions between noticing within and noticing among less salient as they relate to quality. Rather, quality determinations are guided by some central, desirable element or outcome (e.g., decisions that centralize student thinking or activity) as it may apply to a given context. For this study, we compare two approaches to evaluate the quality of decision-making within a professional noticing framework. One rating approach was heavily structured via the use of flow-process charts and privileged decisions that reflected the detection of nuanced details as well as address of multiple students. We refer to this lens as analytic scoring. The other rating approach focused adopted a more holistic approach to evaluating decisions and quality determinations were made according to the presence or absence of broadly desirable elements. We refer to this lens as holistic scoring. *Our aim was to compare these two lenses (analytic scoring, holistic scoring) in the context of evaluating PSET decisions to better understand how differing perspectives and processes influence quality determinations.*

Methods

Context and Participants

Eight modules to integrate equity and professional noticing of children's mathematical thinking were developed by the authors. To facilitate embedding in a class session, each module had a duration of approximately 20 minutes focused on mathematical topics typical of a methods class as well as a particular dimension of equity (Gutiérrez, 2009**).** Some participating faculty members elected to engage in full implementation (minimum of seven modules). Other faculty elected to engage in partial implementation (use of four, five, or six modules). One module, which introduced the concepts of equity and professional noticing, was required as the initial module for all implementation sites, full or partial. This paper reports on one semester of data collected at three institutions, one research and two regionals, in two southeastern states. Two of the settings, one rural, one urban/suburban, completed full implementation and one rural completed a partial implementation.

Data Collection

The Video Assessment on Noticing and Equity (VANE) consisted of prompts for professional noticing and equitable practices observed in an approximately two-minute clip of a 2nd grade class exploring the concept of equality. A problem, 10 + 10 = __ + 5 was presented to the class. The students were encouraged to share their solution and strategy. The clip captures three students sharing, two of whom respond with an incorrect answer but some reasoning and the third with the correct answer with different reasoning. After watching this video, PSETs were tasked with responding to items corresponding to professional noticing component processes (attending, interpreting, deciding). Germane to this study are the PSET responses to the deciding prompt – Imagine that you are the classroom teacher. What might you do next? Provide a rationale for your decision. For this preliminary investigation of varying lenses, we randomly selected 23 deciding matched pre/post responses from full implementation sites and 13 matched pre/post responses from partial implementation sites. We elected to engage in this comparative investigation with relatively small sample sizes as an exploratory exercise that will inform rating processes for the larger study focused on PSETs' development of equitable noticing practices.

Analytic Processes

The selected responses were each scored by two raters using both the holistic scoring lens and the analytic scoring lens (see Figure 1).

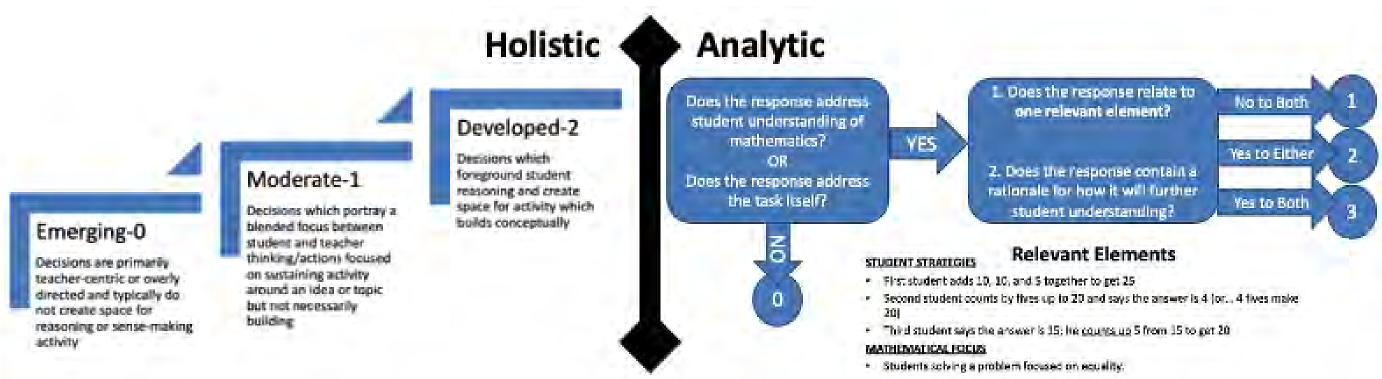

Figure 1: Holistic and Analytic Scoring Lenses

Note, the holistic scoring lens provides descriptions of quality at three levels and creates considerable interpretive space for raters, while the analytic lens is far more structured and provides discrete pathways to guide the rater. The raters had previously engaged in iterative, independent scoring activity with each lens and associated calibration conversations. Thus, there was considerable shared familiarity. For instances of disagreement (for both lenses), raters engaged in negotiated discussion to arrive at a consensus score.

Findings and Discussion

Again, we note that this investigation represents a preliminary examination of different lenses as they apply to PSET deciding. We first examined the outcomes from each lens in terms of rudimentary counts (see Tables 1 and 2). We also conducted 2-tailed paired t-tests to determine statistical significance of rating outcomes (see Table 3).

Table 1: Holistic Scoring

	Score 0	Score 1	Score 2
Full Implementation Pre	20	3	0
Full Implementation Post	15	7	1
Partial Implementation Pre	8	5	0
Partial Implementation Post	10	3	0

Table 2: Analytic Scoring

	Score 0	Score 1	Score 2	Score 3
Full Implementation Pre	2	1	11	9
Full Implementation Post	2	4	13	4
Partial Implementation Pre	1	3	6	3
Partial Implementation Post	1	1	6	5

Table 3: 2-Tailed Paired t-Tests:

Holistic Scoring p-value	Analytic Scoring p-value	
0.324174	0.151834	All paired data
0.436265	1	Partial implementation paired data
0.055668	0.076272	Full implementation paired data

Comparing changes in response counts, pre/post, across the two lenses, PSET decisions tended to receive a low rating (0) when scored holistically and higher ratings (2, 3) when scored analytically. Given the more interpretive nature of the holistic lens, this finding suggests tension between structured ratings processes (Fisher et al., 2018) and the raters more intuitive sense of quality with respect to PSET decisions when ratings processes are more loosely guided. Further, p-values for both partial and full implementations more closely approach statistical significance when scored via a holistic lens vs. an analytic lens. This finding strikes us as somewhat counterintuitive given the notion that more regulated and structured processes tend to minimize chance outcomes.

The deciding component of professional noticing has consistently presented challenges in terms of measurement. (Schack et al., 2013; Thomas, 2017). Determining the quality of decisions requires negotiating the space between specific and highly contextualized moments and broader principles of teaching. In these complex arenas, researchers tend to emphasize structure and guided processes to make the terrain more negotiable. However, our findings suggest that reducing structure and process guidance and creating space for more holistic interpretation in the context of instructional decisions may result outcomes more consistent with researchers' understanding of quality and less likely to be attributable to chance. We intend to further investigate this intriguing hypothesis in subsequent study.

USING ASSESSMENT TOOLS FOR TEACHER LEARNING PURPOSES

Merav Weingarden
University of New-Hampshire
Merav.weingarden@unh.edu

This paper offers a socio-cultural perspective on the mechanism by which research-based assessment tools designed to evaluate mathematics teaching, are used as pedagogical tools for teacher learning. This process is exemplified by the Realization Tree Assessment tool (RTA), showing how pre-service teachers refer to the pedagogical messages valued and devalued by the assessment tool, and which conflicts between these messages they attend to.

Keywords: Preservice Teacher Education, Teacher Educators, Assessment.

Introduction

In recent years there has been a growing interest in reform-oriented pedagogies, such as *student-centered*, *cognitively demanding* and *ambitious* teaching (Brown, 2003; Kazemi et al., 2009; Stein et al., 2000), which aim to support mathematics learning of *all* students at the highest possible level (NCTM, 2014). Accordingly, many efforts have been made to develop tools, such as the IQA – Instructional Quality Assessment (Boston & Smith, 2009) and the MQI – The Mathematical Quality of Instruction (Hill et al., 2008), for evaluating how these pedagogies are being implemented in classrooms. A small but growing strand of research has recently examined the use of these assessment tools also as pedagogical tools, aiming to help teachers implement ambitious teaching practices in their classrooms (e.g., Boston & Candela, 2018). These studies focus on implementing a particular assessment tool and describing teachers' gain from engaging with this specific tool. From a socio-cultural perspective on teacher learning, this paper aims to explore the mechanism by which research-based tools designed to assess teaching are used as pedagogical tools for pre-service teachers (PSTs) who learn how to teach mathematics.

Theoretical Framework

Teacher learning from a socio-cultural point of view draws upon the idea that teacher learning is not just a matter of mastering specific skills or acquiring certain bits of pedagogical knowledge (Horn & Kane, 2015; Nachlieli & Heyd-Metzuyanim, 2021). It is a more holistic process that often requires teachers, especially PSTs, to shift between *Contextual Discourses (CDs)*, which are different perceptions of messages about teaching and learning communicated in various social, cultural, and institutional situations (Thompson et al., 2013). The *pedagogical messages*, which are messages about teaching and learning, include how students learn (e.g., memorizing or exploring), who is the main authority of mathematical ideas (teacher or students), and what are the teacher's roles (e.g., delivering knowledge or supports student thinking). Thompson et al. (2013) differentiate two CDs. The first, *ambitious CD*, values deep understanding of ideas and student engagement in solving complex problems rather than procedural tasks. The second, *traditional CD*, values traditional teaching practices, where the teacher presents a procedure using a model problem and students practice on similar problems.

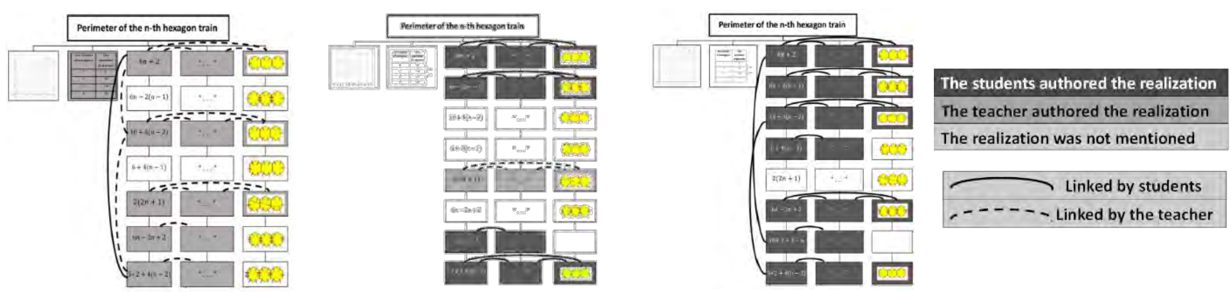
Initiating PSTs into ambitious CD stands at the core of multiple teacher education programs (e.g., Van Es et al., 2017) that often use various pedagogical artifacts or teaching representations such as students' work or video excerpt to promote PST learning processes (Herbst & Kosko, 2014; Kazemi & Franke, 2004). Recently, studies have examined the use of assessment tools as a pedagogical means for teacher learning (Boston & Candela, 2018; Kraft & Hill, 2020). The

Realizations Tree Assessment tool (RTA), for example, was designed to evaluate classroom discussions and was found to be helpful for PSTs to attend to the mathematical objects at the core of a lesson (Weingarden & Heyd-Metzuyanim, 2020). Boston and Candela (2018), which examine the use of the IQA as a reflection tool for teachers, concluded this process: "what is assessed becomes what is valued, hence classroom observation tools have the power to shape and support instructional reforms by highlighting or foregrounding specific features of instructional practice" (p. 427). In what follow I examine the process of "what is assessed" and "what is valued" by relying on the traditional and ambitious CDs. Eventually, allowing to examine how PSTs, while engaging with such tools, refer to various pedagogical messages from different CDs and the tension between them. I exemplify this process on the RTA tool.

The Realization Tree Assessment Tool (RTA)

The Realizations Tree Assessment tool (RTA) (Weingarden et al., 2019) was designed to evaluate the extent to which class discussions provide opportunities for students to attend the various realizations (representations) of the mathematical object and the links between them. The RTA visually depicts the mathematical object at the core of a class discussion, its various realizations, and the extent to which students, rather than the teacher, author narratives about the object. Figure 1 exemplifies three different class discussions assessed by the RTA (Weingarden et al., 2019; Weingarden & Heyd-Metzuyanim, 2021). These class discussions focused on the Hexagon Task in which students were asked to find the perimeter of n hexagon concatenation (the mathematical object). The cells in the RTAs describe the realizations of the mathematical object (e.g., algebraic realizations such as 4n+2, visual realizations of the hexagons pattern) according to who articulated them, the students, or the teacher.

Lesson A Lesson B Lesson C



RTA score: 0.39 RTA score: 0.47 RTA score: 0.87

Figure 1: Three RTA Images and Measures Represent Different Learning Opportunities

Each lesson was depicted by an RTA image quantified into a number between 0 to 1 – the RTA score, based on the ratio of student-authored and teacher-authored narratives and the number of realizations and links mentioned. The presented images and measures show the different extent and levels of opportunities offered during the lesson. Lesson A describes a teacher-centered lesson with almost all realizations and links authored by the teacher. Lesson C, in contrast, shows the students as the main authority in the class discussion. Thus, Lesson A received a lower score (0.39) than Lesson C (0.87). In Lesson B, although students authored most of the realizations and links, the solutions were not linked to each other (by vertical links) as in Lesson C. Thus, Lesson B received a lower score (0.47) than lesson C (0.87). These RTA images and scores (Figure 1) exemplify different pedagogical messages aligned with traditional and ambitious CDs. The pedagogical messages of student-centered teaching (Lesson B, C) and linking between realizations (Lesson C) align with ambitious CD, whereas the pedagogical messages of teacher-centered (Lesson A) and show-and-tell (Lesson B) align with traditional CD.

This paper aims to examine how the RTA can be used as a pedagogical tool for PST learning to teach mathematics by attending to messages from different CDs. Thus, the research questions are: *How do PSTs, by using the RTA, attend to pedagogical messages aligned with traditional and ambitious CDs? And what conflicts between the CDs were illustrated by the PSTs?*

Method

The current study took place within a course for pre-service secondary mathematics teachers. During the course, 33 PSTs were introduced to the RTA tool and its theoretical aspects, then compared and discussed different RTAs (similar to those in Figure 1). Subsequently, they were administered the Calling-Plans task (Institute For Learning, 2015) and an empty RTA of this task (Figure 2). They were asked to shade three RTAs in different ways describing three types of learning opportunities and discuss the similarities and differences between the shaded RTAs.

Long Distance Telecommunication Company A charges a base rate of 45 NIS (equivalent of dollars) per month for phone calls plus 5 agoras (equivalent of cents) per minute of call. Long Distance Telecommunication Company B charges a base rate of only 20 NIS per month, but charges 30 agoras per minute of call. Which service would you choose, and why?

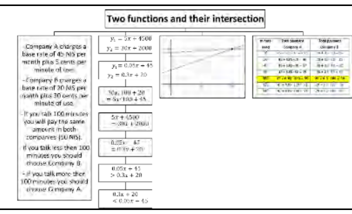


Figure 2: The Calling-Plans Task and the RTA for the Task

The PSTs worked in 11 groups (3 PSTs in each group), and thus 11 worksheets, including 33 RTAs, were analyzed. The analysis was performed in two stages and included analyzing the PSTs' written descriptions about the RTAs they shaded. First, coding the PSTs' utterances according to the pedagogical messages they referred to (e.g., student-centered, rich discussion, teacher directs too much, teacher-centered, student struggle). The coding categories were adopted from studies that examined teacher learning as transitioning between CDs (e.g., Heyd-Metzuyanim, 2019). Second, identifying conflicts between the two CDs illustrated when the PSTs described their shaded RTAs.

Findings

Attending Traditional and Ambitious Contextual Discourses

The most common pedagogical message referred to by the PSTs (9 groups) was the extent to which the teacher and students authored narratives during the lesson. Figure 3 presents an example of two RTAs designed by two groups.

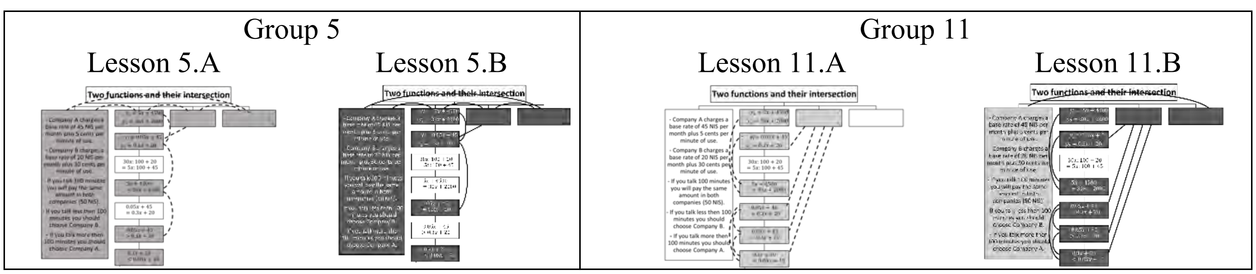

Figure 3: The Extent of Student Authority in the RTAs

Lessons 5.A and 11.A are described by the PSTs as teacher-centered lessons in which the teacher "suggests all of the ideas by herself" and "takes over the discussion and simply shows the students a complete solution to the problem". Lessons 5.B and 11.B are described by the PSTs as student-centered lessons in which "students participated and tried to solve the question on their own" and "discovered many links between realizations". The PSTs, by the RTAs they designed, attended to a pedagogical message assessed by the RTA tool – the extent to which students and the teacher authored mathematical narratives. They attended to this pedagogical message both as aligned with traditional CD (light-shaded RTAs: Lesson 5.A and 11.A), and as aligned with ambitious CD (dark-shaded RTAs: Lesson 5.B and 11.B).

Conflicts Between Contextual Discourses

Although most of the PSTs described the teacher-centered RTAs as less valuable (e.g., "failed attempts") compared to the student-centered lessons (e.g., "ideal lesson"), some of the PSTs pointed out some valued pedagogical messages in these teacher-centered lessons aligned with traditional CD. For example, the PSTs in group 11, while describing Lesson 11.A (Figure 3), indicated that although "the students did not participate in the lesson", this lesson has some advantages. They wrote: "since the teacher explains the solutions by herself, it is possible to go further and deeper with the ideas… students may ask questions that they may not have asked if the teacher had not explained". The PSTs referred to two pedagogical messages aligned with different CDs. One, teacher authority ("explain by herself") aligned with traditional CD and the second, engagement with important mathematics ("go deeper with the ideas") aligned with ambitious CD. They tacitly attend to a conflict between the two discourses by referring to a teacher-centered lesson (traditional CD) as supporting and promoting engagement with important mathematics (ambitious CD). Another example of such a conflict appears in group 6's RTAs. They showed how student-centered lessons are not always valuable as teacher-centered lessons. They shaded an RTA with many student-authored realizations but no links and indicated that "in this situation, the teacher needs to direct students to make these links". The PSTs referred to the conflict between the importance of linking between realizations, aligned with ambitious CD and the teacher as "directs the students too much", aligned with traditional CD.

Discussion

This paper examines how the RTA, designed to evaluate teaching mathematics, is used as a learning tool for PST learning to teach. This was done by relying on the idea that teacher learning occurs when teachers initiate into the ambitious CDs and adopt the pedagogical messages aligned with this CD. Initial findings show that the PSTs, by the RTAs they shaded, attended to different types of pedagogical messages aligned with traditional and ambitious CDs. This allowed them to attend to conflicts and tensions that could occur while two different pedagogical messages from different CDs are embedded in the same lesson.

PSTs attending to different, often competing CDs and the conflicts between them can contribute to teacher educators' efforts to engage PSTs with ambitious teaching practices (Ma & Singer-Gabella, 2011; Thompson et al., 2013). Examining the use of assessment tools as pedagogical tools by focusing on the valued and devalued pedagogical messages aligned with ambitious and traditional CDs, can theoretically contribute to the growing strand of research examining teacher learning using assessment tools (e.g., Boston & Candela, 2018).

Further studies are required to examine how different assessment tools attend to different sets of pedagogical messages and which conflicts can be addressed by using assessment tools as a pedagogical means. This study is the first step towards a better understanding of the mutual relationship between teaching assessment and teacher learning.

USING MINDFULNESS TO SUPPORT THE WELL-BEING OF PRESERVICE K-8 TEACHERS DURING A PANDEMIC

Rachael M. Welder

meb0042@auburn.edu

Heidi Eisenreich
Georgia Southern University
heisenreich@georgiasouthern.edu

This paper reports initial findings from the implementation of a Mindfulness-Based Intervention (MBI) during the COVID-19 pandemic in an effort to mitigate the effects of stress and anxiety on preservice K-8 teachers (PTs) as learners of mathematics for teaching. Three teacher educators, at three U.S. institutions, implemented the MBI in their mathematics content and methods courses for PTs, as a way to connect with and holistically support students during a semester of pandemic-induced online instruction. Initial analysis of survey data (n=136) shows that PTs reported mindfulness helping them to become self-aware and learn strategies for regulating their behaviors. PTs saw value in applying mindfulness outside of the classroom and with their future students. By introducing coping strategies, we were able to show PTs the importance of caring for their mental and emotional well-being and the well-being of their future students.

Keywords: Preservice Teacher Education, Affect, Emotion, Beliefs, and Attitudes, Teacher Educators, Sustainability (of Teachers)

Teaching is a particularly demanding profession (Roeser et al., 2012) and teachers have long endured some of the highest rates of work-related stress among all occupations (Felver, 2016; Johnson et al., 2005). Higher levels of stress have been linked to higher rates of teacher burnout (McCormick & Barnett, 2011). In fact, prior to the COVID-19 pandemic, more than 44% of new teachers were leaving the profession within five years (Ingersoll et al., 2018) and the full effects of the pandemic on teacher retention is yet to be seen. Thus, we argue that supporting preservice K-8 teachers (PTs) in developing strategies to mitigate the negative effects of stress and anxiety should be a consideration of teacher preparation programs. "Mindfulness is an aspect of social-emotional competence that may protect them [teachers] from experiencing burnout and its negative consequences" (Abenavoli et al., 2013, p. 57). Furthermore, research has shown that a significantly larger percentage of elementary PTs experience high levels of mathematics anxiety when compared to other undergraduate students (Harper & Daane, 1998). Therefore, mathematics courses for PTs may provide a fruitful context for introducing such strategies.

The COVID-19 pandemic illuminated these long standing mental-health challenges related to the teaching and learning of mathematics and exacerbated these issues as classes moved online, instructional expectations and situations underwent frequent changes, and teachers and students felt isolated. Thus, three mathematics teacher educators, at three U.S. universities, designed and implemented a Mindfulness-Based Intervention (MBI) for PTs in mathematics content and methods courses, as a way to connect with and provide holistic support for their students during the fall of 2020, a semester of pandemic-induced online instruction.

Background

Mindfulness

Kabat-Zinn (2003) describes mindfulness as "the awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding of experience moment by moment" (p. 144). Mindfulness is often associated with the practice of traditional meditation, which is rooted in Buddhism; however, over the past three decades secular mindfulness as a state, trait, process, and intervention has been adapted in settings such as schools, businesses, and medical facilities (Brazier, 2016; Gupta, 2019). The practice of mindfulness involves three key features of attention-training, "paying attention to the present moment, recognizing and classifying emotions, and experiencing more refined self-awareness in the present" (Ahmed et al., 2017, p. 26). By combining self-awareness, self-regulation, and self-compassion (Roeser et al., 2012), mindfulness can reduce stress (Bamber & Schneider, 2016; Poulin et al., 2008), increase quality of attention (Good et al., 2015), improve resiliency (Salmon et al., 2004), and provide people with tools that allow them "to 'respond' to a potentially anxiety-producing situation with greater effectiveness rather than to 'react' with escalation, panic or fear" (Miller et al., 1995, p. 197).

Mindfulness and Education

Recent and rapid growth in research addressing mindfulness-based interventions (MBIs) for both students and teachers (Felver & Jennings, 2016; Jennings, 2015) has included dozens of studies assessing the effects of mindfulness on college students (Bamber & Schneider, 2016, Bellinger et al., 2015, Brunyé et al., 2013). Research suggests that MBIs, ranging from brief informal activities to formal, sustained programs, may be particularly well-suited for supporting teachers, PTs, and college students in mitigating the negative effect of stress and anxiety (Burrows, 2018; Meiklejohn et al., 2012; Ramsburg & Youmans, 2013). Research regarding teachers indicates that mindfulness training can reduce reactivity, stress, and burnout while increasing teachers' sense of self-efficacy, acceptance of self and others, self-regulation, well-being, classroom management skills, creativity, and ability to cultivate positive student relationships (e.g., Bliss, 2017; Burrows, 2015; Jennings & Greenberg, 2009; Meiklejohn et al., 2012). Less research has examined the effects of mindfulness on PTs (Brown, 2017), although the Mindfulness-Based Wellness Education program at the University of Toronto has found some promising results in increased self-efficacy and social and emotional competence for PTs (Poulin et al., 2008; Poulin, 2009; Soloway, 2011; Soloway et al., 2011).

In addition to reducing negative states such as stress and anxiety (e.g., Bamber & Schneider, 2016), mindfulness has been linked to improving factors that can affect learning such as sustained attention, working memory, and concentration (Chambers et al., 2008; Jha et al., 2007), cognition (Rodgers & Raider-Roth, 2006; Zeidan et al., 2010), knowledge retention (e.g., Ramsburg & Youmans, 2013), and academic achievement (Bakosh et al., 2015; Bellinger et al, 2015; Brunyé et al., 2013; Weger et al., 2012). These findings inspired our design and implementation of an MBI to support our K-8 PTs during the pandemic in an effort to mitigate the effects of stress and anxiety while learning mathematics for teaching. Our work utilizes the theoretical framework of self-regulation learning theory, which postulates that stress can be alleviated and learning can be more effective when learners are able to self-regulate (Roeser et al., 2013; Zimmerman, 1989a, 1989b).

Methodology

During the fall of 2020, we implemented a semester-long MBI in our mathematics content and methods courses for PTs. Integrating mindfulness was seen as an important step in supporting our PTs as well as recognizing the balance needed in the teaching profession and the importance of humanizing education beyond the content. Our intervention consisted of introducing and engaging with students in two short (5-10 minutes) mindfulness practices per week, one completed at the beginning of each class meeting. The MBI was designed to introduce a new form of mindfulness each week, e.g., mindful breathing, mindful listening, mindful movement, body scan meditations, and gratitude journaling, for 15 weeks. Each week, the PTs engaged in two different, yet related, practices for each form. Most practices were implemented by sharing publicly-accessible videos or images made by leaders in the mindfulness community, e.g., Dan Harris and Sharon Salzburg (Happify, 2015).

As part of our data collection, PTs were asked to complete two surveys regarding mindfulness, one at the midterm and another at the end of the semester. Each survey consisted of 10 Likert scale items and 4 open-ended response questions. This report shares the qualitative analysis of responses from 136 PTs to the open prompt, "Mindfulness has helped me…".

Preliminary Qualitative Data Analysis

Initially the researchers read the data and one took the lead to identify major codes that emerged. Then the three researchers met and discussed the emergent codes and reorganized them based on mindfulness literature. This conversation led to code revisions and a new code list with definitions for each code. Next the data were recoded using this finalized list. To establish interrater reliability, the codes were checked by a second researcher who then coded the data a second time. The second coder produced codes that were matched by the original coder by 100%. However, the original coder had some additional codes, which were discussed to reach mutual agreement. Below, we will report on the three strongest themes that were revealed by the three most prevalent codes: self-awareness, self-regulation, and applications (listed in the order in which we will discuss them, see Table 1).

Table 1: Codes/Themes, Definitions, and Count

Code/Theme	Definition	Mid	Post	Total
Self-awareness	Awareness of bodily sensations (e.g., tension), emotions, attention, or automatic reactions	28	20	48
Self-regulation	Behavioral changes made as PTs learned strategies for responding to or managing stress, and/or anxiety	119	78	197
Applications	PTs identified a specific audience or situation where they found or could foresee benefits of using mindfulness practices (such as when focusing in class or for use with future students)	26	27	53

Results

Self-awareness

Self-awareness was a major theme identified by many participants. This included awareness of physical sensations in one's body (such as the breath or muscular tension), emotions, attention/focus, and typical responses to stressors. For example, one PT wrote, "Mindfulness has helped me become more aware of my emotions and feelings." Similarly, a PT reported, "Mindfulness helped me become more aware of how I am feeling and know how to handle the tensions and stressors of the day." Another PT shared, "[I am] more aware of my emotions so I am able to reevaluate my situation." One PT noted, "[I have] become more aware of how I have previously handled stress and anxiety and find new and healthier ways to handle those feelings."

Self-regulation

Self-regulation was the strongest theme identified by far and can already be noted in the sample PT comments above. This included being able to modify one's reactions to stress and anxiety, such as slowing down the body or breathe, being able to relax and calm oneself, and having more control over one’s emotions. The ability to regulate one’s feelings of stress and anxiety was mentioned more than any other code. PTs noted that mindfulness helped them “deal with the stress of school work better,” “control my anxiety,” and “learn how to take time to breathe and take my mind off of what is stressing me out.” One PT shared that the mindfulness practices helped them “realize that in times of stress, I can't JUST push through. I have to take a deep breath and mentally remind myself that I CAN DO HARD THINGS.” Another stated, “It is easy to get caught up in the stress and anxiety of the day, but doing these [mindful] exercises help me when I get worked up.” One PT reported “learn(ing) how to regulate my emotions outside of class. Another prominent code within this theme was a sense of empowerment that seem to arise through the development of strategies to apply in moments of dysregulation. One PT noted, that they can now “identify stressors and develop ways to cope and overcome them.”

Applications

The third code that emerged is that PTs acknowledged specific ways in which they used or plan to use the mindfulness strategies they learned through this MBI. PTs noted that mindfulness helped them concentrate in class. For example, one shared that the MBI helped them, “calm down a bit before class starts.” Another said the strategies helped them to “begin each class with a clean slate, by helping me forget all the stressors and become more focused for class.” One PT even noted that the practices helped them “wake up” so they could pay more attention in early morning classes. Specific to the needs of PTs enrolled in mathematics courses, one noted that mindfulness helped them “handle my math-related anxiety.” Some PTs who were further in their programs and/or involved in field experiences acknowledged potential benefits of using mindfulness practices with their future students. One PT said that it helped them, “think about what to do for some students facing stress,” while another said participating in the activities helped them “find strategies that I will be able to use with my future students to manage stress.”

Discussion

The results of analyzing this single open-response question already shows evidence that the MBI helped PTs develop meta-awareness in ways that empowered them to effectively modify their behaviors, i.e., self-regulate (Vago & Silbersweig, 2012), through the development and application of new strategies. It is interesting that students reported their abilities to regulate their behaviors or mindsets at a much higher rate than their awareness of such things. However, intentional self-regulation requires awareness of the experience (i.e., thought pattern, emotion, reaction, or bodily sensation) one wishes to regulate (Bandura, 1991). Thus, even though the self-awareness code appeared fewer times, the prevalent of the self-regulation code suggests that there was more self-awareness occurring than the PTs reported or were consciously aware of.

This study also found that PTs acknowledged mindfulness as being beneficial to them within the context of the course the MBI was implemented. Thus, future research might explore how MBIs impact PTs’ mathematical achievement and/or self-efficacy in their teacher preparation programs. However, we hope that the benefits PTs experience will support their development of resilience by helping them mitigate the negative effects of stress and anxiety, especially within the first few years of teaching. Therefore, we see value in extending this work with longitudinal research studying the impact of MBIs on teachers as they enter the profession and exploring if they stay in the profession long-term. This study also found that PTs foresaw longer-term applications of mindfulness for supporting their future students. This was particularly interesting as the PTs were not directly asked about their intentions to use mindfulness in their future classrooms. However, longitudinal research could explore the effects of the MBI on PTs’ future application of mindfulness with their future students.

EARLY MATHEMATICS TEACHER PREPARATION EVALUATION RUBRICS FOR THE CONTEXT OF LIVE DISCUSSION FORUMS

Jeremy Zelkowski
The University of Alabama
jzelkowski@ua.edu

Tye Campbell
Crandall University
tye.campbell@crandallu.ca

Teacher candidates bring many beliefs and interpretations of mathematics teaching and learning at the start of their teacher preparation coursework (e.g. methods courses, field experiences, assessment). Well-prepared beginning teachers in many instances requires programs and designed experience to breakdown unproductive beliefs and/or improve dispositions to align to best practices and equitable dispositions for the teaching and learning of mathematics. Our study focused on developing and validating two rubrics to evaluate teacher candidates' talk during live discussion forums in the first month of their initial teacher preparation program coursework with the intent to inform to varying degrees, where teachers candidate talk is situated (or not) in alignment to foundational readings and productive beliefs. Early validity evidence for rubric use is presented with suggestions for informative use and practice.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Preservice Teacher Education; Teacher Beliefs; Measurement

Many secondary mathematics teacher candidates (TCs) enter their preservice preparation programs with traditional (e.g. cultural norms, conventional) beliefs about education, believing, for example, that all or most student learn best in teacher-centered classroom instructional methods and/or performing rote practice with learn-by-example replication/practice (Cady et al., 2006; Conner et al., 2011; Cooney, 1999). Combating such beliefs is laborious since literature suggests TCs are likely to replicate practices most prevalent in their own educational experiences in K-12 mathematics classrooms (Borko at al., 1992; Cross, 2009). This idea is still generally supported by the more recent publication of the National Council of Teachers of Mathematics' (NCTM) *Catalyzing Change in High School Mathematics* (NCTM, 2017), where it is noted that only pockets of excellence exist within the high school for classrooms modeling the eight effective mathematics teaching practices (MTPs) (NCTM, 2014) developed from research over the last few decades. More troublesome in such conventional and culturally/historically normed mathematics teaching methods is the rooting of inequitable opportunities for non-dominant cultures creating a group of students becoming historically marginalized as an outcome (Aguirre et al., 2013). Our work is designed to fit within the challenges of preservice mathematics teacher education that presses to create critical dissonance within the status quo of teacher preparation programs with the designed intent of a resonant harmony of well-prepared, equitable teaching by newly minted mathematics teachers. We recognize this challenging work to rock the teacher preparation magnate model that has generally continued the cyclic pattern of student to TC to beginning teacher that does not significantly alter on a grander scale the teaching and learning of mathematics embedded in the eight MTPs.

Over the course of the last two decades, our preparation program has used and/or developed program measures as a means and intent to be predictive, yet deeply informative, with respect to desired outcomes for interns' (full-time student teachers) mathematics teaching practices and ultimately first-year teaching. We view the importance of internal program measures as needing validity evidence for their effective use to inform and shape the development of all teacher candidates over time that helps shifts beliefs and practices when needed to desired TC outcomes. While we recognize the limitations of the data collection and rubrics presented in this paper, we believe this work presses preparation programs to push boundaries and challenge barriers that have not moved quickly enough to eradicate conventional and culturally/historically normed practices in mathematics teacher preparation to ultimately produce systematic change in K-12 schools in the teaching of mathematics to be equitable for all students. Our work firmly fits within most guiding questions for PME-NA 2022 program, as well as adding to the psychology of how the field views mathematics teacher preparation program components as a learning to teach experience that prepares and aligns to best practices as a systematic requirement to become a licensed teacher of mathematics. Our research questions are as follows:

1. What is the predictive nature of two rubrics scoring first semester teacher candidate discussion forums in relation to entering the teaching profession as validity evidence?
2. To what degree does the alignment of teacher candidates' first semester talk with assigned readings relate to completion of their preparation program?
3. To what degree do teacher candidates publicly stated first semester beliefs (productive or unproductive) during discussions relate to completion of their preparation program?
4. Do males and females (as identified on self-report) show any differences within the analyses given TC imbalance of 2:1 female to male within the preparation program?

Theoretical Framework

The American Educational Research Association, American Psychological Association, and the National Council on Measurement in Education *Standards for Educational and Psychological Measurement in Education* (AERA, APA, & NCME, 2014) introduces the need for validity evidence for measurement within educational contexts. The validation framework for the development, use, and interpretation of rubrics is the central tenet of our study.

Rubric development for affective domains in teacher education is an arduous task. Constructing a case for rubric validity is an ongoing process involving multiple facets of validity evidence, including the notion of the construct(s) in which are sought to be determined. Instruments in social sciences vary in precision and quality in the measurement of a particular construct, whereas the validation process should be centered on rubric interpretation and use (AERA et al., 2014; Bostic et al., 2019; Lavery et al., 2019). Kane (2013) denotes the use and interpretations of instruments [rubrics] require more validity evidence than is the case for less ambitious applications of instruments [rubrics]. Kane (2016) later indicated validation research is not easy but that it is generally sensible to grow solid evidence with manageable efforts.

Situational Perspectives of Rubric Use in Teacher Preparation

Rubrics are used extensively in teacher education preparation programs for assessment and for accreditation purposes, but there has been a lack of validity evidence (published) with arguments for specific rubrics and their appropriate interpretation and use (Hill & Shih, 2009; Howell et al, 2019; Lavery et al, 2019). Well-constructed, systematically developed instruments with validity evidence in mind for their intended purposes have strong potential to provide teacher educators valuable and predictive data in the development trajectory of TCs. Traditionally, rubrics used programmatically are grounded in the documentation for accreditation purposes. That is to say for example, that for the Council for the Accreditation of Educator Preparation (CAEP) or jurisdictional level accreditation, rubrics are used to report aggregate level performance of program completers on an annual basis at different points in time within TCs' program coursework and field experiences. Yet, most of the rubric data is not generate with a TC-level predictive nature in mind but rather for program accountability and documentation to become/remain accredited (CAEP, 2013, 2022). We challenge this status quo in teacher preparation in the use of rubrics beyond that of accountability, but significantly more so, with predictive validity in mind as a means to inform program faculty on their effectiveness of shaping TCs over time to align practices and beliefs to the mathematics education literature that ultimately removes barriers for marginalized students' opportunities to engage with and learning mathematics. Should such internal program rubrics exist, ultimately program faculty can modify program curricular experiences and provide TCs feedback identified earlier. We recognize that some TCs have only a single semester of preparation before the full-time (or extensive) student teaching internship. This fact is presented in our discussions and limitations later.

Teacher Candidate Beliefs in Teacher Preparation

Of particular importance to this study is NCTM's (2014) *Principles to Actions*, designed to describe "the conditions, structures, and policies that must exist for all students to learn" (p. vii). *Principles to Actions* (PtA) advances and redefines NCTM's (2000) six guiding principles for school mathematics: teaching and learning, access and equity, curriculum, tools and technology, assessment, and professionalism. Within each of these domains, NCTM (2014) outlined productive and unproductive beliefs that support or hinder mathematical learning for all students. NCTM's delineation between productive and unproductive beliefs in *PtA* serves as a standard by which TCs begin to think about their beliefs and how potential practices as a result of such beliefs may not be in the best interest of teaching and learning for all students.

Research suggests whole class discussions can positively influence TC beliefs within a whole class (Stohlmann, 2015; White et al., 2016) though less is known about the variation of influence and change on an individual TC level. The field would benefit from empirical research investigating the nature of individual contributions during whole class discussion and how those contributions shift beliefs toward or align to productive visions of teaching and learning mathematics within a teacher preparation programs. For example, if individual contributions during whole class discussion significantly influence TCs' teaching vision and beliefs, program faculty may utilize whole class discussions to learn about TCs' situated beliefs early enough to create situational interventions and even potential remediation activities. Stohlmann (2015) and White et al. (2016) both found engaging TCs in whole class discussions with purposefully chosen questions/tasks/prompts aided in TCs developing productive beliefs. Utilizing whole class discussion allows TCs to construct their own knowledge through discussing relevant material, but it further reinforces positive dispositions by enculturating TCs into a desirable learning environment. Our study is grounded in these ideas about using whole class discussions, which we refer to as TC live discussion forums, as the setting for the purposeful development of two rubrics to record and monitor TCs contributions over three live discussion forums in the first month of teacher preparation [education] coursework.

Methodology

This paper reports on three distinct phases of the study in which rubric development was sought to create a tool to more reliably assess what teacher candidates put forward during live discussion forums. First, the development of two rubrics was needed to align to our research questions. Second, our team then looked to start the validity and revision process of testing the rubrics to move forward to the third phase. The final phase was to analyze the data in which the rubrics development sought to examine TCs alignment to the readings and productive beliefs (or not). Consider that in all mathematics teacher preparation programs, TCs who begin coursework all do not finish the program as certified mathematics teachers. Therefore, our study methodology was to develop rubrics, test the rubrics on existing data to generate validity evidence, and then ultimately have validated rubrics situated to have a predictive ability to improve TC outcomes and program completion aligned to the desired characteristics in the field of mathematics teachers who exemplify productive visions and beliefs about teaching and learning mathematics (i.e. implementing the MTPs).

Context of Participant Generated Discussion Forum Data

Within the teacher preparation program at The University of Alabama, three live discussion forums have existed in the first month of the program for more than a decade. The notes about TC talk have been analyzed qualitatively in the assessment of progress in the program, but never has such analyses resulted in a mechanism to understand which TCs might program faculty provided deeper feedback on their development visions and beliefs about teaching and learning mathematics at such an early stage of the program. A seven-year period of data collection was used in which all three live discussion forums were implemented without deviation, holding the format, readings, and prompts to be consistent, as well as the mechanism for how data was noted and recorded in a spreadsheet. A small subset (~10%) via random selection of the existing data across all seven years was used for the development, test, revision, and initial validation work to finalize the rubrics for the full analysis. It is important to paint a vivid picture of how the data is collected during the live discussion forums.

The data used in this study was collected in a first semester TPP course (fall semester, junior year) which is embedded in a sequence of three consecutive mathematics teaching methods courses prior to the student teaching internship (see Zelkowski et al, 2018, 2021) for more details of program structure and sequence. The three live discussion forums took place at the start of the mathematics technology methods course during the first four weeks where each class was held twice a week for 1-hour 15-minutes (class meeting 2, 4, and 7). Lessons in the methods course between each of the three discussion forums included technology driven activities (see Zelkowski (2013), Bismarck et al., (2014) for examples) with TCs exposed as engaged learners to the eight Standards for Mathematical Practice (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010).

Data Collection

Over seven years, 110 PSMTs (77-female, 33-male) were enrolled in the methods course.

The readings were the first three chapters of *Teaching Secondary and Middle School Mathematics* (Brahier, 2013) titled: (a) Mathematics as a Process, (b) Principles of Mathematics Education, and (c) Learning Theories and Psychology in Mathematics Education. During each live discussion forum, the methods course professor projected a PowerPoint presentation with discussion prompts based on the focus questions of each chapter. The professor remained silent concentrating on accurate notetaking, allowing TCs to engage in an open, student-led forum related to each discussion prompt based upon the focus questions of each chapter. There were no restraints regarding how much individual TCs could talk during each prompt or discussion forum, though the professor encouraged equitable opportunities for all and respect among peers.

For this particular method of data collection (i.e. researcher as complete observer), Creswell (2003) discusses many advantages to this design such as it is useful in exploring topics that may be uncomfortable for participants to discuss, information can be discovered as it is revealed, and unusual aspects can be noticed with the researcher's firsthand experience with the participants. Creswell points to some limitations such as the researcher being intrusive or lacking good attention and observation skills. To mitigate such concerns, the methods professor had already spent five years observing and recording data in such forums. Meetings with students allowed for the methods professor to check and verify the notes taken in years prior to the data used in this study. Given the five years of data collection and checking with students, we are confident that most comments captured reflect the TCs spoken words during the seven-year period of this study's data collection.

The professor took notes by constructing a grid with each TCs name as one column with additional columns for each prompt. TCs had name-tents on display for complete accuracy of comments being recorded. The quality of discourse and level of contribution during each of the three live discussion forums constituted about 3% of the final course grade (about 9% total) as an encouragement to participate early with peers at the start of the methods course sequence.

Rubric Development Process

The development of two rubrics and the validation work for their use to evaluate TCs' discussion contribution were rating two constructs of interest. The first rubric was designed to capture the alignment and interpretation of TCs' responses with the assigned chapter readings. The second rubric was designed to capture the alignment and interpretation of the responses to the unproductive and productive "beliefs about teaching and learning mathematics" within *Principles to Actions (PtA)* (NCTM, 2014, p.11) prior to TCs reading *PtA*.

We initially began with a four-level rubric (0-3) and two raters. We randomly scored about 3% of the forum data using the first rubric iteration. We discovered that an additional rubric-level would be needed and that a revision of the language was necessary as there were too many examples of implicit scoring decisions (e.g. higher or lower with less agreement). The rubrics were revised and retested with a new random sample of responses. After a third small revision of language in a few cells of the rubric, the third iteration was finalized.

In terms of each rubric, our revision process noted above went through three cycles in scoring a small sample until we were confident of removing as much subjectivity as possible between each level of the rubric. Ultimately, having enough levels in Rubric-1 was needed to consider the follow-up talk of a TC in terms of whether they were giving opinion supported by the interpretation of the reading or just giving opinion not supported by the reading. Whereas, Rubric-2, the sole purpose was to identify statements that do not align or do align to the productive beliefs tables in *PtA*. The rubric final iterations are shown in Figure 1.

Rubric-1. Alignment of Response with Reading

Level 0	Level 1	Level 2	Level 3	Level 4
Student did not engage in the discussion forum	Responses across prompts are mostly unrelated to the reading OR reveals misinterpretation of content of chapter	Responses across prompts are mostly related to the reading but is based on opinion rather than the content of the chapter	Responses across prompts mix personal opinion and correct interpretation of content of the chapter	Responses across prompts rely on content of the chapter but might also include some personal interpretation

Rubric-2. Alignment of Response with *PtA* Beliefs about Teaching & Learning Mathematics

Level 0	Level 1	Level 2	Level 3	Level 4
Student did not engage in the	Response across prompts reveals statements which align with	Response across prompts partially reveals statements which align with at	Response across prompts reveals more statements which	Response across the prompts reveals little evidence of statements that align

discussion forum	unproductive beliefs	least one productive belief	align with productive beliefs than not	with unproductive beliefs

Figure 1: Finalized Rubrics for Scoring TCs Alignments within the Discussion Forums

Results

Rater Reliability of Rubrics

One rater scored all three discussion forums for all N=110 TCs with both rubrics which generated 660 spreadsheet cells. We randomly selected 10% of the cells for each rubric for a second rater to score independently. The rater agreement was 78.8%. We discussed our scores that were not in alignment in reference to the rubrics and the TCs discussion forum contributions. Rater one revisited all 660 cells and rescored. Independently, rater two randomly selected another 10% of cells to score for each rubric. There were 6 cells of overlap with the initial 10% selected for a total of 126 cells (19.1% of all). Rater two rescored the initial 66 cells and scored the additional 60 cells. The rater agreement was 88.1%. The results of each rubric scoring are presented in Table 1. We proceeded then to compute the associated Cohen's Kappa, Cronbach Alpha, and Intra-class Correlation Coefficient (ICC) presented in the note of Table 1.

Table 1: Rater Agreement for Rubric-1 and Rubric-2

Rubric-1	Rater 2					Rubric-2	Rater 2				
Rater 1	0	1	2	3	4	Rater 1	0	1	2	3	4
0	6	0	0	0	0	0	6	0	0	0	0
1	0	1	0	0	0	1	0	9	3	0	0
2	0	0	29	4	0	2	0	0	19	2	0
3	0	0	1	19	0	3	0	0	1	20	1
4	0	0	0	2	1	4	0	0	0	1	1

Note. Rubric-1 Statistics: Kappa=0.819, ICC=0.934, Cronbach Alpha=0.966. Rubric-2 Statistics: Kappa=0.822, ICC=0.939, Cronbach Alpha=0.969. All statistics sig. @ p<0.001 level.

Relationship of Rubric Scores to Program Completion

Rubric-1 and Rubric-2 produce two scores for each of the three live discussion forums and total scores (sums of each forum). Of the N=110 TCs, 64 were program completers (~58%), 39 left the program (~35%) for academic and/or personal decisions not to enter teaching, and seven (~6%) eventually entered teaching through an alternative non-certified route. With this knowledge, our interest is whether Rubric-1 and/or Rubric-2 have any predictiveness in classifying TCs as a likely program completer or not from semester-1 discussions. More importantly, rubric scores should provide methods faculty early insights to improve outcomes related to core program readings, beliefs, and ultimately practices.

Two quantitative analysis methods were employed to address the research questions. Zelkowski (2011) stated, "the basic idea underlying this statistical method was to determine whether these groups differed significantly with respect to the mean of" (p.34) rubric levels individually and collectively. Zelkowski further described the use of Discriminant Analysis as a method that indicates the nature of the predictor variables (i.e. both rubrics) in contributing to group separation (i.e. outcome group) through a linear modeling process. We used Chi-square for each rubric across each of the three live discussion forums (six total analyses) considering our TCs three possible outcomes. Because research suggests males and females contribute differently to whole class discussions (e.g. Guzzetti & Williams, 1996), we further examined if there were any differences across TCs gender.

Statistically Significant Findings

Rubric-1 was found to be least predictive of program outcome for all three forums. However, the Chi-Square analyses found statistically significant results for Rubric-1 with the third discussion forum chapter (Learning Theories and Psychology in Mathematics Education) for females but not males. Given the ratio of 77:33 TCs' gender imbalance, this is not surprising. This is further examined in the discussion.

The strongest results were found with the Discriminant Analyses. We found correctly classify males was significant in predicting a final outcome, but not females alone and not all N=110 TCs together in the analyses. Based on each Rubric-2, as well as the sum of both rubrics, males were correctly classified in the analyses into their outcome between 60% and 76%. Rubric-2 scores for chapter 1 forum predicted the outcome 60.6% correctly, chapter 2 forum predicted the outcome 69.7% correctly, and the sum of all three forums predicted the outcome 75.8% correctly. When considering both rubric scores on all three forums (six total scores summed), male outcomes in the program were predicted 69.7% correctly.

Discussion

The purposes of the discussion forums have always been driven by introducing TCs to three foundational chapters setting the stage for mathematics teaching and learning. More importantly, the design engages TCs with peers to hear, listen, and discuss with each other's interpretations of the readings and injecting their own beliefs. Because these three forums immediately provide about 9% of the course grade, there is an early responsibility of TCs to read, be ready to discuss, and openly discuss critical foundations of mathematics education with their peers. We report here that less than 5% of TCs did not engage at least in at least one of three discussion forums.

Program Use of Rubrics

Our intent in the development of these rubrics and working through validation processes for their use and interpretation with desired outcomes, was and still is, to understand TCs potential cognitive conflicts with aspects of mathematics teaching and learning best practices. We further wanted to understand if early semester-1 discussions could be assessed to improve attrition and begin building improved belief structures. Our use of these rubrics in the program serves as informative early indicators of cognitive conflict with readings and/or productive beliefs about teaching and learning mathematics. In our previous program analyses (Zelkowski et al., 2018, 2021), we focused on the impact of key program assessments, coursework, and structural sequence on content knowledge and pedagogical content knowledge for program completers. These two rubrics across three live TC discussion forums provides an early indicator in which personal emails, one-on-one conversations, and high-quality feedback can be provided to TCs to increase their likelihood of program completion if teaching is truly their career desire. We do not see these rubrics as valuable in saving or rescuing those who decide to change majors out of teaching, though we do see their use as indicative and valid to improve outcomes and reduce attrition.

Implications for Mathematics Teacher Education

Rubrics are widely used in teacher education as we previously discussed, including mathematics teacher education. Rubrics serve excellent purposes regarding accreditation of programs, admission to teacher education programs, assignments and grades in coursework, and to provide feedback to TCs. However, the literature rarely points to the issues with the validity of using self-created rubrics for assessment without rigorous validity work having ensued (Hill & Shih, 2009; Howell et al., 2019; Lavery et al., 2019). That is to say, such rubrics generally lack one or more of the categories of validity evidence, or have none at all, for establishing arguments for rubric use in making important interpretations and decisions in mathematics teacher preparation. More precisely, what constructs do rubrics measure and to what degree are the use and interpretation valid? These are difficult questions to face without some process in the validation of the rubrics that methods course faculty may use. We provide our results and findings as a way to encourage rubric use but by generating validity evidence for use and their interpretation. Rubrics as any sort of measure in mathematics teacher education programs, ultimately should be providing faculty and TCs some predictive value about their development towards first-year teaching. Further, we demonstrate a methodology that aligns to the AERA, APA, and NCME (2014) for using rubrics for purposes of decision making, assessment, and programmatic outcomes with aims to reduce attrition and provide objective scoring for TCs.

Conclusion

As researchers, we are interested in examining the 'next step' of remediation when TCs do not exhibit movement towards productive beliefs regarding teaching and learning and/or share personal experiences as 'proof' over well-structured readings (i.e. Brahier). That is, how can methods faculty support learners whose beliefs regarding teaching and learning are not influenced by readings and discussions? We made several revisions to our program design over the last decade to account for these considerations (Zelkowski et al., 2018; 2021; Zelkowski & Gleason, 2018), but there is much to learn regarding effectiveness of program components, course designs, and the validation of key assessments.

We hope this work provides stimulus for discussion, research, and practice towards aiding TCs in developing productive beliefs about teaching and learning mathematics within their preparation program. Developing and validating rubric use and interpretation is a critical piece to not only improving mathematics teacher education, but also measuring the effectiveness of interventions aimed at stronger TC development. This work may serve as an example of the utility of rubrics in mathematics teacher education and provide methods faculty with a process for the validation of rubric use in critical junctions of teacher preparation programs.

Keywords: Affect, Emotions, Beliefs, and Attitudes, Learning Trajectories and Progressions, Pre-service Teacher Education

Learning trajectories focus on expectations related to how learners' ideas develop during an instructional sequence in relation to a learning goal (Simon, 1995). Thus, research on learning trajectories has given little attention to affective aspects of learners' experiences in understanding and exploring mathematical ideas. However, findings from a wide range of studies continue to document the central role of affect in learning (e.g., Cobb et al., 1989; deBellis & Goldin, 2006; Grootenboer & Marshman, 2015). The goal of our study is to foreground the affective experiences of preservice elementary teachers (PSTs) during a fractions unit and to consider how these relate to the conceptual aspects of their learning process.

The affect-focused literature regarding elementary PSTs is sparse and mostly limited to math anxiety (Kelly & Tomhave, 1985; Stoehr, 2017). We seek to both broaden and deepen our understanding of PSTs' affective experiences. Understanding patterns and variabilities in PSTs' affect during their learning is of value to teacher educators. The conceptual challenges PSTs face in coming to better understand fractions and fraction operations are coupled with emotional challenges. It is important to anticipate and plan for these challenges in designing instruction. We draw on the construct of *epistemic affect* (Jaber & Hammer, 2016) which refers to the various feelings, emotions, and motivations that are experienced within work centered on the production, communication, and critique of ideas to explore phenomena and solve problems. This affect might include feelings of vexation when faced with inconsistencies, excitement when figuring things out, and motivation to pursue a puzzling question. These affective experiences are not separable from but rather entangled with the work of sensemaking in mathematics.

The data used in this study consist of discussion boards, written reflections, recordings of class discussions, and interviews with one cohort of PSTs. We focus on weekly reflective assignments that students completed at the end of each class, designed to capture their emotions and feelings experienced during and after each meeting. Early analysis indicates students moved through a variety of affective experiences as the unit progressed. Rather than moving from anxiety to pleasant emotions, PSTs are moving between a variety of emotions that are influenced by external factors including but not limited to new or challenging content, overcoming difficult concepts, and interactions with classmates. Attending to affect could be beneficial to teacher educators as they support PSTs as they move through learning trajectories, especially those charged with emotions such as anxiety.

TEACHING FOR JUSTICE: REFINING A PRACTICUM COURSE FOR PRE-SERVICE TEACHERS IN HIGH-NEEDS SCHOOLS

Monica Grillo
William & Mary, Noyce Scholars Program
mgrillo@wm.edu

Meredith Kier
William & Mary, School of Education
mwkier@wm.edu

Keywords: Culturally Relevant Pedagogy, Social Justice, Preservice Teacher Education

It is more important than ever to prepare teachers who can advocate for minoritized students and social justice. It has been found that preservice mathematics teachers who have opportunities to critically reflect upon the opportunity gap in education and interrogate their own positionality as equity-minded teachers are better equipped to advance social justice in classrooms. In addition to direct cross-cultural experiences, teacher preparation programs can support the preparation of preservice teachers by broadening their perspectives of family and communities.

This poster will share experiences from a course designed to: (1) develop an understanding of pedagogical practices and educational strategies for successful teaching in the high-need setting, especially in the math classroom; and (2) cultivate both cultural self-awareness and cross-cultural consciousness in one's ability to adapt to the high-need environment in a culturally responsive way. The poster depicts how key assignments have been adapted over time to encourage scholars to interrogate their positionalities toward working with diverse others and advocate for marginalized youth as preservice teachers. The assignments we highlight are: Reflections on the utility of key texts; Early field experiences to diverse high-poverty schools; Making positive parent phone calls; and, Engaging in Critical Reflection practices.

Methodology

Each year of implementation, an external evaluation team from outside the scholarship program and university conducted focus-group discussions with scholars about the course, the program, and their teacher-preparation experience. We analyzed the anonymized focus-group data in addition to course assignment submissions, weekly and final reflections on the course, work samples, and anonymous course evaluations.

Findings

The predominant themes that emerged from course and assignment reflections were scholars' increased awareness of how they might "fit" and be successful within a HNS, a more thorough understanding of the inequities in schools and classrooms, and a clearer vision for how they can advocate for students and a more socially-just school system as an early career teacher. The poster highlights our scholars' voices to show how specific assignments contributed to their future thoughts and actions in HNSs. Overall, the course was influential to scholars' understanding of equity issues in education, as evidenced by their reflections on observations, readings, and experiences with prior alumni. The assignments in the course predominately promoted scholars' introspection and reflection of how they might position themselves to address inequities in HNSs. The voices of our scholars iteratively guided our revisions to the course, alongside our personal growth and professional development as social justice teacher educators.

PRE-SERVICE TEACHERS' CLASSIFICATION AND MODIFICATION OF TASKS

Ji-Eun Lee
Oakland University
lee2345@oakland.edu

Keywords: pre-service teacher education, task modification, cognitive demand

Theoretical Perspectives and Research Question

Effective mathematics teaching calls for engaging students in solving and discussing cognitively demanding tasks that promote mathematical reasoning and problem solving (NCTM, 2014). The cognitive demand of tasks has been categorized by their functional and qualitative characteristics, such as *memorization, procedures without connections, procedures with connections, and doing mathematics* (Smith & Stein, 1998). As the opportunity to learn to develop skills of selecting and modifying appropriate tasks is critical, this study investigates the following question: What types of content and pedagogical knowledge do pre-service teachers (PSTs) demonstrate while engaging in the task classification and modification activities?

Data Collection and Analysis

Four fraction-related tasks were provided to 54 elementary PSTs in a Midwestern University in the US. They were asked to complete the following activities: (a) match them with the levels of cognitive demand, and (b) modify two tasks identified as lower-level to higher-level tasks along with justifications and expected students' responses. For the first activity, frequencies were identified. PSTs' written and drawn work in the second activity were analyzed following the inductive content analysis approach (Grbich, 2013).

Summary of Findings and Implications

PSTs were more successful in identifying lower-level than higher-level tasks — *procedures without connection* (87%), *memorization* (85%), *procedures with connection* (74%), *doing mathematics* (72%). Major modification strategies focused on changing the forms and requirements of the tasks (e.g., incorporating story problems and drawings, requiring to explain, asking to solve in different ways). However, some modifications did not raise the level of cognitive demand (e.g., routine story problems focusing on computations only). This tendency is similar to a prior study, reporting teachers' tendency of selecting tasks according to "surface-level features" (Boston & Smith, 2009, p. 123). Some PSTs' anticipated student responses included false representations or excessively detailed work, which were not included in the task directions. This study suggests that PSTs need to be exposed to various tasks and opportunities to analyze and develop tasks beyond the surface level work. Also, giving proper directions aligned with the purpose of the task is another area PSTs need to learn and refine.

'CONVINCING ARGUMENT' IN THE PROBLEM-SOLVING CONTEXT: PROSPECTIVE 1-8 TEACHERS' INTERPRETATIONS

Marta T. Magiera
Marquette University
marta.magiera@marquette.edu

Keywords: Problem Solving, Reasoning and Proof, Teacher Knowledge, Pre-service Teacher Education

Problem-solving constitutes an important aspect of school mathematics. Little, however, is known about how prospective teachers (PSTs) think about mathematical argumentation in context-rich situations and ill-defined problems that lack a clearly defined solution path or single correct answer. Francisco and Maher (2005) argued that in the context of problem-solving, students could learn the practice of explaining and convincing others of the validity of their ideas and develop skills of critically examining and evaluating arguments and ideas shared by their peers. This research adds to the current efforts to support PSTs in meeting the challenges of fostering argumentation in school mathematics by examining PSTs' interpretations of the term convincing mathematical argument. Prior to negotiating classroom norms for argumentation, we explore (a) *How do PSTs characterize convincing arguments in inquiry-oriented problem-solving contexts*, (b) *How do they judge if an argument is convincing when listening to arguments shared by their peers*, and (c) *What do PSTs perceive as a challenging aspect of writing convincing mathematical arguments in a problem-solving context.*

In this research, a mathematical argument in the problem-solving context is conceptualized as a case for a mathematical claim—a solution to a given problem situation. An argument is interpreted as a product or a discursive practice that leads to discovering new mathematical ideas and convincing oneself or others that the given claim (result) is true (Leitão, 2000). Analyzed were written journal responses completed by 33 grades 1-8 teacher candidates enrolled in a Problem-Solving Course (99 journal entries analyzed). In their definitions of convincing arguments, PSTs addressed the validity of claims, logical flow, clarity of assumptions, and accuracy of mathematical representations. When asked to describe convincing arguments in the context of class discussions and presentations, PSTs characterized convincing arguments by their informative power (i.e., how well they could understand the argument, argument clarity, precision, overall organization, level of details). Some PSTs considered the presenter's confidence as a criterion for assessing convincing arguments. Most of the PSTs reported that deciding on the necessary level of details to make an argument comprehensive is a challenging aspect of generating convincing arguments. The results provide a direction for helping PSTs develop a robust knowledge of mathematical argumentation in teacher preparation programs by revealing PSTs' initial views about convincing arguments in problem-solving contexts.

"I AM GOOD AT MATH WHEN…": PRE-SERVICE TEACHERS' MATHEMATICS EFFICACY BELIEFS

Christine M. Phelps-Gregory	Gabrielle E. Mynatt	Martha Frank
Central Michigan University	Central Michigan University	Central Michigan University
phelp1cm@cmich.edu	mynat1ge@cmich.edu	frank1m@cmich.edu

Keywords: Affect, emotions, beliefs and attitudes, Teacher beliefs, Preservice teacher education

Mathematics self-efficacy is defined as a student's belief about their ability to be successful in mathematics (Bandura, 1986; Zimmerman & Cleary, 2006). Previous research has shown the benefits of high mathematics self-efficacy (believing you are good at mathematics). In particular, self-efficacy affects future performance, persistence, effort, self-regulation, resilience, and success on difficult tasks (Cassidy, 2012; Ruch et al., 2014; Sawtelle et al., 2012; Usher et al., 2018; Holenstein et al., 2021). However, most self-efficacy work has been quantitative, often using Likert scales to assess self-efficacy. This quantitative focus often means we lack understanding of what students mean when they say, "I am good at math." In addition, the work has rarely focused on pre-service teachers (PTs). Do PTs define "good" in ways that align with researchers and their instructors?

Research Question, Design, and Analysis

This poster presents preliminary results from a qualitative study that used journaling to examine PTs' definitions of being "good" at mathematics. This work adds to existing work on PTs' mathematics self-efficacy (e.g., Phelps, 2010; Zuya et al., 2016). Participants in this study were 23 elementary PTs enrolled in a mathematics class for PTs taken before the mathematics methods course. Participants completed two written journal entries on their beliefs, which were analyzed with codes developed inductively; two authors worked together to ensure reliability of the codes following Campbell and colleagues (2013). Future work will examine additional beliefs, such as PTs' beliefs about teaching.

Findings and Implications

Results suggest PTs had a variety of definitions of being "good" at mathematics. Some participants (n = 17, 74%) defined being good at math as applying their skills to new contexts and problems; Olivia said, "A successful learner can apply the concepts to different situations and can solve problems using a bank of different strategies." Other common definitions included being able to explain math to others (n = 16, 70%), getting good grades (n = 13, 57%), being fluid (n = 12, 52%) and working hard (n = 6, 26%). However, there was distinct disagreement among some PTs' definitions; for example, some PTs said being "good" at math meant always getting the right answer but an almost equal number of PTs (n = 11, 48%) expressed doubt that right answers or high grades alone meant you were good at math. Mia said, "The grade that I receive is not always a reflection of how successful I was. I have completed many math courses and received an A without actually mastering the material." Overall, these results, and other data we will share in the poster, suggest that PTs may not define being "good" at math in the same way as researchers, their classmates, or their instructors. This has implications for understanding PTs' mathematics self-efficacy beliefs, in particular, what they may mean when they say, "I am good at math." In addition, this work can help teacher educators understand PTs' future teaching and the goals they will strive for their students to achieve.

A NARRATIVE INQUIRY OF A BEGINNING MATHEMATICS CONTENT INSTRUCTOR

Kelsey Quaisley
University of Nebraska-Lincoln
kquigley@huskers.unl.edu

Keywords: Teacher Educators, Instructional Activities and Practices, Preservice Teacher Education

Learning to teach mathematics for prospective elementary teachers (PTs) is challenging. Mathematics content instructors must be prepared to not only teach mathematics content, but engage PTs in understanding children's mathematical thinking strategies, learning trajectories, and misconceptions (Carpenter et al., 1996; Carpenter & Moser, 1982; I et al., 2020). When considering how instructors might best be prepared and supported however, one must recognize that there is significant variation in the backgrounds and expertise of mathematics content instructors (Masingila et al., 2012; Yow et al., 2016) and little is known about the preparation, knowledge, and experiences of mathematics content instructors (Even, 2008; Goos, 2009; Masingila et al., 2012; Oesterle, 2011; Zaslavsky & Leikin, 2004). Furthermore, most instructors who are newer to teaching PTs do not feel prepared and additionally report an absence of training, resources, and support at their institutions (Goodwin et al., 2014; Masingila et al., 2012; Yow et al., 2016). Mathematics content instructors, especially those newer to teaching PTs, need preparation and support that account for their background and teaching context.

In this poster, I describe a beginning mathematics content instructor's experiences learning to teach elementary PTs in their respective teaching context. Specifically, I aim to draw connections from the instructor's background and preparation to their challenges and successes around teaching and learning to teach mathematics content for elementary PTs.

I view instructor learning as occurring through *interactions* with others, while also occurring through *reflection* and inquiry into one's own practices and the practices of others (Cobb & Bauersfeld, 1995). I further recognize that an instructor's interactions and reflections are inseparable from *context, time, and place*, and are deeply rooted in socio-cultural norms (Gutiérrez, 2008; Lave & Wenger, 1991; Rubel & Nicol, 2020; Vygotsky, 1978). Challenges and successes may offer substantial insight into instructor learning. Since they are embedded in experiences, understanding experience is essential to understanding learning. Hence, I engage in narrative inquiry, drawing on Clandinin and Connelly's (2000) *three-dimensional inquiry space* to make sense of one beginning instructor's experiences learning to teach mathematics for elementary PTs. For one semester, I observed all of the instructor's classes and meetings with other instructors, conducted three interviews with the instructor, collected the instructor's teaching and learning autobiographies, and collected the instructor's weekly reflection journals.

Narrative themes connecting the instructor's contexts to their learning to teach mathematics for elementary PTs will be presented. For example, transitioning from evaluating students' work in introductory-level mathematics courses to students' work in mathematics content courses may present challenges for instructors in mathematics departments. I will discuss stories that resonate or create dissonance with the literature on mathematics content instructor preparation and support, and theories for harmonizing instructors' backgrounds with their current experiences.

We present the development and implementation of Carolina Transition to Teaching, a cohort-based, 18-month teacher residency program focused on the recruitment, preparation, and retention of diverse teachers in rural communities. The significance of this work is two-fold: (a) the dearth of teaching candidates in STEM fields at all levels (Cowan et al., 2016); and (b) the ongoing lack of racial diversity found in teacher preparation programs (King et al., 2016). These factors are situated at a time when states are investing less in higher education (Mitchell et al., 2019), leading to the need for innovative approaches alongside more traditional pathways. In this poster we highlight the deliberate interplay of recruitment, preparation, clinical practice, and attention to certification requirements that lead a master's degree and state teaching licensure.

Through a U.S. Department of Education Teacher Quality Partnership (TQP) grant, a flagship university in the Southeastern part of the U.S. developed a teacher residency program with two partner districts located in rural communities. A Network Improvement Community, Carolina Transition to Teaching, including university-based faculty and staff from the College of Education, external evaluators, and district representatives, used systematic methods of inquiry within an improvement science approach (Bryk et al., 2017) to explore and inform implementation as well as to analyze ongoing and retrospective findings as a mechanism for programmatic refinements.

A goal of the Carolina Transition to Teaching residency program is to diversify the professional pipeline to include individuals with a bachelor's degree who are currently working within our partner districts as paraprofessionals or long-term substitute teachers as well as career changers from rural communities. Built upon research-informed components of teacher residencies (e.g., Guha et al, 2017), the structural components of the Carolina Transition to Teaching residency program include: (a) providing a minimum living wage stipend; (b) yearlong practicum in classrooms within partner schools, (c) multiple layers of support through coaching and ongoing professional development; (d) graduate coursework; (e) completing a series micro-credentials to satisfy teacher certification requirements, and (f) induction support during the first three years of classroom teaching.

The initial findings are promising for our recruitment and preparation efforts. For instance, one goal of the Carolina Transition to Teaching residency is to support and prepare teachers while diversifying the workforce within rural districts; through our two rounds of recruitment and preparation, 87% of our participating residents (N=23) self identified as African American or Black, and 17% self identified as male. These data stand out as only 21% of the new teachers in our state identify as non-white and 19% identify as male. Further, 100% of the residents range from 30-70 years old, bringing with them a wealth of knowledge to their residency experiences. As we continue to analyze our research efforts to recruit, prepare, and support the residents in the program, we will share additional findings related to supporting our two cohorts who are or will be practicing teachers in classrooms within our partner school districts.

Teaching with *mathematical action technology* (MAT) is a complex practice (e.g., Lagrange & Monaghan, 2009; Lee & Hollebrands, 2008) that requires attention to learners' thinking and to the role of MAT in supporting productive discussions. McCulloch et al. (2021) found that few teacher preparation programs provide opportunities for prospective teachers (PTs) to engage in implementation of MAT tasks. One way to support PTs in developing complex teaching practices is through the use of teaching rehearsals (Kazemi et al., 2016). To provide PTs an opportunity to engage in the implementation of MAT tasks, we implemented rehearsals focused on orchestrating whole-group discussion of MAT tasks in secondary mathematics methods courses.

Rehearsal is a pedagogy that provides opportunities for PTs to approximate teaching practice (Grossman et al., 2009) with peers in the role of learners, in a space that allows for reflection and growth (Kazemi et al., 2016). In rehearsals, PTs learn to implement pedagogical practices and tools to support learning. Mathematical action technologies are technology tools that allow learners to engage with mathematical objects in a dynamic way as they explore mathematical concepts and make sense of mathematical relationships (Dick & Hollebrands, 2011).

In three secondary mathematics methods courses at three different institutions, we implemented a rehearsal cycle with 20 PTs in Fall 2021. Prior to the rehearsal cycle at all three sites, PTs read about MATs (Dick & Hollebrands, 2011), considered ways in which MATs could serve as amplifiers or reorganizers (Sherman & Cayton, 2015), and discussed ways in which MATs might be enacted (Drijvers et al., 2010). PTs were then required to select, create, or adapt an existing MAT-based lesson using Desmos or Geogebra for use in a rehearsal in which the focus was class discussion of a mathematical concept. The rehearsal cycles included video-recorded enactment of the discussion and a debrief following a viewing of the videos to support reflection. Common data collection included a pre-rehearsal planning survey, videos of the enacted rehearsals, peer rehearsal feedback forms, and a post-rehearsal reflective survey.

Preliminary analysis of the data shows that combining the pedagogies of rehearsals with the use of MATs is a plausible way to fill the gap in mathematics teacher preparation noted by McCulloch et al. (2021). Rehearsals can be used to engage PTs in thinking about decisions they make while integrating MATs in their lesson design and teaching. Findings show PTs felt that this was an authentic experience that helped to grow their thinking about teaching with technology. One PT commented on the experience saying: "it was very helpful to be able to rewatch the video, pause, reflect, and then continue. This allowed for thoughtful, extended critical thinking for our responses." Analysis will continue so as to determine the specific ways in which this pedagogy informs teacher preparation. In this poster, we seek to share findings from our ongoing data analysis.

A CASE STUDY EXAMINATION OF THE RELATIONSHIP BETWEEN PRE-SERVICE TEACHERS' NOTICING AND QUESTIONING

Christine Phelps-Gregory
Central Michigan University
phelp1cm@cmich.edu

Sandy Spitzer
Towson University
sspitzer@towson.edu

Keywords: Preservice Teacher Education; Teacher Noticing; Technology

Mathematics teacher educators and researchers have proposed that a critical knowledge domain for prospective teachers (PTs) is *professional teacher noticing of student mathematical thinking*, often referred to simply as "teacher noticing." Emerging research suggests that teacher noticing supports both high-quality mathematics teaching in the short term (e.g., Jacobs et al., 2010) as well as long-term growth in teacher expertise (Santagata, 2011). Further, research suggests that teacher noticing might also be associated with high quality teacher questioning (Weiland et al., 2014). However, more research is needed to better understand the relationships between teacher noticing and questioning and how these skills support each other.

Research Question, Design, and Analysis

In this poster, we present results from a larger study in which PTs (n = 18) conducted a simulated interview, focused on geometric thinking, with an AI chatbot named "Matilda" (which had been programmed based on children's responses). Previously, we analyzed PTs' questioning patterns in the interview (Spitzer & Phelps-Gregory, 2021). After the interview, PTs wrote an essay describing Matilda's knowledge (including misconceptions) about quadrilaterals, interpreting the evidence and identifying her van Hiele level, and describing what Matilda's teacher should do next. PTs' essays were analyzed in terms of the three domains of teacher noticing, *Attending*, *Interpreting*, and *Deciding* (Jacobs et al., 2010). We then categorized PTs as having either high, medium, or low noticing skills and qualitatively analyzed for differences in their questioning patterns.

Findings and Implications

Our emerging findings suggest that teacher questioning is critical to eliciting the kinds of student mathematical responses that teachers can use as evidence in their noticing. During their interviews, PTs with stronger noticing skills asked more open-ended questions (e.g., "What is shape 2?") and less leading questions (e.g., "Is shape 2 a rectangle?"). In contrast, PTs with weaker noticing skills appeared to struggle to find the right questions to diagnose Matilda's thinking, asking more questions overall and more restatements of previous questions.

Several cases from our data help illustrate these findings. For example, Abigail used a productive questioning pattern, starting with asking "What is shape 2?" When Matilda called it a diamond, Abigail asked multiple follow-up questions, such as "What is a diamond?" In her essay, Abigail focused on the answers to these questions to provide strong evidence for her appropriate diagnosis of student thinking. In contrast, Brianna used many leading questions, such as "So is shape 2 a rectangle?" Brianna asked less follow-up questions than Abigail and, when Matilda named the shape a diamond, responded with "If it is a square, doesn't that also mean it is a rectangle?" In Brianna's essay, she inappropriately cited this exchange as evidence that Matilda had learned. In this poster presentation, we will present these and other cases that exemplify the relationships between questioning and noticing. This has implications for teacher educators in helping PTs develop both the critical skills of noticing and questioning.

Keywords: Self-Efficacy, Design Based Research, Mathematics Education, Pre-Service Teachers

Mathematical modeling is the process of interpreting real world situations with the use of mathematics. The benefits to students when they engage in mathematical modeling include developing reasoning abilities, entrepreneurial thinking, and conceptual understanding of mathematics and other relevant contents (Blum & Niss, 1991; Lesh et. al, 2000; Zbiek & Conner, 2006). It is recommended that preservice teachers' (PSTs) learn mathematical modeling to engage their future students with authentic problem-solving experiences (Association of Mathematics Teacher Educators, 2017). However, research is needed in the area of such learning opportunities and in the area of learners' perspectives while responding to working through mathematical modeling (Asempapa & Sastry, 2021).

This study investigates the effects on PSTs self-efficacy from engaging in a mathematical modeling task. Self-efficacy is defined as "judgements of their capabilities to organize and execute courses of action required to attain designated types of performances" (Bandura, 1986, p. 391). According to Bandura (1986), motivation and behavior influence each other, and through interventions and strengthening these beliefs can increase academic achievement. While much research has involved learning opportunities in mathematical modeling, the importance of teacher's self-efficacy in continuing the practice needs to be explored.

Using design-based research, the three authors worked with PSTs on a modeling task involving two parts: (1) the design of a classroom and (2) the development of a rating or ranking system of the classroom design. The first part of the modeling aimed to use both two- and three-dimensional concepts in geometry for elementary grades, while the second part was designed to compare the classroom designs, as well as learn how involved a grading system is implemented. This modeling task was employed over a course of four classrooms: three undergraduate classes, and one graduate class of students all enrolled in an elementary mathematical content and methods course. With the third author enacting the first iteration of the task, we then revised the lesson, and used the task again in three other classrooms: two undergraduate classrooms with the first author, and one graduate class with the second author.

Coding reflective journals from the PSTs, we utilized Bandura's (1994) four main sources of influence: mastery experiences, vicarious experiences, social (or verbal) persuasion, and somatic and emotional states (pp. 2-3) to guide our analysis. Preliminary results indicate an overall increase in PSTs self-efficacy from this modeling task, in part due to the nature of the task, collaborative efforts of their classmates, with the instructors as a facilitator in the modeling task. In our poster session, we will illustrate the sources of influence on self-efficacy and its connection to specific aspects of the mathematical modeling task. We will also look at the differences between the three authors enacting the mathematical modeling task and highlight general themes from the reflective journals relating to the PSTs self-efficacy.

Keywords: Research Methods; Teacher Beliefs; Preservice Teacher Education

Purpose

This poster summarizes findings from a review of the literature on teacher identity formation. Through this summary, we aim to explore the different methods and theoretical frameworks used by researchers in their teacher identity work. We will discuss strengths and weaknesses of these methodologies, how different methods and frameworks may fit together, and ultimately how they fit with mathematics teacher identity research.

Summary of Methodologies and Theoretical Frameworks Reviewed

Identity is complex with socially formed multiple identities that continue to grow and develop over time (Akkerman & Meijer, 2011; Beauchamp & Thomas, 2009; Chung-Parsons & Bailey, 2019; Ruohotie-Lyhty, 2013). A majority of the studies reviewed employed qualitative methodologies including interviews, narratives, and reflections. Through these qualitative methods, researchers focused on how preservice teachers perceive the teaching profession and how their lived experiences affect their beliefs of teaching (Cross & Hong, 2012; Losano et al., 2018; Pillen et al., 2013). In addition, implementing interviews, narratives, and reflections within the practice of preservice teachers afford students opportunities to reflect and reevaluate the influence their own lived experiences have on their mathematics teacher identities. Along with narratives and reflections, autoethnography has been utilized as a self-reflective cultural narrative, which requires the author of the narrative to reflect and analyze experiences to understand culture and the impact it has on identity, both a process and a product (Anderson, 2006; Austin & Hicky, 2007; Duarte, 2007; Ellis et al., 2011; Hains-Wesson & Young, 2017; Hamilton, 2021; Pinner, 2018; Yung, 2020). While most studies utilized qualitative methods, there were a couple that used quantitative methods including surveys or questionnaires (Harvath et al., 2018; Hong, 2010). Each of these methods bring different strengths and weaknesses into the study of teacher identity in answering different research questions.

Studies examined have also utilized different theoretical frameworks to analyze identity formation within teacher education, for this poster we will highlight three. The first being Gee's four views of identity: Nature, Institution, Discursive, and Affinity (Carrier et al., 2017; Tsybulsky & Muchnik-Rozanov, 2019), another is the two-dimensional Cognitive Process model (Sutherland et al., 2010), and finally, Bronfenbrenner's Ecological System (Cross & Hong, 2012). Each of these frameworks were used to analyze the different experiences, feelings, and/or environments impact on teacher identity formation and were chosen as highlights for this poster given their perceived potential to incorporate autoethnographic activities within each framework. We layout the main structure and ideas in each of these frameworks in order to highlight strengths and weaknesses within teacher identity research as well as their potential to specifically focus on *mathematics* teacher identity.

Keywords: Culturally Relevant Pedagogy; Equity, Inclusion, and Diversity; Preservice Teacher Education; Teacher Noticing; Productive Struggle

Preparing prospective elementary and middle school teachers for the diverse classrooms in which they will teach is of critical importance (AMTE, 2017). Learning to notice children's mathematical thinking and their cultural funds of knowledge provides teachers with opportunities to leverage these student resources to support students equitably and inclusively in their classrooms (Turner & Drake, 2016). The use of videos to support teachers' professional teacher noticing skills and practices has been well documented (Jacobs et al., 2010; van Es, Cashen, Barnhart & Auger, 2017). As part of a larger study, we focus here on salient features of the video selection as considerations in supporting prospective teachers' (PSTs) development of noticing skills specific to student thinking, and the use of cultural funds of knowledge to support productive struggle.

Purpose

While research suggests that productive struggle is an important component of learning mathematics (Hiebert & Wearne, 2003; Hiebert & Grouws, 2007), supporting productive struggle in the classroom remains challenging for teachers to implement (NCTM, 2014; Warshauer, 2015). Thus, we explore specific features of video selections designed to support PSTs understanding of noticing and productive struggle while also drawing their attention to equitable teaching practices that support children's Multiple Mathematical Knowledge Base [MMKB] (Roth McDuffie et al., 2014; van Es, E., Hand, V., & Mercado, J. 2017).

Methods

The study included 40 PSTs enrolled in their final mathematics content course for elementary teachers. They completed three writing assignments with prompts incorporating frameworks on Noticing, Productive Struggle, and MMKB (Jacobs, et al., 2010; Author, 2015; Roth McDuffie et al., 2014) to reflect on and analyze video episodes of productive struggle and the teachers' use of MMKB in the classroom interactions. The video episode selection criteria were based on the presence of: Interaction type, Mathematical content, Productive Struggle, and MMKB.

Results and Implications

We report the specific dimensions considered including the type of interpersonal interaction present (e.g. 1-1 student and teacher interaction or whole class discussion lead by teacher), the difficulty of mathematical content (level of cognitive demand related to PSTs class learning), level of productive struggle, and the complexity of noticing required (inclusion and emphasis on

MMKB). Selection, progression, and use of videos with these dimensions can add an equity lens towards PSTs viewing a more socially just context for learning and teaching mathematics.

INVESTIGATING SECONDARY PRESERVICE TEACHERS' MATHEMATICAL CREATIVITY DURING PROBLEM SOLVING

Anne N. Waswa
University of Georgia
Anne.Waswa@uga.edu

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

Understanding and supporting preservice teachers' (PSTs') mathematical creativity (MC) is important to encourage their teaching with and for mathematical creativity. Research on MC with a focus on teachers has mostly been concerned with in-service and pre-service teachers' conceptions of MC (e.g., Andrade & Pasia, 2020; Beghetto, 2007; Bolden et al., 2010; Lev-Zamir & Leikin, 2011;2013, Shriki, 2010; Author 1, 2019). We extend this line of work by investigating PSTs' MC *as they engage* in problem solving in the context of quadratic and linear growth. The purpose of the study was to investigate the components of MC that are evident when secondary PSTs engage in problem solving including how these components relate to their mathematical meanings for quadratic and linear growth. Participants included three secondary mathematics PSTs at a university in the Southern part of the US. Data were collected using teaching experiment (Steffe & Thompson, 2000) and analyzed using ongoing analysis and retrospective analysis (Steffe & Thompson, 2000).

We adopted Lithner's (2008) framework for creative and imitative reasoning. The framework's criterion for MC includes *novelty* (developing a new sequence of reasoning or re-creating a forgotten one), *flexibility* (using multiple approaches fluently and adapting to new situations), *plausibility* (arguing for ones' choice and/or implementation of a strategy), and *mathematical foundation* (anchoring arguments in the intrinsic mathematical properties of the components entailed in reasoning). We leveraged literature on quantitative and covariational reasoning, (e.g. Carlson et al., 2002; Ellis et al., 2020; Author 2, 2013; Author 2 & Thompson, 2015; Paoletti & Author 2, 2017; Saldanha & Thompson,1998; Thompson, 2011; Thompson & Carlson, 2017) which means attending to the manner in which quantities change together, and specifically coordinating first- and second-differences in quantities. We used the fundamental principles of radical constructivism (von Glasersfeld, 1995) to drive and form the kinds of descriptions that we provide regarding PSTs' mathematical creativity.

PSTs' meanings for linear growth included: constant first differences in the dependent variable with uniform changes in the independent variable and constant rate of growth. Their meanings for quadratic growth included: constant second differences in the dependent variable with uniform changes in the independent variable, increasing rate of growth (constant amount in which the addition increases each time), and conceptualizing quadratic growth using first and second derivatives to describe rate of change and the difference in rate of change respectively. *Novelty* and *flexibility* were evident in PSTs' conceptualizations of linear and quadratic growth through their use of multiple approaches and representations such as tables, graphs, and equations to elaborate these meanings. However, one PST experienced perturbations with the *plausibility* and *mathematical foundation* in terms of her quantitative organization in conceptualizing linear and quadratic growth. Initial findings of this emphasizes the development of conceptual meanings beyond multiple representations to show linear and quadratic growth and leveraging quantitative and covariational reasoning through task design and questioning to develop PSTs' meanings for quadratic and linear growth and support PSTs' MC.

CHARTING A VIABLE LEARNING TRAJECTORY FOR THE DEVELOPMENT OF PRESERVICE ELEMENTARY TEACHERS' UNDERSTANDING OF HIERARCHICAL GEOMETRIC RELATIONSHIPS

Ian Whitacre

dcarorora@fsu.edu

Keywords: Communication, Geometry and Spatial Reasoning, Learning Trajectories and Progressions, Preservice Teacher Education

Scarce literature focuses on PSTs' reasoning related to hierarchical geometric relationships (Browning et al., 2014). Some articles address ways in which PSTs' reasoning has not measured up to researchers' expectations: Researchers find that PSTs have difficulty defining shapes inclusively, exhibit "misconceptions" (Pickreign, 2007), and rely on "personal figural concepts" (Fujita & Jones, 2007). Such findings provide baseline data but do not illuminate a path forward.

In a report of an intervention study, Yi et al. (2020) offer evidence that PSTs' knowledge of geometry can improve significantly over a three-week period. Their description mentions instruction on hierarchical relationships but does not elaborate. The assessment included items involving properties and relationships, focusing on quadrilaterals, but did not address particularly challenging aspects (e.g., categorization of trapezoids). Brunheira and da Ponte (2019) report on a teaching experiment focused on classification of quadrilaterals and then of prisms. An example that they provide of a student's work (their Figure 11) involves what seems to us to be two very different interpretations of Venn diagrams. This distinction is left unexplored. The authors report progress in PSTs' reasoning but also lingering difficulties, and they suggest the need to explore "other factors" beyond those identified in the framework of Fujita (2012), which is based on Van Hiele levels. They refer to such factors as "language interpretation and logical reasoning" (p. 80).

Overall, the literature leaves us with unanswered questions. It does not provide insights into PSTs' geometric reasoning, nor does it document viable learning trajectories for the development of that reasoning (Browning et al., 2014). We believe a key to understanding PSTs' reasoning and supporting their learning related to hierarchical geometric relationships lies in those aforementioned "other factors" that we have not seen explored in the literature to date.

Focusing on PSTs' reasoning about relationships among quadrilaterals, we are charting a viable learning trajectory (Simon, 1995) consisting of two intertwined strands: (a) interpretation and use of language and representations concerning hierarchical relationships and (b) reasoning about properties and relationships. In the first strand, progress is afforded by the development of shared language, most notably to distinguish two ways of using and interpreting Venn diagrams ("set–subset" and "similarities/differences"). Related to the second strand, PSTs explore and discuss relationships in sequence (rectangle–square, parallelogram–rhombus, etc.) with the help of dynamic geometry software. These activities, together with analogies to other contexts (e.g., relating the relationship between rectangles, rhombi, and squares to that between mint ice cream, chocolate chip ice cream, and mint chocolate chip ice cream), appear to support progress in PSTs' distinguishing between inclusive and exclusive definitions, reasoning inclusively about hierarchical relationships, and identifying overlapping sets, leading to the ability to construct "one big diagram" representing a hierarchy of quadrilaterals. Given the contrasting ways of using and interpreting language and diagrams at the beginning of the unit, this is a nontrivial feat. Our ongoing work documents the development of PSTs' reasoning about hierarchical relationships by working from their prior knowledge with an emphasis on communication. It has yielded insights that clarify for us PSTs' reasoning and enable us to articulate a learning trajectory.

Chapter 12:

Professional Development and In-Service Teacher Education

USING VIDEO TO IDENTIFY WHAT IS NOT KNOWN IN STUDENTS' MATHEMATICAL THINKING

Madhuvanti Anantharajan
Stanford University
madhuvan@stanford.edu

Michael Jarry-Shore
Boise State University
mjarryshore@boisestate.edu

Remaining continually curious about students' mathematical thinking is challenging, yet worthwhile, in teaching practice. This paper describes and analyzes two video-based professional learning (PL) activities designed to help teachers go beyond their initial perceptions of what students understand and to identify what else they might learn about students' thinking. The findings suggest the potential of the activities to evoke different types of curiosity about student-thinking and the conditions that may support such questioning.

Keywords: Student-thinking, teacher-curiosity, professional development, early mathematics

Uncovering students' mathematical thinking is accepted as an important part of ambitious mathematics teaching (Lampert et al., 2013). However, the emphasis on immediacy in the classroom often results in teachers lacking the time to be curious about students' thinking and to understand all that is there. Teachers may also not know what else to look for or be curious about when a student seems to understand certain mathematical ideas well. In other words, teachers may not attend to what they themselves do not know about students' thinking. Both these cases may result in teachers paying less attention to student-thinking than needed and responding before having given adequate attention to such thinking. In these challenging situations, it is important for teachers to slow down their own thinking and be curious about the details of students' thinking.

This paper describes two video activities designed to help teachers slow down their own thinking regarding students' mathematical ideas, and support teacher-curiosity about students' mathematical thinking when counting. The first activity helped teachers identify what they could learn about a student's thinking when the student's understanding of early number concepts appeared unclear, and the second helped teachers identify how they might extend what they knew about a student who appeared to have a strong understanding of the concepts involved in the activity. The activities are based on the construct of teacher-curiosity (Anantharajan, 2020) and were part of a professional learning (PL) module designed to support teachers' curiosity about student-thinking.

Literature review and conceptual framework

This study is theoretically based on the approach of Cognitively Guided Instruction (CGI) (Carpenter et al., 1996) and the framework of teacher-noticing of student thinking (Jacobs et al., 2010), which prioritize attending to student-thinking, and using it to determine how teachers can respond to students. The steps involved in these approaches are translated to questions that guide teachers to notice, interpret and respond to student thinking. However, skilled noticing does not automatically help teachers figure out how to respond (van Es & Sherin, 2008). In this context, the framework of teacher-curiosity suggests one way for teachers to respond by introducing specific intermediate steps to help teachers identify what they wish to learn about student thinking, and how they can find out about that aspect of their students' thinking, thus providing a concrete way to move from noticing to responding.

Teacher-curiosity is defined as follows: An instance of teacher-curiosity is one where teachers recognize something as unknown, unfamiliar, puzzling, uncertain, or new in the context of teaching and learning, and feel motivated to initiate inquiry into that instance (Anantharajan, 2020). This conceptualization of teacher-curiosity is based on literature in teacher professional learning, and mathematics education, and understandings of curiosity in philosophy and psychology. Teacher-curiosity is comprised of cognitive, motivational, and active aspects (Audi, 1995, 2017). The cognitive aspect of teacher-curiosity involves an experience of dissonance, not knowing, or confusion and can include surprise, ambiguity, puzzlement, or novelty (Berlyne, 1966; Kashdan, 2004; Lowenstein, 1994) about student-thinking. The motivational aspect addresses the desire to learn more about those aspects of student-thinking that the teacher finds surprising, ambiguous, puzzling, or new, that the teacher wants to learn more about. The active element of teacher-curiosity refers to how teachers go about trying to learn about aspects of student-thinking they are curious about.

Teacher-curiosity can be directed towards many aspects of instruction, including students' thinking. When teachers' curiosity is directed at something they observed or experienced, it may be regarded as 'specific'. For example, if a student counts and says a total number that is one more than the actual total, the teacher may wonder "Did this student count an object twice by mistake or do they not know their number sequence?" While it may relate to understanding a particular instance, specific curiosity may not always be satisfied by information from that instance itself. For instance, in the preceding example, a teacher observing the student in real time would be unable to re-watch the student count. However, they may design other activities or questions to answer the question. When what teachers observe or experience evokes curiosity about something that was not immediately observed or experienced, their curiosity may be regarded as 'diversive.' For example, a teacher may see a student group objects by five and wonder what other numbers the student can group by (Grossnickle, 2016).

The PL at the heart of this study focused on teachers' curiosity about children's mathematical thinking in the domain of counting. Counting involves *counting principles* like one-to-one-correspondence, number-sequence, and cardinality, as well as an understanding of counting *strategies* like grouping (Carpenter et al., 2017).

The current paper focuses on the cognitive aspect of teacher-curiosity. The PL activities were designed to surface the range of potential ideas in student-thinking that teachers could be curious about. Prior work on noticing has focused on identifying what students know and are able to do (Jacobs et al., 2010). The goal of the video activities and corresponding instruments analyzed here was to shift the focus away from determining what students know and can do, to what the teacher-participants *did not* know about what students knew. Approaching children's thinking in this way was intended to provide a starting point to take a stance of curiosity, rather than one of certainty, about student-thinking. The research question addressed here is: How do two video-based PL activities help participants identify what they do not know about students' mathematical thinking?

Methods

The PL focused on Counting Collections. In this activity children count collections of objects. Teachers observe students and ask them to explain their strategies and try to understand students' thinking. The study had six participants. They taught grades TK[1] to 1st grade in three

1 Transitional kindergarten (TK) in the California public school system includes 4-year-olds who turn five after September 2 of the school year, and will enter kindergarten the following year.

schools in California, and four of these participants taught combined K-1 classrooms. They had worked as teachers for between 1 and 20 years, and all of them implemented Counting Collections prior to the PL as well. The PL was informed by research on teacher-learning (Borko et al., 2014; van Es & Sherin, 2008) and supporting curiosity (Kashdan & Fincham, 2004), and was facilitated by the first author. The entire PL comprised of six, weekly after-school sessions of 90-minutes each. Sessions included video-based discussions that were guided by the teacher-curiosity framework. Participants were individually interviewed before and after the PL using a protocol that operationalized the teacher-curiosity framework. The participants were paid a nominal honorarium for their time.

The current paper analyzes participant responses to two video-based activities in the second session of the PL which focused on identifying what is unknown, and therefore possible to be curious about, with respect to student-thinking. Guidelines on planning video-based professional development for teachers (Borko et. al 2014), a framework of criteria for choosing videos portraying students' mathematical thinking (Sherin et al., 2009) and empirical guidelines for interventions to support curiosity (Kashdan & Fincham, 2004) informed the selection of video-clips. Each video contained elements that could potentially push teachers to examine what is and is not known about students' thinking. Each brief video was of a student engaged in a counting activity and who was of a similar age as those the teachers taught. Participants responded individually to instruments developed for these specific video activities. The data analyzed in this paper consist of the responses to these two instruments (Table 1). For this activity the participants were given a research-based list of counting principles and strategies they could refer to as they watched and commented on the student videos.

Video 1: Christian Counts Bears

The purpose of this activity was to draw participants' attention to the unpredictable and the unexpected in students' thinking. The activity was structured in four steps: Provide partial information about student-thinking; invite participants' prediction based on the partial information; provide more information that might be surprising to participants and have participants assess their prediction; and finally, have participants identify what they now do not know about the student's thinking. The conjecture was that participants would want to know what might explain any gaps between their prediction and what the student actually did.

Table 1: Christian Counts Bears Instrument

Questions
[Video paused]
1. Based on what you have seen, what do you expect Christian might do or say next?
2. Why would you expect that?
[Video resumes]
3. Did you see what you expected? [If not, what was different?]
4. Based on this video, what do you not know, or what could you try to find out about Christian's thinking?

In this video, the student, Christian, is seated at a table and a researcher gives him several plastic bears to count. The researcher asks Christian to count all the objects together, count objects by color, and compare the size of different color groups. Christian's counting initially suggests that if objects were to be added to his collection, he would count the entire collection again to find out the total number, rather than remembering how many he previously counted and counting on from there. At one point in the video, the researcher adds more objects to Christian's collection and asks how many he has in total. In the PL, the video was paused just prior to this point and participants were asked to predict in their response instruments (Table 1) what Christian might do next, based on what they had seen so far. The participants then saw the rest of the video, where he seems to count on mentally and says the new total number. Asked how he knew, he explains that he held the previous total in his mind, started to count mentally from the next number and arrived at the new total. This ability was not apparent in the preceding part of the video. Participants were then asked to note whether he did what they had predicted. Finally, participants were asked to reflect and identify what they felt they did not know about Christian's mathematical thinking.

Mohammad Counts Cookies

The purpose of this activity was to explore what else there may be to learn about a student whose understanding is both strong and visible. Unlike the previous activity, here the participants were shown the whole video. They were then invited to propose informed conjectures of what remained unknown but relevant based on the information in the video.

In this video, the student, Mohammad, is seated at a table with a researcher. The researcher asks him to imagine that he has three boxes with five cookies in each. He is then asked how many cookies he has in all. The researcher provides Mohammad a set of blocks which he uses to help him count. He first places three yellow blocks side by side. These may represent the boxes although he does not say so, because he does not count these yellow blocks going forward. On each yellow block he stacks five blocks of other colors. He then counts the first two stacks as 5 and 10. Then he counts on the remaining five by ones. He says that he has fifteen cookies in all. In the video he devises a clear counting strategy and explains his thinking without apparent difficulty. This video gave participants the opportunity to reflect on what they might learn about a student who did not indicate any confusion or struggle. The instrument for this activity had only one question that participants responded to after watching the whole video: Based on what you see in the video, what could you try to find out about Mohammed's thinking?

Coding and Analysis

The data was coded for the type of curiosity that participants expressed, and the mathematical principles and strategies that the participants mentioned in their responses. The responses were also coded for whether participants perceived a strong or partial understanding of the principle or strategy (Table 2). Additionally, for the first video, the analysis also looked at participants' statements about whether or not Christian did what they had predicted.

Inter-rater agreement was calculated with Kappa statistics at the parent and child code levels, and discussion and consensus at the grandchild code level. The Kappa value for the parent and child codes ranged from 0.7-1.0. Agreement values were calculated for the pre- and post-interview transcripts[2]. This instrument and data set operationalized all the elements of the teacher-curiosity framework and was a reliable indicator of the types of responses in more activity-specific instruments like the video response tool that operationalized only the cognitive aspect of teacher-curiosity. After reaching agreement on the interview data the two coders discussed the data from all other instruments, including the instruments analyzed in the current paper to confirm that the

2 In these interviews participants watched a video and responded to questions based on the teacher-curiosity framework, as well as broader questions on the role of curiosity in their own work. The codebook used in the present study corresponds to the questions in the interviews and the elements of the framework.

codebook could be applied to these data as well. The kappa calculations mentioned above were thus for data sources (i.e., interview transcripts) not the focus of this study, but mentioned here because coding those was necessary to developing the codebook used here. Disagreements were discussed to reach consensus.

Table 2: Codes Applied

Type of curiosity	
Specific curiosity	Participant is curious about something that they observe a student do or say.
Diversive curiosity	Participant is curious about something a student might do or say, which they cannot observe at that time.
Mathematical ideas that participants perceive in students' thinking	
a. Counting principles	Principles teachers perceive as constituting child's understanding of counting. (Carpenter et. al. 2017, NRC 2001) Includes: • One-to-one correspondence • Cardinality • Number sequence • Abstraction principle • Order irrelevance • Other principles or concepts (e.g., number conservation, operations, base-ten system, place value).
ai. strong understanding	Teacher implies the child has a comfortable/ fluent/ consistent understanding.
aii. partial understanding	Teacher implies the child is working on understanding, or that the child's understanding is not always consistent.
b. Counting strategies	Strategies children use to count objects. Includes: • Grouping by number • Strategies to keep track • Sorting based on non-numerical qualities • Visual arrangements • Associating number with object • Other strategies
bi. strong understanding	Teacher implies the child has a comfortable/ fluent/ consistent understanding.
bii. partial understanding	Teacher implies the child is working on understanding, or that the child's understanding is not always consistent.

Table 3. Sample of Coded Responses

Question	Bella	Codes	Beth	Codes
2. Why would you expect that?	*He understands that he can touch each one & count it out loud.* *He does not seem to count on.*	ai. One-to-one correspondence; strong understanding bii. Counting on; partial understanding	*He doesn't seem to be keeping track or counting on as he is answering the questions.*	bii. Keeping track and counting on; partial understanding

The responses for each instrument were organized into a single table where each row represented a question in the instrument and each column represented a participant. Thus, all the participants' responses were visible side-by-side. The first author then coded the responses for the mathematical ideas that the participants refer to. Table 3 indicates a sample of two participants' responses to question 2 and the codes applied to Christian Counts Bears.

Results

The coded data indicated multiple patterns. The results for each video are discussed below.

Christian Counts Bears

After watching the first portion of the video, five of the six participants predicted in their written response that Christian would recount the entire collection. This was consistent with what they had observed until that point, where Christian tended to count all the objects each time objects were added. One participant wrote that he would count on from the previous total he counted, if he could remember the total. Four of the six participants also wrote that they expected that Christian would not arrive at the correct total number of objects after counting the final time.

Five participants said he did not do what they expected – in other words, they said their prediction was not correct. One said she had expected that if he counted on he would begin at 14 but he began at 16, and in this sense he did not do what she expected. The aspect of Christian's counting that surprised the participants was his ability in the second portion of the video to count on from a number he held in his mind. This aspect of counting on is what all participants said they could learn more about. For example, Lillian stated in her response, "I would ask him to show me how he counted them all together by adding on" and Hannah stated, "We know he can do the basic idea of counting on. We don't know if he can do it accurately."

Three participants also identified an additional mathematical idea that they wanted to look for and learn about in the student's thinking, namely addition. Bella wondered "Can he add bigger numbers together? What can he add together in his head?"

The participants all expressed two types of curiosity about Christian's thinking. On the one hand, they wished to know more about things that would help explain why he had counted on, and why their own predictions were not accurate. For example, Beth stated, "I would like to find out how high he can count with one-to-one correspondence. (When he counted the 12 bears, he did not have one to one)." The other type of questions were related to what else Christian knew or could do as a kindergartener, or related to the general body of ideas related to number and counting. For example, Stacey wondered, "Would he be able to add together 2 smaller groups of bears?" In summary, the participants used what they had seen upto the point the video was paused to predict Christian's future moves and discovered that their prediction was not accurate. Rather, participants found that Christian's understanding and skills were more complex and advanced than they anticipated. Consequently, participants perceived that there were aspects of his thinking that they did not know about and identified what they could learn about his thinking.

Mohammad Counts Cookies

In their responses after watching the entire video of Mohammad, all the participants went beyond Mohammad's 'correct answer' and identified further aspects of his thinking they could try to learn about. All the participants attended to the details of what they saw Mohammad do and posed questions about what he understood. Lillian wondered if he could subitize the quantity of five blocks. Bella said she would ask him to explain his strategy for "figuring out 15."

The participants all wondered if Mohammed understood how to count by groups of 5 or 10. This ability to skip count or count by grouping can be seen as a precursor to multiplication and the participants may have wanted to determine this before exploring multiplication with him. For example, Hannah wondered, “Can he count by 5s? if there were 25 would he count on starting at 11 still? Or would he make groups of 10? Count by 5s?”

Without a particular element of surprise or dissonance evoked by the video, the types of questions that participants posed were of two types. The first was to clarify aspects of what they saw him do. The questions posed by the participants also make clear that despite completing the task with apparent confidence and giving the right answer, there were aspects of what the student did in the video that were not clear and thus possible to clarify. For example, Beth stated, “He was good at counting on. I would like to know more about how he keeps track.” The other type of questions that participants posed had to do with related mathematical ideas that they could explore with the student, to find out what else he understood and to what extent. For example, Rita wrote, “I could try to find out what he knows about 10s. [Can he] use a 10s frame?” In summary, the participants identified aspects of Mohammad’s thinking that were related to what he was able to do but were not apparent in the video.

Discussion

This paper looks at how two video-based activities helped participants in a PL identify what they could further learn about students’ mathematical thinking. The experience of the participants in the two activities was quite different. For the Christian Counts Bears video, participants were likely curious about what was unknown because of the nature of the video the facilitator chose, the way the viewing of the video was structured (i.e., pausing at an opportune time), and how inviting predictions required participants to process the information they had up to that point. These steps appeared to seed dissonance and give rise to participants’ puzzlement. The dissonance or disequilibrium that resulted from participants predicting what the student could do then finding out that the prediction was not accurate likely evoked participants’ questions about what more they could learn. It was also striking to note that the participants readily stated that the student did not do what they predicted, which indicates a certain humility and openness on the part of the participants to revise their thinking. It also potentially suggests that the structure of the activity may have helped them revise their thinking by focusing on their surprise rather than evaluating whether or not their prediction was correct.

For the Mohammad Counts Cookies video, participants had to draw on their own knowledge and experience to assess the information from the video and imagine what other information they would like to have. The response of the participants affirms Kashdan and Fincham’s (2004) recommendations for interventions to facilitate curiosity, which informed the design of the task. These include developing “tasks that capitalize on novelty, complexity, ambiguity, variety, and surprise,” “enjoyable, group-based activities,” and “tasks that are personally meaningful” (p.490). The video-based PL activities may also provide participants cues for practice, to attend to the unexpected and unknown aspects of their own students’ thinking.

With the Christian Counts Bears video, making an inaccurate prediction and seeing some surprising aspects of the student’s thinking may have provided a starting point to learn more about aspects of the student’s thinking, such as counting on or keeping track of counting, as well as consider other mathematical understandings that may explain what he did, such as addition. The teachers’ questions might have been motivated by a desire to resolve the dissonance they experienced, which can be a strong motivating factor in learning (Chinn & Brewer, 1993).

For the Mohammad Counts Cookies video, participants considered a wide range of ideas they could learn about in Mohammad’s thinking, despite his apparent confidence and correct answer. The structure of the video activity may have helped participants identify what else they could learn about Mohammad's thinking. This includes the sequencing of the video after Christian Counts Bears, which may have primed the participants to reflect on what is known or unknown about the mathematical thinking of the student in a video. This mental priming, as well as the explicit invitation to consider what else the student may know, may have helped participants identify the wide range of mathematical ideas they could explore with this student.

Although participants did not explicitly refer to Mohammad's understanding of multiplication in Mohammad Counts Cookies, they did want to learn about his understanding of grouping and skip counting, which can be a step towards multiplication. Teachers often tend to associate multiplication with older students (Carpenter et al., 2017). However, the participants' responses suggest that activities like these may provide opportunities to slow down, look beyond the correct answer, and uncover the seeds of such "advanced" ideas in younger students as well.

Both types of curiosity that participants displayed towards student-thinking – specific and diversive – implicitly acknowledge that there is more to learn about students' understanding than is initially apparent. The findings however indicate that specific curiosity may be further unpacked into questions that seek two types of answers: information that will help resolve a feeling of dissonance as the result of a surprising occurrence or an incorrect prediction, and information to explain what is observed. The former can help teachers correct misconceptions or assumptions about students, and the latter can help teachers make sense of the knowledge and understanding that a student demonstrates in the moment.

In the context of video-based PL activities, it is possible that some specific questions can be resolved by re-watching the video. For example, Rita asked of Christian's counting, "Where does his 1-to-1 [correspondence] stop?" Watching the video again with this question in mind may help her answer this question. But not all questions can be answered by re-watching the video because the information to answer some of the specific questions that participants asked is not present in the video. They would need to interact with the student and give him more tasks to find out, like asking him to count all bears by ones, or asking him to explain how he keeps track, asking him to count the collection again using the strategy that he just used – all ideas proposed by the participants. Thus, these questions indicate specific curiosity to the extent that what the student does in the video triggers participants' questions though the answers may not be in the video.

On the other hand, diversive questions can help teachers use their observations as a starting point to wonder what else the student may know or understand. In this sense, diversive questions may help teachers plan their response to and next steps even with students who seem to have strong mathematical understandings. In the context of the PL itself, diversive or "what else" questions may be an effective way to close the video activities, so as to invite teachers to continue thinking about what they might learn about a student's thinking, including their own. Developing the capacity to pose these questions can also help teachers approach student-thinking with the attitude that there is always more to learn. PL activities can thus be designed to elicit all these different types of questions about student-thinking.

Limitations and future work

As this is a small dataset, further research is needed to determine to what extent these findings are applicable to other PL contexts. Further, the participants in the study already implemented Counting Collections and were interested in teaching that elicits and responds to student-thinking. It would require further research to understand whether and in what ways teachers with other pedagogical approaches respond to the activities described in this study.

A CATALYST FOR CHANGE: A TEACHER'S EXPERIENCES WITH SUPPLEMENTARY CURRICULAR MATERIALS ENRICHED WITH INTERACTIVE SIMULATIONS

Sebnem Atabas
University of Southern California
atabas@usc.edu

Ian Whitacre
Florida State University
iwhitacre@fsu.edu

This study aims to understand a middle school mathematics teacher's instruction and reflections on her experiences with supplementary curricular materials enriched with interactive simulations—PhET interactive simulations (sims) and sim-based materials—over two years. We conceptualize Linda's (pseudonym) teaching in terms of both thinking and doing. Regarding Linda as doer, results show significant differences in Linda's instruction, favoring sim lessons compared to non-sim lessons. Regarding Linda as thinker, results show increased attention to problems of practice related to teaching, as well as more productive framing of problems of practice. When these two findings are taken together, shifts in what Linda did and thought illustrate the potential for high-quality supplementary materials to function as a catalyst for change as we map the flow of shifts in what Linda thought and did across two years.

Keywords: teacher learning, interactive simulations, problems of practice, framing

Purpose

In the light of research suggestions, teachers have been tasked to empower students to experience mathematics as a dynamic process of exploration (Boaler & Greeno, 2000; Langer-Osuna, 2017) rather than recalling a static body of knowledge. This task demands teachers to create a fundamentally different learning environment in which teachers "draw information out of students" (Boaler, 2003, p. 4) rather than transferring the information to students. Given the challenges of "moving away from a language of skills ('students will calculate slopes') to the language of understanding ('students will identify common features of linear growth')" (p. 62), to transition from one teaching approach to the other is not an easy task (Horn, 2012).

Even if many teachers engage in informal reflection on their teaching on a daily basis, it might be challenging for teachers to be critical about their instructional decisions and know what to change about their teaching (Hart et al., 1992). Then, the question becomes how to create opportunities for teachers to be critical about what they do in classrooms and "*rethink* their teaching, rather than merely extend their existing practice" (Horn et al., 2017, p. 51). Related to this question, there are some promising research findings on the use of technology (Goldenberg, 2000) and supplementary curricular materials (Matewos et al., 2019) in challenging routine instructional practices and the existing interplay between students, teachers, content, and activity (Zbiek et al., 2007). As a special technological tool, we focus on PhET sims (phet.colorado.edu) and supplementary curricular materials designed around them—sim-based materials.

Teachers often use online supplementary curricular materials with the intention of improving student engagement or learning (Polikoff et al., 2018). However, it is well-documented in the literature that teachers may end up being the ones engaging in learning. For example, in their effort to create a learning environment for students to engage in mathematics in more meaningful ways, Wood et al. (1991) realized how "the classroom had simultaneously and unintentionally become a learning environment for the teacher as well" (p. 588). Building on research on learning through teaching, teachers often develop their understanding of students, content, and teaching as they use unfamiliar tasks (Leikin, 2005).

Building on the research findings on the potential of supplementary curricular materials and instructional technologies to be catalysts for change (Kaufman et al., 2018; Matewos et al., 2019), this study explores the potential of sims and sim-based materials to motivate shifts in a middle school mathematics teacher's approach to teaching mathematics. For this purpose, we recorded what Linda *did* in her sim and non-sim lessons and what she *thought* about her experiences with these materials over two years. Accordingly, we asked the following questions:

1. How did Linda's instructional practices in the sim and non-sim lessons compare in terms of instructional quality over two years?
2. What problems of practice did Linda identify as she used sims and sim-based materials over two years? How did she frame these problems of practice?
3. What, if any, alignments were there in Linda's identification and framing of problems of practice and her instructional practices as evidence of professional growth?

Conceptual Framework

Given the complexity of teaching, identifying shifts and changes is not an easy task. To capture a complete picture of teacher change, we conceptualize teachers as both *doers* and *thinkers* (Horn et al., 2017) (Table 1). The field of mathematics education made important progress in developing measures for instructional quality based on instructional practices aligned with a reform approach in which the instruction builds on student thinking and ideas (Boston, 2012; Marder et al., 2010; Thompson & Davis, 2014). Some observable indicators of what teachers *do* in the classroom include the rigor of tasks as planned and implemented, teacher questioning (e.g., exploring mathematical relations), accountability of student–teacher and student–student interactions (e.g., linking mathematical ideas), teacher's press for knowledge or thinking, and students providing knowledge or thinking in response (Boston, 2012).

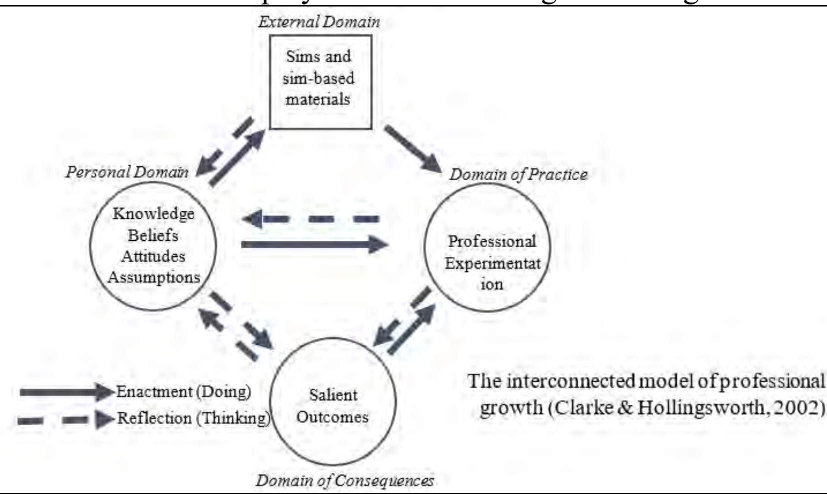
One important resource to get access to teachers' *thinking* is problems of practice that they identify in their talk (Horn & Little, 2010; Vedder-Weiss et al., 2018; Windschitl et al., 2011). For example, 'students' difficulties in mathematics' can be a problem of practice that teachers may identify. In addition to identifying this problem of practice, how teachers frame the problem of practice (Dyer, 2020; Vedder-Weiss et al., 2018) adds an interpretive stance of teachers' *thinking.* Building on the same example, the teacher may frame the problem as an inherent student characteristic (e.g., some students are born with a "math gene" and some are not) or as a lack of learning opportunities available in the classroom (e.g., the context of the problem did not afford students to make sense of the content). These two framings have important consequences for what teachers might do in the classroom.

Aligned with the conceptualization of teachers as doers and thinkers, Clarke and Hollingsworth (2002) presented an interconnected professional growth framework including teacher reflection and enactment, showing the interplay between personal domain (e.g., knowledge), external domain (e.g., curricular materials), domain of practice (e.g., teacher's instructional practices), and domain of consequences (e.g., outcomes of teacher questioning) (Table 1). Our conceptual framework enabled us to capture what a teacher did and thought and the interplay between the two across the domains of interconnected professional growth model.

Table 1: Conceptual Framework

Teacher as a *Thinker*	Teacher as a *Doer*

• What *problems of practice* teachers identify (Horn & Little, 2010; Vedder-Weiss et al., 2018; Windschitl et al., 2011) in their talk. • The way(s) teachers *frame* the problems of practice (Bannister, 2015; Dyer, 2020; Jackson et al., 2017; Snow & Benford, 1988; Vedder-Weiss et al., 2018) they identify in their talk.	• Instructional quality assessment (IQA) (Boston, 2012) comprised of eight rubrics below: - Potential of the Task - Implementation of the Task - Student Discussion Following the Task - Rigor of Teachers' Questions - Teacher's Linking Contribution - Student's Linking Contribution - Teachers' Press for Knowledge or Thinking - Students Providing Knowledge or Thinking • Each rubric is scored on a scale from 0 to 4
Teacher as doer and thinker (Horn et al., 2017)	
The Interplay between Thinking and Doing	



Methods

Participant

Linda was a middle school mathematics teacher with 11 years of teaching experience at the beginning of the study. During her participation in the study, she was teaching in a Title 1 school in the southeastern United States. Her students were predominantly white (64%), with students who were identified as African American (15%), Hispanic (18%), and others (3%). Overall, Linda shared many characteristics not uncommon with other middle school mathematics teachers. She identified her teaching as teacher-centered. She was knowledgeable about student-centered pedagogy based on her professional learning experiences (e.g., undergraduate program). She was struggling with student engagement and looking for some resources to increase student engagement. At the start of this research, Linda participated in a two-day workshop where she was familiarized with PhET simulations and provided with sample sim-based lessons. Besides the workshop, she received no structured support (e.g., professional development). The instructional materials designed by the PhET research team and other teachers were accessible to her through the website. She decided which sims and corresponding sim-based materials to use.

Our goal with our case study selection was to understand a middle school mathematics teacher's use of supplementary curricular materials enriched with interactive simulations. Yin (2018) highlighted the goal of doing case study research is to develop "analytic generalizations"

(p. 23), which are defined as "The logic whereby case study findings can apply to situations beyond the original case study, based on the relevance of similar theoretical concepts or principles" (p. 349). We believe this case study can inform other teachers in situations beyond Linda's case and make connections to the theory of teacher learning (LeCompte et al., 1993).

Data Collection

We observed and recorded lessons in two of Linda's 7th grade math periods during the 2017–2018 and 2018–2019 school years. In the first year of the study, Linda taught three sim-based lesson modules, each comprised of 3–4 consecutive days of teaching with the use of sim-based materials, in one of her class periods in which data were collected. She taught the corresponding non-sim modules in another class period in which data were collected. The data set included video recordings of seven sim lessons and six non-sim lessons in Year 1 and 10 sim lessons in Year 2. Linda used the same sim-based modules in the first year and second year of the study. We also conducted interviews with Linda at three time points: the beginning of Year 1, the end of Year 1, and the end of Year 2, as well as collected written reflections after she taught each sim-based module (Figure 1).

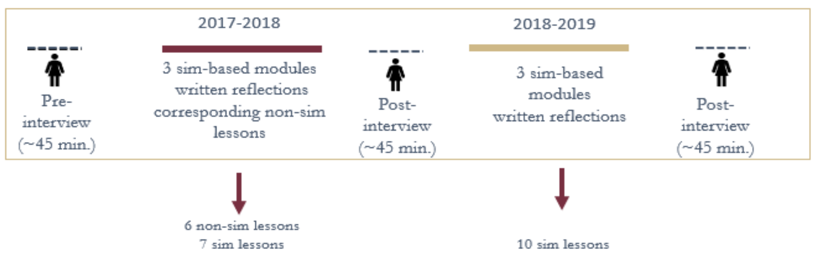


Figure 1: Data Collection

Data Analysis

To answer the first research question on what Linda *did,* we used video recordings of Linda's teaching in sim lessons and non-sim lessons. We analyzed the instructional quality of each lesson by using IQA (Boston, 2012; Matsumura et al., 2002) and assigned a rubric-specific IQA score for each type of lesson—sim lessons versus non-sim lessons. To examine whether sim lessons resulted in statistically higher levels of instructional quality, we ran seven permutation tests (one for each of our seven IQA rubrics) (Good, 2013).

We used Linda's written reflections and interviews to answer the second research question on Linda's thinking. We separated them into idea units (Jacobs et al., 1997; Tekkumru-Kisa & Stein, 2015). In each idea unit, we identified what problem of practice (Horn & Kane, 2015) Linda discussed and how she framed the problem of practice (Dyer, 2020; Snow & Benford, 1988). We organized our coding chronologically to identify shifts across two years.

To answer the last research question, we examined the interplay between what Linda did and thought as she started using sims and sim-based materials over two years by using the interconnected model of professional growth framework (Clarke & Hollingsworth, 2002). This framework enabled us to map the flow of change between four domains: external domain (e.g., sims and sim-based materials), personal domain (e.g., knowledge, assumptions), domain of practice (e.g., sim-based activities used by the teacher, questions the teacher pose to students), and domain of consequences (e.g., student engagement, student learning).

Results

Differences in What Linda Did in Class with a Focus on Instructional Quality

Regarding Linda as *doer*, results showed that IQA scores were significantly higher in sim vs. non-sim lessons on four rubrics: implementation of the task, student discussion following the task, rigor of teacher's questions, and teacher's linking (Table 2). More specifically, in sim lessons, Linda encouraged students to elaborate their thinking and explore mathematical meanings with some effort to make connections between their contributions. Thus, students had more opportunities to develop their own strategies and present their work and their thinking to the whole class. Please note that we excluded the rubric on the potential of the task because sim-based materials were provided to Linda. We were interested in what Linda was doing with sim-based materials when she used them in her lessons rather than the potential of these tasks.

Table 2: Mean of IQA Rubric Scores in Non-sim and Sim lessons

	Potential of the task	Implementation of the task	Student Discussion Following Task	Rigor of Teachers' Questions	Teacher Linking	Student Linking	Teacher Press	Students Providing
Non-sim Lessons (Year 1)	2.50	2.00*	1.50*	1.50*	1.33*	1.17	2.17	2.00
Sim Lessons (Year 1 & Year 2)	3.80	3.20	2.80	2.87	2.07	1.80	2.93	2.67

*$p < .05$.

To give the reader a sense of what Linda's sim and non-sim lessons looked like, we briefly describe the lessons focusing on the same topic—scale factor, part of the unit on proportional relationships. In the non-sim lesson, Linda went through a worked example in the book, which comprised of three steps as follows: (1) write the scale as a fraction, (2) convert the fraction to a unit rate, (3) multiply the unit rate by actual length to find the missing value. In contrast, the sim lesson started with an open-play time for students to explore how the sim works (click to open the sim). After exploring the sim, Linda asked students to create a figure on the sim and scale it by a scale factor of 2 and 3, as well as to predict how the perimeter and area of the figures would change as the original figures were scaled. After students compare their predictions with the actual values (the sim can show the actual values of the perimeter and area of the figures with a click on a button), Linda asked students:

> What do you think happened to the area? Why was not as simple as it is, just multiplying it [the area of the original figure] by 3?... Any ideas of why you think that is? It [the scale factor] definitely affected the area differently? (Sim Lesson on Scale, Year 2)

Based on these qualitative descriptions, in the non-sim lesson, finding the missing values asked in the problems was the end of the discussion. Whereas, in the sim lesson, the scaled figures served as the data for students to develop a rule that explains how scale factor affects the perimeter and area of a shape—if they affect the perimeter and area differently, what was the reason? While these contrasts between sim and non-sim lessons were important, Linda's takeaway from this experience was worthwhile, as discussed below.

What Problems of Practice Linda Identified and How She Framed Them?

Regarding Linda as *a* thinker, there was a shift in Linda's attention from problems of practice related to students to problems of practice related to teaching. At the beginning of the study, Linda heavily focused on problems of practice related to students (e.g., students not engaged)

(89% of the problems of practice). In Year 2, by contrast, Linda focused on problems of practice related to *her* teaching (e.g., ask good questions) (62.5% of the problems of practice) (Table 3).

Table 3: Number of Problems of Practice Related to Students and Teaching

	Number of Problems of Practice related to Students (%)	Number of Problems of Practice related to Teaching (%)	Total Number of Problems of Practice (%)
Pre-Interview	8 (89%)	1 (11%)	9 (100%)
Year 1	13 (52%)	12 (48%)	25 (100%)
Year 2	9 (37.5%)	15 (62.5%)	24 (100%)

Aligned with Linda's increasing attention to her teaching, in the post-interviews, Linda talked about her struggle in asking good questions, limitations in her content knowledge, and how much to tell students to scaffold their thinking (Table 4a and 4b). In addition to these new problems of practice emerged, Linda's description of these problems got more sophisticated. For example, in Year 1, Linda framed the importance of teacher questioning especially for students who might struggle, whereas, in Year 2, Linda reframed teacher questioning as a tool to support student learning, not only for students who struggle but also for expanding student thinking as she said:

> Coming up with the right questions to ask them. Like both ends of the spectrum … when they are struggling but also … when they think they got it … there is always more. I mean, aside from the generic "explain your thinking," … how to encourage them… and also like "can you find another way," … for ones who are struggling but also when they do get it. And how to push them but not just give them more work to do. (Post-interview, Year 2)

Although these percentages show a shift in Linda's attention, it is important to note that an increase in the number of problems of practice related to teaching does not necessarily indicate a positive change over time. It is equally important to examine Linda's framing of these

Table 4a: Problems of Practice Related to Students Over Two Years

	Students not engaged	Students not motivated	Students have a mindset of "I am not good in math"	Some students struggle more	Some students play schooling	Do not notice patterns Linda expects	Struggle with working on open-ended tasks	Struggle with understanding math concepts (e.g., coming up with a rule)
Pre-interview	3	1	2	2	0	0	0	0
Year 1/Sim	0	1	1	2	1	2	6	0
Year 2/Sim	0	0	1	0	1	0	4	3

Table 4b: Problems of Practice Related to Teaching Across Two Years

	Attend student experience	Avoid mis-conceptions	Know your goal	Anticipate student struggle and responses	Teacher's limited content knowledge	Ask good questions	Decide how much to tell	Anticipate what students know	Step back
Pre-interview	1	0	0	0	0	0	0	0	0
Year 1/Sim	1	2	1	1	2	3	2	0	0

Year 2/Sim	0	0	1	1	1	9	1	1	1

problems of practice related to students and teaching. Our analysis of Linda's framing of these problems of practice showed evidence that Linda's conception of what it meant to be a good student was challenged. She was surprised about students who were typically on track and following instructions because these students struggled with new expectations in sim lessons and expected Linda to tell them what to do. In a post-interview, Linda said,

> Often in the sim activities, they [students] are asked a question that they do not know how to answer right off their head. So, there is an immediate pushback; well, I do not wanna do this, I do not wanna do this… but when I just stop giving them how to, there has been a difference. (Post-interview, Year 2)

Linda was also surprised by students who were typically unengaged because in sim lessons, these students made important contributions to the discussions. In her written reflections in Year 1, Linda wrote, "The students that surprised me the most were the students that are usually the 'unmotivated' ones." Thus, Linda's prior framing of students who were *on track* or *unengaged* was challenged. Another reframing was about student engagement. In the pre-interview, Linda expected sims and sim-based materials to increase engagement; however, she was not clear about what aspects of sims would make that difference. Starting in Year 1, Linda framed student engagement in connection to the curricular materials she used. In a post-interview, Linda said,

> I realized that me going over problems at the board and asking the students questions required little from the students… That is what I am trying to say in a sim lesson versus a non-sim lesson. There is not much opportunity for them to contribute their ideas, whereas, in sim lessons, there is much more opportunity, which is also a part of more engagement. (Post-interview, Year 2)

Students were contributing their ideas and figuring things out by themselves rather than following Linda going over the problems on the board, and that was the reason for increased student engagement in sim lessons.

The Interplay Between What Linda Did and Thought as Evidence of Professional Growth

Regarding the last research question, we identified three flows of change evident in the interplay between what Linda did and thought over two years. The first flow of change was about Linda's seeing students as more capable and problematizing who were motivated and engaged. As Linda started using sims and sim-based materials—external domain—she practiced not telling students what to do and encouraging them to explore—domain of practice. In response, she observed students figuring things out by themselves, especially the ones who were considered unmotivated and unengaged—domain of consequences. This consequence created an opportunity for Linda to reflect on her assumptions about who was engaged and motivated to learn mathematics and what students were capable of doing—personal domain. Overall, induced from her observations in her classroom, Linda started seeing students more capable and student engagement in connection to the curricular materials she used.

The second flow of change started with Linda stepping back and listening to students—domain of practice. Consequently, students brought different ideas and thoughts, often different than what Linda expected to hear—domain of consequences. Linda repeated her questions hoping that students would bring what she expected to hear; however, this did not happen, and Linda ended up limiting student thinking by asking close-ended questions through the end of the lessons—domain of practice. This flow was reflected in Linda's personal domain as an expressed struggle in asking good questions to leverage student thinking. Importantly, not telling students what to do created a need for some practices that Linda was not readily comfortable with, and she showed ownership of the problems of practice (e.g., asking good questions).

The final flow of change was about teaching mathematics with a conceptual orientation. As Linda started using sims and sim-based materials, the nature of mathematics they were working on became more about the concepts, relations, and connections rather than procedures and computations. Thus, in sim lessons, she more frequently asked "why" and "how" questions to uncover student ideas—domain of practice. In addition to Linda, students also asked questions to make sense of the mathematical ideas and concepts (e.g., "What does random mean?") part of their effort to make sense of the mathematics. However, Linda and her students struggled in coming up with those explanations—domain of consequences—and this struggle was resolved with Linda's shift to procedural focus through the end of the lessons. Again, Linda identified this as a problem of practice related to her personal domain by identifying limitations in her content knowledge in connection to her struggle in maintaining the mathematical focus on conceptual ideas—personal domain. Although Linda was not readily capable of maintaining the conceptual focus, she developed an awareness and, more importantly, a need to improve her content knowledge.

Discussion and Conclusion

These findings support the recent findings on the potential of supplementary curricular materials in creating shifts in teachers' instructional roles and doubt induced by their own teaching (Matewos et al., 2019). Linda started using sims and sim-based materials with the intention of increasing student engagement; however, "the classroom had simultaneously and unintentionally become a learning environment" (Wood et al., p. 588) for her as well. She showed some shifts in her instructional practices, in the problems of practice she identified, and in her framing of these problems of practice. Using sims and sim-based materials created a rich experience where she problematized her previous conceptualization of student engagement as stable and connected it to the nature of work students are tasked to do. She started seeing students as more capable, became critical of her own instructional practices and content knowledge, and identified areas for improvement. These shifts, especially seeing students as more capable and student engagement in connection to what students are tasked to do, are important steps to engage in efforts to improve teachers' instruction (Jackson et al., 2017).

As discussed before, creating learning environments aligned with reform recommendations—more equitable learning opportunities for students—is not an easy task for teachers (Horn, 2012). Teachers' experimentation with student-centered pedagogy as they use well-designed supplementary curricular materials can create opportunities for teachers "to *rethink* their teaching" (Horn et al., 2017, p. 51), identify what particular practices need to be improved in their own teaching, and a desire to improve (Horn & Kane, 2015). Given the teachers' more frequent use of online resources and social media with the pandemic (Aguilar et al., 2021), teachers are becoming more aware of the available resources on online platforms. Thus, there is a need to understand the influence of these materials on what teachers *do* in their classrooms and what teachers *think* about their experiences with these materials. Doubt induced by teachers' own teaching and ownership of problems of practices (e.g., asking good questions) has the potential to further teachers' efforts to improve their instructional practices. In future work, we aim to explore the role of interactive simulations, tasks, and student contributions in affording the shifts we identified in what Linda did and thought over two years.

In the wake of national movements calling for attention to equity, colleges, departments, and instructors are now faced with various responsibilities to implement practices and structures to support diversity, equity, and inclusion (DEI). This project aims to design a professional development program for mathematics graduate teaching assistants (MGTAs) by helping them learn evidence-based teaching practices to support diverse groups of learners in engaging mathematics activities. Part of these efforts included investigating department leaders' understanding of equity. This paper focuses on interviews with department leaders at a large, public, research university. Our analysis shows that despite the implementation of university structures focused on improving equity, department leaders had very different understandings of equitable teaching, and reported differences in how equity factors into their roles.

Keywords: Professional Development, Equity, Inclusion, and Diversity

Introduction

The majority of mathematics graduate teaching assistants (MGTAs) spend between 12 to 20 hours each week working for mathematics departments as instructors or teaching assistants (Selinski & Milbourne, 2015). In some departments, MGTAs have the opportunity to teach their own courses, while in other departments, MGTAs do not teach their own courses but instead lead recitations or lab sessions that support large enrollment courses taught by faculty members. During a two-year master's degree program, MGTAs might have the opportunity to teach as many as seven classes or lead as many as 24 recitations, and in a six-year doctoral program 15 classes or 60 recitations. At some doctoral-granting institutions, MGTAs teach up to 68% of Calculus I courses (Selinski & Milbourne, 2015). This means that during their graduate programs, MGTAs contribute to the learning experiences of hundreds, if not thousands, of undergraduate students.

Because of their significant impact on the teaching and learning of undergraduate mathematics (Ellis, 2014; Miller et al., 2018; Selinski & Milbourne, 2015), it is important to address MGTAs' development as educators. One important piece of this preparation is addressing equity and inclusivity in their classrooms. To this end, we have designed a professional development (PD) program specifically for MGTAs focused on equitable, inclusive, and engaging teaching practices. Our vision is to have this PD program adopted as a permanent department structure, with the aspiration of creating more equitable learning environments through a larger systemic change process (Reinholz et al., 2020). Change initiatives benefit from

department-level implementation because departments represent relatively coherent units of culture (Reinholz & Apkarian, 2018). This coherence may support innovation efforts more broadly and can contribute to the sustainability and effectiveness of the implementations (Reinholz et al., 2018).

Departments are not monolithic, though, and contend with differing goals and varying cultural and institutional issues. Consequently, the first stage of this project is to investigate perspectives of faculty members serving in departmental leadership roles to learn about various supports and barriers that might impact an MGTA PD program. This requires "exploring clashes of values that may lie at the heart of institutional resistance to change" (Reinholz et al., 2020, p. 3), as transformation efforts need to unite stakeholders in an ongoing and cyclical process to adapt to changing contextual factors (Reinholz & Apkarian, 2018; Smith et al., 2021).

In this report, we address two research questions that inform the development of the MGTA PD program:

1. How do department leaders conceptualize equitable teaching?
2. What role does equity have in department leaders' positions and considerations?

Theoretical Framework

We utilize Reinholz and Apkarian's (2018) adaptation of Bolman and Deal's (2008) four-frame model of organizational change to study departmental cultures and change within them. This framework provides context for exploring how department cultures may support or hinder change initiatives by taking into consideration institutional structures and norms through a systems approach (Henderson et al., 2011; Kezar, 2011). In particular, the four constructs, or frames, explored are: *structures*, *symbols*, *power*, and *people*. Reinholz and Apkarian (2018) define these frames:

> *Structures* are the roles routines and practices of a department; their enactment and meaning are dependent on *symbols*, which are the norms, values and ways of thinking in a department; changes are ultimately enacted by *people* whose individuality impacts their intentions and perceptions; and the distribution of *power* determines who makes certain decisions and influences interactions (p. 7)

For this report, we focus on the people frame, which is also referred to as the human resources frame (Bolman & Deal, 2008). This frame highlights that each department is composed of individuals that have their own goals, agency, needs, and identities (Reinholz & Apkarian, 2018). The department needs people (and vice versa) and exists to serve human needs, especially those of students, who have their own unique goals (Bolman & Deal, 2008). Tensions within the people frame can be caused by the differing needs, goals, and values amongst various stakeholders within the department. Department chairs, in particular, are well positioned to provide leadership in navigating these differences, such as by creating an inclusive and supportive culture for faculty, staff, and students (Bystydzieński et al., 2017; Fried, 2003; Hecht et al., 1999; Wergin, 2003).

Data Sources and Methods

We report on the analysis of baseline interviews with leadership in one mathematics department at a large, public, PhD granting university prior to implementing a PD program for MGTAs focused on equitable and inclusive teaching practices. We characterized department leaders as those who we identified as powerbrokers with the ability to influence department-level decisions regarding MGTA PD. For example, the department chair, the graduate chair, experienced coordinators, and those who contribute to existing MGTA PD within the department received invitations for interviews. Our focus on these important figures is in recognition that "change effort requires sanction from the appropriate power holders to succeed" (Reinholz & Apkarian, 2018, p. 5). Three of the six department leaders accepted our invitation and were interviewed. These interviews were audio recorded and transcribed. For this report, we refer to these interviewees by their roles: (1) the department chair whose role is to oversee the entire department in its research and teaching missions, (2) the associate chair whose role is mostly to support the department chair and take on tasks delegated by the department chair, and (3) the graduate chair whose role is to oversee graduate admissions and the progress of graduate students through either the master's or doctoral program. Each of the participants are mathematicians who had either been invited to serve in their specific role or volunteered to serve in their role when the position became vacant.

The semi-structured interview protocol focused on learning about how equity and inclusivity were addressed by the department as a whole and with respect to the MGTAs' teaching practices, how equity and inclusivity were understood by department leadership, and the department leaders' perceptions of the department and its direction. Some questions that were asked included: How would you like MGTAs to engage with students?; What is most important to you for MGTA professional development?; How would you describe equitable teaching?; and, In what ways does the department or college value equity and inclusivity?

Analysis

For our first phase of analysis, we used an inductive open-coding approach (Miles & Huberman, 1994) for interview responses that related to our research questions regarding department leaders' conceptualization of equity and the role of equity in their position. Our second phase of analysis incorporated an axial coding method to surface emerging patterns and distinctions from our codes. Additional consideration in this phase was given to the department leaders' positions in the department. Lastly, we utilized the people frame as an explanatory construct to make sense of what we were seeing in the data. In particular, we referenced this frame to conceptualize how department leaders were contending with the varying needs, goals, and values of the stakeholders that their position was responsible for addressing, as well as their own.

Findings

There was a noteworthy difference in department leaders' responses to questions about equitable and inclusive practices. In particular, the department chair expressed significant institutional pressures, such as how the department would be 'measured' in whether and how it supported diverse groups of students. In comparison, the other department leaders expressed little, if any, institutional pressures in their respective roles. Thus, we saw their different leadership roles as moderating their views and descriptions of equitable and inclusive teaching practices. We address each leader's responses to questions related to equity and inclusivity and the context of their roles in those responses.

The Department Chair

When the department chair was asked "*How would you describe equitable teaching?*" he did not provide a direct answer, instead describing the pressures he felt from society as a whole as well as those from the institution. With regard to societal pressures, he stated "our society is just rigged in a way [that] makes it really hard for some people to succeed… I'm keenly aware from my position right here that the forces that affect all of those things are way deeper than anything that happens when they set foot in my classroom." With this in mind, he went on to describe "equitability" in his own teaching as "[making] sure that I'm not accidentally saying something that's going to make someone doubt whether they belong … And so, for me, it's just, you know, don't inflict more damage."

The department chair shared that much of his work and how he directs some of the focus of the department is mandated by the dean's and the institution's focus on DEI. One example of this was the requirement that each department in the college needed to establish a DEI committee. The department chair shared, "I can't claim … that I was the instigator of this, although, you know, eventually we would do it. But the dean requires this." Because of the mandate, the department chair had assembled a committee of faculty and graduate students who had each expressed interest in DEI issues in the department. The department chair had given the committee an assignment to write a mission statement for the department that focused on DEI.

In comparison to the two other department leaders, the department chair experienced significant institutional pressures and scrutiny. His voiced his frustrations several times during the interview, noting:

> Every now and then I get held accountable. You know, math departments are very vulnerable in this regard because, you know, D-F-W rates and graduation rates. I can't tell you how many times I've sat around a table with [de-identified]... And we get going on student success or failure rates in classes and next thing I know, everybody in the room is looking at me going what are you going to do about that? […] And-and one of the things that has upset me most is that every now and then a crusading high-level administrator walks into my office and throws some statistics down in front of me about how achievement gaps are particularly bad in mathematics. And you know, I don't deny or debate any of that.

Consequently, the department chair's focus on equity was mostly based on "hard-nosed measurables" because that was the lens by which his performance would be measured by the institution.

As a result, he described some of the work in his leadership position consists of advocating for the mathematics faculty and the DEI work and training that they engage in. These efforts seemed to come with disheartenment over his view that the university's president reiterates the existing inequities instead of acknowledging the work that is done:

> [I]t's extraordinarily demoralizing. Because I know that my faculty are … going to the seminars and the workshops where they are being trained … in developing the ways to be inclusive and to implement teaching practices that promote equitability and inclusivity. I know they're doing that work. But when I hear my president saying those things over and over again, as if it's … endemic to the institution, it's a blow … But I think it's important … to see and acknowledge the people who are doing the work … even if it's not showing up in the measurables yet, to acknowledge that it is happening.

This focus on measurables led to his recognition of a need to collect and track data for his department. He shared that this would enable him to guide his department with regard to PD to ensure they are collectively "making any progress." Consequently, he suggested that when evaluating equity related efforts, "one looks for impacts and sort of measurable effects."

The Graduate Chair

When the graduate chair was asked "*How would you describe equitable teaching?*" he shared that he perceived equity to mean equality, that "every student is treated in the same fashion in a classroom." He characterized inclusive teaching as "you can't leave anybody out." However, he described that "the system" should not be changed for students, stating "the kid that for whatever reason doesn't show up half of the time, or, … for whatever reason [is] the one that, you know, looks funny to you or act[s] weird. No you can't … change the system for any of those people." The graduate chair did not view DEI as a principal component of his role and he expressed little accountability towards equity in his position. This was interesting given that the department chair proudly noted that the department had worked "very hard to make sure that our graduate admissions policies and practices are inclusive and holistic. And we are keeping track of our progress in terms of diversity and in terms of, you know, what-what the demographics of our incoming classes [of graduate students] are."

When asked about whether he encourages faculty and MGTAs to engage in opportunities focused on inclusivity and equity, the graduate chair responded:

> I personally don't do it … I really don't think in these terms, so it's funny. I try to run the graduate program, okay.. [laughter]. You know, which is a very different thing than leading a college or department. So personally, I do not do that. I do not encourage faculty members or TAs to go and engage in those types of opportunities. But I see the leaders, you know, above … me. I see those do it definitely, and I think it's their role. I mean I'm not trying to duck responsibility.

In this statement, he implicitly acknowledged that his role as graduate chair had different requirements than the department chair's role, and so he did not feel similar pressures to attend to DEI-related issues. Yet, he eventually recognized that there are aspects of MGTAs' potential future careers that could involve DEI, such as academic tenure, promotion, and hiring practices; he expressed, "I think those have really tightened up already and have at least in my opinion become equitable and inclusive."

The Associate Chair

Unlike the department chair and graduate chair, when the associate chair was asked "*How would you describe equitable teaching?*", he was able to explicitly reference various student supports, such as the need to create a welcoming environment that would promote access and accommodate different learning styles. He suggested the need to contend with various barriers to student learning. One point of emphasis, his response contrasted with the graduate chair's conceptualization because he suggested providing flexibility for students, especially during the COVID-19 pandemic. He added that flexibility was also needed due to other aspects of students' lives, such as other jobs and pressures that might interfere with their learning.

The associate chair described the various ways in which DEI related to different aspects of his position prior to becoming associate chair. He referred to advocacy training that was required to participate in various hiring committees, and similar training that was needed for his previous role as department chair. He also described roles he had served in that were directly related to department's vision for DEI, such as being co-chair of a committee that established department acknowledgements regarding DEI values. Part of this responsibility required finding common ground amongst department members with regard to DEI values.

The associate chair also discussed his efforts at promoting diversity within mathematics to the department community and emphasized the importance of this with graduate students. He acknowledged the overrepresentation of while male mathematicians and the need to "make a sustained effort to say this is not all there is, and bring up a contribution of female mathematicians." These efforts included organizing department colloquia and events, such as one to show a movie on a prominent mathematician from an underrepresented background, which was followed by “long conversations.” Similarly, he discussed the memberships that the department has with various regional and national alliances and described his participation.

Department Leaders’ Views of PD for MGTAs

The leaders were asked questions about MGTAs’ teaching roles and professional development. The associate chair was the only department leader to mention equitable teaching when discussing the important teaching outcomes for MGTA PD. He described the need for MGTAs’ teaching to be responsive to the needs and backgrounds of the student body, and to be able to provide a classroom environment that is welcoming and accessible:

> For professional development I think-well two things come to mind: one is, you know, pedagogical tools to-to-to address different backgrounds in the students, to accommodate different teaching styles. And together with that is, you know, tools for providing a welcoming environment and an environment that promotes the access and equity.

This sentiment was in opposition to what the graduate chair suggested. To him, an ideal outcome would be a successful continuation of the status quo. He described this as: “[W]e want to give it along, pass it along to the next generation … you know, try to see yourself as a little link in a chain, you know, where you pass on from the next, to the next generation. And then they’ll do it again, hopefully.” Lastly, the department chair had a more individualized conceptualization than the other two leaders. He suggested that the most important outcome of MGTA PD would be for better career preparation, sharing: “I have to view graduate study as a professional pathway. You know, this really is something that you’re doing because you think it leads to a career. You’re not doing it for personal growth or, you know, to become a better citizen or stuff like that.”

Discussion

While the college and department have explicit diversity action plans and statements, and despite awareness of various department and institution DEI initiatives, the three department leaders shared very different visions of equity and equitable teaching. This embodies Gutiérrez’s (2002, 2017, 2018) description of the word equity as being complicated by a long history of conceptualization. In her work, she shares that this often results in the word *equity* retaining simplistic or superficial definitions that refer to a wide range of meanings and contexts that have led many to believe that they are speaking of the same ideas/topics despite having different definitions. The differing viewpoints, values, and goals of these department leaders highlight possible tensions that change initiatives might have to contend with, as described by the people frame.

Because of his unique position, we were particularly interested in the department chair’s views on equity. The department chair's communications about equity seemed largely influenced by other university officials, including his dean. He adopted language that he attributed to these leaders, especially his focus on “measurable outcomes.” Similarly, the department chair’s view on equity seems to be shaped by, or aligned with, his description of the university president’s focus on “endemic” deficiencies instead of the work that faculty are doing. He shares a bleak view that efforts within the classroom could only hurt students instead of help. Yet, this understanding of equity does not serve the students of the department, nor does it respond to the students’ needs and identities. The department chair’s seeming indifference towards explicitly addressing equity in the classroom does not bode well for departmental change and innovation efforts in this regard; especially as he is uniquely positioned to provide leadership in directing support towards such efforts.

One key aspect of the people frame that surfaced with the individual goals and agency amongst the three department leaders. A range of accountability towards integrating or encouraging DEI efforts emerged in our analysis. On one end of the spectrum, the graduate chair seemed to shun any responsibility for advocating for DEI, sharing that he thought it was the responsibility of those "above" him, saying that "I think it's their role." Meanwhile, the department chair felt it was his responsibility to advocate for the DEI-related work of those in the department. And lastly, the associate chair recounted various ways that they supported DEI in their work, both explicitly in their actions or implicitly by participating in related PD.

Conclusion

We conclude with thoughts about how this work may influence the development of our MGTA PD program focused on equitable teaching practices. Through our analysis we found several tensions within the people frame that were caused by the differing needs, goals, and values amongst the department leadership. Our analysis yielded several barriers and supports for our planned implementation of the MGTA PD program. First, the different understandings of equity and equitable teaching demonstrate challenges of explaining the program and its learning outcomes to various leaders and stakeholders within the department, including leaders, faculty, and MGTAs. The MGTA PD program focuses more on qualitative measures of teaching (e.g., engaging students and creating welcoming environments) and might not be accepted and supported by a department chair who feels under pressure to produce "hard-nosed measurables." Second, given that the graduate chair does not view it as his responsibility to encourage opportunities focused on equity, such a PD program may experience challenges with MGTA recruitment and sustainability. Similarly, his view that ideal PD outcomes would enable the perpetuation of current teaching practices is in opposition to our project's vision of changing teaching practices.

The interviews also surfaced various supports for the implementation of our PD program. Department leaders shared that college and university leadership are focused on avenues to leverage DEI efforts. Although the graduate chair demonstrated disinterest in advocating for equity-related opportunities, the other department leaders highlighted that there are faculty members who value these experiences and efforts. Leveraging such college- and university-level support will be instrumental in building, and maintaining, a sustainable MGTA PD program.

EMOTIONAL KNOWLEDGE OF MATHEMATICS TEACHER

CONOCIMIENTO EMOCIONAL DE DOCENTES DE MATEMÁTICAS

María S. García González
Autonomous University of Guerrero, Guerrero, Mexico
msgarcia@uagro.mx

Emotions come into play as teachers make decisions, act, and reflect on the different purposes, methods, and meanings of math teaching. In order to learn more about the emotions of mathematics teachers, this paper shows the emotions experienced by 81 Mexican teachers who teach mathematics in middle school and high school. Emotions are contextualized by the theory of the cognitive structure of emotions, narrative and drawings were used to express their emotions. According to the results, three frequent and common emotions were identified in the teachers, happy-for, satisfaction, and disappointment. Fear was the only frequent emotion in high school teachers; it occurred at the beginning of their teaching, due to the lack of pedagogical content knowledge.

Keywords: Emotion, Teacher Educators.

Emotions and Mathematics Education

In recent years there has been a growing interest in the study of emotions in education (Graesser, 2020). In particular, the field of mathematics education classifies the emotions of teachers into two groups: negatives and positives. Negative emotions imply unpleasant experiences during the teaching moment; stress, demotivation and burnout syndrome are among these emotions. Burnout syndrome is an emotional disorder caused by job stress which leads to experience anxiety or depression (Schutz & Zembylas, 2009; Rodríguez, Guevara & Viramontes, 2017). Experiencing high levels of intensity of this group of emotions could even lead to abandoning the profession (Hannula, et. al, 2007). The most frequent negative emotion experienced by mathematics teachers is mathematics anxiety (Fennema & Sherman, 1976; Brady & Bowd, 2005; Bekdemir, 2010). On the contrary, positive emotions imply pleasant experiences when leading a class; some of these emotions are enthusiasm, joy, satisfaction, and interest (Di Martino & Sabena, 2011; Anttila, et. al, 2016).

According to the results of the investigations, there are two triggering situations for negative emotions in mathematics teachers: (a) emotional experiences as students: generally, those who experienced negative emotions related to mathematics continue to experience them after they become mathematics teachers, retaining the belief that mathematics is difficult (Coppola, et. al, 2012); and (b) the knowledge of the academic discipline: many of the teachers in charge of teaching mathematics are not specialists in the contents of the school curriculum (Philipp, 2007).

In order to expand and communicate what teachers feel while teaching mathematics, this paper presents 81 cases of mathematics teachers who communicate their emotions through narrative and drawings. This communication was carried out collectively in four different workshops, coordinated by the author; these workshops were held outside the teachers' working hours. The aim of the workshop was to create a place where the mathematics teachers could talk about their emotions during teaching with colleagues from other places and from the same or different school levels. Feeling heard and listening to other teachers, they find similar emotional histories and are allowed to reflect on how emotions affect their teaching.

OCC Theory and Emotional Knowledge

Because language is a functional means to talk about emotions, this work makes use of the Theory of the Cognitive Structure of Emotions (Ortony, Clore & Collins, 1987), also named OCC theory after the initials of the authors, to study emotions. OCC theory analyzes emotions from the narrative of a person about their emotional experience; it ignores completely the behavioral and physiological evidence that are also recognized as sources to investigate emotions. OCC theory defines emotions as “valenced reactions to events, agents or objects, with their particular nature being determined by the way in which the eliciting situations is construed” (Ortony, Clore & Collins, 1987, p.13). This definition implies that an emotion appears when a person values a specific situation; this situation is recognized as a triggering situation, and the appraisal is expressed by an emotion word.

The analysis of emotions in OCC theory is not only focused on the emotion words, although linguistic evidence is taken into account, but also considers the triggering situations. This is because daily language has several words that could be used to refer to different aspects of the same type of emotion. For example, the word distress refers to a moderate fear, while the word panic gives evidence of an intense level of fear, but they definitely refer to same type of emotion, fear. The OCC considers some emotion types (OCC typology of emotions, Table 1), and gives a generic definition for each of them, focusing on the triggering situation and the emotion word. In this way, the analysis of an emotion depends on its interpretation based on the proposed definition.

Table 1. Emotion types according to the OCC theory.

Class	Group	Types (sample name)
Reactions to events	Fortunes-of-others	Pleased about an event desirable for someone else (happy-for) Pleased about an event undesirable for someone else (gloating) Displeased about an event desirable for someone else (resentment) Displeased about an event undesirable for someone else (sorry-for)
	Prospect-based	Pleased about the prospect of a desirable event (hope) Pleased about the confirmation of the prospect of a desirable event (satisfaction) Pleased about the disconfirmation of the prospect of an undesirable event (relief) Displeased about the disconfirmation of the prospect of a desirable event (disappointment) Displeased about the prospect of an undesirable event (fear) Displeased about the confirmation of the prospect of an undesirable event (fears-confirmed)
	Well-being	Pleased about a desirable event (joy) Displeased about an undesirable event

		(distress)
Reactions to agents	Attribution	Approving of one's own praiseworthy action (pride) Approving of someone else's praiseworthy action (appreciation) Disapproving of one's own blameworthy action (self-reproach) Disapproving of someone else's blameworthy action (reproach)
Reactions to objects	Attraction	Liking an appealing object (liking) Disliking an unappealing object (disliking)
Reactions to events and agents simultaneously	Well-being /Attribution	Approving of someone else's praiseworthy action and being pleased about the related desirable event (gratitude) Disapproving of someone else's blameworthy action and being displeased about the related undesirable event (anger) Approving of one's own praiseworthy action and being pleased about the related desirable event (gratification) Disapproving of one's own blameworthy action and being displeased about the related undesirable event (remorse)

Ortony, Clore and Collins (1987).

On the other side, Emotional Knowledge is a construct that refers to the information teachers have about their own emotions while teaching mathematics (García-González, 2020). This emotional knowledge is developed, as the mathematical and didactic knowledge, and the development implies the following abilities:

1. Recognize that we feel, because emotions are part of our human nature.
2. Be able to recognize the emotion we experience in a specific situation.
3. Put a name to the emotion; this is knowing the emotion word that clearly represents what we feel.
4. Recognize the triggering situation for what we feel.
5. Distinguish the negative emotions from the positive ones.
6. Regulate the emotions we experience, being able to act in consequence.
7. Be capable of helping others, like our students, on their self-knowledge emotionally.

In this paper, the focus is on the first five abilities of emotional knowledge.

Methodology

This study involved 81 Mexican teachers who teach in middle school (students from ages 12 to 15), and high school (from ages15 to 18). These teachers attended voluntarily four different virtual workshops carried out from July 2020 to November 2021. Attendance to the workshop was as follows: workshop 1, 30 teachers, workshop 2, 15 teachers, workshop 3, 15 teachers, and workshop 4, 21 teachers. The data collection was carried out through two techniques, drawing and narrative, both of which have been tested for their functionality to express emotions through written and pictorial language (García-González & Martínez-Padrón, 2020).

Teachers are asked to draw, individually, a drawing of an emotional experience while teaching mathematics, but this drawing should not include emotion words. Then, they show it to other teachers who will identify the emotion expressed. After the observers talk about the emotion in the drawing, the teacher that draws should say if it was the actual emotion he or she wanted to communicate. Most of the times the observers match the correct emotion. Finally, the teacher that draws is asked to write the emotion word associated to the drawing, and to describe the situation that triggered the emotion. In other activity, teachers are asked to take considerable time to write their histories as mathematics teachers. Each one of them reads it in an intended session; from this narrative the listeners should comment on a positive or negative emotional experience. Both techniques were carried out in the workshops to develop emotional knowledge.

The drawings were collected in drive files for later analysis. The teachers were asked to authorized the dissemination of their products for research purposes, taking care of anonymity.

According to OCC theory, a type of emotion is identified by 2 specifications: 1) Concise phrases that express all the eliciting conditions of the emotional experiences. The evidence highlights these phrases in bold. 2) Emotion words that express emotional experience. The emotion words are highlighted in italics.

Therefore, emotion words and triggering situations were identified in the drawings and narratives. Then, with the help of the OCC typology, a reinterpretation of the evidence was carried out based on the definitions of the emotions, and the emotion type that better describes the evidence was selected.

The teachers are listed from 1 to 81, and it is highlighted whether they are male (M) or female (F). In the evidence, the code T1-M means male teacher listed with number 1, and T48-F means female teacher listed with number 48.

Results

Figure 1 shows twelve emotions identified along with their frequency (number of teachers having that emotion), the same teacher experienced several types of emotions. No distinction is made between educational levels because fear was the only emotion experienced just by the high school teachers and not by the middle teachers. Table 2 shows the triggering situations of these twelve emotions.

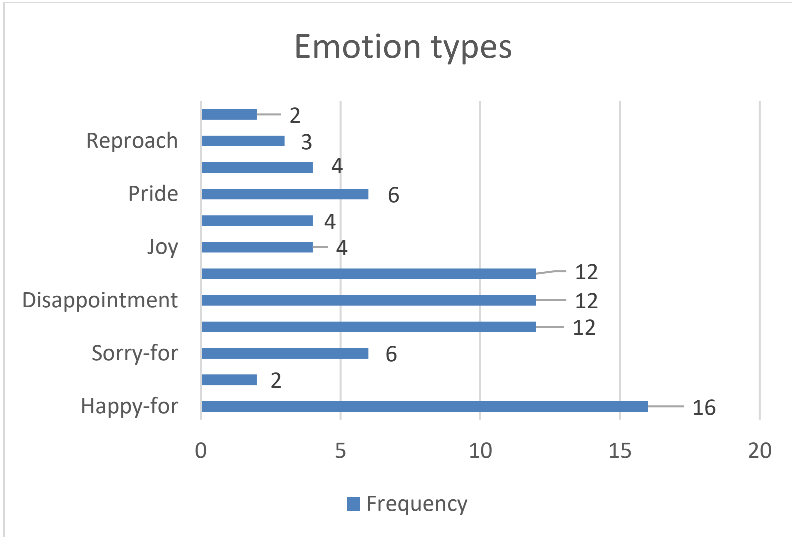

Figure 1. Teachers' emotions.

Table 2. Triggering situations of the emotions.

Emotion type	Triggering situation
Happy-for	Students' learning, Scores/text, concept understanding.
Resentment	Problem solving.
Sorry-For	Students' indifference to the understanding of concepts, internet access, students' problem-solving
Satisfaction	Students' problem-solving, participation/paying attention in class, appropriate teaching resources.
Disappointment	When students' learning is not achieved, the lack of students' paying attention/participation online, low students' scores, excess of work in virtual mode.
Fear	Lack of pedagogical content knowledge.
Joy	The management of the classroom, the attention of students.
Distress	The resolution of the test by the student.
Pride	Acknowledgement of the work of the teacher, students attending to recommendations, achievement of personal academic goals.
Self-reproach	The lack of pedagogical content knowledge, students' lack of understanding.
Reproach	Distraction in virtual class, dissatisfaction with the score, the unwillingness of students.
Liking	Teach using technology, the application of mathematics.

Below it is focused the presentation of results on the two most frequent emotion types, satisfaction and fear.

Satisfaction

All teachers have expectations of their students. Two expectations were identified in the participants, solving problems and participation or attention in class. When these expectations become real, teachers experience the emotion of satisfaction (pleased about the confirmation of the prospect of a desirable event). In addition to their expectations of students, also were identified expectations for themselves, such as those associated with online teaching. With respect to students' problem-solving the drawing of T48-F expresses her happiness (pleased) because the student solved the problem; it can be noted the smile that is drawn on her face.

T48-F: *I feel happy* when the **student managed to solve the problem** (Figure 2).

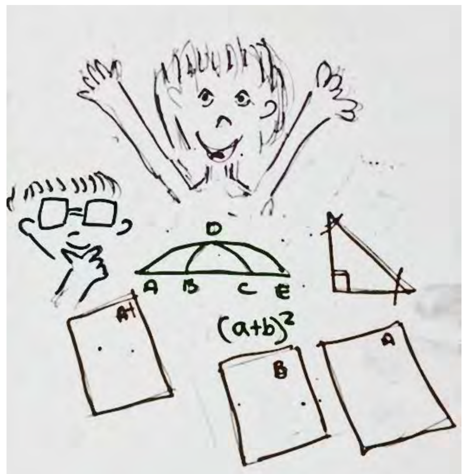

Figure 2. Satisfaction emotion-problem solving. T48-F.

Fear

Fear is defined as being "displeased about the prospect of an undesirable event". This emotion was only identified in high school teachers, and it was a consequence of the lack of Pedagogical Content Knowledge (PCK, Shulman, 1987) at the beginning of their teaching practices. The teachers were surprised when they recognized that teaching mathematics required more than just knowing mathematics (T15-M).

> T15-M: I felt a bit of *fear* when I knew that **I was in charge of a large number of students (50),** *I was uncertain* if **I would be able to control them,** … *I was attacked by the fear of knowing* if **my ideas and my way of teaching could be correctly understood and assimilated by my students,** … I thought I had a huge advantage: I knew mathematics, but my didactic was weak.

Discussion and Conclusions

Figure 1 shows the range of emotions that a teacher can experience when teaching mathematics, and is made up of positive and negative emotions. The case of the emotions of reproach and self-reproach is striking, where the agents that trigger them are the teacher himself, in the case of self-reproach, due to low PCK, and the student is reproached for his distraction in class, and his unwillingness to learn. Recognizing what we feel, putting a name to the emotion, and knowing the situation that triggers it, account for our emotional knowledge.

Previous studies have documented mathematical knowledge as a triggering situation of negative emotions in a Mexican middle teacher (Diego's history García-González & Martínez-

Sierra, 2020) due to his teaching training. In this case, were identified PCK as the triggering situation of fear in high school teachers; we can also explain it from teacher formation. In Mexico, most of the high school teachers have a strong mathematical training because they study for a mathematical career or a related college degree as physics or actuaries. However, PCK is not always part of the curriculum for these degrees.

Fear was triggered at the beginning of their teaching practices by their poor PCK. This group of teachers recognized their extensive mathematical knowledge but they felt powerless regarding to the teaching part. So, they had to look at how to change this triggering situation by means of courses and their own practice, which gave teachers more confidence, as T15-M said.

Having emotional knowledge becomes as important as having mathematical knowledge and PCK, because emotions guide the actions of the teachers. For example, teachers who are afraid because of their lack of PCK may, in the worst case, abandon their teaching labor. On the other hand, the results make us reflect on the need to develop emotional knowledge in their training, as the mathematical and didactic knowledge is developed. In this sense, Marbán, Palacios & Maroto (2020) underline the need to establish specific mathematics affective intervention programs and incorporate them into the didactic training process of pre-service teachers.

The previous excerpts confirm that teaching mathematics requires not only mathematical knowledge but specialized knowledge to teach it, in the words of Carrillo-Yañez, et. al (2018). This matches with Pekrun (2021) who points out that teachers need more than knowledge in the discipline to teach, referring specifically to the emotion and motivation of the teacher. With regard to this result, it is relevant to mention that the lack of mathematical knowledge triggers negative emotions in primary educators because many of the teachers in charge of teaching mathematics are not specialists in the contents of the school curriculum (Philipp, 2007). The data on this study point out that the triggering situation of negative emotions in high school is the PCK and not the mathematical knowledge; as mentioned earlier, these cases can be associated with the formation of both groups of teachers.

This paper examines the impact of an intensive professional development on practicing teachers' mathematics discussion-leading practice. A tool for examining specific discussion-leading moves was used to measure change in teachers' practice as observed through submitted video recordings of mathematics discussions. Participants included 33 teachers from three school districts who submitted a total of 193 videos across the study. The findings reveal that the professional development had differential impact on participating groups. We explore group attributes that could contribute to these differential outcomes.

Keywords: Professional development, classroom discourse

Improving the teaching of mathematics remains a national priority and is critical for improving the learning opportunities for mathematics students. Reforms designed to improve teaching and learning have often centered on curriculum and standards, though studies demonstrate that "no in-school intervention has a greater impact on student learning than an effective teacher" (p.1, NCATE, 2010), indicating that closer attention to teaching quality is essential. This is no small task, given the scale of the teaching force. There are simply not enough teachers with the knowledge and teaching skills needed to reach all students (NCTQ, 2008; Ball & Forzani, 2009). This challenge requires robust professional development that can contribute to improving the teaching and learning of mathematics.

We argue that teachers profit from well-designed opportunities to develop new visions for practice, learn more about students' thinking, or work on specific mathematical topics. However, such opportunities are often insufficient to support teachers with the complexity of classroom teaching. These kinds of professional opportunities focus on critical resources for instruction, but not on the details of practice itself. The professional development (PD) that is the focus of this research was an effort to address the challenge of supporting the learning of practice, specifically mathematics discussion-leading practice. We situated the PD in a "common text" for working on practice, where participants engage in a form of "legitimate peripheral participation," followed by structured opportunities to enhance their capabilities with discussion-leading practices.

Theoretical Framework

Our work is grounded in three bodies of work – conceptions of teaching and learning, teacher learning, and discussion-leading practice. We conceive of quality teaching as critical in advancing mathematics education. Mathematics teaching is something that people do; it is not merely something to know. Teachers must use knowledge flexibly and fluently as they interact in specific contexts with students, with the aim of helping those students become proficient with mathematics. Conceptualizing the work of teaching as interactions among teachers, students, and content, in environments (Cohen et al., 2003) has important implications for the design of PD. It means that simply knowing a lot of math is not enough to be able to help students learn mathematics. Teachers must understand mathematics content and practices in specialized ways that are attuned to their learners. Simultaneously, teachers must be able to engage in teaching practices that enable them to interact with subject matter and students in multiple organizational formats, and support students' interactions with the mathematics being studied. Furthermore, the complex nature of mathematics teaching and the ever-changing nature of the environments in which teaching happens, also require a commitment to, and means of, professional learning in, from, and for practice. Thus, teaching requires the integrated use of specific knowledge and skills in particular contexts of instruction. This emphasis on (a) knowledge use, (b) attention and responsiveness to learners, and (c) context forms the basis of our approach.

Decades of research have demonstrated that many approaches to PD do not adequately support increases in teachers' capabilities (e.g., Coalition for Evidence-Based Policy, 2013; Cohen & Hill, 2001; Garet et al., 2001; Jacob et al., 2017). Often, teachers participate in a patchwork of sessions where presenters share ideas and raise enthusiasm without sufficient focus on teachers' opportunities to develop mathematical knowledge (Little, 2001; Wilson & Berne, 1999), adequate engagement in practice (Darling-Hammond, 1998), or connection with practice (Ball & Cohen, 1999; McLaughlin, 1990; Olson & Craig, 2001). Typically, U.S. teachers' PD opportunities are neither sufficiently "curricular" nor effective for improving practice. In contrast, the structure of our PD reflects the five elements of effective PD identified by Desimone and Garet (2015). First, our PD had a "content focus," --the practice of leading discussions in elementary mathematics, focusing on number and operation, which spans elementary grades. Second, the PD was designed to be "active" with opportunities to engage in leading discussions. Third, the PD was "coherent" in focus, centered on building skill with leading mathematics discussions. Fourth, the 36 hours of PD is aligned with the "sustained duration" associated with positive outcomes for teachers and students (Lynch et al., 2019; Yoon et al., 2007). Finally, "collective participation" was embedded across the PD.

The PD was designed to support the learning of teaching practice by situating learning inside of elementary mathematics classroom instruction. The PD used a classroom as a "common text" for working on practice, where participants were not only watching and discussing, but were engaged in developing and learning practice. This common text creates opportunities for participants to 1) examine lesson plans and student tasks, 2) discuss the plans and tasks with the teacher of record, making adjustments together, 3) observe the enactment of the discussed lesson, including deviations from and adjustments to the planned lesson, 4) collaboratively review students' daily work in response to the teaching, and 5) debrief the teaching of the lesson, unpacking together adjustments and deviations from the plan, the mathematics that unfolded during the lesson, and moves the teacher made to engage students in mathematics discussion (see Shaughnessy et al., 2017).

In addition to engaging in this collective legitimate peripheral participation, the PD involved a focused work designed to improve skill with leading mathematics discussions. Our definition of mathematics discussions entails a period of sustained dialogue among students and the teacher where students respond to and use one another's ideas to develop collective understanding. This requires teachers to engage in areas of work, including launching and concluding the discussion, recording and representing content, and orchestrating the discussion by eliciting and probing student thinking, orienting students to one another's thinking, and making contributions. For a detailed description of this work, see Shaughnessy et al. (2021). Our study investigates the impact of the described PD on teachers' enacted discussion-leading practice.

Methods for Studying Professional Development Impact on Practice

Participants

The full study spanned three iterations of the professional learning involving variations of the setting of the PD (on site or remote) and the components of the PD (peripheral participation with and without the focused discussion-leading session). This paper focuses on three participant groups from iterations 1 and 2 and reports on the impact of the full PD (both peripheral participation and the focused discussion-leading session) on their discussion-leading practice.

Group H1 consisted of 12 teachers from one school district in the midwestern United States, 10 of whom had completed more than three years of mathematics teaching. This group attended on site. Two researchers co-facilitated the practice-based discussion session.

Group H2 consisted of 10 teachers from one school district in the midwestern United States (different from the district in Group H1), seven of whom had completed more than three years of mathematics teaching. This group attended on site and one of the facilitators from Group H1 led the practice-based discussion session.

Group A2 consisted of 11 teachers from a large urban district in the northeastern United States, nine of whom had completed more than three years of mathematics teaching. This group gathered in one location with the other Group H1 facilitator to live-stream and engaged via a chat function in the peripheral participation portion before engaging in the practice-based discussion session with the facilitator.

Data Sources

The PD goals were multi-faceted, taking on many aspects critical to the teaching of mathematics. These goals included teaching practice, mathematical knowledge for teaching, language for talking about teaching, and skill in close observation of teaching and students. However, the primary goal was to increase participants' skills with leading mathematics discussions. The additional foci of enhancing language for talking about teaching, building skill with close observation, and building mathematical content knowledge were in service of this primary goal of improved discussion-leading practice.

This focus on improving mathematics discussion-leading practice necessitated the collection of participants' mathematics discussion-leading practice before and after the intervention. Six videos were collected from each of the 33 participants in the months immediately preceding and immediately following the PD, three pre-PD (in the last two months of school prior to the PD) and three post-PD (in the first two months of school). The set of three videos consisted of two lessons identified by participants as examples of mathematics discussions and one lesson provided by the research team. The selection of mathematical tasks used in a discussion and the content focus impacts the moves that teachers can make when leading discussions as well as the overall trajectory of the discussion, so the third video record of a mathematics lesson used a provided task accompanied by a detailed lesson plan. The video recording of the provided lesson also allowed for a more direct comparison across participants. The topic, task, and lesson structure were constant across participants and across time periods (pre and post). A small number of videos were not included in the analysis. Four videos from Group H1 and one video from A2 were not included in the analysis due to the format of the lesson (lecture only, completing practice problems, or small group instruction only).

Data was also collected around the supporting foci, both to measure incoming skill in these areas and to measure potential changes resulting from the intervention. One such measure was utilized for examining changes in teachers' mathematical knowledge for teaching. The Learning Mathematics for Teaching survey (LMT, 2008), was selected as a pre- and post-intervention measure of teachers' mathematical knowledge for teaching. The PD itself had multiple content strand foci as the PD encompassed both peripheral participation in a grade 5 mathematics program focused on fractional reasoning, operations with integers, and mathematical argumentation as well as a practice-based discussion session focused on number and operations. The trajectory of the classroom content is naturally dependent on students' progression and uptake of the content alongside the teachers' decisions about the trajectory of the work. For that reason, an LMT form focused on the Number and Operations was used. The LMT was administered in the same time frame as the video collection.

Selection of Tools for Data Analysis

Many measures exist for evaluating student outcomes of mathematics lessons, but fewer measures exist for measuring mathematics teaching practice, specifically mathematics discussion-leading practice. To determine changes in both the overall quality of the mathematics and in the specific moves that teachers were using in their discussion-leading practice, tools that are oriented on these qualities were needed.

Mathematical Quality of Instruction. The Mathematical Quality of Instruction instrument was selected to measure the overall mathematical quality of the lessons (Hill et al., 2008). This tool is not aligned with any particular orientation to the teaching of mathematics (e.g., reform-oriented instruction) or to a particular lesson structure, but rather to the depth and quality of the mathematics content available to students during instruction allowing us to discern, for each lesson, the richness of the mathematics, the precision and accuracy of the mathematics instruction, students' involvement with content through Common Core-aligned mathematical practices, and the teacher's ability to interpret and respond to students' mathematical ideas.

Discussion Leading Checklist. A complimentary tool was designed to examine teachers' specific discussion-leading moves. In prior work, a discussion-focused checklist tool was developed to formatively assess beginning teachers' practice. Using the tool entailed recording the presence or absence of particular discussion-leading moves to support the noticing of the work done by teachers in a specific discussion. A previous study showed that the tool was able to reveal variations in practice across teachers and provide fine-grained detail about the skill of teachers in leading mathematics discussion while also accounting for existing classroom norms (Shaughnessy et al., 2021). Because our PD involved practicing teachers, we expanded the list of possible moves in the checklist to more accurately capture the range of moves made by experienced teachers. These additions included advanced areas of work, such as supporting students to make connections and extending and revising student ideas. The checklist tool was designed to capture the presence or absence of particular moves. The tool was not designed to judge the skill with which the move was enacted or students' responses to the move. This is in tension with our desire to capture the quality of teaching. However, the decision was made to account for teachers' attempts to enact different discussion leading moves as we are considering the learning of teachers. Our main goal is to determine whether teachers are trying out new work to improve their practice. We know that trying out new work often results in less than perfect outcomes, particularly in early implementation. We did, however, want to capture problematic implementation to determine whether problematic enactment increased, decreased, or stayed the same before and after the intervention. To that end, the checklist tool also included a section for "issues" such as consistently ineffective probes, as well as an overarching rating indicating whether the instruction in the video was aligned with our definition of a discussion. This overarching rating is meant to serve as an acknowledgement that discussion-leading is more than the sum of the parts that can be captured in a checklist tool.

The tool necessarily focuses on specific observable moves that teachers make while leading a discussion, categorized both by the phase of the work (e.g., task set-up, discussion launch, orchestration, conclusion) and by the buckets of work that teachers must do (e.g., eliciting and probing student thinking, orienting students to one another's thinking, supporting students to make connections). This organization allowed for observations about the density of work in a particular area (e.g., the number of different moves a teacher used to orient students to one another's thinking) and the spread of work across a discussion (e.g., whether a teacher was doing work in all possible areas or if the work was concentrated in one or two areas). Each observable move was marked as present, not present, or not applicable (NA). The code of NA was used judiciously in cases where the move was unnecessary. For example, NA could be used if the task selected precluded a range of responses or methods to be shared or if the teacher did not need to further probe student contributions due to the level of detail of the contribution. Many moves had possible available codes of "once," "more than once," and "student initiated" to support the ability to analyze the frequency and the extent to which established norms seemed to be influencing the work of the teacher. For our analysis, these three codes were collapsed to present.

Data Analysis Methods

Mathematical Quality of Instruction. The 193 videos in this study were coded using the discussion checklist tool and the MQI. MQI coders attended MQI training and were certified as raters. Videos were double-coded for both instruments using associated coded books. Coders met to reconcile discrepancies for each video prior to entering final codes and resolved differences via discussion and referencing the codebooks. MQI coding was applied to equal-length chapters of the full video (approximately 7.5-minute segments), with the number of chapters determined by the length of the video. Each chapter was scored on five domains. The full video was scored on nine factors and assigned one overall score for the lesson. Chapter scores were used to create aggregate video scores for the chapter-specific points. In addition, aggregated pre- and post-intervention MQI scores were created for each participant using mean scores.

Discussion Checklist. The discussion checklist coding was applied to videos. Composite scores were created for each area of work represented in the discussion checklist tool. For those areas where work was consistently possible, sum scores or scaled mean composite scores were used to represent the amount of possible work that occurred relative to the available work. For example, an Orienting composite variable was created using the sum of the "present" moves. There were five possible moves - posing questions to students about others' ideas, asking students to restate another's idea, responding to another student's idea, adding to an idea, and interpreting the strategies of others – that could be observed. For eliciting, a scaled mean score was used to represent that there were four possible moves - eliciting multiple ideas, eliciting a range of responses, engaging several students in sharing ideas, and eliciting students' mathematical processes. A scaled mean was used to enable comparison between teachers who had all four moves available and those who only had three moves available due to task selection (e.g., a range of student responses is unlikely given the task). Composite variables included task setup, discussion launch, eliciting, probing, orienting, generic orienting, connecting/ extending/ revising, concluding, and issues. A detailed description of the checklist items associated with each composite score can be found in Table 1.

Table 1: Composite Variable Descriptions

Variable	*Description*
Task Set Up	Composite score takes into account the work the teacher does to help students make sense of the task (including reading, restating, and unpacking context), whether the teacher maintains cognitive demand of the task, and whether the students are sufficiently prepared to begin the mathematical work.
Launch	Sum score takes into account whether the teacher had the attention of all students before launching the discussion, is concise and on-task during the launch, and explicitly states the goal of the discussion.
Eliciting	Scaled mean score takes into account the work of eliciting multiple ideas, eliciting a range of responses, engages several students, asks about processes. Because not all tasks allow for a range of responses, a conditional mean was calculated based on whether a range was possible, then the mean was scaled.
Probing	Score takes into account the work of posing questions to get students to explain their understanding of relevant mathematical content or processes, or follow-up questions focused on why a student did particular work.
Orienting	Sum score included posing questions to students about others' ideas, asking to restate another's idea, responding to another's idea, adding to an idea, and interpreting the strategies of others.
Generic Orienting	Sum score accounted for generic orienting moves such as encourages the class to attend/listen/respond, uses turn-and-talk to encourage discourse, elicits student to student discourse, and uses moves that require all to respond to others' work.
Revising	Score focuses on moves to supports students to revise their work.
Connecting/ Extending/ Revising	Composite mean takes into account moves including asking students to identify similarities/differences, supporting students to connect to past work, supporting students to connect to the problem context, supporting students to connect between representations, examining efficiency, generating hypothetical situations to extend thinking, and supporting students in revising their thinking.
Concluding	Sum score accounting for the teacher making a closing statement, supporting students in remembering a key idea, and taking stock of the discussion.
Issues	Sum score accounting for problematic moves such as inaccurate revoicing, mathematically problematic contributions, over-scaffolding, consistently using ineffective probes.

Aggregated pre- and post-intervention discussion checklist scores were created for each participant using mean scores. Kruskal-Wallis tests and independent samples tests were performed on pre-data to determine whether differences between participants by study group existed. Significantly different distributions were found for study groups, indicating that separate analysis of these groups is necessary. For each group of teachers, independent samples tests were examined for the discussion checklist score pre and post PD. These tests included Levene's test for equality of variances and *t*-tests for equality of means. Paired samples *t*-tests for aggregated case data were examined by study.

Findings

Examining the data disaggregated by study group, we noticed differences in outcomes of three groups who received the full PD. Next, we unpack the features of these groups, their experiences, and their outcomes to investigate factors that influence participant outcomes.

Group H1. The first group of participants received PD in the first iteration of the study. The content of the peripheral participation experience focused squarely on setting up tasks for productive work, eliciting and probing student thinking, and supporting students to engage with others' ideas, the foundation for orienting students to one another's thinking. The participants observed minimal full-class mathematics discussion-leading work. The student group was not accustomed to engaging in discussions and the teacher had extensive groundwork to do to move toward productive discussions. The focused discussion-leading session supported participants in building their knowledge and skill with launching discussions, orienting students to one another's thinking, representing and recording content, and concluding discussions.

This group entered the professional development with a group LMT score of approximately 0.51 standard deviations above the mean. Overall, few discussions were led prior to the PD, with approximately 20% of the submitted pre-videos rated as aligned to our definition of discussion. Despite a low number of discussions being led, the mean score of the submitted lessons (M = 3.222, SD = 0.43) on the MQI Whole Lesson Mathematical Quality of Instruction was slightly above the middle rating of 3.0 on a 1-5 scale.

Following the PD, this group showed a nearly significant (p = 0.053) increase on paired t-tests in the number of discussions led, with approximately 36% of submitted post-videos demonstrating a discussion. This group also showed significant increases in task set-up (p = 0.012), eliciting (p = 0.009), and concluding (p = 0.016). Nearly significant increases were shown in probing (p = 0.077), generic orienting (p = 0.084), and revising (p = 0.056).

Group H2. The second group of participants received PD in the second iteration of the study. The content of the peripheral participation focused on the full spectrum of discussion-leading practice, beginning with work on setting up tasks for discussion and eliciting student thinking, followed by orienting students to the thinking of others, with the sophistication of orienting moves increasing across the experience. The content of the focused discussion-leading session was identical to the first iteration.

This group entered the professional development with a group LMT score of approximately 0.27 standard deviations below the mean. Overall, few discussions were led prior to the PD, with approximately 15% of the submitted pre-videos rated as aligned to our definition of discussion, a slightly lower percentage than Group H1. The mean score of the submitted lessons (M = 2.7407, SD = 0.49) on the MQI Whole Lesson Mathematical Quality of Instruction was slightly below the middle rating of 3.0.

Following the PD, the group showed no significant difference in the number of discussions (p = 0.347) or any category captured by the checklist tool. Near significant increases were seen in generic orienting (p = 0.069).

Group A2. The third group of participants received PD in the second iteration of the study. The peripheral participation was completed via live-stream and the focused discussion-leading session was delivered by the facilitator who co-facilitated the session in the first iteration of the study. The content of the peripheral participation was identical to that of Group H2.

This group entered the PD with a group LMT score of approximately 0.65 standard deviations above the mean. A high number of discussions were led prior to the PD, with approximately 89% of the submitted pre-videos rated as aligned to our definition of a discussion.

Additionally, the mean score of the submitted lessons (M = 3.8611, SD = 0.54) on the MQI Whole Lesson Mathematical Quality of Instruction was well above the middle rating of 3.0.

Following the PD, the group showed no significant difference in the number of discussions or categories captured by the tool. Nearly significant increases were seen in connecting/extending (p = 0.055) and revising (p = 0.080).

Discussion and Implications

There were clear differences in the outcomes of the three study groups, with study group H1 showing the most gains from the PD. We hypothesize three potential reasons for these differences. The first potential hypothesis focuses on the content of the peripheral participation. Group H1 experienced peripheral participation where the discussion-leading work of the teacher was slower in pace, more repetitive, more deliberate, and more challenging than that of the peripheral participation of Group H2 and A2. It is possible that the pacing and repetition made this work more accessible to participants than the smooth, quickly progressing work of iteration 2, thereby allowing participants to consider the specific moves the teacher was making and how they might be incorporated into their own classrooms. They may also have identified directly with the challenges of this work and were ready for the same challenges in their own classrooms.

A second possible hypothesis for the differences is related to incoming knowledge and skills. Groups H1 and A2 both entered the PD with above average mathematical knowledge for teaching and above average mathematical quality of instruction as measured by the whole lesson MQI score. Group H1, however, was not engaged in consistent discussion-leading, unlike Group A2. One explanation for the changes seen in Group H1 is that they had the mathematical knowledge to lead discussions and strong general mathematical instructional skill, but did not yet have discussion-specific skills, but improved in this area following the PD. In contrast, Group A2 brought mathematical knowledge, general mathematical instructional skill, and high discussion-leading skill and so they had less room for improvement. Group H2, on the other hand, entered with low mathematical knowledge, below average mathematical quality of instruction as measured by the whole lesson MQI score, and the lowest level of discussion leading practice of the three groups. It is possible that low mathematical knowledge combined with below average mathematical quality of instruction meant that these teachers were not yet ready for the pace of the PD or to focus on discussion-leading practice.

One final hypothesis is related to contextual factors, which were not measured by the instruments described in this paper. The teachers in Groups H1 and A2 were in consistent school environments where their grade level assignments were stable and their administrators appeared to support their involvement in the PD. Participants in Group H2, on the other hand, discovered during the PD that they would all be changing grade-level assignments due to administrators' decisions based on student outcome data. Learning about this change likely distracted their focus and a grade change can be challenging for implementing new techniques.

Further analysis is needed to determine which of these factors most impacted the PD outcomes. However, the current results do point to the importance of teachers' incoming knowledge and skills to the outcomes of mathematics professional learning.

The analysis reported here examined the initial relationship-building activities a research team engaged in with educators and children at a local elementary school, as they began to develop a partnership. In our initial interactions and activities with educators, we had three goals: 1) to develop relational trust, 2) to get to know the institutional settings in which teachers worked, and 3) to design responsive professional learning alongside teachers and leaders. In this brief report, we focus on the second goal and examine the following question: How do you come to know the adults and children in a school in order to design professional learning? We discuss our findings in relation to understanding school leaders' vision for teaching and teacher learning; teacher support structures and accountability; and teachers' experience, dispositions, and practices. Implications for improving learning conditions for each and every learner are discussed.

Keywords: professional development, elementary school education

In this brief research report, we discuss findings from an analysis that examined the initial relationship-building activities a research team engaged in with educators and children at a local elementary school, as the practitioners and researchers began to develop a partnership. The school reached out to the university for assistance in supporting teachers' instructional practices in mathematics. Simultaneously, the researchers were interested in finding a school partnership where they could study how teachers learn to facilitate classroom discussions. The larger goal is to develop a long-term collaboration with mutual aims to engage in school-wide learning and transform educational outcomes for students. Thus, we had three goals in our initial activities with teachers and school leaders: 1) to develop relational trust (Bryk & Schneider, 2002), 2) to get to know the institutional settings in which teachers worked, and 3) to design responsive professional learning alongside teachers and school leaders. In this brief report, we focus on the second goal and examine the following question: How did we come to know the adults and children in a school in order to design professional learning in partnership?

Perspectives

Research-practice partnerships (RPPs) are defined as "long-term collaborations aimed at educational improvement or equitable transformation through engagement with research." (Farrell et al., 2021, p.5). Scholars have identified five principles of RPPs: 1) RPPs are long-term collaborations, 2) RPPs work toward educational improvement or equitable transformation, 3) engagement with research is a leading activity in RPPs, 4) RPPs intentionally organized to bring together a diversity of expertise, 5) partners in RPPs employ strategies to shift power relations in research endeavors to ensure all participants have a say (Farrell et al., 2021).

Aligned with each of these principles in different ways, our goal was to get to know an elementary school and build relationships to support the development of a research-practice partnership. This is important for three reasons. First, by learning about the school and working to build relationships, we aimed to build trust and encourage the partnership to become a long-term partnership that is mutually beneficial to ourselves and our school partners (Henrick et al., 2017). Second, becoming familiar with the students and teachers supported our endeavors to design professional learning aimed at more equitable instructional practices. Third, developing relationships with teachers and school leaders helped exemplify our desire to center and honor the expertise of school staff, which helps amplify teachers' voice and shift power relations.

The analytic approach that we take views schools as lived organizations (Cobb & Smith, 2008), which means we are trying to understand the work that teachers and school leaders are accomplishing, and the interconnections between them. It is important to uncover teachers' workplace practices to understand possibilities for the ways in which teachers can interact with students and with the content they teach (Cobb et al., 2003; Cohen et al., 2003; Resnick, 2010). Examining the institutional setting can include understanding: 1) for what teachers are held accountable; 2) what set of supports teachers currently receive, 3) the curriculum materials and messages around what is valued in teaching and learning; 4) how the instructional program is set up (e.g., whether there is tracking for mathematics); 5) teachers current opportunities for collaboration and access to expertise and key resources; and 6) individual teacher's current stances, dispositions, and instructional practices (Cobb & Smith, 2008; Diamond, 2007).

Methods

Context and Data Collection

This study is part of a larger project focused on understanding how elementary school teachers facilitate classroom discussions. As part of this project, we partnered with Partner Elementary School (PES; a pseudonym) to provide job-embedded professional learning experiences using the Learning Labs structure (see Kazemi et al., 2018) centered on enacting classroom discussions. For this study, we leveraged data from pre-interviews with teachers and school leaders, observations of weekly grade-level meetings, and observations of Learning Lab planning meetings and events. Interviews with school leaders were conducted that focused on their goals for students' learning and teaching, conceptions of teacher learning, and instructional leadership. Interviews were conducted with teachers who agreed to participate in the research activities prior to their first Learning Lab. Interviews lasted approximately 45 minutes and included questions regarding teachers' perceptions of classroom discussions and about the settings within which they work. Learning Labs were conducted in half-day sessions with grade-level teams; each team participated in two Learning Labs (for a total of 12 Labs). Prior to each Learning Lab, in order to be responsive to teachers' current instructional realities, the research team met with the teachers during their grade-level team meetings to understand the mathematics content in the upcoming unit. Field notes were captured after each weekly meeting. With information gathered from the teachers, the research team then met to plan the upcoming Learning Lab, identifying goals for teacher learning based on our understanding of teachers' needs. Finally, each Learning Lab was video- and audio-recorded and teachers were asked to complete exit tickets at the end of the Learning Lab.

Data Analysis

We examined a subset of the data through iterative rounds of qualitative data analysis to explore teacher support structures and teachers' experiences, dispositions, and instructional practices within the institutional setting. First, we read all sources in the subset, recording preliminary jottings (Saldaña, 2016) as a form of pre-coding. We next re-read the sources and applied a priori provisional codes informed by Cobb & Smith's (2008) proposed support structures to improve mathematics teaching and learning. This a priori scheme provided structure to the data before we engaged in open coding to locate emergent themes within and across provisional codes (Saldaña, 2016). Open coding was conducted by teams of two, during which we convened in small groups recursively to engage in consensus conversations. We finalized the codebook and used axial coding to create substantive themes that aligned with and illustrated components of getting to know a school partner (Maxwell, 2005; Saldaña, 2016).

Results

Understanding School Leaders' Vision for Teaching and Learning

Understanding how and why principals enact leadership within particular school improvement and change efforts is important (e.g., Leithwood, 2019). Thus, we wanted to understand how the school leaders at PES considered goals for students' learning in mathematics, the envisioned mathematics instruction they wanted taking place in classrooms, and their vision for how teachers improve their mathematics teaching and how they conceived of teacher learning. We also were interested in understanding how they enacted instructional leadership practices that were intended to support the teaching and learning of mathematics, including what they were holding teachers accountable for and their role in supporting teachers to make sense of policy messages from the district and state. While we do not have room to detail responses here, we learned that the school leaders' main mechanism of direct support for teachers was "doing walk-throughs and giving feedback, being in [grade-level meetings], so that I can hear what the teachers are saying and feeling and talking about, but then also I can help throw in those questions to help them think about some ideas…." (Principal Interview, 34:30) The principal also talked about the utility of a notice and wonder protocol for pushing teachers to think differently.

Teacher Support Structures and Accountability Expectations

Through our interviews with teachers and the school leaders, we learned about a number of supports and related expectations, including professional learning opportunities, weekly collaborative time, and curricular support. When we inquired about teachers' current opportunities for professional learning, we found out that the school received university-supported literacy coaching, with visits approximately 3-4 days per month. Most teachers reported not having support in mathematics during the current nor prior school years. There were no school, university, or district-based mathematics coaches, nor were there district-wide professional development opportunities in mathematics.

With respect to collaborative time, we learned that teachers had one 45-minute block of time each week to work in grade-level teams. This was a shift from prior years when grade-level teams met twice per week. During this time, there was an expectation that teachers would follow a particular agenda and discuss particular ideas, guided by the school leaders. There appeared to be time for teachers to discuss current problems of practice.

The teachers were expected to use the district-adopted Bookworms curriculum for English language arts and the online version of Eureka Math curriculum (called "Zearn") in mathematics. Teachers described the challenge around returning to the classroom in Fall 2021 amidst the pandemic and the requirement that each day students would spend time on the computer engaging in fluency practice, watching an actor explain the mathematical ideas of the lesson and solving a related task online. One teacher described:

> Our Math block is 70 minutes, which sounds unbelievable. Woo. But really, the amount of time that I have to do the instruction is really 30 minutes… I've got to get through the word

> problem and my little lesson and then Zearn [online computer program] starts at 1:00. And then they do their Zearn. And during the time that they're doing their Zearn, then I'm pulling my RTI small group instruction. So I look at that 30 minutes of time. (Ms. C, 18:43)

Other teachers similarly expressed concern with the amount of time students' spent on computers with the online curriculum, and whether and what they had opportunities to learn about mathematics. However, teachers shared with us that their teaching evaluations were tied to the amount of time each week students completed online mathematics lessons (a district mandate) and most felt that they had no choice but to do what was being asked of them by district leaders.

Teachers' Histories and Instructional Approaches

Through our one-on-one interviews with teachers and visits to classrooms, we learned about their histories, their current instructional practices as well as their dispositions related to teaching. While many of the teachers we interviewed were quite experienced in the classroom, they were greatly influenced by the district expectations for using the online Zearn curriculum. Despite these constraints, teachers were committed to "doing what was best for the students", a refrain we heard often across teachers. We were especially curious how whole-class discussions were happening in classrooms, which was part of our project goals. For example, we saw an opportunity for more whole class discussion in the context of Ms. C's explanation of a "little lesson" that she leads ahead of the students' work time on the computers. Other teachers similarly felt that they could not lead whole class discussions because of the demands of the math block and because their curriculum was not organized around students engaging in whole class discussions.

We also learned about interesting variation in the extent to which teachers were adhering to district expectations around curriculum, and wondered about how to capitalize on those local productive adaptations (Russell et al., 2020). For example, one teacher chose to use a more inquiry-oriented curriculum to support her mathematics instruction instead of the district-adopted curriculum. She was asking her other same grade-level teachers to consider joining her.

We analyzed teachers' responses to instructional vision questions to get a sense for whether teachers shared a vision for mathematics teaching. We also attended to common language that they used so that we could make explicit connections to their ways of talking and their goals when appropriate. This allowed us to consider initial teacher learning goals that are appropriate for different groups of teachers in the school.

Discussion

We set out to provide other mathematics education researchers with ideas for the types of activities and interactions that we used and found helpful in getting to know our school partners. Through our interactions, we identified aspects of the current institutional setting where there were synergies through existing expertise or initiatives we could take into account (e.g., weekly grade-level team meetings, principal instructional leadership through pressing teachers during planning or feedback after watching instruction). We also identified points of tension where we would need to actively think with our partners about how to navigate the competing demands (e.g., teacher evaluation system emphasizing computer curriculum coverage which was perhaps at odds with leaders and teachers' desires to support student discussion). While the analysis examined one case of relationship building, our findings have broader impacts on society as we consider the relationships necessary in partnerships that work to improve learning conditions for each and every learner. In a subsequent analyses, we plan to examine how we used these relationship building activities and what we learned about teachers' institutional settings to design professional learning that will challenge a settled mathematics learning status quo.

WHAT DO THE EMERGING THEMES IN HIGH SCHOOL TEACHERS' JOURNALS TELL US ABOUT THEIR THINKING?

Beste Güçler
University of Massachusetts Dartmouth
bgucler@umassd.edu

Jane Chunjing Ji
University of Louisiana Monroe
ji@ulm.edu

We examine in-service high school teachers' journals to explore the emerging themes in a mathematics content course for their professional development. We use a sociocultural perspective and characterize journals as signifying teachers' communication and written discourses about their thinking and experiences in the course. We use applied thematic analysis to analyze the emerging themes. Our results demonstrate the complexity of teacher thinking and suggest that teachers do not necessarily separate their thinking about themselves or mathematics from their thinking about their students; similarly, they can take different roles as teachers and learners in a given context. Our results indicate exercising caution about potentially operating with an oversimplified picture of teacher thinking via compartmentalized pieces, especially if such frameworks are used to measure teacher thinking, knowledge, and development.

Keywords: Communication, discourse, professional development, calculus

Introduction

Journal writing has been used in mathematics education for various purposes. Our literature review about journaling revealed that, in the context of mathematics education, journals were mostly used with students. Such work examined students' mathematical thinking and cognitive skills; problem solving; their beliefs and attitudes about mathematics, and rarely, their mathematical communication (e.g., Baxter, 2008; Farmer et al., 2003; Liljedahl, 2007; Rolka et al., 2006). Journals have also been used in teacher education, particularly in relation to reflective thinking and practice (e.g., Schön, 1987). Considered mainly as reflection tools,—although what is meant by reflection is rarely defined in these works— researchers used journals to examine teachers' professional knowledge and experience; professional identity; dispositions and beliefs in teaching and learning; pedagogical and professional development; their reflective and critical thinking on various issues; and experiences in their teacher education programs and courses (e.g., Joseph & Heading, 2010; Garmon, 2001; Mewborn, 1999; Snyder, 2012). Compared to the literature on journaling in the context of general teacher education, the literature on journaling specific to mathematics teacher education is sparse and primarily focuses on pre-service teacher education at elementary levels. Our work focuses on examining in-service high school mathematics teachers' journals in the context of a mathematical content course they took as part of their professional development since what teachers take from their experiences in professional development remains a challenging issue to address in mathematics education research (Farmer et al., 2003).

Regarding the theme of PME-NA, our work challenges (a) the dominant cognitive approach that is often used while examining reflection as well as student and teacher journaling, and (b) the traditional psychological approach that views participants' accounts of events and their experiences as unreliable, implying a mistrust towards "subjects" of a study. We will use a sociocultural approach to conceptualize reflection and journals and consider our participants' accounts of their experiences as authentic sources through which we can gain more information about their thinking and development in professional development settings. We address the following questions: What themes emerge in high school teachers' journals in relation to their thinking in a calculus content course they took for professional development? What do the emerging themes in these teachers' journals indicate regarding their thinking, knowledge, and development? Our findings challenge the dominant trends in mathematics teacher education research that view teacher knowledge as consisting of distinct types or pieces of knowledge that can be identified and measured through multiple-choice tests, mainly conceptualized from the perspective of the researchers (rather than those of teachers), and mainly utilizing cognitive perspectives.

Theoretical Framework

The study uses a sociocultural perspective that conceptualizes thinking as communicating and discourse as a "special type of communication made distinct by its repertoire of admissible actions and the way these actions are paired with re-actions…discourses in language are distinguishable by their vocabularies, visual mediators, routines, and endorsed narratives" (Sfard, 2008, p. 297). From this lens, thinking and communicating are not viewed as separate but connected activities; examining learners' discourses (communication), is tantamount to examining their thinking. Consistently, we characterize journal entries as written endorsed narratives involving the reflections (defined as meta-level discourses, i.e., discourses about discourses) of the teachers with respect to mathematics, their pedagogical approaches and practices, and their overall experiences and thoughts in the course. We view journals as written discourse with a communicational function (with one's self or others). By examining journals, we explore the (emergent) thinking of teachers in relation to the professional development course. Rather than viewing journals as signifying potentially "unreliable" accounts of participants' thinking, we view them as consisting of narratives that provide us with authentic information, from the participants' perspectives, of what they consider to be an honest account of their thinking and experiences.

Sociocultural approaches also highlight the interpretive aspect of research and the importance of context in meaning-making (Denzin & Lincoln, 2000). Consistently, we do not consider the narratives of the teachers in their journal entries as proxies for (often decontextualized and generalized) entities such as their cognitive schema, knowledge (or lack thereof), metacognition, beliefs, or attitudes. We consider these narratives as contextual indicators of teachers' discourses and thinking, keeping in mind that, while these narratives signify the authentic voices of the teachers, research is also an interpretive process that includes the researchers' presuppositions, theoretical perspectives, and personal stories (Denzin & Lincoln, 2000).

Background

This work is part of a larger study that took place in a postsecondary mathematics content course on calculus taken by in-service high school teachers as part of their professional development requirements (in our case, there was also one pre-service teacher taking this course, which was a programmatic exception). The researcher was the instructor of the course. The larger study hypothesized that an instructional approach that specifically attends to the tacit aspects of the mathematical discourse on various calculus concepts could support teachers' learning of those concepts (Güçler, 2016). A critical component of instruction was to elicit rich classroom discourse as well as reflection on and explication of teachers' mathematical discourses to promote learning.

Since we wanted reflection (meta-discourse) to be a continuous and consistent aspect of the course, the teachers also kept weekly journal entries throughout the course where we asked them to reflect on any aspect of the course that they wanted. We collected these journals thinking that they would give us more information about how the teachers' thinking about calculus concepts evolved over time and help us triangulate the data we obtained. Further, we wanted to elicit teachers' authentic voices about their own experiences independent of the potential constraints of the questions we posed to them in the pre- and post- explorations. Although the primary focus of the original study was on teachers' mathematical discourse, the journals gave us richer information that went beyond teachers' mathematical thinking and learning. This paper only focuses on the discursive themes that emerged from the teachers' journals as they reflected on their experiences in the course and the implications of the results in terms of teacher thinking, knowledge, and development.

Methodology

The participants of the study were 1 pre-service, 7 in-service high school teachers taking a mathematics content course on calculus over the course of 13 weeks. Except for the pre-service teacher, the participants' experiences ranged 4–12 years. The journal entries were collected in the course of a semester and consisted of 11 entries for each teacher. In these journals, the teachers were asked to reflect on any aspect of the course or classes without any specific prompt from the researchers. This task was deliberately left open-ended so that the teachers could write about whichever issue interested them or puzzled them from week to week, at their discretion, to elicit their authentic voices. Most teachers kept their journals electronically, as a text document. Three kept physical journals in the form of written notes, which were scanned and transcribed (verbatim) to electronic text documents at the end of the course. These electronic journals were later transferred to the NVivo 9 software package and all the emergent coding took place in this software environment.

We used applied thematic analysis (Guest et al., 2012) to examine the emerging discursive themes in the teachers' journals. Unlike the initial focus of the study which put teachers' mathematical discourses at the forefront through an a priori coding structure (we do not report on those in this paper), the emerging themes helped us identify the discursive patterns which put teachers' mathematical discourses at the background. In other words, in the context of these emerging themes, the teachers could still be communicating about mathematics, but our focus was not on their mathematical discourse per se but on the larger theme that included the mathematical communication.

In addition to the researcher, four doctoral students were involved in the coding and analysis of the data. The project team met each week; reported on and discussed the emerging themes; and compared the coding of the previous week and elaborated on the specific instances and cases in which our coding differed until we reached agreement. This iterative, generative, and interpretive process was repeated until saturation, eventually resulting in about 90% interrater agreement.

When coding, our first focus was on segmentation, which concerns how to bound the text (Guest et al., 2012). To assure our coding did not ignore the contexts in which the discourse emerged, we characterized a segment as consisting of an excerpt that signified a complete thought so that the meaning of the segment can "clearly be discerned when it is lifted from the larger context" (Guest et al., 2012, p. 52). Therefore, in our analysis, segments often consisted of multiple sentences, which also helped us avoid overrepresentation of themes and promoted exploring relationships among the themes.

The first themes in our initial examination of the journals emerged from contexts where the teachers referred to themselves as teachers (SAT: self as teacher) or learners (SAL: self as learner). Future iterations of coding resulted in the emergence of subcategories under these two categories. We noted that, within the context of SAL, the teachers discussed their own content-related (mathematical) difficulties (CD) and communicated about their enhanced learning (EL) in the course. Under the theme of SAT, three sub-categories emerged: TC, which refers to the contexts in which teachers wrote about the factors they thought constrained their teaching; SD, which refers to the contexts in which the teachers wrote about their students' difficulties about mathematical content they either experienced before or can now anticipate; and TS, which refers to the contexts in which the teachers wrote about their teaching strategies. After further examination, two subcategories emerged under TS: ES, where the teachers wrote about their existing strategies, and FS, where they wrote about the strategies they would use in the future as a result of their experiences in the course. Other emerging themes included the contexts in which the teachers' talked about the influence of the instructor (II) and the influence of their peers (PI) in the classroom in shaping their thinking and experiences in the course.

Results

Space constraints do not allow us to elaborate on all the emerging themes and their relationships in detail, so we primarily focus on the themes SAL, SAT, and some of their subcategories and relationships since they were the most dominant themes in teachers' discourses in their journals. We want to highlight that we do not make claims about teacher identity in the context of our study because, although some aspects of the teachers' discourses in the themes SAL and SAT may give us some insights about their identities, we believe that the data we have about SAL and SAT is insufficient to provide a rich and meaningful depiction of the teachers' identities, which are multi-faceted and require a data collection process that goes beyond merely examining their journal entries.

In teachers' journal entries, we identified 166 occurrences of the theme SAL and 156 occurrences of the theme SAT. We identified 71 occurrences in which the participants referred to themselves as teachers and learners in the same context (SAL ∩ SAT). Therefore, in about 43% of all SAL contexts, the participants also referred to themselves as teachers and in about 46% of all SAT contexts, the participants also referred to themselves as learners. The following excerpts provide examples for the themes SAL, SAT, and SAL ∩ SAT. All the names used in the study are pseudonyms and Steve is the only pre-service teacher in the course.

[1] Lea: I now understand that 'one to one' means simply that each *x* value is paired with exactly one *y* value, with no two x's being paired with the same *y* (injective). Also, 'onto' is when all elements in both sets are used (surjective). I am glad that I learned about these terms and their definitions. (SAL)

[2] Carrie: As a teacher, my experience shows that modeling is very challenging for students. They struggle analyzing graphs to create a story and creating graphs for verbal models. Today's class activity would lead into a great discussion regarding modeling, slopes, displacement, velocity, acceleration, etc. This is an activity that I will use in many of my classes as well as share with many of my colleagues. (SAT)

[3] Martin: I am continuing to struggle with the concept of derivative. I am grasping the rules, but I am having trouble with the concepts and applications. I can now understand where students can have trouble when I teach this. The main issue I am having deals with the concept of continuity. There was a question on homework that dealt with whether the first derivative was defined but the second derivative was not. I still am having trouble

understanding that concept, so as a teacher I can now understand that my students may have trouble with similar issues as well. (SAL ∩ SAT)

As can be seen from these excerpts, the teachers' discourses indicate that they can take different roles as teachers and learners in a given context. In addition, their discourses also indicate that there may also be other themes or subthemes embedded in a given context in addition to SAL, SAT, and SAL ∩ SAT. For example, in excerpt [1], which is coded as SAL, Lea also mentions that she "now understand[s]" the terms and "learned about these terms and definitions", which indicate enhanced learning and/or understanding as a component of SAL. Therefore, we also coded excerpt [1] as EL, based on our definition of this theme. In excerpt [2], Carrie refers to herself as a teacher (SAT) but she also mentions the activity in her professional development course as an activity she will use in her own teaching as a future teaching strategy as a component of SAT. Therefore, we also coded excerpt [2] as FS. In excerpt [3], Martin refers to himself both as a teacher and a learner (SAL ∩ SAT). When writing about himself as a learner (SAL), Martin mentions his content-related struggles and difficulties, so this excerpt also provides a context for CD as a component of SAL. On the other hand, he associates the difficulties he has with derivative with the difficulties his students would have about the concept, so we also see the theme SD as a component of SAT in the same excerpt. The examinations of the segments we identified as signifying a complete thought reveal the complexity and dynamic characteristics of teacher thinking, knowledge, and development. Excerpts [1-3] show that, even in such a small set of exemplars, we can see the emergence of themes, subthemes, and how they can be intertwined in complex but crucial ways.

In this paper, we want to also focus on CD, SD, and contexts in which both themes occurred (CD ∩ SD). Note that excerpt [3] shows how a teacher can think about his own difficulties and his students' difficulties in the same context, and provides an example for the theme CD ∩ SD. In what follows, we provide examples for the themes CD and SD:

[4] Fred: Oh, I have to get out of the habit of thinking of a function as a single rule or rigid model describing a situation – think piecewise! I struggled with the functions defined piecewise in today's class. (CD)

[5] Sally: This week, we talked about why continuity and limits were connected and how they related to each other. Most students have difficulty understanding that if you have a continuous function then the limit exists but that doesn't necessarily mean that if the limit exists then the function is continuous. It is a one-sided relationship and tends to be misconstrued as relationship that works both ways. (SD)

We identified 91 occurrences of the theme CD, 86 occurrences of the theme SD, and 50 occurrences of the theme CD ∩ SD in the teachers' journals. Therefore, in about 55% of all CD contexts, the teachers also mentioned their students' difficulties and in about 58% of all SD contexts, they also mentioned their own content-related struggles in the course. This major overlap may be interpreted in various ways. This finding may be an indicator that teachers' own difficulties with calculus concepts can significantly inform their thinking about their students' difficulties and vice versa in a context. If that is the case, a potential association of CD with teachers' mathematical content knowledge and the association of SD with teachers' pedagogical content knowledge can be very problematic. The characterization of teachers' own mathematical thinking and knowledge as aspects of their mathematical content knowledge and their knowledge of student thinking as an aspect of their pedagogical content knowledge is quite common in mathematics education research focusing on teachers, where these "types" of knowledge are characterized as distinct, albeit related, components of teacher knowledge. Our results, however, show that these constructs may be almost inseparable within a given context in a way that may make it very challenging to identify or measure which "type of knowledge" teachers may have at a given time, especially if such measurement is being made through one-shot multiple-choice tests or decontextualized assessment problems and/or instruments .

Another potential explanation for the major overlap may be due to the teachers' profound struggles in this calculus content course and, in the absence of familiarity with the conceptual aspects of calculus and rich thinking about student difficulties about calculus concepts, the teachers mainly referred to their own struggles as resources and means for anticipating most of the student difficulties about calculus. In fact, there is some evidence in our data that the teachers who struggled most with the content were also those whose discourses included a larger number of occurrences for the theme CD ∩ SD.

Within the context of SAL, the relationship between CD and EL may also be worthy of some elaboration. In teachers' journal entries, we identified 91 occurrences of the theme CD, 53 occurrences of the theme EL, and 27 occurrences of the theme CD ∩ EL. In about 30 % of all the CD contexts, the teachers also mentioned enhanced learning or understanding and in about 51% of all the EL contexts, they also mentioned their content-related difficulties. The following excerpts provide examples for the themes CD, EL, and CD ∩ EL.

[6] Milo: I had a bit of confusion today when we started discussing derivative. If I recall, finding the derivative of basic functions is not too difficult, but understanding the meaning behind it and why-that's created a headache for me today since I don't know those meanings. (CD)

[7] Steve: I believe I am leaving this class with a better understanding of every calculus concept we covered, and for that I feel like I am prepared to be an efficient and effective teacher of calculus. Thank you for helping me attain a greater understanding about these topics, topics I already thought I was knowledgeable in. (EL)

[8] Lea: As we continue our discussion of limits in class, it is clear that I struggle and have much to learn conceptually about limits and other concepts of calculus. Although I am thoroughly enjoying the challenges brought forth each week, at times I am very humbled in the realization that there is a lot that I still struggle and need to learn about these calculus concepts. For example, this week I learned that we can view a limit being a process or a product or both depending on context! (CD ∩ EL)

The results and the excerpts indicate that challenging teachers mathematically can be a good strategy to promote teacher development (enhanced learning). Although teachers may not realize every occasion where they experience a difficulty as an opportunity to learn, our results suggest that when they reflect on their learning and explicitly mention enhanced learning, they seem to have a tendency to think about the contexts in which they struggled with mathematics. Professional development environments which do not only put teachers in a teacher role reflecting on student thinking but also in a learner role where they genuinely struggle with content and reflect on their own mathematical thinking have the potential to provide rich learning opportunities for teachers. In addition, the existence of the theme EL as an emergent theme in the journals, which is elicited through the teachers' own voices and discourses, can also suggest that journal entries may be useful resources for teacher educators in assessing teacher learning or development in professional development situations. We promote the use of journals as potential teacher assessment tools because we believe they may provide context regarding teacher thinking, which is a critical component when examining their development and also because of the connections we observed between the themes EL and FS as will be discussed next.

In teachers' journals, we identified 53 occurrences of the theme EL (as a component of SAL), 43 occurrences of the theme FS (as a component of SAT), and 21 occurrences of EL ∩ FS (as a component of SAL ∩ SAT). In about 40% of all the EL contexts, the teachers also mentioned pedagogical strategies they would use in the future and in about 49% of all the FS contexts, the teachers mentioned enhanced learning or understanding. Excerpt [7] provides an example for the theme EL. The following excerpts provide examples for the themes FS and EL ∩ FS.

[9] Ron: I liked in class how you asked the class to use one word to define function and then asked the class to use those words to form a definition. I feel that in teaching algebra II, I will use this approach since this could really get the students thinking. Students can take their previous knowledge of functions or any other concepts and reason through that when defining the concept. (FS)

[10] Sally: I can now say that when I start teaching functions next year, I will approach this topic completely different. I will now open my students up to a more discussion-based approach where we can openly look at the definition of function and talk about what makes something a function and what makes something not a function. This way they aren't trained to only know linear or quadratic functions. They won't consider a function just the "equation" or "graph" or "table" but know why the table represents a function or why the rule represents a function. My own learning and understanding of the topic in a deeper way helped me think about changing how I teach functions. (EL ∩ FS)

The results and the excerpts suggest that, although the teachers did not necessarily consider all the contexts in which they mentioned enhanced learning as opportunities to also reflect on the teaching strategies they would use in their future practice, almost half of their discussions about their future pedagogical strategies included teachers referring to their enhanced learning in the context of the course. This also suggests that changing teacher practice may be closely related to teachers changing their thinking (enhanced learning) about mathematical concepts.

Discussion

The results of the study demonstrate the complexity as well as the dynamic and situational nature of teacher knowledge, thinking, and development. A contextual analysis of teachers' (meta) discourses based on their authentic voices indicate that the teachers in our study did not separate their thinking about themselves or mathematics from their thinking about their students; similarly, they took different roles as teachers and learners in a given context. These findings challenge the existing trends in defining and measuring teacher knowledge, where such knowledge is often characterized as consisting of compartmentalized pieces (e.g., mathematical content knowledge, pedagogical knowledge, pedagogical content knowledge, mathematical knowledge for teaching). Contextually, these distinctions can be blurred, much more integrated, and complex. The emerging themes in the teachers' journals provide a cautionary tale regarding the potential dangers of providing an oversimplified picture of teacher thinking, knowledge and development (Beswick et al., 2012).

Schoenfeld (2007) highlights the importance of exploring which type(s) of knowledge that the measures assess and notes that "much needs to be done in fleshing out the relevant knowledge base to be tested and determining how well the items used actually reflect the desired competencies" (p. 204). Fauskanger (2015) found that the multiple-choice responses teachers provide in the assessments of their mathematical knowledge for teaching may not reflect their knowledge as expressed in their open-ended, constructed responses and noted that a teacher could give an incorrect response to the test item but demonstrate conceptual understanding in the latter context. There may also be clashes between the researchers' and teachers' expectations and interpretations of the test items, their goal, and what they are supposed to measure (Fauskanger, 2015). Beswick et al. (2012) note that the precise way in which different types of teacher knowledge are conceived and "how aspects of such a conception beyond 'facts that are known' is incorporated" in such models is not clear (p. 133). It is important to note that, despite their problematization of the current approaches towards assessing teacher knowledge, researchers may still operate from only a cognitive view and may still provide attempts to "refine" or "expand" the characteristics of different types of teacher knowledge for better and more reliable assessment (e.g., Fauskanger, 2015; Beswick et al, 2012; Schoenfeld, 2007).

Characterization and assessment of teachers' knowledge or development based on knowledge compartmentalization and on the cognitive "knowledge-as-acquisition" metaphor (Sfard, 2001) can be problematic since this may not reflect the multi-faceted, dialogical, social, cultural, and contextual nature of teachers' thinking, knowledge and development, especially when viewed from sociocultural lenses which often characterize learning and development as occurring through enhanced participation in mathematical communities of practice (Lave & Wenger, 1991) through the "knowledge-as-participation" metaphor (Sfard, 2001). Our findings suggest that the theoretical frameworks that go beyond cognitive constructivism can be useful in our explorations and (re)interpretations of what we mean by teacher knowledge, thinking, and development and whether, and how, to assess them through standardized instruments. We believe sociocultural frameworks have a lot to offer to the field as we continue thinking about these critical issues, particularly if we want to put the voices of the teachers at the center of our discussions about teacher education in mathematics education research.

In this study, we examined one group of elementary mathematics teachers' experiences in connecting mathematics to the real world. The professional development collaboration was designed to connect mathematics to the real world, particularly connecting to students' funds of knowledge. We interviewed seven elementary teachers about their experiences in connecting mathematics to the real world and to what they knew about their students. We categorized the teachers' responses resulting in the Connecting Mathematics to the Real World framework. Our findings show that while almost all teachers had implemented typical word problems as a way to connect mathematics to the real world, none had incorporated contexts relevant to their students' lives. However, most of the teachers expressed interests in developing lessons that were more relevant to their students' lives.

Keywords: Social Justice, Culturally Relevant Pedagogy, Elementary School Education, Equity, Inclusion, and Diversity.

Purpose of the Study

The purpose of this study is to examine one group of elementary mathematics teachers' experiences in connecting mathematics to the real world before engaging in a professional development. Research question: *What are teachers' experiences in connecting mathematics to the real world at one elementary school?*

Literature & Theoretical Framing

What Does Connecting Mathematics to the Real World Mean?

Extant scholarship has explicated several ways that teachers can connect mathematics to the real world. These include a) situating problems in story contexts (typical word problems), b) analyzing real-world data or real-world situations (that may or may not matter to the students per se), or c) connecting to students' funds of knowledge (both mathematically and with the context). We discuss each of these below.

Word/Story problems. One common way to connect mathematics to the "real" world is through story problems (Gainsberg, 2008). However, these story problems are often created with common but unimportant contexts, for example, a focus on “apples, puppy dogs, and ice cream” (Koestler, 2012) rather than on issues students really care about. These word problems might be about 2 trains that meet somewhere or purchasing 42 watermelons and so forth. Though the math is put in a story context, these problems are often simply exercises to do, not real problems that students are motivated to solve. When asked to create word problems with real-world connections, most teachers tend to focus on the math rather than the context (Lee, 2012).

Analysis of real data, bring in real-world issues (not necessarily relevant to the students in the class). Teachers can bring in real data or real-world issues to connect mathematics to the world (Gainsberg, 2008; Gutstein, 2006). However, this data may not always be meaningful to students or focus on problems they care about solving. These data might focus on measuring physical objects, census data, examining a newspaper article, etc. The problem contexts or data may be designed to support students’ development of a sociopolitical disposition (Frankenstein, 2012; Gates & Jorgensen, 2009). However, teachers may not use a critical lens when implementing such tasks (Bartell, 2013; Lee, 2012)

Connecting to students’ funds of knowledge (FoK). Another approach is creating problems designed to build on children’s mathematical thinking (CMT) and Cultural Funds of Knowledge (CFoK) (González et al., 2005; Turner & Drake, 2016). Problem types that fall into this category connect to the students’ mathematical knowledge bases as well as to the students’ and their communities’ interests, experiences, and backgrounds (Civil, 2007; Wager, 2012). Turner and colleagues (2012) studied how prospective teachers (PTs) develop their understanding of students’ multiple mathematical knowledge bases. As PTs develop meaningful connections between students’ multiple knowledge bases and their instruction, they can “facilitate ongoing and purposeful incorporation of multiple mathematical knowledge bases” (p. 78).

Prior frameworks (Gainsberg, 2008) for connecting math to the real world have distinguished between the first two but have not yet incorporated the third: an explicit focus on the students’ FoK. We build on the first two categories and add students’ FoK to emphasize the relevance of students’ lives to create the framework for this paper (see Table 1).

Methods

Participants and Contexts

Seven elementary teachers from one public elementary school in the Pacific Northwest of the United States participated in the study. These teachers were at the beginning of a professional development collaboration designed to connect mathematics to the real world based on connecting to students' funds of knowledge. The teachers spanned grades K-5, a student success coach, and a special education teacher.

Data Collection

The research team conducted individual 30-minute semi-structured interviews with each participant. Interview questions focused on the teachers’ experiences in connecting mathematics to the real world and what they knew about their students, the students' families, and the community. For example, we asked:

- Tell me what you know about your students’ interests and experiences outside of the classroom.
- Tell me about your students as math learners.
- What experiences, if any, do you have with connecting math to the real world?
- What are some real-world topics that you are interested in exploring with kids in math?

The interviews were recorded and transcribed.

Analysis

Analysis began with one research team member carefully reading all the transcripts and highlighting keywords and sentences from each transcript to fit into existing categories: Typical Word/Story Problems, Analysis of Real Data/Bringing Real-World Issues, Connecting to Students Funds of Knowledge. During this same initial reading, the researcher also highlighted new keywords that indicated new categories. For example, several teachers highlighted that they followed the curriculum and as such, we added "following curriculum" as a category. Another category that emerged was "cross-curricular connection to the real-world outside mathematics." Once the initial categorization was completed, additional research team members discussed the categorizations and came to an agreement on all categorized segments. Below we discuss each theme.

Results

Table 1 shows the summary of the teachers' experiences in connecting math to the real world. Below we discuss each theme.

Table 1: Teachers' Experiences in Connecting Mathematics to the Real World

Teachers' Experiences in Connecting Mathematics to the Real World	Number of Teachers
Following Curriculum	4
Typical Word/Story Problem	6
Analysis of Real Data/Bringing Real-World Issues That Might Not be Relevant to Students Personally	2
Connecting to Students' Funds of Knowledge	0
Bringing the World into the Classroom (Cross-Curricular Connection to the Real World Outside Mathematics)	3

Following Curriculum

Four teachers began their responses by mentioning that their curriculum provides connections between math and the real world and they followed it. Teacher A mentioned, "I kind of just go with like… the stories in the curriculum." Teacher F said, "I know that the curriculum attempts to do somewhat of it." These four teachers' experiences with typical word/ story problems were closely related to the curriculum. The three teachers who did not mention the curriculum each shared at least one example in another category.

Typical Word/Story Problem

Six teachers shared their use of the typical word/story problems as their experiences in connecting math to the real world. Teacher A and Teacher F used bunk beds and apple boxes for 10 frames since the curriculum provided them. Teacher A said, "Our first unit was like bunk beds and apple boxes, so we are really focusing on 10 frames and manipulating numbers within a 10 frame." Some teachers considered using students' names in the word problems as a way of connecting math to students: "I'll pick like some student names and put it in the word problems" (Teacher C) and "I've also tried to connect problems to students lives actually using students in the problems just throwing out names" (Teacher D). Teacher E shared that he used ice cream shops and shopping mall contexts for decimal operations. He said, "ice cream math and shopping mall math or whatever with the decimals to kind of like help them through things a little bit."

Analysis of Real Data/Bringing Real-World Issues That Might Not be Relevant to Students Personally

Two teachers shared analysis of real data or bringing real-world issues as their experiences in connecting math to the real world. Teacher E said he has implemented the 'Million Dollar Project' many times. He said, "I sent them to a site for houses… gave them million-dollar… they had to spend exactly a million dollars or else they don't get their million dollars." Teacher G shared her experiences in creating a small classroom economy: "They have to come in and they have to do the work, do the math, show their work, explain, help someone, and then you are paid. You are a math consultant, and so they have their own banks… at the end of the week, they can buy a goodie."

Connecting to Students' Funds of Knowledge

None of the teachers shared their experiences in connecting math to students' funds of knowledge. However, six teachers shared that they want to find and implement real-world connections that are relevant and connected to their students on a personal level (their interests), as well as family and cultural levels.

Bringing the World into the Classroom (Cross-Curricular Connection to the Real-World Outside Mathematics)

Three teachers shared their experiences in bringing the real world into the classroom outside mathematics. When Supreme Court Justice Brown Jackson was confirmed, Teacher A introduced the confirmation debate to her students. Students read about the story of the justice and saw the picture of the Supreme Court Justices. She commented that "I had not thought about how to bring math into that but I bet we could figure out a way." Teacher C shared her experience in scavenger hunts: "I've done scavenger, like a nature scavenger hunt, like finding shapes in nature." Teacher E's students were interested in Pokémon Cards, so he regularly provided time to his students for Pokémon cards trading.

Conclusion and Discussion

In response to our research question '*What are teachers' experiences in connecting mathematics to the real world at one elementary school'* we found that while almost all teachers had implemented typical word/story problems as a way to connect mathematics to the real world, yet none had used contexts relevant to their students' lives. However, most of the teachers were interested in developing lessons that would be more relevant to their students' lives. Teachers A and D explicitly stated that they were interested in making their mathematics lessons relevant to their students. Teacher B was interested in culturally relevant and social justice related mathematics lessons. Teacher C wanted to develop lessons related to time and money because her students showed interest in time and money. Teacher E was aware of his students' interests outside of mathematics, but he was more interested in how to connect mathematics to his own interests to make it real-world mathematics. Teacher F expressed her interest in connecting math lessons to students' cultural and family heritages. Teacher G shared that she wants to help her students to understand how math is in their daily lives.

Understanding how teachers think about connecting mathematics to the real world was important as we began our professional development collaboration. Just as we wanted our teachers to build on their students' funds of knowledge (González et al., 2005), we wanted to build on the teachers' funds of knowledge when working with them. Knowing where they started helped us develop an opening activity to develop a shared understanding of how we thought about connecting mathematics to the real world.

EXPLORE TEACHERS' COLLECTIVE LEARNING THROUGH LESSON STUDY FROM A PERSPECTIVE OF NETWORKING THEORIES

Rongjin Huang
Middle Tennessee State University, USA
rhuang@mtsu.edu

Xingfeng Huang
Shanghai Normal University, China
xfhuang@shnu.edu.cn

Although the effects of Lesson study (LS), a teacher collaborative professional development approach, on teacher professional learning and students learning have been widely documented, the theories for understanding of LS has just emerged as a research field. Interconnected Model of Teacher Professional Growth (IMPG) and Documentational Approach to Didactics (DAD) have been used individually to document teachers' professional learning. In this study, a networked framework is proposed by locally integrating these two theories. A lesson study facilitated by a researcher was conducted in Shanghai China. The data sets including all videotaped meetings and research lessons are collected and analyzed. The results show that the teachers' resource system evolved from adoption to adaptation with consideration of student learning. This study contributes to networking theories and its usefulness in LS context.

Keywords: Professional development, Teacher educators, teacher knowledge and beliefs.

Introduction

Lesson study (LS), a collaborative teacher professional approach, originated in Asia, has been adopted around the world (e.g., Huang et al., 2019). Although the effects of LS on teacher professional learning (knowledge, beliefs, disposition), teacher professional learning community, and students learning have been widely documented (Cheung & Wong, 2014; Willems & Bossche, 2019), the theories for understanding of process and products of teacher learning through LS have become an emerging research field (Huang et al., 2019; Lewis et al., 2009); Specifically, various theories have been utilized to frame and understand LS (Borko & Potari, 2020). Yet, most previous studies use a single theoretical lens for understanding LS (Widjaja et al., 2017; Clarke & Hollingsworth, 2002; Pepin et al., 2017; Trouche et al., 2019). Due to the complexity of teacher professional learning in collaborative LS settings, a networking theories approach may provide an alternative way to deepen understanding of the complex phenomena (Prediger et al., 2008; Shinno & Mizoguchi, 2021; Trouche et al., 2019). In this study, we aim to frame our study from a networking theories approach through which the Documentational Approach to Didactics (DAD) model (Trouche et al., 2020) is enriched by incorporating the ideas from Interconnected Model of Teacher Professional Growth (IMPG) (Clarke & Hollingsworth, 2002).

Research Background and Theoretical Framework

Chinese lesson study and teacher learning

Chinese LS has some unique features (Huang et al., 2017), including (1) the repeated teaching of the same content to different students, with immediate feedback from their colleagues and knowledgeable others; (2) a focus on refining the teaching of particular content or improving teachers' particular instructional skills; and (3) knowledgeable teaching researchers' involvement who are officially responsible for organizing school-based teaching activities and evaluating teachers' teaching and students' learning. Overall, Chinese LS provides a platform for improving teaching practice (Chen, 2020; Wei & Huang, 2022), developing teachers (Fang, 2017), implementing new curriculum (Qi et al., 2021), and linking theory and practice (Huang et al., 2016).

Theoretical framework

Both DAD and IMPG models are rooted in the sociocultural perspective. They have been used to capture different aspects of teacher learning (Clarke & Hollingsworth, 2002; Trouche et al., 2019).

DAD theory. Resources refer to what has the potential of 're-sourcing' teacher activity (Adler, 2000) at the core of instruction. To capture the features of mathematics teacher professional development through the lens of their interactions with resources, a specific conceptual framework, named Documentational Approach to Didactics (DAD) has been developed over the past decade (Gueudet & Trouche, 2009; Trouche et al., 2020). This study focuses on dialectical relationship between the teacher and the resources: the teacher permanently adapts the resources s/he is working with (this is the *instrumentalization* process), while these resources, their constraints and affordances, contribute to configuring teacher's activity (this is the *instrumentation* process). In DAD, a *document* is defined as the outcome of joint resources combined with knowledge guiding usage, and the process of developing the document is called documentational genesis (Pepin et al., 2013), which occurs through iterative processes of preparation/design and enactment (Trouche et al., 2019). Understanding teacher's documentation work needs to consider resources evolving process through successive implementations for addressing different issues which is named as *documentational trajectory* (Trouche et al., 2020).

IMPG model. Situated in a social and cultural perspective, the IMPG model (Clarke & Hollingsworth, 2002) posits that teacher change happens through enactment and reflection in four domains: Personal Domain (PD), Domain of Practice (DP), External Domain (ED), and Domain of Consequence (DC). PD includes teacher knowledge, beliefs, and attitudes and/or orientation, DP refers to teacher's experimentation (classroom practices), ED involves the external source of information or stimulus, and DC refers to the salient outcomes of experimentation perceived by the teachers. To emphasize collaborative learning during professional development programs, Prediger (2020) proposed an adapted IMPG model for portraying teacher professional development in collaborative contexts. In her model, the Personal Domain is extended to a Collective Domain (CD, Shared practice and orientation) and the Domain of Practice is extended to a Domain of Inquiry (DI, collective inquiry of new teaching practice).

A way for networking the two theories. We use integrating locally as a strategy for networking the theories of DAD and IMPG. The DAD model portrays the dynamic relationship between teachers and resources to generate documents, but the mechanism of documentational genesis remains unknown. The feature of IMPG model which emphases the dynamic among the different domains including the collective domain and external domain could be integrated into the DAD model to strengthen the model. Yet, based on the modified IMPG model by Prediger (2020), the documentational genesis can be seen as a dual process between the Collective Domain and Resources (External Domain, and Domain of Consequence) through Domain of Inquiry. Thus, we proposed a model for networking DAD and IMPG (see Figure 1): Teachers in the DAD theory are regarded as the collective domain from the IMPG perspective and resources in the DAD theory are the same as the External Domain (ED) and Domain of Consequence (DC), which includes textbooks, online resources, concrete models, students' performance in pretest, as well as advice and materials provided by researchers outside the teacher community.

Documents in the DAD theory are regarded as the outcomes (resources and ways of using them) of Domain of Inquiry, which mainly include the agreed ideas in meetings and resulting products of lesson plans and enacted lessons. The Documentational Genesis in the DAD theory therefore triggered by the dynamics (enactment and reflection) between the Domain of Inquiry and other three domains. The Domain of Inquiry is a collective and collaborative process during lesson planning meetings, research lesson observation, and post-lesson debriefing meetings in an LS Group.

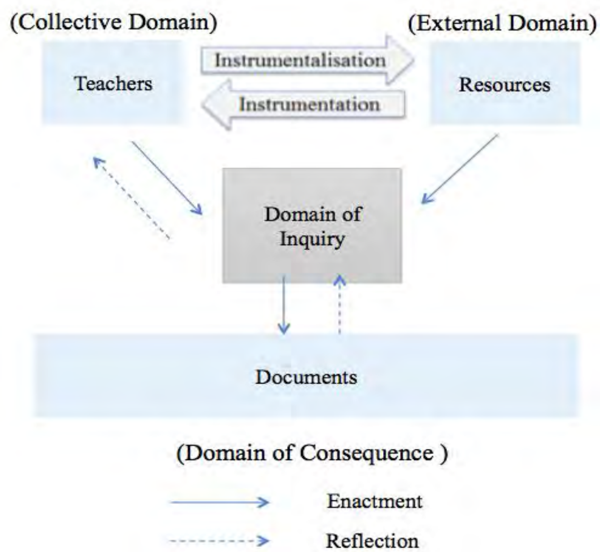

Figure 1. An Adapted DAD Model by incorporating IMPG ideas

From this adapted framework, this study aims to explore how teachers' growth by their documentation works by addressing the following research questions:

(1) How does the documentational genesis work through the enactment and reflection between the Domain of Consequence and the others?
(2) How does teachers' document system develop during the lesson study process?

Methods

The participants and the process of the LS

The researcher, Dr. Huang, from a teacher education university and seven mathematics teachers in an urban elementary school in Shanghai form an LS group. Dr. Huang works with pre-service mathematics teacher education program and research on mathematics teacher professional development, and teachers are from a Teaching Research Group (TRG, an institutionalized Chinese teacher professional learning community, see Yang, 2009) in the school. Mrs. Miao, the lead designer of teaching plans and enactor of research lessons, and the other six teachers Mr. Bao, Mr. Tan, Mr. Li, Mrs. Ji, Mrs. Wen, and Mrs. Zhao were all experienced teachers with teaching experience from 6 to 15 years. This lesson study went through four phases over four weeks. The first phase-*study* (29 April, 2021) involved the researcher and his graduate students sharing relevant research literature and the presentations of angle measures in different mathematics textbooks with the teachers. The teachers discussed the possible and specific content and task design on the size of angles. After the meeting, the researcher designed a pretest for the teachers to understand their students' learning readiness and provide the foundation for designing the lesson. The second phase-*plan* (6 May, 2021) began with a brief presentation by the researcher on students' misconceptions about angles and the size on the pretest and their strategies for comparing angle size. Then, Mrs. Miao presented her lesson plan and the TRG discussed the lesson plan. In the third phase -*teaching and reflection*, based on the feedback from the LS group, Mrs. Miao revised the lesson plan and enacted the lesson in her own class (12 May, 2021). The researcher and other teachers in the LS group observed the lesson. A post-lesson discussion followed immediately. The teachers and the researcher evaluated the enacted lesson and identified issues that occurred and provided specific recommendations for improving the lesson. In the fourth phase – *re-teaching and reflection* (19 May, 2021), Ms. Miao again enacted the lesson in another class, which the researcher and other teachers observed together. The post-lesson reflection followed. Finally, a post-test was conducted for students' learning outcomes in the second class.

Data sources. In this study, the data consisted of three components. The first is the four videos of teachers' group meetings; the second is the two videotapes of enacted research lessons; and the third is the lesson plans and slides designed by teachers before the lesson study, and the lesson plans and slides developed during the lesson study.

Data analysis. Teachers' lesson plans and slides and the meeting videos at each stage were used to analyze and describe teachers’ document system and paint documentational trajectory. Based on the research questions and the adapted DAD model, Dr. Huang generated an analytical frame for identify participating teachers’ documentational genesis. The frame focuses on the actors’ roles in meetings and classrooms (researcher, teachers, and students) surrounding the interactions (enactment or reflection) between the Domain of Inquiry and each of other three domains. Four research assistants watched the videos (meetings and lessons) and took notes independently. After watching each video, the researcher and the assistants had a group meeting to identify the major features of document work and document system at each individual phase. Any disagreements during the meeting were resolved through extensive discussion. The documentational genesis is summarized in a Table 1. The same process was applied to analyze all the videos in different stages. Finally, a diagram for presenting teachers' documentation work during the LS (Trouche et al., 2019) was created, which includes five major stages for the teachers' documentation works in line with the four phases of the LS. In the Results that follow, the document system and documentational genesis will be presented in narrative and documentational trajectory development over the stages will be summarized.

Results

The results are presented in five stages in line with the four lesson study phases. These are: 0)(pre-lesson study): Previously developed materials by TRG and e-resources identified by the teachers to support their inquiry into lesson design before the lesson study; 1): the resources provided by the researcher and misconceptions occurred on the pretest promoting the teachers’ consideration of concrete manipulatives used for developing a lesson plan; 2): The resources used to produce and revise the lesson plan through the collective inquiry, and the questions from the researcher eliciting the teachers’ rethinking about learning goals of the lesson; 3): The enactment of research lesson facilitating the teachers’ reflections on students’ learning, resulting in further refinement of the lesson plan; 4): Reenacting the research lesson facilitating the teachers’ reflection on how to use students’ misconception as teaching resources. The following narratives demonstrate how the results are supported by empirical data.

Lischka, A. E., Dyer, E. B., Jones, R. S., Lovett, J. N., Strayer, J., & Drown, S. (2022). Proceedings of the forty-fourth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Middle Tennessee State University.

Stage 2: The resources used to produce and revise the lesson plan through the collective inquiry, and the questions from the researcher eliciting the teachers' rethink the lesson goals.

Documentational genesis. At this stage, the researcher's ideas (ED) impacted on the teachers' inquiry. The researcher questioned whether recognizing acute, right and obtuse angles should be included as one of the learning objectives in this lesson. He believed that the most challenging part is to establish the concept of the size of the angle, which lays the foundation for comparing the size of the angle and identifying acute, right and obtuse angles. Inspired by the researcher's question, the teachers further discussed and agreed that after developing the concept of the size of the angle, angles could be compared, and acute and obtuse angles could be developed through comparing with right angles. Mr. Tan believed that students could perceive that the size of angle is related to the openness of the angle but are difficult to understand that it is irrelevant the length of the two sides. They finally agreed on the use of strips to construct angles and to help students develop the concept of the measure of angles through manipulative activities: (1) using the strips (with same length) helps students to experience that the rotation of one side of an angle creates different angles, and to recognize the two perspective toward an angle: a shape (formed by two rays from the same vertex, static) and a rotation (process of generating the angle, dynamic); (2) using the strips with different lengths to construct angles with in the same and/or different sizes to help students realize that the length of the sides of angle is nothing to do with the measure of the angle.

In summary, the triggered by the researcher's questioning, the teachers collectively discussed their ways of helping students' development of the concept, finally resulted in a new design of lesson plan. Thus, the collective domain (teachers' knowledge and beliefs about teaching the topic) changed and the domain of consequence developed, which contributed to the development of their document systems (see Table 1).

Table 1. The teachers' documentational genesis during the Stage 2

Documentational Genesis			
Domain of Inquiry (DI)	Teacher (CD)	Reflection	The teachers' inquiry facilitated them to develop their knowledge of the measure of an angle and beliefs concerning with teaching and learning of the topic.
	Resource (ED)	Enactment	The researcher's question resulted in the teachers' inquiry into the objective of the lesson. The concrete model also impacted teachers' inquiry into designing tasks for student learning
	Document (DC)	Enactment	The teachers' inquiry resulted in the new design of the lesson plan (new objectives of learning and newly designed tasks).

Document system. In this stage, the analysis of documentational genesis (Table 1) shows the teachers' documentation work. Firstly, there is the *instrumentation* process, where the researcher's question as a Resource directly triggers the Domain of Inquiry (of the LS group), and then Domain of Inquiry facilitated the teachers' rethinking and reflection. Second, it is the *instrumentalization* process, where Mrs. Miao with her colleagues further improved their documentation system with refining the lesson plan. In the revised lesson plan, the learning goals of the lesson focused on recognizing and comparing the size of angles only while removing the content of acute, right and obtuse angles to the next lesson. Correspondingly, they modified the activities to explore the size of the angle based on a more refined learning progression, i.e. from constructing angles in different sizes through manipulatives, to comparing two angles that are close in size using concrete tools.

Summary. Based on the adapted DAD model, this study paints the learning of a group of teachers in a lesson study as the process of their development of document system and uncovers their learning mechanism through documentational genesis. The results show that the teachers' documentational trajectory went through four stages. Teachers become active resource adapters and producers. The teachers' document system has been developed through the reflections and enactment. Both the *instrumentation* and *instrumentalization* process are reflected during the dynamics between the Domain of Inquiry and the other three domains. Overall, the teachers' document system developed from adopting traditional resources (e.g., the textbook and shared materials in TRG) with a focus on delivering of subject content to designing the lesson creatively by adapting both traditional and additional online resources (e.g., online videos and manipulatives) with a focus on student-centered active learning.

Conclusion and discussion

In the section, we highlight the contribution of this study in three aspects as follows:

Document system and its development as an effect of LS

The Chinese LS process provide an effective mechanism for teachers to develop their capacity in instruction design through the enrichment and refinement of their document system as demonstrated in this study. Thus, this study contributes teachers' learning through LS by extending their learning as document system development. Moreover, this study also demonstrates the critical roles played by the researcher. For example, how to provide the resources (both ideas and resources) with teachers, and how to facilitate teacher discussion and reflection by raising meaningful questions. This finding about the critical role of knowledgeable others played in the lesson study is aligned with other studies (Gu & Gu, 2016; Li, 2019).

Enrichment of DAD by uncovering the documentational genesis process

According to DAD, teachers' learning is regarded as the development of document system through the interactions between teachers and resources. The interactions are featured by *instrumentation and instrumentalization* process. Although DAD's theory recognizes a collective perspective and explores the development of teacher document systems within a community of practice (Wenger, 1998), the process of interaction between teachers and resources are not appropriately explored (Trouche et al., 2019). In this study, we examined documentational genesis as a process of enactment and reflection between Domain of Consequence and the other from the IMGP perspective. With the cycle of LS, the documentation genesis process is described in detail, thus, both document system and its development through lesson study are revealed vividly. Therefore, his study contributes to enriching DAD by illustrating the documentational genesis.

Networking theories by locally integrating two theories

The strategies of synthesis and local integration focus on developing theory by combining a small number of theoretical approaches into a new framework (Prediger et al., 2008). In this study, we adopted a locally integrating strategy by incorporating the interactions among four domains in the IMPG model into DAD theory to explore the mechanisms of documentational genesis. As demonstrated in this study, by employing the adopted DAD model, teachers' learning through LS has been extended and described in great detail. Therefore, the locally integrating framework in this study could, on the one hand, explain the mechanisms of teacher documentational genesis and, on the other hand, describe teachers' professional development through the changes of the document system.

Limitations and further studies

Since there is no follow-up data (after the lesson study) nor interviews with the teachers, we are unable to make any claims about how teaching this specific topic can sustain the teaching of other topics. In further studies, these two data sets should be purposefully collected and analyzed to explore teacher document system development through LS.

DEVELOPING EMPATHY THROUGH EPISTEMIC ACTIVITIES: TEACHERS' EXPERIENCES LIVING AND LEARNING IN BASE 7

Marc Husband	Evan Throop Robinson	Lisa Lunney Borden

This research report describes new insights into how teachers develop empathy for learners and build capacity for more responsive teaching. To develop empathy, we introduce an epistemic activity for teachers involving an unfamiliar base system that promotes the construction, communication, and critique of knowledge. Teacher responses from two professional learning groups provided data for analysis. A phenomenographic approach was used to analyze survey data and report teachers' experiences. This study suggests that teachers developed empathy—putting themselves into a students' sense-making experience and seeing the value in their work. Additionally, specific interactions that arose from the investigation influenced teachers' future teaching practices. Results show that teachers recognize and appreciate students' feelings and desire further sense-making opportunities for their future practice.

Keywords: Professional Development, Teacher Noticing, Affect, Emotion, Beliefs, and Attitudes

Objectives

What does it feel like to be a learner of mathematics? How can teachers build empathy for the learning experiences of their students? This research report answers calls in the literature for more course activities that provoke pre-service teachers' expression of empathy—seeing the merits of how students make sense of mathematics (e.g., Jaber, Southerland, & Drake, 2018). In our own work, we have also considered activities that aim to build empathy with in-service teachers. The purpose of this research report is to describe a study involving teachers' experiences solving one addition question: 13 + 6 using a base 7 place-value system. In our activity, we used the context of "living on Mars" to create dissonance and support teachers as they transitioned to thinking and working in an unfamiliar base system. This is important because normally teachers are familiar with the math they are aiming to teach in their classrooms. Mathematics education researchers (e.g., Lin & Hsu, 2018; Zazkis, 1999) recommend teachers work on questions in different base number systems because the experience puts them in a students' shoes and thus can develop empathy for mathematics learners. PMENA has invited us to consider notions of dissonance and harmony. This study aims to help teachers develop empathy through experiencing their own sense of dissonance (working in an unfamiliar base system) to appreciate the journey to harmony (meaningful learning). We believe such experiences help to build teacher capacity to support the learning conditions for all students.

Developing empathy for how students grow mathematics understanding is an important part of teacher education because of its promise for supporting teachers to be more responsive in their practice (Jaber et al., 2022). Research in mathematics education often associates responsive teaching with developing a practice of noticing. Teacher noticing has become a highly valued practice for effective teaching of mathematics because of its potential to reframe what a teacher looks for, interprets, and takes up in the classroom (Jacobs, Lamb & Philipp, 2010). For example, responding to student thinking by noticing student strengths (Jilk, 2016) or identifying moments in a lesson that are conducive to building on student thinking (Leatham, Peterson, Stockero, & Van Zoest, 2015). Yet, responding to students' ideas in the moment is challenging for teachers because of the unpredictability of student thinking (Foster, 2014; Rowland & Zazkis, 2013). The question guiding this research is: *How do educators respond to activities that aim to help them to develop epistemic empathy?*

To prepare for lessons that are responsive to mathematical thinking emerging from activities, teachers are encouraged to anticipate multiple solution strategies, listen to and observe students' ideas during activities, and respond by selecting student samples that orchestrate discussion around a lesson goal (Smith & Stein, 2018). While a lesson goal may be the focus when aiming to develop content, in this study, educators were more inclined to think about the kinds of emotions taking place in the classroom and the teacher moves to facilitate rich learning experiences in their own work. While the lesson activity elicited empathy for students' sense-making experiences in number, it also provoked ways that teachers might respond to student thinking by anticipating actions they can use with future learners.

Conceptual Perspective

To frame this study, we draw on the concept of epistemic empathy. Educational researchers (e.g. Horsthemke, 2015) have previously used this concept to talk about knowledge development. Specifically, for mathematics and science educators, Jaber et al., (2018) define *epistemic empathy* as "the act of understanding and appreciating someone's cognitive and emotional experience within an epistemic activity, meaning an activity aimed at the construction, communication, and critique of knowledge" (p.14). A conceptual perspective involving empathy fits well with the objective of elementary teachers learning in a different number system because the experiences aim to grow their perspectives on how students develop mathematical understanding in our base 10 system. For example, teachers working on questions in a base 7 place value system can help build a teacher's appreciation for students' "cognitive and emotional experience" by putting themselves in students' shoes to learn how adding works in an unfamiliar base system. In terms of the epistemic activity, the context of learning in a base 7 world (e.g., Mars) for adding 13 and 6 aimed to provoke the following actions: a) working in small groups to construct multiple solution strategies and representations, (the construction) b) engaging in peer-to-peer and peer-to-instructor dialogue (the communication) and c) developing and critiquing mathematically convincing arguments (the critique).

Methods

This study used a phenomenographic approach that collects data to study participants' experiences and perceptions of that experience. Mason (2002) says that "[t]he aim [of phenomenography] is to describe and characterize different ways of experiencing" (p.162). Phenomenography is a qualitative research approach with a long history in higher education. The approach develops qualitatively different categories of experiencing a phenomenon from the collected data through an iterative process (Kinnunen & Simon, 2012). Data is derived from a wide range of experiences/conceptions of the same phenomenon. This is accomplished by asking people to describe, in their own words, the phenomenon and how they experienced/conceptualized it personally. In the sessions, we provided the teachers with the following reflective question: *How does working in a base 7 context influence your practice?* The first author started the analysis by identifying statements related to the research question. As we examined the data, we began to see trends in what teachers shared. Our first iteration of the analysis showed largely that responses were either emotional or pedagogical in nature. These themes are described in this paper; yet we intend to deepen our analysis through further iterations to examine themes within these broader categories.

Data Sources:

We generated data from two sources: one group of 20 math educators, coaches and mentors participating in monthly virtual professional learning (VPL) meetings and another group of fifteen elementary teachers participating in a 10-day in-person professional learning (IPL) course. All teachers in both groups agreed to participate in the study. In the second year of the VPL group, teachers worked individually on 13 + 6 in base 7 before sharing solution strategies with the whole group. The teachers in the IPL group were randomly assigned to blackboard workspaces in five groups of three on the third day of the course. Teacher reflections on their experiences working with base 7 were collected as written data (IPL) and audio/video data (VPL) and analyzed for this research.

Results

Many teachers in the VPL and IPL mingled in base 10 while working with base 7 during the investigation. In other words, the task challenged them to use what they knew about adding in base 10 in novel ways. In both groups two strategies emerged as possible solutions (see figure 1): a) Mingling in base 10, the teacher moves one unit from the 6 to make 14—two 7's in 14 and 5 more is 25; and b) The teacher uses regrouping and/or counting strategies in base 7 to get 22.

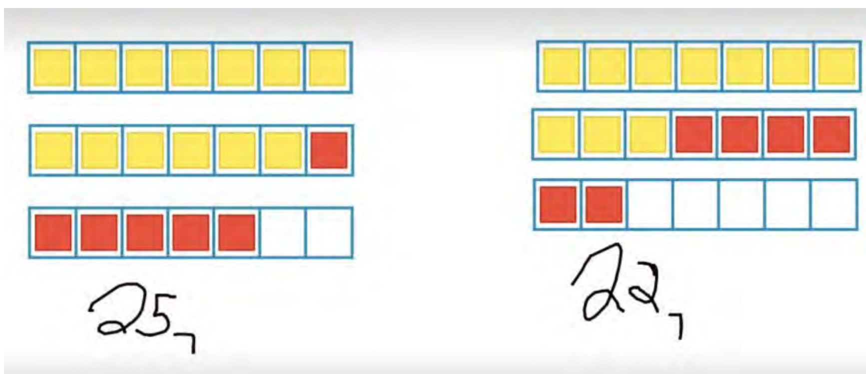

Figure 1: Two solution strategies for 13 + 6 in base 7

Based on both groups of teachers' oral and written reflections working with base 7, the following two categories emerged from analyzing the data: (1) recognizing and appreciating students' feelings in learning mathematics, and (2) desiring similar sense-making opportunities for future students. These categories are related insofar as both involve valuing students' mathematical thinking, but they have distinct features. The first category focuses on, identifies, and talks about feelings that emerge through their process of determining an answer, often aligned with dissonance. For example, the following comment made by a teacher in the IPL group talks about the disappointment she felt from realizing her answer was incorrect, "After finding out my answer was actually incorrect, I experienced a sense of disappointment because I guess I really wanted to be right and was proud of my group for going through so many steps to get to where we did." She elaborated on how her own feelings of disappointment made her think about the ways "students will feel disappointed when they have worked so hard and end up getting the incorrect answer." Here, she recognizing the dissonance her students experience as she builds empathy. In a similar way, a teacher in the VPL group said that the experience "put [her]self in the place of kids and what they might be struggling" to understand. She went on to connect her feelings about struggling in the base 7 activity with "what [students are] going through every day when we are trying to teach place value". Again, this recognizes dissonance.

The second category is distinctly different because comments under this category identify teaching actions that support sense-making and share the characteristic of teachers' desiring similar learning opportunities for future students. In other words, they are seeking harmony. For example, a teacher in the IPL group commented that peer "dialogue, disagreements, and prompts from our teacher" provided opportunities to "self-correct…misconceptions" that their group faced. This teacher goes on to say that she intends to provide "similar experiences for [her] students to engage in discourse with their peers with building new mathematical learning." Engaging with peer ideas that are different from your own was also important to a teacher in the VPL group. After comparing his work to how his colleagues "approached the [base 7] problem differently," he said that students also need "opportunities to see how someone did something different [because] it gives you a more holistic approach to solving math problems in general." These moves promote harmony seeking.

Discussion

Through creating dissonance for teachers, we put them in a situation where they needed to strive for harmony. Working in base 7 allowed teachers to develop empathy for appreciating students' cognitive (e.g., getting an incorrect answer, understanding) and emotional experiences (e.g., feeling disappointed, struggling). Teachers' comments also valued the interactions they experienced while solving the question (e.g., peer dialogue) and expressed a desire to provide similar experiences for their future students (e.g., comparing different strategies). This experience provoked teachers to envision themselves enacting practices like the ones they experienced as learners during the activity. Instead of preparing to respond to students' ideas by anticipating multiple solution strategies (Smith & Stein, 2018), teachers in this study prepared to respond to students' mathematical ideas by anticipating teaching actions like peer dialoguing and using different strategies for comparing and analyzing student work. Of particular significance in this study is how the nature of living and learning in base 7 supported Jaber et al.'s, (2018) call for more course activities that provoke expressions of epistemic empathy and extended this to in-service teachers. That is, the base 7 task initiated the construction of multiple solution strategies, communication between peers and their instructor, and a critique of two different solutions that emerged during the investigation. Overall, we see that this work put teachers in a state of dissonance that invited them to seek harmony in much the same way their students experience learning. This develops epistemic empathy. While the epistemic empathy provides teachers with a perspective on how their students are experiencing learning, engaging in this task also provided teachers with insight into pedagogical practices that can move their students from dissonance to harmony.

As mathematics teacher educators working to better understand how to train teachers to enact justice-oriented practices, we situate our work in the guiding question: "How does your work have an impact on society more broadly, beyond individual mathematics classrooms and school districts?" Results from our development and implementation of a semester-long course for teachers shows that teachers can be supported to find reasonable avenues for action to take up in their classrooms, though they begin without a sense of empowerment or understanding of resources to do so. Our teacher participants are eager to leverage their unique knowledge and role in their contexts to advocate for the changes they envision—changes that create more socially just contexts for learning and teaching mathematics.

Keywords: Social Justice, Teacher Educators, Equity, Inclusion, and Diversity, Instructional Vision

Introduction

Reform documents (e.g., NCTM, 1989; 1991; 2000; 2006) call for making classrooms more equitable in the sense of making mathematics accessible to all students. Many have argued (e.g., Gutstein, 2003; NCSM & TODOS, 2016), it is also necessary to address broader social, political, and ideological issues present in classrooms, schools, and communities to reach these content goals. Mathematics teacher educators (MTEs) are tasked with fostering well-prepared teachers who "are equipped to question existing educational systems that produce inequitable learning outcomes for students" and are able "to advocate for themselves and challenge the status quo on behalf of their students (AMTE, 2017, p. 21-24)." Practicing classroom teachers bring an abundance of expertise and knowledge of their students, content, profession, and communities. However, due to their perceptions of their role and responsibilities, some teachers feel ill-equipped or powerless when working to make changes within and beyond their classrooms (Picower, 2011; Raygoza, 2016). MTEs can come alongside such teachers to support them to leverage their unique knowledge and positions to advocate for the changes they envision.

We describe a graduate-level course for in-service teachers intended to interrogate issues of justice in teaching. Teachers entered the course with a desire to make their classroom instruction more equitable but had not always found opportunities to do so. As described by one teacher-participant, Josh (all teacher names are pseudonyms):

> Given the structures of state-mandated high stakes testing, funding that is tied to those test scores, and the tyranny of centrally designed scope & sequence requirements, teachers barely have time to find new research-based ideas for their students let alone the freedom to implement strategies on their own.

Given this starting point, the course aimed to support the teachers' inquiry and actions into their own contexts. The purpose of this brief report is to disseminate the opportunities teachers found to envision and act after being supported with structures and tools to investigate their positionality, settings, and goals. Specifically, we ask, *when teachers are provided support to investigate their positionality, settings, and goals in relation to social justice, what avenues for action do they take up in their classrooms?*

Framing

NCSM and TODOS (2016) propose a three-stage cycle of acknowledgement, action, and accountability (AAA) to tackle issues of inequity. They call for those working in the field of mathematics education to use the AAA cycle to first acknowledge that mathematics education is unjust, then they call for action to "re-frame, re-conceptualize, intervene, and transform" mathematics education, and finally they demand accountability to ensure change endures (p. 1). By implementing an AAA cycle to promote change, teachers look to address harmful practices that range from issues in their individual classroom to school or district policies.

When addressing harmful practices teachers must understand how their positionality is impacted by contextual and historical factors (Tien, 2019). Teachers must be supported to not only understand their individual identities and their impact within the context they teach, but they must also know how the socio-political histories have shaped the experiences and issues they seek to dismantle. By developing political knowledge for teaching (Gutiérrez, 2013), teachers begin to see how historical, political, and ideological factors interact. This awareness allows for teachers to implement justice-oriented pedagogies to help students become advocates for social justice. The Learning for Justice Social Justice Standards (2018) provide a framework that teachers draw upon when planning to address injustices within their context. In this paper we draw upon the AAA cycle as a structural framing to analyze how teachers take up the social justice standards to imagine new possibilities in their contexts.

Methods

Positionality

We are all White-female mathematics teacher educators in tenure-track positions teaching undergraduate and graduate mathematics and mathematics education courses. We intentionally name our Whiteness because we are aware of the privilege given to us in a society dominated by White supremacy. Our work has evolved to better understand how to train teachers to enact justice-oriented practices, especially in areas of the United States where such practices may be unwelcomed by people in power. We have continually reflected on how our positionality has influenced the creation and analysis of the course presented in this paper.

Context and Participants

We draw from the AAA cycle for this work, in a three-level, nested way (see Figure 1). At the first level, is our (as the teacher educator-researchers and instructor) use of AAA. Our acknowledgement includes our positionality and activities to determine the needs of our teacher participants. This knowledge, coupled with our analysis of the current climate towards addressing inequities in schools from a global and geographically specific lens, informed our action: the intentional design and implementation of a master's level course for PK-12 practicing teachers. This course–described as an advanced study of and design of curriculum models for diverse learners–was taken by eight students pursuing a master's in education in curriculum and instruction, all of whom are current or former teachers. Roughly split into thirds, each portion of the class concentrated on either the concept of acknowledgement, action, or accountability, as detailed in the middle column of Figure 1. And as a culmination of learning and experience (and course accountability), students in the course ended with an acknowledgment-action-accountability project of their own.

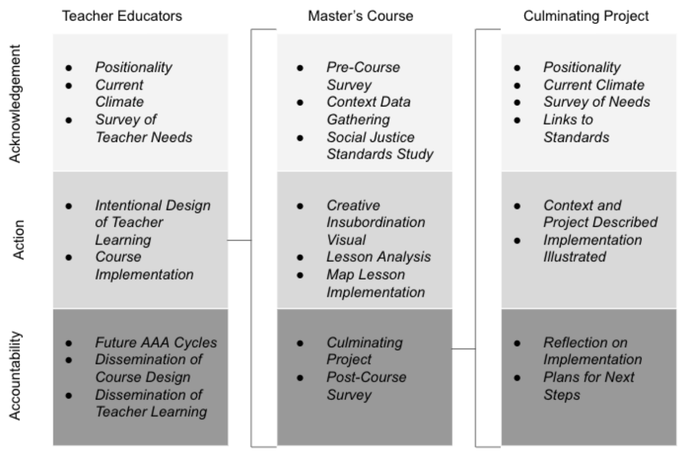

Figure 1: Nested Levels of Acknowledgement, Action, and Accountability

Data and Analysis

For this analysis, we draw data from our teachers' culminating projects (see Figure 1), specifically their acknowledgement and action pieces. The acknowledgement includes a write-up of their positionality, a problem statement, and articulated relationship between their work and the Learning for Justice Social Justice Standards (2018). Using narrative inquiry, "research [which] aims to explore and conceptualize human experience as it is represented in textual form…aiming for an in-depth exploration of the meanings people assign to their experiences" (Salkind, 2010, p. 1004), we look at the interplay between teachers' acknowledgement and action. Due to time constraints of the course, the action and accountability were mostly theoretical and not enacted. Our choice to exclude analysis of the accountability piece is due to the purely theoretical nature of many of the submitted reports. While teachers had time in a single semester to consult peers, administrators, and other community stakeholders to develop their action plans, they did not have time to implement them.

Results

To understand the ways that teachers imagined possible actions of social justice in their teaching, we first identified the Learning for Justice Social Justice Standards (2018) that were named within their culminating projects. Next, we focus on two teachers' specific projects to illustrate how the same standards were addressed in different contexts. Table 1 displays the standard addressed in each teacher's culminating project. The standards are organized by Domain, with most teachers choosing to address diversity in their project, and standard 6 being the most common standard, "Students will express comfort with people who are both similar to and different from them and engage respectfully with all people" (p. 3).

To highlight the different approaches to the standard, we share findings from two teachers, Gloriana and Amy. Gloriana's culminating project proposed the school-wide solution of using restorative circles to address her school's infraction system of discipline. Her experience as a classroom teacher has led her to believe that "student-teacher relationships are heavily involved in students' disciplinary issues and in how they are addressed. A mistake in addressing these issues may harm the student-teacher relationships..." Consequently, Gloriana sought to set up restorative circles to provide students opportunities to express themselves with their peers and teachers in ways that are respectful, productive, and contribute to positive classroom relationships.

Amy's culminating project addressed the same standard, but within her individual classroom. As a high school geometry teacher, Amy shared that her students struggled with conditional statements. Additionally, as an African American woman who grew up in a predominately White space, Amy never had the opportunity to integrate her culture and lived experience into her schooling. She chose to address these two concerns by creating a lesson on conditional statements that guided students to explore the relationship between a statement's hypothesis and conclusion through a cultural lens. Students were directed to create their own statements, such as, "If you were Cesar Chavez, then you dedicated your life to la causa." In a Socratic seminar, students share their statements and share their culture with their classmates.

Discussion

We envisioned teachers' first act towards taking up justice-oriented work in their classrooms and contexts as what could be reasonably accomplished in a semester-long gradate course. Using NCSM and TODOS's (2016) AAA cycle as a frame, teachers' culminating projects were an acknowledgement and plan for action. We found teachers' foci on social justice standards varied by their own positionality, contexts, and identified needs of their students and schools. Close examination of teachers' culminating projects show that mathematics educators seek to address social justice at both the classroom level (e.g., Amy) and system levels (e.g., Gloriana), which would directly impact the culture and climate of their mathematics classrooms as well. Teachers' second acts are to come; enactment of their action and accountability pieces. Through this work, we anticipate our teachers will move from being "equipped to question existing educational systems that produce inequitable learning outcomes for students," which we found them to be at the end of the course, to being able "to advocate for themselves and challenge the status quo on behalf of their students" (AMTE, 2017, p. 21-24). While these results are preliminary, we are encouraged by the possibilities of teacher learning experiences that are framed using the AAA cycle towards combating harmful practices and promoting justice-oriented change at both the classroom and systems level.

CORRELATING TEACHERS' ENGAGEMENT IN ONLINE DISCUSSIONS WITH THEIR PERSISTENCE IN PROFESSIONAL DEVELOPMENT

Anthony Matranga
California State University San Marcos
amatranga@csusm.edu

Jason Silverman
Drexel University
Js657@drexel.edu

This paper reports on a correlation analysis of two cohorts of mathematics teachers' patterns of participation in online asynchronous discussions and their persistence in a sequence of professional development workshops. Findings indicate that increased access to colleagues' knowledge resources and more frequent dispersion of these resources across the social network related to persistence. We discuss how variations in the design of our online workshops may have impacted teachers' potential to persist in the professional development. The findings have implications for network-based instructional strategies that could increase mathematics teachers' potential to persist in online professional developments.

Keywords: Professional Development, Online and Distance Education

Objectives and Purpose

Developing discourse-rich instructional practices that are responsive to student mathematical thinking is a challenging process. Learning to implement such practices takes time and is unlikely to occur in "one-shot" professional developments or even a short workshop. Indeed, there is consensus that sustained duration is a feature of effective professional development that supports teacher learning and instructional improvement (Darling-Hammond et al., 2017; Desimone, 2009; Dille & Røkenes, 2021; Sztajn et al., 2017; Sancar, Atal, & Deryakulu, 2021). Online settings afford sustained professional development because they allow for flexibility in when, where, and how teachers participate (Fletcher et al., 2007). Further, online settings are less susceptible to local norms and instructional practices that can influence the focus of teacher collaboration (Cobb et al., 2001) and have counterproductive effects on their instruction (Munter & Wilhelm, 2020). Despite the importance of sustained professional development and the benefits of online settings for supporting teacher collaborative learning, little is known about the extent to which teachers persist in online professional development and how various factors, events, and conditions impact their persistence. In this paper, we report on our examination of relationships between patterns in teachers' interactions in our online professional development and their persistence in the workshops.

Theoretical Framework

We draw from social capital theory to frame our investigation of teachers' persistence in online professional development. A central assumption of social capital theory is that individuals have social, cultural, and intellectual resources and increased access to these resources through participation in a social network has many benefits for "upward mobility" (Burt, 1992; Coleman, 1988). Resources flow through a social network as individuals interact with one another (Light & Moody, 2020) and different positions in a network can support or constrain individuals' actions and access to resources (Burt, 2004). For example, those who emerge as *central* members of a network by interacting with a large proportion of colleagues have increased access to resources and a role in dispersing them throughout a network (Freeman, 1979).

Although there is no research we are aware of investigating relationships between teachers' centrality and persistence in professional development, studies of undergraduate education have illuminated such relationships (Dawson, 2008; Thomas, 2000; Tinto, 1975). For example, Zwolak et al. (2017) found that students with higher centrality in an undergraduate physics class social network were more likely to enroll in the next class in the program. Furthermore, in a randomized control trial, Turetsky et al. (2020) implemented an intervention that supported students in becoming more central in a "gateway" bioscience course social network. Students in the intervention group that increased their centrality were more likely than the control group students to take the next course in the bioscience sequence. Drawing from these studies and social capital theory, we conjecture that teachers' increased access to and engagement with colleagues' resources in online discussions could impact teachers' overall interest in professional development and potential to persist. The current study takes a first step at investigating this conjecture by correlating teachers' centrality in online asynchronous discussion forum conversations with their persistence in a sequence of three online workshops.

Methodology

This research was conducted as part of an online synchronous and asynchronous professional development that featured a sequence of three 6-week workshops. The workshop goals included supporting mathematics teachers in shifting towards more student- and discourse-centered instructional practice by engaging in problem-solving, examining student math work, and connecting these experiences to models of mathematics lessons, including the "Launch, Explore, Summarize" model, 5 Practices for Orchestrating Productive Mathematics Discussions, and the "5-E" model. Each workshop built on the previous one by further connecting teachers' work to their classroom practice. Workshop one included four week-long online asynchronous discussion forum conversations that connected teachers' collaborative problem-solving and analysis of student work to their classroom practice. These discussions prompted participants to make an initial post and to submit at least two response posts to their colleagues. Workshops two and three used teachers' collaboration in workshop one as a context for thinking about how to provide effective feedback to students.

We recruited two cohorts of participants to complete the professional development workshops. The first cohort (C1) included 16 participants who completed workshop one together in the spring of 2021. The second cohort (C2) included 10 participants who completed workshop one together in the summer of 2021. The primary difference between the spring and summer version of workshop one was that the spring 2021 version was six weeks and the summer version was two weeks. We implemented the accelerated summer workshop so that participants could potentially take two workshops (one and two) in the summer. We offered the second workshop in summer 2021 to both cohorts and 13 of the 26 participants completed the workshop. We offered the third workshop in the fall of 2021 to the 13 participants who completed workshop two. Nine of these 13 participants completed the third workshop. The 26 participants have between 4 and 9+ years of teaching experience across K-16 grade bands and their geographical locations vary across the United States. 75% of the participants identified as female and 25% identified as male. The racial breakdown of participants is as follows: 70% White, 18% Black, 2% Latino, 8% Asian, 2% Native Pacific Islanders.

The two data sources for this study included participants' interactions from workshop one discussion forums and persistence data across the three workshops. We defined an interaction as an occasion where a participant responded to their colleague's post on the discussion forum. We modeled this collaboration with two social networks (one for C1 and one for C2), where the nodes represented participants and directed edges represented a response post from one participant to another. Using social network analysis, we generated the following basic network characteristics for C1 and C2. C1: *edges*=153, *density* (the proportion of edges to possible edges)=52%, and *reciprocity* (the proportion of interactions that are reciprocated)=50%. C2: *edges*=77, *density*=56%, and *reciprocity*= 48%. We used a three-point scheme to denote participants' persistence in the workshops. Specifically, if a participant only completed workshop one (did not persist), we denoted their persistence with a zero. We denoted completion of workshop one and two with a one and completion of workshop one, two, and three with a two. We imported the interactional and persistence data into R (R Core Team, 2021) and used the statnet package (Butts, 2020) to conduct the analysis.

The analysis involved measuring participants' centrality in workshop one social networks and then correlating centrality measures to their persistence. Given the lack of research on teachers' persistence in online professional development, we used a range of centrality procedures such as out-degree (the number of posts sent), in-degree (the number of posts received), betweenness (a measure of dispersing information across the network), out-closeness (a measure of access to other's posts), and in-closeness (a measure of other's access to one's posts). Table 2 provides an overview of several participants' centrality measures (top and bottom rank ordered according to outdegree). Finally, we calculated the Pearson correlation coefficient and corresponding significance levels between participants' centrality measures according to their cohort and their persistence in the sequence of workshops.

Table 1: Centrality and Persistence Data

Cohort	Participant	Outdegree	Indegree	Betweenness	Out-Closeness	In-Closeness	Persistence
C1	P1	17	9	0.100788	0.761905	0.571429	1
C1	P2	15	16	0.079033	0.695652	0.666667	2
C1	P15	2	6	0.016052	0.457143	0.551724	0
C1	P16	1	2	0	0.410256	0.470588	0
C2	P17	18	7	0.131638	0.916667	0.55	0
C2	P18	15	9	0.389121	0.846154	0.785714	1
C2	P26	1	4	0	0.37931	0.578947	2
C2	P27	1	4	0.004798	0.478261	0.578947	0

Results

Table 2 presents results from the correlation analysis. We found a positive and significant correlation ($p<.05$) between cohort one's betweenness centrality and their persistence in the sequence of workshops. Betweenness centrality quantifies the number of times a participant falls on the shortest path (in terms of connections) between two other, unconnected participants in a network. In online discussions, this means that a participant with high betweenness centrality is responding to posts authored by participants who are not communicating with one another and increasing the dispersion of knowledge resources across the network. Thus, this correlation means that cohort one participants who more frequently dispersed knowledge resources across the network in workshop one were more likely to persist in the sequence of workshops.

We also found a positive and significant correlation between cohort one's out-closeness centrality and their persistence in the sequence of workshops. Out-closeness centrality is calculated by taking the sum of the reciprocal of participants' shortest outwardly directed path lengths (the number of "jumps" one makes in a network to get to their peers). In online discussions, this means that a participant with high out-closeness centrality has increased access to colleagues' knowledge resources through direct engagement with their posts or engagement in a thread initiated by a peer who they did not directly interact with. Thus, this correlation means that cohort one participants who had increased access to and engagement with colleagues' knowledge resources in workshop one were more likely to persist in the sequence of workshops.

Table 2: Correlation of SNA Measure and Persistence

SNA Measure	Cohort 1	Cohort 2	SNA Measure	Cohort 1	Cohort 2
Out-degree	0.4953055	-0.4804152	Betweenness	0.5720269*	-0.5694836
In-degree	0.4300999	0.04415746	Out-Closeness	0.5010315*	-0.5337503
			In-closeness	0.4885712	-0.2476399

*p<.05

Discussion

This report provides initial support for our conjecture regarding the importance of teachers' social capital through access to and engagement with peers' knowledge resources for their persistence in online professional development. These findings suggest that there are implications for central participation in a network that are in addition to those documented elsewhere (e.g., academic success (Saqr et al., 2020), development of MKT (Silverman, 2012)). Further, our findings extend research correlating centrality in discussion networks with persistence in college to the context of online mathematics teacher education. Establishing a research base that documents factors, conditions, and events that impact teachers' persistence in professional development can inform design and implementation strategies. For example, we plan to test a strategy for impacting teachers' persistence that includes increasing peripheral participants' betweenness centrality by prompting them to share connections they notice in colleagues' ideas on a discussion forum.

Our findings also showed that centrality was not correlated to persistence for cohort two. One explanation for this could be differences in the timeframes of workshop one. As noted above, cohort one participated in a 6-week version while cohort two participated in a 2-week version of workshop one. Our ongoing analysis indicates that the structure of cohort two's network was less reflective of a community than cohort one's network. Even though there was a range in centrality measures for cohort two, the accelerated timeframe may have reduced opportunities for teachers to engage deeply with their peers' resources; thus, impacting how they perceived the potential benefits of participation and perhaps their "sense of belonging" (Baumeister, & Leary, 1995). This opens up a question about how the length and quality of initial professional development experiences impact teachers' potential to persist in the professional development.

As the need remains for sustained and effective professional development that supports mathematics teachers in developing discourse-rich and student-centered instructional strategies, additional research is required to gain deeper insight into factors, events and conditions that impact teachers' persistence in professional development. One future area of inquiry that could extend this work might include investigating relationships between teachers' centrality in online discussions, individual attributes (i.e., gender, MKT, etc.), network structures (e.g., cliques (Joksimović et al., 2016)), and persistence. We are currently exploring statistical network models such as exponential random graph models to investigate these relationships (e.g., see Bjorklund & Daly, 2021; Lusher et al., 2013).

JAPANESE INSTRUCTIONAL CIRCLES

Matthew Melville
Purdue University Fort Wayne
Melbob@udel.edu

The purpose of this report is to elucidate a common professional learning opportunity in Japan, instructional circles, that has not yet been studied systematically or described in detail. Through an in-depth look at these instructional circles, I provide a detailed description of how Japanese teachers identify instructional problems and how they analyze them as a group to improve their teaching practices. Data was gathered through an ethnographic approach to better understand how these instructional circles function for the teacher participants. Categories for observation were based on literature about professional development and my own experiences with Japanese professional learning. Learning about instructional circles can also provide a pool of new ideas about professional learning. Understanding new ways of doing things, and the conditions in which they operate might help us whether and how we want to adapt them for our own practices.

Keywords: Teacher Knowledge, Instructional Activities and Practices, Mathematical Knowledge for Teaching

Introduction

In the last two decades, Japan has had a strong performance in international mathematics assessments. Beginning with early international studies of mathematics and science (FIMSS, SIMSS), to more recent iterations of the study International (TIMSS), Japan has scored in the top five spots in both the fourth grade and eighth-grade mathematics assessments (McKnight, 1987; Hiebert et al., 2005, McFarland et al., 2017). Because Japan has consistently performed high in these assessments, its instructional systems have become the focus of many studies.

Researchers have attempted to understand instruction through studying various aspects of Japanese educational systems. Some of the aspects that have been studied include examining classroom structure (Stigler & Hiebert, 1999), looking at the influences and usage of textbooks and other curriculum materials (Melville, 2018), and highlighting the quality of instructional features (e.g., Hiebert et al., 2005; Corey et al., 2010). Although instruction is only one factor that might account for high achievement, researchers have identified patterns in instruction in these countries that are often aligned with recommendations for best practices (Stigler & Hiebert, 1999; Takahashi, 2006; Watanabe et al., 2008).

Learning about the teaching methods in Japan that include many practices recommended for U.S. classrooms has led to an interest in how teachers *learn* these methods. Most studies have pointed to lesson study as the driving factor of Japanese teachers learning these high-leverage teaching practices. Based on my experiences living in Japan and continuing to interact with Japanese teachers, I have identified other professional learning opportunities that might contribute significantly to Japanese teachers' practices. One opportunity that could be especially influential I will call *instructional circles.* These are voluntary meetings of teachers in which participants learn about and discuss instructional problems they bring to the group.

The goal of this report is to elucidate a common professional learning opportunity in Japan that has not yet been studied systematically or described in detail. Because this study is embedded in Japanese culture, the aim is not to provide descriptions that can be imported to other cultures. However, descriptions of professional learning in other cultures can be used to reflect on one's practices and provide new ideas or insights that can be adapted to achieve professional learning goals in local settings.

To better understand these instructional circles, this study was guided by the following research questions:

1. How are Japanese instructional circles designed to provide learning opportunities for teachers? What structural features do they include that could contribute to teachers' learning opportunities?
2. How do teachers engage in the features of instructional circles and with each other to support their learning opportunities?

Through better understanding how instructional circles are designed to provide learning opportunities, and how teachers can support those learning opportunities through their engagement in the professional learning opportunity, I have been able to find evidence of practices that differ from normal professional learning practice.

Literature Review

The purpose of this literature review is to determine what aspects of Japanese instructional circles should be investigated. I first looked at what features of professional learning opportunities (PLOs) other researchers have found to be important to study. Then I considered additional features of PLOs I identified from participating in learning circles. Using these features, I can develop guiding features to look for when answering the first research question. I then looked at different features of teacher learning to guide what evidence I should pay attention to when addressing the second research question.

Consensus Features of Effective Professional Development

Although there is no complete agreement about what constitutes effective professional development, there are a small set of features around which consensus is building. Desimone (2009) and Gusky (2003) have synthesized research and have identified the following five features: Content, Active Learning, Coherence, Duration, and Collective Participation. These five categories have often been used to determine the types of features of effective professional development; however, further research has been done to better define some of these features. Gibbons and Cobb (2017) state that the feature of Active Learning covers a broad range of activities and further defines that category as the pedagogies of investigation and pedagogies of enactment. Whereas pedagogies of investigation focus on the analysis and critiquing of classroom practice, pedagogies of enactment focus on planning for, enacting, and rehearsing high-quality teaching practices. Furthermore, there has also been a greater emphasis on attending to student thinking during professional learning opportunities (Gibbons & Cobb, 2017; Grossman et al., 2009).

Observed Features of Instructional Circles.

My previous experiences have allowed me to become familiar with many different types of professional learning in Japan. The professional learning opportunities in Japan have some features that differ from those commonly found in the United States. I am interested in whether and how Japanese instructional circles include these features.

Knowledgeable Other. In Japanese professional learning opportunities, the role of "knowledgeable other" is commonplace (Takahashi et al., 2013; Takahashi & Yoshida, 2004; Yoshida, 1999). Some knowledgeable others that I have observed being present include the district math specialist, vice principals, principals, the superintendent, or university professors. I am interested to know if and how the role of knowledgeable other is important in Japanese instructional circles. I am also interested to know if the role of the knowledgeable other is like the other types of professional learning found in Japan.

Teacher preparation. When attending a PLO, Japanese teachers often prepare extensively (Melville, 2021). The planning that they conduct during lesson study is one of the main features that transfers to teachers' everyday practices (Melville, 2017). This idea that teachers need to prepare to attend professional development is something that is not commonly discussed in the research.

Administrative aspects. The most well-known form of professional development found in Japan is lesson study (Takahashi et al., 2013). One interesting feature of lesson study is the complex organizational structure. Lesson study can be operated at the school level, district level, regional level, and national level. Lesson study takes on a different form depending on these levels as well. Because of the intricacies of the organizational structure of lesson study, I am interested to learn about the organizational structure of Japanese instructional circles.

Features of Teacher Learning

De Jong et al. (2019) studied aspects of teacher groups that enable teacher learning that I thought were pertinent to instructional circles based on my familiarity with this specific learning opportunity. The categories include the content of teachers' conversations, roles and responsibilities teachers adopt, community features that typify the teacher groups, interdependency of the teacher interactions, and motivation for teachers to attend the learning activity.

Methods

Data was gathered through an ethnographic approach. Specifically, I followed the ethnographic guidelines for mathematics education outlined by Eisenhart (1988), namely, participant observations, interviews, artifact collection, and researcher introspection. From the literature on effective features of professional development and features of teacher groups that encourage teacher learning, I developed a guidebook of important features to look for when coding the observations, interviews, and artifacts. While coding, I separated claims about important features of instructional circles from the structural aspects of the professional learning opportunities that enabled learning opportunities.

Results

For this proposal, I provide one exemplary instance of an instructional circle to provide a rich description of both the structural aspects, as well as how the teachers engage with these features of instructional circles.

Teacher-Led Improvement Practices

Instructional circles prioritize teachers in all aspects of the professional learning opportunity. For each instructional circle session, one teacher provides a problem of practice to be investigated, while the other teachers offer previous experiences or research to suggestions solutions to that specific problem. The problems of practice selected by the teachers are also very specific, or at a very fine grain-sized problem. The discussions around these problems of practice lead to collective interpretation from all those involved, which connections to their future work (Horn et al., 2017). For example, Figure 1 is a board work plan provided by one of the teachers to set up his problem of practice. Mr. Kinjo included his question of the day, possible student solution methods, and the learning goal he wanted to achieve. Mr. Kinjo posed two problems of practice for discussion from the group, A) He wanted to know how to better launch his task through asking a better thought-provoking question (Hatsumon) and B) he was worried that his

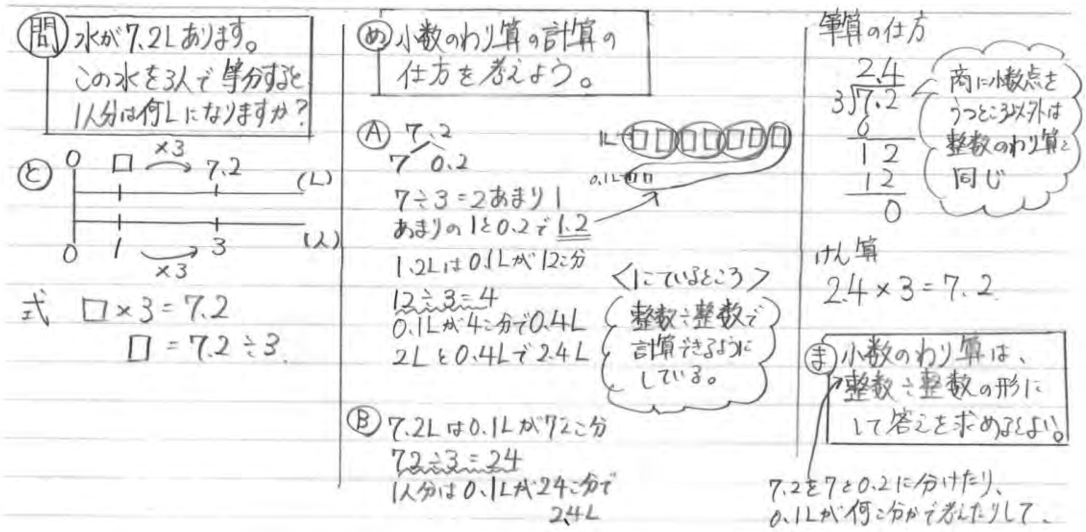

Figure 1: Boardwork Plan

students would not be able to understand the second potential student solution method. The teachers then took turns discussing potential ways to engage students in the lesson through a good thought-provoking question, as well as providing insight as to why students should be able to engage in the potential solution method. In conclusion, the teachers did not come up with mandatory questions Mr. Kinjo should use, or even if he should include the second solution method should be used. Instead, they provided their thinking and rationale and then left Mr. Kinjo to make the decisions that will best serve his class.

Educational Significance

In general terms, I see two main contributions of this study. The field of education has researched professional learning/professional development rigorously. New ideas, such as coaching, have emerged as interesting features that can also be effective methods of professional development. Learning about instructional circles will provide an opportunity to step back from the current research and look at professional learning from a different perspective. The benefit of taking this reflexive step is to learn new and interesting ways to benefit our teachers. Learning about instructional circles can also provide a pool of new ideas about professional learning. Understanding new ways of doing things, and the conditions in which they operate might help us whether and how we want to adapt them for practice in U.S. settings.

This study examined how the social interactions that mathematics teaching assistants (TAs) have within their institution influenced their professional identity development as early-career undergraduate instructors. We drew on a sociocultural perspective of professional identity development in higher education to examine TAs' interactions with students, faculty, and other TAs. We qualitatively analyzed five mathematics TAs' responses to semi-structured interviews and found that some dimensions of their identities were more frequently situated within specific relationships, while others were evident in multiple relationships. Overall, the social interactions were sites for professional identity development. Identity is a complex construct, and a better understanding of how professional identity is developed can inform higher education institutions on ways to support positive identity development of future mathematics instructors.

Keywords: Professional Identity, Teaching Assistants, Higher Education

Introduction

Research on classrooms and pedagogies in recent decades has elucidated the central role of professional identity in teachers' learning and development (Beijaard et al., 2004). We draw on this research, particularly the notion that identities are complex, dynamic, social, contextual, multi-faceted constructions (Solari & Ortega, 2020) and that they underscore teachers' pedagogies, affect their motivations to teach, inform their instructional approaches, and guide the way they navigate their profession and execute their roles (Berger & Lê Van, 2019; Sachs, 2005). A large body of research has explored the identity development of mathematics teachers in teacher education programs and K-12 contexts (e.g., Sachs, 2005), however, there is still limited work examining the professional identity development of individuals involved in higher education mathematics instruction - particularly mathematics teaching assistants (TAs).

Mathematics TAs play a crucial role in undergraduate instruction and are, in many ways, early-career mathematics instructors. After their graduate studies, many TAs continue to teach in higher education, but historically, STEM graduate programs have inadequately prepared their students to teach and have done little to help them develop their identities as educators (Hancock & Walsh, 2014). Thus, examining graduate students' development of their professional identities is especially important and can inform the ways mathematics departments, and broadly, institutions, prepare their graduate students to be future educators. We drew on a sociocultural perspective of professional identity (Beauchamp & Thomas, 2009; Solari & Ortega, 2020) development in higher education (Clarke et. al, 2013) to frame this study. A sociocultural lens accounts for the institutional contexts that TAs navigate, the social domains that exist, interactions with members of their community that occur, the roles individuals perform, and the intrapersonal domain, or identities they assigned to themselves. Our research questions were: (1) How did mathematics graduate students reflect on their developing professional identities? (2) How did TAs' professional identities develop within social interactions?

Framing and Literature Review

Researchers have previously defined and classified the construct of identity in numerous ways. Identities can be institutional, based on an affiliation with a group, or even discursive (Gee, 2001). Additionally, identities can be independent or interdependent (Fryberg & Markus, 2003), and they can be based on others' perceptions (Markus & Wurf, 1987; Sfard & Prusak, 2005). Drawing on these notions, we view identity as: "a dynamic view of self, negotiated in a specific social context and informed by past history, events, personal narratives, experiences, routines, and ways of participating" (Bishop, 2012, p. 38). Framing these ideas in a professional environment, we define professional identity as an ever-changing view of one's obligations, role, and attitudes situated in institutional, social, and cultural contexts. A professional identity includes emotional components such as attitudes and beliefs (Wenger, 1999), which are often left out when considering one's self-perceptions. Factors that influence professional identity include the direct work environment, the wider context of higher education, interactions with students, and professional development activities (van Lankveld et al., 2017), which serve as a basis for examining how situated contexts can affect graduate students' professional identities.

More specifically, we drew on a sociocultural perspective of professional identity development in higher education to frame this study (Beijaard et al., 2004; Gee, 2001; Clarke et al., 2013). The formation of professional identity in higher education is a social and contextual process, and the other actors with whom an individual interacts play salient roles in helping an individual build identities and meanings for themselves as a professional (Solari and Ortega, 2020). Mathematics TAs navigate a complex interpersonal network that involves students, faculty, and other TAs, all situated within a broader institutional context and the mathematics discipline. The expectations of this community, the institution, and the discipline can shape the roles that TAs perform, thus affecting their professional identity development as higher education instructors. Situated within a specific institutional context and the mathematics discipline, we examined emerging professional identities that resulted from four key relationships (See Figure 1). We acknowledge that factors outside of the institutional context, mathematics discipline, and the four key relationships we have identified here (e.g., family, relationships, stress of the profession, etc.) can also affect professional identity.

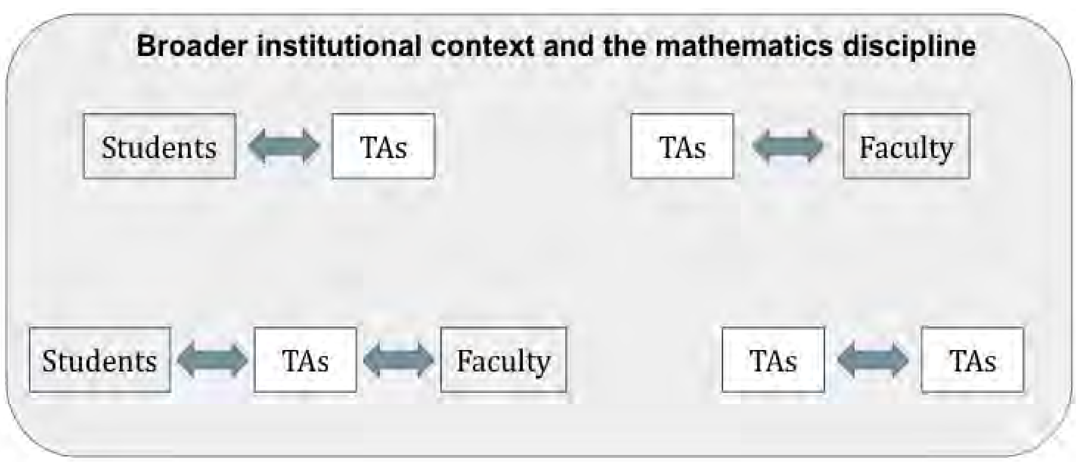

Figure 1: Teaching Assistants' Relationships within an Institution

Method

This study was conducted at a Minority-Serving Institution in California. It was a part of a larger project that examined the experiences of transfer students enrolled in a set of courses designed to develop proof-construction competencies and support transfer students' transition to a four-year university. Purposeful sampling (Creswell, 2013) was used to recruit five PhD students in the mathematics department who served as TAs for an introductory proof course, which was situated in number theory and set theory. All participants facilitated online sections of the course, were in the 2nd or 3rd year of their doctoral program and had prior experiences as TAs. Three self-identified as male and two self-identified as female. We use the pseudonyms Federico, Nestor, Wyatt, Kaitlyn, and Lisa to refer to the five TAs interviewed for this research project. We conducted semi-structured interviews (Rubin & Rubin, 2011) over Zoom that focused on the TAs' experiences enacting sections remotely, the ways the course supported underrepresented and non-traditional (i.e., transfer) students, and the TAs' perceptions of their identities and roles as TAs and early-career educators. The research team first open-coded the TAs' responses and identified themes in the TAs' reflections. The team recoded the corpus of data using the following second round codes to describe the complexity and multidimensionality of their professional identities: *content-deliverer, sensemaker, community-builder, assistant, supporter, mentor, resource sharer, learner, beliefs and values,* and *demeanor.* The research team discussed and wrote memos about emergent themes in how the TAs described their professional identities, and also coded for the individuals that TAs described as salient to each facet of their identities (i.e., students, faculty, and other TAs).

Findings

We found that graduate students reflected on their developing professional identities in a number of different ways, with their professional identities developing within certain social contexts (e.g., Student-TA relationship, TA-Faculty relationships, Student-TA-Faculty relationships, TA-TA relationships) in which the TAs were situated (e.g., *content deliverer* was most associated with the Student-TA relationship). It is important to note that professional identity is a complex construct, and all interactions and relationships are influential in developing identity. However, we only present the most salient professional identities that emerged from the TAs' reflections on the four relationships.

Professional Identities That Developed from the Student-TA Relationships

In this section, we highlight the important aspects of the TAs' professional identities most situated in the relationship between students and TAs: *content-deliverer*, *sensemaker, community-builder*, *supporter*, and *beliefs and values*. The TAs noted that they were engaged in these different relationships with students as part of their roles. We describe each aspect of their identity and highlight examples of instances when the TAs revealed their perceptions of their identities as it relates to students.

Content-Deliverer. As *content-deliverers,* the TAs viewed themselves as individuals who delivered mathematics content to students, whether presenting the same content professors lectured on or reviewing material from previous classes. For instance, Wyatt explained, "I found that I'm more effective as a TA when I can just cover a lot of material, because my strength is being able to explain it in a digestible way." Here, Wyatt identified himself as someone who delivers content and he saw his effectiveness in this role. Another TA, Nestor, described his identity as a *content-deliverer,* saying that "I should just be like a - not literally but, like a bit of a copy paste of what the professor has said in lecture. Sometimes just repetition." Nestor believed his role is to reinforce the same content to students in section that the professor delivered during lecture. We found that *content-deliverer* was an important aspect of TAs' professional identities illustrated by all participants.

Sensemaker. The professional identity of *sensemaker* emerged as TAs described engaging in sensemaking efforts of the circumstances and individuals around them. In the social context of Student-TA relationships, the TAs engaged in sensemaking to better understand their students' experiences including students' content knowledge, emotional well-being, challenges related to their university experiences, and difficulties associated with the remote-instruction brought upon by the COVID-19 pandemic. For instance, Kaitlyn made sense of the challenges the students in her class faced noting: "There's also an intensity that comes with Math A that maybe make students feel a little bit more, I don't know fearful about doing perfect in the class or whatever." In another instance, Lisa remarked about the unique challenges students of a particular gender face when she said, "The people who speak out are male, but there [are] definitely a few female students who were talkative. But yeah so that's all I really noticed." In this moment, Lisa made sense of the gender and social dynamics in her classroom and how those affected their participation. We found many instances of sensemaking centered around students' experiences and this illustrates that a salient part of TAs' professional identities involved how they noticed, made meaning, and took action to attend to their students.

Community-Builder. *Community-builder* referred to the instances when TAs described taking action to build community with students or among students. Most instances of a TA building community took on one of two forms. The TA either worked to create community among students or the TA would talk with students about non-mathematics related topics during office hours. For example, Lisa commented, "I tried to do a lot more of like breakout sections and like try to get students to talk to each other, because I was like you don't ever see each other, trying to talk to each other." Lisa engaged in community-building efforts to get her students to interact with one another on Zoom and to become more familiar with one another. Later, Lisa commented that she often tried to start class with a question to get to know what and how her students were doing outside of the class. She expressed that she was able to best engage with students on a personal level during office hours: "I'll mostly be, like 'Anyone do anything fun on the weekend?' and then usually be met with silence. But in office hours, I had students like linger around and talk to me, so that was fun." Many of the efforts related to building community were in response to the challenges presented by the pandemic, as TAs would often express difficulties with building community in the online learning environments in which they taught.

Supporter. TAs reflected on how they supported students through encouragement, offering emotional support, and advocating for their students; these encompassed the professional identity of *supporter.* TAs reported capitalizing on the interactions with students in office hours and sections to support their students. They recognized that part of their professional identities and roles included attending to students' affect and emotions, and they were cognizant of providing students with support throughout the quarter. For example, during the remote instruction brought upon by COVID-19, TAs recognized that it was an extremely difficult time for students and described themselves as being someone to whom students could talk, beyond just discussing the mathematics content of the course. For example, Nestor described an interaction during one of his synchronous office hours when he conversed with a student about aspects of each other's lives that did not directly relate to the mathematics content. He said, "I don't know exactly how we ended up there, but I guess she just needed someone to talk to that night, and I was the one for whatever reason, because in Zoom you can't really reach out to anybody else. Right?" He recognized a student's need and was able to provide her with some emotional support. Other ways that TAs provided support for the students was to advocate for them. Federico described listening to students' requests and complaints during office hours and relaying that information to the faculty. Through advocacy, offering encouragement, and overall, showing care, we found that TAs were active *supporters* of their students.

Beliefs and Values. As they reflected on their relationships with students, we also found a set of *beliefs and values* that described what TAs believed about their students, how they understood their students learned, and how TAs thought they should help their students engage with mathematics. Federico, for example, shared that his students did not learn in the same ways, and TAs should be able to support and teach all students. This belief affected his approach to teaching. In another example, Wyatt described how in his past experiences as an undergraduate student, he was taught mathematics through a narrow lens, and he believed that students needed to be allowed to be creative in mathematics for them to learn well. A common belief that many of the participants held was that a TA should help students engage with mathematics by creating learning spaces where students would feel comfortable to participate, make mistakes, ask questions, etc. This idea of fostering a comfortable space for students was the most prevalent belief that the TAs held. For example, Kaitlyn said, "I think there's a little bit of gaining that trust in your students. That they could come, they feel like they can come to you with all their questions…You want them to feel comfortable." This belief about how TAs should teach mathematics can influence their pedagogies and the ways they interact with students.

Professional Identities That Developed from the TA-Faculty Relationships

Next, we focus on the interactions between TAs and faculty. In this social context, faculty were the instructors on record for the sections the TA managed. The three key facets that TAs reflected on related to their professional identities that were most evident in this relationship were *assistant*, *learner*, and *sensemaker*. Evidence of these professional identities included the TAs assisting with grading, answering students' questions, sharing their own learning of content (and enjoyment in learning this content), and making sense of their relationships with faculty. The professional identities of *assistant* and *learner* only occurred in the TA-Faculty relationship, while *sensemaker* also occurred in the Student-TA relationship.

Assistant. Quite frequently, the TAs would position themselves as individuals whose purpose and role was to assist the faculty. This notion underscores the professional identity of *assistant*. The TA used words like "helper" or "grader" to signify their role as an assistant to the faculty member with whom they worked. For instance, Lisa shared, "[I] just do some of the grunt work of the grading and background work that needs to get done. You know, it shouldn't lie fully on the professor's hands. Just a helper, a solid helper." In this instance, Lisa identified and gave merit to helping and assisting the faculty she was working with through grading exams and doing background work. Additionally, Kaitlyn, reflected on her role and expectations as an assistant and said, "As far as the professor goes, you know, they expect you to go through homework problems and answer questions that students have and grade a little bit." In this moment, Kaitlyn acknowledged that many faculty members had specific expectations of their teaching assistants. Additionally, Federico described his relationship as an assistant to his faculty member, noting, "He told me things to do. That's what I did." The consistent use of language, such as "He told me things to do," and "grunt work," and the description of TAs' self-described roles frequently occurred across the data set. The professional identity of an *assistant* was only observed in the context of TA-Faculty relationships.

Learners. We observed another dimension of professional identity that only appeared in the social context of relationships involving TAs and faculty: *learners*. TAs described their experiences as learners, both past and present. This illustrated that they were not only teachers and individuals meant to deliver content or support students. TAs saw themselves as learners of content, learners of pedagogical methods, and learners of resources. Nestor described his experience of learning content in a new way, explaining, “I feel like every time I revisit a concept… I always learned something new, just for myself or like a different perspective, different angle, because the professor looks at it from a different, in a different way.” Nestor identified himself as a learner through his exposure to former content through a new lens, expressed his enjoyment of having the opportunity to be a learner, and engaged with the content differently from how he previously learned it. This professional identity signifies an important role that TAs can take up and it is their capacity to see themselves as both instructors and learners.

Sensemaker. TAs reflected on their professional identity as *sensemakers* within Student-TA relationships in instances when the TAs tried to better understand students’ experiences. Within the social context of TA-Faculty relationships, *sensemaker* describes how TAs noticed and made meaning of their relationships, interactions, and experiences with faculty. For example, Wyatt made sense of a faculty’s pedagogy and instructional practices, saying, “Well, you know, in an ideal world, of supposing that they had more time to concentrate, I think one thing they could do is just help TAs better know how to grade assignments.” This moment highlighted Wyatt making sense of how a faculty member interacted with him and could support him as a TA. He was forming thoughts on the pedagogical practices of faculty from past and current experiences while making sense of what could be done to better assist TAs. In another instance, Lisa commented on her experience with faculty and what she felt would best benefit her as a TA. She explained, “I think just more communication of like what is actually expected of us. Sure, you're supposed to teach four sections, do certain amount office hours, work the math lab, but, how do you do all those jobs?” Lisa was actively making sense of her past and current experiences with faculty, while also considering how to improve that relationship. She identified areas where faculty could improve their practice through understanding TAs’ challenges and reflecting on their experiences working with these students. Broadly, the professional identity of *sensemaker* entails the active process of understanding, making meaning, and taking action within a TA’s social context.

Professional Identities That Developed from the Student-TA-Faculty Relationships

We distinguish the Student-TA-Faculty relationship from just the Student-TA relationship and the TA-Faculty relationship because we observed that TAs often described themselves as individuals who bridged students and faculty. Therefore, these aspects of their professional identities and roles were the result of understanding how they mediated the various expectations, perceptions, and needs of both students and faculty. As Kaitlyn noted, “it’s kind of exactly what it seems: like you’re this middle ground between the professors and the students.” TAs identified two aspects of their professional identities in relation to *both* faculty and students: *content-deliverer* and *demeanor*. TAs delivered content in order to meet their students’ needs, in light of what the faculty member had taught, and they presented themselves to students often in response to how they understood their students perceived the faculty.

Content-Deliverer. Although TAs reflected on their professional identities as *content-deliverers* within the Student-TA social context, TAs revealed that faculty delivered content in one way, but as TAs, they should deliver the content differently to better attend to the needs and expectations of students. Often, TAs reflected that offering the content in ways that were different from the faculty would be beneficial to the students. Nestor shared, “If you revisit the…same concept, maybe through a different angle, then you can understand it better.”

Demeanor. The second aspect of TAs' professional identities within the Student-TA-Faculty social context was *demeanor*. TAs acknowledged students' perceptions of faculty (usually in a negative way), and TAs portrayed themselves in ways that differed from faculty. When asked about her primary role, Lisa said, "Just to be someone who is less scary than the professor. My job is just to be approachable." Here, Lisa noted that approachability was an important consideration for TAs because of the common perception that professors were "scary." Similarly, Kaitlyn shared, "I think part of our role as a TA is just to, sort of, be that middle ground between the scary professor and any intimidation." The ways in which Lisa and Kaitlyn portrayed themselves, particularly as caring and approachable to students, shed light on their understanding of *demeanor*. How TAs presented themselves to students was an important part of their professional identities, particularly in relation to mediating students and faculty.

Professional Identities That Developed from the TA-TA Relationships

Lastly, the ways that TAs navigated their responsibilities and roles alongside other TAs highlighted their capacities to be *resource sharers* and *supporters* of each other. Reflecting on her experiences with remote instruction, Kaitlyn revealed how the TAs in the mathematics department supported each other by giving advice, and they used various online platforms to share resources that may be useful to address the challenges of conducting sections online. She explained, "I think we gave advice to each other, and we have a Discord [online platform] for our math grads, so people talked about teaching advice and…what programs they like to use, apps they like to use to teach." TAs supported each other by offering advice and directing each other to teaching resources. These relationships illustrate the dimensions of their professional identities best described as *resource sharers* and *supporters.*

Discussion

Through a sociocultural perspective on professional identity development, we found that the relationships and interactions that TAs have with members of their mathematics community and institution were sites for identity development. Beauchamp and Thomas (2009) wrote that identity "is shaped and reshaped in interactions with others in a professional context," and we found that TAs reflected on a range of professional identities. Certain aspects of their identity were more frequently situated within specific relationships such as *supporter* most often occurring within the Student-TA relationships, and *resource sharer* most often occurring within the TA-TA relationships. However, other dimensions of their professional identities such as *content-deliverer* and *sensemaker* were evident in multiple relationships such as the Student-TA, TA-Faculty, and Student-TA-Faculty relationships. We found that the Student-TA relationship was not only the most frequently mentioned interaction but also through which multiple dimensions of their professional identities were revealed.

While the key tenets of each professional identity remain the same across the relationships (e.g., *sensemaker* refers to noticing, making meaning, and taking action), the ways TAs perceived themselves as such depended on their company (e.g., the student or the faculty). For example, in the context of a Student-TA relationship, being a *resource sharer* may look like a TA providing resources to students to support and engage learning. However, in the context of a TA-TA relationship, being a *resource sharer* may entail a TA sharing instructional resources with other TAs. This is consistent with existing research that acknowledges that the construction of professional identity development is complex, and that different relationships and interactions influence different aspects of their identity (Berger & Lê Van, 2019). Moreover, as the TAs reflected on their experiences and interactions, we noted how their professional identities were linked to their instructional practices and pedagogies. Each TA exhibited a unique set of identities, and this was revealed through the ways they individually reflected on their roles and interactions.

We extend the literature on professional identity development in higher education by examining mathematics TAs as early-career undergraduate instructors. A sociocultural perspective on professional identity development affords an exploration of the key interactions that TAs engage and the dimensions of their identity developing and intersecting across these relationships and interactions. Limitations of this study include the limited number of participants (five) and that the participants of this study served as TAs for the same introductory proof course. In addition, all five participants were TAs for online sections of the proof course and this environment could elicit different aspects of TAs' professional identities than in-person instruction. Future research can examine more mathematics TAs across a broader range of courses, such as calculus, linear algebra, etc. Furthermore, for this study, we only focused on four key social context relationships, but TAs professionally interact with many other individuals including peers in other departments, staff, various organizations, and professionals outside of the institution. Future research can more closely examine the larger, complex network that TAs navigate and how identity is developed within this network, can focus on just one type of interaction (e.g., TA-TA), or can focus on one aspect of professional identity (e.g., *community-builder*).

Conclusion

The professional identities of mathematics instructors in higher education is still a largely under-researched area of mathematics education. With many mathematics graduate students continuing to become teaching faculty themselves, it is imperative that we examine how their professional identities are developed, particularly related to their experiences as TAs. The professional identities that mathematics TAs develop through their social interactions and relationships with members of their professional community not only influence their current positions as TAs but provide a foundation for their future careers, pedagogies, and practices. Identity development is a constant process throughout the careers of mathematics educators, and it is important to acknowledge that even prior to formal appointments as a teaching faculty, their experiences – such as serving as TAs during their graduate programs – have already shaped their professional identities. A sociocultural perspective of identity development affords a lens through which researchers can identify and examine the extent to which experiences related to being a teaching assistant impact the development of professional identity as a mathematics instructor. Understanding the nuances and complexities of how professional identities of future educators are developed can inform higher education institutions on how to better develop positive professional identities of mathematics graduate students.

Mathematics professional development (PD) has had many small victories but has not brought about a widespread change in what constitutes typical mathematics instruction. This theoretical essay argues that many PD projects have been based on an assumption that the aims of the PD should be ambitious, but ambitious PD requires that a large set of criteria be satisfied (active learning, coherence, duration, teacher buy-in, etc.). Even then, ambitious PD may only reach a minority of teachers who are ready to make the transformation. An alternative approach is incremental PD, which starts with a teacher's contextual constraints and ubiquitous practices, offering modest but meaningful "nudges" for their instruction. These nudges are intended to be easily taken up by teachers, providing a sense of success that leads to them sustaining the practices and being portable enough to be easily shared with other teachers, allowing for scale.

Keywords: Professional Development, Instructional Activities and Practices

There have been vast investments of both time and money for teacher professional learning, yet despite these investments, mathematics instruction in the United States has remained largely unchanged (Karp & Schubring, 2014; Stigler & Hiebert, 1999). Professional development (PD) focused on teachers' instructional practice often faces three overarching challenges: (1) making a direct impact on the teachers in the PD, (2) sustaining outcomes beyond the life of the PD project, and (3) scaling up the PD (Heck et al., 2019; Karsenty, 2021). In attempts to overcome these challenges, scholars have made progress studying the characteristics of effective PD (e.g., Desimone, 2011; Wilson & Berne, 1999) and mechanisms by which the PD might spread (e.g., Morris & Hiebert, 2011). Still, despite these efforts, the lack of widespread reform in mathematics instruction persists (Wilkie, 2019).

We contend there is an important assumption underlying these challenges—namely, that PD should be targeted at instructional change that is ambitious or transformational (e.g., Kazemi et al., 2009; Kraft & Hill, 2020). Ambitious instruction, characterized by being disciplinarily rich and student-centered (Cohen, 2011), is something many mathematics education scholars strive toward and make the centerpiece of their PD for teachers. But what if we instead start with a more modest goal? Like Star (2016) and Litke (2020), we argue incremental changes could also be the goal of PD. In this paper, we discuss how this shift from ambitious to incremental goals for PD changes the instructional foci (Litke, 2020; Star, 2016) and leads to redefining success, rethinking the starting points for PD, and new mechanisms for sustainability and scaling.

Starting Points for Incremental PD

Teachers' Constraints

Many professional developers adhere to researchers' recommendations for effective PD in format, duration, and contextual features (e.g., Desimone, 2011, Feiman-Nemser, 2001). It is generally agreed upon, though with some dissent (Sims & Fletcher-Wood, 2021), that attending to criteria such as active learning, coherence, substantial duration, and teacher buy-in are necessary for implementing PD aimed at promoting ambitious instruction; however, it is unclear that PD aimed at modest incremental improvements needs to meet these same criteria. Central to the idea of incremental PD is that professional developers offer small suggestions for improvement—which we refer to as nudges—based on a teacher's current practice. Thus, we argue the starting place for incremental PD is teachers' constraints and contextual realities, which typically include limited planning time, conventional curriculum and resources, conventional expectations from students and parents, limited professional collaboration structures, and more.

Many of these constraints are often at odds with the criteria for effective PD. For example, Desimone (2011) and others have suggested PD requires a substantial investment of time, but we also know that many teachers do not have enough time for planning (Steen-Olsen & Eikseth, 2010). An incremental approach to PD would be designed with such constraints in mind. For example, the PD may simply offer a small nudge that does not take much time and that supplements existing curriculum materials, nudging toward a conceptual connection or a brief opportunity for student choice on their problems. These nudges, though small, could be more impactful than a teacher whose constraints prevent them from engaging with ambitious PD at all. If the nudge fits within the teacher's time constraints and aligns with the curriculum and their community expectations, and seems to be a slight shift in a positive direction, we hypothesize that this will yield high levels of buy-in, which is perhaps a necessary criterion for ambitious PD and incremental PD alike, but the latter can generate the buy-in from more teachers.

Ubiquitous Practices

Often PD is designed to promote ambitious practices such as robust classroom discourse (Herbel-Eisenmann et al., 2017), enacting cognitively-demanding tasks (Smith et al., 2008), argumentation, and reasoning (NCTM, 2009), and many others. These PD efforts aimed at ambitious practice are worthwhile. Yet, ambitious practices are difficult to achieve, typically resulting in pockets of success because they often require major shifts in teachers' existing practice. This discrepancy between current practice and ambitious practice can potentially position teachers in a deficit manner. We bear in mind Spangler's (2019) call to "consciously respect teachers and…avoid deficit approaches in our thinking about teachers" (p. 3).

Thus, in contrast, incremental PD would focus on the commonplace, daily pedagogical practices teachers are already comfortable with. For mathematics teachers, such practices might include demonstrations with worked examples (Atkinson et al., 2000), students' independent work time on problem sets (Otten et al., 2021), or the teacher going over homework at the board (Otten et al., 2015). An example might be comparing two procedural worked examples instead of simply doing one after the other (Litke, 2020). Another example is adding a single reversibility problem (Dougherty et al., 2015) to an existing exercise set. The intention is that teachers can immediately understand how they would incorporate these nudges into the practices they already employ, but also understand the nudges bring some modest yet meaningful benefit.

Sustaining and Scaling Incremental PD

Sustaining Modest Changes

Sustaining teacher change, especially ambitious change, has long been a challenge in teacher education (Liu & Phelps, 2020). We contend that an incremental approach can lead to sustainable change in at least two ways. First, incremental PD will focus on changes close enough to teachers' existing practices that the change is less disruptive and can be incorporated regularly. As Thaler and Sunstein (2008) have found regarding human change in general, if we want a change to take hold, we need to make it easy for people to do. Moreover, by attaching the incremental changes to common occurrences in the classroom, those changes can carry forward for the teacher by becoming their new instructional "habits," so to speak. As Star (2016) noted, it can be powerful to make a 10% improvement in a typical practice a teacher uses in 90% of their lessons rather than seeking a 90% improvement in a practice they only use 10% of the time.

Second, sustainability can come from the incremental PD delivery mechanism itself. When grant-funded (ambitious) PD projects are completed, the resources to continue teachers' learning are often depleted. The PD may involve summer workshops and follow-up sessions throughout the school year. Such models may impact teachers' instruction, but sustaining the change is challenging as projects end and teachers, administrators, and curriculum materials come and go. Instead, by aiming for incremental improvements to PD, delivered in small packages, teachers can learn them in a short time or more flexible formats (e.g., videos) and can try them relatively quickly. This would also allow the creation of artifacts that can be reviewed on demand. Thus, sustainability is gained from the low resource cost associated with delivering incremental PD, which also allows it to be shared among practitioners, leading us to the issue of scale.

Scaling Modest Changes

Another long-standing challenge for the field is the ability to scale PD initiatives (Heck et al., 2019; Karsenty, 2021). Here, we consider scale in terms of reaching a large number of practitioners. Because of the profound change entailed for most teachers concerning ambitious mathematics instruction and the confluence of factors needed for this change to occur, it seems optimistic to expect that ambitious PD might eventually scale to 10% or more of mathematics teachers. But again, as Star (2016) pointed out, it can also be beneficial to many students if 90% of (conventional) teachers make some small improvements to their instruction. As mentioned above, PD aimed at incremental changes would not require the same extensive resources as more ambitious efforts. The freedom to deliver specific, actionable practices via on-demand formats, such as videos, downloadable documents, or social media suggestions will allow for the scaling of those efforts by the PD creators and practitioners themselves. Moreover, by offering an incremental improvement to a ubiquitous teaching practice, we are increasing the likelihood that the improvement can be shared from person to person because many other teachers will also recognize the applicability of the suggestion to their own teaching.

A second notion of scale is the consideration of whether or not the incremental practices will scale toward future, substantial changes. It seems plausible that when teachers enact small improvements, they may gain confidence and feelings of success, which may lead them toward the addition of more small improvements. These small improvements may eventually lead them quite far from the conventional instruction they began with. This is not to say that the accumulation of incremental changes is necessarily equivalent to an ambitious change, but sustained improvements that have the potential to spread to other teachers should be welcomed, nonetheless. And the relationship between multiple incremental changes and larger ambitious changes can be explored empirically, which is where we now turn.

Questions and Final Considerations

What are some of the empirical questions that we can ask about incremental PD for mathematics instruction? There are a few that are of immediate interest to us:

1. Because incremental PD should be rooted in a teachers' unique contexts and built upon their existing ubiquitous practices, to what extent will certain nudges work across multiple contexts and for various teachers? There are some commonalities in many teachers' situations, so we hypothesize some generality for certain nudges. Still, we have to examine the balance between the general applicability of nudges and the individualized preferences of teachers (what aspects of their teaching do they want to be nudged on?).
2. What are some of the characteristics of teachers who are likely to respond positively to incremental PD, and what are the characteristics of those who are able to proceed directly to ambitious PD? As discussed above, we hypothesize that a majority of mathematics teachers can be well served by incremental PD, particularly those who may be resistant to ambitious PD. Still, if teachers respond positively to ambitious efforts, then we would support ambitious PD in those particular cases. Further research is needed, as well as further input from teachers themselves, to help us understand the differences.
3. In what ways can we measure the incremental changes in teachers' instructional practice when some of the changes are designed to be subtle or modest? Some of our current methods for assessing the impact of PD hinge on larger changes, but with incremental PD, we will need to be able to track the small changes and whether they are sustained.
4. Can deep, systemic issues of inequity and injustice in mathematics education be meaningfully addressed in an incremental manner? We agree that, in many ways, transformational change is needed and time is of the essence, but is there a role for incremental change in immediately bringing about some equitable practices or in setting the stage for later, more profound changes?
5. Given the multitude of small changes that could be proposed to a teacher, how will we decide which to employ and when? Relatedly, what are the sequences of incremental changes in instruction moving toward? Perhaps incremental instruction could be guided by the larger goals of ambitious instruction. It is an open question, however, whether and how an accumulation of such small changes yield (or not) a more substantial change long-term. Munter (2014) found teachers' visions of high-quality mathematics instruction can gradually increase in sophistication, but can one type of vision or pedagogy gradually shift into a different type altogether? One hypothesis is that incrementally improving conventional instruction will eventually increase the likelihood that teachers will respond positively to ambitious PD. A second hypothesis is that improving conventional instruction will lead to teachers feeling more confident and affirmed in what they do, so they will not transform away from conventional instructional models. A third hypothesis is that the incremental changes are simply independent from ambitious goals for instruction.

In embracing an incremental approach to PD, meant as a complement to the ongoing ambitious PD efforts, we contend that many of the persistent challenges in relation to the limited impact, sustainability, and scale of efforts to improve mathematics teaching may be addressed, or at least explored and understood from a perspective distinct from the ambitious approach.

We explored how elementary teachers designed argumentation-based lessons in the context of robotics-integrated mathematics classrooms. We analyzed data collected from two teachers who taught elementary mathematics and robot programming during their engagement with a professional learning course. In the course, teachers learned to use argumentation in teaching mathematics, science, and programming. We analyzed their lesson plans to understand how they structured their lessons to use argumentation in robotics-integrated mathematics classrooms. We also examined the teacher interview data collected after the course ended to capture their understanding of argumentation. Our data analysis results showed that the ways that teachers designed argumentation-based mathematics lessons with robotics and programming were largely aligned with their interpretations of argumentation. The study findings are discussed and future studies are suggested.

Keywords: Professional Development, Integrated STEM / STEAM, Computing and Coding, Classroom Discourse

Current K-12 standards and mathematics education researchers emphasize the importance of learning and teaching argumentation in mathematics classrooms (e.g., National Council of Teachers of Mathematics, 2014; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; Staples & Newton, 2016). Collective argumentation occurs in the classroom when students and teachers work together to make a claim and support it with evidence (Conner et al., 2014). The benefits of using argumentation in the classroom include the development of student conceptual understanding of mathematical ideas, mathematical autonomy, communicative skills, and authentic mathematical practice (e.g., Andriessen, 2006; Staples & Newton, 2016; Yackel & Cobb, 1996). We believed that teaching programming through argumentation also could have benefits such as conceptual understanding of programming ideas, especially when teachers use pedagogical practice already in use in their mathematics classrooms to teach programming, thus increasing the possibility that teachers incorporate programming in mathematics classrooms.

In this paper, we report our study of elementary teachers who learned to teach mathematics and programming through argumentation. The following research question was addressed: *How do elementary teachers design argumentation-based lessons for robotics-integrated mathematics instruction at the end of a professional learning course in which they were introduced to use argumentation in teaching programming?*

Related Literature and Theoretical Framing

There is a natural connection between programming and mathematics (Savard & Highfield, 2015). The merits of using programming and robotics in mathematics education have been well-documented. For example, research has shown that mathematics activities integrated with programming and robotics can support student understanding of mathematics (e.g., Wei et al., 2011), develop student spatial abilities (e.g., Keren & Fridin, 2014), and provide students opportunities to express their mathematical thinking and reasoning (e.g., Ke, 2014). However, there is little research on the experiences of teachers who teach both programming and mathematics in their classrooms. The present study explored how teachers designed argumentation-based mathematics lessons with programming and robotics. To understand teacher learning about the use of argumentation in teaching programming and mathematics, we analyzed their lesson designs and interviews considering the context that they were situated as elementary teachers using a situative perspective (Peressini et al., 2004).

Methods

This study examined how elementary teachers designed argumentation-based mathematics lesson plans integrated with robotics toward the end of a semester-long professional learning course. The course occurred in a school district in the southeastern United States. Nineteen elementary teachers recruited from five different elementary schools were enrolled in the course. The course consisted of four face-to-face meetings (approximately 10 hours in total) and eight online exercises. Three instructors co-taught programming and robotics as well as the use of argumentation in teaching mathematics, science, and programming.

During the first two face-to-face class meetings, participating teachers discussed *argumentation* in mathematics and science classrooms and analyzed examples of classroom episodes identifying components of an argument (e.g., claim, data, and warrant) and focusing on teacher actions in argumentation. Throughout the course, teachers learned a variety of robots using block-based programming language. Before the last face-to-face class meeting, teachers were assigned to design and teach a mathematics lesson focusing on argumentation in their classrooms. They video-recorded a part of their lesson and discussed how they supported student argumentation during the fourth face-to-face class meeting with other teachers. After this meeting, teachers were asked to design a unit plan including three to five lessons integrating robotics and argumentation into mathematics classrooms. Our focused data to answer the research question was these integrated lessons.

We focused on two teachers, Cari and Malia (pseudonyms), as they implemented robotics and argumentation in their mathematics classrooms. Cari was an experienced teacher, and Malia was a novice teacher (see Table 1 for teachers' background information). Their robotics-and-argumentation-integrated mathematics lesson plans and post-interviews were analyzed. Using open coding (Strauss & Corbin, 1990), we first examined their robotics-and-argumentation-integrated mathematics lesson plans line by line, focusing on the parts in which they described student argumentation activities. We then made a memo for each teacher describing the ways that they designed lessons to create argumentation in their classrooms. Finally, we examined how each teacher understood and interpreted argumentation using the interview data. We also made a memo for each participant describing their views on argumentation.

Table 1: Teachers' Background Information

Teacher	Grade	Years of Teaching Experience	Previous Experience with Programming and Robotics	Previous Experience with Argumentation
Cari	3rd	16-20 years	Little	Little
Malia	5th	3-5 years	Intermediate	Little

Results

This section reports how Cari and Malia designed their argumentation-based robotics-integrated mathematics lessons and their conceptions of argumentation in elementary classrooms.

Cari's Lesson Designs for Creating Argumentation in the Robotics-Integrated Mathematics Classrooms

Cari designed 2-day-long robotics-integrated mathematics lessons for 3rd graders focusing on the concepts of perimeter and area. The learning goal of the first-day lesson was that students would be able to program robots to trace the perimeter of a given square. Cari created the second-day in-class activity to engage students in programming their robots, drawing different shapes with the same perimeter but different areas. Cari expected her students to work on these activities in pairs and make claims for each movement of the robots. She anticipated that argumentation would occur between and among students when they work together to figure out the area or test out their code with their robots and also when they disagree with each other. She emphasized that when team members agree on a claim suggested by a team member, the team can move on to the next step for solving a given task.

Cari's Conceptions of Argumentation

For Cari, argumentation was perceived as the process of arguing, proving, justifying, convincing others, and building a consensus within a classroom community. She believed that the benefit of engaging students in argumentation was to help students gain the confidence of speaking out their voices in public places (e.g., classrooms) and sharing their ideas with others. She believed that the more confident students become, the more student participation occurs in argumentation. She also noted that student claims might not always be correct but giving them opportunities to experience defending their claims in class helps students develop their skills of arguing and convincing others, which she saw as necessary life skills.

Malia's Lesson Designs for Creating Argumentation in the Robotics-Integrated Mathematics Classrooms

Considering her 5th graders, Malia designed 2-3 day class activities for her mathematics and robotics integrated lessons. The lesson goal of the first-day activity was to have students graph points on a coordinate plane and program their robots to move from one point to another. Malia expected students to find the area and perimeter of a geometrical shape they created by connecting the points on the plane. She designed the second- and third-day activities to have students explain their knowledge of graphing points on the plane and using the robots. Malia expected students to work with their groups collaboratively during the activities and specified how she wanted students to complete the activities. However, she did not discuss when, how, and what arguments would occur during student participation in the activities within her written lesson plans.

Malia's Conceptions of Argumentation

Malia saw argumentation as a process of explaining and agreeing or disagreeing with others' ideas. She thought that the critical component in argumentation was the justification part. Malia saw the use of argumentation in teaching programming would be relevant when prompting students to explain why their code works or does not. She noted that making arguments might be challenging for students when they did not know how to explain or justify their answers (claims). She also thought that students might not see justifications necessary, particularly when they think something is obviously true. She believed that engaging students in argumentation could improve their writing skills as they learn to justify with evidence.

Discussion and Conclusion

Both Cari and Malia saw argumentation as a transferable skill that students can develop in both mathematics and programming classes. They thought that engaging students in argumentation would help students learn how to argue and reach a consensus in the classroom. We also found the way that the teachers designed argumentation-based robotics-integrated mathematics lessons was largely aligned with their conceptions of argumentation. This finding is aligned with many prior studies that have shown the close relationship between teacher pedagogical conceptions and classroom practice (e.g., Kim et al., 2013). Another finding was that Cari specified when, what, and how student argumentation would occur during the robotics-integrated mathematics activities that she designed. In contrast, Malia, a novice teacher did not. We conjecture that for a novice teacher, it might be challenging to anticipate student argumentation in the classroom.

In their lesson plans, both teachers did not clearly describe their expectations of how students would use mathematics or programming knowledge when justifying their claims about each robot movement during the activities. They also did not plan on how they would facilitate student argumentation. Future studies are needed to see how teachers actually enact argumentation in their classrooms based on their lesson plans and explore the support teachers need in planning integrated lessons for productive classroom argumentation.

Understanding and utilizing the Five Practices for Orchestrating Productive Mathematics Discussions (Smith et al., 2009; Stein et al., 2008) has grown in importance as teachers continue to be challenged to engage their students in student-centered, discourse-based instruction. We argue that by engaging in rehearsals of the five practices and decomposing practice, the teachers are not only able to advance their understandings of each of the five practices, but also gain knowledge of its value in their classroom practice and its role in the supporting student development. Preliminary results from analysis of our online professional development suggest that participants learned more about utilizing the five practices within their classrooms and are able to share the role they believe it has in their classroom practice.

Keywords: Instructional Activities and Practices, Professional Development, Teacher Knowledge

Objectives and Purposes

Our work focuses on the design and implementation of a three-part online professional development devised to support teachers as they (1) work collaboratively to develop mathematical and pedagogical knowledge and (2) seek to integrate this knowledge and experience into their classroom. Specifically, the professional development activities feature a continual interplay between activities focused on the development of mathematics knowledge for teaching (Renninger et al., 2011; Shumar, 2017) and classroom practice, increasing the likelihood that teachers' online experiences will connect to and support changes in their instructional practices. In this paper, we report on one component of this work which seeks to help teachers unpack the Five Practices for Supporting Productive Mathematical Discourse (Smith et al., 2009; Stein et al., 2008) using rehearsals (Anthony et al., 2015, Kazemi et al., 2016), which provide "a space where teachers can deliberately experiment with practices in less complex settings" (Webb & Wilson, 2022, p. 129). The current paper documents teachers' participation and experiences in rehearsals and explores their use of the five practices within their classroom practice.

Theoretical Framework

According to Smith et al. (2009), the five practices for mathematical thinking and discussion are:

> (1) anticipating student responses to challenging mathematical tasks, (2) monitoring students' work on and engagement with the tasks, (3) selecting particular students to present their mathematical work, (4) sequencing the student responses that will be displayed in a specific

order, and (5) connecting different students' responses and connecting the responses to key mathematical ideas. (p. 550)

These practices help teachers to think about and utilize their students thinking to advance mathematical understandings of the entire class. The practices encourage teachers to spend more time in the planning phase to be better able to facilitate productive discussions among the students (Smith & Sherin, 2019). Stein et al. (2008) encourage teachers to utilize the five practices as a "method for slowly improving the quality of discussions over time" (p. 26).

In this project, teachers' engagement with the five practices within the professional development was situated in a rehearsal (Anthony et al., 2015, Kazemi et al., 2016) of the five practices during the course of the workshop. The design of the professional development workshop was built on allowing the teachers time to practice and experiment with the five practices in a non-threating way (Webb & Wilson, 2022) and allowed the teachers to analyze and reflect on each of the Five Practices without the constraints or pressure of time or "live" students. Each module in the workshop was designed to allow teachers to engage with a different practice:

Module 1 – Talking Notice/Wonder and Doing the Math represents the work of anticipating student thinking;
Module 2 – Looking at Student Work represents monitoring students' work;
Module 3 – Reacting to Student Work represents selecting and sequencing; and
Module 4 – Connecting to the Classroom represents connecting responses to others and mathematical ideas.

This design essentially decomposes each of the Five Practices into 1–2-week online modules. Therefore, we argue that by engaging in these structured rehearsals and with the support of both colleagues and facilitators, teachers can learn about the practice, use it to analyze a set of student work, and develop conjectures for potential instructional moves. Thus, the teachers are better positioned to do this work in their own classrooms.

Methods

We investigated teachers thinking about and unpacking of the five practices in two iterations (C1 & C2) of an online professional development workshop. The workshop included four modules designed to scaffold the rehearsal process as well as utilize the five practices. Teachers engaged in solving and discussing solutions to a problem (anticipating), noticing and wondering about a set of student work (monitoring), organizing their notices and wonders in meaningful ways (selecting and sequencing), and making decisions about what to do next for individual students and whole class discussions (connecting). The two iterations of the workshop differed in length and methods of engagement. C1 (n=13) participated in a two-week workshop consisting of six discussion boards, three synchronous sessions, and four journal entries. C2 (n=9) participated in a six-week workshop consisting of five discussion boards, six synchronous sessions, and four journal entries. In this research, we explore the research question: *In what ways do teachers see the role of the five practices for mathematical thinking as a means to providing feedback to students?* In particular, we seek to understand teachers thinking about and use of the five practices in their classrooms.

Data for this paper consisted of participating teachers' posts to one discussion board, one journal entry and transcripts from two synchronous sessions (see Table 1 for prompts provided to the teachers for each data set). Data analysis included a three-phase process, beginning with pre-coding, where the entire project team reviewed the entire data corpus multiple times to become familiar (Ravitch & Carl, 2015). The second phase featured open coding of the data by at least two members of the research team. In this phase, every effort was made to capture the theoretically significant ideas (such as terms from the Five Practices and student-centered, research-based classroom practices). In the final phase, the research team resolved any inconsistencies in the coding and developed and tested conjectures regarding themes in the coded data. They met to generate a theoretical memo that was be based on both the field notes and the patterns and themes from the coded data (Miles et al., 2014).

Table 1: Analyzed Prompts

	C1 (summer 2021)	C2 (winter 2022)
Discussion Board #5	Share something from the article (Smith et al., 2009) that connects to what we have been working on. How might you implement a version of it in your classroom?	Imagine that you are using EnCoMPASS to help you implement the 5 practices in your classroom. Brainstorm ways in which you think this might be accomplished. (You might share examples using the work you have done with the Driving to Work student responses.)
Journal #4	What do you see as the role of the 5 practices for mathematical thinking in providing feedback to students?	What do you see as the role of the 5 practices for mathematical thinking in providing feedback to students?

Results

While we continue to code additional data and revise and refine our conjectures regarding emergent themes, preliminary findings reveal a connection to the five practices, a desire to utilize them more within their classrooms, and challenges they have faced. Four themes are discussed.

The first theme that emerged was teachers beginning to see the how and why they might use the five practices in their classrooms. Examples of excerpts in this category included, (1) GA noted, “I have also learned that structuring class discussions around solutions (incorrect and correct) should work towards the larger learning goal. The five practices serve the role of structuring discussions around challenging tasks and providing a framework for building complex mathematic ideas.” (2) MJ noted, “I think their [the five practices] role is to keep us teachers focused on the ‘mathematical ideas at the heart of the lesson.’ It's a sturdy, efficient, organized framework on which to build our feedback and plan our lessons and direct the course of mathematical discourse during class.” These excerpts indicate that while math teachers are aware of the five practices, they need more support to build their foundation for success and professional development is the space for this work to be conducted.

The second theme was that while five practices are hard to do, it was even harder to learn, especially in real time. As an example, KL stated, “I like that we are getting this practice in this scenario as selecting is one step of the 5 practices that I find difficult to do in real-time in the classroom. Practicing in isolation is helpful.” Teachers appeared to recognize the benefit of engaging in practice or rehearsal of the five practices so that they can gain understanding of their use in low-stakes environments. By participanting in professional development that encourages and supports this practice, teachers can feel more confident utilizing the five practices in their classrooms.

The third theme indicated an awareness that in addition to learning more about the five practices, teachers needed support with how to get access to student thinking (and not just student answers). As an example, MD noted:

> If I were to implement a version of this [marble problem] in my classroom… I'd do this initial notice/wonder activity at the end of a lesson on Friday. I'd collect the students' notices/wonders, and then use those over the weekend to build my anticipated answers/approaches and prepare for the actual lesson on the problem for the following week. Out of all the five practices, anticipating the responses is probably the trickiest, and I think it really gets better with experience or as they mentioned, using work produced by prior classes, publishes responses, etc. No one has the actual time in school to have several teachers work the problem and get feedback (what a pipedream), so I think this prelude with notice/wonder would be very useful for this purpose.

This category highlights the importance of students engaging in the tasks assigned before the five practices can be thought about and that utilizing noticing and wondering as an engagement practice is useful for planning and implemenation.

The fourth theme was the need for expanding the five practices to support equity in the classroom. As an example, SS stated:

> I work with students with disabilities so explaining their thinking can be challenging. Sometimes I see students struggle to find the right words to explain their work/answers. I am going to try to highlight what they did correctly to alleviate some of the anxiety they may be feeling. In our group discussion the other night it came up that written feedback should be both specific and doable. I am thinking these same guidelines apply to classroom conversations with students. I am going to try to ask more specific questions about their work.

While the five practices provide a structure of guiding productive and supportive classroom discussions, there are still students who may be left behind depending on the implementation utilized by the teacher. It is important for teachers to realize that while monitoring, selecting, and sequencing, they also need to be aware of students who may not be in a place to be chosen and how to they keep those students engaged in the discussion.

Discussion

Based on the preliminary findings, the teachers not only enjoyed learning more about the five practices and their implementation, but also felt as if it provided thoughtful ways to continue the engagement within their classrooms. They felt that by participating in the rehearsals or "practice in isolation" they were able to build their skills before working with their students. They demonstrated the need to engage all students by allowing them entry into the problem utilizing notice and wonder processes. Finally, they noted that to be implemented equitably teachers need to be aware of the students and how they are engaging in the discussions.

These findings demonstrate the potential for online professional development to provide experiences that allow teachers to think deeply about common frameworks for student-centered instruction, such as the Five Practices, and for them to reflect on the details of implementation. Current work includes further analysis of these online workshops as well as analysis of teachers' reflections on their post-workshop goals for instruction. We expect to see additional support of these themes within the teachers' reflections as well as the possibility for new themes to emerge.

In this paper we examine how facilitators' prior experiences as mathematics teachers frame their work when facilitating a practice-based professional development (PD) for the first time. We focus on the experiences of a novice facilitator of StoryCircles, a professional learning process in which teachers collectively script and visualize a problem-based lesson, arguing about their rationales for different decisions connected to discussions of students' work. We situate the challenges the facilitator encountered by identifying the expectations that were not met while she was facilitating and offer possible connections to the PD design. We close by suggesting a perspective to account for facilitation challenges.

Keywords: Problem-Based Learning; Professional Development; Teacher Educators.

Background and Theoretical Framing

In recent years, research on the facilitation of professional development (PD) programs has received growing attention due to facilitators' key role in the implementation of educational initiatives (Rösken-Winter et al., 2021). Within this emerging field, scholars have discussed the preparation of facilitators (Lesseig et al., 2017), their knowledge and practices (Borko et al., 2014; Karsenty et al., 2021), and facilitators' professionalization processes (Schwarts et al., 2021). When referring to novice facilitators who are also practicing mathematics teachers, the main difficulties described in the literature are related to their limited capacity to lead in-depth discussions with teachers (Borko et al., 2014) and to the complex navigation between their multiple identities as facilitators, teachers, and colleagues (Knapp, 2017). PD facilitators find it difficult to gauge the extent of their involvement in managing participant discussions (Lewis, 2016) and they struggle to enact their ambitious goals when designing and implementing activities (Jackson et al., 2015). Overall, these results support the argument that "being a good teacher does not necessarily imply the ability to help others develop their teaching" (Even, 2005, p. 334). In spite of this work, there is still much to learn regarding the underlying factors that constrain facilitators working in the context of practice-based PD. In particular, it is important to understand in what ways complexities of the activity of facilitation rather than deficits of the facilitators themselves, might account for difficulties observed.

This paper seeks to frame the challenges of facilitation as rooted in facilitators' implicit expectations about learning in practice-based PD settings. For that purpose, we refer to facilitators' challenges in the context of the PD triangle offered by Carroll and Mumme (2007, see Figure 1). This triangle embeds the well-known instructional triangle (Cohen et al., 2003), including its claims about the interconnections between the different components of instruction, into the facilitators' level. The PD triangle includes the three vertices: the facilitator, the teachers (hereafter, referred to as participants or practitioners), and the practice of teaching and learning mathematics in the place of the content (see Figure 1). As in the case of the instructional triangle, we can hypothesize this PD triangle to be situated in environments, particularly the institutional environments that enable practitioners to participate. This framing allows us to situate facilitators' expectations with respect to the other components of the PD environment. The expectations we are interested in refer to how and what participants are supposed to learn (participants-practice arrow), and the facilitator's role with respect to this learning (how the facilitator relates to practice, or the facilitator-practice arrow, and how the facilitator relates to the participants, or the facilitator-participants arrow). We hypothesize that facilitators' years-long experiences as practicing mathematics teachers who have also participated in PD inform these expectations and influence facilitators' practices in ways that are not always discernible for them and for developers of PD environments.

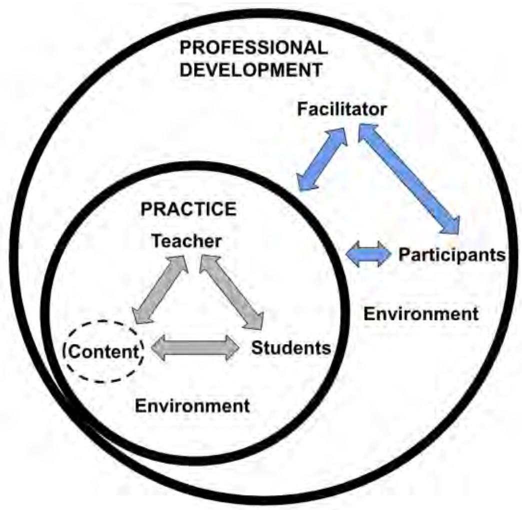

Figure 1. The PD triangle (adapted from Carroll & Mumme, 2007, p. 11)

This paper focuses on facilitation in a practice-based PD, where practitioners "learn in and from practice" (Cohen & Ball, 1999, p.18) by collaboratively inquiring on artifacts of practice, analyzing them and arguing about them. In such settings (i.e., ones that center on practitioners' reflections and where there is no specific content to be taught), the facilitator's role as a moderator of practitioners' discussions is even more complex (Schwarts et al., 2021). In this context we ask, how do facilitators' expectations based on their prior experiences shape their work facilitating a practice-based PD?

Context: The Story*Circles* process

The context of this study is Story*Circles* (Herbst & Milewski, 2018), a process of teacher collaboration that aims to engage practitioners in collective scripting, visualizing of, and arguing about a problem-based lesson. Story*Circles* has evolved over its various iterations, but it has consistently maintained the goal of having practitioners represent their practice through storyboarding a collective lesson (see Brown et al., 2021; Milewski et al., 2018, 2020 for examples). Inspired by Japanese lesson study (see Herbst & Milewski, 2018), the main design concepts of Story*Circles* include opportunities for rapid prototyping of lessons and a user-centered design (Herbst & Milewski, 2020). Thus, the discussions that are at the core of Story*Circles* position practitioners as experts and support them in talking with one another about their rationale for making certain, sometimes competing, decisions in the classroom.

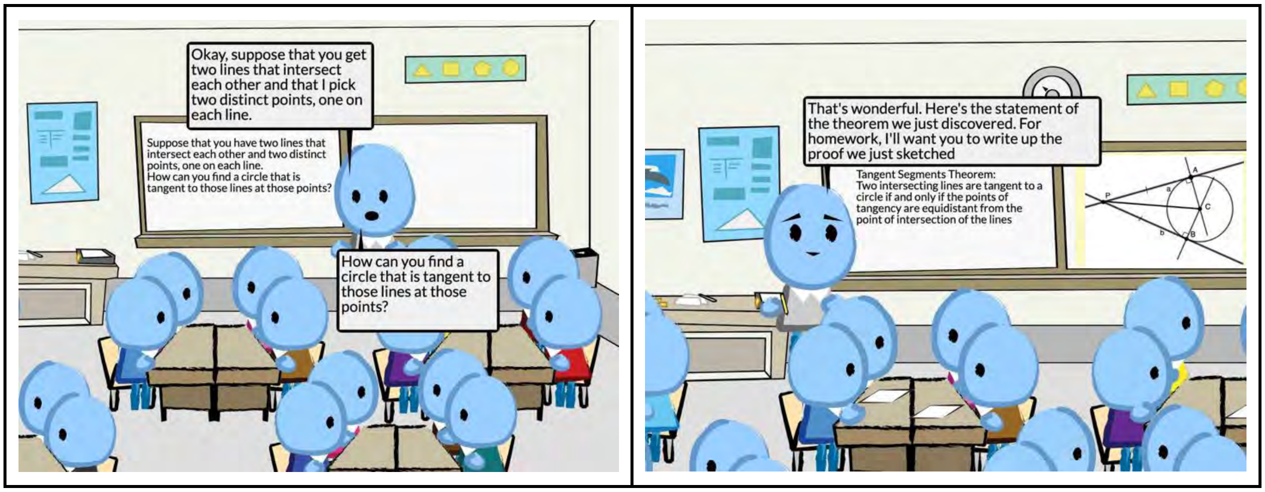

Figure 2. Scenes at the beginning and the end of the Tangent Circle lesson (© 2021, The Regents of the University of Michigan, used with permission)

In the iteration of Story*Circles* considered in this report, that took place between February and April 2021, secondary geometry teachers engaged over six weeks in discussions focused on a problem-based lesson aimed at introducing the tangent segments theorem. This lesson starts with the posing of a problem (see Figure 2, left) and ends with the statement of the instructional goal of the lesson (Figure 2, right). The lesson is illustrated in a storyboard using cartoon characters to represent a teacher and their students. Given the problem and the instructional goal of the lesson and one potential instantiation of the lesson provided to them in advance, participants started this Story*Circle* at the visualization phase, annotating what the provided version of the lesson looked and felt like to them and inserting comments where they thought the teacher might have done something differently. During six weeks they prototyped alternatives to those moments including alternative moves to manage whole class discussions and review students' work. Participants were expected to collectively argue about alternative ways in which the teacher could have handled events in the lesson, scripting the alternative scenes, which would also be storyboarded and visualized. As they scripted potential instantiations of how the lesson might unfold, it was expected they would engage in argument about decisions the teacher would make in the lesson. Connecting it to the role that experimentation plays in Clarke and Hollingsworth's (2002) model of teachers' professional growth, Milewski et al. (2020) have described Story*Circles* as "virtual professional experimentation" (p. 624). During Story*Circles*, practitioners worked on the different segments of the lesson in a combination of synchronous and asynchronous activities. These different forms of interaction permit practitioners to dedicate time to tinker with particular moments in a lesson and consider alternative ways of handling various contingencies that might arise in an instance of the lesson.

The avowed goal of each cycle of Story*Circles* is to produce a representation of a collaboratively developed lesson. Although the particulars of the entire design of Story*Circles* are beyond the scope of this paper, we describe three different design features unique to the present iteration of the Story*Circles* design. First, participants were not expected to attend every synchronous meeting – each participant was scheduled to attend only three or four out of six such meetings, so every synchronous meeting included a subset of participants (and not always the same people in each subset). Second, the meetings were not intended to build on one another; instead, each of them focused on a specific segment of the lesson. Third, by design, the facilitator is not responsible to use the software to prototype the lesson scenes the participants propose; rather two assistants (undergraduates skilled in the storyboarding software) are present in every synchronous meeting. These storyboarders represented suggestions participants made in real time during discussions. The resulting storyboards served as collective artifacts the participants could use to visualize what the lesson looked and felt like so as to argue about decisions the virtual teacher had made later on and possibly occasioning new scripting or revisions.

Method

This study is part of a five-year research project focused on teachers' learning about discussion-based teaching of Algebra and Geometry lessons. The facilitators for the 2021 iteration of Story*Circles* were practicing secondary school teachers in their content area. For Geometry, the facilitator was Quincy, an experienced teacher who had been a participant in a previous iteration of Story*Circles*, and this was her first time facilitating the work. Fourteen participants took part in this cycle.

Data collection and analysis

To identify how the facilitator's prior experiences in teaching and professional development framed her management of the Story*Circles* process, we searched in our records for evidence that her expectations were not being met. This approach builds on the idea that individuals' tacit expectations can be revealed through their reactions to deviations from customary practices (Herbst et al., 2011). The data corpus for the 6-week cycle includes, among other things, recordings and transcriptions of six synchronous meetings and follow-up debriefs (6*90 minutes). Using thematic analysis (Braun & Clarke, 2006), records were inspected for evidence that the facilitator's expectations were not fulfilled. This evidence included moments during facilitation or in the follow-up debriefs in which the facilitator expressed (using statements or gestures) surprise, confusion, conflict, discomfort, or puzzlement. We also searched for the sources of these expressions as could be inferred from the facilitator's expression (e.g., when she said "It's a different mindset here, having help", we inferred that her expectation to work individually, rather than have storyboarders representing the lesson that participants script, is related to her classroom experience in which she does not have assistants). After the identification of these moments, they were organized according to themes and were mapped to highlight the interrelations between the facilitator's expectations, the experiences that were likely to shape those expectations, and the design principles of Story*Circles*.

Findings

The following are two prominent themes from the analysis that are representative of the facilitator's expectations.

Theme 1: The traditional turn taking that animates the PD triangle

The first theme illustrates the facilitator's difficulty in adjusting herself to work in collaboration with the storyboarders and to manage time. To illustrate this difficulty, we provide some more details on the work of storyboarders during PD discussions. Story*Circles* synchronous meetings usually open with a question that the facilitator poses about a scene in the lesson at hand (for example, "Are there things that the teacher might say in their introduction of that student work?", Turn 242, second meeting). While participants raise alternatives, the storyboarders create images that represent the participants' suggestions and incorporate them into the representation of the lesson (see example in Figure 3). These images are an essential component of the argumentative process in Story*Circles* since they provide a shared representation on which participants can argue. However, after Quincy's facilitation of the first meeting, she reflected that the use of these new images was in fact overwhelming for her:

> So I guess the part that I felt most awkward about was like transitioning between that, and then like jumping down to the depictions [...]. Partly I was worried like I… did I give them [the storyboarders] enough time to depict before jumping down? so I was stalling on that a little bit (Turns 546-547, first meeting debrief).

This quote reveals the facilitator's difficulties in managing a discussion while simultaneously considering the materials the storyboarders were creating and the time they needed to create them. In addition, she mentions that moving between slides and referring to ad-hoc ideas was "awkward". She expressed similar feelings two weeks later, after the third meeting:

> Not sure how to like really utilize what you guys [talking to the storyboarders] are doing on the depicting, like I can see you're like going crazy, I don't know if I need to like just dive into the depiction earlier (Turn 601, third meeting debrief).

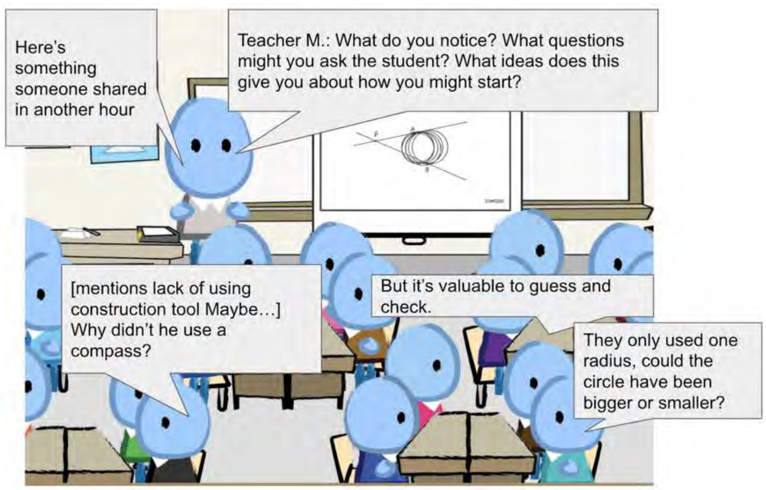

Figure 3. Image created by the storyboarders during the third synchronous meeting (© 2021, The Regents of the University of Michigan, used with permission)

Beyond knowing when to use the images, another source of tension for Quincy was how to use them: In this meeting, the storyboarders represented almost every comment made by participants. Doing so resulted in many new images, illustrating different pathways in the lesson, that Quincy felt obliged to "utilize". All of the above evidence points to Quincy's expectations of having control, both on the timing and on the mediation and interpretation of participants' contributions. This claim is supported by another comment made in the debrief of the third meeting, where Quincy compared facilitation to teaching:

> When I'm teaching off of the Google slides right now, like every day, I'm in control of them or I'm having the students interact with them, so it's very [...] It's a different mindset here, having help (Turn 681, third meeting debrief).

These moments suggest that Quincy's expectation of having full control is informed by her experiences as a mathematics teacher, used to working individually ("It's a different mindset here, having help", Turn 681). That is, "having help" is something she is unaccustomed to, and perhaps, at that moment, she felt that the work of the storyboarders did not help her at all. This challenge points to a disruption in the traditional turn taking between teachers and students (e.g., McHoul, 1978), or between facilitators and participants. In the latter case, the facilitator is commonly the only one who is responsible for the interpretations of the participants' contributions and their mediations with the PD content. Even if participants raise unexpected ideas, the facilitator knows (even if only tacitly) that it is her job to address them. However, in Story*Circles*, the participants' ideas are also interpreted by the storyboarders. The expectation that her facilitation role is similar to that of a teacher seemed to activate in Quincy the expectation that her job included managing more interactions—namely ensuring that: (1) participants' ideas are explicit enough for the storyboarders to depict, (2) the storyboarders have accurately captured participants' ideas. In addition, as described above, she appeared to take responsibility for pacing the discussion according to the time depicting took, even though storyboarders were not part of the conversation. It follows that even for practitioners who are familiar with managing discussions and allocating turns of talk, facilitating a Story*Circles* discussion is a challenging task as it may involve a decreased sense of control. We posit that such disruption, although challenging for facilitators, is an important feature of the learning environment offered in Story*Circles*: It requires participants to explicate their arguments, specify them, and explain how they relate to previous comments. That is, because the participants are able to see their own and others' contributions represented visually in real time, the participants are in an environment in which they have greater opportunities, and perhaps feel more accountable, to engage with and reflect on one another's comments. This, along with the facilitator's prompting, recruit participants' attention to others' arguments, and sharpens the ways they communicate and argue about their practice. For the facilitator, however, it adds layers of complexity.

Theme 2: The agreed-upon goal of the meetings

The second theme alludes to the ways the facilitator envisioned the goals of Story*Circles,* which were sometimes in conflict with the program design and the participants' goals. This tension was manifested in Quincy's goal to improve the storyboarded lesson in a certain way, including her expectation to build on previous meetings while doing so. As mentioned above, a main design feature of Story*Circles* is that only subsets of the enrolled participants engage in each synchronous meeting. Accordingly, all but one of the participants who attended the second synchronous meeting had not been present in the previous meeting. Quincy planned to work in this meeting on part of the lesson where the students were stuck and the teacher redirected them by discussing with them pre-selected students' work, as had been decided by the group who participated in the first meeting. However, when she asked the participants which pieces among the pre-selected student work they would like to present, they did not answer her question, but instead wanted to work on improving the beginning of the lesson. The facilitator, while surprised by this initiative, followed the participants' lead. Nonetheless, in the end of the meeting, she told the participants:

> I sort of… I mentally… I guess [I] was expecting to pick up the conversation where we left off with a totally different group of people, and maybe that wasn't the most realistic expectation. You guys brought different ideas to tonight, and so we had a little different conversation (Turns 540-541, second meeting).

The facilitator's expectation was to continue visiting the lesson chronologically picking up where it had been left by participants the prior week, however, the participants in this second week might not be ready to deliver to that expectation inasmuch as they had not necessarily reviewed what the prior week's group had done. Quincy followed the participants' ideas, although her expectation had been that the participants would go along with her goal, and contribute to the group's common attempt to improve the lesson. When reflecting on this meeting, she noted that, "I just didn't expect it with adults, for some reason" (second meeting debrief, Turn 703), "it" refers to the derailing from the original plan. This expectation is also evident in the following reflection, taken from the debrief of the fourth meeting:

Project leader:	So you started saying that you were worried at the beginning, what do you mean? (Turn 553, fourth meeting debrief).
Quincy:	Well, when they were like "we don't do proofs".[...] Oh well, that's the premise of this lesson. If we're not gonna play that game I don't know where we're going. But they came around, I think it was nice that Quintin [one of the participants] could help bring everybody in (Turns 554-557, fourth meeting debrief).

This statement indicates that Quincy was disrupted by the participants' divergence from the path she envisioned (i.e., discussing proving), which suggests that she had in mind the expectation that their scripting of the lesson during the meeting should contribute to the direction that had been set in the prior meeting ("If we're not gonna play that game I don't know where we're going"). This highlights a tension present in Story*Circles* and related to the role of the lesson as a motif for the work (representing the lesson is the avowed goal of the activity) but not the outcome of activity (learning with and from colleagues is the outcome of the activity). Along those lines, the lesson serves as a resource that enables participants to learn how to work together and communicate on their practice, under the premise that the lesson itself can evolve in multiple ways, each having its own merits, and participants can ponder on their decisions without being encumbered by the expectation to enact best practices. The facilitator's uneasiness with the takeover by the participants showed that she expected to be able to maintain alignment between the avowed goal and the expected outcome, as a teacher usually does. Interpreting this tension with the PD triangle, the facilitator seemed to take for granted the equivalence between avowed goal (which refers to content) and expected outcome (which refers to having conversations and arguments about practice among colleagues) and found that equivalence disrupted by the participants' desire to construct yet an alternative lesson. We hypothesize that her expectations may stem from her experience as a teacher who is used to having students agree with her on the purposes of lessons.

Discussion

Above we described two implicit expectations a facilitator had when leading Story*Circles* for the first time. These results corroborate previous findings about facilitators' difficulties to lead PD activities (Borko et al., 2014; Jackson et al., 2015; Jacobs et al., 2017). The method used in this study shows that such challenges can stem from the expectations facilitators bring with them from their prior experiences as mathematics teachers in the classroom and as participants in other PD programs. Although some of the disruptions described above (such as the presence of storyboarders) represent idiosyncratic characteristics of Story*Circles*, situating them in the PD triangle (Carroll & Mumme, 2007) allows us to generalize into broader themes. That is, the first theme illustrated a disruption in the communication among participants and facilitator about practice, while the second showed disruptions in the facilitator-practice edge of the triangle. We highlight that both disruptions were features of the original design, aiming at defamiliarizing practice in a way that would encourage practitioners to collaborate (Herbst & Milewski, 2020). StoryCircles is not purposefully designed to disrupt facilitators, yet the observation that disruptions happened offers insights into how the innovative nature of practice-based PD programs is complicated and cannot be simplified to a train-the-trainer model. The analysis above leads us to suggest that the implicit expectations the facilitator held, which surfaced only when she facilitated Story*Circles* for the first time, point to implicit norms that shape facilitating and participating in PD settings. These norms are related to the instructional norms that are obtained in mathematics classrooms. The analysis suggests that teachers-become-facilitators carry with them the norms of the instructional triangle as they strive to make sense of the activity of running professional development. The facilitator's implicit expectations seem to align to the expectations instruction imposes on classroom teachers and that have been described using the theory of the didactical contract (Brousseau, 1997; Herbst, 2003).

This framing can help situate and explain the challenges of novice facilitators, by revealing the complexity involved in the work of facilitation. In the same way that improvement or change in teaching is bounded by regularities that are difficult to depart from (Herbst, 2003), we showed how facilitators' practices are constrained by implicit expectations that exist even if they are at odds with the explicit design of the intervention. These results can contribute to the current discussions on issues of fidelity, integrity, scaling up, and implementation (e.g., Jacobs et al., 2017; Karsenty, 2021): Rather than assuming that the PD design principles and goals are transparent for facilitators, that all they need is training and good will to implement PD programs with fidelity, this study shows that considerations of implementation require attending to the background expectations teachers-become-facilitators bring with them to the job. The same capacities and experiences that give them street credibility to lead practice-based professional development can hamper their capacity to manage practitioners' learning of practice.

In this paper, we discuss the case studies of two professional development (PD) participants: Nhung Tran and Stella Miller. This data comes from an NSF-funded grant studying inquiry and equity within mathematics instruction at a two-year college. We analyze participant conceptualizations of equity using Gutiérrez' (2009) equity framework. By considering the dominant axis (Access and Achievement) and the critical axis (Identity and Power), we identify places of dissonance, or Nepantla, that emerge for each participant. We discuss how these tensions give us valuable information as we consider future iterations of PD on the MPIE project.

Keywords: Equity, Professional Development

Community colleges often do not have the infrastructure and culture for supporting professional development that focuses on instruction (Edwards, Sandoval, & McNamara, 2015). Further, professional development that is offered are often one time workshops that do not provide meaningful and sustained opportunities for faculty to improve their practice (Bailey & Smith Jaggers, 2015; Huber, 2008). This places much of the responsibility of instructional improvements on the shoulders of the instructors themselves. This issue coupled with state mandates to redesign remedial mathematics courses (e.g., California, Tennessee, Florida, etc.) and initiatives to increase participation of *mintorized learners* in STEM raises two important questions: 1) How do faculty shift their practices as it relates to equity in response to attending PD and 2) How should professional development be designed to support faculty in two-year college practice? In this paper, we take up the former question and characterize how participants describe their beliefs about equity and how they shift over time.

Theoretical Framework

We drew upon Guttieréz' (2009) framework of equity. This framework is composed of two axes – the dominant axis concerning Access and Achievement, and the critical axis concerning Identity and Power. These elements help us understand how to "play the game" of education in order to "change the game". In other words, in order to move towards more equitable and liberatory systems, one must understand and leverage the current systems and structures in place. The framework also discusses the important concept of *Nepantla*, which resides at the intersection of the dominant and critical axes, highlighting the dissonance that inherently occurs between dominant and critical axes (Gutierrez, 2009; Gutierrez, 2017).

The dominant axis is so labeled as it is perceived as representing the most fundamental aspects of equity; in other words, it represents the elements often required for students to "play the game" in traditional education settings. The dominant axis is composed of Access, which is a "precursor" for the other pole of the dominant axis–Achievement. Access represents the opportunities that students have to engage in their education. Equitable access implies that all students have the resources they need to to learn. Achievement cannot occur without this Access, but Achievement also represents a distinct and important element of this framework. The reality is that providing students with the resources to learn (i.e., access) does not guarantee successful outcomes (i.e., achievement). Students deserve support along their journeys, in addition to access, to help them accomplish tangible results–to reach achievement. Research also shows that even when controlling for measures like access and achievement, equity gaps still exist (Oakes, 1986; Spencer et al., 2016). This introduces the necessity of the critical axis.

The critical axis is made up of Identity and Power, where Identity is a "precursor" for Power. The goal of this axis is to utilize the unique frames of references, backgrounds, and resources of students in a way that empowers them to become critical citizens who can ultimately change the game. Oftentimes, many students feel that they have to give up parts of their identity in order to assimilate in the classroom. In order to ensure that students, particularly students who are historically discriminated against, are not leaving parts of themselves out of the classroom, issues surrounding identity are essential to consider. Identity can be attended to by leveraging the history of the students as well as their cultural and linguistic resources. When students are given the opportunity to fully leverage their identities, they are afforded a greater wealth of Power from which to draw upon. The dimension of Power considers the social transformation at different grain sizes ranging from moment-to-moment interactions within the classroom to helping to create societal agents of change. Additionally, the Power dimension can be measured in the reconceptualization of education as a humanistic pursuit.

Within the Gutiérrez (2009) equity framework, tensions exist at the intersection of the dominant and critical axes. To address this, Anzaldúa (2015) discusses the Aztec concept of Nepantla, which refers to "a space of tensions, of multiple realities" (Gutierrez, 2017, p. 13). In this space, several conflicting views are held simultaneously. For example, instructors may see the need to change their practices while also preferring their current routines, and being resistant to implementing new ideas in the classroom. This allows the opportunity to leverage ideas from each perspective and to collate them, creating a "third space." Within this coalescent space, an individual is opting to exist within the dissonance, rather than simply choosing one view over the other. This dissonance may be uncomfortable, but if one is able to stay with the tensions long enough, new perspectives and knowledge have the potential to emerge. While Access, Achievement, Identity, and Power are each important, attending to one alone does not constitute equity; yet, leveraging all four of these is no easy feat. Therefore, Nepantla gives perspective to the messy process that occurs along the journey towards equity. More broadly, considering Nepantla in the work that we do allows us to more fully understand the ideas and perspectives across and within individuals that at first glance might seem contradictory. By considering Nepantla within professional development, we are more able to leverage the beliefs and ideas that participants currently hold, and use them to guide further growth along each individuals' journey.

Methods

This study is part of the Mathematics Persistence through Inquiry and Equity (MPIE) project at a local two-year college– Southern Hispanic Serving Institution (SHSI). The MPIE project is studying SHSI's response to a state-mandated change regarding mathematics courses. Specifically, the state mandate requires that students enroll in transfer level mathematics by the end of their first year. Using cycles of design research, the MPIE project aims to build the capacity of math instructors in the two-year college to foster student success, and investigate the effects of the capacity-building effort. The primary focus of this project's capacity building effort is on the professional development (PD) for two-year instructors. The MPIE project is a regional partnership between a two-year and four-year institution, both Hispanic Serving Institutions (HSIs) located in the same region and serving the same student population. A key outcome of our work will be improved understanding of how department-based mathematics course reform can be accomplished at a two-year HSI.

There were a total of 7 participants in the PD. Participants were math instructors at the college, most of whom taught a variety of courses including gateway courses. Participants met six times, two hours each in the fall (for a total of 12 hours). The PD consisted of activities that shared resources that could be used in their courses (e.g. Desmos, mathematical tasks, norms, etc.) and practices that could be implemented during classroom whole group discussions. The five practices from Smith & Stein (2018) and Gutiérrez's four dimensions of equity (2009) were discussed during PD and provided a guide for understanding the intersection of equity and inquiry in participants' practices. Instructors also had assignments outside of PD centered on inquiry and equity, such as taking an equity lens to their syllabi, as well as modifying and implementing tasks that were inquiry-oriented.

For this paper we conducted case studies focusing on two participants, Stella Miller, a middle-aged white woman, and Nhung Tran, a middle-aged Vietnamese man. We selected them as cases because they appeared to have similar views about equity and worked frequently together during the PD sessions. Where race and gender played a role in these conversations, we find it relevant to include the identities of these two participants. Given their similar perspectives on equity, we found their cases to provide insight about their trajectories during the course of PD. Further, each provided a unique perspective from their instructional roles as part-time (Stella) and full-time (Nhung) instructors.

The data for this study are comprised of professional development session artifacts, participant reflections, interviews, Application, Collaboration, and Exploration (ACE) assignments, Zoom recordings of PD sessions and PD facilitator and observer debriefs. Drawing upon our theoretical framework we analyzed the data of our two participants, Nhung Tran and Stella. We split into pairs to analyze the PD artifacts. Both pairs then split up, such that each individual was focused on one participant's data (Stella or Nhung). Pairs then met to compare and verify analysis. Our analysis process consisted of looking through the PD artifacts in chronological order to understand how the participants were thinking about equity over the duration of the PD. We then identified open-coded themes related to the participants' trajectories and presented data to support the themes, which were shared with all of the authors (Miles & Huberman, 1994). Below we unpack the themes for each participant.

Findings

Case 1.

Stella has been an educator for nearly 30 years. She has been an instructor at SHSI for over 20 years. She is, by choice, an adjunct instructor. She teaches introductory math courses including liberal arts mathematics, college algebra, and trigonometry. During PD, Stella actively participated and was willing to share her ideas with the group; she also consistently engaged with the in-between session ACE assignments, giving the different prompts attention, though not in the way we had anticipated. We illuminate her story over the course of professional development next.

Stella Miller at the start: Equity is Equality (Pre-PD, Session 1). In an interview prior to professional development, Stella described herself as an "organized, consistent, rule follower".

When asked about equity, she said that students would describe her as equitable because regardless of student situations, she treats everyone the same. Because of this, Stella described her class as being a place where regarding personal beliefs and identities:

> there's going to be a time where we've got to just turn that off and go with what you're doing and what am I doing in this classroom? I am teaching all the students here…And I'm going to do that to the best of my ability. And that's how I feel like I'm being equitable.

Stella in these instances describes her beliefs of equity as equality, which, from her perspective, justifies looking over various aspects of student experiences or identities. So long as she is doing her best to engage all of her students in mathematics, and to treat them all equally, that is what she constitutes as a learning environment that attends to equity.

While there are certain aspects of students' identity that Stella perhaps does not prioritize in the classroom, in early professional development sessions, she also shared thoughts informed by her personal experiences with students by discussing the importance of "getting to know your audience". She demonstrated an example of how this has impacted her practice by sharing that she chooses not to talk about traveling with her students, because through experience of getting to know her students over the years, she recognizes that this topic may not be relatable for them, implying a recognition of socioeconomic differences. In a debrief survey after session one, Stella expressed an eager interest to learn from her peers by listening to their ideas and experiences, also stating the need "to recognize our own personal strengths and weaknesses and see how we can best work with/around them. That take[s] a lot of listening to others for sure."

Stella Miller at middle: Resistance emerges (PD sessions 4 & 5). When Stella was introduced to the student profiles in the fourth PD session, she demonstrated resistance to accounting for student profiles for selecting and sequencing students' mathematical work. She describes it as "an extremely hard task," because reading the profiles did not in any way inform who she would choose. She asserts that "the reality is I am not colorblind, but I try to think that the profile of the students, their color, their gender, their this or that, does not matter to me!" To Stella, the dimension that she finds relevant with respect to equity is how students participate in the class– "the quietness versus the outspokenness." In the next PD session, facilitators followed up on the same task and asked participants specific questions regarding identity in relation to student profiles. We continued to observe resistance during this activity. When asked what identities the PD participants noticed about student profiles, Stella responded that the "identities were that half the students talked and half did not." When we pair this response with her earlier response about not being colorblind, it becomes more clear that Stella values verbal participation of students in her class when considering equity rather than gender or race. For Stella, student participation relies heavily on the agency of each individual student– from her perspective, students engage to learn in the way that best serves them. If a student is participating in a class discussion, they should not be discouraged from doing so. Similarly, if a student is silent and chooses not to participate in class, she assumes that is best for their learning style and she does not want to force them to speak up.

When Stella was asked if she was familiar with narratives that are relevant to student profiles, she stated that if there is a certain profile that is congruent with historical narratives, it should not be ignored. She states that "...after being in the classroom for 25 years, that is just reality… I think it would be silly to not use prior experience, it's like ignoring history." However, she also mentions that each individual is a new person coming into each class and that they may not conform to the dominant narrative. This tension between expecting students to behave a certain way versus breaking the mold highlights Stella's resistance but also willingness to change her mind based on experiences.

Stella Miller at end: Equity is justification for existent practices (Session 6 and after PD interview). Towards the end of the semester, Stella shared some of her thoughts about PD in an exit interview. When asked about equity, she shared, "now this one, I have to say, this one has been more of a learning for me". Stella went on to share how she had not previously considered equity in relation to participation within her classroom. While Stella had discussed previously how she "works the crowd" by working with students who are louder and more quiet in the class, she now saw and described how these practices were related to equity because it was attending to various and differing student needs. While this marks a shift in how Stella describes equity compared to her first interview, a shift which Stella herself recognized was present, there was not strong evidence of any major shifts in her actual teaching practices. Rather, she saw how her existing practices could be viewed as equitable practices.

Stella also shared in the interview a recent personal experience in the classroom that had her thinking about shifts that could occur within her teaching practices. She discussed how she had recently come to realize that a student in her class did not speak English fluently, and had been utilizing a peer in the class to translate what was going on during class time throughout the semester. When she realized towards the end of the semester that this was occurring, she expressed feeling "embarrassed" and "ashamed" for not knowing the student better. She then discussed how had she known sooner, she could have made some adjustments to her teaching to better accommodate this student. While Stella did not articulate these ideas in connection to equity, we again see how her personal experiences do impact her teaching practices, and that they also are slowly moving her towards a direction of more equitable practices in the classroom.

Case 2.

Nhung Tran has been teaching at the two-year college level for over 10 years. He is currently a full time instructor at SHSI where he teaches a variety of introductory mathematics courses including college algebra and statistics. In addition, he often teaches courses for preservice mathematics teachers. Throughout the PD sessions Nhung constantly asked questions and was vulnerable with his own practice. His inquisitiveness and curiosity help us in understanding his views about equity in practice. Below we unpack Nhung's trajectory with respect to his equity development into three phases, the beginning of the PD, the middle of the PD, and the end of the PD.

Nhung Tran at the start: Inquiry is easier to talk about than equity. (Sessions 1 & 2). The PD began with having participants share their ideas about inquiry and equity. For Nhung Tran, inquiry was easier to speak to than equity. He had concrete ideas about teaching practices that fostered inquiry, but only vague notions about equity. This was reflected in PD artifacts, where Nhung brought up questioning strategies and the use of multiple representations to promote inquiry. However, for equity, he did not generate any ideas when reflecting on equity on his own, and only offered sufficient work time for all students as a way to attend to equity as "not everyone works at the same pace" when Nhung was thinking about equity with his PD partner. The reason for this was Nhung's belief that mathematics is universal, meaning that it is objective and accessible by anyone. This lack of consideration for equity was reinforced in a post classroom observation of Nhung. During the interview Nhung described how he had not thought about equity specifically, instead he just focused on aspects of his practice that he thought teachers should provide, such as equal opportunities and ensuring the content was accessible. After the third author raised different questions about decisions Nhung made during instruction that were equity related, Nhung began to reflect on why he had not considered them. This marked a shift in how Nhung described equity in the following sessions.

Nhung Tran at the middle: Tensions begin to surface (Sessions 3 & 4). Tensions began to surface in Nhung's mind about how to both attend to equity oriented practices simultaneously with students' identities and work. This point is evidenced by two activities in session 4. The first of which asked participants to consider classroom norms that were inquiry- and equity-oriented. During this activity Nhung agreed that norms such as students asking questions, getting help from each other, and not being afraid to make mistakes are important. In the next activity PD participants were provided with a collection of student work with student identity profiles. Stella and Nhung were paired for this activity, and when Stella shared her thoughts about student identity, and this activity being challenging, Nhung agreed. Nhung expressed struggling to see how an instructor could select and sequence mathematical work for sharing with the class using students' mathematical work while simultaneously attending to the students' identities. Despite some of the student profiles including characteristics such as being afraid to share ideas during whole-group or making mistakes, which he named in the previous activity as important, he still struggled to see how those aspects and students profiles are connected to equity (e.g., students' identities, their work, and past experience should play a role in who is selected and when during whole-group discussion). Additionally, his personal verbalized biases about students' identities (e.g., Asian females being quiet), reflect this disconnect.

Nhung Tran at the end: (Session 5 & 6). In the last two sessions of PD we continued to focus on the intersection of student profiles and teacher practice. We revisited the activity that had participants select and sequence students' work. Instead of selecting and sequencing the work of the students, Nhung and Stella, who were partnered together again, decided to have all of the students share their work at the board and have their peers ask questions and make comments. In practice this move is not necessarily bad, however, in the context of the activity it is an example of the participants not using their power as instructors to think about how and why they may call on students. Additionally, when probed, Nhung and Stella mentioned if they had to call on a student they would call on John, a White male in the class who is always the first student to have his hand raised, has an A in the class, likes to work by himself and only seems engaged when he is talking. In Nhung's last interview he continued to talk about equity in the ways he described in the beginning (e.g., good teaching is equitable), but he also described needing to understand some of the biases he had and wanting to be more intentional about his practice.

Discussion

We first discuss our findings as they relate to the elements of the dominant axis from Gutiérrez' (2009) equity framework. For Stella and Nhung, Access plays a key role in both of their conceptions of equity. Both believe that if they provide quality mathematics instruction for students and establish classroom environments that encourage participation, then students have equitable access to learning. However, this places the agency upon the students to engage in class. For Achievement, it is not clear from the professional development sessions or interviews how Stella and Nhung make sense of this element, other than the fact that it is apparent that they care for their students to succeed. Participants' lack of attention to Achievement could be a result of the PD facilitators' emphasis on inquiry and equity using the five practices from Smith & Stein (2018), which focuses more on teacher practices that lead to more productive classroom discussions. While we see these conceptions of Access as a starting place for understanding equity, the lack of attention towards Achievement raises questions for the accountability that Nhung and Stella take with regards to their students' success. Findings related to the critical axis further expand upon this idea.

When considering the critical axis, we see mostly superficial or partial attention from Nhung and Stella towards Identity and Power. With respect to Identity, Nhung does briefly describe the importance of addressing his biases; however, he struggled in making a connection between the identities of students and how those identities can impact their classroom experiences. Stella sees Identity differently, wherein she seems to conflate or reduce the identities of her students to their type of classroom participation. Instead of considering the identities and experiences of her students, she focuses more on her own lived experiences with students and how that relates to her teaching. The second part of the critical axis is the Power dimension which is leveraged differently by Nhung and Stella. While Nhung acknowledges and describes the power he has in practice to be more equitable, Stella focuses more on the power that students have–they must choose to engage in a way that is best for their own learning. Stella relinquishes the power and responsibility she has as an instructor and focuses instead on the power of student agency as a means for success in the classroom, which aligns with Stella's consistent focus on the Access dimension. With regard to Identity, we again see both Nhung and Stella struggling to take responsibility for attending to the identity of their students in the classroom. For Power, we see Nhung acknowledging the role he plays in the classroom, but is unsure of how to leverage his power to support his students. Stella acknowledges her role as well, but highlights she only provides students with resources, leaving them to exercise their agency and control over their own success.

With respect to the dimensions of the equity framework, Nhung and Stella hold several conflicting views. Nhung and Stella both focus heavily on Access, and not as much on Achievement, Identity, and Power. In Gutiérrez's framework, Nepantla refers to the tension between these different dimensions. With Nhung, in particular, we see Nepantla with his tendency to be easily convinced by Stella during breakout sessions, which leads to shifts in his thinking. Due to his uncertainty, Nhung had a difficult time exploring and establishing beliefs regarding equity. There is a dissonance for Nhung between his open-mindedness to hearing others' ideas, and his own personal beliefs regarding what equity should entail within the class. For Stella, Nepantla is most evident in her resistance to acknowledge Identity. Her strong emphasis on student agency seems to serve as a barrier to considering other ways of being responsible for her students and their success, creating a dissonance between her sincere care for student success, and her responsibility to supporting them in their mathematical endeavors. By identifying these instances of Nepantla, we see these tensions for Nhung and Stella as opportunities for future growth within our continued PD efforts, which we discuss next.

When considering these findings in relation to what they mean for PD efforts, a few questions and reflections arise. When considering our first research question– how participants shift their practices from PD– these case studies of Stella and Nhung highlight an important follow-up question: how does the resistance of one participant affect the progress of other participants? While we see growth in both Stella and Nhung over the course of professional development, we also identified resistance, particularly from Stella, when attending to ideas relating to the critical axis (Gutiérrez, 2009). Because Stella and Nhung were paired together in several of the PD sessions for breakout room discussions, we wonder how this might have impacted Nhung's experience, and how the conversations around equity and identity might have looked different if he had been paired with a less resistant partner. There were multiple moments during PD where Nhung raised an idea and Stella pushed back, which in response, Nhung would walk back on his thoughts to agree with Stella. How might Nhung's thoughts regarding equity have evolved otherwise if paired with a partner that took up his ideas in ways that pushed him to think about the ideas he raised and how they might impact his practice? Where Stella often expressed the value in hearing her peers' experiences, we also wonder how pairing her with various other partners might have differently impacted her perspectives regarding equity. We plan to explore this research thread further, and use these findings in the design of PD in upcoming semesters.

This reflection also relates to our second research question–how should PD be designed to support two-year college faculty. As we continue to use design cycles to improve our PD efforts, we can strategically pair participants with partners in future sessions to see if we notice any changes in how participants shift their practices compared to this first semester of PD. These cycles of design also allow us to reflect on the growth that we have observed of participants thus far, and to adjust our efforts and plans to better foster further growth in coming semesters. As these two case studies have outlined, we see dissonance between where participants currently think and engage with the concept of equity and where we hope they will eventually conceive equity. We see this dissonance as an important opportunity to reflect upon, and thus an opportunity to improve our efforts with PD moving forward.

Conclusion

The case studies of Nhung Tran and Stella Miller provide insight about two-year college instructors' beliefs about equity and ways such beliefs might shift. Using Gutiérrez' (2009) dimensions of equity as an analytical lens we gained further understanding about how these instructors think about equity and the influence they can have upon each other's thinking. In particular, this work highlights tensions, or Nepantla, that emerges from the discussion of these topics. We see such dissonance as opportunities for further growth as we work towards building harmony between equity and mathematics education. This work will inform future PD design that attends to activities and group pairings which can support instructors to see equity in ways that attend to both the critical and dominant axes.

This 5-year mathematics professional development project involves 27 elementary teachers prepared and supported as Elementary Mathematics Specialists (EMSs) in high-need urban schools. They complete a university's K-5 Mathematics and Teacher Supporting & Coaching Endorsement programs and participate in Professional Learning Communities and individual mentoring. Described here are data collected at the end of Year 1, illuminating the ways in which they are engaging in teacher leadership, especially coaching. The EMSs are a distinctive population as informal teacher leaders, with a primary responsibility of teaching students. Central to the project is the university-school-community partnership, with findings illuminating reciprocity with mutual benefits, such as high quality clinical experiences for teacher candidates, coaching for novice teachers, and engagement with families and caregivers.

Keywords: Professional Development, Instructional Leadership, Elementary School Education

Purpose of the Study

The context of this study is a 5-year professional development project for 27 elementary teachers in high-need urban schools who are prepared and supported as Elementary Mathematics Specialists (EMSs). They are completing a university's K-5 Mathematics and Teacher Supporting & Coaching Endorsement programs and participating in Professional Learning Communities and individual mentoring. This study specifically examined the ways in which they engaged in teacher leadership during Year 1 of the project. This question guided the inquiry: How are the EMSs providing teacher leadership, including self-reported coaching practices?

Theoretical Perspectives and Related Research

The specific roles and responsibilities of EMSs vary (Baker et al., 2021), dependent upon the contextual needs and plans of schools, school systems, and states (McGatha et al., 2015). EMSs can serve as classroom teachers, instructional interventionists, and informal or formal teacher leaders. Within these wide-ranging responsibilities, EMSs' work as a teacher leader often involves coaching other teachers. This coaching can occur in a variety of one-on-one and group contexts. Productive activities for mathematics coaches with groups include: engaging in the discipline (e.g., mathematics through worthwhile instructional tasks), examining student work, analyzing classroom video, and participating in lesson study, while those with individuals include co-teaching and modeling instruction (Gibbons & Cobb, 2017). Further, McGatha (2015, 2017) examined related studies and determined that coaches' ways of interacting with individual teachers could be considered on a continuum from more-directive (e.g., modeling lessons, providing resources) to less-directive (a process of collecting data from observed lessons, providing feedback, and engaging teachers in thought reflection), with the latter more powerful for prompting changes in teachers' instructional practices. There are a number of coaching models evident in the extant literature, including content-focused coaching, instructional coaching, and cognitive coaching (Yopp et al., 2019). Cognitive coaching, which was emphasized in this project, is a particularly powerful approach that relies heavily on coaches' use of reflective questions to encourage teachers to refine their professional knowledge base through self-assessment and self-direction (Costa et al., 2016). All in all, context and need drive EMSs' highly varied ways of working, providing a warrant for studying their differing roles and responsibilities.

EMS preparation programs should focus on the in-depth and multidimensional development of content knowledge for teaching, pedagogical knowledge for teaching, and leadership knowledge and skills (AMTE, 2013). Programs should have a two-fold emphasis: fostering expertise as a teacher of mathematics and as a teacher leader who serves as a *more knowledgeable other*, supporting colleagues' instruction and other efforts within mathematics education such as curriculum development and community connections. When it comes to leadership knowledge and skills, specialized courses should prepare EMSs to "take on collegial, non-evaluative leadership roles within their schools and districts. They must have a broad view of the many aspects and resources needed to support and facilitate effective instruction and professional growth" (AMTE, 2013, p. 8). Several years of program development, implementation, and evaluation have revealed the salience of program experiences being embedded in practice, with strong connections and enactment within EMSs' classrooms, schools, and/or districts (Reys et al., 2017). When considering states offering pathways for advanced specialist certification, there are notable differences in EMS preparation programs related to duration, number of course hours, course emphases, field practicum experiences, and delivery (EMS and Teacher Leaders Project, 2022; Spangler & Ovrick, 2017). This variability is linked to differences in program goals and provides a warrant for study of EMS preparation programs. More inquiry needs to focus on the development of teacher leadership and how EMSs engage in this work, including coaching and associated practices (Yopp et al., 2019).

Methodology

The design of this study includes a descriptive, holistic singular-case approach (Yin, 2014). The inquiry occurred during the COVID-19 health pandemic, which had changed the functioning of schools and classrooms, thus influencing the EMSs' efforts as teachers and teacher leaders. The researchers were mindful of this contextual element throughout the study.

This study's context is a mathematics professional development project focused on the development of 27 elementary teachers as EMSs in high-need urban schools. Multiple partners are involved, including a university, school district, and non-profit organization. Project goals include the development of EMSs who deliver ambitious mathematics instruction and serve as mathematics teacher leaders in a variety of ways, such as coaching university teacher candidates (henceforth called teacher candidates), providing professional development to their peer teachers, mentoring novice teachers at their school sites, supporting the non-profit's after-school tutoring program, and engaging in community connections that promote key relationships and shared responsibility for students' learning. The project also aims to promote equity and access in mathematics, support teacher retention in high-need schools, and situate teacher candidates in a hiring pipeline. Since the EMSs' primary responsibility is teaching students, their role as a mathematics teacher leader is an informal one. The project is 5 years in duration and at the time of this study, the participants had completed 1 year and were emergent teacher leaders.

The teachers were selected to participate in the project based on criteria that identified them as successful, experienced teachers of mathematics with interest in and aptitude for teacher leadership. All are employed in a large, urban school district in the southeastern USA. They teach in 22 elementary schools, which collectively serve 91% students of color, with the largest populations being 44% Hispanic and 36% Black; 69% of students are eligible for the federally-funded free and reduced lunch program. The participants self-described as 24 females and 3 males, with 70% self-identifying as persons of color (41% Black, 7% Hispanic, 7% Asian, 7% Hispanic/White, 4% Hispanic/Black, 4% Black/White). They were a highly educated group, with 100% having a master's degree and 33% holding an educational specialist degree; further, they were experienced teachers, on average having 10.5 years of teaching experience (range of 5-22 years). Teaching positions varied widely and included: three kindergarten, one first grade, two second grade, five third grade, one fourth grade, seven fifth grade, four STEM/Math Specials, one English to Speakers of Other Languages, one Special Education, one Early Intervention Program, and one Accelerated Content. Of these participants, two taught in Dual Language Immersion settings, including Spanish (2nd grade) and French (5th grade). Within these differing grade levels and foci, all taught mathematics, including some for part of the day and some for all of the day. Notably, this group of participants represents the diversity of teachers from which students learn mathematics in elementary schools.

In this project, the participants are prepared and supported through completion of a university's K-5 Mathematics Endorsement (K-5 ME) and Teacher Support & Coaching Endorsement (TSCE) programs during the first 2 years, along with participation in Professional Learning Communities (PLCs) and individual mentoring for the entire 5 years. See Table 1 for these elements, along with the timeline. The endorsement programs include four elementary mathematics content courses integrating pedagogy, one course focusing on teacher leadership and coaching, and two internship courses, with one focusing on mathematics and the other coaching. Overall goals of both programs (AMTE, 2013, 2017) are development of: effective and equitable mathematics instructional practices (NCTM, 2014, 2020); deep and broad knowledge of elementary mathematics, including *specialized content knowledge* (Ball et al., 2008); productive mathematical beliefs and professional agency; and teacher leader capabilities, including coaching skills.

Table 1: Timeline and Project Elements Aimed at Preparing and Supporting EMSs

Year 1		Year 2			Years 3-5
Fall 2020	**Spring 2021**	**Summer 2021**	**Fall 2021**	**Spring 2022**	
1 TSCE course (Teacher Leadership & Coaching)	1 K-5 ME course (Number & Operations)	1 K-5 ME course (Data Analysis & Probability, 2-week summer institute)	1 K-5 ME course (Algebra & Rational Number) and 1 TSCE course (the Internship)	2 K-5 ME courses (Geometry & Measurement and the Internship)	
PLC and Mentoring	PLC and Mentoring		PLC and Mentoring	PLC and Mentoring	PLC and Mentoring

In addition to preparation for teacher leadership in the endorsement programs, support for the EMSs as they serve as teacher leaders is provided through a PLC and individual mentoring, both facilitated by the project's program director. PLCs and individual mentoring generally focus on: building a community of learners within each PLC, augmented support for developing effective and equitable mathematics instruction, and targeted support for what is called in this project *teacher leader activities*. The three PLCs are clustered around grade levels/teaching focus, with each having nine EMSs, and meet monthly eight times across the school year.

To lead instructional change and support wide-ranging improvements, the EMSs engage in a number of teacher leader activities across the 5 years in their school, district, community, and other contexts, applying their teacher leader strategies and skills learned in the K-5 ME and TSCE programs and the PLC. Two primary teacher leader activities include coaching a teacher candidate each year and supporting the nonprofit's after-school tutoring program for at least 1 of the 5 years. Other teacher leader activities are selected based upon the needs of the school and in consultation with school leadership. The PLC serves as a context for collaborative selection, planning, and reporting on teacher leader activities, in addition to individual conferences with the program director. Toward the beginning of the school year, each EMS proposes 3-6 specific teacher leader activities in writing to the program director, describing in detail the activities anticipated content, duration, frequency, and outcomes. The program director consults with the project's leadership and collaboratively refines with each EMS a plan for specific teacher leader activities to accomplish across that school year. Check-ins related to progress across the school year are included in both PLC meetings and individual conferences. Each EMS provides documentation at the end of each year of this work in a Teacher Leader Record.

Data were collected at the end of Year 1 in two ways. All participants completed a Teacher Leader Record (TLR), documenting various aspects (i.e., content, duration, frequency, and outcome) of their teacher leader activities across the year. For this study, only the aspect of content is included as data. The content section includes a detailed description of the teacher leader activity and the rationale for implementation, including what exactly the activity was and why they chose to do that activity. Data were also collected from all participants via a survey of mathematics coaching practices (Coaching Practices Survey [CPS], Yopp et al., 2019). The CPS is designed to capture the extent to which a coach uses certain practices related to instructional coaching in mathematics that were drawn from coaching models in the extant literature (Yopp et al., 2019). The instrument contains 20 items and uses a 7-point Likert type scale, with a higher rating indicating more self-report of particular coaching practices (ranging from very descriptive of my coaching to not at all descriptive of my coaching). This collection of 20 items exhibits good internal consistency (Cronbach's alpha estimated at 0.81).

The research team includes four university professors and the project's program director, collectively holding expertise in a variety of methodologies, along with two doctoral students. The analysis of the TLR focused on the content of the teacher leader activities, which largely involved examination for frequency of activities and clustering into categories when possible. Data from the CPS were dichotomized for analysis in order to identify practices that are descriptive or not of participants' coaching. For an item, if the response was descriptive at all (rating of 7, 6, or 5) it was assigned a 1, and the other responses of not descriptive or equally not descriptive/descriptive (rating of 4, 3, 2, or 1) were assigned a 0.

Results

The analysis of the TLR shows all participants provided teacher leadership in a number of ways, with each participant reporting 3-6 distinct teacher leader activities, dependent upon the scope and scale of each activity. Each participant coached a teacher candidate, serving as a classroom mentor teacher and/or university coach, with a total of 27 teacher candidates impacted.

The analysis of the TLR also shows that during Year 1 over one-third (n=10) of the EMSs supported the non-profit's after-school tutoring program. This support was driven by the needs of the after-school tutoring program, based upon consultation with the program's leaders. The EMSs' initial efforts largely focused on collecting and organizing tools and resources to support remote learning, then broadened to include curriculum analyses with revisions. All of this work had an intentional focus on supporting mathematical content that students were concurrently learning in their classrooms. The curriculum analyses involved careful review of the existing guidelines and materials used in after-school tutoring sessions, starting in August and spanning the entire school year, and providing feedback on how to increase cognitive demand during instruction, implement tasks that are worthwhile and engaging for students, and utilize more manipulatives and tools to improve conceptual understanding. Further, the EMSs provided additional resources and supplements to that curriculum, with the continued aim of increasing rigor, conceptual understanding, and enjoyment of mathematics.

Additional teacher leadership is evident from the analysis of the TLR. Eleven of the participants reported leading professional development of some kind for fellow teachers at their schools that focused on mathematics education (e.g., PLC, grade level planning sessions, district-wide and school-wide workshops). Ten formally mentored new teachers at their schools, in addition to coaching a teacher candidate. Other teacher leader activities focused on outreach to parents and families. Twelve EMSs facilitated a Math or STEM Community Event for families and students in their respective schools. Twelve led workshops or created resources for parents focused on mathematics as a direct response to remote learning struggles or language barriers (e.g., instructional videos, bilingual resources). While the fore-mentioned categories were the most frequently reported, the EMSs engaged in a number of other mathematics-focused activities. Examples include co-presenting at national conferences, serving on leadership teams within the school district, creating original content for use with teachers and students, facilitating after-school boot camps or tutoring for students, and writing grants to procure resources.

Based on these findings from the TLR the participants were engaged in coaching in a number of ways, and a descriptive analysis of data from the CPS provides insights into their mathematics coaching practices. Since these participants were informal teacher leaders and serving as EMSs in a variety of ways, with their coaching focusing on both teacher candidates and colleagues, these descriptive data show variability and provide contrast with those who serve in a mathematics coach role of primarily working with fellow teachers. The analysis shows that three participants rated 18 of the 20 items as descriptive of their coaching practices and at the other extreme, four participants rated five or fewer of the 20 items as descriptive. Twenty of the 27 participants rated 10 or more items as descriptive of their coaching practices, with seven participants rating fewer than 10 items. The distribution of the dichotomized data is near normal with a negative skew.

An item analysis comparing the identification ratings indicated that 56% of the items are descriptive of mathematics coaching practices. Interestingly, the four lowest-rated items, which were rated by 26%, 26%, 30%, and 33% of participants as descriptive of practices, all focus on collaboration and communication with the principal or other school administrators about mathematics coaching (e.g., discussing the school's vision for mathematics instruction, progress being made toward that vision, and teachers' needs; collaborating to ensure a clear message about effective mathematics instruction). This seems to indicate that the principal or administration at these school sites is not actively involved in the coaching practices of the participants. Since the participants are informal teacher leaders, with a focus in part on coaching teaching candidates, it is not surprising that there is variability in how much they work with school leaders in their coaching responsibilities. In contrast, Table 2 shows the seven highest-rated items, which 70% or more of the participants indicted as descriptive of their coaching practices.

Table 2: Most Prevalent Coaching Practices on the CPS (≥70%)

3. I coach teachers on needs that I observe in the teacher, even when the teacher is unaware of these needs
5. I always make sure that coaching conversations with mathematics teachers are grounded in the mathematics content
9. I try to provide the teachers I coach with an understanding of how the mathematics they teach supports learning beyond the grade level they teach
11. I encourage the teachers I coach to reflect on similarities and differences among mathematics topics in the curriculum
12. I help teachers plan their lessons
16. I reflect on state assessment data to identify curriculum areas that need to be strengthened
19. I encourage teachers to set personal improvement goals for mathematics

Discussion

Given the notable variability of EMS preparation programs across the USA (EMS and Teacher Leader Project, 2022), there has been a call for "developing a knowledge base for the preparation of EMSs", including how "elements of an EMS program are necessary for productive outcomes" (Reyes et al., 2017, p. 231). Teacher leadership, including coaching and associated practices, have not been widely studied (Yopp et al., 2019). Further, EMSs ways of working are highly varied, driven by need and context, which provides a warrant for study of their roles and responsibilities. Accordingly, this inquiry focused on how EMSs in a preparation program are engaging in teacher leadership, especially coaching. The participants' primary responsibility is teaching students, thus they are a distinctive population as *informal* teacher leaders. Further, they were largely teachers of color, working in urban schools that served students historically marginalized in mathematics. Notably, these EMSs were selected for this project based upon a rigorous process and are subsequently participating in a rigorous preparation program, which contrasts with the too often practice of those who are simply the most effective mathematics teacher being selected to serve as a teacher leader or coach.

Our project provides an example of a preparation program guided by standards and research, with this study's findings illuminating the important outcome of teacher leadership. The findings of the CPS show mathematics coaching practices that they were and were not using, providing considerations for how they can better communicate and collaborate in their coaching with school administration. The findings of the TLR provide insights into their teacher leader efforts. Each EMS coached a teacher candidate, serving as a classroom mentor teacher and/or university coach. A total of 27 teacher candidates were impacted, strengthening the university-school partnership, contributing to high quality clinical experiences for teacher candidates, and building teacher capacity for coaching and mentoring others at the school sites. The project provides a pipeline of teacher candidates to be hired at the high-need, urban schools, addressing a teacher shortage in school district. For these teacher candidates, program data show 70% are from underrepresented groups in the teaching profession, contributing to the much needed diversity of the teacher workforce as recent data show 78% of public school teachers in the USA are White (National Center for Education Statistics, 2021).

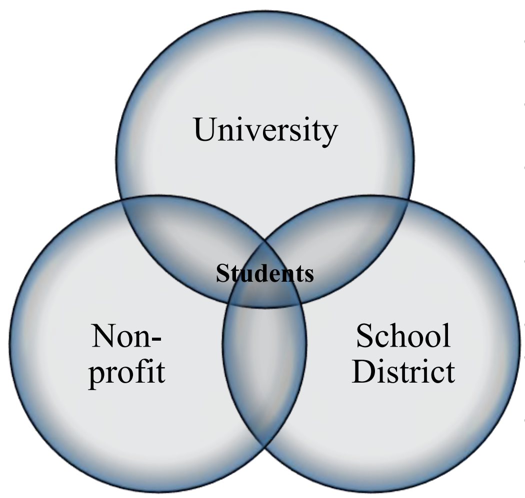
In addition, their teacher leader endeavors supported community connections and intentional interactions with parents and caregivers, which are important for fostering these key relationships and shared responsibility for students' learning in mathematics. Notably, their work focused on curriculum development in the after-school tutoring program aims to improve mathematical learning experiences for students. Since some of these students are in the EMSs' classrooms, the EMSs should receive direct benefits from this work via their students. Additionally, their teacher leader efforts focused on coaching and facilitating professional development, positioning them as a *more knowledgeable other* for a community of practice within a school, aiming to influence teachers and the school's mathematics program as a whole (Campbell & Malkus, 2014). All in all, their teacher leader efforts across the 5 years of the project and beyond aim to have a wide-ranging effect on mathematics teaching and learning at their school sites. Further, their support for a novice teacher at their schools should foster teacher retention during the novice teachers' induction period in the profession. A body of research shows that individual mentoring of those in the first 3 years of teaching is critical for retention in the profession (Desimone et al., 2014; Ingersoll et al., 2012; Ingersoll & Smith, 2004; Stanulis & Floden, 2009).

It is hoped that the *proximal* goals of improving EMSs' mathematics instruction with them in turn supporting others (e.g., fellow teachers) in doing the same, should influence the *distal* goal of enhanced student learning and understandings in mathematics. This project intentionally supports students who have been historically marginalized and under-served in mathematics education. These students are largely from traditionally underrepresented groups, and selection criteria for the project ensured the EMSs are a diverse group, with 70% identifying as persons of color. This is significant as increasing research shows students of color benefit from having teachers of color (Carver-Thomas, 2018). Further, during the K-5 ME program the EMSs are immersed in mathematics teaching and learning that supports equity, diversity, and inclusion and provides explicit and intentional opportunities for all children to learn rigorous mathematics (Aguirre et al., 2013; Bartell et al., 2017; NCTM, 2020, 2021; National Council of Supervisors of Mathematics [NCSM] and TODOS, 2016). They learn about enacting lessons that leverage children's mathematical, cultural, and linguistic strengths, while nurturing positive student identity in mathematics. For example, not only should instructional tasks have high levels of cognitive demand, they should hold cultural relevance whenever possible and draw on students' home, cultural, and language experiences (NCTM, 2014, 2020). Emphasized are culturally responsive and sustaining pedagogies, instruction for multilingual learners, and mathematics serving as a lens for understanding and critiquing the world (Harper, 2019; NCSM and TODOS, 2016; Rubel, 2017). Equity and access within mathematics education are through-threads of this project, supporting students who have been historically under-served.

This project also aims to support teacher retention of the EMSs, an aspect that is addressed in the high-quality preparation and support as well as the community of teacher leaders being cultivated. Notably, the extant literature shows that teachers who engage in teacher leadership have feelings of an upward professional trajectory, thus increasing their own satisfaction and retention in the teaching profession (Tricario et al., 2015). With this project occurring in the context of the COVID-19 health pandemic, the sudden, unanticipated shift to emergency remote teaching followed by concurrent instruction of face-to-face and virtual learners have generated tremendous challenges and angst for K-12 teachers. Those were and continue to be trying times for teachers, testing their resilience, fortitude, and persistence in the profession. Throughout, the EMSs have found community and comradery with one another. The project is providing a space for supportive and open, safe conversations as they grapple with the tremendous demands placed upon them as educators, which has been illuminated through both anecdotal data and initial interview findings. Their passion for and commitment to mathematics education are apparent, which brings us hope that our goal of retaining EMSs in the school district will be successful.

Given the numerous and various ways the EMSs are serving as teacher leaders, the results show they are making a difference for a number of stakeholders, including fellow teachers, novice teachers, teacher candidates, students, school administrators, parents and families, and community partners. When considering these various stakeholders, critical to this project is the strong partnership between the university, school district, and non-profit organization. Notably, robust school-university-community partnerships support *simultaneous renewal* (Goodlad, 1994) of all partners. This renewal is a process of partners concurrently changing, growing, and improving, with a focus on innovative, high leverage, research-based pedagogical practices (American Association of Colleges for Teacher Education [AACTE], 2018). Central to these partnerships is *reciprocity*, where there are mutual benefits for all involved (National Association for Professional Development Schools [NAPDS], 2021). Figure 1 displays some of the fore-described mutual benefits, with supporting students and their mathematical capacity for success at the center.

- Strengthened university-community connections
- Enhanced after-school tutoring curriculum
- Improved mathematics instruction
- EMSs invested in community



- Strengthened university-school connections
- Improved mathematics instruction
- Positive influences on colleagues and school's mathematics program
- High-quality clinical experiences for teacher candidates
- Reinforced hiring pipeline
- Improved teacher induction and retention
- Engagement with families/caregivers

- Strengthened community-school connections
- Enhanced support for students' mathematics learning
- Shared responsibility for students' learning

LESSONS LEARNED DURING TWO TEACHER EDUCATORS' SHIFT TO SYNCHRONOUS ONLINE MATHEMATICS EDUCATION COURSES

Lynda R. Wiest	Teruni Lamberg
University of Nevada, Reno	University of Nevada, Reno
wiest@unr.edu	terunil@unr.edu

This paper describes a self-study conducted by two K-8 teacher educators in relation to their shift to teaching synchronous online mathematics education courses. They each wrote three independent self-reflections for a total of four courses (one undergraduate, three graduate) that they later analyzed and discussed for common themes in relation to the following topics: challenges (online teaching in general and for mathematics education courses), instructional adjustments, favorable aspects of teaching mathematics education courses online, skills gained that would benefit future teaching in any mode, equity considerations in teaching courses online, and recommendations for future online mathematics education courses. They report their findings in relation to these broad categories and use structured reflection on their experiences to recommend practices for online mathematics education teaching and learning.

Keywords: Online and Distance Education; Teacher Educators; Instructional Activities and Practices

The purpose of this study was to investigate our own practices as mathematics teacher educators during a required shift to online teaching, without sufficient experience and preparation, during the COVID-19 pandemic. To do this, we engaged in self-study.

Self-study in teacher education involves investigating one's own practice from one's own perspective, with the intent to draw conclusions about both general and specific practices (Berry & Kitchen, 2020; Pinnegar et al., 2020). This self-examination, which takes place with an understanding that teacher educators' practice occurs within interactions among human, material, and non-tangible elements and within an environment that is uncertain in many ways and is always subject to change, can contribute to the research base on the pedagogy of teacher education (Hordvik et al., 2020). In particular, Berry and Kitchen (2020) note, "Self-study has important contributions to make in these times [the COVID-19 pandemic] for documenting the experiences and insights that come from radical educational change" (p. 123).

Online synchronous teaching via videoconference technology has been shown to be challenging for teachers due, in part, to lack of adequate preparation for this type of instruction in relation to such areas as possessing appropriate technology skills and facilitating interaction among course participants (Cassibba et al., 2021; Rehn et al., 2018). Further, online instruction has been shown to increase teacher workload and challenge teachers emotionally, and that it must be designed carefully in order to provide equitable education rather than exacerbating educational inequities (Cassibba et al., 2021; Kaden, 2020). In a study of mathematics teacher educators, Huang and Manouchehri (2019) found that some of the challenges include posing appropriate tasks, selecting appropriate online tools and technologies, and engaging all students. Despite these challenges, those who teach mathematics have hastily learned to adapt new technology uses, such as writing tablets and mathematics software, and to take advantage of online applets and videos in efforts to simulate in-person classes (Cassibba et al., 2021; Huang & Manouchehri, 2019).

Methods

We, two long-time mathematics teacher educators, investigated our own shift to synchronous online teaching in 2020 and 2021. The two investigators have been teaching preservice and in-service mathematics education courses for 26 and 18 years (first and second author, respectively). For this study, we reflected on four mathematics education courses, three graduate and one undergraduate. One graduate course was taught by the first author, and the other three courses were taught by the second author. The graduate course topics were advanced K-8 mathematics methods, fractions/proportional reasoning, and problem solving. The undergraduate course was K-8 mathematics methods for preservice teachers.

During our online teaching, we first individually responded in writing to a set of four questions that we considered relevant to our shift in teaching mode. In a second wave, we added three questions to which we also wrote responses individually. Finally, after examining each other's responses to look for common themes, we wrote more detailed narrative responses to the questions we determined to be most salient in our initial reflective writings. In total, the questions focused on challenges (online teaching in general and for mathematics education courses), instructional adjustments, favorable aspects of teaching mathematics education courses online, skills gained that would benefit future teaching in any mode, equity considerations in teaching courses online, and recommendations for future online mathematics education courses. The final set of questions after the first two rounds of writing were:

1. Which aspects of switching to synchronous online teaching were most challenging?
2. What were some drawbacks or challenges of teaching a *math education* course online synchronously?
3. What instructional adaptations did you make in order to conduct effective synchronous online teaching?
4. What were some favorable aspects of teaching a math education course online synchronously?
5. What are some professional skills you gained by teaching online synchronously, such as skills that might transfer to your in-person teaching or other work responsibilities?
6. What equity issues, if any, did you notice while teaching online synchronously?
7. What suggestions can you make for teaching a synchronous online math education course effectively?

In the third and final round of our data collection, we wrote more "fleshed-out" responses to numbers 3, 4, and 7 in order to focus on data-based recommendations for online mathematics education courses.

To analyze our data, we read each other's three rounds of writing and compared them to our own, looking for major themes. We revisited the data (written reflections) several times until we believed the identified main themes accurately reflected the data (Strauss & Corbin, 1998). We then discussed our understanding of those themes and specific examples – or others generated through discussion that we had neglected to include in our writings – to illustrate them.

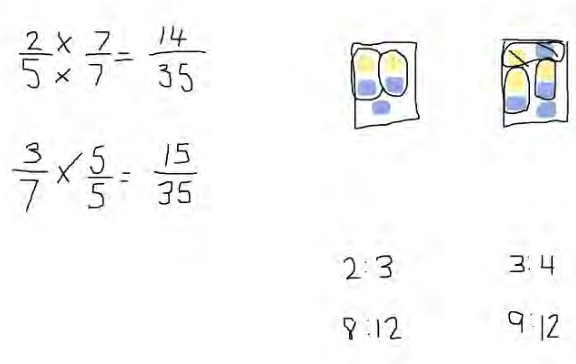
Results

Some key findings from our self-study include:

- *Challenges*: appropriate and effective use of technology; adjustments to class instruction, class assignments, and class policies and expectations; maintaining student engagement

- *Pros*: ability to see all students close up (except when spread onto more than one screen); ability to place students into groups quickly and randomly; incorporation of technology into class sessions due to its immediate access (e.g., to research information and to explore websites); greater ease of facilitating equitable whole-group participation (students muted and acknowledged in order to speak); easier access to guest speakers
- *Cons*: variable learning settings for participants; students appearing on more than one screen; joint mathematics tasks that involve drawing, use of physical materials, and sharing work that can't be shown side-by-side; limitations and potential failure of technology
- *Instructional adjustments*: greater use of technology and potentially breaking up material more by independent and group work; use of Zoom's whiteboard feature, Jamboard, Google Docs, and the video camera in doing mathematics tasks; greater pre-planning so that students can be provided needed materials in advance or asked to come to class with particular materials that would normally be housed in the classroom
- *Equity considerations*: variable settings that are more conducive or less conducive to class engagement; differing access to technology (e.g., inability to keep video on without high-speed internet) and different levels of technology skills; potential to engage all students to a more equitable degree (e.g., see earlier comment in "pros"); potential social stratification based on "window" into each other's personal lives

Our trepidation regarding how to have students engage in collaborative mathematics learning involving discussion and drawing was eased by students immediate jumping to use of tools that served those ends. In terms of drawing tools, students used the videoconference whiteboard in small groups and saved their work to show when we returned to the whole-group setting. They also used Jamboard, Word drawing tools, and other technological drawing tools, copied images from online into Word documents, and made drawings they took photos of to share in the videoconference system or simply held their work up to the camera. For example, one small group working to solve a word problem about which of two lemonade recipes would have a stronger lemonade flavor (a proportional reasoning problem) in a breakout room saved the following whiteboard work to share when we returned to the whole group to share and discuss problem solutions (they were expected to seek multiple solution methods):



Discussion and Conclusions

The findings of our self-study support some existing research results, for example, the fact that technology use can benefit teaching and learning (Alenezi, 2017) but that technology skills can be a drawback to online teaching Fransson et al., 2018) and instructors must be prepared to teach students how to use needed technologies (Bryans-Bongey & Graziano, 2016). However, the fact that our shift in practice was sudden and the nuance with which we self-reflected on our practice yielded important additional insights into online teaching for mathematics teacher educators.

One thing we observed in our writing and discussions was that the rapid and substantial learning we engaged in during our shift to online mathematics education classes is likely to influence our in-person teaching. For example, we will be more likely to consider use of online tools and resources in the classroom and supplemental online course platforms and to consider use of laptop and tablet computers and even smart phones in the physical classroom.

Despite the challenges we experienced in hastily switching to teaching mathematics education courses online, we were surprised to find that we believed this type of teaching could be highly effective. However, we noted that we needed sufficient time and preparation to learn to do this well, similar to that which has been reported by others (Cassibba et al., 2021; Rehn et al., 2018). We also learned that we must draw on our students for assistance in how to navigate good practices in online teaching and to observe and listen to their preferred methods of learning and demonstrating their knowledge online. Our own learning during this experience was favorably influenced by our students' awareness of technologies and tools to use that we had not been aware of previously. The benefits of quick and varying groupings for collaborative work and easy access to online learning resources (e.g., applets and videos) thrust us into new ways to support students' learning, which mirrors what others have experienced in teaching mathematics online (Cassibba et al., 2021; Huang & Manouchehri, 2019). However, we acknowledge that we need to continue to examine the implications of this relatively new instructional mode on different students in relation to equity considerations. Our thrust into structured, collaborative self-examination was a good start toward exploring new ways of teaching in a technological world that will benefit us in both online and face-to-face teaching now and in the future.

As critical race theorists would remind us, those most impacted have the greatest insight to create change. This paper applies a critical race theory framework to explore the leadership experiences of two African American and one Latinx American mathematics teacher educator and how they address issues of race, racism, and (in)justice in teacher professional development. Data analysis from semi-structured interviews, publicly available webinars and podcasts, and other published materials from the educators (eg. articles and books) reveal how they engaged teachers to attend to issues of race and racism by challenging persistent masternarratives about mathematics and mathematics ability; centering on counternarratives on the cultural identities and mathematical understanding of students of Color, and engaging in community-based pedagogies to promote coalitional resistance.

Keywords: teacher educators, social justice, professional development, equity, inclusion, and diversity

Study Purpose

Critical race theory (CRT) has seen steady growth in use as an interpretive lens to analyze and challenge racism in K-20 context and policy (Ladson-Billings & Tate, 1995; Solorzano & Yosso, 2002). Yet, a gap exists in applying CRT in mathematics education and the actions mathematics teacher educators must take to address racial and social (in)justice in teacher professional development. Martin (2019) discussed this point in his critique of the silence of anti-Blackness and white supremacy logic in the politics of mathematics. Gholson & Wilkes (2017) builds on similar claims to highlight the prevalence in mathematics education of racial scripts which divide, sort, and stratify, along a caste hierarchy placing whites at the top and Black at the bottom (Wilkerson, 2020).

As educators, scholars, and community organizers with deep commitments to equity and racial justice, our work is situated by the impact of a legacy of educational injustices (Ladson-Billings, 2006) in which the mathematics education system must be reimagined. We draw on CRT as it specifically acknowledges racism as endemic and actively confronts white supremacy within mathematics education. We extend and apply this framework to chronicle the paths of mathematics educators of Color whose scholarship addresses the racial challenges thrusted upon teachers and learners of Color and the gatekeeping nature of the mathematics discipline.

Specifically, this study explores the leadership experiences of two African American and one Laxinx mathematics teacher educator and how they address issues of race and racism in teacher education. Data include semi-structured interviews, publicly available webinars and podcasts, and other published materials (eg. articles, books) to answer the research question: What knowledge can we gain from the stories/narratives of mathematics educators of Color as they explore their experiences in, with, and for creating professional development that attend to race, racism, and racial justice in mathematics education? Study findings reveal the ways in which educational histories, cultural and ancestral roots, the students served, and current equity leadership informed their perceptions and engagement with racial justice. Our paper raises questions to the field about how we understand social justice leadership in mathematics education and support current and aspiring leaders of Color who seek to promote racial equity in their work.

Theoretical Framework and Literature Review

Our project is motivated by pressing issues in mathematics education: 1) longstanding racial injustices that have come to the fore in U.S. society and mirrored in mathematics education (Gholson & Wilkes, 2017; Martin, 2019), 2) mathematics teachers and teacher educators are majority white, while serving a disproportionate number of students of Color (deBrey, et al, 2019); and 3) mathematics serving as a gatekeeper to nearly all aspects of success. As such, we are interested in interrogating and disrupting the role mathematics education plays in perpetuating white supremacy. With few exceptions (e.g. Battey & Leyva, 2016; Martin, 2015, 2019), the literature has not significantly examined how whiteness and white supremacy culture function in mathematics education (see Martin, 2015, 2019). We draw on Critical Race Theory (CRT) (Ladson-Billings & Tate, 1995) to interrogate aspects of whiteness in mathematics classrooms, schools, and the education system. CRT has its origins from Critical Legal Studies, developed in the mid-1970s from the work of legal scholars of color, such as Derrick Bell, Mari Matsuda, and Kimberle Crenshaw, interested in investigating and transforming the injustices that were brought about due to issues of race, racism, and power in our society (Delgado & Stefancic, 2001). Although CRT began in legal studies, it expanded to other disciplines, including mathematics education. Within the field of education, CRT scholars (Davis & Jett, 2019; Solorzano & Bernal 2001) outlined several key tenets which inform our research methodology, including (a) centrality of racism; (b) intersectionality and anti-essentialism; (c) commitment to social justice; (d) voices and counterstories; and (e) interdisciplinary perspectives.

Centrality of Racism

The first tenet of CRT is the notion that racism is not a random, isolated act of racist individuals; rather, racism is a normal feature and embedded within systems and institutions. According to Delgado and Stefancic (2001), racism "is the usual way society does business" (p.7). Mathematics education by design has a legacy of systemic epistemicide of communities of Color—the erasure of knowledge systems, including languages, experiences, and interpretations of the world, and ways of coming to know and understand—through exclusion from its functions, curriculum, and pedagogy (Yeh et al., 2021; Louie, 2017; Martin et al., 2010).

Intersectionality and Anti-Essentialism

CRT recognizes multiple identities – race, class, gender, sexuality, ability - and their positions within intersecting relations of power. According to Delgado & Stefancic, "intersectionality means the examination of race, sex, class, national origin, and sexual orientation and how their combinations play out in various settings" (2001, p. 51). Identities are not fixed; anti-essentialism acknowledges the fluidity and constant shift of cultural identities within an oppressive system (Gillies, 2021). While our society and mathematics education are often organized along binaries (e.g. right or wrong, math smart or not, innate or social), CRT scholarship sees the complexities required to examine and abolish systems of oppression. For example, racism and ableism are interwoven in mathematics education, in which mathematical "smartness" is an ideological system that perpetuates whiteness and serves as a tool for stratification (Yeh et al., 2020; Leonardo & Broderick 2011). Ability is commodified and seen as property; success is measured in terms of achievement of numerical target, and such data are used to construct and constitute some students as "mathematically smart" while simultaneously constructing and constituting others as "not-so-smart," deficient, or learning dis/abled (Yeh, et al., 2020). CRT tenets of intersectionality and anti-essentialism challenge these binary systems and instead seek ways to counter these paradigms that uphold inequities in education. In challenging these definitions, we are not only incorporating intersectionality and anti-essentialism but challenging dominant ideologies themselves.

Commitment to Social Justice

CRT is about empowerment. Anzaldúa (1987) refers to the term borderland consciousness, the ways of knowing and being Peoples of Color produced in multiple and often contradictory physical, social, and political spaces. Their worldviews as students and educators of Color include homegrown ways of knowing as well as western epistemes. These approaches empower educators and students of Color in that they recognize the advantage of having insights into the experiences of the Oppressed and the Oppressors and can reveal the cracks that support social change (Anzaldúa, 1987; Collins, 2000; hooks, 1989). Our work here is to attend to and leverage the multiple ways of knowing mathematics educators of Color to offer recommendations for ways to take action for social justice.

Voices and Counterstories

Dr. Mari Matsuda (1987), one of the legal practitioners from the original movement, argues that the work of justice must center on the voices that have been left out. Matsuda refers to them as "voices from the bottom," Anzaldua (1987) calls them "mestiza," and hooks (1990) advocates for using these excluded voices to produce transformative knowledge. Counternarratives build from the belief that communities of Color hold deep resources and ways of knowing and being that are particularly important in disrupting colonial ideologies pervasive in mathematics. Yet, much of these rich and collective ways of knowing and being have not yet been made visible. It is through centering the voices of communities of Color to offer historical accounts, interpretations, and cultural practices as resources to question and challenge dominant narratives.

Interdisciplinary Perspectives

CRT scholarship challenges ahistoricism and the unidisciplinary focus of most research analyses. It is predicated on analyzing race and racism in both historical and current contexts from an interdisciplinary or transdisciplinary approach (law, sociology, education, psychology, ethnic/gender/disability studies, etc.) which is needed to better understand the systemic nature of racism and white supremacy. For example, few scholars explore mathematics as an agent of carceral state; yet, violence is enacted through institutionalized policies, such as school disciplinary practices that offer brutality, suspension, expulsion, and detention often occurs in STEM classrooms (Bullock & Meiners, 2019; Gholson & Wilkes, 2017). An interdisciplinary perspective recognizes, interrogates, and then disrupts systems of violence and trauma experienced in and beyond mathematics classrooms.

Method

Critical Race Theory served as our methodological framework. We understand that race is a sociohistorical and political construct, created to empower whites and oppress people of Color; as such, we use counterstorytelling (Delgado and Stefancic, 2001) to capture experiences in discussion and praxis that attend to race, racism, and racial justice. This study includes one African American male math educator, one African American female math educator, and one Latinx female mathematics teacher educator in which their self-selected pseudonyms are Francis Cox, Etta Falconer, and Katherine Johnson, respectively. The criteria for participant selection included the following: 1) self-identification as an educational leader of Color; 2) extensive experience (20+ years) as a classroom teacher and mathematics instructional coach; and 3) research and teaching that focuses on examining the ways education intersects with issues of race, equity, and justice in communities that have historically been, and continue to be, underserved by schools (e.g. Black, Latinx, Indigenous, or immigrant populations).

Attending to story, theory, and praxis, the data sources include three semi-structured, in-depth interviews (roughly 1 hour each), three publicly available webinars and podcasts (1 hour each), and other published materials written by the participants (e.g., articles, books). Analysis began with the webinar and podcasts. For the webinar and podcasts, we created an accompanying transcript. Each transcript was divided into talk segments, where each segment represented a central idea the interviewee focused on during a posed question or activity. At least two of the seven members of the research team coded and categorized each webinar and podcast through a critical race analytical lens and tenets of CRT (e.g., centrality of racism; intersectionality and anti-essentialism; commitment to social justice; voice and counterstories; and interdisciplinary perspectives) as well as from the K-12 and higher education scholarship on racialized experiences of teachers and students of Color cited in the literature review. Example codes included definitions of mathematics, racial hierarchy, transformational resistance, intersectionality, and color blindness. Coding allowed us to categorize the data into overall themes as codes that were repeatedly used across the three cases, which were then placed into overarching themes. After the research team member coded the podcast/transcript, coding was discussed by the research team of seven for agreement. Disagreements were resolved through discussion. After coding each educator's podcasts and workshops, we interviewed three of them . Interviews were about 60 minutes each. Interview questions began with:

1. What should mathematics instruction look like when it centers on the mathematical brilliance of Black, Indigenous, Latinx, and multilingual students and their communities?
2. How do we support the creation of school systems or structures for teachers to have the school-wide support to implement and learn equitable practices in math ed?
3. Most of our workshop consultants are white mathematics teacher educators, what resources would help them to be able to authentically engage in racial justice work?

Interviews were transcribed and analyzed using the same codes as described above. Triangulation of data allowed us to gain a better understanding of the experiences of the three educators. We used publicly available podcasts, webinars, interviews, and published articles as methodological procedures to triangulate the data.

Results

Our findings reveal three major themes. All three educators of Color discussed the need to situate education within broader societal contexts and the need to challenge white masternarratives that position mathematics and mathematics ability as singular, individualistic, and ahistoricized. They described their own and students' cultural identities and understanding and its connection to mathematics teaching and learning and the need for coalitional resistance to disrupt whiteness in mathematics teacher education.

Challenging Persistent Masternarratives.

All three described specific ways in which mathematics education itself functions as a white space in historicized context, naming the contemporary forms of institutional, structural, and everyday racism in the here and now rather than just the past. Specifically, they called to rethink what constitutes mathematical knowledge and what constitutes knowledge production in mathematics education. In his interview, Francis highlighted the need for mathematics teacher educators to explicitly shift away from the white frame:

> I would say that it should look the same or similar as when it centers on the mathematical brilliance of white students right, so it should have examples and images of people that reflect their culture and the contributions that people from their history and culture have made to the field of mathematics, it should include examples that also reflect students that are African American, Latinx, Indigenous, multilingual students.

In the quote above, Francis highlights that racial equity work in mathematics teacher education requires us to examine critically whose histories, cultures, and experiences are centered in mathematics curriculum and the ways in which whiteness is made hegemonic as it is positioned as the normative and communities of Color as the exception. He further explains that,

> Looking at mathematics from a kind of diverse Black perspective, there's a book called "The Crest of the Peacock: the Non-European Roots of Mathematics." Now [it] does get into some pretty heavy mathematics, at some point, you know so it's not for the faint of heart right, but you know I think anyone can [at] least engage in it to get an idea to dispel the myth that you know mathematics is a European invention and endeavor right? That it is a human endeavor right? Rochelle Gutiérrez says mathematics needs people, just like people need math mathematics right and, and I think we've moved too far away from that notion that mathematics is a human endeavor that all humans engage in right, whether they realize it or not.

All three math educators explicitly called to broaden curricula, classroom environments, and school cultures to explicitly attend to the voices, perspective, histories and experiences of communities of Color. In the webinar led by Francis Cox and Etta Falconer, the workshop opening mathematical task asks participants to match the professions of Black dentists, Black professional athletes, Black doctors, and Black lawyers to "the corresponding number of Black professionals in the United States". The opening task explicitly attended to participant bias and public narratives around Black professions. During the interview, Etta Falconer stated, "representation really does matter. So it's important that you make sure that all students can see themselves reflected in the curriculum." Every mathematical task and student vignette used in the professional development workshop focused on the agency and identity construction of Black youths and the ways in which social structures mediated their mathematical identity formation.

Cultural Identity and Understanding.

The mathematics educators used storytelling to center on the experiences of communities of Color and as examples to generate action. Both Katherine and Francis began interviews sharing their mathematics experiences as students and teachers in which their experiences shaped their work and commitments. As a student, Katherine "felt dehumanized in class. I felt invisible. I use the word invisible when I talk about my schooling" and Francis worked in "neighborhoods that had experienced poverty and other kinds of trauma, and, you know, large numbers of students who have been underserved." While their experiences could be viewed as "challenges", their stories testify to the normalization of such experiences for children and teachers of Color AND the strength and resilience communities of Color developed. They saw themselves in the students and teachers of Color they served.

All three educators talked about the importance of developing mathematics learning experiences that shift from damaged based narratives to student strengths by building from their cultural identities and understandings. Katherine in a podcast interview talks about the importance of recognizing the brilliance of children and embedding their culture in the mathematics classroom:

> So we expect that all students are brilliant. That's a mindset issue. We talk about growth mindset. This is more than that. This is knowing that all students and believing that they're brilliant, and they bring knowledge, mathematical knowledge into the classroom, right. So that's one of the pieces. The other piece is also bringing that cultural competence, right. I'm caring enough about the math that you're doing, and I want to learn about it. And, and I want to share the math that I do, too, you know. We talk about real world math all the time. It's really not real world, many of the problems that we see in books are contrived. Real world math is the math that kids are actually doing with their families. And so, how do we tie that into the standards and bring those into the classroom, like my colleague [anonymized] said, as tasks, as activities, because that's going to build students' cultural competence. And I think sometimes it brings, well, I know it brings the community together, cause the more I know about Maura, Joe, and Stella, the better I get to perform as a student, because now I know how they best understand math, what they care about, the math they do in their everyday life.

Katherine in a webinar describes how she was able to learn more about her students by having them draw their own multiplication array, describing context from their families and family experiences. In particular, she gives the two following examples:

> One is about a student talking about his uncle, how they played baseball, and his array was a 3 by 10. Then another student who actually was a multilingual learner and talking about her Vovo, and how they may visualize the tacos together in Brazil.

Similarly, in their workshop and interviews, Etta and Francis centered on stories of Black students to expose, analyze, and critique the racialized reality of Black youths in mathematics education. Etta described an experience where she felt challenged by a female student, and some of those challenges stemmed from her strengths being directed at Etta. Instead of conceptualizing it negatively, Etta reassessed these as strengths. During her interview, Etta shared her thinking out loud, "How can I leverage that? How can I leverage that strength, that leadership and tenacity that she has in mathematics?" The counterstories used followed a similar format of centering on the standpoint of Black students, critiquing unfair practices and ideologies, and pointing to possibilities and actions.

Coalitional Resistance

All three educators discussed the importance of organizing forms of learning for mathematics teachers and students that provided new identity pathways where people work together to critique, re-imagine, strategize, design, and re-make how they can engage with the mathematics and each other. The community was identified as a site for learning, organizing, and activism. A central theme is the importance of community responsive pedagogies in which mathematics educators must begin by learning from the community to develop curriculum and pedagogy responsive to community needs, strengths, and contexts. Francis explicitly attends to this during his interview when he shares a story how teachers were wary of having community members come to the educators' homes even though the teachers visited the community members' homes.

> It's a two way street. Right? It's like we want, you know, the community to come into the school, but we don't want to go into the community, you know? I remember in the teacher education program at UCLA, they really were encouraging the teachers to do home visits…And they have this meeting afterwards, and you know this gathering and after gathering the parents asked the teachers if they could come visit their home. And the teachers were often, "Wait, whoa wait a minute," right. And so you know we want, we, it seems like we only want this relationship to be one way right. We have, it has to be doable by, it has to go in both directions right, we have to be willing to go out into the community and into and find out what are the, the the assets.

During the interview in which Katherine was asked to share ways to create school systems or structures to implement and learn equitable practices in mathematics education, she shared:

> So when we talk about dismantling racism, the way we do that is to humanize all of our neighborhoods and our kids by bringing them there. Like our teachers need to come out of the schoolhouse and really go into places. There's so much to be learned, actually, seeing and learning and listening and then not talking. Don't talk, just ask questions and listen.

During a teacher professional development workshop, Francis stated, "And our definition of expert is anyone who can contribute to the knowledge of the group. Therefore any one of your students can be an expert, given the opportunity."

In the quotes above, Katherine and Francis describe how connecting to and learning from students' and in communities are critical to countering masternarratives of who and what mathematics is and for and who can be seen as the experts and teachers of mathematics. This also includes challenging masternarratives in teacher professional development in which the mathematics educator or consultant are seen as the expert to professional learning spaces in which the mathematics educator begins by learning in, for, and with the school teachers to move towards collective action. For example, in a podcast interview Francis talks about his PD practices.

> Anytime that I write a grant with a district or get a request from a school to do professional development, one of the first things I want to do is meet with the teachers themselves, or represent, representatives of the teachers to find out, what are their concerns? What is it that they want? What is it that they need, right, so I think that's the most, because teachers want to feel important.

Discussion

As critical race theorists (Davis & Jett, 2019; Dixson & Rousseau, 2005; Matsuda, 1987) would remind us, those most impacted have the greatest insight to create change. In this paper, we extend and apply this framework to chronicle the paths of mathematics educators of Color whose scholarship addresses the racial challenges thrusted upon teachers and learners of Color and the gatekeeping nature of the mathematics discipline. What knowledge can we gain from the stories of the three mathematics educators of Color as they explore their experiences in, with, and for creating professional development that attend to race, racism, and racial justice in mathematics education? All three mathematics educators of Color discussed the need to situate mathematics education within broader socio-political contexts and the need to challenge white masternarratives that position mathematics and mathematics ability as singular, individualistic, and ahistoricized.

As we think about creating culturally sustaining spaces for students and teachers of Color, we are also reminded to consider how mathematics teacher education is supporting mathematics educators of Color. School administrators and leaders in the United States are disproportionately white. As a field, we need to consider the practical, on-the-ground support provided to in-practice and in-preparation leaders of Color. Dr. Patel's (2017) notion of token or incremental inclusion is helpful. How much of current equity efforts are token change? For example, having a lone teacher leader of Color assigned to an all-white equity committee or to expect collaboration simply by putting a group of educators and families in a room, without acknowledging that the same hierarchical power dynamics responsible for long-standing inequities will quickly reassert themselves. How often are we socializing nondominant students and educators into norms, expectations, and agendas that have been set without their perspectives or input?

As mathematics educators and education researchers, we are trained in academic spaces in which Western intellectual culture is espoused as "objective science". When whiteness and white supremacy serve as the marker of what is considered normative and excellence, there is a deep need for unlearning and relearning of the possibilities to engage with students, teachers, and communities in more ethical ways. These activist-educators have taught us powerful lessons about historical injustice as well as community resistance, cultural practice, and ethical responsibilities that should fundamentally shape how we approach mathematics teacher education and research. This necessitates an examination of the mathematics teacher education system and the ways it reproduces racial injustice. Particularly in devising practices, structures, and policy interventions to address racial (in)justice, CRT calls for considering unintended consequences of proposed remedies, addressing intersecting policies and structures, and acting intentionally to ensure that harm is not further replicated within our mathematics education system.

We have designed and implemented an innovative online video-based professional development model for mathematics coaches in rural contexts that includes an online course, one-on-one video coaching with a mentor coach, and video clubs. As a part of this project, we were interested in the coaches' professional noticing (e.g., Jacobs et al., 2010; van Es & Sherin, 2008; van Es, 2011) as evidenced primarily through video clubs (i.e., Walkoe, 2015). The intent of the poster will be twofold: (a) share the design of our online video club for coaches and (b) share our process for researching coach noticing during video clubs as well as at the beginning and end of the project.

Video clubs provide collaborative learning opportunities for teachers (Barnhart, 2016; Dobie & Anderson, 2015) and have shown to be beneficial for mathematics teachers in rural contexts (Choppin et al., 2019). Our project focused on mathematics coaches in rural contexts, so we adapted the typical video club focus on classroom instruction, to coach-teacher interactions in coaching conversations (Carlson et al., 2017). The coaches in our project watched excerpts from one-on-one coaching cycle conversations and engaged in small group discussions, facilitated by an experienced mathematics coach. We were interested in the role of video clubs to support the development of the noticing of mathematics coaches, so the following research questions guided our work: (1) How did coaches exhibit noticing in written records of video clubs?, and (2) How did coach noticing change from the beginning of their participation in the project to the end?

To answer the first research question, we collected written data from coaches as they watched video excerpts in eight video clubs across two years. We provided a specific *see, think, and wonder* protocol that prompted participating coaches, in writing, to identify (*see*) specific moments in the coach-teacher interactions, create interpretations (*think*) about the thinking of the teacher and coach within this moment, and pose questions (*wonder*). The methodology to examine coach noticing through written records is in its infancy, so the poster would report on our most current data analysis processes and findings to the point that we have results. To answer the second research question, we interviewed each coach prior to participating in project learning experiences. As a part of the interview, we provided coaches with three vignettes from transcribed one-on-one coaching conversations, each representing a range in coaching styles. Coaches were asked a series of questions about what they noticed about teacher thinking and the coach's interaction with the teacher. The analysis for this process is underway. We will report findings from a subset of our data for the poster. Our focus on video clubs for coaches adds to the existing literature base on both noticing and video clubs in mathematics education.

BRIDGING PROFESSIONAL DEVELOPMENT AND MATH TEACHERS' CONTEXTS

jmunson@northwestern.edu

Keywords: Professional development, Learning theory

While teacher education research has coalesced around features of effective professional development (PD), there exists a persistent gap between PD and practice, which we argue is driven by the decontextualization of teacher learning opportunities. PD designs, even those that adhere to principles for efficacy, often provide learning opportunities out of context, away from the teachers' own students, school, curriculum, leaders, and, ultimately, the constraints and assets stemming from each. Teachers learn about practice and learn to enact practice in a more clinical setting and then must translate their emerging learning into real and complex settings that present their own challenges. Separated from their local contexts, teachers may not have the opportunity to learn to negotiate those challenges during their professional learning experiences.

Guided by Rogoff (1995), we hypothesize that the disconnect between professional learning opportunities and teachers' contexts may explain some of the failure of PD to lead to meaningful changes in practice. Teacher educators have been moving toward embedding teacher learning opportunities in classrooms (e.g., Gibbons et al., 2021; Munson et al., 2021). However, we do not yet know how deepening the connection between PD and instructional contexts might influence teacher learning, or how PD might be designed to support teachers in negotiating the practices they want to implement and the contextual constraints they face in doing so. In this study, we analyzed one practice-based PD program for 22 early career secondary mathematics teachers serving lower income communities across the US to address the following question: In what ways do teachers make their local contexts visible during practice-based PD?

Teachers participated in a two-week summer residential institute. They returned to their schools and attempted to implement the practices they learned, while participating in monthly video coaching, both one-on-one and in small groups. This design included opportunities for concentrated teacher learning separated from context (i.e., summer institute) and support in context (i.e., coaching). We analyzed recordings from the summer institute and the coaching sessions to identify instances in which the participants described features of their local teaching context when engaged in professional learning. We inductively coded these instances by topic and then categorized them based on the activity during which they occurred (e.g., rehearsal planning, one-on-one coaching). Each instance was also coded by the speaker and the listeners.

In our preliminary analysis, we found several patterns regarding when and what context became public. First, all participants were asked to describe their contexts during the summer institute, and while what they shared varied (e.g., student population, courses, administrative support), they frequently shared contextual challenges. Second, some teachers continued to bring their contexts into the summer institute's professional learning discussions, but several did not, indicating a gap in how, and possibly to what degree, teachers were grappling with their contexts as they engaged in learning away from their settings. Finally, all teachers brought their contexts into the school-year coaching, discussing barriers they faced, assets they could and did leverage, and strategies for negotiating both toward the goal of pedagogical change. These findings highlight the importance and challenge of promoting connections between teachers' pedagogical learning opportunities and the contextual realities of implementation.

Keywords: Instructional Activities and Practices, Professional Development

Researchers have begun to explore professional development (PD) aimed at incremental improvements to instruction (Litke, 2020; Star, 2016). The intention of such an approach is to enact modest improvements to teachers' existing instruction in ways that recognize and build from teachers' current practice. If we are to seriously entertain the notion of incremental PD, we must identify and study practices that would undergird such an approach. Our purpose is to propose a definition for such practices which we term high-uptake practices.

We define high-uptake practices as pedagogical actions that are readily and frequently utilized by teachers. Consistent with three potentially overlapping dimensions of practicality theory, high-uptake practices are clearly articulated teacher actions (instrumentality), aligned with a teacher's current instructional approach and context (congruence), and the expected benefit from implementing the practice exceeds the effort and resources to enact it (cost) (Doyle & Ponder, 1977; Janssen et al., 2013). High-uptake practices are not contingent upon the quality of the action, but rather by the rate at which teachers incorporate them into their instructional repertoire. Consider if we were to suggest teachers adjust students' independent work time to include not only solving individual problems but also selecting two problems that contrast with one another. We hypothesize that the practice of choosing contrasting problems would be a high-uptake practice because it is:

- a specific action that can be implemented without delay (i.e., teachers do not have to wait for a certain lesson or content topic to try it out; instrumentality & cost);
- presented to teachers who already employ independent work time and is close enough to current practice that teachers have confidence in enacting it (congruence); and
- a change that aligns with teachers' underlying goals (e.g., higher student engagement by avoiding monotony, helping students to identify bigger ideas rather than only procedural execution; cost and congruence).

Presently we are working to determine whether practices we hypothesize as high-uptake actually are high-uptake. We will specify what separates a high-uptake practice from, say, a medium- or low-uptake practice. This process will allow us to understand what and why practices are high-uptake so we can then study how such practices impact students' learning.

Keywords: Teacher professional development, teacher educators, teacher knowledge.

Lesson study (LS), a teacher-centered and student-focused professional development approach, has been adopted around the world (Huang et al., 2019). Research has documented the positive effects of LS on teacher professional learning (Cheung & Wong, 2014; Willems & Bossche, 2019). Recently, cross-cultural lesson study has been utilized to expand teacher collaborative learning (Huang et al., 2021; Isoda et al., 2021). However, the machinimas of and effect of teacher learning through lesson study cross-culturally is still largely unknown (Huang et al., 2021). This study aimed to examine participating teachers' learning through a cross-cultural lesson study from the Cultural-History Activity Theory (CHAT) perspective (Engeström, 2001).

The CHAT portrays a collective and dialectical perspective of learning that included interactions between different single systems within a single activity, different tools that are mediated by the cultural and historical roots of the system such as community, the rules and division of labor that are interplayed to achieve the goals. *Contradiction* is denoted as the 'historically accumulating structural tensions within and between activity systems' (Engeström, 2001, p. 137) and CHAT views contradictions as driving forces of expansive learning when new goals/objects, concepts and motives emerge (Engeström & Sannino, 2010).

In this study, two lesson study teams collaborated. A lesson study team in Shanghai, China included six mathematics teachers from a public middle school. A lesson study team in Ohio, USA included six interdisciplinary teachers from an arts school, two of whom focus on teaching mathematics. All teachers had completed their bachelor's degree and had more than five years of teaching experience. Each team was facilitated by a researcher from a local university and cross-cultural meetings were mediated by a third researcher. The cross-cultural lesson study took place including study, plan, teach, and reflect over six months. The activities included two meetings devoted to identifying learning goals and content commonly taught across cultures; one meeting for sharing lesson plans; developing a public lesson of the identified topic by each team; reviewing the shared videos of research lessons by each individual team; and one meeting for discussing the videos of research lessons cross-culturally. The data collected were lesson plans, meeting notes, videos of research lessons and cross-culture sharing meetings, and final teacher interviews. From the CHAT perspective, the data analysis focused on identifying the contradictions and the ways of dealing with them through the different phases of LS.

The identified contradictions included: (1) concrete activity (USA) vs. variation practice (China); (2) making sense of the concept through exploring real life situation (USA) vs. applying knowledge and skills in real life situations (China); and (3) fully active engagement, communication and sense making (USA) vs. heavily mathematics knowledge and skill application and problem solving. Through addressing the contradictions over the LS process, teachers from the two countries have learned and intended to adopt some new ideas and effective strategies from each other to improve their own teaching.

We see the need for professional development research to explore how teachers initially make sense of students' mathematical thinking. Using the core principles of Cognitively Guided Instruction to support teachers in understanding student thinking (Carpenter et al., 1996; Carpenter et al., 2015), we interviewed elementary students and shared the reports of their strategies and thinking with their teachers. In an analysis of the teachers' discussions about the reports, we respond to the following questions in our study: How do teachers make sense of students' mathematical thinking in reports that attend to student strategy use?

Students across an entire elementary school who were present in October (K-5, N=334) engaged in cognitive interviews (see Kazemi et al., 2016; 3-5 tasks were given depending on age) with researchers (including the authors). Results of each interview were compiled by classroom and grade level. The reports highlighted trends in student strategy use across problems as well as recommendations to support future student learning. Facilitated by the first author, sixteen teachers met as grade level teams to explore the report, discuss noticings about student work, and consider future steps. Data included audio recordings, transcripts, and researcher memos of the meetings. Analysis examined teachers' perceived constraints and imagined possibilities for taking up practices that center student sensemaking, given their context for teaching (e.g., Goh et al., 2017; Knapp & Peterson, 1995). The first two authors independently coded data then met to come to consensus on categories of teachers attending to student thinking.

With regards to student thinking, the teachers initially attended to student correctness within the different problems (e.g., "no one in my class can count to 80"). With continued focus on student sensemaking and strategies used in the reports and prompted by the facilitator, teachers shifted to consider student understanding. For example, when pointing out how her 1st graders attempted to add 6 + 7, Leah commented that one student "had some sort of understanding of 'we're putting things together.'" We found that teachers' reflections included constraints for incorporating the practices from the reports that showed a tension between district expectations and what teachers recognized as best practices for supporting student sensemaking. For example, many teachers believed that the curriculum's pace was too fast and encouraged students to rush through activities, with little emphasis placed on understanding. Overall, reports like these can help teachers collectively inquire into students' thinking and consider opportunities for students to make sense of and discuss cognitively demanding mathematics tasks in their instruction.

This poster presents a proposal for an addition to an ongoing study in which students (n=34) in a mathematics teacher education program have completed autoethnographies over the past 3-4 years. As these students are now entering the teaching profession, we feel the autoethnographic activities from the preservice program can be extended into the experiences of the teaching profession to help in-service teachers develop their identities as mathematics teachers.

Statement of the Problem

The first years of teaching are some of the most critical years of teaching, and if teachers do not feel confident in who they are as a teacher, they are at risk for experiencing burn out and end up leaving the profession (Beauchamp & Thomas, 2009; Hodges & Hodge, 2017; Losano et al., 2018; Lutovac & Kaasila, 2014; Molfino & Ochoviet, 2019; Pillen et al., 2013; Ruohotie-Lyhty, 2013). Identity is a key component in teachers feeling confident in their role of teaching mathematics. Researchers have studied identity formation in educators but have not found an agreed upon definition of identity. However, many agree that identity is socially formed, constantly changing, and consists of multiple subidentities (Akkerman & Meijer, 2011; Beauchamp & Thomas, 2009; Chung-Parsons & Bailey, 2019; Darragh, 2016; Noonan, 2019; Ruohotie-Lyhty, 2013).

Purpose

Autoethnography is self-reflective cultural narrative requiring the author to reflect upon, and analyze experiences to understand culture and the impact it has on identity; both a process and a product (Anderson, 2006; Austin & Hicky, 2007; Duarte, 2007; Ellis et al., 2011; Hains-Wesson & Young, 2017; Hamilton, 2021; Pinner, 2018; Yung, 2020). This gives teachers space to understand how their culture and lived experiences impact how they fit into the teaching profession.

Qualitative methods, including interviews with teachers, can be informed by developing autoethnographic activities within Bronfenbrenner's Ecological System (Cross & Hong, 2012) and Gee's views of identity (Carrier et al., 2017; Tsybulsky & Muchnik-Rozanov, 2019). Bronfenbrenner's Ecological System breaks down environments in which people are situated while Gee illustrates different parts of identity (Carrier et al., 2017; Cross & Hong, 2012; Tsybulsky & Muchnik-Rozanov, 2019). Our purpose is to illustrate our theoretical framework that situates autoethnography within these two existing frameworks (Bronfenbrenner's Ecological System and Gee's views of identity) in identity formation. Ultimately, we aim to design reflective questions to engage mathematics teachers in examining their lived experiences in each level of environment and identity through our created framework.

Chapter 13:

Statistics, Probability, and Data Science

TEACHERS' GOALS FOR SEEING WITH DATA

We present an interview study of 6th grade math and science teachers' expressed goals for engaging their students with data. We explored this across disciplinary boundaries to contribute to a body of knowledge that can support the development of a more coherent experience for students across math and science classes. Our teachers were all highly motivated to engage their students with data, and all wanted their students to see things with their data models. However, we observed consequential differences in the kinds of things they wanted students to see. Here we describe these differences and discuss potential implications for practice.

Keywords: Data Analysis and Statistics, Modeling

What do students see when they build, revise, and use data models to carry out statistical investigations? After all, professional researchers use data models to set the "conditions for seeing" the phenomenon they are studying (Lehrer & Schauble, 2010). And seeing with data models is always an interdisciplinary accomplishment because it is a "meta-discipline" that stretches across many different communities (Wild, Utts, & Horton, 2018). The interdisciplinary coordination necessary for seeing the world with data models means this is a challenging learning goal for students. Although standards documents across different STEM education communities now include significant focus on data and statistics (AAAS, 2011; Franklin et al., 2007; National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010; NRC, 2012), little is known about how to coordinate these experiences for students across diverse disciplinary contexts. If students are to be supported to see with data models in ways that support them to generate knowledge about the world around them, then much work is needed to better understand how to coordinate learning across disciplinary boundaries.

Here we contribute to this need by exploring middle school mathematics and science teachers' expressed goals when they engage their students with data. We conducted this study within a larger design-based research project where we are developing and studying a coordinated approach to teaching data across math and science classes. In our early work we quickly developed a felt sense of some differences among our teachers in their motivations for using data in classes. To better understand their perceptions of their own practice we interviewed all math and science teachers in the 6th grade at our partner school. In these interviews we identified significant differences in the types of things teachers hope their students "see" when working with data, which we think are consequential for teachers' practice during these lessons. We share these findings here with two goals in mind. First, we hope that a better understanding of teachers' instructional goals related to data and statistics across different disciplinary communities will be a small contribution toward building a more coherent learning experience for students. And second, we aim to provoke a conversation about extending the contexts for research on teaching and learning data beyond mathematics and statistics classes to better understand how these ideas take shape across more diverse disciplinary communities.

Interdisciplinary Coordination in Seeing with Data

How do plants grow? Are temperatures increasing across the planet? Does this new treatment help patients recover from this illness? Empirically grounded answers to questions like these require a specialized form of seeing where practitioners work to create a data model that amplifies features of a phenomenon relevant to the question while reducing the features deemed irrelevant (Latour, 1999). This means data are not simply numbers, they provide a lens to see the world in in new ways and the correspondence between the context of the data and the numbers themselves provides justification for the meaning generated from the data (Cobb & Moore, 1997).

Although research on teaching and learning of data and statistics has almost exclusively taken place in the context of mathematics or statistics classes, data models involve coordination among a complex set of interdisciplinary ideas and decisions such as posing a question, deciding upon appropriate attributes to measure, establishing operational measurement techniques, designing sampling plans, structuring variable data to create distribution, measuring features of the distribution with statistics, and building probability models of sampling variability to inform claims about difference (e.g. Arnold, Confrey, Jones, Lee, & Pfannkuch, 2018; Petrosino, Lehrer, & Schauble, 2003; Lehrer, Kim, Ayers, &Wilson, 2014; Lehrer & Romberg, 1996; Lehrer, Kim, & Schauble, 2007; Konold & Pollatsek, 2002). Take for example the phrase commonly used to describe a critical aspect of building a data model, “collecting data.” This phrase suggests that the data are simply “out there”, and that a researcher’s job is to gather them in the same way one might “collect” leaves, or coins, or baseball cards. However, data are not *collected,* but are *created.* Mathematizing the world requires any number of decisions about measurement and sampling that can create significant differences in the data produced. And the knowledge necessary to make these decisions in justifiable ways almost always stretches across disciplinary realms.

Research Methods

In our larger project we aimed to engage students with data modeling across math and science classes in ways that are consistent with the interdisciplinary work STEM professionals engage in when they see the world through data. We conducted this work in partnership with middle school teachers, so it was important for us to begin our work by working to understand their goals for their students when they engage them with data in their classes.

We conducted individual interviews with each of the 6th grade math (N=5) and science (N=3) teachers at our partner school. We also interviewed one special education teacher that worked in math and science classes as inclusion support. The teachers have a wide range of backgrounds, with most teachers having degrees in education, and some with degrees in non-education fields such as Leadership and Ethics, Biology, Recreational Management, and Accounting who obtained alternative licensure. The teachers have between 1 and 22 years of teaching experience in subjects including mathematics, science, social studies, and English, and have taught students between elementary and middle school age ranges. The teachers work at a large middle school in the South-Central Region of the United States of America with a diverse student body. For example, 28% of students in the school are English learners and 50% are considered low-income. Our sample represents a group of teachers that are committed to improving their practice, weekly collaborate on their lessons in PLC meetings, and are motivated to partner with projects like ours to develop new approaches to teaching in their school. In addition, the math teachers had been working for over four years on improving their teaching about data and statistics using an innovative approach called Data Modeling (Lehrer, Kim, Ayers, & Wilson, 2014).

We conducted individual, semi-structured interviews over video calls in the summer of 2020. Each interview took approximately 40 minutes to complete, and asked teachers to share information about their backgrounds, classroom practices, perspectives on using data in their classrooms, and how they plan their lessons. To understand how they thought about engaging their students with data we asked them about how important they feel it is for their students to learn to use data, and what their learning goals are for students using data displays, statistics, probability, and modeling.

Members of the research team transcribed all interviews verbatim and inductively analyzed transcripts of the interviews. We used an inductive approach to create in-vivo codes, characterizing responses in the teacher's own words. Then we discussed our initial findings and identified major categories to characterize in the data. Once we coded independently, we met to agree on consensus codes and then worked together to identify themes. Throughout this process, our research team regularly came together to share and discuss coding results, and in instances where discrepancies arose between codes, the team worked until we had a consensus.

Results

Teachers often wanted students to "see" many different things with their data. Although we did not use this word in our questions, all our teachers used it extensively in describing their goals. Teachers thought that it was important for students to learn to see things with data, but there were significant differences in the types of things they want students to see. We describe these different goals here in two categories: Unproblematic Seeing and Problematic Seeing.

Unproblematic Seeing

Sometimes teachers wanted students to see things in a straightforward, unproblematic way. These comments often ignored or minimized the complexity of seeing with data to emphasize the desired goal of seeing some important learning goal. So, the goal aims for students to see things with data in unproblematic ways without the view being obstructed by complexity or uncertainty. Within this category there were two different things teachers wanted students to see in unproblematic ways.

Teachers sometimes wanted students to use their data to see conventional principles or explanations of a phenomenon under investigation. For example, one of our science teachers named Ms. Manchester described a goal of her lab in the following way.

> "Probably, a concrete example we do with that is the elephant toothpaste lab and the, recording the temperatures... through recording the, the temperatures and graphing, that they can see, see a chemical reaction taking place... they can actually track that huge increase in temperature, and then how it slowly drops off. And that kind of is the, the number form of, you know, what's going on with, with the chemical reaction."

Seeing change in temperature and interpreting them as chemical reactions requires a complex arrangement of ideas and practices. Here though, Ms. Manchester aims for her students to see the change in temperature in a straightforward manner without the uncertainty and complexity that would come with building and using a data model to do this work.

Other times teachers described a desire for students to see statistical or mathematical practice in a straightforward way that minimizes complexity. For example, another science teacher in our project named Ms. Kent articulated significant complexity in the ways her students choose to generate data, but once she began talking about data analysis, she said students would "graph or show it [the data] in some way so that they can use it as evidence to justify whatever their claim was at the end of that lab or experiment." She did not elaborate on complexity in the work students would do, although she had just emphasized the complexity in creating data.

Problematic Seeing

When teachers wanted their students to engage in problematic seeing they aimed for them to see the complexity and uncertainty in making claims with data models. Instead of wanting students to draw a straight line from their data to a phenomenon or particular analytic technique they wanted them to problematize this line by encountering challenges, uncertainty, and multiplicity in data models and claims. For example, Mr. Trumbull described the following goals for his students when working with measures of center.

> "But help them see that the average is not the only way to calculate a best guess… But like I'd really like more than to see like the power of median. … And I think that, that is made really visible in in data where you're right, you calculate the mean, but what on earth is that really telling you? It's basically telling you nothing. Or, yeah, you calculate the mean, but look at what these outliers are doing to it, they're making it inaccurate."

He wanted his students to not only use mean and median, but to encounter the complexity of multiple ways to index center, and relations among distributional characteristics and these methods. At other times the teachers described a desire for students to see and question investigation protocols to better understand the challenges associated with creating data. Mr. Houston said he wanted students to ask questions like the following with data.

> "…what happened? How does my data compare to somebody else's data? Why did that happen? I guess just basic, basically, understanding what, you know, what we did and why it happened. Could it be something in the procedure? Could it be an error? Could it be an outlier? You know, how do we make sense of that? Should we do this again, you know, to see if we get the same results?"

In these examples, and across the comments in this category, teachers described a desire for students to see challenges and uncertainty in modeling the world with data.

Discussion

We believe that these differences in goals for teachers are consequential for the ways they engage their students with data. For example, if a teacher's goal is for students to primarily see a phenomenon in an unproblematic way, then they are likely to find complexity and uncertainty as a distraction. However, if a teacher aims for students to problematize the work of seeing with data models, then these features of an activity will be seen as productive. However, more work is needed to better understand the relationship between these different goals and teaching practice.

Finally, we do not see these categories as static characteristics of a teacher. All our teachers made comments across these two categories. However, there were differences in the proportion of comments made in one category or the other. So, although we don't believe these are static characteristics, we do think that they are consequential for teachers and influence their practice. If we are going to make progress in supporting students to learn about modeling data across disciplinary boundaries, then it will be important for us to continue to develop an understanding of how teachers conceive of their teaching practice as it relates to data and statistics across disciplinary boundaries of schooling.

PSYCHOANALYSIS AND PROBABILISTIC THINKING

Alexander S. Moore
Virginia Tech
asm1@vt.edu

Psychoanalysis is largely overlooked in mathematics education, yet is relevant to many aspects of the field, such as the institution of the school, curriculum and instruction, and content. Specifically, one content area where psychoanalysis is both exceedingly relevant and absent is that of probability education. In this critical literature review, I resurface important literature on the topic of psychoanalysis and probabilistic thinking, providing a Lacanian synthesis of its relevance in the future of probability education research. Important concepts such as subjectivity, epistemology, and linguistics are explored, all of which hold massive implications for probability education researchers in their interpretations of students' probabilistic thinking. The purpose of the paper is to demonstrate the relevance of psychoanalytic theory to probability education research, and to introduce the idea of such an alignment to researchers.

Keywords: Research Methods, Probability

The purpose of this literature review is double. First, literature on the topic of psychoanalysis and probabilistic thinking is resurfaced and synthesized for the mathematics education research audience. Second, a synthesis of the literature and related psychoanalytic concepts are elaborated and discussed from a Lacanian point of view apropos probability education research.

Psychoanalysis is a theory—juxtaposed against positive psychology—that acknowledges the existence of the unconscious and thus understands itself through its own limits; it can be thought of as the "first psychiatry" that existed before modern psychoactive medicines. The work of early pioneers such as Sigmund Freud is well-known in popular discourse although it is widely misunderstood by those who do not study it professionally. Perhaps the second most well-known psychoanalyst coming out of the Freudian tradition was the French psychoanalyst Jacques Lacan whose work is notoriously difficult to understand. Much of his published work comes from the transcriptions of his yearly *Seminars*. Despite Lacan being trained in medical school as a Freudian, he built on or reinterpreted many of Freud's foundational ideas after he began his own practice. As a result, Lacanianism has largely become its own school of thought in psychoanalysis, although it is based in the Freudian tradition rather than in the other major school of psychoanalytic thought—the Jungian tradition (see Bailly, 2009). The word "Lacanian" has come to represent "courageous and radical commitment to understanding the depth and vastness of the human condition, with full acceptance of the impossibility and ineffability of that task" (Gerson, n.d.).

Psychoanalysis is different from other types of psychological theories because it is largely based on speculative analysis of the analysand and their speech, and the interaction between their conscious and unconscious desires. An analysand can be an individual person, a group of people, or an institution (e.g., the state). In the case of mathematics education, all three are relevant: for example, a student or teacher, a classroom, and the curriculum or school itself as situated within a particular political and cultural context. While the case of the unconscious in a single subject (e.g., a student) might be obvious, the unconscious is also present in groups of people and institutions: in the form of spirit (e.g., Hegel's notion of world spirit), through the economy of ideology (see, for example, Žižek, 1989/2008), and by that which conditions discourses (Lacan, 1993). Additionally, psychoanalysis is not concerned with mathematical concepts' existence *as* *such* or what might be described as "out there" or as ontologically positive in-and-for themselves. Indeed, Lacan even used mathematics to develop a system of Lacanian Algebra that he used to describe concepts so that people would not fall prey to intuitive understandings of psychoanalytic concepts—a trap of the Imaginary (see next section; also see No Subject, 2019)—because there is no metalanguage that would guarantee the universality of mathematics through the conferral of meaning.[1] In other words, according to Lacan, the ingenuity of mathematical symbols *qua* signifiers is that you have "to explain what you are going to do with them" (Lacan, 1991, p. 2).

Background on Relevant Lacanian Concepts

Signifiers and Signifieds

The incorporation of Saussurean linguistics into psychoanalysis was one of Lacan's major contributions to psychoanalytic theory. Signifiers are, for Lacan, mental images of the sound of a sign. In other words, signifiers are the meaning(s) psychically assigned to a symbol, word, idea, or other sign by a subject, as interjected into an already-constituted network of meaning made up of other signifiers. Jöttkandt (2016) describes this relationship as:

> What one hears in speech is the signifier rather than the signified. The signified is not what we hear (in the auditory sense) but something that must be read. In order to signify, the signifier must undergo an act of signification. This process can be described as the signifier, *S*, becoming shot through or injected with signifieds, *s*, that have undergone a certain operation: a transfer occurs whereby a signified crosses over the bar [in Saussurean notion, *S/s*,] that separates signifier and signified to be a signifier, *S*. (p. 145)

A crucial property of signifiers is that they are meaningless and belong to a closed system of constantly re-conferred meaning, following the transference of meaning back to a signifier that signifies nothing:

> The signified is something quite different – it's the meaning [… that] always refers to meaning, that is, to another meaning. The system of language, at whatever point you take hold of it, never results in an index finger directly indicating a point of reality; it's the whole of reality that is covered by the entire network of language. (Lacan, 1993, p. 32)

However, this meaninglessness is what gives signifiers their power: "The more [a] signifier signifies nothing, the more indestructible it is" (Lacan, 1993, p 185). Moreover, the signifier is what constitutes[2] the subject: he[3] is merely a system of signifiers that, for himself, structure the ways in which he interprets the meaningfulness of signs in everyday life. Because signifiers *qua* signifiers are meaningless and closed, acting as a subject for another signifier to confer meaning onto, there is always one signifier missing at the beginning of the chain, thus rendering the whole chain meaningless. A string of signifiers only makes sense in retrospect by reaching the end by punctuating it, as evidenced by the necessity of having to hear an entire sentence before one can

1 Elaborating more on this point is outside the scope of this paper. Readers interested in more relevant discussion of philosophy of mathematics may find Jöttkandt (2016) to be of interest.
2 The field of the signifier is related to the field of l'Autre, which is the precarious Symbolic entity that—among other things—confers onto each person his subject position; it is only from this position that one begins to speak.
3 I acknowledge the failings of the English language apropos gendered pronouns. I use he/him/his in this paper in the admittedly archaic general sense to mean an individual Subject (one person), regardless of gender. I do not use they/them/their for that purpose because of the linguistic detraction that it makes from conceptualizing the Subject in their subjectivity, viz. situating the identifying voice in the radically-subjective first-person view (of the Subject). The distinction between he/him/his and they/them/there is purely linguistic.

retroactively assign/understand the meaning of the entire sentence, beginning back with the first word and the string of all words comprising the sentence.

The Structure of the Ego

In Freudian and Lacanian theory, the ego consists of three parts: the ideal ego, the ego-ideal, and the superego. The ideal-ego "stands for the idealized self-image of the subject (the way I would like to be; how I would like others to see me)" (Žižek, 2007, p. 80). The ego-ideal is "the agency whose gaze I try to impress with my ego image, the big Other who watches over me and propels me to give my best, the ideal I try to follow and actualize" (Žižek, 2007, p. 80). The Superego is

> the same agency (*l'Autre*) as the ego-ideal, but in its revengeful, sadistic, punishing aspect. It is what pushes us towards the expectation of certainty, even if certainty is absent—which it always is in actuality. Nothing forces anyone to enjoy except the superego. (Žižek, 2007, p. 80)

Further, the superego makes enjoyment an imperative. *Jouissance* qua enjoyment—in reality—brings as much pain as it does pleasure, so the superego is also responsible for things like the drive to do things that bring us pain. In late capitalism, Lacanian psychoanalysis elucidates that enjoyment is not only an imperative but has also become a "kind of weird and twisted ethical duty" (Žižek, 2007, p. 80).

The Psychic Registers: Imaginary, Symbolic, and Real

Lacanian theory is largely based on the structure of three psychic registers or realms of Lacan's theory of psychic reality: the Imaginary, the Symbolic, and the Real.

The *Imaginary* is the register of images ("picture thinking" or *Vorstellung*) and their relation to the ego. The *Symbolic* is the register of logic, meaning, and symbols as they determine the subject; for example, the Symbolic contains language and law, since they are always-already constituting the people who raise children into the same ordering structures. The *Real* is the register that resists representation, what cannot be symbolized, logically represented, or represented through pictures or *Vorstellung*, where words fail, "gut" feelings, anxiety, that residue that cannot be reduced, the foreclosed element that can be "approached but never grasped: the umbilical cord of the symbolic" (Lacan, 1979/1998, p. 280). In short, the Real is that which does not rely on my conception of it. Lacan describes it algebraically using Lacanian algebra because it is simultaneously already here and continuously emerging, and thus "cannot be conceived" (u/wokeupabug, 2015).

A newborn baby enters the Imaginary through not knowing that she is a separate person from the mother or primary caregiver; "as it gains a visual image of the world and itself"—for example, the first time she recognizes herself in a mirror—she "starts to understand that [she] is a distinct object" (u/wokeupabug, 2015).

The Symbolic can be described by the interactions experienced with other subjects: "Those we come in contact with use language to communicate and tell us how to see the world (how to Symbolize it). Eventually all experiences are filtered through language" (u/wokeupabug, 2015). This starts when the baby enters into language.

The Real cannot be defined but can be described through examples and metaphors. For example, the Real is evidenced in "[A]n experience or thought occurs that creates a response so sudden or inexplicable and that language we have does not have time or sufficiency to explain it and we experience something primal—it cannot be Symbolized" (u/wokeupabug, date).

Reddit user u/wokeupabug described the three registers as follows, using lay terminology and metaphor to craft a useful triad of examples:

> The *Imaginary* is like this: Suppose you think you're working late at the office and you think you're alone, and you start absently picking your nose while you work, then in the middle of it you realize your co-worker hasn't left yet and has totally caught you in the act. You suddenly feel very different about yourself, right? That's the Imaginary.
>
> The *Symbolic* is like this: Suppose you're at a party and you're meeting people for the first time, and after some basic introductions when you settle into the conversation, they ask what you do. Unfortunately, you've been depressed for the past year, you were doing school, but you failed a couple courses and didn't go this year, and you haven't been able to find a job in the meantime. You're kind of embarrassed and don't really know what to tell them. A couple years later you're at another party and the same thing happens, only now your situation has changed, and you report that you just finished your degree and are working a help desk job in an IT department with some good opportunities for advancement. You feel differently about yourself after giving this report about what you do, right? That's the Symbolic.
>
> The *Real* is like this: You're getting ready for work in the morning, running late, but you've got to iron your shirt. Ok, you iron it, get ready to head out, as you're putting your jacket on you remember you may not have turned off the iron. So you go check; actually, ok it's off. You head out the door but think you were actually a bit hasty, you barely glanced at the iron when you checked, and you're not really confident you saw it right. It'll only take a minute, you jump back in to check the iron; yup, it's off. So you head out, the whole time down the street you're thinking gee you probably should have unplugged it to make sure, you start imagining it catching something on fire and think about what an asshole you'd feel like if your house burnt down over something simple like this, and it drives you a bit nuts all morning. That's the Real. (u/wokeupabug, 2015)

Lacanian Synthesis of the Literature Results

Signifiers and Vindication, and the "Types" of Probability

Psychoanalysis first reveals that the misrecognition of signifiers—e.g., "probability" and "chance"—in probabilistic thinking is an important topic of study. This is not a novel focus of probability education research; quite the contrary, as probabilistic thinking is well-known to contain complicated disjunctions of meaning in the minds of students (e.g., Abrahamson, 2014; cf. Chassan, 1956; Jones et al., 2007). Chassan (1956) published one of the first papers on the matter. As with any writing, his claims must be considered within the historical context in which they were written. At the time, the emergence of quantum mechanics had created something of a philosophical crisis within the physics and mathematics communities, as the foundational tenets of determinism on which both fields had been built were up for question.[4] The development of probability theory had always been somewhat separate from the rest of the mathematics community. The philosophy that had guided the development of probability up until the middle of the 20th century had been mainly deterministic in nature before the advent of quantum mechanics created questions about determinism apropos mathematical philosophy. Chassan claimed that this existential crisis that the physics and mathematics communities were facing—the main contest of which was the philosophy of probability theory—could be solved through the use of psychoanalysis. "Probability theory is applicable when the initial state is so complicated that it is impossible in practice to ascertain it accurately enough to determine the final state uniquely…" (p. 56). This is precisely the same case as in the unconscious and thinking about

4 For example, the debate of Heisenberg's Uncertainty Principle.

probabilistic events such as causality and chance: that "nothing malfunctions more than human reality […] One is always being fooled" (Lacan, 1993, p. 82).

Chassan drew primarily on Freud's work describing the connection between determinism, chance, and superstitious beliefs,[5] in which he separates the commonly committed conflation of real chance with psychic accidents. For Chassan, the difference between "real" chance in the external world and the psychic reality of the person doing the thinking about it was not delineated in any mathematical literature. This naïve conflation was the cause of the philosophical conflicts developing over the (in)determinism of probability. Chassan, using Freud, sought instead to suss the external and psychic realities apart, one being a product of psychology and the other being a product of the conditions of the physical external reality. However, Chassan broke with Freud over his claims of causality, instead articulating a position that would later become more aligned with Lacan. Lacan's work was just becoming available in published form at this time; for example, Lacan's major break with the established Freudian psychoanalytic school had only occurred three years prior to this paper's release, in 1953, and at the time was only available as a French transcript of a talk he had given in Paris that year. That same year, in 1953, Chassan had written an analogous paper[6] to the 1956 paper, but focusing on the interrelation of *statistics* with psychoanalysis. Chassan stated that, "The acceptance of the usefulness of thinking in terms of probabilities in psychoanalysis confronts the research investigator who would seek to establish probability statements with considerations of observation and objectivity" (p. 58). The most relevant point he makes in both papers is that of intuition and *a priori* judgments—and how subjective experiences are the determining limits of them for an individual.

To shore up the relevance of signifiers to probabilistic thinking, I next discuss the concept of vindication—elucidated in the located literature— which implicates the importance of using psychoanalysis in research on students' probabilistic thinking. Moncayo and Romanowicz (2015) discuss the interesting psychological relationship between "certainty" of quantitative measurement in the soft sciences (such as education) against the—as they argue—more appropriate concept of probability. The chapter is a critique of the famous adage by Edward Deming: "In God we trust; all others bring data." The authors argue that within the quantitative paradigm, probability is the only appropriate numerical concept for measuring "the things that cannot be measured" in the soft sciences—as opposed to the "hard" causality. "Lacan distinguished between lawful regularity and causality and placed causality on the side of chance. On the side of chance, causality is the same as the absence of causality or causality in the form of a gap" (Moncayo & Romanowicz, 2015, p. 77). Here we begin to see the relationship between the unconscious and probability: the word "probability" was chosen when probability theory was developed out of the mathematical study of games as opposed to the rowdier term "chance," which connotes gambling and so forth. The signifier probability and the signifier chance ostensibly connote different things happening but in reality are the same. By my reading, the article shows that probability and the mirage of certainty are psychic products of the Real; thus, the normal distribution is a Symbolic distribution, representing regularities within the randomness.

A "personal" probabilistic understanding was further developed by van Fraassen (1983), who wrote about the difference between *personal probability* and *frequentist probability* in an edited volume that connected physics with psychoanalysis. At that time, with the advent of quantum

5 Viz. Freud (1938).
6 Viz. Chassan (1953).

mechanics becoming more salient, psychoanalysis was beginning to be seen as a useful tool in understanding the existential nature of the horizon towards which mathematics and physics were heading. In the chapter, van Fraassen (1983) attempted to establish connections between the frequentist approach to probability (counting frequencies of occurrences) and the personal approach to probability (subjectivist or Bayesian, dealing with degrees of belief in an event happening), stating that "the use of probabilistic language to express personal opinion about a single event can be understood in a way that avoids the major problems with which frequentists have struggled" (p. 295). He begins the chapter with a vignette:

> Yesterday I said, 'I promise to give you a horse.' But I did not give you anything, and today you accuse me of the heinous immorality of breaking a promise. No, I reply, I am not guilty of that at all, but only of the much lesser offense of lying. All that happened was that yesterday I stated falsely that I was promising to give you a horse. (p. 296)

Evaluating this vignette, van Fraassen argues that there are two ways to analyze attitudes: reasonableness and vindication. The former concerns the present, and the latter concerns the future. Further, reasonableness requires vindication: "Let the frequentist equate probabilistic expression of opinion with something else; and let him investigate the conditions under which such vindication is not *a priori* excluded" (van Fraassen, 1983, p. 297). Use of reasonable and vindication to analyze statements of personal or subjective probability address the failings of language apropos probabilistic concepts through what van Fraassen calls *calibration*. Calibration is a way of measuring or "frequentizing" one's subjective judgments apropos probabilistic statements "as indicators of actual frequencies" (van Fraassen, 1983, p. 300). It consists of evaluating one's personal probabilistic claims afterwards to see how well they fit the observed frequencies of events. Adjusting one's personal probability through calibration leads one towards what van Fraassen calls *coherence*. We can then assume that coherence is a frequentist's way of intentionally adjusting an individual's signifying chains apropos the language associated with the frequentist's claims and the subjectivist's claim. Through calibration, van Fraassen attempts to unify the divide between personal and frequentist probability, although the implications for psychoanalysis are not well sussed out in the chapter.

Joyce (2005) extended van Fraassen's arguments about the analytic potential of subjectivity, employing the notions of specificity, ambiguity, and sufficiency. In his paper, he focuses on evidence for probabilistic events, and claims that types, weight, and balance of evidence form a basis for subjective interpretation of probabilistic events. Consider a probability word problem that describes some conditions of an event, and perhaps an existing knowledge about how some of the events have already turned out. The problem is providing evidence in the form of those given statements. The individual subjectively interprets the statements of evidence, evaluating to what extent each piece of evidence exhibits specificity towards the probabilistic situation being considered, how much ambiguity there is around the conditions of the situation, and the extent to which the evidence given is sufficient for making a personal probabilistic statement (as informed by the non-personal evidence given) about the situation. It seems that Joyce's extensions of van Fraassen's arguments provide a finer grain of the subjectivist's reintegration to frequentism.

We can build on our understanding of Chassan through van Fraassen's intervention and Joyce's elaboration, in that psychoanalysis not only splits apart probability into what is "out there" and what is "inside us," but that psychoanalysis also allows us to reunify them through an interpretation of events *a posteriori*. In my interpretation the psychic registers of psychoanalysis reveal the following homology: Frequentist = Imaginary, Theoretical = Symbolic, Personal/Subjective = Real. Thus, psychoanalysis gives us a framework for understanding these three forms of probability in relation to each other.

The Superego and Desire

Britton (2021) argues that the "should" of superegoic expectation is used heavily in probabilistic thinking. Britton develops the notion of Belief/Doubt as an ego function that is mediated by the superego's expectations of "should." Crucially, these are psychic constructs which are separate from the material, external reality. This leads to implications for the way we understand what people think "should" happen, including the relations of causality with belief and counter-belief. The author gives an example of a case study patient: "She could not derive any security from belief unless she regarded it as knowledge; probability did not exist for her, only certain doubt or certainty" (p. 72). Thus, probability leads to anxiety because its signification is at conflict with the psychic reality of certainty and doubt. In external reality, there is only probability, but we psychically insist on certainty in our interpretation of the world (e.g., the superego's assertions). Thus, the superego filters the way in which the signifiers of probabilistic concepts (e.g., likelihood, chance) are being chained together in the unconscious.

Connecting desire and the superego, Rohy (2019) elucidates the connection between probability, psychoanalysis, and sexuality:

> Comparing the detective's investigative task to the process of psychoanalytic interpretation, Slavoj Žižek argues that 'every final product of the dream work, every manifest dream content, contains at least one ingredient that functions as a stopgap, as a filler holding the place of what is necessarily lacking in it.' This is the crucial clue, the telling symptom (p. 50).

Like a detective in one of Poe's mystery stories, the psychoanalyst's task is to transform what "appears to be accidental or random into a narrative of motivated causality. The difference is to a large extent one of perception: an anomaly that weak thinkers dismiss as 'coincidence' may in fact be nothing of the sort" (Rohy, 2019, p. 46). An example of this is the gambler's fallacy. The gambler's fallacy confronts the Real and the Symbolic through the failure of notions such as the anticipation of "being owed" or "being due." For Lacan, the Real cannot be represented or assimilated, whereas the symbolic is precisely the register of representation and assimilation. The Real, which creates the tension of the gambler's fallacy, opposes meaning, including causality. Our difficulty in thinking probabilistically might be related to the fact that we are socialized as gendered and sexualitied[7] people from childhood, assuming heterosexual necessity instead of queer accidentality, vis-à-vis suppression of the Real (see Jöttkandt, 2016; Tomšič, 2016). If true, this engendered orientation towards heteronormativity would function as a technology for predisposing us to think about "what should be the case" (heterosexuality and cisgenderism as "normal" or "standard"; what "should" be the outcome of a probabilistic event) when really there is no such thing: there is only maximum probability—viz. that most people, for biological reasons, are indeed heterosexual and cisgender—underlaid by motivated causality. My argument for this homology comes from the irreducibility of sexuality, in psychoanalysis, to meaning.[8]

---

7 Elsewhere (Moore, 2021), I have used this term in parallel with the term gendered to denote categorical determinations of the process of sexual identification, such as the same process that occurs in human socialization apropos gender.

8 Due to space limitations, I will not elaborate on this further here, although interested readers may find Zupančič (2017) of interest. I have been exploring this connection in my work elsewhere (e.g., Moore, 2022).

Conclusion: Towards a Future of Psychoanalytic Probability Education Research

Psychoanalysis possesses the potential to enhance the study of the teaching and learning of probability. There are several key concepts from psychoanalysis that provide a useful and innovative reframing of issues in probability education research. The first is the logic of the signifier and the three registers of psychic reality; they are both related to vindication and the different "types" of probabilistic thinking. The second is the superego and its complexification of the signifiers in probabilistic concepts.

To briefly recapitulate and close with an imperative takeaway, probability learning leads to anxiety because its signification is at conflict with the psychic reality of certainty and doubt. The superego drives towards certainty when it is not there. Thus, psychoanalysis affords a unique yet crucial perspective on understanding probabilistic thinking. Future studies into students' probabilistic thinking should take up these psychoanalytic concepts in theoretical orientation and methodological considerations.

BRIDGING FREQUENTIST AND CLASSICAL PROBABILITY THROUGH DESIGN

The frequentist and classical models of probability provide students with different lenses through which they can view probability. Prior research showed that students may bridge these two lenses through instructional designs that begin with a clear connection between the two, such as coin tossing. Considering that this connection is not always clear in our life experiences, we aimed to examine how an instructional design that begins with a scientific scenario that does not naturally connect to theoretical probability, such as the weather, may support students' bridging of these two models. In this paper, we present data from a design experiment in a sixth-grade classroom to discuss how students' shifts of reasoning as they engaged with such a design supported their construction of bridges between the two probability models.

Keywords: Probability, Design Experiments, Middle School Education, Integrated STEM.

There are distinct views of probability in the literature which differ not only in the way they define probability but also in the nature of their emerging solutions to the solving of problems (Batanero et al., 2016). The classical view of probability is one of the earliest approaches and is connected to chance in games. From this view, probability is considered as a fraction of the number of favorable cases divided by the number of all possible cases. This definition was created on the assumption that "all possible elementary events were equiprobable" (Batanero et al. 2016, p. 5), which is applicable to most situations in games. However, this view has been criticized because the idea of equiprobable outcomes is not always valid in natural phenomena.

The other most common approach, the frequentist view, sees probability as a convergence of relative frequency when a random experiment is repeated infinitely many times. According to Cosmides and Tooby (1996), humans have more experience with encountered frequencies in their observation of the world, therefore students would be more receptive to frequentist probability where data is collected through experience. In contrast to the connection to real-life experiences, the frequentist ideas of probability are not appropriate when discussing a single event or when the experiment cannot be repeated multiple times under the same conditions. This frequentist view is only an estimation of probability that results from a series of repetitions.

Considering the above, Lee et al. (2010) claim that since most everyday probabilistic situations (such as weather forecasting) "do not allow for the classical approach to probability" (p. 91), it is necessary for students to examine situations where it is possible to both calculate classical theoretical probability and make the connection to the frequentist experimentally collected empirical probability. Similar to Lee et al. (2010), many researchers have claimed that developing a connection between the classical and frequentist views is helpful for students to fully grasp the concept of probability (e.g., Henry & Parzysz, 2011; Ireland & Watson, 2009). During the learning process, students need to distinguish between the two models and understand when each one can be used for solving problems (Batanero et al., 2016).

Prodromou (2012) argued that while the two models differ, they are complementary and not mutually exclusive. She engaged pre-service teachers (PTs) in dice rolling tasks related to both theoretical and experimental probability and examined how they developed a bidirectional relationship between the two, explaining that "PTs perceived the theoretical probability as the intended outcome and the experimental probability as the actual outcome. In the opposite direction, PTs considered the theoretical probability as the target towards which the experimental probability is directed" (p. 866). This notion was also highlighted by Stohl and Tarr (2002), who reported that the tasks that engaged students in bidirectionality of probability helped students to develop robust inferences about probability. To engineer this bidirectionality, they started with coin tossing and dice rolling designs, and then used three different computer simulation tasks, two of them using experimental probability as a tool to evaluate theoretical probability and the other using theoretical probability as a tool to anticipate the result of the experiment.

Many supported that the connection between classical and frequentist probability is grounded in the Law of Large Numbers (LLN) (e.g., Drier, 2000; Prodromou, 2012; Stohl & Tarr, 2002), which states that larger numbers of trials performed for a given event lead the relative frequency for that event to approach the theoretical probability. A study by Aspinwall and Tarr (2001), examined how sixth graders' understanding of experimental probability related to sample size and the LLN using designs with flipping chips, spinners, and dice. They demonstrated that probability simulations can challenge students' preexisting conceptions. However, they also noted that there were challenges in developing the understanding of the role that sample size played in determining experimental probability through the LLN. Aspinwall and Tarr (2001) claim this theorem has been shown to be challenging and nonintuitive for students. Students may not recognize when to use the LLN (Fischbein & Schnarch, 1997), or they may believe that the LLN applies to small numbers as well (Tversky & Kahneman, 1971).

Researchers found that offering students multiple representations of data supports their understanding of the connection between theoretical and experimental probability. Stohl and Tarr (2002) reported that the use of graphs and tables enables students to see bidirectionality of probability by involving them in representing and analyzing data with different forms. Similarly, Ireland and Watson (2009) claimed that multiple representations in computer simulations can help students perceive how theoretical probability is connected to experimental probability. In their experiment with digital mixers and spinners, students made a connection between theoretical and experimental probability by comparing data in various representations.

Using computer simulations as a mode of representation provides students with the opportunity to collect large amounts of data in shorter periods of time, which addresses the limitations of time constraints and resources that Biehler (1991) argued students encounter as they explore the concept of probability. Computer simulations also support students' connection-making between classical and frequentist approaches of probability (Ireland & Watson, 2009; Prodromou, 2012). Abrahamson and Wilensky (2005) used modified coin flipping computer simulations to help students develop their understanding of experimental probability by bridging the gap of theoretical probability with simulating and collecting large amounts of experimental data. Paparistodemou (2005) conducted a study where students were able to manipulate aspects of the computer environment to affect the generation of random events. The students manipulated the simulation in multiple ways to make use of the LLN to achieve the target probability.

While many studies have examined how students construct bridges between the two models of probability, their designs involved beginning with a clear connection between the two, such as coin tossing or dice rolling scenarios (e.g., Abrahamson & Wilensky, 2005; Prodromou, 2012). However, our real-life experiences of probability, such as predicting the weather, do not always have clear theoretical probabilities that can be calculated. Consequently, we started with the conjecture that it is possible to support students' bridging of these two models by first engaging them with probability scenarios situated in the context of science. We hoped that this would make use of students' realistic experiences to construct more meaningful connections between the two models. Specifically, we explored: *(a)* What kind of design that starts with the frequentist perspective without a clear connection to the theoretical probability and moves to the classical perspective would support students' bridging between the two models? *(b)* How may students' reasoning progress as they shift between the frequentist and classical perspectives?

Methods

In this paper we report on the results of a whole-class design experiment (Cobb et al., 2003) in a sixth-grade classroom in the Northeastern U.S. The class met in ten 15- to 50-minute sessions via Google Meet due to COVID-19 restrictions. To test our conjecture we designed two simulations, one based on the frequentist and one on the classical model, along with investigation and interview questions. We chose a scientific context because our previous work (e.g., Panorkou & Germia, 2021; Panorkou & York, 2020) showed that sixth-grade students can engage meaningfully with mathematical concepts in a setting integrated with science concepts. We focused on the topic of weather because research showed that students consider weather events as a relevant context for probability discussions (Chick & Baker, 2005).

The Weather Forecast simulation (Figure 1) is based on the frequentist model and generates the results of an imaginary weather forecast. The chosen Data Set determines the forecasted percentages of days that are expected to be rainy and sunny. The Run Size determines how many times the simulation runs the experiment. The larger the chosen Run Size the more accurate the resulting forecast will be for the chosen Data Set. After exploring this simulation, students were asked to gather data about the results of different Run Sizes in a table and graph these values on a log-scale plot of Percentage of Rainy Days versus Run Size to observe how the results tend towards certain probabilities for each Data Set as the Run Size increases.

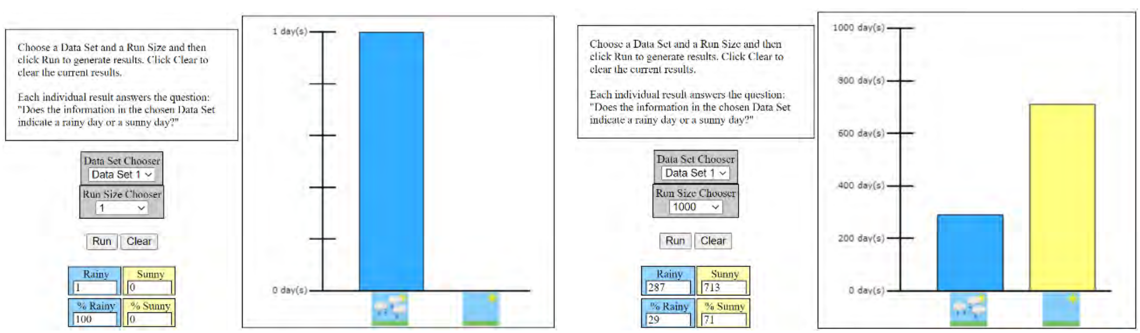

Figure 1: The Weather Forecast Simulation Showing Different Run Sizes for Data Set 1

The Chance of Rain simulation (Figure 2) is based on the classical model and represents weather data for every day during the month of June for 20 years in a certain location. The data is not based on a real location but was instead chosen to provide certain ratios of the different outcomes. Each of the 600 individual data points indicates if that day was sunny, cloudy, rainy, or stormy. The student can view a random day, a specific day, an entire specific month, or a bar chart summarizing all 600 days. As in the classical model, the probability of each weather outcome for any given day can be described by a fraction with the total number of days in the denominator. After exploring the simulation, the students were asked to gather data by clicking on the View Random Day button 100 times, recording what the weather was for each of these random days, and then comparing this to the probability fractions for each type of weather.

Figure 2: The Chance of Rain Simulation Showing the Different Data View Screens

In this paper, we focus on the analysis of one pair of students, Violet and Anne, to describe a chronological account of the progression of their reasoning about probability and the design decisions that the researcher made to support the development of their reasoning further. Of the three pairs of students recorded, this pair was chosen for an initial analysis due to completeness of data and their work with the research team member who was also part of the design team.

Findings

At the beginning of the design experiment, Violet and Anne were asked to state if they knew anything about weather reports or the concept of chance in predicting rainy or sunny weather. Violet made a connection to a recent snow day and mentioned weather forecasters talking about the chance of snow, saying, "There's a 50% of snow, 50% chance that snow might come. Well, when they say that they're not completely sure if it's going to come though." Her reasoning shows a classical understanding of probability as a percent.

Next, students were asked to explore the Weather Forecast simulation. First, they examined Run Size 1 for Data Set 1 (30% rainy, 70% sunny) and identified that it was sometimes rainy and sometimes sunny. As Violet said, "it only got rainy two times so it's not always rainy" showing the classical perspective of considering two rainy times out of the total number of runs. They then tried Run Size 5 and identified that it was now more likely for the predictions to be sunny than rainy. As Violet stated, this is because "it mostly shows that it's going to be more percent chances of being sunny than rain," illustrating that she was starting to notice a pattern in the data. Subsequently, students were asked to explore the larger Run Sizes (10, 50, 100, 500, 1000, 5000, 10000, 50000, 100000) and observed that there are usually more sunny than rainy days. However, they were not yet ready to bridge the connection to a specific theoretical probability.

In the next task, students were asked to use the simulation to record data in a table with the percent rainy and percent sunny for a single run for each size (Figure 3). When asked if they saw a pattern, Violet replied "I got 30 and 70, 3 times. … But I'm a little surprised I got the same one three times because I thought I was gonna get different more but then I got the same." This collection of data was challenging Violet's preconceptions about the expected probability.

They then graphed the data from their tables and compared their graphs to each other (Figure 3). Violet identified that their graphs were similar, but not the same: "When I got to 100 my number, her number, like the Run Size started to get a little different from 100 to 1000. But then when we got into the even bigger numbers, we had the same again." Violet was beginning to identify patterns in the Run Sizes, but the limitations of collecting random data was impeding her ability to make a claim that larger Run Sizes are more precise than smaller Run Sizes.

Run Size	% Rainy	% Sunny
1	0%	100%
10	30%	70%
100	28%	72%
1,000	31%	69%
10,000	30%	70%
100,000	30%	70%

Run Size	% Rainy	% Sunny
1	0%	100%
10	30%	70%
100	29%	71%
1,000	28%	72%
10,000	30%	70%
100,000	30%	70%

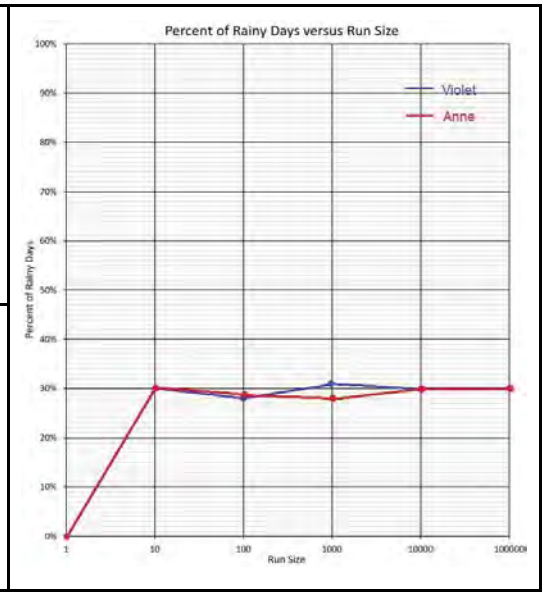

Figure 3: Recreation of Tables and Graphs of Data Set 1

Run Size	% Rainy	% Sunny
1	100%	0%
10	90%	10%
100	93%	7%
1,000	90%	10%
10,000	90%	10%
100,000	90%	10%

Run Size	% Rainy	% Sunny
1	100%	0%
10	100%	0%
100	88%	12%
1,000	90%	10%
10,000	90%	10%
100,000	90%	10%

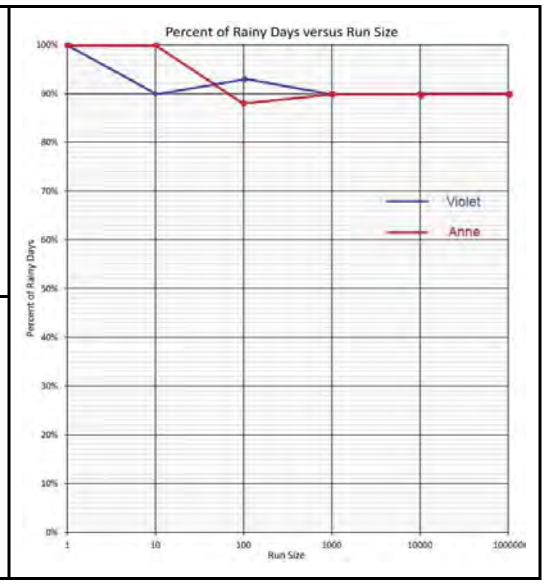

Figure 4: Recreation of Tables and Graphs of Data Set 2

The students went through the same process for Data Set 2 (90% rainy, 10% sunny). As Figure 4 shows, Anne got 100% rainy for Run Size 1 and 10, and 90% rainy for Run Sizes 1,000 to 100,000. When asked to make a numerical prediction about the chance of rain Violet replies, "there is 100% chance in the beginning of the day in the graph. But then it gets lower. So, I'll put it between, like 99 and 100%, it's gonna rain." Her reasoning shows that she erroneously considered the x-axis to represent time of day rather than Run Size and this led her to struggle in identifying what the different probabilities represented. The researcher then intervened to clarify this and asked her to explain what happens when the Run Size increases:

> Violet: I think you should run the simulator, seven times. Or a lot of times, because the number you get the most is probably the percentage of rain or the chances of rain, you're gonna get that day. Because if you run it one time, you're probably not going to get the right answer. Cause it could say that it's going to be 100% sunny when you run it one time, but it's probably going to be rainy that day. But when you run it like seven or more times, you're gonna get probably the same number like two or three times. But if you get it more than that, it means that it's probably going to be that weather that day.

Violet identified that there was a "right answer" or target theoretical probability that the experimental data should approach. She was also able to observe the limitations of small Run Sizes. However, for her a Run Size of "seven" or "a lot of times" was large enough to make a claim about the effect of the increased Run Size.

At this point the researcher modified the original design and discussed coin flipping and dice rolling aiming to examine whether the focus on the classical approach would help them in developing their frequentist understanding. Violet was able to bridge the connection between flipping a coin and its theoretical probability by saying there was "a 50% chance because there's like half a chance you're going to land on tails." They struggled with understanding the theoretical probability of the dice, but Violet used her understanding of experimental probability to bridge the connection to the theoretical probability by explaining the chances of rolling a one:

> Violet: Yeah, six possibilities, you can get it, but most of the time, you're not gonna get it. It's like, 10 out of 100, that you're probably going to get one. When you roll the dice, you're not going to get the number, most of the time, you're not going to get the number you wanted.

After this introduction to classical probability, they engaged with the Chance of Rain simulation and used the bar graph (Figure 2) to calculate the theoretical probability for each weather type in June (Figure 5, left). The students then collected 100 data points using the View Random Day button (Figure 5, right).

Weather	Days	Fraction of Total Days
Sunny	300	300/600 = 1/2
Cloudy	150	150/600 = 1/4
Rainy	75	75/600 = 1/8
Stormy	75	75/600 = 1/8

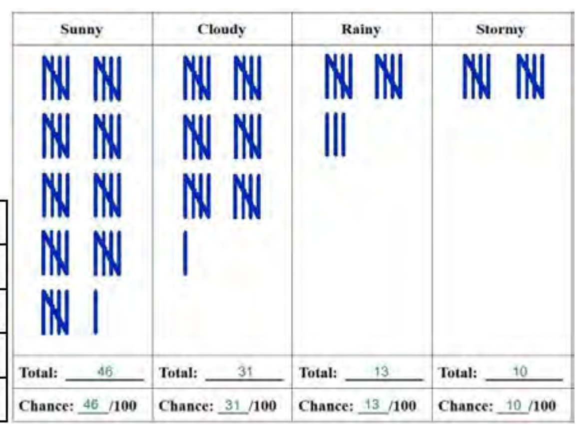

Figure 5: Theoretical and Experimental Probability for Chance of Rain Investigation

Working with the probabilities in fraction form required that they use strategies to compare fractions, which made connecting the probabilities more difficult. They discussed rainy and stormy which each had a theoretical of “one-eighth” and then created 12.5/100 as an equivalent fraction to compare it to their experimental 10/100 and 13/100. As Violet stated, “I tried simplifying some of them to see if I got closer to the same number.” They were able to connect the experimental to the theoretical probabilities. As Anne stated, “they’re all in the same thing cause like 10, if it was 11 it would have been more closer, like 11, 12, 13. But I think they’re like, equal.” They were then asked why they collected 100 data points, and not more or less:

Anne: So that you could get a good amount of like, sunny, stormy, rainy, and cloudy. And, it won’t have to only be sunny, cause maybe if you did 10, it would maybe be like 30 sunny maybe like two stormy, three rainy.

Violet: I do prefer 100 more than 10. But I tried it out. I clicked the view Random Day button 10 times. And I actually got rainy, stormy and cloudy. But I only got like two chances of sun.

They both saw the limitations of a small sample size and Violet even used experimental data to help support her point. At this point the researcher brought up the example of coin flipping again in another modification of the experimental design, to help illustrate what happens as the sample size increases. They discussed how it was more believable that they would get heads repeatedly with small sample sizes, but Violet explained:

Violet: When the number gets bigger, the more unbelievable it gets that you’re gonna get tails, or heads like that much. I mean, it could be possible to get heads or tails, like three or two times the same. … Because if I take a few minutes to flip my small watch 100 times, I’m most likely going to get tails and heads at the same time. Because like I said, there’s two sides of a coin.

Violet showed some understanding of the LLN and the advantages of larger sample sizes by using her understanding of experimentally flipping a coin and connecting it to the target theoretical probability of flipping a coin, bridging the frequentist and classical perspectives. Anne then showed similar reasoning when talking about the possibility of a computer simulation flipping heads 100 times in a row, saying, “there might be a 50% chance that the computer might just get like heads 100 in a row and then there’s like the other 50% chance,” showing that with large samples, she would expect the results to approach the target theoretical probability.

At this point they were asked to return to the Weather Forecast to continue their discussion on the LLN in a modification of the design. The researcher bridged the transition by continuing the discussion on the 100 data points collected and what they thought would happen if they collected more data. Both students agreed that collecting more than 100 would have been better with Violet saying, “if we did 200, the higher we go, I think it might be the easiest to compare them,” and Anne saying, “maybe if we did more than 100 maybe it would be like, close to each other. A little bit.” They had both explained the limitations of smaller sample sizes and agreed that larger sample sizes could make it easier to compare to the theoretical target.

However, when asked to draw conclusions about what happens as the Run Size gets larger from the graphs of the Data Sets, they still had difficulty connecting those thoughts to their analysis of the graphs. As Violet stated, “sometimes it goes higher, and then lower, and then it’s gonna go higher,” and Anne said, “it was one at the bottom, then at the top, then at the center, then at the top again.” Here they were focused on the variation of the data points and had not developed the covariational reasoning to connect their data to the Run Size. The researcher decided to prompt them to discuss the ‘gaps’ between their data points (Figure 4), which was a productive design modification:

Violet: [Looking at the right of the graph of Data Set 2, Fig. 4] Well, for the first three, there's not as big a gap because they're all 90. [Looks at the left of the graph] That's a big gap. Because for the last one here, it's 89. But this one's 100. That's sort of a big gap.
Anne: [Referring to Data Set 1, Fig. 3] Because you were comparing like there was a big gap or if they were closer to each other. Most of them were closer to each other, especially the 30 and the 29 and stuff.

This discussion was productive in helping them distinguish the pattern with smaller Run Sizes compared to larger Run Sizes. Violet was able to summarize this:

Violet: Because as larger as it gets, it shows how likely the number you picked is going to be the answer. Like in my graph as the numbers got bigger, it showed 30, two times. So that means it's gonna be 30% chance of rain. So as larger as the number is, is how it's going to be or how it may be. … Because the run number did get larger, and it did show why it's gonna be that percentage.

Violet's explanation shows her understanding of the LLN and how it can be used to approach the target theoretical probability or "answer." Anne mostly agreed with Violet's thinking but questioned what amount of data was sufficiently large. Despite this continuing limitation, Violet and Anne developed their understanding of experimental probability to predict a theoretical probability using the LLN, through their bidirectional engagement with the two simulations and the use of multiple representations of probability.

Discussion

Our results show that our design that started with a frequentist perspective without a clear connection to theoretical probability and moved to the classical perspective supported students' construction of a bidirectional link (Prodromou, 2012) between the two probabilities. While engaging in the simulations, the students' learning process was not linear but rather it was their transitions between the different representations that helped them develop bridges of the two models. Through these transitions, students developed an understanding of the LLN by emphasizing the strength of large numbers and the limitations of smaller Run Sizes.

The scientific context of the weather showed to be productive in illustrating the utility of probability for understanding phenomena in the real world. Bringing in examples of flipping coins and tossing dice helped bridge the gap for students in connecting the two probability models. Interaction with data by engaging with multiple modes of representations, including simulations, tables, and graphs, also fostered the students' understanding of this connection.

This experiment was limited as we only analyzed the reasoning of one pair of students. Thus, for future research, we would like to investigate other pairs to see how their connection of theoretical and experimental probability would develop. We would also plan to continue revising our design by exploring further how we can support students' struggles related to reading graphs, comparing fractions, and understanding what Run Size is sufficiently large.

Acknowledgments

This research was supported by a grant from the National Science Foundation (#1742125). The data presented, statements made, and views expressed are solely the responsibility of the authors. We would like to thank Jay Singh, Archana Prasad, Anthony Cuviello, and Richard Tashjian for their help in the design of the simulations and activities.

IN-SERVICE HIGH SCHOOL STATISTICAL TEACHERS' REASONING ON SIGNIFICANCE TESTS WITH SIMULATION

In this paper we address the following questions: How in-service teachers use simulation to solve p-value problems? And how do teachers reason when solving significance test problems with simulation? The answers to two p-value problems by 19 in-service teachers who worked in teams on an on-line update course are analyzed. The course was conceived as a design experiment. Teachers were able to learn to use the Fathom software, but some resistance to the informal approach is observed in teachers' need to make more calculations than necessary to solve the problems. Misconceptions about significance level, and the documented verificationist conception of statistical tests were also observed.

Keywords: Professional Development, Data Analysis and Statistics, Problem Solving, Technology.

Introduction

Significance tests have been subject of controversy. Some dissonance critique comes from their widespread use in experimental areas and users' overconfidence in its results, however most of the criticisms do not regard the tests themselves, but to the misuse of tests by experimental researchers (Batanero, 2000, p.75). Resonant harmony may come from statistical education that might contribute to the better understanding and application of statistical inference. Simulated sampling distributions (SSD) offer an alternative to teach significance tests that avoid its theoretical complexity emphasizing the statistical logic of its procedure. It seems that, after some instruction, high school students can achieve well within this so-called informal approach. However in-service high school teachers are not familiarized with it and little research has been done about their related reasoning. It is well known that hypothesis tests are complex and hard to understand because they relate multiple concepts (e.g., sampling, population, *p*-value, sampling distribution) and are not intuitive in nature (Lane-Getaz, 2017; Vallecillos, 1995). This complexity is usually avoided by university teachers by means of exposing the theme to its students as a mechanical series of steps that must be followed which helps to draw 'scientific' conclusions. However, a big part of the method and important details of the whys of this process remains unknown to a big amount of the population that yields to a misuse of tests, even from experimental researchers (Batanero, 2000). For over 20 years (e.g., Hesterberg, 1998), statistical education research has promoted the use of simulated sampling distributions (SSD) to teach an informal approach of hypothesis tests because "technology allows students to be directly involved in the 'construction' of the sampling distribution focusing on the process involved, instead of being presented only with the final result" (Ben-Zvi, Bakker, & Makar, 2015, p.298). However, and maybe due to the little time allocated in the curriculum to hypothesis tests at the university level, the classical approach is still the most common way to teach it. This has led to researchers in statistics education to explore the possibility of teaching the fundamental ideas of this topic from high school level (e.g., García-Ríos, 2017; Matuszewski, 2018) to foster the reasoning of students of those grades about samples and sampling (Ben-Zvi et al., 2015), empirical sampling distributions (Noll & Shaughnessy, 2012), and statistical inference (Saldanha & Thompson, 2014). But, as previously said, high school teachers are still not familiarized with this informal approach to significance tests. With the general objective of exploring this possibility, our research questions are the next two: How in-service teachers use simulation to solve *p*-value problems? How do teachers reason when solving significance tests problems with simulation?

Conceptual Framework

Simulated Sampling Distribution (SSD)

"The term *empirical sampling distribution* (ESD) refers to a finite distribution of sample statistics from repeated samples of a population" (Noll & Shaughnessy, 2012, p.514). An important feature of an ESD for teaching is that it can be obtained through a series of repeated sampling actions that the student can perform from a few instructions done in a rudimentary way with manipulatives and pencil and paper. An SSD refers to a simulated distribution, in our case, in Fathom (Finzer, 2014). An SSD is a concrete, simplified and approximated version of a theoretical sampling distribution. It depends only on three given conditions: 1) The sampling is random and with replacement, 2) A determined sample size and, 3) The proportion in the population of the attribute under study.

Significance Tests with Simulation

An SSD allows the researcher to calculate the probability that a randomly chosen sample will have a proportion p or another more extreme proportion. Such a probability is called the *p*-value. If the *p*-value of a given sample is less than a significance level α (small) the sample is unusual, and technically, the sample is said to be significant. That is, if it is assumed that a population has a proportion for an attribute (null hypothesis) and for some reason the researcher suspects that this has changed, a significance test is a process to argue in this sense. The logic of this test is to assess how unusual a given sample is, assuming the null hypothesis to be true. To accomplish this, it is necessary to generate an SSD with the proportion indicated by the null hypothesis. This SSD will permit us to estimate the *p*-value and compare it with a significance level α. An unusual sample (p-value $< \alpha$) would support the decision to reject the null hypothesis, otherwise there would not be enough evidence to reject it. In the present report we use the expressions significance test problems and *p*-value problems as synonyms.

Note: Both random sampling and sample size are crucial to ensure the quality of the inference. However, in this study they are considered implicitly, without promoting an explicit discussion with teachers about it.

Informal Inferential Reasoning

Informal inferential reasoning (IIR) is increasingly gaining significance in statistics education research (e.g., Bakker & Derry, 2014). In this study we follow Schlinder & Seidouvy (2018) adopting the definition by Zieffler et al. (2008, p.44) who described IIR as *"the way in which students use their informal statistical knowledge to make arguments to support inferences about unknown populations based on observed samples"*. It is important to acknowledge that this is a construct to describe the way in which *"students use their knowledge to argue and make statistical inferences about an unknown population based on observed samples, and without using the formal methods or techniques of inferential statistics, such as the use of the theoretical sampling distribution, standard deviation, standard score, etc"* (García-Ríos, 2017, p. 31). One of the purposes of this research is to explore how teachers react to this paradigm switch, that is, how easy it is to them to adopt the alternative informal approach and the use of SSD to make inferences, discarding formulas and traditional approaches.

Statistical Knowledge for Teaching (SKT)

With the overall purpose of organizing the course we divided the activities into two different categories. The first kind of activities assess the teachers' subject matter knowledge, related with their own conceptions and reasoning about significance test and the second, the pedagogical content knowledge, related with the students' conceptions, the teaching strategies and the curriculum knowledge. Both categories are part of the statistical knowledge for teaching (SKT) (Groth, 2007, 2013). It is convenient to mention that this framework was used as a theoretical guide to classify the activities, and that the tasks presented on this report are only related to the subject matter knowledge, which we can subdivide into two kinds of knowledge: common content knowledge, which is represented by teachers conceptions on significance tests, and specialized content knowledge, related with the software use and the generation of an SSD within it.

Background

It is known that students can establish relationships between the sampling distribution and the parameter with which it was generated and evaluate the probability of a statistic (Jacob & Doerr, 2013) and that high school students may achieve a good understanding of the relationship between the theoretical proportion in the population and the proportion in the sample (Batanero et al., 2020). Some of the findings when working with high school students with *p*-value problems similar to the proposed on this report are that they intuitively take the decision of rejecting or not the null hypothesis in three different ways: a) They look for the majority in the SSD forgetting the sample proportion; b) They compare the mode of the SSD with the null hypothesis, or; c) They do not use the SSD to take the decision, and only evaluate the sample proportion (Sánchez, García-Ríos, Silvestre, & Carrasco, 2020). The first two could be explained with the hypothesis that students interpret the SSD as a simulated population, this means that they are learning something which they will have to repeat (repeated sampling) with real populations if they want to make inferences. However, those conceptions seem to be overcomed when confronted with similar problems and teachers' feedback.

Little research has been done with in-service teachers at high school level. Matuszewski (2018) worked with three in-service teachers and found that it is important for teachers to have *"some form of multiplicative sampling reasoning"* (p. 223) in the sense of Saldahna and Thompson (2002) and to possess statistical vocabulary before being confronted with those kinds of activities. Matuszewski also found that after a few activities with simulation, teachers can improve their understanding on the logic of hypothesis tests. In our case, to design the course, it was also assumed that teachers may have the same conceptions of students when confronted with significance test problems (Thompson, Liu, & Saldanha, 2007).

Method

A twenty-hour on-line course with 19 high school in-service teachers was carried on in December 2021 by the authors. The purpose of the course was to instruct teachers on the SKT of the informal approach to significance tests. This report discusses only the first part of the course related to the subject matter knowledge and focuses on the observed teachers' reasoning on significance tests with simulation.

The course was imparted trough the Zoom platform. Sessions were divided into two types, plenary sessions and team working sessions. Plenary sessions were useful to expose the subject and instructions, and to discuss the solutions for the problems.

The overall course has been planned as a design experiment: with pragmatic as well as theoretical purposes, with carefully designed tasks based on discussion and existing literature, and with produced data that could be analyzed at several levels within a learning ecology that "include the tasks and problems that [teachers] are asked to solve, the kinds of discourse […], the norms of participation […], the tools and related material means provided, and the practical means by which classroom [instructors] can orchestrate relations among these elements." (Cobb et al., 2003, p.9).

Participants

The course was presented to professors under an inter-semester update scheme at a public high school in México. In addition to their particular interest in the content of the course (since they have many courses to choose from), teachers had the incentive to obtain points with which they would be benefited at work. Teacher's experience varied from two to twenty-five years teaching statistics at high school level.

From the nineteen in-service teachers, sixteen claimed to have studied hypothesis tests. However, only eleven professors indicated that they had taught hypothesis tests, perhaps because it is the last topic on their agenda. Only six teachers reported being familiar with Fathom. Thirteen teachers are engineers, five are physicists or mathematicians, and one is an actuary. In addition, among the participants there was one professor with a doctorate degree, fifteen with a master's degree and three had only a major's degree.

Tasks and activities

As an introduction to the course teachers were familiarized with Fathom with an exposition about how to simulate some basic probability models. Specifically, the simulation of tossing a coin and creating the relative frequency graph and graphing the sampling distribution of tossing a die. Then, they were taught how to create an SSD with the example of tossing ten times a coin and received a step-by-step pdf manual of how to create an SSD.

This report presents the analysis of the answers to two significance test problems (see Appendix A). With the overall purpose of presenting an informal simplified version of significance test to teachers, proportion problems with categorical variables were chosen. Those kinds of problems permit the teachers to confront students with a simpler version of significance tests avoiding explanations about, for example, statistics parameters or more complex statistical tests as means of comparison.

Those problems were presented to teachers after the introduction session in the 2nd and 3rd sessions. Teachers had one hour to answer each problem. Six teams of teachers were formed. Not all the teachers were present during the sessions, so teams had two or three participants. Teams were created trying to equilibrate the experience of teachers, so almost all teams had at least one ten or more years' experienced statistics teacher. Team working served teachers to answer the problems and create a report that they were asked to upload to a shared folder. Between the first and the second problem we had a plenary discussion in which two teams of teachers exposed their answers and received feedback. Only the plenary sessions were videotaped, and only one answer was received by each team, which, with the videotaped sessions, composes the material of analysis for this report.

Analysis

Answers were analyzed at two different levels. The first one was with a focus on the use that teachers made of the software. The second with a focus on their reasoning about significance tests. For the first analysis five specific items were chosen to measure how teachers used the software. Those were the simulation of the urn, the simulation of one sample, the repeated sampling simulation, the generation of the sampling distribution, and the use that teachers made of the SSD to make inferences (see Table 2). Each team received a 1 if evidence of the item was present in their response or a 0 if not. The totals per problem were calculated to compare how they evolved between the first and the second problem. Two different phenomena were observed in the teachers' answers. Some of the teachers already had experience with Fathom, so they used more tools than necessary to make the decision. On the other hand, some teams were not familiarized with it, so they misused the software. Those characteristics were coded as "over simulated" and "under simulated" respectively (see Table 3). Finally, a brief description of how teachers used the technology was done. Combined, those three items permitted us to better understand how the teachers used technology to simulate distributions and make inferences.

For the analysis of the teachers' reasoning about significance tests, a two-way reading was carried on over the answers teachers gave to both problems. The first consisted of the description, comparison, and coding of answers to observed patterns. Then, the codes were transformed into categories that formed the basis of the review on a second way analysis. Each answer was then analyzed systematically through this lens, receiving a 1 point if the code could apply to the answer or a 0 if not. This permitted us to dismiss the codes that only appeared once.

Once this classification was made, more specific descriptions of the categories were done, and answers were chosen that were representative of each code. A theoretical interpretation of those codes is discussed in the conclusions.

Results

Table 2 shows the totals that teams obtained per item in simulation. Precise descriptions of how teachers missed the points are given down.

Table 2: Teachers' use of simulation

	Urn simplified representation	**One sample simulation**	**Repeated sampling simulation**	**Generation of SSD**	**Correct use of SSD as a measure of variability**	**Total**
Problem 1	3/6	6/6	5/6	5/6	4/6	23/30
Problem 2	6/6	6/6	6/6	6/6	4/6	28/30

On Problem 1, since the null hypothesis was a half-divided population, it was sufficient to simulate an urn with two balls. One of the teams simulated this hypothesis with a 1000 random pick of balls (p=0.5), which gives an approximation of the null hypothesis, but is more complex than the necessary. This team received a 0 in the "urn simplified representation" and was classified as "over simulation" in Table 3.

Table 3: Under and over simulation

	Under-simulation	Precise simulation	Over simulation
Problem 1	**1/6**	**2/6**	**3/6**
Problem 2	**0/6**	**3/6**	**3/6**

Table 4 shows the codes that we obtained with a short description on the second column and a brief example of a representative answer for each code in the third column.

Table 4: Codification

Code	Description	Example
Correct H0	Teachers correctly define the null hypothesis (In Problem 1 p=0.5 and in Problem 2 p=0.1)	On Problem 1, teachers simulate an urn with two balls, one with an "N" and another with a "P". This is enough to simulate a half divided population.
Correct answer	Teachers correctly decide to reject or not the null hypothesis (In Problem 1 they must reject it, and in Problem 2 not)	Team 4 responded to the first question of Problem 1: *"We consider that the information obtained from the sample is sufficient to reject the hypothesis that the population is divided in half"*
Hypothesis tests	Teachers transform the significance test problem on a hypothesis test problem proposing an alternative hypothesis	Team 3 answer to the first and second questions of Problem 1: "*Null hypothesis: p=0.5* *Alternative hypothesis: p>0.5* *The null hypothesis is rejected (p=0.5), the alternative hypothesis is accepted (p> 0.5), so what is stated in the problem is correct"*
Verificationism	Teachers understand significance tests as a process to verify or tests a hypothesis	Team 5 answer Problem 1 arguing that: "*The information obtained from the histogram proves that the probability of consumption is greater for the consumption of coca cola."*
Misconception about significance level	Teachers understand significance level as an interval, if the proportion of the sample falls within this interval they said it is 'significant', so they do not reject the null hypothesis	Team 2 answer Problem 2 arguing that: *" Of 5000 samples of size 120, drawn from a population where 10% of the items are defective, in 14.64% of them the items are defective, therefore, the number of defective parts that came out in the sample is within the level of significance"*
Mistrust on sample or sampling size	Teachers argue that 'if the sample size was bigger, results were better too'. Some of them reason that if the simulated samples were more, the results were better too.	Team 4 answered the 4th question of Problem 1 arguing: *"We cannot be certain that this is how the general population behaves. We could increase the sample size (over 180) and the number of cases in the simulation (over 500) to increase certainty"*

Another example of "over simulation" was one team that, on Problem 1, having correctly simulated the SSD also used Fathom to calculate the means and standard deviation of samples. This team took the decision of rejecting the null hypothesis based on those calculations, and not on the proportion of samples that fell in the queue of the SSD. This team also received a 0 in the "Correct use of SSD" in Problem 1. One team, in Problem 1 only simulated 100 samples in the repeated sampling simulation item, which is not enough to approximate the normal distribution, so this was classified as under-simulation. Their decision of rejecting the hypothesis was made only based on the proportion of the real sample (a misconception observed in high school students too (e.g., Sánchez et al., 2020)). In general, the plenary discussion of the first problem led the participants to have better results in the second problem as shown in Tables 2, 3 and 5. An extended discussion about those results is presented in the conclusions.

Table 5 shows the frequency of appearance of each code in each of the problems. The two first codes could be considered as qualitatively different to the others because they could be measured as a yes or no answer. However, both types of codes are presented in the same table to contrast them.

Table 5: Frequencies of Codes

Code	Problem 1	Problem 2
Correct H0	5/6	6/6
Correct answer	4/6	6/6
Hypothesis tests	2/6	2/6
Verificationism	3/6	0/6
Misconception about significance level	1/6	3/6
Mistrust on sample or sampling size	2/6	1/6

Discussion and Conclusions

Our research questions were the next two: How in-service teachers use simulation to solve *p*-value problems? How do teachers reason when solving significance test problems with simulation? Most research on statistical knowledge for teaching has been done with pre-service teachers (e.g., Batanero et al., 2018; Thompson et al., 2007) but little with in-service teachers. Part of our work was made based on the hypothesis that in-service teachers may have the same misconceptions as students when confronted with similar problems. We found that this could apply in some cases, as in the difficulties presented to understand significance value (misunderstood as an interval of acceptance of the null hypothesis), in the intuition that bigger sample sizes are more representative of the population, and in the verificationist conception of statistical tests (see Table 5). However, important differences were observed when working with experienced in-service teachers. It seems that, contrary to the students, and to pre-service teachers, in-service teachers reasoning about *p*-value problems may be strictly procedural and conceptually misunderstood, that is, their intuition is to use calculations and formulas (as standard deviations and standard scores) and specific concepts as significance level, even if sometimes misused (see Table 5). This phenomenon could generate resistance when confronted with a different approximation to the same theme. The approach to significance tests with simulation promotes the generation, visualization, and interpretation of an SSD. Fathom offers the possibility to reduce calculations to the minimum (replaced with knowledge of commands), favoring the understanding of the logic of significance tests. But in-service teachers' intuitions made them calculate the exact values, maybe, as looking for certainty to corroborate the observed in the SSD. How would this mistrustfulness about the process manifest in front of students? Positive observations are that in-service teachers already interpret SSD as a mathematical entity to measure variability that may replace the normal distribution, and that, after a little feedback, they start to substitute their formal knowledge by the alternative informal approach to significance test.

Informal and formal approaches to significance tests are not presented as contrary versions, but they are the opposite and complementary sides of a continuum in which formality and informality become relative. One of the objectives of this course was to show to teachers the way in which students can go from one side to the other, following a more intuitive way aided by technology. It was observed that the manipulation of the software was not a barrier for in-service teachers. Limitations are in the interpretation teachers made of SSD, and more research must be done in this sense to reduce the gap between students' intuitions and teachers' procedural formality. That is, it must be understood by researchers and teachers that the use of this alternative approach to significance test does not guarantee by itself the correct interpretation of the logic behind statistical inferences.

Some limitations of our design were that the chosen problems only confronted teachers with a part of the statistical cycle (the inference), and not with the overall scientific process of posing questions, planning an experiment, collecting, and organizing data, and obtaining conclusions. Since our research is centered on statistical reasoning and not on statistical thinking this is not a problem to us; yet it could be from the part of teachers since it is recommended to teach all the cycle and not only present to the students the inferential logic. One suggestion is that problems could be accompanied with theoretical text and discussions to familiarize teachers with results of research, for example, about the misinterpretation of significance value. During the last session teachers expressed their interest to use this informal approach with their students.

Appendix A

Problem1

It is traditionally believed that half of the population that drinks cola prefers Pepsi, and the other half prefers Coke. However, for advertising purposes, Coca Cola advertising presumes that the majority (more than 50%) of the population that consumes cola prefers Coke instead of Pepsi. To support this claim, he surveyed 180 randomly selected people who regularly consume soft drinks. Of the 180 participants, 104 people preferred Coca Cola. Is the sample information obtained sufficient to reject the hypothesis that the population is divided in half at a 5% level of significance?

Correct answer: Null Hypothesis (H_0): p=0.50, N=180, *p*-value=0.021, H_0 is rejected.

Problem2

If the daily production of a factory machine has more than 10% defective items, it needs to be repaired. To check the quality of the machine, the supervisor takes a random sample of 120 pieces of the day, and this contains 16 defective pieces. With these data and a significance level of 5%, should the supervisor request to repair the machine?

Correct answer: Null Hypothesis (H_0): p=0.10, N=120, *p*-value=0.143, H_0 is not rejected.

Both problems were accompanied by the following questions

1. Answer the problem
2. Explain your conclusion
3. Detail step by step how you arrived at your answer. You can use images of the program (print screen) to have a complete report.
4. How sure are you of your conclusions?

Acknowledgements

The research reported in this paper had the support of a CONACYT scholarship.

LEARNERS' USES OF DESIGNED COMPUTER SIMULATIONS IN PROBABILISTIC AND STOCHASTIC SETTINGS

Karoline Smucker
Eastern Oregon University
ksmucker@eou.edu

Simulations play a key role in statistics and probability education, and are important tools for students and teachers. This report presents preliminary findings from design research investigating the impact of computer simulations on learners' approaches to tasks involving probabilistic modeling, sampling, and stochastic reasoning. Five preservice secondary mathematics teachers engaged with a series of seven tasks, with a goal of understanding their use of the computer simulations in the course of problem solving. The designed simulation environments were created using the Common Online Data Analysis Platform (CODAP). Analysis of one participant's approaches suggests that the simulation was used in several distinct ways; in particular it was used to confirm, to test, and to investigate/refine.

Keywords: Technology, Data Analysis and Statistics, Probability, Design Experiments

Instruction in statistics and probability has long relied on the use of both physical and virtual simulations. Research suggests that these tools can be used for a variety of purposes, including to test/develop hypotheses about probabilistic models (English & Watson, 2016; Konold & Kazak, 2008), develop understanding related to sampling and variation (Saldanha & Thompson, 2014; van Dijke-Droogers et al., 2020), and understand or apply randomization-based procedures within statistical inference (Garfield et al., 2012; Watson & Chance, 2012). In some instances, learners may utilize or design a simulation environment to model a setting where the underlying probability distribution is known (Ferreira et al., 2014; Kazak et al., 2015), while in other instances learners may be asked to make inferences in a scenario where the underlying model is "hidden" in some way (Konold et al., 2011; Stohl & Tarr, 2002).

While all of this research showcases the many uses for computer simulations in statistics and probability instruction, less is known about why learners may use a simulation in the course of problem solving. This is especially important to consider in light of recent advances in software like the Common Online Data Analysis Platform (CODAP, https://codap.concord.org) which gives students the ability to easily engage with designed simulations or create their own models. Both researchers and teachers must consider why and when students might utilize these tools. This design research used clinical interviews to investigate the following question: for what purpose do learners use a computer simulation environment to tackle tasks involving expectations, likelihoods, and drawing inferences based on both known and unknown distributions?

Theoretical Perspective

This research considers the ways that learners (specifically secondary preservice teachers) engage with computer simulation technology in probabilistic and stochastic contexts. From a sociocultural perspective, tools play a key role in mediating learning (Vygotsky, 1987); it is of interest to understand how specific simulation tools are utilized by learners in these contexts (Kazak et al., 2015), especially as these tools become more widely available. Researchers must also consider the affordances of the specific tool being used (for example, what representations are available and what variables can be manipulated), and how these may impact learners' approaches and use of the technology (Bumbacher et al., 2018). It has been suggested that computer simulations can play a key role as learners engage in inquiry based on constructivist principles including discovery learning and conceptual change (Lane & Peres, 2006). In discovery learning, learners are asked to hypothesize about what they believe will occur, test it empirically, and then attempt to explain their results, especially any conflict between their observations and predictions (Ireland & Watson, 2009; Sharma, 2016). We attempted to gain understanding of how learners use specific simulation environments in the course of problem solving, including whether/when they propose solutions or make predictions and how the simulation impacts their conclusions and/or confidence.

Methods

Design principles were utilized in this investigation. This type of research attempts "to develop a class of theories about both the process of learning and the means that are designed to support that learning" (Cobb et al., 2003, p. 10). This methodology is highly interventionist, and utilizes cycles of implementation and reflection to iteratively test hypotheses about thinking and learning, often through the use of designed tasks and activities. Theory which is built within design research is expanded and/or refined as it is tested in new contexts.

A series of five semi-structured clinical interviews (Goldin, 2000) was implemented virtually via Zoom with five preservice secondary mathematics teachers in Summer 2021, investigating their approaches to a designed sequence of seven tasks using the CODAP sampler tool. This tool allows the user to adjust the type of sampler, along with the number of items/samples drawn, and create/organize various representations of data gathered by the sampler. The designed tasks fell into two primary categories. Some tasks involved known theoretical distributions (like the binomial distribution), while for others the distribution was unknown (and involved a mystery sampler). Five of the designed tasks involved known distributions, while two involved unknown distributions. The tasks were selected, modified, or created based on contexts found in prior research related to sampling and probabilistic/stochastic modeling (i.e. Ferreira et al., 2014; Kazak et al., 2016; Konold et al., 2011).

Data included video recordings of the Zoom sessions, along with still images of any written work and CODAP screenshots. Following principles of design research, analysis was both prospective and retrospective (Cobb et al., 2003). After each round of interviews, the research team met and considered changes to the order of tasks or specific prompts based on what occurred. After the interviews were complete, more in-depth analysis of the data began, highlighting when and how simulation was utilized by the participants. For this paper, we will consider the work of one participant, Bridget (a pseudonym).

Preliminary Findings

Three distinct uses of simulation emerged as Bridget engaged with the designed tasks: simulation as a tool for confirmation, simulation as a tool for testing, and simulation as a tool for investigating and refining. These uses were related to the task context (known vs. unknown distributions) and Bridget's confidence in any solution she had prior to accessing the simulation.

Simulation to confirm

In several instances, the simulation was utilized primarily as a confirmation tool after Bridget had reached a solution she was confident in. When considering Katie's Walk, a task which prompted Bridget to investigate the fairness of Katie's plan to visit one of five friends based on the results of four coin flips (traveling north or east after each flip), Bridget created a systemic list prior to accessing the designed simulation environment which included all 16 possible outcomes and which friend would be visited (Figure 1, left side). She used this information to justify her conclusion that Katie's plan is not fair by calculating the likelihood that each friend would be visited and connecting it to the number of heads flipped.

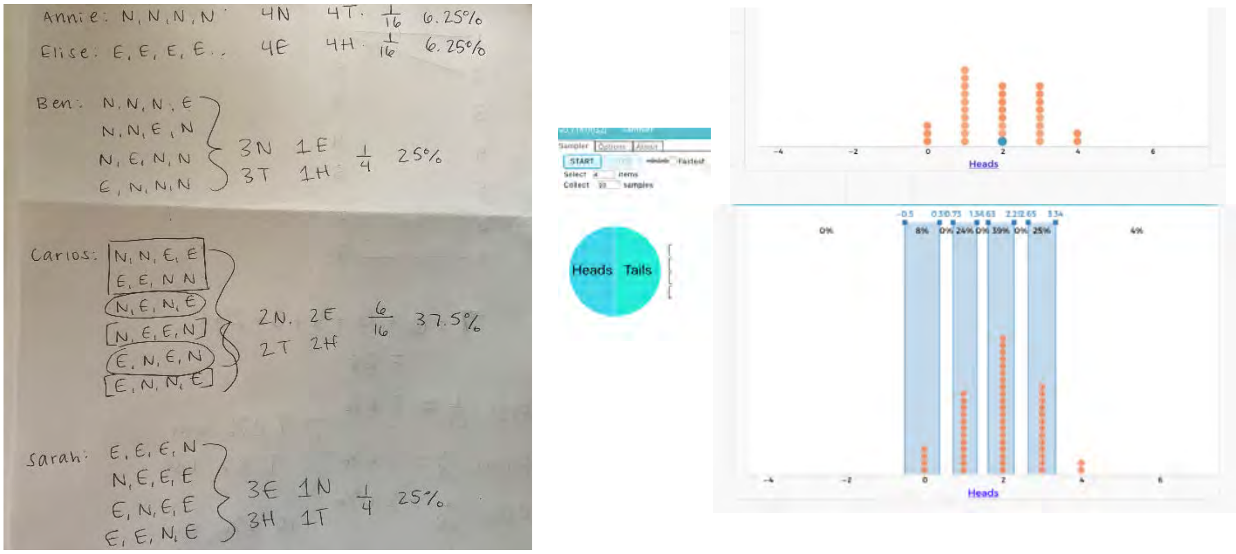

Figure 1: Bridget's initial work (left) and graphs in the simulation (right) for Katie's Walk

When Bridget finally accessed the simulation, she already had a solution that she was very confident in. In this instance, the sampler was already created with a pre-made spinner representing heads/tails, along with a graph which would showcase the number of "Heads" for each set of four flips. Bridget collected trials until her data "matched" the solution she had in mind. When her initial data (31 trials, top graph) did not have Carlos (2 Heads) visited the most, Bridget said, "I don't think this simulation is wrong, but I don't think what I wrote is wrong either . . . I would have liked for them to match". She then collected 20 more trials (bottom graph), and felt much better about this result, saying, "Aha! This is kind of the picture I had in my head". At this point, she felt no need to collect additional data because "there's nothing really that I'm questioning". She only felt the need to collect data until it confirmed her expectation.

Simulation to test

Another use of simulation occurred in situations when Bridget was testing a proposed solution. This involved contexts where she was less confident. One example of this is the Chip Bag task, which asked her to consider what would happen if two poker chips were drawn from a bag containing 3 green chips and 1 blue chip (theoretically the likelihood is 50/50 to draw two greens versus one of each color). Bridget's initial hypothesis was that she would be most likely to draw two green chips because of how many greens were in the bag, but she struggled to explain why this would be the case. She then stated that she would like to "set the situation up on the website" (CODAP), and created a mixer which modeled the context. In this instance, the simulation was not being used to confirm a solution she had high confidence in, but to test an idea that she was unable to explain outside the simulation.

Bridget first collected 20 samples, and found that getting two greens was more frequent (12 vs. 8). This appeared to align with her hypothesis, but she noted that 20 was not very many samples. She then collected another 80 samples and was surprised to see two greens become slightly less frequent than one of each color. She then collected an additional 200 trials which continued this pattern. This caused Bridget to reconsider her original hypothesis. She said, "I don't really feel like that's my hypothesis anymore; I kind of want to let that go". Utilizing the simulation gave Bridget evidence to reject her idea that drawing two greens was the most likely outcome, but the simulation did not provide her with insight on what a new hypothesis might be. She said she wanted to "go back to the math" and consider how she might model the context.

Simulation to investigate/refine

The third distinct way that Bridget utilized simulations in her task approaches was as a tool for investigating and refining her ideas. This primarily occurred as she engaged with tasks involving an unknown distribution. In these instances, Bridget was content to present an approximation as her "final" solution. She gained confidence in her ideas/approximations with increasing data.

For example, as Bridget engaged with the Mystery Marble Bag task, which involved sampling from a hidden bag of marbles of various colors in CODAP, the mystery nature of the task led Bridget to immediately begin her investigation in the simulation. She collected 10 marbles, then 15, then 30, and finally several sets of 50 as she considered what she might be able to say about the bag's contents. Based on her first sample of 50 including 31 greens, and being told that the bag had 180 total marbles, she first predicted 111 green marbles using a proportion, stating that this would be "a rough estimate", and to get a more precise solution she could "do more samples". This eventually led her to take nine additional samples, calculate the average number of greens (32.4), and use a proportion to get a more "exact" estimate of 117 greens. Bridget believed that she could continue this process and make her estimate more precise, but seemed confident that this approximation was close to the true value. For Bridget, use of the simulation as a tool for investigation and refinement was characterized by increased confidence as she collected more data, a willingness to provide approximations as solutions, and a belief that while she could continue to collect data, what she had was enough to make tentative inferences.

Discussion/Limitations/Next Steps

This paper provides initial analysis of one participant's use of the designed computer simulations. Bridget utilized the CODAP simulations in three ways. In instances where she had a clear solution, she collected data to confirm her theoretical ideas. She also utilized simulation as a tool for testing her ideas when she had less confidence; this provided evidence as to whether her hypothesis had merit or if she should let it go. Finally, in cases where Bridget considered an unknown distribution, she investigated the context and gained confidence through collecting data to refine her ideas. She was content in these instances to provide approximate values as her solutions. Understanding the ways that learners may utilize simulation technology in probabilistic and stochastic settings is important for researchers and teachers as they attempt to understand student thinking in these areas and develop appropriate simulation-based activities. For example, collecting data in pursuit of a specific results (simulation to confirm) is not acceptable practice when performing statistical analysis and inference; this is something teachers and researchers may need to consider further.

However, this analysis represents only one learner's approaches, limiting the scope of these tentative/preliminary conclusions. The research team is currently considering the other four participants and how they compare to Bridget. Initial analysis has shown some similarities to her work (especially the use of the simulation as a confirmation tool), but more in-depth analysis is needed. In addition, this study considered one specific group of learners (secondary preservice mathematics teachers). In order to create a more comprehensive model of how learners use computer simulations in probabilistic/stochastic settings, future iterations of this design research will investigate different groups (for example K-12 students, other groups of undergraduates) and contexts (for example students working in pairs/groups or in a classroom setting).

INVESTIGATING CRITICAL STATISTICAL LITERACY HABITS OF MIND

Nina G. Bailey
University of North Carolina at Charlotte
nbaile15@uncc.edu

As data drive our world and decisions, there has been a consistent call for statistical literacy (SL) and data science in K-12 mathematics by researchers and professional organizations over the last few decades (e.g., Craig, 2018; Gal, 2002; Gewertz, 2020; National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010; Wallman, 1993). More recently, this call has shifted toward including SL from a consumer orientation and has been amplified by the need to consume statistical information and avert misinformation amidst the COVID-19 pandemic (e.g., Engledowl & Weiland, 2021; Watson & Callingham, 2020). SL is conceptualized from the consumer orientation as the skills needed to effectively make sense of statistical messages in the real world. Despite this growing emphasis on SL and data science, there is a disconnect between the skills needed to effectively consume real world statistical messages and what is taught in schools (e.g., Nicholson et al., 2019). All of which illuminates the need for articulating Critical Statistical Literacy Habits of Mind (CSLHM) for making sense of such messages, particularly using a critical lens. The purpose of this study is to explore the similarities and differences of how people enact CSLHM when presented with data representations from the media.

This study draws on Gal's (2002) SL model and Weiland's (2017) framing of critical statistical literacy (CSL). Gal's work provided a solid starting point for describing the habits of mind needed to enact CSL. Weiland's CSL framing more explicitly stressed the importance of placing emphasis on sociopolitical inequity and the actions needed to disrupt and dismantle such inequity. Specifically, I use the CSLHM (Authors, 2019, under review) which operationalizes the habits of mind needed to enact CSL. The CSLHM framework has seven components: questioning sample size and methods, recognizing appropriate statistics, desiring additional information, acknowledging alternate explanations, recognition of one's own sociopolitical consciousness, employing active citizenry, and acknowledging ethical considerations.

In this instrumental multiple case study (Yin, 2018) there were four cases; each defined as a group of individuals with similar backgrounds with respect to statistical knowledge, statistical self-efficacy (Finney & Schraw, 2003), and critical consciousness (Diemer et al., 2020). There were five participants in each case. Each participant took part in a semi-structured task-based interview (Goldin, 2000) in which they were asked to make sense of data representations shared on Twitter. All tweets included a static or interactive graph and were related to social justice issues. Data were first coded using the CSLHM framework (DeCuir-Gunby et al., 2011). Next, I looked for emerging themes across the codes to write up case summaries. Preliminary findings suggest that statistical knowledge, statistical self-efficacy, and critical consciousness appear to influence the enactment of CLSHM. The poster will share further detail on the operationalization of Gal's (2002) and Weiland's (2017) framings to develop the CSLHM, the case criteria, findings specific to each case, a cross case comparison, and implications for how to best support learners in developing CSLHM in any environment.

DATA SCIENCE STUDENTS' DEVELOPMENT OF COMPUTATIONAL ACTION: A DESIGN-BASED RESEARCH STUDY

Karle Flanagan
University of Illinois at Urbana-Champaign
kflan@illinois.edu

Keywords: Data Analysis and Statistics, Social Justice, Design Experiments

Poster Proposal

In today's age of information and data, data science literacy is necessary. Students in all disciplines need basic data science skills to be successful at their jobs. The need for data scientists has expanded well beyond the tech industry to many other disciplines, for example business and the humanities (Irizarry, 2020). There is widespread acknowledgment that the job market for people who have data science skills is strong, and there is evidence that demand for this type of labor far exceeds supply (Baumer, 2015). However, data science skills and conceptual understanding of data science topics are not only necessary to prepare students for being employees, but also for being citizens (Finzer, 2013). In other words, it is important for college students to become critical consumers and producers of data who know how to answer real world questions, think about the implications of data science, and make decisions under uncertainty both in the workforce and in their everyday life. The skills that students learn in their data science courses empower them to understand the world, question the status quo, and think about important issues of social justice and equity. However, social justice issues are typically not emphasized in data science courses. In their recent book, *Data Feminism*, D'ignazio and Klein (2020) discuss how data science needs feminism and that we need to rethink the way that data science is taught.

Using this book as motivation, I designed a curricular study using design-based research methods (Brown, 1992; Collins, 1992) to improve the labs in a large college-level introductory data science course. Using the theory of distributed cognition, I designed labs that contained scaffolds and artifacts that help students to develop communication skills and increase awareness of using data science for social justice. The goal was for students to gain computational action by engaging with coding exercises, individual reflections, and group discussion questions in the labs. Computational action is a relatively new construct for computing education that emphasizes the idea of ensuring the skills that students learn inside the classroom can help them outside the classroom (Tissenbaum et al., 2019). The labs were designed to be collaborative, and the students worked together in small groups to use data science to explore social justice issues. I specifically focused on two labs that occurred during week five and week nine of the 16-week semester. The first lab covered visual displays of data and explored salary discrepancies among different genders. The second lab covered simulation and had the students simulate jury selection and analyze a trial where the random jury selection was in question. Throughout the iterations of this study, I collected pre and post lab survey data, audio recordings to understand how the students gained computational action during the labs, and I conducted interviews with the students after completing these labs. I had two research questions guiding this study. The first looked at the design process and the second looked at how the students gained computational action. Most of the data collected was qualitative and was analyzed using different types of discourse analysis and thematic analysis (Braun & Clarke, 2006). The outcome of this study is a set of design principles for improving labs in data science courses.

CREATING DATA STORIES: STUDENTS' REASONING SKILLS WHEN WORKING WITH AN ONLINE PLATFORM

Franziska Peterson
University of Maine
Franziska.peterson@maine.edu

Keywords: Data Analysis and Statistics, Integrated STEM / STEAM, Technology

The purpose of this preliminary study was to investigate how students in one 9th grade earth science classroom reason about data when constructing evidence-based scientific explanations during Data Story assignments using an online data platform. A critical component of science learning is developing the ability to obtain meaning from a set of data, critically evaluate it, make a claim, and effectively communicate scientific ideas (National Research Council, 2012). Multiple studies have shown that students find it difficult to connect data to the real world (Pfannkuch, Regan, Wild, & Horton, 2010; Whitacre & Saul, 2016).

A Data Story is an interdisciplinary, scaffolded written argumentation assignment that requires students to analyze and graph authentic, real-world data to draw their own conclusions. Students worked with datasets assigned via TuvaLabs.com, a commercial data visualization platform, to analyze authentic, real-world data, select graphs, and to draw their own conclusions (Tuva, 2022). It allows students to easily explore and manipulate data by dragging and dropping variables on axes and selecting any kind of graph or statistical calculation. Students had to select an earth science dataset and construct a Data Story for their chosen data set. All Data Story assignments were analyzed with a rubric and then four purposefully selected students were chosen for follow-up interviews who represented a range of scores from high to low. During the interview, students were asked to explain how they created their Data Stories, and to create one while the interviewer was watching and share their thinking in the moment. These interviews were transcribed and analyzed using coding techniques guided by grounded theory (Corbin & Strauss, 2008) to identify themes.

Findings indicate that how students approach the variables in the data sets from the online platform, and what preconceived notions about graphs they have influence the quality of their Data Stories and reasoning skills. The student who created the most successful story, looked through all possible variables in the data set and thought about which variables could tell an interesting story. The student also mentioned things like, "If I was the scientist who collected this data, what would I be interested in?" They would drag and drop the carefully chosen variables on the axes and interpret the graph. Students who were less successful with their Data Stories tended to drag and drop variables on the axes seemingly at random until they liked how the graph looked. They would then try and interpret their graph. This often led to variable choices that did not tell a sensible story about the science data. Thus, thinking about the variables within the science context seems to be an important step that needs to be explicit when working with online platforms. Students also shared that they 'had to find a correlation'. They wanted their graphs to fit a picture they had in mind. Students did not seem to be comfortable with data that showed relationships that differed from correlated variables. These findings are currently being used to inform teacher professional learning experiences. Some science teachers might not be aware of what types of challenges students can face when reasoning quantitatively about data from a mathematical perspective. Thus, helping science teachers develop more interdisciplinary teaching skills can enhance their students' quantitative reasoning and data literacy skills.

EXAMINING THE ROLE OF SUBSCRIBED IDENTITIES IN SOCIAL CONTEXT DATA ANALYSIS TASKS

Jennifer M. Seat
Middle Tennessee State University
jms2dr@mtmail.mtsu.edu

Keywords: Data Analysis and Statistics, Social Justice, Technology, Affect, Emotion, Beliefs, and Attitudes

Recent world events have focused on current systemic inequities present in society. These problems are not new to scholars in education. One way to help students both explore and potentially overcome such systematic biases is Teaching Mathematics for Social Justice (TMSJ; Wager & Stinson, 2012), which has become a well-documented practice in mathematics education. Hackman (2005) claimed that understanding multiple perspectives and narratives allowed ideas like TMSJ to be successful. One way to include multiple perspectives is to use narratives from non-dominant sources. A second way is to explore the identities and experiences present in a classroom community. Hahn Tapper (2013) described identities as composed of two types of labels: ascribed and subscribed. Ascribed labels come to an individual from others and are typically related to appearance and status. Subscribed labels are labels individuals choose for themselves. Hahn Tapper (2013) stated that subscribed labels were more influential than ascribed labels in determining the effects on the behavior of individuals. One particular way to think about students' narratives is to focus on the roles that lived experiences and subscribed labels play in interactions with complex multivariate datasets.

Findings from the statistics education literature can help understand how lived experiences can influence student interaction in a social justice context. Wroughton and colleagues (2013) found that when the study's findings aligned with participant beliefs, the students were more likely to accept the sampling method, regardless of bias. Similarly, Queiroz and colleagues (2017) explored the role of affect in students' interpretation of social statistics. In this study, one striking example documented how a student nearing completion of formal training responded negatively to a statistic about bicycle safety due to personal experience with the loss of a loved one in a bicycle accident. These are single-point evaluations of fine-grained statistical content, but they indicate that statistics content and experience cannot be separated.

This interview-based study explored how participant subscribed identity influenced their interaction with a sizeable multivariate dataset. Participants were prompted with the general statement, "Use the provided data to find a noticeable difference or demonstrate there is no noticeable difference between groups represented in the data." Participants used variables associated with their subscribed identities to serve as an entry point to the task. This choice meant that variables selected by participants were related to their identities. This relationship between identity and selected variables gave a unique insight into how participants reason with data that contradicts their personal experiences. Participants' use of data to make sense of these contradictions takes different paths depending on the level of the contradiction. For minor discrepancies that can be considered only a small fraction of the data set, participants tended to dismiss the cases represented as different from the perceived trend. For more significant discrepancies that can be thought of as entire classes, participants were more actively engaged in developing explanations for why the class may not follow the anticipated pattern. These patterns can help understand how students may engage in TMSJ tasks that are based on data.

Chapter 14:

Student Learning and Related Factors

RELEVANCE AS PERCEIVED BY HIGH SCHOOL STUDENTS IN DECONTEXTUALIZED MATHEMATICS LESSONS

Aamina Adil
Boston University
aamina@bu.edu

Kihoon Lee
Boston University
klukelee@bu.edu

Leslie Dietiker
Boston University
dietiker@bu.edu

When mathematics educators work towards making mathematics more relevant, they often think about including more real-world applications into mathematics lessons. But what happens when a lesson is devoid of real-world contexts? In what ways can students find it relevant? This study explores how high school students perceived relevance when they were asked to describe their experiences during decontextualized mathematics lessons. Students highlighted how they found certain characteristics of the lessons to be useful in their learning and how they perceived relevance through different feelings experienced in the lessons. This, in turn, broadens our understanding of what relevance means to students.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Curriculum, High School Education

For many years, educators have attempted to incorporate relevant-increasing strategies and interventions in the classrooms, as they have been shown to increase student motivation and performance (e.g., Lazowski & Hulleman, 2016). However, mathematics educators often assume that to be relevant, mathematical content must be connected to real-life contexts with a wide emphasis on incorporating mathematical content that students can see and apply in the world around them (e.g., NRC, 2003; Wilkerson, 2021). While this association is important in its own regard in helping students connect with mathematics and see its importance in their everyday lives, it blinds us from looking at other ways of conceptualizing relevance. One way of expanding our understanding of relevance is to examine it from the perspective of students in order to develop better intervention strategies that will help them find meaning in what they learn (Albrecht & Karabenick, 2018).

This study forms a part of a larger research project which is studying the characteristics of decontextualized high school mathematics lessons that were specially designed to increase aesthetic opportunities for the students (referred to as *Mathematically Captivating Learning Experiences*, or MCLEs). Since the lessons were decontextualized, and because relevance is tightly connected with contextualization, we predicted that students would not find MCLEs relevant. However, surprisingly, using the relevance measure from surveys given to students after lessons, no association was found between the relevance measure and the type of lesson, suggesting that students viewed the decontextualized MCLEs to be as relevant as the non-MCLEs, some of which were contextualized (Dietiker et al., in progress). These results motivated us to look deeper into the views of the students regarding the decontextualized lessons to broaden conceptions of relevance from their perspective.

In this paper, we describe the different categories that emerged from student interviews conducted after the MCLEs, giving examples of their statements that explain what or how they found some aspect of the lesson as relevant, in order to begin to answer the question: *In what ways do students perceive decontextualized high school mathematics lessons to be relevant?* We end with a discussion on how the findings of our study can help expand perceptions of relevance, and what this can mean for the mathematics education community.

Theoretical Framework

Various definitions of relevance have surfaced within the past years (Albrecht & Karabenick, 2018). While some researchers relate relevance with utility value (e.g., Hulleman et al., 2017), others frame relevance in terms of meaningfulness (e.g., NRC, 2003) or the fulfillment of intrinsic and extrinsic goals (e.g., Keller, 1983). Schamber and Eisenberg (1988) argue that most of the notions used to describe relevance, such as usefulness and satisfaction, depend on the perception of an individual. By presenting relevance as a complex cognitive phenomenon which involves the relationship between an individual and their surroundings, Schamber and Eisenberg suggest exploring relevance by questioning the individuals to describe their own perceptions of how they form connections with the topic of information (Schamber & Eisenberg, 1988). In this paper, we define *relevance* as an individual's perception of how an experience was useful in meeting their needs and desires, such as how an activity evoked a sense of satisfaction, which further facilitated a student's learning. When the experience fails to fulfill the individual's needs or desires, then the perception of the relationship is defined as irrelevant.

Recent educational studies that have incorporated student perspectives related to relevance reflect similar notions of fulfillment of an individual's needs and desires. For example, the concept of satisfaction formed the basis for a study that asked college students to produce a list of strategies used by their instructors that increased course relevance for the students (Muddiman & Frymier, 2009). Drawing from Keller (1983), Muddiman and Frymier (2009) define relevance to be a "student's perception of whether course content *satisfies* personal needs, personal goals, and/or career goals" (p. 131, italics added). They identified four ways educational activities could be viewed as relevant by students: how the content was linked to examples drawn from students' lives beyond the classroom, how the teaching style of the instructor helped students relate with the material, methods and activities that encouraged participation and group work, and course supports provided by the teacher that helped them improve their performance. Similarly, Dobie (2019) questioned middle school students about their perceptions of how mathematics lessons were "useful" (p. 28). Student responses from this study fell under two broad categories: *applicability of content* and *features of the learning experience*. Both these studies suggest that in addition to relating relevance with how the content was applicable in their outside lives, students also found relevance in certain teaching strategies, methods, and activities.

We aim to add to what is known about what can make mathematics learning relevant by looking at the perceptions of high school students on mathematics lessons which were specially designed to be decontextualized.

Methods

The current study analyzes perceptions of relevance from statements students made when asked to describe important aspects of their learning experience during an MCLE. Eighteen MCLEs were implemented in six different classrooms from three high schools in the Northeastern region of the United States. One school was a small charter school in the city with a predominantly Latinx student population, the second school was a large urban public high school with diverse racial and ethnic groups, and the third school was a large suburban public high school with a predominantly white student population. Immediately after each MCLE, two to five students were selected as a representative sample in terms of gender and ethnicity and interviewed about their aesthetic experiences during the lesson. The audio recordings of the interviews were then transcribed for data analysis. The current study analyzed a total of 44 interview transcripts from ninth to twelfth grades in the 2018-19 academic year.

During the interviews, students were asked to describe their lesson experiences with the aid of, but not limited to, a given list of positive, neutral, and negative aesthetic descriptors. While none of the questions asked by the interviewers concerned relevance, student perspectives on certain needs and desires often emerged from student remarks.

The data analysis consisted of three major coding passes through student interview transcripts. Each pass consisted of multiple cycles where two coders first independently scrutinized student utterances and then came together to align any differences. During the first pass, the researchers read through the interviews to identify student utterances that included elements of perceived relevance or irrelevance, asking, "In what ways is this student expressing how the experience met their needs and/or desires (or not)?"

The major criteria for evaluating utterances for this pass included highlighting the connections to relevance by placing primary focus on the quality of usefulness. One student's remark clearly reflected one of such instances:

> We told each other what we knew about trigonometry before we went into the lesson. ... It kind of gives you an idea of how people around you know and, like, how they understand the topic. It makes you feel more safe talking to people about it.

For this student, the interaction with their peers through the conversations on the topic prior to the main lesson was useful as a way to understand how others perceived the topic. Such an interaction fulfilled their need by rendering a sense of safety within the in-class discussions.

Also included were statements where students lamented the lesson's failure to meet their needs or desires, which in turn implied how a different aspect of the lesson could have helped fulfill those missing needs or desires. For example, a student explained how they felt less curious in the lesson as they already had an idea of what they were learning, indicating the missed opportunity where the lesson could have been relevant for this student if their desire to learn content outside of their prior knowledge was fulfilled.

On the other hand, while student utterances with positive aesthetic reactions were initially selected as potential candidates for reflecting relevance, many of them were excluded because of a lack of conclusive connection to relevance. For example, a student stated: "I actually really enjoyed this lesson because it was, like, something I never thought would actually occur during a math problem, and the calculator didn't actually have another solution." While this student expressed excitement and enjoyment over the unexpected outcome of the calculator, these reactions did not indicate how this desire was useful to the student. Therefore, this statement was excluded from further analysis.

The first pass resulted in the identification of 55 utterances where students highlighted different aspects of the decontextualized lesson as being relevant to them. After the student utterances relating to relevance were identified, the researchers made a second pass at creating categories of relevance. Since our lessons were decontextualized, Dobie's (2019) major category of *applicability of content* was excluded from our framework and we started with her four subcategories: *method of interaction*, *structure of the activity*, *representation being utilized*, and *value of learning new or important things*. However, unlike Dobie's (2019) study, our student population was not asked explicitly about the ways in which they found the mathematics lessons relevant. In addition, all the MCLEs involved particular characteristics of sequencing activities in order to spark student curiosity with some portion of collaborative small-group problem solving. With such differing characteristics of our study, all of Dobie's (2019) categories needed adjustment to accurately represent the themes that emerged from the student statements. In particular, we modified the subcategory *structure of the activity* because, while some students found particular activities to be useful, a greater number of utterances highlighted that the *sequence* of activities throughout the lesson was perceived as relevant. Since the sequence of the activities was a feature of the entire lesson and not of a particular activity, we broadened the category as *structure of lesson*.

On the occasion of encountering utterances that expressed needs and desires that were not captured by the modified categories, we developed new categories to reflect the new themes, by looking for patterns across the interviews to find expressions of similar needs and desires. For example, when we noticed that multiple students described how they valued making meaningful progress in the lesson on their own, we created the category: *sense of accomplishment*.

With a new set of categories, a final coding pass of the data was carried out to solidify categories that captured the emerging themes of the selected utterances. We then selected representative student utterances for each finalized category.

Findings

The student perceptions of the relevance of decontextualized mathematics lessons can be classified into two broad categories: *characteristics of the lesson students perceive as relevant* and *ways in which relevance is experienced by students during the lesson*. Each of the broad categories consist of multiple subcategories. While there were many instances where students talked about what or how something was relevant, there was at least one instance in each subcategory where students expressed a lack of fulfillment of their needs or desires. Many ways students discussed relevance also fell under several subcategories, both within and across the two main categories. We now describe each category in greater depth.

Characteristics of the Lesson Students Perceive as Relevant

This category describes aspects of the lesson that students identified as enabling them to develop a deeper understanding of and connection with the subject of the lesson. Four subcategories emerged under this category: *interaction with others*, *representation*, *structure of lesson*, and *learning new and unexpected ideas*.

Interaction with others. Students stated that small group interactions with their classmates or guidance from their teacher was often useful in furthering their understanding or helping them get closer to an answer. This interaction was sometimes in the form of a remark or question from either their teacher or one of their peers, or even both, that redirected them to better ideas for solving a problem. For example, a student mentioned, "[The teacher] gave me an idea when she told us how to draw the figure, she came to my group and said, 'try to describe it like you're trying to describe it over the phone.'" Many students also valued collaborative activities that helped them discuss ideas and share thoughts with each other, as evident in this statement: "it was enjoyable too, cause I got to talk about it with the people in my group, … it helped me understand it better." This utterance highlights interactions with other students as an effective medium to fulfill the student's need for greater understanding.

Some students, though, further explained how certain features curtailed the effectiveness of these peer interactions. As one student stated: "When a student describes it, it actually confuses me more. And, like, the way that they explain it is confusing because they put a lot of words into it." For this student, the wordiness and ambiguity in the explanation provided by a fellow student did not allow the interaction to be effective. Thus, having clarity in the exchange of ideas and thoughts emerged as a feature that supported the interactions to be relevant for the students.

Representation. The different ways in which mathematical ideas were presented were often perceived by students as useful in helping them build conceptual understanding and figuring out how to solve problems. The following utterance highlights a student's appreciation for physical representations in developing understanding of the meaning of a formula:

> I like using the little triangles and the diagrams because it showed you how it was going to work instead of just saying "oh, this is the formula that she showed on the board with the 2x thing." Instead of showing us that and how it works, we get to see and physically feel how that works.

This student statement reflects the fulfillment of their need of a visual and tangible representation to understand the concept rather than simply being given a formula with which to work.

In addition, students also appreciated forms of representation that facilitated pattern recognition. For example, a pattern apparent in area models helped one student make sense of polynomial division. Other students highlighted how finding patterns usually meant that "something's right." A student avoided having "holes" (i.e., gaps) in tile patterns because "it wouldn't have looked nice I feel like. … it would have been like 'oh that looks wrong or something.'" One student struggled with "letters and words" that came up in a lesson on logarithm identities, but eventually figured her way out "because of the pattern that makes sense." For these students, finding patterns in these different representations turned out to be a useful way to evaluate their strategies while solving problems.

Structure of lesson. Students expressed how they valued several features involving the way mathematical content (e.g., statements, activities) unfolded across the lesson. They explained how revisiting a topic before diving into the actual lesson, how seeing their teacher perform a calculation, or how being able to derive formulas on their own instead of having them being written on the board increased their understanding of a topic. Several students appreciated having a "hands-on" activity in the lesson which involved cutting, drawing, or playing with shapes, as it increased engagement in the activity, which in turn facilitated their learning process. For instance, a student stated, "I like what we're doing, like, all these different activities and stuff, because if you make it fun then it helps us learn even more."

While these students described particular structural aspects of the lesson, such as a fun activity or a good launch, as being useful in furthering their learning, other students highlighted how the overall flow of the lesson contributed to a meaningful lesson experience. A student particularly pointed out how the slower pace of the lesson helped him process the new concepts: "It was, just, like, a smoother class. It went, like, slower, and, like, we actually took time to explain. And I'm like, 'okay, I understand this,' and I knew the new formula and all the stuff."

Students also described how their teacher can misdirect them into mistakenly assuming something which later results in a surprise or can question them in ways that build their curiosity, as captured by the following student remark: "I felt this lesson was pretty interesting because, like, we have expectations, and she, like, leads into our expectations and then we find out, like, it's wrong. And I'm like, 'now we need to learn why it's wrong.'" This element of unexpectedness that was achieved through the ways these lessons were structured turned out to be important in captivating students as it satisfied their desire to be curious about what they were learning.

Learning new and unexpected ideas. Many students expressed a desire to learn about new and surprising content and valued lessons that presented them with such opportunities. For example, a student mentioned how not knowing about the content beforehand pushed them to want to know more about a new idea: "Today I was a little bit curious because we didn't really know a whole lot about the material." Other students described how the mathematics lessons had shown concepts that were contrary to their previous understandings, therefore finding the value of unexpected ideas. Below is one example of such an instance:

> I would say [the lesson was] surprising because we had two solutions, and the calculator said something else. I would say, for once the calculator disagrees with us, or something like that, where the calculator's right, and we're wrong, or something like that. And I guess I would say [I was] frustrated at some points because it was like, "wait, but, like, how does that work?", which made me want to listen to [the teacher] more.

Notice that, in these student statements, their curiosity (i.e., their desire to learn more) was spurred through learning *new* (i.e., not knowing about the material) or *unexpected* (i.e., discrepancy between the solutions derived by the students and their calculator) ideas. In particular, as shown in the utterance above, such new and unexpected ideas can accompany the element of surprise.

On the other hand, the inverse of such instances also emerged in one interview, where one student explained how their existing content knowledge interfered with their learning experience:

> It was interesting to kinda, like, learn them, but at the same time, I kinda had a guideline already of what I was learning ... because, to find triangles, it's always base times height divided by 2. [Having prior knowledge made me] less curious, because, like, I already knew what it was.

Had the element of new and unexpected ideas been present in this lesson, this student's desire to learn something outside of "the guideline" may have been fulfilled.

Ways in which Relevance is Experienced by Students during the Lesson

This category explains the ways in which students perceived a lesson experience as useful or satisfying. All such remarks emerged as feelings, which were subcategorized into: *sense of accomplishment* and *sense of belonging*.

Sense of accomplishment. Many students perceived resolving challenging tasks on their own or getting them right as a feeling of accomplishment. In particular, while getting the correct answer was mentioned and valued by many students, the sense of achievement was not simply derived from getting the correct answer; it also involved making meaningful progress in spite of prior negative feelings (e.g., fear, frustration). The student utterance below highlights one such instance:

> I began the class period very frustrated and uninteresting because I didn't get the answer right away, like I usually do. But then, towards the end, I was mostly amused. … I actually got an answer at the end. … Any time that I have a problem, and I don't get it right away, and it takes me some time, like it did today, I feel like once I get it right, even if it's something small, then I'll get excited."

Although this student was initially frustrated, their progress towards the solution, despite being small and time-consuming, evoked a sense of accomplishment.

Likewise, the emergence of a self-belief that they were able to "figure it out" (i.e., the belief that the fear of getting something wrong could be surmounted) was the main element that contributed to students' sense of accomplishment. One student, after explaining how they were "just kind of nervous" and worried "what if that was wrong?", continued:

> And then I was like, “look! this is, like,” I'm thinking, “this is similar to what we were looking for, even if it was wrong,” I was thinking. And I figured out something, and I was like, “oh, that's interesting” … I was proud.

This student came to a realization that even if their answer was wrong, it could work as a meaningful aspect of problem-solving. Such remarks often involved explanations of how they were “proud” that they were able to do something on their own and contribute to something worthwhile.

Sense of belonging. Having a sense of belonging within the classroom or a student group was also identified as a way for students to perceive relevance. Their desire to not be alone was fulfilled by finding common interests or sharing a wholesome and engaging class experience with their peers. One student explained how often their peers’ disengagement to the class prevented their learning: “some people are just, like, sleeping, they're just tired, ... some people have side conversations [when] I'm trying to learn.” However, they proceeded to indicate how, in this particular lesson, their classmates were more engaged, which created a “drive to actually understand [the lesson].” In other words, for this student, what they desired and needed was to be in sync with their classmates and to have a sense of community.

Other times, such a sense of belonging accompanied other aforementioned categories such as *interaction with others* or *structure of lesson*. For example:

> I felt more comfortable with [this way of teaching], and helped me learn, and like working in groups helped me, like, interact with other students, and, like, hearing their ideas and, like, make everything, like, make sense, putting it all together. … So, working, like, with other students and the teacher going back and forth, like, working in pairs and the teacher explains and then, like, discussing with the whole class. It, like, makes me feel comfortable in the class. Like, sometimes I'm in class, [it] can get kind of stressful, and it makes you feel like you're with other people and you're not alone, and it just feels like relief. … We had, like, different ideas and points of views, and then going on the paper and actually doing it out and realizing, like, what each person was thinking and seeing what they thought and what I thought, like, I feel like that really showed how people think and how you can, like, come together as a team, as a group.

The above statement captures the way in which the structure of the lesson (i.e., collaborative work followed by teacher explanations and then a whole class discussion) facilitated interaction with other students (i.e., a discussion of different thoughts and ideas), leading to a sense of belonging (i.e., feeling comfortable and relieved):

Overall, this category highlights the importance of having a community where students can come together, even with different perspectives, leading to a sense of relief and comfortableness.

Discussion

We are gratified to see that high school students can find mathematics lessons meaningful and are able to connect with them, even when the content is decontextualized. While we do not discount the importance of using real-world applications in our mathematics lessons to allow students to see mathematics in the world around them, our research sheds light on other ways mathematics can be perceived as relevant by students. This new way of looking at relevance opens up ways for mathematics educators to rethink pedagogical approaches that aim to increase relevance in classrooms. For example, teachers can structure lessons in ways that present elements of surprise, as our research suggests that students tend to value content that goes against their expectations, and that surprise often led to an increased curiosity in what they were learning. Moreover, since our study concentrated on high school lessons only, the varied perceptions of relevance pave the way for making even abstract advanced mathematics content meaningful to students, without necessarily making a connection to the real world — especially when such a connection is difficult to make or is divergent from students' actual life experiences. Furthermore, many of the students connected relevance with positive aesthetic experiences and identified irrelevance with negative or neutral feelings, suggesting a potential connection between aesthetic experiences and perceptions of relevance.

While our study identifies varied perceptions of relevance, the nature of our study presents some limitations. Although our schools had diverse student populations, our data only comes from schools located in the Northeastern region of the United States. Furthermore, since we were able to interview only a few students after each lesson, our study potentially limits the number of different views obtained. More research with varied school settings could help expand these findings.

We hope that this research study will help the mathematics education community recognize the ways relevance can be conceptualized from the perspectives of students, in turn making mathematics more meaningful for all students.

Acknowledgments

This material is based upon work supported by the National Science Foundation under Grant No. 1652513. We would also like to thank our teacher participants and other research team members for their help in collecting and organizing the data and giving valuable feedback for this study.

TOWARDS AN ELABORATION OF CONCRETENESS FADING: REFLECTIONS ON A CONSTRUCTIVIST TEACHING EXPERIMENT

Joseph Antonides
Virginia Tech
jantonides@vt.edu

Michael T. Battista
The Ohio State University
battista.23@osu.edu

Over half a century has passed since Bruner suggested his three-stage enactive-iconic-symbolic model of instruction. In more recent research, predominantly in educational psychology, Bruner's model has been reformulated into the theory of instruction known as concreteness fading (CF). In a recent constructivist teaching experiment investigating two undergraduate students' combinatorial reasoning, we utilized an instructional approach that maintains the enactive-iconic-symbolic stages of CF, but through a gradual and much elaborated process. We found that our theory of levels of abstraction explicated the "fading" effect that is central to CF. In this theoretical report, we discuss how CF can be elaborated by our instructional approach and theoretical perspective.

Keywords: Learning Theory; Instructional Activities and Practices; Advanced Mathematical Thinking; Mathematical Representations

Introduction

Substantial research points to the potential affordances of using manipulatives in mathematics teaching (Bouck & Park, 2018; Carbonneau et al., 2013; Domino, 2010; Moyer-Packenham & Westenskow, 2013; Peltier et al., 2020). However, *how* should manipulatives be used to benefit student learning? From a constructivist perspective, manipulatives—by which we mean physical or virtual objects on which sensory-motor actions may be performed—do not carry inherent mathematical meaning (Ball, 1992; Wheatley, 1992). Students must *construct* the meanings that they come to associate with representational forms, even when, from a more knowledgeable person's perspective, those forms "look like" the concepts they are intended to represent. Thus, the shift from using manipulatives to using formal *symbols* for a given concept needs to be given careful consideration (Clements & McMillen, 1996; Fennema, 1972; Resnick & Omanson, 1987).

Research suggests one effective means for introducing abstract symbols and ways of operating on them in ways that are meaningful to students is the three-stage enactive-iconic-symbolic "concreteness fading" (CF) instructional model, originally proposed by Bruner (1966), and similarly the concrete-representational-abstract (CRA) model. Within the CF model, a concept is first represented using "concrete" materials on which students may perform sensory-motor actions, followed by "iconic" representations which may include graphic or pictorial forms, and lastly "symbolic" representations such as words or letters for the concept.

The purpose of this theoretical paper is to suggest a potential elaboration of the CF model using a theory of levels of abstraction (Battista, 2007), and an elaboration that emerged from a teaching experiment investigating two preservice teachers' combinatorial reasoning (Antonides & Battista, under review). Our instructional approach utilized concrete/enactive tasks in that students were asked to enumerate permutations represented as "towers" by constructing towers using physical, multi-colored connecting cubes (cf. Maher et al., 2011). Our students used these manipulatives to enumerate towers 3-cubes, 4-cubes, and 5-cubes-high, all the while constructing numerical symbols and computational expressions that were explicitly linked to their tower constructions. Gradually, the students' reasoning shifted from operating on towers to operating primarily on symbolic representations, which they could later use to reason in novel situations. This theoretical report seeks to establish two claims: (a) that our instructional approach represents a case of a much-elaborated instantiation of CF, and (b) that our theoretical framework focusing on students' levels of abstraction serves to explicate the "fading" effect that is central to CF.

Concreteness Fading and Related Perspectives

Bruner argued for a theory of instruction that includes three broad representational forms: enactive, iconic, and symbolic. According to Bruner (1964), "Their appearance in the life of the child is in that order, each depending upon the previous one for its development, yet all of them remaining more or less intact throughout life" (p. 2). *Enactive representations* are characterized by sensory-motor actions within experiential situations; Bruner suggests examples of riding a bicycle, tying knots, or driving a car. *Iconic representations* "[summarize] events by the selective organization of percepts and of images, by the spatial, temporal, and qualitative structures of the perceptual field and their transformed images" (p. 2). To reason about an experience, such as riding a bicycle or tying a knot, a student can call forth internalized mental representations as material on which to operate. *Symbolic representations* include, in particular, words that are used to point to particular conceptual referents. Symbols, unlike icons, typically do not bear a perceptual resemblance to the objects that they represent.

Goldstone and Son (2005) introduced the term "concreteness fading" to refer to the process of successively decreasing the level of concreteness of a simulation for a scientific concept, with the eventual goal of "attaining a relatively idealized and decontextualized representation that is still clearly connected to the physical situation that it models" (p. 70). While Goldstone and Son related CF to Bruner's theory of instruction, their formulation of CF did not specify a three-stage representational sequence.

McNeil and Fyfe (2012) formulated CF as a three-step gradual fading process, similar to Bruner's recommended model. They conducted the first study to experimentally test the benefits of such a three-stage progression, specifically within the context of undergraduate students' learning and transfer of the properties of an abelian group of order three (associativity and commutativity, and the existence of inverse elements and an identity element). The students were randomly placed into one of three instructional conditions: generic, which used abstract symbols (two-dimensional shapes); concrete, which used iconic representations of measuring cups; and fading, which used a concrete-to-generic approach with an explicit linking of the two representations through an intermediary, Roman numeral-based representation. Their results showed that students in the fading condition performed significantly better than students in the generic or concrete conditions.

Notably, McNeil and Fyfe's "concrete" condition did not involve perceptual materials on which sensory-motor actions were performed—a distinction from Bruner's characterization of the enactive. However, Bruner's focus in his original formulation of the three-stage model seemed to be on *children's* intellectual development, whereas McNeil and Fyfe's study focused on undergraduates. This raises important questions about the nature of "concrete" and "enactive" representations. What do these terms mean? Fyfe and Nathan (2019) "use the term concrete representation to refer to any external representation" (p. 410), which they suggest may vary along at least two dimensions: physicality and perceptual richness. The physicality of a concrete representation refers to whether it is two-dimensional (such as a drawing, consistent with Bruner's term iconic) or three-dimensional (such as physical cubes). Perceptual richness typically refers to the visual features maintained by a representation, such as colors, patterns, or texture. Fyfe and Nathan defined CF "as the three-step progression by which a concrete representation of a concept is explicitly faded into a generic, idealised representation of that same concept," which they suggested is accomplished "by removing perceptual and conceptual information either within or across lessons until one arrives at the representation that involves the least effort to infer and generalise the invariant relation" (p. 411). Fyfe et al. (2014) also suggested "fading" may occur "by encouraging structural recognition and alignment" (p. 19).

CF is related to additional theories of instruction and learning. For instance, CF is a form of the more general notion of progressive formalization (PF), a model of instruction in which students first gain experience about a concept through concrete materials, then transition to operating on symbols that are conceptually grounded in these initial concrete experiences (Nathan, 2012). According to Nathan, the PF model combines advantages of both concrete and abstract representations:

> Concrete entities are meaningful to learners early on and so provide accessible entry points, abstractions transcend the applicability of the representations and rules from any one context, and *grounded abstractions* support learners understanding of what the formalisms "say" and how they apply widely to new application areas. (p. 139)

CF is also related to the types of mathematical activity suggested by Gravemeijer (1999; see also Gravemeijer, 2002). Students operating at the level of referential activity use models that are conceptually grounded in experientially real task settings. At the level of general activity, students transcend from operating with "models of" to operating with "models for," meaning "students' reasoning loses its dependency on situation-specific imagery," which Gravemeijer suggests "can be seen as a process of reification" (p. 164).

Context of Our Proposed Elaboration

We conducted one-on-one constructivist teaching experiments (Steffe & Thompson, 2000) with two preservice middle school teachers with the goal of developing second-order models of the students' concepts and actions/operations for enumerating permutations. To help make our students' reasoning salient, and to provide sensory-motor experiences that we hypothesized would serve to conceptually ground our students' developing mathematical meanings, the tasks included in our study generally represented permutations of n objects as n-cube "towers," each tower comprised of n different colors of cubes connected together with a vertical spatial orientation (see also Maher et al., 2011).

As noted in the Introduction, we claim that our instructional approach represents an instantiation of CF. Indeed, both students (DC and NK, neither of whom had studied combinatorics previously) initially counted tower possibilities by constructing towers 1-by-1 using the available perceptual materials—consistent with Bruner's descriptions of *enactive* representations, as well as Fyfe and Nathan's (2019) definition of the broader term, *concrete*. As the tasks became increasingly complex, DC and NK transitioned from relying on 1-by-1 construction techniques alone to constructing partial sets of towers before generalizing multiplicatively. They could mentally imagine towers that they had not yet constructed, consistent with Bruner's meaning of the term *iconic* representation. Each student progressed to constructing multiplicative operations without needing to first operate on towers, but justified using (and thus conceptually grounded in) this sensory-motor cube-towers context. This is consistent with Bruner's characterization of *symbolic* representations, as well as Nathan's (2012) description of abstract representations in the PF model of instruction. Ultimately, each student was able to construct, through a process of guided reinvention (Gravemeijer, 1999), a generalized formula for counting permutations. The instructional sequence through which our students constructed their formulas, and a brief summary of each student's reasoning, are provided in Table 1. Note that students were provided with physical cubes to construct 3-, 4-, and 5-cube towers, and more than enough cubes were available to construct all 3- and 4-square towers (but not 5-square towers, of which there were 120 possibilities).

Table 1: Instructional Sequence and Summary of Students' Reasoning

Task	Summary of DC's Reasoning	Summary of NK's Reasoning
1. Counting 3-cube towers each containing 3 colors of cubes	Constructed towers systematically one-by-one using physical cubes	Constructed towers systematically one-by-one using physical cubes
2. Counting 4-cube towers each containing 4 colors of cubes	Constructed 12 towers one-by-one, organized by base color, then multiplied $6\times4=24$	Reasoned there are six 3-cube towers for any 3 colors, and 4 possible top-cube colors, so there are $6\times4=24$ towers
3. Counting 5-cube towers each containing 5 colors of cubes	Used enactive processes to enumerate 4-cube permutations with a fixed cube in the fifth position, then multiplied 24×5	Reasoned there are 24 4-cube towers for any 4 colors, and 5 possible top-cube colors, so $24\times5=120$ towers
4. Counting 6-cube towers each containing 6 colors of cubes	Multiplied 120×6	Multiplied 120×6
5. Counting 9-Cube towers each containing 9 colors of cubes	Multiplied $720\times7\times8\times9$	Multiplied $720\times7\times8\times9$
6. Counting 20-cube towers each containing 20 colors of cubes	Multiplied $362{,}880\times10\times\ldots\times19\times20$	Described the multiplication $20\times19\times\ldots\times2\times1$
7. Counting 100-cube towers each containing 100 colors of cubes	Described the multiplication $1\times2\times\ldots\times99\times100$	Described the multiplication $100\times99\times\ldots\times2\times1$
8. Counting *n*-cube towers each containing *n* colors of cubes	Described the formula $1\times2\times\ldots\times n$	Described the formula $n\times(n-1)\times(n-2)\times\ldots\times2\times1$

Theoretical Perspective

We adopted a psychological constructivist view of mathematical knowing and learning (cf. Piaget, 1970; von Glasersfeld, 1995). Within this view, a *concept* is a mental representation of a phenomenon that is stable enough to be re-presented (e.g., visualized or described) in the absence of relevant sensory-motor input (von Glasersfeld, 1991). An *action* refers to either a physical transformation on perceptual material or a mental action on imagined/re-presented material. An action constitutes an *operation* when (a) it is internalized (so that it can be performed mentally), (b) it is reversible, and (c) it can be composed with other mental actions (Piaget, 1963). A *scheme* is a way of operating under certain situations. It consists of an assimilatory mechanism for recognizing situations along with an integrated set of abstractions used to mentally represent the situation at hand (i.e., a *mental model*); a sequence of actions/operations associated with the assimilated situation; and a set of expectations or anticipations about possible results from those actions (Battista, 1999; see also von Glasersfeld, 1995).

Levels of Abstraction

To frame and analyze our students' conceptual progressions, we used Battista's (2007) theory of levels of abstraction, a reformulation of Piaget's theory of abstraction via Steffe and von Glasersfeld (Steffe, 1998; Steffe et al., 1988; von Glasersfeld, 1995). Battista's original levels of abstraction were generally stated and could be used to analyze and interpret student understanding of concepts and operations across a wide range of mathematical domains. At the *perceptual/recognition level*, an item from one's experiential flow is isolated and entered into working memory. Sensory properties necessary to recognize future instantiations of the item are empirically abstracted. At the *internalized level*, abstracted object-concepts may be re-presented (i.e., visualized) in the absence of relevant perceptual input, or abstracted actions and action sequences may be re-enacted in the absence of relevant kinesthetic signals prompting the abstracted action sequence. At the *interiorized level*, the student's understanding of the abstracted item becomes generalized in that they can apply the item to reason in novel situations. It is at this level that structures, patterns, and abstract forms are abstracted from particular sensory-motor contexts (Steffe et al., 1988). In particular, it is at the interiorized level that actions can be come operations, as the action can be performed in thought, is reversible, and can be composed with other mental actions. At the *second interiorized level*, the student constructs symbols as conceptual "pointers" to interiorized material, and these symbols are used as substitutes for the originally abstracted material in reasoning. At the *third interiorized level*, more complex operations can be performed on these symbols, such as curtailing sequences of symbolic operations into more condensed forms.

We used the original levels to explicate students' progressively abstract conceptualizations of, and operations on, spatial material within permutation enumeration contexts. However, through our data analysis, we found a need to elaborate the theory by developing an additional, empirically supported set of levels of abstraction. This new set of levels served to explain students' abstractions of *computational operation schemes* (COS), and we found the original set of levels occurred in parallel with this new set of levels. When a sequence of symbolic computations has been perceptually abstracted, the student can re-enact the action sequence step-by-step, but only with external cues such as instructions or a formula. The student can activate this COS when they recognize a situation as being similar to the original one in which they abstracted the sequence of computations. Once internalized, the sequence of computations can be performed, step-by-step, without such external cues. At the interiorized level, a student's understanding of a COS shifts from its step-by-step performance to analyzing the meanings and results of each computational operation, enabling them to apply meaningful deviations from the original and to adapt their COS to reason about novel situations. At the second interiorized level, the student can treat the sequence of operations of their COS as a *conceptual symbol*, meaning they can operate on the COS itself. For instance, they could reverse the sequence of operations, or they could decompose its constituent components and rewrite each computation in terms of this decomposition. At the third interiorized level, the student can algebraically generalize their COS using variable expressions. At the fourth interiorized level, the student can construct and conceptually operate on written/verbal symbols as pointers to their algebraically-generalized computations (e.g., $n!$ as a symbol for $n \times (n-1) \times (n-2) \times \ldots \times 2 \times 1$).

To summarize, the levels of abstraction sequence occurs first on actions/operations on objects, then reappears as an individual transitions to numerical, algebraic, and other forms of symbolic mathematical reasoning. The inter-relationship between the original set of levels for actions/operations on objects and the levels for computational operations is illustrated in Figure 1.

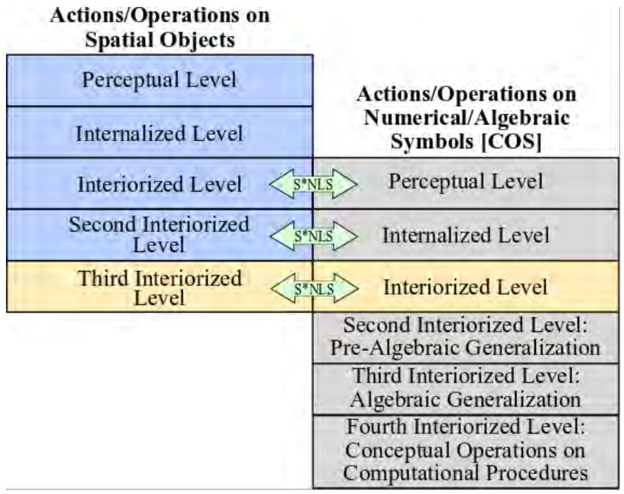

Figure 1: The Two Sets of Levels of Abstraction, Linked via S*NLS

Links between the two sets are made via S*-numerical linked structuring (S*NLS). S*-structuring is the mental process of constructing an organization or form for sequences of physical/mental actions on perceptual/imagined material; numerical (or N-) structuring is the process of constructing an organization or form for a set of numerical/algebraic symbols; and S*NLS is a form of reasoning that coordinates S*-structuring and N-structuring consistent with a learner's understanding of the relevant spatial/numerical properties (Antonides & Battista, 2022).

Discussion

As noted in the Introduction, we believe that our instructional approach and theoretical perspective provide an elaborated description of both the cognitive mechanisms that underlie CF and its instructional implementation—two sites in which Fyfe et al. (2014) called for additional research. First, incorporating multiple levels of abstraction greatly elaborates the notion of concreteness "fading," with each abstraction level fading some of the "concreteness" of the previous level, as illustrated in Figure 2.

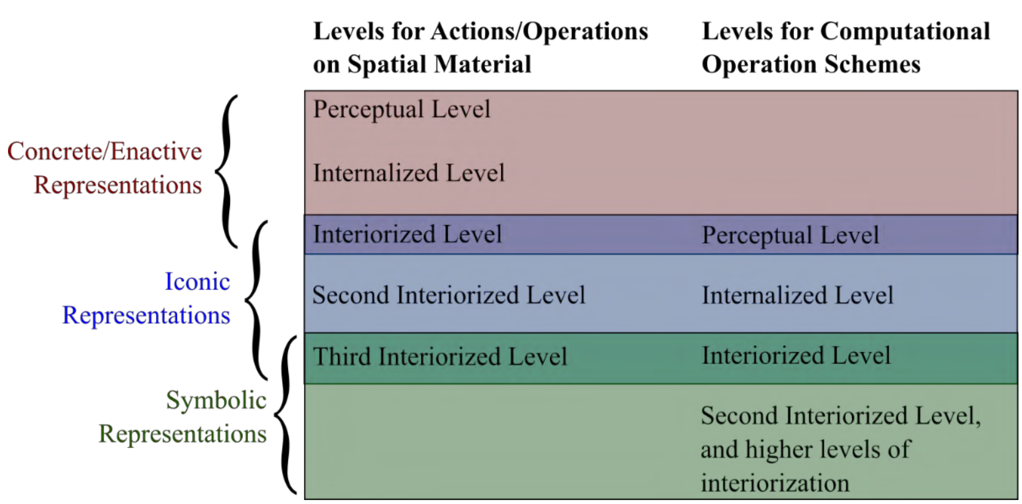

Figure 2: Elaborating Concreteness Fading Using Levels of Abstraction

At the perceptual and internalized levels of abstraction, student reasoning about a given mathematical concept is constrained to the original perceptual context in which the concept was initially encountered, with relevant figurative (or "concrete") materials perceptually available. We hypothesize that even in the shift from perceptual abstraction to internalization, many of the sensory properties initially registered into memory become "faded." Upon reaching the interiorized level, mathematical ideas can be extended beyond this initial sensory-motor context, and more abstract representations, such as drawings and motor-kinesthetic items (e.g., counting using fingers), become available to the student. Interiorization affords the construction of a more generalized structure from a student's actions on sensory-motor material, enabling a shift from concrete/enactive to iconic/enactive representations. For instance, DC and NK interiorized the structure of a 3-cube tower; for DC, this was reflected in his spatial structuring [base cube] + [reversible 2-cube tower]. He used gestures and verbal descriptions to describe aspects of his reasoning, but still strongly linked to the cube-towers context. At the second interiorized level, DC and NK constructed and operated on symbols, such as NK's enumeration of 4-cube towers by multiplying 4×6 *without* needing to construct towers one-by-one.

At the third interiorized level, students' focus of attention begins to shift from actions/operations on the context-specific spatial material to their computational processes themselves, thus emerging upon the symbolic stage within CF theory. DC and NK, at this level, performed more complex symbolic computations, such as enumerating 9-cube towers by multiplying $720\times7\times8\times9$. Our students' reasoning then focused entirely on their computational operation schemes, without reference to cube-towers (though they could, if asked, explain their reasoning in terms of towers).

Second, our theory uses S*NLS (Antonides & Battista, 2022) to elaborate Fyfe et al.'s (2014) discussion of structuring and linking to elaborate the connection between concrete and formal symbolic representations. This connection is illustrated by the levels of abstraction occurring in parallel in Figure 2, with concrete representations on the left and formal symbolic representations on the right, linked via S*NLS as illustrated in Figure 1. Our S*-structuring perspective emphasizes the importance of providing students with opportunities to act on sensory materials when forming their initial combinatorial conceptualizations and reasoning; for us, S*-structuring represents a cognition-based elaboration of Lockwood's (2014) set-oriented perspective, as students draw on their concrete/enactive S*-structuring experiences to conceptually ground symbolic computational formulas and expressions.

Lastly, our investigation and theoretical framework which draws on mental models elaborates Fyfe et al.'s claim that "the concrete stage enables learners to acquire a store of images that can be used when abstract symbols are forgotten or disconnected from the underlying concept" (p. 13). In fact, while mental images may be a constituent part (such as stored mental representations of particular towers or sets of towers), it is *mental models* that enable students to conceptually operate with the combinatorial composites and symbolic manipulations (Battista, 2007).

Furthermore, returning to Fyfe et al.'s (2014) call for describing ways to optimize the fading technique, using the theory of levels of abstraction to guide CF seems to have great potential for optimizing its instructional use. As opposed to the representations used by Braithwaite and Goldstone (2013) in their concreteness-fading study of combinatorics with undergraduates (specifically, letter sequences followed by arithmetic explanations for factorials), we provide a very different and much elaborated interpretation of concrete versus abstract representation, as well as CF, for combinatorial reasoning. Indeed, our "fading" is accomplished by starting with small-number permutations of physical cubes and incrementally increasing this number so that actual manipulation of cubes becomes impractical and necessarily needs to fade into the background as symbolic representations are abstracted and come to the fore. At this point, students start operating on symbolic representations, first with simple arithmetic operations, then with pre-algebraic to algebraic operations, with the fading being accomplished by increasing levels of abstraction, generalization, and consequent symbolic representation. All-the-while during our fading, the students were encouraged and supported, via S*NLS, to directly connect reasoning on each new problem to reasoning on the previous problem using the powerful mathematical reasoning of recursion.

Finally, we view the process of generalization to be a critical component of CF. Drawing on Ellis et al.'s (2021) research synthesis of generalizing actions, CF often involves "deriving broader results from particular cases to form general relationships, rules, concepts, or connections" as well as "extending one's reasoning beyond the range in which it originated" (p. 2), which the authors connected to the process of abstraction. Thus, in our teaching experiments, an essential component of our CF is progressive formalization (Nathan, 2012) in which students *incrementally generalized* their reasoning, again via S*NLS, as they moved from considering small-number to large-number towers. Consistent with our instructional approach, we hypothesize that the enactive stage of instruction may be more effective when it becomes impractical or impossible for the student to completely model the task situation using concrete materials, which would create an intellectual need for a transition to a different symbol system. This hypothesis is one potential avenue for future research. Fyfe et al. (2014) similarly argued that CF enables concepts to be "generalized in a manner that promotes transfer" (p. 12). Consistent with this claim, in later teaching-experiment sessions, DC and NK transferred their cube-based reasoning about permutations to permutation tasks not involving cubes, with both students referring back to their reasoning about permutations of cubes. This suggests the perceptual context of constructing and enumerating permutations of cubes provides powerful mental models for applying and transferring one's reasoning about permutations.

Conclusion

In this theoretical report, we have suggested a potential elaboration of CF theory using our recent teaching-experiment research and theoretical perspective. Our elaborated theory of levels of abstraction explicates the fading mechanism central to CF, with multiple levels of abstraction occurring within enactive-iconic-symbolic representational stages and with specific levels of abstraction at the transition between stages. Our investigation provides a case of implementing a much-elaborated instantiation of CF in the context of one-on-one instruction. We acknowledge that the one-on-one nature of our investigation is a limitation of our study, and it could explain our positive findings. However, significant research has found CF to be a powerful instructional method for supporting transfer of mathematical and scientific concepts (Bouck & Park, 2018; Fyfe et al., 2014). In future research, we intend to investigate how our instructional approach (with appropriate adaptations) may support student learning in classroom-based contexts.

Worked examples have been shown to improve student learning in algebra. However, less is known about how to design worked examples to support student learning in online settings. We explore how college students react to worked examples that vary in their degree of extensiveness and dynamicness. In an online, within-subjects study, 109 college students viewed six worked example presentations: 1) static concise, 2) static extended, 3) sequential concise, 4) sequential extended, 5) dynamic history, and 6) dynamic no history. Students rated the helpfulness of each worked example and explained their rating. We found that students rated the static concise presentation as the most helpful and the dynamic no history presentation as the least helpful example. Responses were coded by researchers for common themes and revealed insights that may inform how researchers and teachers design worked examples for online environments.

Keywords: Learning Theory, Instructional Activities and Practices, Metacognition, Technology.

Purpose of the Study

Worked examples are an effective means of instructional support for math education (e.g., Booth et al., 2015; Carroll, 1994; Foster et al., 2018). However, worked examples have primarily been presented the same way, with research focusing on how static images of worked examples that display major derivations align with students' underlying cognitive mechanisms and in turn support learning (e.g., Sweller, 2006, 2020). Recently, Scheiter (2020) called for broadening the research on example-based learning beyond pure cognitive mechanisms to incorporate non-cognitive theories. While some affective factors have been investigated in relation to example-based learning (Hartmann et al., 2020; Tempelaar et al., 2020), we propose that analyzing students' perceptions of online worked examples may also a) advance our understanding of how worked examples impact student thinking and b) inform future iterations of worked examples that optimize support for student learning in online settings.

Previously, we tested the effectiveness of six worked example formats that varied in presentation but matched in content and found that grade-school Algebra I students improved in their ability to simplify equations after completing instructional practice with any of the six worked example formats (Smith et al., 2022). Since all of the worked example formats led to comparable learning gains among Algebra I students, we now aim to understand how different features of worked examples affect students beyond learning gains alone. In this study, we assess college students' perceptions of the six worked example formats on simplifying equations to gather student feedback that might inform future designs of worked examples for online math learning environments. Specifically, we ask: 1) *Which worked examples are rated as the most vs.*

least helpful? 2) *What themes emerge in students' explanations for their rating?* 3) *How do students' explanations for the most helpful and least helpful worked example presentations provide further insights into the features to which students attend?*

Theoretical Framework

Frameworks of self-regulated learning (SRL; e.g., Bjork et al., 2013; Dunlosky & Ariel, 2011; Nelson & Narens, 1990) broadly model learning as a cycle between students monitoring and controlling learning tactics based on self-assessments of their progress in developing content knowledge or skills. Recent evidence showed that students were able to self-regulate learning by deciding if and when to use worked examples or practice problem solving (Foster et al., 2018). However, students tended to underutilize worked examples, and were more likely to study worked examples *after* problem solving. These student behaviors contrast with evidence that studying worked examples is more effective *prior to* problem solving (Leppink et al., 2014; Van Gog et al, 2011). Although students are able to self-regulate learning, Foster and colleagues (2018) call for more research on how students' self-regulation decisions are related to learning outcomes. More broadly, we posit that students' perception of worked examples may influence the ways in which they regulate learning and impact learning outcomes.

Here, we compare students' reactions to six different formats of worked examples varying in their extensiveness and degree of dynamicness based on cognitive load theory (Sweller, 2006) and perceptual learning theory (Gibson, 1969; Goldstone et al., 2017), respectively. We reason that there are two primary competing hypotheses as to which worked example format students will perceive as most helpful. First, based on cognitive load theory, students may prefer the *concise static* worked example as it provides only the major derivation steps to a problem without splitting their attention across multiple sources of information in worked examples. Second, based on perceptual learning theory, students may prefer the *dynamic* worked examples that show fluid transformations between each derivation step. Aligned with perceptual learning theory, the additional visual cues may help direct students' attention towards relevant actions for problem solving and raise awareness of perceptual cues to aid with problem solving. However, it is unclear how much detail and animation may be helpful, prompting us to also explore the effect of studying *dynamic* compared to *static* and *sequential* (an intermediate version that presents each equation line as a new animation) worked examples that vary in their amount of detail. As a first step towards understanding students' perception of the worked examples, we asked college students to rate the helpfulness of the worked examples as well as to explain their ratings.

Methods

A total of 109 students from a private university in the Northeastern U.S. participated for partial course credit. The sample afforded 80% power to detect the effect of $f > 0.35$ at $p < .05$.

Students completed a 30-minute online, within-subjects study designed as an assignment in ASSISTments, an online homework and research platform (Heffernan & Heffernan, 2014). Within the assignment, students completed six pairs of worked examples and practice problems, with each pair followed by two survey items, in a randomized order. For each worked example, students were instructed to study the worked example then enter the solution as an answer. On the following page, students completed a practice problem that matched the equation structure of the worked example without any instructional support or feedback. Immediately following each pair, students were asked how much they agree with the following statement: "*The worked examples were helpful for learning how to solve equations*". Students rated their perceived helpfulness on a 6-point Likert scale (1=Strongly Disagree; 6=Strongly Agree). They were then prompted to explain their rating in an open-response textbox that appeared below on the same screen which said, “Please use the open response to explain your answer.”

We designed six worked example presentations that varied in their visual features but not in content. Specifically, we manipulated the degree of *dynamicness* (static, sequential, or dynamic) and *extensiveness* (concise or extended) of each worked example. We adapted six worked examples that were designed for seventh-graders from Rittle-Johnson and Star (2007), so they were similar in content and difficulty. Previously, we also used these worked example presentations to investigate their differential effects on learning among Algebra I students; we found that students did improve from pretest to posttest on simplifying equations after completing instructional practice with any of the six worked example presentations (Smith et al., 2022). In this study, students viewed all six of the following formats in a randomized order.

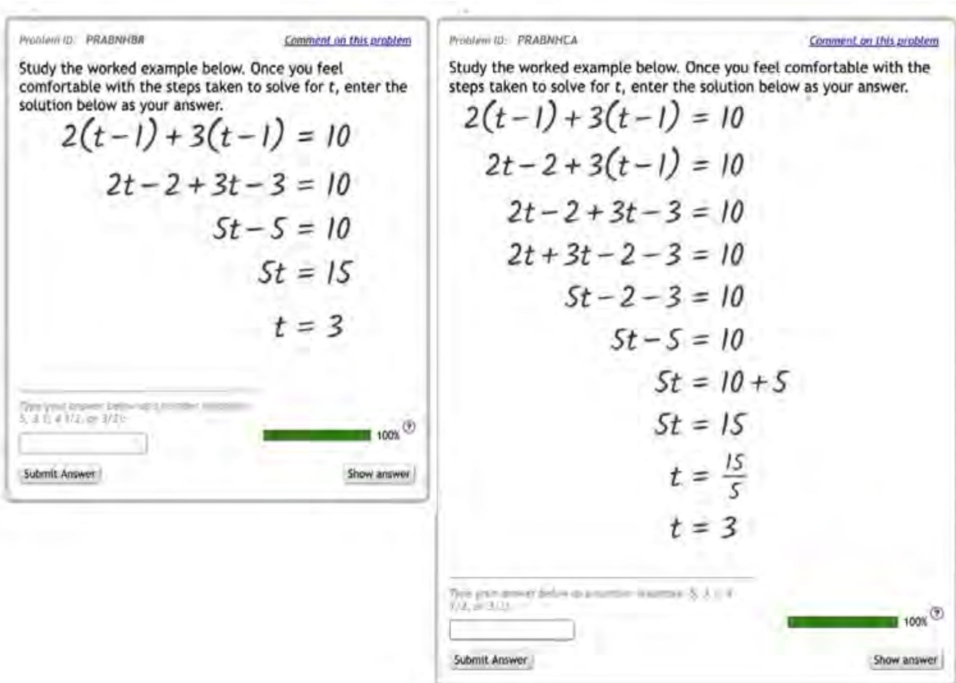

Figure 1: Static Concise Presentation (Left) and Static Extended Presentation (Right)

The first four conditions were based on a 2×2 design, differing in (a) length (i.e., concise or extended), and (b) the dynamicness of the worked example, (i.e., static or sequential). The *concise* worked examples displayed only the major steps in the derivation while the *extended* worked examples showed every step in the derivation. Static presentations mirrored the most commonly used design of worked examples in math (e.g., Rittle-Johnson & Star, 2007), presenting each worked example as images (Figure 1). The sequential worked examples were displayed as a looping GIF video that presented the static worked examples line-by-line in approximately 3-second intervals, creating a step-by-step history of the derivation over time. By varying the length and dynamicness, we created four different worked examples: *static concise*, *static extended*, *sequential concise*, and *sequential extended*.

Additionally, we created two presentations which displayed dynamic transformations of the expression and varied in whether the history of the derivation was displayed or not. The *dynamic history* worked examples showed looping videos of the transformation process through a screen recording. For example, to transform $2(t-1)+3(t-1)=10$ to $2t-2+3(t-1)=10$, students watched as the 2 was dragged over the parentheses to enact the transformation and record the result of the action on a new line (Figure 2). Each step of the problem was shown on the following line and a history of the steps taken was displayed sequentially. The transformations in the *dynamic no history* presentation were identical to those in the *dynamic history* presentation, but all occurred on one line of the equation without creating a derivation history.

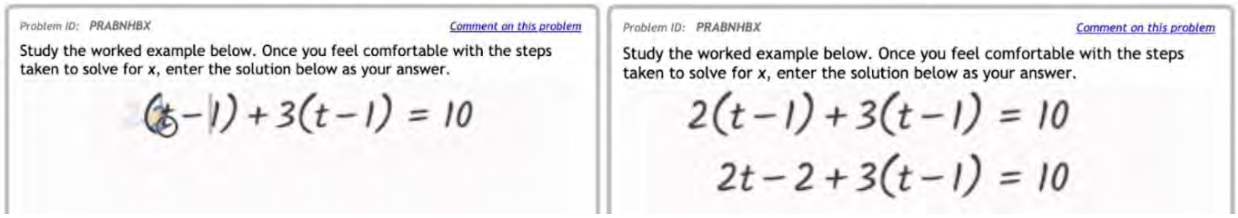

Figure 2: The *Dynamic History* Presentation Shows the Process of Each Transformation

Approach to Analysis and Results

Research Question 1: Perceived Helpfulness Ratings of Worked Example Presentations

To first compare how students rated the different worked example formats, we treated students' ratings (on a 6-point scale) as a continuous variable (Robitzsch, 2020). A one-way ANOVA revealed a significant effect of worked example presentation on students' rating, $F(5, 648) = 5.76$, $p < .001$. Post hoc comparisons using Bonferroni correction indicated that the mean rating for the *static concise* presentation ($M = 5.17$, $SD = 1.21$) was significantly higher than the *dynamic no history* ($M = 4.22$, $SD = 1.56$), *sequential extended* ($M = 4.59$, $SD = 1.44$), and *dynamic history* ($M = 4.60$, $SD = 1.53$) presentations, ps $< .05$. Further, the mean rating for the *static extended* presentation ($M = 4.92$, $SD = 1.31$) was significantly higher than the *dynamic no history* condition ($M = 4.22$, $SD = 1.56$), $p < .01$ (Figure 3). There were no significant differences in students' rating between the *sequential concise* presentation ($M = 4.61$, $SD = 1.38$) and any of the other presentations.

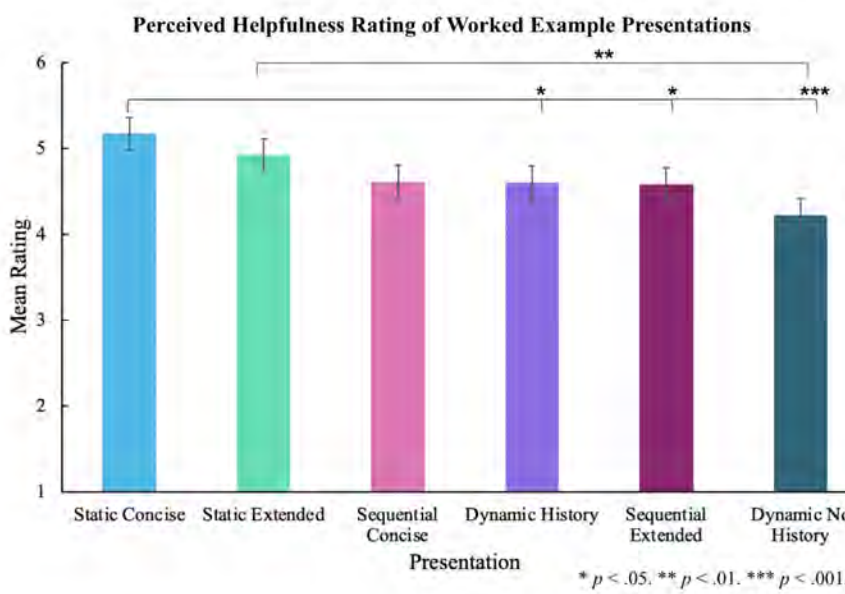

Figure 3: Average Perceived Helpfulness Rating of Each Worked Example Presentation

Research Question 2: Themes Among Students' Explanations

Next, we identified common themes in students' explanations of why they found each worked example helpful or unhelpful. Two researchers independently coded the 654 explanations with 79% initial agreement and then resolved discrepancies together to create the final codes. The following themes emerged: amount of content, video speed, dynamic coherence, and visual features (Table 1). Importantly, students' explanations were coded as whether they included a reference to one or more of the themes rather than whether students found each feature to be a positive or negative feature of the worked example presentation.

Table 1: Themes Identified Across Students' Explanations

Theme	Definition	Student Example
Amount of Content	Comments on the quantity of information presented in the worked example	*"I like seeing each step in the problem (regardless of how "trivial" the step is). It helps me see the train of thought that I'm supposed to be having while solving the problem."*
Dynamic Coherence	Comments on the presence or absence of fluid transformations and transitions that connect steps and actions.	*"The transitions may have helped but made it more visually confusing"*
Speed	Comments on the speed of the animations	*"It was very slow and hard to focus on"*
Visual Features	Comments on visual features such as font, spacing, styling, and format	*"…The font is very clear…"*

The themes identified were not exhaustive or mutually exclusive: students' explanations could be coded as pertaining to none, one, or more than one theme. As a result, 303 of the 654 explanations were not labeled as matching any of the above themes. For example, one student explained the problem-solving process rather than describing why they found the example to be helpful or unhelpful: "*By using the distributive property, the 3 was multiplied to the h and the −2, and the 5 was multiplied to the h and the −2. Like terms were added together, and h was isolated by simple algebra*." Conversely, another student's reaction to the *sequential concise* worked example referenced amount of content, video speed, and dynamic coherence:

> *While this animation laid out all the necessary steps to solve the equation, the steps were revealed somewhat spastically and it was almost startling to the eye to watch the equation being solved. Additionally, this animation left the viewer with little time to slowly work through the problem at their own pace and go back to a previous step if they were confused. This is because the format of this animation was a bit stressful.*

Table 2 presents the frequency of explanations that were labeled as containing one or more of the described themes by condition and overall. Students commented most often on the *amount of content* presented followed by the *dynamic coherence* of the worked examples and *speed* of the worked example. Miscellaneous visual features such as font and format were less often noted.

Table 2: Frequency of Themes Across Conditions

Worked Example Condition	Theme			
	Amount of Content	Dynamic Coherence	Speed	Visual Features
Static Concise	15	20	18	6
Static Extended	30	11	5	6
Sequential Concise	33	17	30	9
Dynamic History	16	36	12	9
Sequential Extended	16	24	19	6
Dynamic No History	31	31	21	7
Total	141	139	105	43

Research Question 3: Students' Explanations for Most and Least Helpful Presentations

Finally, to delve deeper into how students attend to features of worked examples and to contribute findings to cognitive load and perceptual learning theories, we explored how students' reactions to the *static concise* and *dynamic no history* presentations may explain their highest and lowest helpfulness ratings, respectively (Table 3). A closer inspection revealed that students found the *static concise* worked examples familiar and helpful because students could self-pace how they studied them. Twelve students praised the opportunity to self-pace themselves; further, four students noted that they would have preferred to also have instructional explanations accompany the *static concise* worked example. On the other hand, nine students positively noted that the *dynamic no history* presentations were helpful by providing explicit transitions between derivation steps while 38 students noted that the format caused confusion, and the derivation disappearing as each new line appeared required more effort and time to process.

Table 3: Sample Explanations for Static Concise and Dynamic No History Presentations

Static Concise	Dynamic No History
"the worked example was very helpful because steps were concise and understandable and the numbers didn't move around or disappear."	"Having all of the steps on the same line during the animation can be cumbersome if a student trying to learn the process has a specific question about a particular set and has to wait for the full animation to finish for it to restart."
"The example showed the steps, so I could understand the process. However, if I did not know how to do it already I may have been confused because there were no	"This worked example really helped as it would physically move each number around so you would physically see what was happening and then show what it would produced so you would

written instructions of what the person did.”	know where each number was going. This helped with visualizing what was taking place.”
“With few steps, this is not too hard to follow. But with larger numbers or more written steps, this would easily become overwhelming!”	“I think it would have been more helpful to see the steps written out statically rather than in a gif. It could be difficult to keep up, especially if you didn't understand a step right away.”
“I could look at the whole problem at my own pace.”	“Was way harder to follow what was happening without everything written out; once the directions disappeared I couldn't follow the solution anymore”

Discussion

This study is a foundational effort to explore how students respond to worked examples in ways that may not be reflected through learning gains alone. To integrate students’ perspectives on worked example designs for algebra, we asked college students to rate the helpfulness of six worked example presentations and to explain their ratings. We found that students rated the *static concise* presentation as the most helpful and the *dynamic no history* presentation as the least helpful. Students’ explanations for their ratings revealed that they commonly attended to the following elements of the worked examples: *amount of content*, *dynamic coherence*, *speed*, and other *visual features*. On the one hand, students revealed that the *static concise* presentation was familiar to previous classroom experiences and allowed for self-pacing, potentially supporting students’ chances to self-regulate their learning. On the other hand, the *dynamic no history* presentation required more effort to process, rendering it less helpful. These findings advance cognitive theories of mathematics learning and provide implications for researchers and teachers.

Our finding that students rated the *static concise* presentation as the most helpful aligns with cognitive load theory and explanations for the worked example effect. Specifically, students preferred the presentation with the least amount of information and content which likely prevented students from feeling as though they were studying redundant information or splitting their attention between different areas of the worked example (Sweller, 2020). This presentation is also a commonly used format for algebra worked examples (e.g., Rittle-Johnson & Star, 2007) and multiple students commented that they found it familiar with their past experiences.

Further, the finding that students found the *dynamic no history* presentation the least helpful aligned with prior work comparing different formats of worked examples. In particular, Lusk and Atkinson (2007) exposed college students to worked examples on proportional word problems that were: *fully-embodied* with an animated parrot that used gesture and gaze, *minimally embodied* with a static parrot who could only talk, or *voice-only* worked examples that provided only an audio description for the worked example. They found that while learning gains were the highest in the *fully-embodied* condition, students who studied the *minimally embodied* worked examples had the lowest levels of cognitive load. Lusk and Atkinson’s (2007) results suggest that extra information presented through animation and dynamic videos may support learning but may also present more challenges to students as they study worked examples with animations. Although ample research has demonstrated the benefits of perceptual scaffolding in math to direct students’ attention towards important cues in notation (e.g., Goldstone et al., 2017), perhaps the fluid transformations displayed in the *dynamic no history* worked example presentation provide extraneous distractions that increase demands on, rather than offload, students' working memory.

Students' explanations for the static concise and dynamic no history presentations indicated important visual features to consider when modifying these worked example presentations in the future. Namely, students indicated that they would find the worked examples more helpful if accompanied by written explanations for each step in the derivation. Further, if researchers or instructors choose to use a dynamic version of worked examples in classroom instruction or online practice, slowing the video speed or providing students with the autonomy to pause videos may reduce the cognitive effort and time that students indicated needing to process the *dynamic no history* presentations.

Importantly, we acknowledge that students' ratings and explanations for the helpfulness of the worked examples may be influenced by their own content knowledge. Specifically, the study materials were developed based on middle-school math content and might have been too easy for our sample of college students. However, by conducting this study with college students, we received thoughtful reactions to the worked example formats that still provide insights that may inform future iterations of worked examples used for online instructional practice.

Looking ahead, conducting comprehensive studies with algebra students may help delineate cognitive and non-cognitive mechanisms of learning and inform the design of worked examples for online learning environments. For instance, the six worked example presentations here were modeled after principles of cognitive load theory and perceptual learning theory; future studies should measure how students' cognitive load is impacted and how students may be impacted by studying different worked example presentations at different stages of learning. Further, it may be worthwhile to investigate the relation between students' learning gains, cognitive load, and perceptions of helpfulness. For instance, Whitehill et al. (2019) found that learners' subjective ratings of various tutorial videos (i.e., how helpful the videos would be for others) were highly correlated with their later learning gains. Participants who found the videos helpful learned more than those who did not find the videos helpful, confirming their initial bias towards the videos. These findings suggest that learners might be able to gauge the effectiveness of instructional support or that learning may be modulated by learners' perceived helpfulness. Regardless of the directionality of the influences, students' perceived helpfulness of the instructional materials may be closely related to learning outcomes, warranting further investigations of how this effect may impact the effectiveness of worked examples.

Analyzing students' perceptions of six worked example formats revealed that students prefer worked examples with minimal instructional content in a static image rather than worked examples with animations and fluid transformations between steps. These findings provide insights for researchers and teachers as they design algebra worked examples for online settings.

Acknowledgments

We thank Nellie Rushton and Lilly-Beth Linnell for coding students' responses. Additionally, the research and development reported here was supported by the Institute of Education Sciences, U.S. Department of Education, through the Small Business Innovation Research (SBIR) program contracts 91990019C0034 and 91990018C0032 to Graspable Inc. A 2D SHAPE COMPOSITION LEARNING TRAJECTORY OF A STUDENT WITH DIFFICULTY IN MATHEMATICS

Angela Crawford
Boise State University
Angelacrawford1@boisestate.edu

Aysia Kernin
Boise State University
aysiakernin@u.boisestate.edu

This study explores a spatial reasoning learning trajectory of a student with difficulty in mathematics. Using a teaching experiment methodology across 15 instructional sessions, we observed how the student responded to instruction based on an established 2D shape composition learning trajectory (Sarama & Clements, 2009). A narrative microgenetic analysis identified conditions that were likely to have promoted learning. The analysis shows the student's actual trajectory was similar to that of the hypothesized learning trajectory. Challenges to progress emerged around teacher-guided components of instructional support. We describe how a student-centered approach and mathematizing through specific praise was generative of learning, while explicit guidance was not. We discuss how the guiding conjecture of the teaching experiment evolved and how it is situated within the broader literature base.

Keywords: Learning Trajectories and Progressions, Students with Disabilities, Geometry and Spatial Reasoning.

Students with learning disabilities and math anxiety often experience dissonance in mathematics learning spaces. The "clamor" created for the individual as they interact with mathematics and with others in the mathematics environment can, at times, be intense. This work centers the learning experience of Eva, a nine-year-old student with learning disabilities and anxiety. We wish to take an anti-deficit stance and refer to Eva as a student who has experienced considerable difficulty in mathematics learning situations.

An approach to instruction that has potential for harmonizing the learning environment for students who have experienced difficulty in mathematics is the use of learning trajectories (LTs). We conducted a teaching experiment with Eva that investigated spatial reasoning LTs. Here, we present a narrative microgenetic analysis of one of those trajectories, Eva's actual 2D shape composition LT and describe features of the experience that were supportive of and hindrances to her progress.

Theoretical Framework

In the United States, mathematics interventions are commonly supplemental programs intended to provide more intensive and individualized support (Powell et al., 2013). There is a consensus among researchers that students in interventions benefit most when this support is designed to be systematic (Fuchs et al., 2021). Systematic instruction includes features such as connecting to previously learned mathematics, using accessible number and visual representations, and gradually increasing complexity.

However, there are disagreements around instructional delivery format and what should structure the increasing complexity across lessons. Many researchers contend that instructional delivery must incorporate explicit, direct methods (e.g., Grigorenko et al., 2020). In contrast, other researchers are using carefully structured sequences of tasks that build on students' thinking and direct their attention to mathematical relations without initial explicit guidance (e.g., Hunt et al., 2020; Xin et al., 2016).

LTs offer another potential way to provide structure to support the learning of students who have experienced difficulty in mathematics learning situations. Research has shown positive effects of mathematics instruction based on LTs for young students at risk for later difficulty in mathematics (Clements & Sarama, 2007; Clements et al., 2019; Clements, Sarama, Baroody et al., 2020). Further, research indicates that instruction based on geometry trajectories can support learning in other mathematical domains and support executive functions which have been shown to be important to mathematics achievement (Clements et al., 1997; Clements, Sarama, Layzer et al., 2020; Schmitt et al., 2018).

LTs structure learning through developmental progressions, sequenced learning goals based on the progression, and tasks designed to support progress toward the goals (Sarama & Clements, 2009; Simon, 1994). The systematicity provided by the developmental progression is something that distinguishes instruction based on LTs from instruction that is more typical of intervention contexts for students who have experienced difficulty in mathematics. Whereas a typical intervention approach is to identify components of the target knowledge or skill and provide instruction for each component, instruction based on an LT focuses on intermediary phases of reasoning or acting that culminate in the desired knowledge. Simply put, rather than breaking a mathematical task down into smaller parts in order to learn how to do it, the ability to perform the task is built up "naturally" based on a students' current knowledge. Tasks can be designed to draw on a variety of instructional delivery formats–explicit instructional principles, incorporate multi-modal delivery and response, or first elicit student thinking before guiding that thinking toward more sophistication and abstraction.

2D Shape Composition as a Developmental Progression

The 2D shape composition LT (Clements & Sarama, 2021; Sarama & Clements, 2009) involves children gradually developing understanding of and attending to geometric attributes and mentally anticipating results of combining shapes. At an early stage of the trajectory, Piece Assembler, when children begin to put smaller shapes together to compose larger shapes, they do so through trial-and-error. At the next level, Picture Maker, children can combine several shapes to make part of a picture but still use trial-and-error. They select a shape based on a general shape or approximate side length, and can fill in puzzles that indicate the placement of the shape (interior lines are present). When children reach the Shape Composer level, they can anticipate shapes that are needed to fill in a larger region and choose shapes considering angles and side lengths. They can also intentionally use rotation and flipping to correctly orient shapes. This is followed by Substitution Composer in which children use trial-and-error to make multiple versions of a composite shape by combining shapes in different ways. The subsequent levels, Shape Composite Repeater and Shape Composer--Units of Units, involve understanding composite shapes themselves as part of larger shapes and working with patterns that combine composite shapes.

Method

We describe a teaching experiment with Eva, followed by a narrative microgenetic analysis. Teaching experiments apply methodological consistency within a naturalistic setting (Confrey & Lachance, 2000; Steffe et al., 2000). A guiding theory or conjecture is tested through intentional teaching, data collection, and on-going analysis. The conjecture that guided this teaching experiment is that an established LT supplemented with individualized supports can facilitate learning in a student who has experienced difficulty in mathematics learning situations.

This narrative microgenetic analysis had two important elements: (a) focusing on identifying conditions that might promote learning (Lavelli et al., 2005; Siegler, 2006), and (b) identifying a plot that links data as unfolding temporal development (Polkinghorne, 1995). The first element, conditions that promote learning, is based on a density of observations during a period of time during which we hope to see change. These observations can describe types of statements or behaviors, how the statements or behaviors change, the rate at which change occurs, possible sources of change, and how widely generalized the knowledge (Siegler, 2006). The second element, the resulting "story," gives shape to a multitude of factors that are at play.

Participants

Eva is a multi-racial girl living in the western United States. At the time of this teaching experiment, Eva was nine years old and in grade 3. Two years prior to this study, Eva underwent a neuropsychological evaluation which identified the following challenges: attention deficit with unspecified impulse-control and conduct disorder, speech-sound disorder, specific language disorder with impairments in written language and mathematics, and generalized anxiety. Eva attends a public charter school in a small city and has received special education services in a pull-out program ("resource room"). Upon meeting with Eva's mother, we discussed Eva's difficulties in mathematics and talked about ways to provide her with additional academic support without increasing her anxiety. We gained informed parent consent and student assent following guidelines established by the university's Institutional Review Board.

We recognize our roles as participants in this research. As a teacher, one of us conducted the teaching experiments in relationship with Eva and her mother, who was present for all the sessions. This relationship involved negotiating goals, activities, what was to be attended to and what was not, as well as negotiating interpersonal interactions and trying to establish trust. As researchers, we both continue this relationship with Eva through our interpretations of the videos, transcripts, and memos. We take the position of bracketing ourselves into this narrative, rather than attempting to position ourselves outside (Connelly & Clandinin, 2006).

Teaching Experiment Procedure

The first author, Angie, conducted all of the teaching experiment sessions. The sessions took place in the winter and spring of 2020 amidst the COVID-19 pandemic. The meeting dates were flexible to allow for family needs and local quarantining requirements. All sessions took place at Eva's home, and Eva's mother was present to support Eva's well-being and engagement. There were 15 teaching experiment sessions, each ranging from 30-45 minutes. Due to the pandemic and to limit factors that might contribute to Eva's anxiety, it was not possible to have an additional researcher present during the sessions. During each session, Angie asked Eva's permission to video record the activity and only recorded when Eva stated she was comfortable with it. We recorded nine of the 15 sessions.

Tasks described in this paper come from the 2D shape composition LT (Clements & Sarama, 2021; Sarama & Clements, 2009). These tasks involved placing pattern blocks (colored, wooden blocks in shapes of triangles, squares, trapezoids, hexagons, and two different rhombuses) into "puzzles" that provided outlines of a composite shape (puzzles may contain all, some, or no interior lines). We were open to adjusting the sequence of tasks and delivery format as needed to support Eva's engagement and documented the nature of and rationale for any changes to the LT.

We used a planning protocol for documenting instructional decisions and reflections on Eva's activity. The protocol included prompts for observations, outcomes, adjustments made, and rationale for adjustments. These plans were shared with two colleagues. One colleague, with expertise in early mathematics instruction for students with learning disabilities, advised on the tasks and supports. A second colleague, with experience with children with anxiety, advised on the plans in light of Eva's affective responses.

Data Sources

Data sources were the planning protocols previously described, field notes from each session, photographs of student work, videos and transcriptions, and a post-hoc observation protocol. The second author, Aysia, completed the post-hoc observation protocol as a way to triangulate observations and interpretations of Eva's responses. This protocol recorded several features of the interactions: the task description, student behaviors (strategies, demonstrations, comments), teacher behaviors (explanations, providing time to work without interruption, additional supports), and any other observations. Aysia completed the protocol for each video. It was common to pause and re-watch segments of a video file multiple times to capture all necessary data.

Data Analysis

We used a form of narrative analysis adapted for microgenetic studies that can account for the multidimensional nature of learning in individuals (Lavelli et al., 2005). This approach comprises five stages. The first involves viewing videos repeatedly to identify a list of potential "frames," the specific viewpoints or phenomena which could be a focal point for analysis. In the second stage, we constructed descriptive, chronological narratives, one for each session of the teaching experiment to document the sequence of events. To ensure accurate and comprehensive narratives, we each wrote an initial narrative for half of the sessions and then reviewed and revised the narratives written by the other. Thoughts related to frames, explanations, interpretations, questions or reflections were recorded in a parallel set of memos. In the third stage, we used the chronological narratives to discuss possible configurations of frames that seemed profitable ways of portraying learning. This study presents the frames of Eva's activity within the 2D shape composition LT and Eva's response to components of instructional support. The fourth stage involved re-reading the chronological narratives to look for evidence of stability or change over time and to develop stories that synthesize a preliminary "plot." Evidence to confirm or refute this plot was then gathered through an in-depth analysis of the data sources with particular attention to overt behaviors and strategies. In the fifth and final stage of analysis, the stories and evidence were used to create a narrative that synthesizes our views on Eva's experience.

Findings

We conducted a microgenetic study of Eva's learning experience with LTs. We present the frames of 2D shape composition activity and Eva's response to components of instructional support in narrative form, highlighting Eva's responses we believe are representative of Eva's experience.

The Story of Eva's 2D Shape Composition Trajectory

Sessions 1—4: Piece Assembler. In the first session, Eva did not want to solve puzzles, and she abandoned the activity. She returned when asked if she wanted to create her own picture, and she created a figure from a favorite cartoon with each block playing a unique role in the picture (i.e., one shape for each part of the picture, no shared sides). In the next sessions, Eva's activity suggested she recognized triangles, squares, and hexagons, but she did not name them. She used trial-and-error to fill shape outlines. When asked why she picked a particular shape, she would describe the shape as "skinny" or point at an angle or single side without further responses. We used "mini-puzzle" task cards with outlines of 2 shapes to control complexity and encourage Eva's intentional selection of shapes and her use of turning to orient them appropriately. Eva created her own picture of a dog in which three shapes combined to make a part of the picture (dog's head and ears). See Figure 1 for photos of Eva's work at this level.

Figure 1. Images of Eva's work at Piece Assembler level (sessions 1—4).

Sessions 5–7: Picture Maker. Eva placed several like shapes together to create sections of a puzzle when the interior lines were provided. She found this "easy" and asked for harder puzzles. We provided puzzles that had fewer interior lines but with some exterior line "cues" such as clear indicators of a triangle or rhombus. She continued to select recognizable shapes first. For example, she filled a rhombus with two triangles, thus composing without an interior line, but also shared she could have used "the red piece" instead. See Figure 2 for images of Eva's work during these sessions.

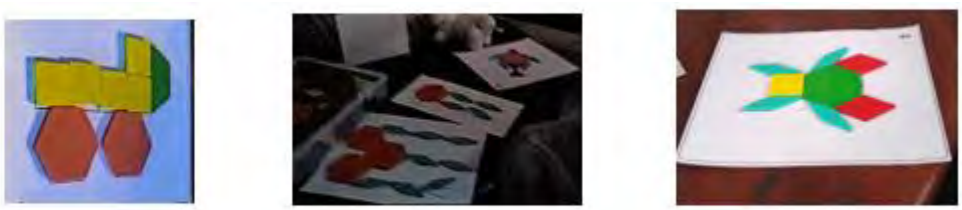

Figure 2. Images of Eva's work at Picture Maker level (sessions 5—7).

Sessions 8-14: Shape Composer. Eva described puzzles with interior lines provided as easy, and now she began to fill in those with fewer interior lines and more shared sides. During the first sessions at this level, Eva was showing more evidence of intentional actions by looking at the picture and then selecting a particular block. When a selected shape did not work at first, rather than try to turn and orient it differently, Eva would return to the container and look for something else. She showed more perseverance, trying several blocks before abandoning the task. Once she placed a block that appeared to fit but in combination with additional blocks no longer did so. Rather than replace any, she added a block that overlapped others to fill the empty space.

In later sessions at this level, Eva spent more time thinking about what would fit before selecting a block. Eva began to intentionally turn the blocks to orient them. Also, she began to see herself as an expert and wanted harder puzzles. We introduced pentomino puzzles, and Eva returned to trial-and-error and resisted guidance or suggestions. In session 14, though she still used trial-and-error, she did use rotations and flips to try different orientations of the pentomino to see if it fit. Images of Eva's work at Shape Composer level are shown in Figure 3.

Figure 3. Images of Eva's work at Shape Composer level (sessions 8—14).

Session 15: Substitution Composer. Despite her previous confidence, on this day Eva did not feel ready for "expert" puzzles. She did complete a pentomino puzzle with two pieces and no interior lines which shared a two-unit long side by applying turns and flips. She filled a pattern block puzzle two different ways, but she became frustrated on the third attempt and said she "tried her hardest."

Figure 4. Image of Eva's work at Substitution Composer level (session 15).

The Story of Eva's Response to Instructional Supports

Having learned that Eva was very anxious about math and that math instruction usually focused on numbers, we decided to focus on spatial reasoning tasks. Perhaps unsurprisingly, a challenge arose during the first session. Eva tried a few pattern blocks to fill in a puzzle and did not find they fit and said she wanted to do something else. Angie suggested looking at another section of the puzzle, but Eva got mad, stood up from the table, grabbed a scooter, and rode around her home's patio. Eva returned when Angie said they would do something different and brought out a whiteboard and markers. At the end of the session, Angie asked if Eva would make any picture she wanted with the pattern blocks. Eva made an image of a cartoon character she liked.

Based on interactions like that just described, Eva's engagement was a primary factor in task selection and instructional decisions. We selected activities that would be accessible to her and provide her with quick successes. For example, in the second session, we gave Eva a puzzle with no shared sides and easily recognizable shapes (i.e., square, triangle, and hexagon). For the next few sessions, we gave Eva mini-puzzle cards, each with two blocks, gradually increasing the proportion of the shared sides and gradually introducing less recognizable shapes (i.e., trapezoid and two rhombuses). Eventually these cards only provided the outline with no interior line. After Eva completed a few of these mini-puzzles, we offered her a larger puzzle that incorporated the shapes she had just worked with and asked if she wanted to try it. Using this approach of offering accessible puzzles and choices, Eva began filling in more complex shapes, perhaps due to increasing confidence or awareness of attributes or both.

We initially planned to discuss mathematics involved in tasks and to mathematize her activity to support her naming of shapes, noticing and describing attributes, and orienting shapes to compose a larger shape. However, when Angie discussed how many blocks were used in a section or tried to show the difference between angles of different shapes, it elicited avoidant behaviors–stopping participation, leaving the table, and expressions of frustration, anger, or sadness. This was even more evident when Angie asked Eva for a verbal response in return. Eva expressed that she didn't know how to answer Angie's questions or answered by repeating what

Angie had just said. The following transcript illustrates one of the times when Eva was upset by Angie's approach to providing guidance:

Angie: But you know what I see? I see lots of gaps and holes. I wonder if there's another way that might work better. Is there another way that will work better?... [Eva starts making humming noises] I just want you to show [Angie pauses]…. Does that work? …[Eva makes a noise like "grrr"]
Eva: This is right.
Angie: This is right? [Eva makes a noise like "grrr"] How do you know that?
Eva: [sounds as though she is growling out the words] It looks just like it.
Angie: It looks just like it?
Eva: [loudly] Yes it does.
Angie: Okay. Okay, all right.
(Simultaneously) Angie: Eva, I'm gonna use that description that you just used… Eva: I'm in the yellow.
(Simultaneously) Angie: I'm going to ask you to…. Eva: I'm in the yellow!
Eva: I…am...in…the…yellow!
Angie: Yes, I heard you say that.
Eva: You don't continue if you're in the yellow.

Angie stopped and looked to Eva's mother who explained that when at school 'in the yellow' means that Eva is upset, and it is a time to bring in tools to help Eva regulate her emotions.

Eva consistently responded negatively to guidance in the form of explicit explanations, discussion of math involved in the tasks, or corrective feedback. However, if mathematizing Eva's activity came in the form of specific praise, such as, "Wow! What great problem solving! I saw you *turn* the block to find out if it would fit another way," it had a much more positive effect. Angie would mimic Eva's activity while giving the praise, emphasizing important terms and motions. Eva would then continue to draw on that behavior or strategy in future puzzles. Eva also appeared to learn the names of some of the pattern block shapes after hearing them in the context of praise across several sessions.

We settled on an approach that offered Eva choices of puzzles that very gradually increased in complexity and which were likely to elicit some of the behaviors or strategies we hoped to see. We then used praise to draw her attention to those elements. Thus, our conjecture needed to be revised: engagement and progress would be supported by a gradual, systematic increase in complexity allowing for student choice and mathematizing through specific praise.

Over the course of the sessions, Eva began to express confidence. In session 7, Eva said she wanted "a very, very hard one." When Angie asked what she would do if it was too hard, Eva said she would "think hard about the shape." In session 8, she said, "Give me all challenge." In session 11, she picked a puzzle she said "would be hard for other people." By session 14, Eva said she was an expert and didn't know why she had to do the puzzles again. For this session, we had also planned to switch to puzzles that involved pentominoes rather than pattern blocks to encourage her attention to "turning" and "flipping." Eva's interest in the new puzzles was piqued, but it was clear when these were introduced, that her persistence with these still depended on early successes.

Discussion

This microgenetic study provides information on several different aspects of Eva's learning: presence of change, rate, stability, sources of change, hindrances, and generalization (Siegler, 2006). Eva's actual trajectory in 2D shape composition aligned with the established LT (Clements & Sarama, 2021; Sarama & Clements, 2009). Eva demonstrated increasing ability to use multiple pattern blocks to compose larger composite shapes with fewer lines as interior cues. She spent more time working in Shape Composer level than in the previous levels as she became more intentional in selecting and rotating blocks to complete the puzzles. Rather than suddenly demonstrating multiple actions that comprise a higher level in the progression in a single session, Eva demonstrated gradually more sophisticated actions-on-objects across sessions. These changes also appeared to be stable. In fact, Eva found tasks of a similar level of difficulty "too easy." Eva also appeared to be close to generalizing some use of attributes and transformations (i.e., turning and flipping) to solve problems with pentominoes.

A teaching experiment intentionally applies and tests a conjecture in real teaching and learning interactions (Confrey & Lachance, 2000; Steffe et al., 2000). Teaching, data collection, and analysis are responsive to the students, and conjectures are evaluated and revised accordingly. We found that Eva quickly abandoned tasks for which she did not possess a ready solution strategy. We also found that directing Eva's attention prior to activity, providing explicit explanations or demonstrations, or drawing attention to challenges were ineffective in engaging her with the task. Our conjecture evolved to state that a gradual, systematic increase in complexity which allowed for student choice and mathematizing the student's activity through specific praise would support engagement and progress. As we adjusted instruction to align with this conjecture, we found Eva expressed growing confidence and willing engagement in 2D shape composition tasks. We ensured she had the opportunity to choose puzzles and begin to solve them without any guidance at first, allowing her the opportunity to approach the task in whatever way made sense to her. We ensured systematicity by carefully selecting or creating puzzles that gradually increased in difficulty. We supported her continued use of strategies or vocabulary by providing specific praise when strategic thinking was observed and naming the shapes she had used.

A noteworthy aspect of these findings is that the revised conjecture problematizes recommendations that instruction intervention contexts should incorporate explicit explanations and specific corrective feedback (Grigorenko et al., 2020; Fuchs et al., 2021). A direct, explicit instructional approach did not encourage Eva's engagement with mathematical tasks. Rather, this study adds to other research which has shown students who have experienced difficulty in mathematics learning situations can benefit from instruction which elicits and builds on student thinking (e.g., Hunt et al., 2020; Xin et al., 2016). In Eva's case, that guidance was most successful when it also celebrated her successes. We are continuing to analyze Eva's responses to better understand how guidance impacted her engagement in other LTs. We believe these findings add to the literature which suggests LTs can provide a structure for establishing more "harmonious" mathematics learning situations for students like Eva.

FIFTH GRADE STUDENTS' MATHEAMTICS IDENTITY, STUDENT ACHIEVEMENT, AND CLASSROOM EXPERIENCES

Jennifer Cribbs

Juliana Utley
Oklahoma State University
Juliana.utley@okstate.edu

Drawing from a sample of 63 fifth grade students in one school setting, we conducted a pilot study exploring students' self-reported mathematics identity and how it correlated with math achievement and experiences in their mathematics classroom. Data were analyzed using linear modeling to determine which variables were predictive of mathematics identity. Results indicate that achievement and students' classroom experiences associated with assessments, a focus on memorization, and teacher strategies were predictive of their mathematics identity. This work informs the field by expanding on our understanding of how important aspects of students' classroom experiences contribute to their mathematics identity development.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Mathematics Identity

Decades of research has shown that non-cognitive factors matter when it comes to student persistence in mathematics (e.g., Boaler & Greeno, 2000; Maltese & Tai, 2011; Sasson, 2021). More specifically, mathematics identity is connected to students' career choice in mathematics and mathematics-related fields (Cribbs et al., 2020; Godwin et al., 2016). Recent research suggests that students' ninth grade mathematics performance, high school STEM GPA, and their mathematics identity are a strong predictor of twelfth grade students' mathematics achievement (Brohrnstedt et al, 2021). Further Zhang and colleagues (2021) found that when compared with other affective measures (self-efficacy, math interest), "mathematics identity had a significant relationship with mathematics achievement" (p. 60). These studies highlight the essential role that mathematics identity has on students' engagement and continued participation in mathematics. However, little research explores this construct quantitatively to better understand trends in identity development throughout students' K-12 schooling experience or how teachers are supporting students' mathematics identity development for students in general (expanding beyond small groups of students). Graven and Heyd-Metzuyanim (2019) indicate that all but two studies in their review of literature on mathematics learner identity had eight or less participants. Additionally, middle grades mathematics (5^{th}-8^{th} grade) is a pivotal time in a student's schooling as it is often a time when attitude and interest toward mathematics begins to drop (Harter, 1981; Marsh, 1989; Zhang et al., 2021). However, there have been calls for teachers to help students' develop a productive mathematics identity, seen through various NCTM publications (Aguirre et al., 2013; Fernandes et al., 2017) as well as in the new CAEP standards for preparing secondary mathematics teachers (NCTM, 2020).

Theoretical Framework

In our study, mathematics identity draws from Gee's (2001) work framing identity in terms of *being a certain kind of person* and Cobb and Hodge's (2011) extension of that work into specific aspects of identity – with this study focusing on core identity. Core identity is described as being a more enduring sense of identity, which becomes more stable as experiences accumulate (Cribbs et al., 2022). The construct of mathematics identity is comprised of three sub-constructs, recognition, interest, and competence/performance, and has been shown to be a valid and reliable measure with adults (Cribbs et al., 2015). Interest is defined as an individual's desire or curiosity to think and learn about mathematics. Recognition is defined as how the individual views themself and how the individual perceives others view them in relation to mathematics. Competence/performance is defined as an individual's beliefs about their ability to understand and perform mathematics.

With these studies and calls from NCTM in mind, the purpose of this study was to develop a mathematics identity instrument that could be used with middle grade students and explore how this measure could be used to examine how mathematics identity correlates with other variables of interest, such as achievement and teacher practice. For the purpose of this paper, the instrument development component is not included. Aligned to this purpose, the following research question guided the current study: Are students' mathematics achievement and classroom experiences in their mathematics classroom predictive of their mathematics identity?

Methods

Participants

This study include 63 students in grade 5 in one school in a mid-western state. These students were in different blocks with the same mathematics teachers. Sixty-three percent of the students identified as male, 35% identified as female, and 2% did not respond. Forty-nine percent of the students identified as White, 14% as multicultural, 13% as American Indian/Native American, 13% as Other, 5% as Black/African American. Additionally, 5% indicated they did not know their race. The average age of students was 11 with a range of 10 to 12 years old.

Data Collection and Analysis

Paper and pencil surveys were administered at the end of the spring semester by one member of the research team. Survey items included demographics (e.g., age, race), a measure for mathematics identity, student math achievement, and items related to students' experiences in their mathematics classroom.

The measure for mathematics identity included 11 items on a Likert-scale (1= not at all, 5=very much so). Four items aligned with the sub-construct recognition (e.g., I see myself as a math person). Three items aligned with the sub-construct interest (e.g., Math is interesting), and four items aligned with the sub-construct competence/performance (e.g., I understand the math I have studied). Mathematics identity items drew from prior research indicating that these items were valid and reliable for adult students (Cribbs et al., 2015). The mathematics achievement variable was measured with the question "on average what grade did you make in math this year" with responses ranging from 1=A to 5=F. Students' responses to classroom experiences included items related to technology (e.g., I used a calculator on tests), conceptual versus procedural learning (e.g., …during math class this year…required memorization of procedures in math class), mathematics teacher characteristics (e.g., my teacher was enthusiastic about mathematics), collaboration and discussion (e.g., we worked in small groups), connections and relevance of content (e.g., my teacher makes connections to real-life math applications), and classroom environment (e.g., students were disrespectful to you). These items were on a Likert scale (1=Never, 5=Always) and drew from prior research (Cribbs et al., 2020).

Linear modeling was conducted to address the research question, exploring if students' mathematics achievement and classroom experiences in their mathematics classroom predicted students mathematics identity.

Results

Table 1 details the results of the linear model. The dependent variable was the mathematics identity construct and the independent variables included students' mathematics achievement and perceptions of classroom practices. Only significant variables, with a significance level of $p < 0.05$, were included in the final model. Gender was also tested in the model as a potential control variable but was also removed as it was not significant.

Table 1 Linear Model Predicting Students' Mathematics Identity

(n=63)	Estimate	SE	t value	p-value	Effect size
Intercept	-4.21	5.56	-0.76	0.45	
Mathematics Achievement[1]	6.16	0.95	6.46	***	0.59
Classroom Experiences					
Required memorization of procedures in math class	2.56	0.63	4.03	***	0.40
Tests or quizzes required new insight and creativity	-1.97	0.70	-2.83	**	-0.30
My teacher highlighted more than one way of solving a problem	3.55	0.79	4.48	***	0.44
My teacher made mathematical errors	-1.68	0.75	-2.23	*	-0.21

*p<0.05 **p<0.01 ***p<0.001

Note: [1] this variable was reverse coded so that a higher value indicated a higher grade in the mathematics course

The results indicate that students' mathematics achievement (as shown by their math grade for the current academic year) was highly predictive of students' mathematics identity. Additionally, four classroom experiences reported by students predicted mathematics identity. Two of these practices were negative predictors "tests and quizzes required new insight and creativity" and "my teacher made mathematical errors." Positive predictors were "required memorization of procedures in math class" and "my teacher highlighted more than one way of solving a problem." These results will be discussed in more detail in the next section.

Discussion

While achievement predicting student outcomes is not a new finding, this study adds to literature by providing evidence of the correlation between student achievement and mathematics identity. Of the variables in the model, mathematics achievement had the largest effect size at .59, indicating a moderate to large effect. This finding is consistent with other research noting that students' prior achievement was predictive of 12th grade students' mathematics identity (Bohrnstedt et al., 2021). While that study explored prior achievement from 9^{th} grade, this study indicates that this relationship exists even at the elementary level.

The predictive classroom practices are more challenging to interpret. Three of the significant items, "required memorization", Tests and quizzes", and "mathematical errors" might align to the idea that students experiencing clear instruction could help them feel more competent with the math concepts. For example, prior research notes that students who experience instruction where teachers "explained ideas clearly" was predictive of students mathematics identity (Cribbs et al., 2020). These results could be representative of students need for a foundational understanding mathematical concepts in order to build their sense of competence and reduce their sense of anxiety. The last significant item related to the students' teacher highlighting more than one way of solving a problem. It is worth noting that this item had the largest effect size after student achievement, indicating the influence it had on students' mathematics identity. Having a chance to see different ways of thinking could be correlated to students' mathematics identity in several ways. While seeing these various methods may aid in students understanding (competence) with the content, this practice could also help students feel as if their ideas are being represented and shared with the class – potentially receiving validation from the teacher and/or their peers (recognition).

It is important to note that these results are very preliminary as the mathematics identity instrument has undergone additional revisions based on the findings from this pilot study. In addition, mathematics achievement and classroom experiences were self-reported by the students. However, students' perceptions of what occurs in the classroom are essential to exploring and understanding students' mathematics identity.

Connecting to the Conference Theme

This line of research, along with other work connected to mathematics identity, helps to provide a picture for how classrooms can serve as spaces for students to feel valued and supported. It is my hope that this unique approach to exploring identity through quantitative methods will serve to move the field forward and provide a lens for improving "learning conditions for each and every mathematics learner." A measure for mathematics identity could provide an efficient way for researchers and/or educators to assess influences on students' identity development. This could include interventions such as informal STEM programs for students or teachers embedding recommended equity-based practices based on professional development or literature.

MODELS BUILT BY UNIVERSITY STUDENTS WHEN SOLVING AN MEA ASSOCIATED WITH THE STEP FUNCTION

MODELOS CONSTRUIDOS POR ESTUDIANTES UNIVERSITARIOS AL RESOLVER UNA MEA ASOCIADA A LA FUNCIÓN ESCALONADA

Carlos Enrique Flores-Gasca

cefg.mat@gmail.com

Verónica Vargas-Alejo
Universidad de Guadalajara
veronica.vargas@academicos.udg.mx

This article presents the results of a research related to identifying and analyzing how university students built, modified, and refined their models to make sense of a situation where the step function underlies. A Model Eliciting Activity [MEA] was designed and implemented in an online environment. The participants in this study were 12 college-level first-term students. The theoretical framework that was used for the design of the activity, the implementation and the analysis of the results was the Models and Modeling Perspective. As a result, it was observed that the students were able to modify and extend their histogram models to step functions.

Keywords: Problem solving, modeling, precalculus, technology.

Introduction

Among the different types of functions, we can find the step function. This type of function is important in the economic and social areas, among others, since it allows describing, manipulating, and predicting various phenomena close to everyday life (Kaput & Roschelle, 2013). Furthermore, in calculus courses, the concept of a step function is a preamble to topics such as limits and continuity.

Researchers such as Doerr, Ärlebäck & Stanic (2014), Kaput & Roschelle (2013), Mochón and Maroto-Cabrera (2002) have identified that students –at different educational levels– present difficulties in modeling situations close to real life associated with piecewise functions. As well as interpret graphs of this type (Mochón & Maroto-Cabrera, 2002).

The objective of this research was to identify and analyze, based on models and modeling perspective [MMP] by Lesh & Doerr (2003), the models that university students built, developed, and externalized during the resolution of an MEA associated with the step function. It was interesting to know how the MEA could contribute to the development of students' knowledge about this function. The research was carried out through the virtual environment Zoom, as a consequence of the COVID-19 pandemic. The research question was, what models did the students build and externalize when solving the MEA "The Tokyo 2021 Olympic Games" in which the concept of step function underlies?

Conceptual Framework

Learning mathematics, based on the MMP of Lesh & Doerr (2003), involves a process of building, modifying, and refining models by students by engaging them in solving MEAs (Brady & Lesh, 2021; Sevinc, 2021). The models that are built at the beginning are often unstable, but these are continually refined and evolved to become shareable and reusable. Models are "conceptual systems (consisting of elements, relationships, operations, and rules that govern interaction models) that are expressed by external notational systems, and are used to construct, describe, or explain the behaviors of other systems" (Lesh & Doerr, 2003, p.10).

From the MMP, the design and implementation of MEAs are proposed as tools to engage students in the need to build models that enable them to describe, manipulate or predict phenomena close to everyday life. MEAs are designed based on the six principles for designing activities (Lesh, Cramer, Doerr, Post & Zawojewsky 2003): a) The Reality Principle, b) The Model Construction Principle, c) The Self-Evaluation Principle, d) The Model externalization Principle, e) The Simple Prototype, and e) The Model Generalization Principle.
Lesh (2010) proposes a *Quality Assessment Guide* to analyze some criteria as shareability and reusability of tools and artifacts that students produce during MEAs. Shareability and reusability "are among the most important criteria which are emphasized implicitly or explicitly in MEA problem statements" (p. 17). The guide permits analyze the types of models that students build, develop, and externalize when solving an MEA. These can be of five levels of action: 1) the model requires redirection, 2) it requires major extensions and refinements, 3) it requires only minor editings, 4) it is useful for this specific data given, and 5) it is shareable and reusable.

Based on the results of an investigation, based on the MMP and the covariational reasoning framework (Carlson et al., 2002), Montero-Moguel & Vargas-Alejo (2022) proposed a "Guide for the evaluation of models related to the concept of function [GEMF], which allows classifying the type of models built by students when solving MEAs that encourage the construction, modification, extension, and refinement of the function concept" (p. 226). Two of the models that the researchers proposed as part of the GEMF are as follows (Table 1): T1 Model, and T2 Model.

Table 1: Classification of models (extract taken from Montero-Moguel & Vargas-Alejo, 2022, p. 227)

Model T1. The model requires direction
The model is not associated with the function (exponential, in this case) that allows to better describe, interpret, predict, and control the situation. Students associate a linear behavior to the situation. Students need additional comments from their classmates or questions that encourage reflection by the teacher, that allow them to redirect their way of thinking. In relation to covariational reasoning, students show level 1 of Carlson et al. (2002, p. 358): "the images of covariation can support the mental action of coordinating the change of one variable with changes in the other variable (MA1)".
Model T2. The model requires major extensions or refinements
The model is associated with the (exponential) function that best describes the situation; however, students are unable to dissociate linear behavior. The student needs to work further to obtain greater extensions or refinements. Regarding covariational reasoning associated with the function that best describes the situation, the student shows coordination and direction of the variables. Students' reasoning relates to level 2 of Carlson et al. (2002, p. 358): " the images of covariation can support the mental action of coordinating the direction of change of one variable with changes in the other variable ".

In this classification, the results of Carlson et al. (2002) about that the learning of functions requires students develop their covariational reasoning are considered. Covariational reasoning is defined as "the cognitive activities involved in the coordination two varying quantitative while attending to the ways in which they change in relation to each other" (p. 357). Carlson, Larsen, and Lesh (2003) identified that involving students in solving MEAs allows revealing the development of their covariational reasoning. The MEAs "can be designed to promote a significant development of covariational reasoning in a short period of time, they have the potential to provide valuable information for researchers and teachers" (Carlson et al., 2003, p. 470). That is, they allow observing the processes that students use to differentiate, integrate, and refine relevant constructs (Lesh & Doerr, 2003).

Methodology

The research was qualitative because one of the objectives was to know the type of models that the students built and how these were modified and refined when solving the MEA. In particular, the teaching experiments research (Lesh & Kelly, 2000) was used. This type of research focuses on "focus on development that occurs within conceptually rich environments that are explicitly designed to optimize the chances that relevant developments will occur in forms that can be observed". (Lesh & Kelly, 2000, p. 192. One of the characteristics of the teaching of experiments is that the teacher is an integral part of the system he studies. By interacting with it, the teacher can observe how the student modifies, expands, and refines her knowledge when solving MEA (Lesh & Kelly, 2000).

The participants were 12 students, from 18 to 20 years of age. They were starting the Mathematics I course in the first semester of the Bachelor of Economics, so they had not seen, as part of the curriculum, the concept of step function. The modality was online.

The implemented activity (Figure 1) was designed based on the six principles for developing MEAs (Lesh & Doerr, 2003). The context was close to the students' career. The MEA was made up of three parts: a journalistic note of the context of the problem, questions about the context, and one problem. The mathematical idea behind the MEA is the step function. The students had to write a letter addressed to Alexa Moreno, as well as to gymnasts with similar difficulties to get a hotel accommodation which expense was the minimum possible from certain assigned budget as a loan. Data from three different hotels were provided (Figure 2).

> The directors of CONADE, to support the athletes, have agreements with three hotels: Shinjuku Tsukuyami, Tokyo Grand Palace and Dragon Palace. The hotels have accessible costs for the stay of the athletes (page 4, page 5 and page 6). In addition, the directors of CONADE offered a loan of $25,000 pesos. This is so that the athletes can stay during the two weeks of the Olympic Games.
>
> However, the interest rate on the loan is high. Therefore, it is necessary to plan the lodging of the athletes very well (that they spend the least amount of money possible) in any of the three hotels.
>
> Write a letter to the athletes explaining how they should plan their stay at any of the three hotels. You can write the letter in a way that helps athletes plan their accommodations at other hotels in the future.

Figure 1: Extract from the MEA "The Tokyo 2021 Olympic Games"

Figure 2: Extract from the MEA. Data provided of the situation

The implementation of the MEA was carried out in four phases, in an online environment.

1. **Resolution of the warm-up activity.** During the class, the teacher sent the file with the journalistic note to the students through Zoom. Individually they read and answered the questions. The answers were discussed in a group session.
2. **Resolution of the Situation.** The students were grouped into teams of four students to solve the MEA (teams A, B, and C). The teacher interacted through questions, constantly, with each team.
3. **Group discussion and closing of the session.** The teams presented their letters, discussed, and evaluated them with the support of the teacher and the group.
4. **Resolution of the MEA as an extra-class task.** The teacher asked the teams to build a new letter based on the final contributions –models–.

The duration of the MEA implementation was approximately 110 minutes. The data sources were a) the video recording of the session, b) the letters, c) procedures by the students and d) the teacher's notes. For data analysis, two categories of the GEMF (Montero-Moguel and Vargas Alejo, 2022) were adapted to the characteristics of the step function. Two researchers analyzed the results.

MT1, the model requires redirection. The model is not associated with the step function that allows describe and manipulate the situation. Students identify the variables and how they vary but have difficulty describing the relationship between them. Students can draw polygon graphs or histograms, even they can do only operations. They need additional feedback from their peers or the teacher to allow them to redirect their thinking.

MT2 The model requires major extensions and refinements. The model is associated with the function that best describes the situation; however, students have difficulty dissociating the histograms from the step function. Even when they observe the relationship between the variables, they do not identify or find difficult to describe and interpret the relationship between the variables, for example in the points associated with the extremes of each interval of the step function in its different representations.

Results and Discussion

This section describes and discusses the results obtained by implementing the MEA. In particular, the types of models that were built, modified, and refined by the students of team B are described and discussed. The evolution of the models of this team B is representative of what happened in the group.

First Model

Team B initially analyzed how much it would cost the gymnast to stay in each hotel for two weeks. The team found that she would have to pay $25,500 to stay at the first hotel, $24,500 at the second hotel, and $25,000 at the third hotel. As a result of the results obtained, the team carried out the following conversation.

b_1: I think gymnasts can't stay in just one hotel… how much budget do we have?
b_2: It is $21,500… if we consider that Alexa stays the first three nights in the first hotel, the next three nights in another hotel and so on?

After these questions, the team redirected its way of proceeding. The team considered that the budget could be optimized if the gymnasts booked in two or more hotels during their stay.

Observations to the first model. Team B related data based on their initial interpretation to the question posed in the problem. The model was not associated with the step function, it was a MT1. According to MMP "early models are expected to be relatively barren and distorted compared with later models" (Lesh, 2010, p. 17), "the things students see in a given activity often varies a great deal from one moment to another—as attention shifts from one perspective to another, from the big picture to details, or from one type of detail to another" (Lesh, Cramer, Doerr, Post & Zawojewsky 2003, p. 54). Also, the models that students built are shaped through interactions with their peers and the teacher.

Second Model

Team B rethought how the gymnasts would be housed and considered proposing a stay that included more than one hotel to fit the budget.
b_4: Look, if Alexa and the others stay three nights at the Shinjuku hotel, they are only going to pay $6,000, then if she stays another three nights now at the Dragon Palace then she only will pay $4,500… that is already $10,500.
b_3: Then you must consider the price for every three nights in the hotels and that it is… just see what happens from Sunday to Monday.
b_1: From Sunday to Monday, you only pay $500 at the Tokyo Hotel… let is take that for the first week and that it is, we have week one and we do the same with week two.

Once the team had finished comparing the accommodations costs for the gymnasts during their stay, team B plotted the number of nights on the x-axis and the price on the y-axis (Figure 3). The team first plotted the points associated with the price per night of the plan of lodging and then joined the points using line segments. The team related the variables (number of nights and the price) by means of a polygonal-type graph, without giving meaning to the line segments drawn. That is, the team had difficulty coordinating the change in one variable with changes in the other variable (Carlson et al., 2002).

Observations on the second model. According to Vargas-Alejo et al. (2016), it is common that students plot points and join them to represent situations of this type. Team B's model was not associated with the step function. The students needed to interact with their teacher, who through questions made them reflect on the relevance and meaning of the segments that joined the dots. The model was MT1 but compared to the first model, it has more representations where the identification of variables and how they are related is observed.

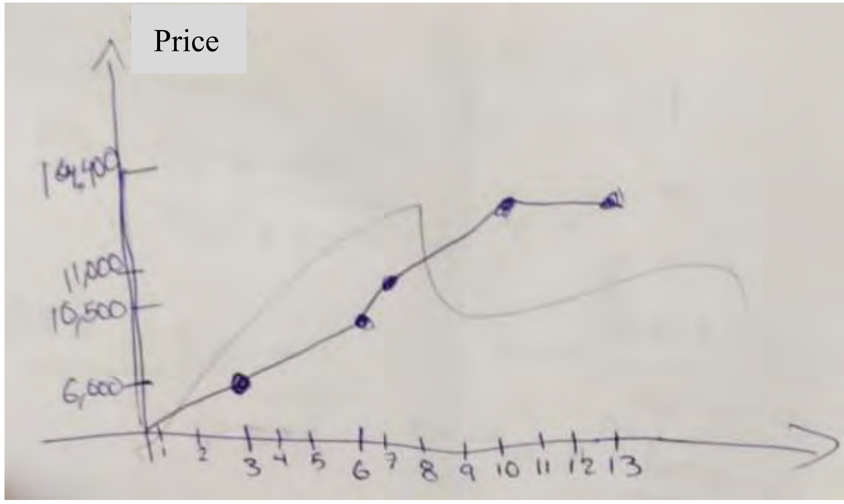

Figure 3: Polynomial type graph built by Team B

Third Model

Team B changed its way of thinking, since the teacher intervened in the discussion by asking the following questions: what is price? What do the plotted points mean in the context of the problem? What do the segments connecting the dots mean in the context of the problem? The team answered the first question as follows.

b_3: Well, the price that Alexa is going to pay due to the hotel accommodation, right, teacher?
b_2: The price is not... it would be the cost, right? It's just that the microeconomics' teacher told us that the cost is what the good cost or the product [*the student was trying to explain the concepts*] and the price is the cost plus the profit.
b_3: You are right teacher; it is the cost.

The team answered the second question as follows.

b_2: Look, where it costs three on the axis below [He pointed to the x-axis] there are three nights teacher, and there the gymnasts must pay \$6,000, where there are six nights there they must pay \$10,500 and so on.

To answer the third question, the team had difficulties.

b_4 : we don´t know teacher, they always come together, right?

Based on this interaction, Team B changed their thinking and wrote their gymnasts' accommodations proposal in terms of cost per number of nights. The Team constructed a histogram (Figure 4).

Observations to the third model. According to De Villiers (1988) and Vargas-Alejo et al. (2016) the students often create histograms to model problems like the one discussed in this document. It was necessary for team B to interact with their classmates and the teacher, during the group discussion (phase 3), so that they could analyze, redirect their way of thinking, and modify their model, which was still MT1. The team still had difficulty representing the coordination of the change of one variable with changes in the other variable (MA1, Carlson et al., 2002).

According to the data provided, you have a loan of $21,500 pesos. In addition, we consider that your stay could be like this:

In the first week, you could stay (from Monday to Thursday) at the "Shinjuku Tsukuyami" hotel with a cost of $6,000, the following 3 nights, you will stay at the "Dragon Palace Hotel" with a cost of $4,500. The last night, you will stay at the "Tokyo grand Palace hotel" with a cost of $500. In total, the first week you will pay $11,000.

In the second week you will stay at the "Tokyo Grand Palace" hotel at a cost of $8,400.

In total, you will pay $19,400 for two weeks.

Figure 4: Extract from Team B Letter

Fourth Model

During phase 3, the teacher asked the students to present their models and discuss them for review, comparison, and evaluation. The students identified that the step function model was the best to describe the situation. Team B presented the following model as an extra-class task (Figure 4 and Figure 5).

Dear athletes,

We provide you with the following proposal for your accommodation in Tokyo, Japan. With this proposal, you will be able to participate in the Olympic Games this year. We know that CONADE's resources are scarce. We also know that CONADE lent them the amount of $21,500 pesos.

The amount of money that CONADE lent you is limited, and unfortunately it must cover all your expenses. To help you, we carried out an exhaustive review of the packages offered by hotels (which have an agreement with CONADE); We detail below the plan that we consider beneficial for you and your present.

Week 1

Three nights (Monday-Tuesday, Tuesday-Wednesday, Wednesday-Thursday) you will stay at the "Shinjuku Tsukuyami" Hotel, you will pay $2,000 pesos per night. The following two nights (Thursday-Friday, Friday-Saturday) you will stay at the "Grand Palace" Hotel. In that hotel you will pay $1,500 pesos. The last night of this week (Saturday-Sunday) you will stay at the same hotel (Grand Palace). You will pay $500 pesos. In total, you will pay a cost of $9,500 pesos in the first week.

Week 2

Three nights (Sunday-Monday, Monday-Tuesday, Tuesday-Wednesday) you will stay at the "Grand Palace" hotel at a cost of $2,000 pesos per night. The following two nights (Wednesday-Thursday, Thursday-Friday), you will stay at the "Shinjuku Tsukuyami" hotel at a cost of $1,200 pesos per night. The last night (Friday-Saturday) you will stay at the "Tokio Grand Palace" hotel. In that hotel they will pay $600 pesos. In your second week, you will pay a total cost of $9,000 pesos.

Based on our proposal, you will pay a total of $18,500 pesos for two weeks. With this proposal, you will save $3,000 pesos. With this money, you can pay off the CONADE loan faster. In addition, the interest on the loan would be lower. We take the opportunity to add our graphic proposal for a better understanding, so that you can visualize and examine it. Greetings athletes. Good luck.

Figure 4: MT2 of Team B

It can be seen in Figure 4 that team B modified the plan of lodging, in such a way that the gymnasts could pay a lower amount. The team proposed a stay of $18,500, that is, $1,000 less than the budget described in the third model. Figure 5 shows how the team described the planning through graphical and tabular representations. It considered that the gymnasts should pay $6,000 for the first three nights, then they should pay $3,000 for the next two nights, and finally they should pay $500; $9,500 for the first week. While, for the second week, the team considered that for the first three nights they should pay $6,000, for the next two nights they should pay $2,400 and, finally, for the fifth, and sixth nights they should pay $600.

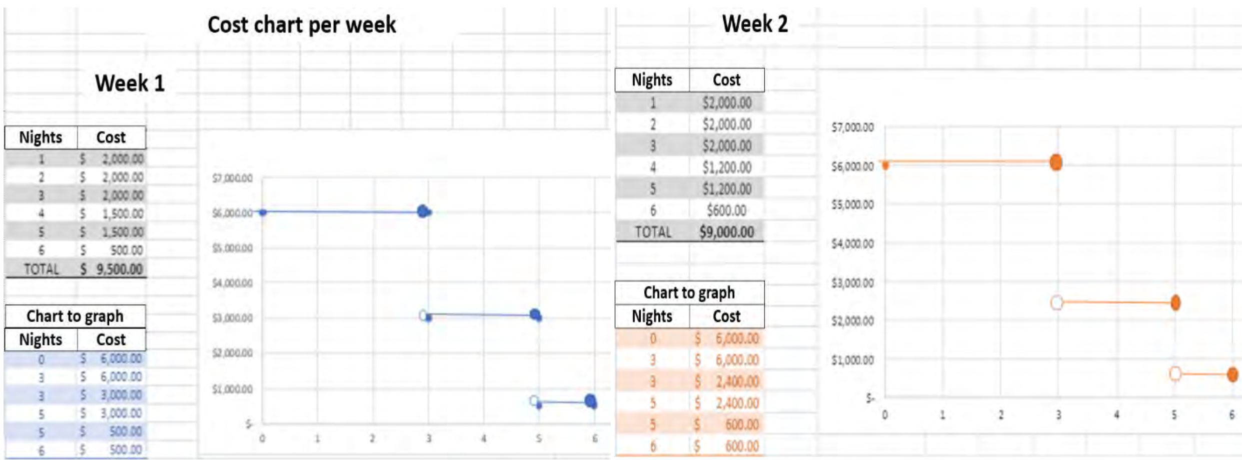

Figure 5: MT2 of Team B

Observations to the fourth model. Team B identified and related the variables that were involved in the situation through verbal, written, tabular, and graphic representations. The total cost was considered constant for each interval of number of nights. The team optimized the total cost of the gymnasts' stay compared to its previous proposal. It had difficulty denoting the endpoints of each interval of the step functions on their graph; however, the team managed to coordinate the direction of change of one variable with respect to the other variable (Carlson et al., 2002). The model that the team B built was associated with the step function, it can be classified as MT2. According to Kaput and Roschelle (2013), it is natural that students have difficulties in constructing graphs of the step function. Especially when they have not been taught in their math courses to model problems involving the use of constant and discrete functions.

Final thoughts and conclusions

In response to the question, what models did the students build and externalize when solving the MEA "The Tokyo 2021 Olympic Games" in which the concept of step function underlies? Team B students built and externalized two types of models: MT1, which was modified and extended from group interaction to become MT2. Although this last model still requires refinement, the model was no longer a histogram, it had characteristics of the step function. The reported findings show us how the students developed knowledge about the step functions and gave it meaning in terms of the proposed situation.

Acknowledgment

The research was supported by CONACYT through postgraduate student scholarships.

This paper describes the conceptions about complex numbers that a group of university students has, these were built from the application of an activity sequence centered on these numbers. This sequence is based on the APOS theory, some aspects of semiotic representation theory, and the use of digital technology. Particularly, both the general results of a pretest and a posttest are shown and compared. Additionally, the example of a student is analyzed to show evidence of how the mental structures and mechanisms that define the students' conceptions are built through the implementation of the sequence. The results show how the activity sequence allowed students to coordinate algebraic and geometric processes on complex numbers to improve their conceptions.

Keywords: Complex Numbers, APOS Theory, Conceptions, Undergraduate.

Introduction

Researchers who have taken the teaching-learning of complex numbers as an object of study have reported various difficulties in students and trends in the teaching of this concept (Panaoura et al., 2006; Pardo and Gómez, 2007; Randolph and Parraguez, 2019). In teaching, they have identified an emphasis on the algebraic register, which results in a loss of essential characteristics of complex numbers (Distéfano et al., 2012). This teaching approach limits students in the construction of mental structures and mechanisms related to the geometric representation of complex numbers in their different forms. Therefore, the need to include the geometric register in teaching is established to favor the conversion and coordination of processes (Aznar et al., 2010) for the characterization of the elements of the concept under study. Derived from this problem, the research objective was to improve the conceptions about the complex numbers of students who start their university studies from the design and implementation of a teaching sequence based on the APOS theory, the use of digital technology, and with a focus on the geometric representation of those numbers. In this way, we provide an answer to the following question: how do students' conceptions of complex numbers change when they participate in a teaching sequence with the aforementioned characteristics?

Theoretical Framework

In order to become the objective of this research, we consider the elements of the APOS theory, initially developed by Dubinsky and a group of researchers (Arnon et al., 2014), as well as some elements of the theory of semiotic representations (Duval, 2006). From the APOS theory, a student's conceptions are developed in a context when he is faced with solving problems that involve the use of mental structures and mechanisms (Dubinsky, 2014). The structures are actions, processes, objects, and schemes that are transformed from the use of mechanisms such as: internalization, coordination, reversion, encapsulation, decapsulation, among others. These transformations and their relationships are shown in Figure 1, which is adapted from the work of Arnon et al. (2014).

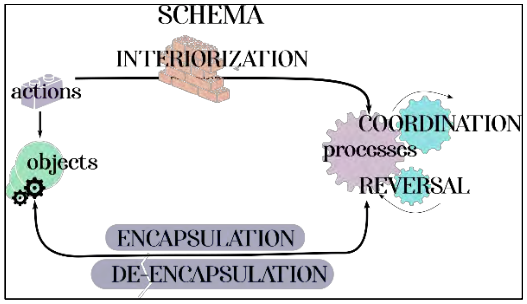

Figure 1: Mental structures and mechanisms cycle

The cycle begins with actions on previously constructed mental objects. In this conception, the student needs external help, which is why they require explicit steps for execution. When the actions are reflected, they are internalized and result in a process. Another way to build processes is through the coordination and reversal of two or more previous processes. In this conception, the student can explain the generality of the concept and describe its characteristics. To favor the development of this mental structure, we consider, like Duval (2006), that mathematical activity needs the articulation between the different semiotic representation systems, and this is achieved when the student can make treatments and conversions, these transformations allow the construction of processes and consequently when these processes are encapsulated, mental objects are achieved.

The object is established when the process can be seen in its entirety, that is, the student can perform actions on this object through encapsulation and it can be returned to the processes that made up the object through decapsulation. Thus, if the set of these structures is consistent, it allows the construction of the scheme. This cycle of structures and mechanisms constitutes the theoretical aspect of the APOE theory, but the same theory contemplates methodological elements, which is called the research cycle.

Methodology

For the development of the research, the research cycle proposed from the APOE theory (Asiala et al., 1996) was followed. This cycle is made up of three elements (Figure 2). The first element is the theoretical analysis, which is developed from the epistemology of the mathematical concept and results in the construction of a genetic decomposition. Arnon et al. (2014) defines genetic decomposition as a hypothetical model that describes the structures and mechanisms that an ideal student requires to understand a concept. The second element is the design and implementation of the instruction, this design addresses the characteristics of genetic decomposition, and leads and transforms the previous conceptions of the students, which is explained from the cycle of mental structures and mechanisms. The third element is the collection and analysis of data, this enables the comparison of the preliminary genetic decomposition and the developments obtained in the analysis. It is worth mentioning that this cycle is repeated with the intention of perfecting the genetic decomposition.

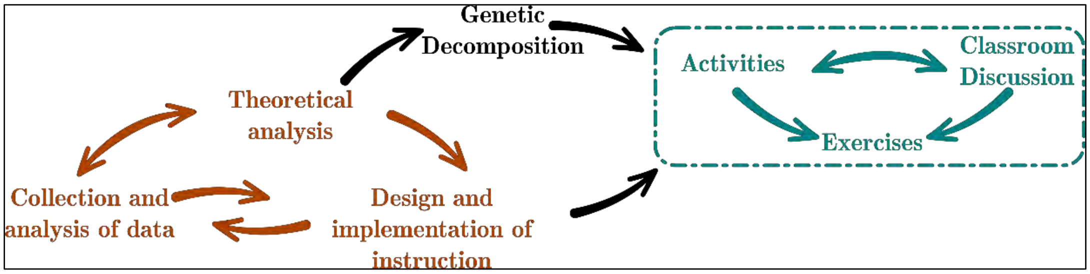

Figure 2: Research cycle and ACE Teaching Cycle

The implementation of the activities was developed from the ACE teaching cycle (Arnon et al., 2014). The acronym for this cycle (Figure 2) presents its elements: (A) activities, (C) class discussion and (E) exercises. In the first moment of the cycle, the activities are guided and elaborated tasks to favor the construction of mental structures arranged in the genetic decomposition, from this moment it is suggested to incorporate teamwork. The second moment is the discussion in class, here it is possible for the students to work in small groups, and that the discussions are guided by the teacher and complemented through worksheets and technological tools. The third moment considers the exercises, whose purpose is to help to consolidate and evaluate the conceptions that have been developed in the activities and the discussion in class. Therefore, the activities of this research were designed taking into account the genetic decomposition and the ACE cycle, for reasons of space and the focus of this writing, no details are given about the design, but they can be consulted at the link: https://www.geogebra.org/m/zx5ww8bf.

Population and method

The investigation began with the application of a pretest, later the sequence of activities was implemented considering the ACE teaching cycle, and finally a posttest was applied. The questionnaires have the same characteristics and are made up of two parts, their application was made individually. The sequence has ten activities and has two teaching cycles. The first cycle comprised of activity 1 to activity 6 with discussions every two or three activities, as required by the group, and ended with activity 7. The second cycle is made up of activities 8 and 9, a general discussion, and ended with activity 10. Activities 7 and 10 were considered exercises. The activities were carried out in teams. The general study was developed with a group of 15 first-semester students of the degree in electrical mechanics from a public university in Mexico. The application of the questionnaires and the sequence of activities was carried out in the hybrid modality.

To carry out the analysis, initially a general comparison was made between the pre- and post-test results of the entire group. Subsequently, and to account for how the conceptions of the students changed throughout the implementation of the sequence, one student (E1) was chosen. According to the teacher's criteria, E1 was characterized by having a performance below the group average, but was responsible, participative, showed interest in learning mathematics and, in addition, showed interest during the implementation of the sequence. Given that E1 teamed up with another student who was characterized by having an above-average performance (E2), this last student will also be mentioned in the results.

Result

In the first part of the pretest, students were inquired about previous objects related to complex numbers. That is, to solve a quadratic equation whose solutions are complex, and perform two operations in which the imaginary unit had to be recognized. In the general results, the students did not perform actions on the imaginary unit object from the square root of a negative number, so there is no imbalance in their mental structures. This is because 9 of 15 students recognized the square root of a negative number as a solution to the equation (Figure 3a). Another 4 of 15 students recognized the imaginary unit, but had errors in the algebraic treatment (Figure 3b).

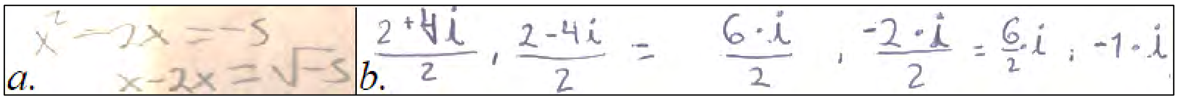

Figure 3: students' responses of the first part of the pretest

The second part of the pretest includes explicit elements of complex numbers. 3 reagents were proposed, in the first and second it was asked to determine the module and the argument of a complex number: first from its representation in the complex plane, and then from its binomial form. In question 3, it was asked to determine the real part and the imaginary part of a complex number given its module and argument. The results show that 13 of 15 students did not answer that part of the questionnaire (Figure 4a) and only 2 of the 15 presented actions on the object prior to distance to establish the value of the module (Figure 4b). In general, most of the students did not present previous conceptions related to complex numbers.

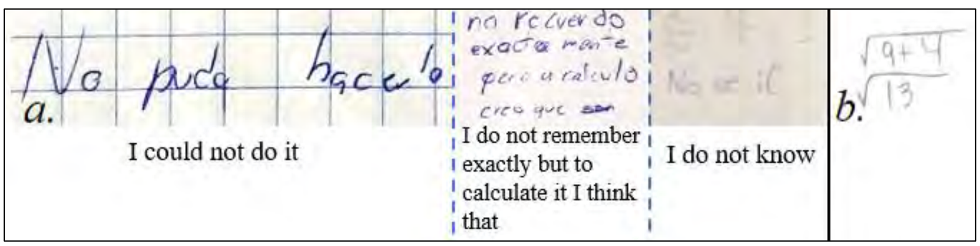

Figure 4: students' responses of the second part of the pretest

In general, the results in the pretest allowed us to conclude that the students had difficulties and did not associate their previous objects with the complex numbers, and therefore did not perform actions on them. On the other hand, in the post-test there is evidence of the construction of new mental structures such as actions, processes and objects. In the first part, 11 out of 15 students presented approximations to the imaginary unit more frequently than in the pretest (Figure 5). There are processes on complex numbers (Figure 5a); however, in the first question, 8 of 15 students showed difficulties in operating with fractions associated with the imaginary part of the complex number (Figure 5b). In the operative part, second question, 6 of 15 students presented difficulties in the properties to operate with the imaginary unit (Figure 5c).

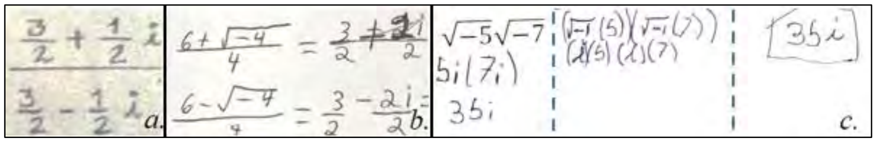

Figure 5: students' responses of the first part of the postest

In contrast, in the second part of the post-test, 14 of 15 students presented an important evolution in the construction of new mental structures through the characteristics of complex numbers in their algebraic and geometric registers. Geometric and algebraic actions are evidenced on objects such as: coordinates, angle, distance between two points, trigonometric ratios, among others (Figure 6a). The students identified the explicit elements of each notation and used the different complex number notations in their treatments, in particular ordered pair, polar and trigonometric (Figure 6b).

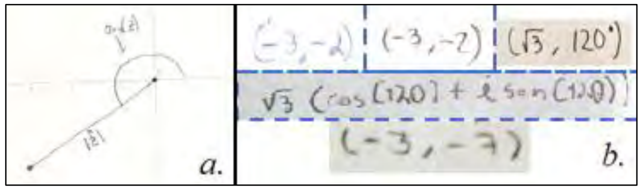

Figure 6: students' responses of the first part of the postest

In the second part of the post-test there is evidence of algebraic and geometric processes and their combinations that allowed the students (13 out of 15) to develop generalities for the representations of complex numbers. It is worth mentioning that the group discussion and teamwork guaranteed these generalities, since in the post-test questionnaire the students worked with specific cases. The geometric processes allowed the students to represent the elements of the complex number in the different quadrants of the complex plane, as well as to convert to the algebraic register with the use of the trigonometric ratios and the distance between two points. The students performed treatments on the algebraic register to find the values of the module and argument. They used generality to find the argument from the arctangent with the real part and the imaginary part, the students added 180° when considering that the complex number is located in the second or third quadrant (Figure 7a). Similarly, these processes are also explicit in the item in which the module and the main argument are explicitly given to obtain the real and imaginary part and represent the number in the complex plane (Figure 7b).

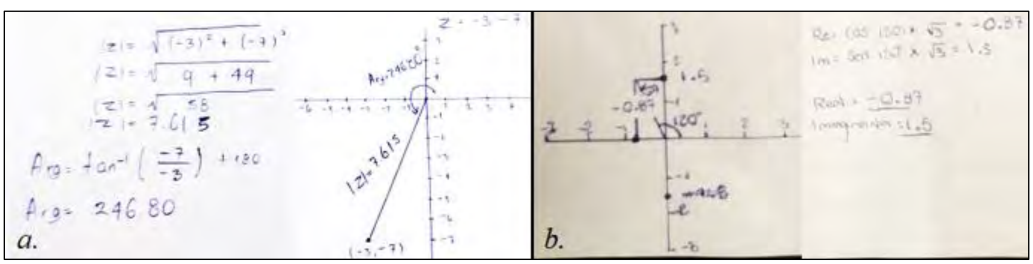

Figure 7: Algebraic and geometric processes in student's responses

The results allow us to establish that, in general, the students built new mental structures from the development of the sequence of activities. To detail these structures, the case of a student (E1) is exemplified, for this the trajectory of it is established and a description of its conceptions is made. In the results of the first part of the pretest, the student did not present actions on previous objects of complex numbers and presented difficulties on objects such as solutions of quadratic equations and properties of real numbers. E1 did not answer the second part of the pretest.

As mentioned, in the development of the sequence of activities E1 worked as a team with E2. In activities 1 and 2, the students built actions on previous objects such as: angle, distance between two points, coordinates and trigonometric ratios. They identified in the complex plane each one of the elements of the complex numbers, these actions were established when they represented different complex numbers in the quadrants of the plane through the applet. An example of these algebraic actions is shown in Figure 8, in which the students worked in the second quadrant. Also shown are the worksheets in which they determined the modulus and argument values for a specific complex number.

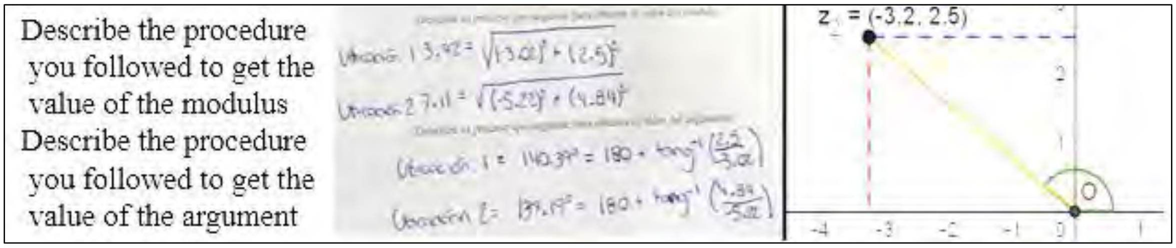

Figure 8: E1 and E2's response in activity 2 of the sequence

The geometric actions of the students considered specific complex numbers within the complex plane, identified the different elements of the complex numbers, and found their values by means of the trigonometric ratios and the distance between two points (Figure 8). In particular, E1 participated in the team discussion mentioning the differences of the complex numbers when they are in each quadrant. From the reflection of the actions in each of the quadrants, the students established the generality to find the module, an argument (Figure 9), the real part and the imaginary part, which gave way to algebraic and geometric processes.

¿Cómo hallaste los argumentos? Explica tu desarrollo

[sic]

como el valor de x es 0 en ambos tenemos que tomar el valor de y. y así podemos opservar sus angulos. si es positivo son 90 grados, si es negativo son 270 grados.

How did you find the arguments? Explain your procedure

since the value of x is 0 in both we must take the value of y, and thus we can observe their angles. If it is positive, it is 90 degrees and if it is negative, it is 270 degrees.

Figure 9. E1 and E2's response in activity 3 of the sequence

Algebraic and geometric processes helped students build and relate the elements of complex numbers in each of these representations. The students started from the geometric register in its polar form and made the conversion to the algebraic register, this allowed them to characterize and find the real part and the imaginary part. These constructions were based on their previous knowledge about trigonometric ratios, in this way E1 and E2 found the generality through the reflection of examples that they chose with the applet. E1 systematized the particular cases raised by E2, this allowed E1 to raise the generality, which he expressed in the discussion with E2 (Figure 10). This generality was achieved from the coordination of geometric and algebraic processes. Regarding the processes related to the module and an argument, the students worked in activities 5 and 6 with sets of complex numbers. The students were able to describe different sets of complex numbers with their elements in the cases of a constant modulus and argument.

PARTE REAL= COS ARGUMENTO X MODULO	PARTE IMAGINARIA = SENO ARGUMENTO X MODULO
PARTE REAL = COS ALFA X R	PARTE IMAGINARIA = SENO ALFA X R
Real part= cos argument x modulus	Imaginary part= sine argument x modulus

Figure 10. E1 and E2's response in activity 4 of the sequence

In activity 7, E1 worked individually, evidencing processes that involve reversal, since in previous activities they usually started with the geometric register of complex numbers, but here they started with the algebraic register. E1 presented in the development of the questions algebraic and geometric processes, when using and describing the generalization of the characteristics of the complex number. Additionally, E1 presented a characterization of the representations, in particular the ordered pair and trigonometric form, and performed conversion and treatment to determine the values of the module and the argument of a number (Figure 11).

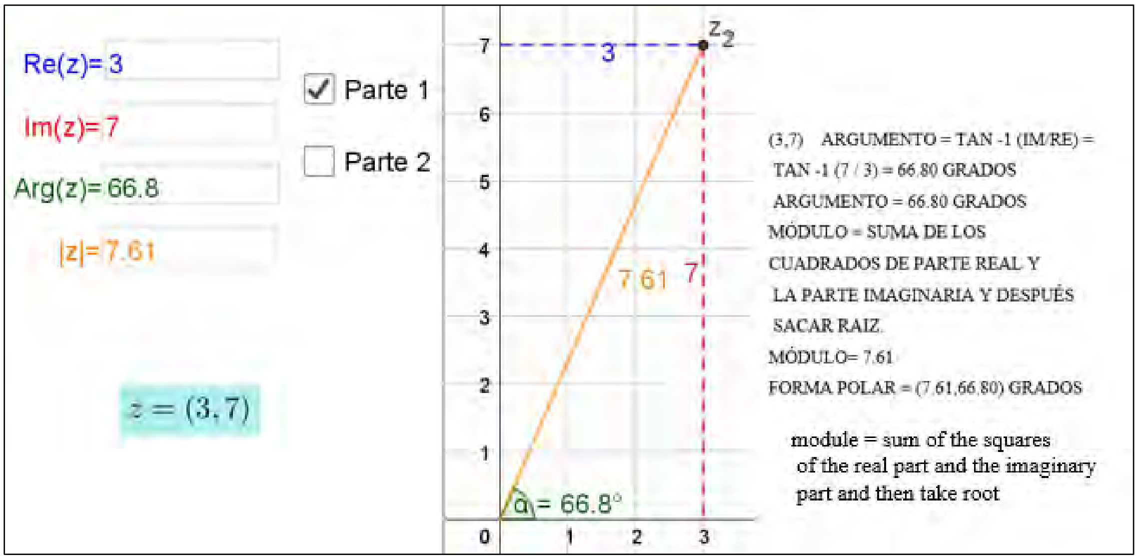

Figure 11: E1 and E2's response in activity 7 of the sequence

The second cycle of teaching is made up of activities 8 and 9. These activities are focused on the arguments and the imaginary unit. In activity 8, students E1 and E2 presented difficulties in establishing the generality of the main argument when they worked as a team. However, in the general discussion some students presented different results, and in this way students E1 and E2 reflected and were able to generalize the arguments from the main argument, and from additional questions asked by the teacher. In this sense, Oktaç et al. (2019) affirm that there is no division between the teacher and the researcher since they have the common goal of enabling the construction of mental structures. Additionally, the authors establish that the construction of mental structures does not always occur in a linear fashion.

In activity 9 the students established the relationship between the modules and the arguments from the geometric register, and the students understood the binomial and trigonometric notations of complex numbers. This cycle concluded with activity 10, which was worked on individually and is called an exercise. Here, E1 coordinated previous processes to build new algebraic and geometric processes that allowed him to characterize elements of the new representations (Figure 12a), as in the post-test questionnaire where the construction of these mental structures in the student was evidenced, he identified and related those elements of the complex number, in addition, used and understood the different representations and notations of complex numbers (Figure 12b).

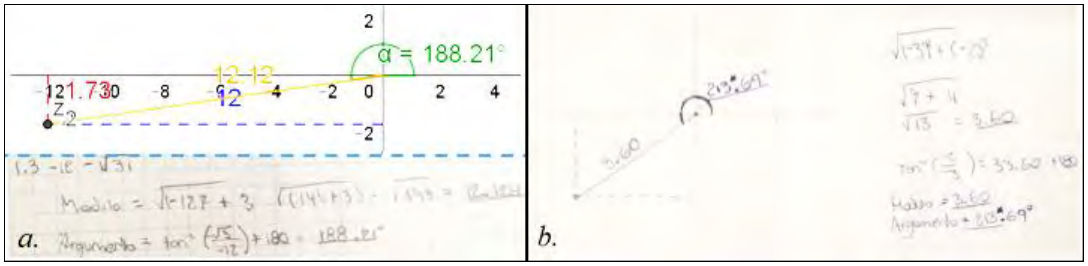

Figure 12. E1 and E2's response in activity 10 of the sequence

Conclusions

The results show that most of the students built mental structures related to complex numbers from the development of the proposed sequence of activities, thus improving their conceptions. The sequence guided students to start from previous objects that led them to activate their mechanisms and articulate the different representations of complex numbers. This allowed generating and coordinating algebraic and geometric processes that in some students can be characterized as objects due to their argumentation in the discussions and their development in the worksheets.

An important element in the design of the sequence of activities is the approach that was given to the registry of geometric representation of complex numbers to later make a conversion to the algebraic registry, and in this regard, evidence was given of how the conversion and treatment in this record allowed students to reach higher level mental structures. In addition, the interaction that the students had with the applets that make up the sequence gave rise to the first actions that led the students to internalize them to build processes on complex numbers. Similarly, the general discussions contemplated in the teaching cycle allowed the students to present their results and argue based on the work with their classmates. According to the results, it is essential that the teaching of complex numbers involves different representations where students have the possibility of expressing generalities about the different elements of these numbers.

SELF-EFFICACY DURING THE COLLEGIATE TRANSITION AND THE IMPORTANCE OF TASK ALIGNMENT: A CASE STUDY

Jordan R. Gill
Lansing Community College
gillj12@star.lcc.edu

This case study examined how a period of transition could affect a student's mathematics self-efficacy (MSE) and their ability to productively struggle on challenging mathematics problems. This study focused on a single student named Candice who was making the transition from high school to college. Candice initially reported high levels of MSE to start the semester but experienced difficulty adjusting to her first college mathematics class, which was taught in an active learning style. Interviews with Candice revealed that her initially reported high MSE was associated with her ability to successfully complete her high school mathematics courses. The structure of her active learning style classroom presented new challenges that did not align with this MSE. This potentially resulted in a lowered state of MSE and a lack of engagement with productive struggle both inside and outside the classroom.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Undergraduate Education; Computational Thinking; Problem-Based Learning

Mathematics self-efficacy (MSE), or a person's belief in their ability to perform or learn mathematics, has repeatedly been linked to positive outcomes such as achievement in mathematics (Hackett & Betz, 1989; Multon et al., 1991; Thomas et al., 1987; Usher et al., 2018) and persistence on mathematical tasks (Lent et al., 1984; Multon et al., 1991, Ruch et al., 2014). Despite the link to positive outcomes, little work has been done to examine how MSE changes during the transition from high school to college. This is especially important when considering that the transition to college can bring new levels of expectations and different types of tasks than what students may be used to. This case study focuses on a single first-year college student who reported high MSE to start the semester but struggled to adapt to the collegiate environment.

Theoretical Framework

MSE refers to peoples' beliefs in their ability to perform or learn mathematics successfully (Bandura, 1986; Zimmerman & Cleary, 2006). Research suggests that judgements of self-efficacy are task-specific (Bandura, 1986; Pajares & Miller, 1995), that is, self-efficacy for a class or the field of mathematics (generalized MSE) might not match MSE for solving specific problems (task-specific MSE). However, those with high MSE for problem solving may also be more likely to hold high MSE for being successful in mathematics courses, which potentially explains why measures of MSE that are not task specific (generalized MSE) often predict problem solving outcomes. As put by Pajares and Miller (1995), "prediction is enhanced as self-efficacy and performance correspondence more closely matches."

Productive struggle is defined by Hiebert and Grouws (2007) as the effort a student must put forth in order to understand a difficult mathematical concept. Hiebert and Grouws emphasize that the word struggle does not relate to any feelings of frustration or despair when facing overly difficult problems but is instead a reflection of an individual's willingness to "muddle through" (p. 388). Self-efficacy is thought to play a major role in student's willingness to engage with productive struggle. Research agrees that those with higher levels of self-efficacy will be more likely to persevere in the face of obstacles (Lent et al., 1984; Multon et al., 1991, Ruch et al., 2014). Research also agrees that students with high MSE are often more effective when facing difficult tasks that require them to analyze situations and choose appropriate mathematical techniques (Holenstein et al., 2021).

Literature Review

Research suggests that MSE is important as students with high levels of MSE are commonly associated with higher achievement (Multon et al., 1991; Thomas et al., 1987, Usher et al., 2018) along with the choice to pursue mathematics-related majors (Hackett & Betz, 1989). Additionally, research suggests that those with higher MSE are more likely to persist in both long-term and short-term situations. Research suggests that those with high MSE are more likely to persist within mathematics related majors (Lent et al., 1984) and are more likely to persist on mathematical tasks (Multon et al., 1991). Much of this previous research has been quantitative in nature and there is a need for qualitative support.

In addition, for students undergoing the transition from high school to college mathematics courses, self-efficacy may play a vital role in this transition (Chemers et al., 2001); in particular, high MSE may be vital to help students overcome the struggle of transitioning to college mathematics. However, while MSE may aid transition, it should also be noted that the transition itself can have potential effects on MSE. Bandura (1986) suggested that periods of transition may be the time when self-efficacy levels are most likely to be disrupted. While research generally agrees that MSE is stable long-term (Bandura 1986; Middleton & Spanias, 1999), the issue of stability is rarely addressed in research (Lane & Lane, 2011).

Research also puts particular importance on the role of productive struggle in generating deep mathematical understanding. Research suggests that the process of productive struggle is vital to understanding new conceptual ideas (Heibert & Grouws, 2007; Handa, 2003). Students who engage in productive struggle may develop higher levels of creativity and a greater ability to reflect on their own ideas (Nadjafikhah et al., 2012). Like with self-efficacy, periods of transition could affect a student's willingness to engage in productive struggle. Previous research has mostly been devoted to conceptualizing the process of productive struggle or identifying whether it occurred (Zeybek, 2016). Little work has been done to examine how student engagement with productive struggle may change in new settings. In the present study, I will examine both MSE and productive struggle during a period of transition, specifically for a first-semester college student who experiences new task expectations.

Methods

This study focuses on a first-year calculus student named Candice who took part in a larger study examining transitionary effects on MSE and mindset for collegiate mathematics students. Students from three courses (intermediate algebra, calculus, and discrete) were invited to take a survey that focused on MSE and mathematical mindset. The survey was adapted from the self-report questionnaire found in Pintrich and DeGroot (1990), the May (2009), and Blackwell (2003). Students responded on a 5-point Likert scale to MSE statements that included a mix related to mathematical tasks (such as "I am sure I can do an excellent job on the problems and tasks assigned for my math classes") and success in math courses (such as "I expect to do very well in my mathematics classes"). Two interviews were conducted during the semester with students who scored significantly higher or lower (one standard deviation above or below the mean) than their classmates on the MSE portion of the survey. The present study focuses on Candice, whose survey results showed she held higher MSE than most of her classmates. Candice is a unique and illuminating case because her high MSE was rooted in her ability to be successful in high school mathematics courses and this did not align well with the structure of her active learning style course. Over the course of the two interviews, this misalignment potentially caused a lowered sense of MSE and contributed to a lack of engagement with productive struggle.

Interview Protocols

The first interview served two purposes. The first purpose was to confirm what students reported in their surveys and establish baselines for each student's MSE. The second purpose was to ask participants to solve two challenging mathematics problems and to examine whether they engaged in productive struggle. The two problems are listed below in Table 1.

Table 1: Interview Session problems.

Problem 1
In a certain state, there are four towns, situated at the vertices of a square of side 10 miles. The department of transportation wants to construct a road network connecting these towns, so that it is possible to travel from each of the four towns to the other three towns. Constructing a mile of road costs two million dollars. Due to a budget crisis caused by tax cuts, the department of finance can only grant 55 million dollars for the project. Is this amount sufficient?
Problem 2
Find two numbers and such that $x - y$, x/y, and xy are all equal. (from Posamentier & Solkind, 1996).

The two problems asked were ideal for determining whether students engaged with productive struggle. First, when students proposed solutions, students could easily verify whether their answers were correct. This eliminated the scenario where a student stopped working because they believed they had solved the problem. Secondly, these problems were non-typical, and participants chose the types of mathematical approaches they took in solving the problems. As previously discussed, MSE is expected to play a significant role in student success when this level of analysis is required (Holenstein et al., 2021).

Participants were given each problem separately with Problem 1 being presented first. To allow for productive struggle, students were told that they could work on the problem for as long as they liked. Students could ask clarifying questions to help them understand the situation being presented. In Candice's case, Candice asked clarifying questions like "We don't know the size of each town right?" and "Does each town have to connect to a single point or can there be one long road?" The interviewer answered these clarifying questions to ensure students like Candice could grasp the problem being asked and choose whether to engage in productive struggle. After the first interview students were later invited back to a second interview to learn if their current courses or the transition to a college environment had affected their view of mathematics, their MSE, or their study habits.

Coding and Reliability

Candice's interview (along with those from the larger study) was audio recorded and then transcribed. Four interviews were randomly selected from the larger pool and coded using codes developed inductively from the data (Seidman, 2013). To establish coding reliability, a method outlined by Campbell and colleagues (2013) was used. Coded sections were labeled with the appropriate code as well as brackets. The codes were then removed from the interview, leaving the bracketed sections visible on the transcribed interview. A second qualified individual then coded the bracketed sections using the developed codebook. Coders initially agreed on 71% of the bracketed sections. Differences between codes were then negotiated and several codes were either combined or deleted. A fifth interview was then coded using the same method and the agreement percentage rose to 93.5%. The remainder of the interviews were coded by the original coder using the established codebook.

For the problem-solving section of interview one, each student's written work was saved in addition to the audio recordings. Each solution attempt was coded as showing no evidence, some evidence, or high evidence of productive struggle. To establish trustworthiness for the problem portions, both coders each initially suggested the level of evidence they felt was present and then differences were debated until both coders agreed.

Results

In this results section, Candice's initial MSE will be discussed along with some of the background information she provided about herself. From there, Candice's solution attempts to Problem 1 and Problem 2 will be discussed and contrasted with the results seen from other calculus students in the study. Finally, Candice's results from interview 2 will be discussed, specifically how her course had impacted her view on her MSE and how this had impacted her solution attempts during the first interview.

Introduction to Candice

Candice was one of seven calculus students recruited and was interviewed during her first semester of college in the fall of 2018 at a large midwestern university. Her first collegiate mathematics class was a calculus course that used discovery-based methods and active learning as its main method of delivery.

Candice's initial survey results suggested that she held relatively high MSE compared to many of her classmates. During her first interview, Candice confirmed her high MSE when she said, "I would say I'm pretty confident. I really enjoy math, so I like the challenge of it." Candice prided herself on being a responsible student and favorably compared her study skills to other students. It became apparent during this first interview that Candice's high MSE was rooted in her ability to successfully navigate mathematics courses, but not necessarily in her ability to complete mathematics problems. Candice said, "I expect to do well overall. I think there are some students who don't know how to study, or they don't want to study. So, I think compared to certain students, I'm going to do better." Candice could not ever recall a time where she had not studied for an upcoming mathematics test or exam and saw her study skills as something that separated her from other students.

Despite her high MSE, Candice acknowledged that she had been having difficulties to start the semester in her calculus course. Candice said, "I'm struggling a lot right now, but it is only the first couple of weeks… I know I'll eventually get it. I feel like I just have to get back into school and get back into math, I guess." Candice suggested that she was actively trying to rectify her early struggles but noted that she had less opportunity to interact with her college professors. Candice said, "In college you don't get as much time with your teachers, so I've emailed my teacher already a couple times."

Candice's Lack of Productive Struggle

Candice showed no evidence of productive struggle on either of the problems presented during the first interview. This was already a surprising result considering Candice's high MSE, but her results stood out even further when comparing her solution attempts to those provided by calculus participants in the broader study. Specifically, Candice showed no productive struggle in situations where calculus students were generally more likely to (see problem 2).

Problem 1. On the first problem, Candice provided a solution attempt that showed no evidence of productive struggle. Candice gave an initial attempt at the problem that connected all four towns in a square configuration. Candice's initial configuration can be seen below in Figure 1.

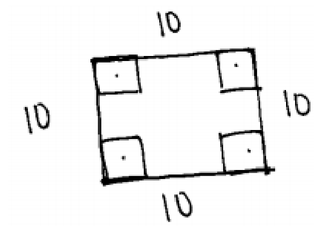

Figure 1. Candice's initial attempt at problem #1.

Candice calculated the cost of her initial configuration and concluded that it would be too expensive. Candice spent a few minutes thinking before drawing a triangle on her paper. Candice then started entering numbers into her calculator. When the interviewer asked what she was entering in Candice said, "I'm just trying to figure out, I guess, trying to make a line through the middle somehow. I'm trying to use the area of a triangle to figure out how long the line would be." Candice had drawn a right triangle and incorrectly used the formula for the area of a triangle in an attempt to find the length of the hypotenuse (see figure 2). Candice then laughed and said, "This is a tough problem." Candice spent approximately two more minutes in silence thinking about the problem before deciding to stop her attempt.

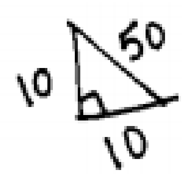

Figure 2. Candice's second drawing.

Candice's attempt was labeled as showing no evidence of productive struggle as she did not progress past the most common configurations (square and X configurations) that most students initially tried. Candice's acknowledgement of the difficulty of the problem seemed to be a point where she had the option to "muddle through" but instead chose to end her attempt rather quickly.

Problem 2. On problem 2, Candice again showed no evidence of productive struggle. Her entire attempt consisted of using her calculator to test values for x and y and at no point did Candice attempt to set up an equation or employ any algebraic techniques. Candice did not write down anything on her paper and stopped her attempt after about five minutes of working. Candice's results here are especially interesting when considering the other calculus students interviewed in the broader study. Of the seven calculus students interviewed, Candice was the only participant who showed no evidence of productive struggle on problem 2. Further, all six solution attempts provided by the other calculus students incorporated algebraic techniques (such as setting up equations). It may be the case that the algebraic nature of the problem and the presence of variables caused the problem to feel familiar to calculus students and had a positive effect on their willingness to productively struggle. The fact that Candice's attempt did not incorporate these same techniques is curious and is perhaps explained by the source of Candice's high MSE as well as by the difficulty she experienced in her calculus course.

Possible Explanations for Candice's Lack of Productive Struggle

Candice's results stand in contrast to what previous research has found. She entered the semester with higher MSE than many of her peers but showed less evidence of productive struggle on the problems presented in the first interview. This contradiction is potentially explained by the task-specific nature of Candice's MSE, specifically that her high MSE was rooted in her ability to complete mathematics courses (and potentially only traditional lecture style courses). The problems presented in the first interview may not have aligned with Candice's high MSE since the problems required Candice to choose her own mathematical techniques without the backdrop of a classroom lesson or unit. In other words, since the problems given in the first interview were devoid of a classroom context, Candice may not have felt that she had the resources she needed to complete the problems. Candice was asked if a lack of context affected her attempts to which she responded, "I think it does because say if that one (problem 1) is geometry, then I would know some basic equations to use versus if that one (problem 2) is algebra, then I would know the basic equations for algebra." These responses may indicate that despite Candice's lack of productive struggle, she may have been more confident in her ability to complete them in a setting with a more narrow focus (such as a classroom).

There may have been additional misalignment between Candice's MSE and the tasks presented in her calculus course. This potentially resulted in lowered MSE and engagement with productive struggle on mathematics problems, including the problems presented in the first interview. During her second interview (six weeks after the first interview), Candice said, "The majority of this semester, I haven't known what's going on." Candice pointed to the active learning style of the course as a major reason for the difficulty she experienced. Candice said, "I don't think the material is more difficult, I think the way it's being taught is more difficult… I don't think the rest of the math classes are taught in this way." Candice elaborated and said "The teacher will talk about it conceptually and try to explain it conceptually. I can understand that part of it, but when it comes to the math, I don't actually know how to do the math." Candice backed up her claim by explaining:

> So, say we're looking at a graph and we're taking the second derivative of a function. I'll know that the second derivative is like the concavity of the original function, but I won't necessarily know how to find the concavity of the original function. I'll know what it means, but not necessarily how to find it.

This seemed to suggest that Candice was able to understand many of the concepts and definitions but did not have a full understanding of the procedures needed to solve problems.

Interestingly, Candice made an unprompted link between her struggles in calculus to her lack of productive struggle during the first interview. Candice said:

> I've felt unsuccessful a lot. Sometimes, I guess it affected how I worked on the problems. You know how we did that problem in the first session? I just wasn't getting it and I was just like, I give up now. I feel like when I come to problems where I just don't know where to start or what to do, I just kind of accepted my failure.

While the other calculus students interviewed may have been encouraged by the algebraic nature of problem 2, Candice may have had the opposite reaction. Specifically, since the procedural aspects of calculus seemed to be the primary points of difficulty for Candice, the presence of an algebraic problem may have actively dissuaded her from engaging in productive struggle.

While Candice recognized that she did not fully understand the calculus content, she still seemed to pride herself on her ability be successful in a classroom setting. Candice said, “I don’t think because I’m doing bad in this math class, that I’m not a good math student anymore.” Candice’s choice of phrasing here is interesting in that she chose to say, “good math student” instead of something like “good at math.” This may provide further evidence that Candice’s MSE remained rooted in her ability successfully navigate mathematics courses. Further, her positive outlook for the long-term may be based on the idea that future courses may revert to a typical lecture style and her belief that she would be able to successfully navigate that type of course.

Discussion

While high MSE is generally associated with higher levels of persistence (Lent et al., 1984; Multon et al., 1991, Ruch et al., 2014), this study provides evidence that instances of transition (that potentially bring new task expectations) may disrupt this relationship. While Candice entered the semester reporting high MSE, it became clear that this was linked to her ability to succeed in mathematics courses and not necessarily to her ability to solve mathematics problems. Candice did not show evidence of productive struggle on either problem, but her effort level on problem 2 was noticeably less than that of her peers. This seems to be related to her lowered MSE for the procedural aspects of problems. This provides further evidence that self-efficacy is task-specific (Pajares, & Miller, 1995) and may also provide some insight into why previously successful students may struggle in environments that have different expectations (such as active learning). Students like Candice, whose MSE is tied to previous success in high school courses, may struggle adapting to the levels of analysis required in an active learning style class.

This study may also provide insight into the stability of MSE. In this instance, a student making the transition to college experienced negative results which negatively impacted her MSE. This study provides support for Bandura (1986), who theorized that periods of transition could cause the stability of MSE to be disrupted. This study provides an example of a decline in MSE that occurred during the transition from high school to college and it is possible this period of instability had negative long-term ramifications as well. Candice reported that she was “accepting her failure” when encountering difficult problems, which inhibited her from developing a full understanding of certain procedures. This suggests that students’ first collegiate courses could potentially have long-lasting impacts on both MSE and achievement.

Conclusion

The results of this study elevate the theoretical importance of task-specific self-efficacy. While generalized MSE seems to hold positive relationships with academic success and higher levels of persistence, these results may be dependent on students remaining in environments that fostered the high levels of MSE to begin with. When students transition to new environments (such as high school to college or a lecture style to an active learning classroom), success may be directly tied to the specific tasks that will be required and their self-efficacy for those specific tasks.

This in-turn has important implications for educators. The first implication is that educators need to appropriately model the ways in which students should engage with course content, especially if the course is “non-traditional.” Students may enter a classroom with limited experience analyzing advanced mathematical tasks and educators need be accommodating to novices if this is the expectation. As put by Holenstein and colleagues (2021), educators should make sure that "tasks are taught in a way that allows for individual levels" (p.14). This also underscores the need for available resources (tutors, office hours, etc.) for students when they encounter difficulty. As Candice mentioned, face-to-face time with professors is often limited, so students need avenues by which they feel they can accomplish the work when outside the classroom.

The second implication for educators is to be aware of the effect that transition can have on student MSE. Students who report traits that generally produce favorable outcomes (such as high MSE or growth mindset) can still experience declined states of MSE that affect their engagement with course material. As seen here, Candice had identified that she was struggling as early as three weeks into the course but had not yet decided that the course was out of her control. Six weeks later, however, she had come to decide that many components of the course were lost on her. This underscores the need for intervention at multiple points throughout the semester as it appears students may write off their chances well before the end of a course.

COLLEGE ALGEBRA STUDENTS' ATTITUDES TOWARD MATH AND GRAPHS: AN EXPLORATORY FACTOR ANALYSIS

Livvia Bechtold	Courtney Donovan	Heather Lynn Johnson
CU Denver	CU Denver	CU Denver
Livvia.bechtold@ucdenver.edu	Courtney.donovan@ucdenver.edu	Heather.johnson@ucdenver.edu

We report on results from a mixed methods study investigating a measure of students' attitudes toward math and graphs. At the beginning of eight consecutive fall and spring semesters, we distributed a fully online attitude survey, adapted from Pepin (2011), to undergraduate College Algebra students. Our report includes two samples, Validation (n=1256) and Calibration (n=712). Our research team qualitatively coded students' responses into five categories: positive, mixed, ambiguous, negative, detached (Gardner et al., 2019). Next, we quantitized those qualitative codes into a four category scale, which condensed the mixed and ambiguous categories. Conducting an Exploratory Factor Analysis, we found that students' attitudes grouped by topics (math and graphs). We conclude with implications for research and practice.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Data Analysis and Statistics, Research Methods, Undergraduate Education

We report on a mixed methods study in which we examine undergraduate students' attitudes toward math and graphs. Our population is students who enroll in College Algebra, one of the earliest credit-bearing mathematics courses at U.S. institutions (Blair et al., 2018), with a history of challenges for student success (Gordon, 2008; Tunstall, 2018). Analyzing students' responses to a fully online, open-ended survey, we investigate a measure of students' attitudes. We aim to contribute to the field's knowledge about the attitudes of College Algebra students.

A key aspect of our study is the quantitizing of qualitative data (Sandelowski et al., 2009). Quantitizing is a process of assigning numerical values to non-numerical data. In so doing, researchers can illuminate patterns and peculiarities arising within large data sets via quantitative analysis strategies. Our quantitizing has allowed us to transform qualitative attitude codes into a four-category scale, which then afforded an exploratory factor analysis.

Theoretical Framework

We adopt Di Martino and Zan's (2010) multidimensional perspective on students' attitudes toward math. That is, students' attitudes toward math comprise three interrelated dimensions: their emotional disposition toward math (e.g., how they like or dislike math), their perceived competence toward math (e.g., how they feel about their capabilities when it comes to math), and their vision of what math is (e.g., what they view math to be). This stance blurs boundaries between McLeod's (1992) categories of beliefs, attitudes, and emotions as distinct components of mathematical affect.

Drawing on this perspective, Pepin and colleagues (Ding et al., 2015; Pepin, 2011) developed a survey including three open-ended response questions, addressing each of these dimensions. In their analysis, they coded students' responses according to three categories: positive, negative, and neutral. Yet, students' attitudes toward math could have complexities beyond just a positive or negative attitude (e.g., Di Martino, 2019). For example, a student could feel that mathematics is "boring and cool at the same time." Hence, future studies could make room for complexities in students' attitudes, via instruments and coding mechanisms.

Methods

The Attitude Survey

We adapted the attitude survey that Pepin and colleagues (Ding et al., 2015; Pepin, 2011) to include five open-ended response questions and to be in a fully online format (Johnson et al., 2019). Table 1 shows the survey questions. The first three questions were the same as those used by Pepin and colleagues. We added the last two questions to address students' attitudes toward graphs in two areas: emotional disposition (like/dislike) and perceived competence (can/cannot). We decided to include students' attitudes toward graphs, because students worked with graphing activities as part of the broader research projects of which this study was part. To allow for a range of responses, we did not require students to select like/dislike or can/cannot. Students were to type in responses to each of the questions; they could complete the survey on a mobile phone, tablet, or computer.

Table 1: The Attitude Survey

Attitude Survey Questions
I like/dislike math because____
I can/cannot do math because_____
Mathematics is______
I like/dislike graphs because _____
I can/cannot make sense of graphs because_____

Data Collection

We collected data in conjunction with two U.S. National Science Foundation funded research projects, examining undergraduate college algebra students and instructors. One aspect of both projects was to investigate students' attitudes toward mathematics. The first project took place at a single institution and concluded in Summer 2020. The second project began in Fall 2020, and extended the efforts to four institutions.

Across eight consecutive spring and fall semesters (Spring 2018 through Fall 2021), we administered the attitude survey to students enrolled in college algebra. In our broader study, we administered the attitude survey in both the beginning and end of the semester. For this analysis, we drew on only those responses from the beginning of the semester. We made this choice to allow for a greater sample size.

We separated our data into two samples. The validation sample (n=1,256) was collected from students who responded between Spring 2018 and Spring 2021. The calibration sample (n=712) was collected from students who responded in Fall 2021. The Fall 2021 sample was greater than other semesters because student responses included a large, lecture style course at one of the institutions. Hence, we decided to use responses from that semester to calibrate our findings with the validation sample.

Data Analysis

We mixed qualitative and quantitative methods for data analysis. First, we engaged in qualitative coding, following the coding scheme put forward by Gardner et al. (2019). Second, we quantitized the qualitative data (Sandelowski et al., 2009), to turn qualitative codes into a scale via Rasch Analysis (Bond et al., 2015). Third, we conducted an Exploratory Factor Analysis (EFA) to examine construct validity.

Qualitative Coding. We drew on students' responses to the five questions in Table 1 as sources of data for their attitude towards mathematics. We coded their responses to extend beyond binary choices of positive or negative (Gardner et al., 2019). Table 2 lists the five categories, including a brief description and sample response. Along with positive and negative, we added the codes of Mixed and Ambiguous, to indicate when student responses evidenced more than one code (Mixed) or when student responses could be coded as positive or negative (Ambiguous). In addition, we included the code of Detached, to indicate when a student separated the content of math or graphs from their connection to it. As cautioned by Di Martino (2019), students' statements about the utility of mathematics (e.g., "math is useful" which we coded as detached) pointed to something other than a positive attitude toward mathematics.

Table 2: Attitude Survey Qualitative Codes

Code	Description	Sample Response
Positive	Like/Can	I like graphs because they represent what a function will look like
Mixed	More than one of these codes: positive, ambiguous, and/or negative	Mathematics is boring and cool at the same time.
Ambiguous	Code could be positive or negative	It is hard for me.
Negative	Dislike/Cannot	I cannot do mathematics because I forget the steps
Detached	Separates the content from their connection to it.	Mathematics is filled with a lot of rules!

For the validation sample, each question was coded by two trained coders. Each coder received training with a coding rubric, then independently coded responses. After coding, they met to identify disagreements, and then calibrated the disagreements via discussion, consulting with an expert coder if needed. As the data set grew, our team trained a machine to assist with the qualitative coding process. Beginning in Spring 2021, we used the machine learning program to assist with the qualitative coding process, verifying with human coders via the earlier process if there was less than 70% confidence by the machine coding.

Quantitizing the qualitative codes: Rasch analysis. Via Rasch analysis (Bond et al., 2015), we transformed the qualitative codes into a mathematically supported scale, ordering the codes according to the level of positivity expressed by each category. This resulted in a collapsing of the Mixed and Ambiguous codes. Our scale was as follows: 0-Detached, 1-Negative, 2-Mixed/Ambiguous, 3-Positive. Category probability curves indicated an even distribution of the four categories with clearly advancing steps. Rasch-Andrich thresholds increased with category values with no evidence of step misfit. Per Linacre (2015), Mean Square (MNSQ) infit values should be less than 2.0; our values ranged from 0.91 to 1.24.

Exploratory factor analysis (EFA). We conducted EFA to examine construct validity. Specifically, to explore how items grouped together mathematically compared to the intended theoretical groupings. We used Bartlett's test of sphericity and the Kaiser–Meyer–Olkin (KMO) measure of sampling adequacy to assess the suitability of the items for factor analysis. We assessed dimensionality using principal components analysis.

Results

Our analysis revealed that the samples were adequate and the items were suitable for factor analysis. The Validation sample (KMO = 0.549) and the Calibration sample (KMO= 0.524) were over the 0.5 minimum threshold. Bartlett's test was significant at $p < .001$ with a $\chi^2 = 548.89$ validation sample, and a $\chi^2 = 282.17$ for calibration sample.

For the validation sample, two factors were retained, the first with eigenvalues of 1.698 and 1.192, combined explaining 57.8% of the total variance (Table 3). Two factors were likewise retained for the Calibration sample (eigenvalues of 1.60 and 1.24), explaining 56.71% of the total variance. Using a Varimax rotation, the first factor we called Attitude Towards Math; it included the first three questions from Pepin (2011, Table 1). The second factor we called Attitude Towards Graphs; it included the two new questions about graphs.

Table 3: Attitude Survey Item Statistics

Item	Calibration Mean	Calibration Factor Loading	Validation Mean	Validation Factor Loading
I like/dislike math because____	2.09	0.68	2.07	0.66
I can/cannot do math because_____	2.39	0.61	2.35	0.61
Mathematics is______	1.81	0.13	1.85	0.21
I like/dislike graphs because _____	2.10	0.71	2.12	0.70
I can/cannot make sense of graphs because_____	2.30	0.71	2.28	0.69

Discussion

The results of our EFA analysis reveal that items loaded by topic: math and graphs. Hence, students' emotional disposition or perceived competence toward math and graphs may not align with each other. Our analysis points to interrelationships between dimensions of attitudes put forward by Di Martino and Zan (2010).

We found a difference between the attitudes coded in the Validation (n=1256) and Calibration (n=712) samples. Interesting, the Validation sample had more negative codes while the Calibration sample had more positive codes. In the Validation sample, 28% of responses were coded positive and 41% negative. In the Calibration sample 46% of responses were coded as positive and 23% coded negative. We conjectured that the Calibration sample had more positive attitudes in part because students were returning to in-person learning that semester.

We address two limitations. Because our data sources were limited to students' responses to the attitude surveys at the beginning of the semester, our results report only students' attitudes at the start of the course. Furthermore, our resulting attitude scale condenses Mixed and Ambiguous to a single code, potentially dampening some complexities in students' attitudes.

Our study contributes to research investigating attitudes toward math and graphs in an under-studied population, undergraduate students in early credit bearing mathematics courses, such as College algebra. Students' mean response codes (Table 3) indicate that they entered College Algebra with more positive than negative emotional dispositions and perceived competence toward both math and graphs. Future studies can investigate links between students' attitudes toward math and graphs and their engagement in the course.

This study examined the role of student generated drawings to offload cognitive demands of a mathematical problem. We used Unit Transformation Graphs to compare students' thought processes when they had to solve the problem mentally, and when they were allowed to use pen and paper. The results indicated that the possibility to rely on drawings helped the participants to free up working memory resources and complete a cognitively demanding fractional task.

Keywords: Cognition; Learning Theory; Number Concepts and Operations; Problem Solving.

Background

A growing body of research within psychology of mathematics education has been aimed at understanding students' cognitive affordances and constraints in doing mathematics (e.g., Bull & Lee, 2014; De Smedt et al., 2009). In particular, prior literature revealed an important role of working memory (WM) – a psychological construct for human's ability to simultaneously store and process information (Baddeley & Hitch, 1974; Daneman & Carpenter, 1980; Ma et al., 2014). WM is limited and varies widely among individuals. If the complexity of a cognitive task requires to operate with multiple items at the same time, students' WM may be overloaded and they become unable to process the requested amount of information. In this case, it is natural for an individual to seek ways to offload the cognitive demands on their WM. Once information is offloaded into the environment, a student then has more mental space available to progress on task (Kirsh, 2009).

A typical example of cognitive offloading is hand gesturing. For instance, Alibali and DiRusso (1999) investigated the role of gestures on the counting abilities of children. They suggested that finger counting allows children to physically instantiate some aspects of the task and, therefore, offload cognitive demands on their WM. Goldin-Meadow et al. (2001) measured the number of items students can hold in their mind when they are explaining a mathematical task. The results indicated that the participants are able to recall more items when they are allowed to gesture. Similar results supporting the beneficial effect of gesturing on WM were achieved in other studies (Cook et al., 2012; Ping & Goldin-Meadow, 2010; Wagner et al., 2004).

Drawings are considered to be a mediation tool for thinking and for meaning making. Vygotsky and Cole (1978) pointed out that human beings' mental activities are supported and developed by means of signs that are the products of their internalization processes and are called psychological tools. Vygotsky (1981) then suggests a list of examples of psychological tools, including drawings. Therefore, as drawings are composed of systems of signs and, thus, physically represent the original properties of an object of thought, they allow an individual to transmit some pieces of information into the environment and, therefore, reduce cognitive demands, playing the role of an important offloading mechanism.

Empirical research was done to examine the impact of student generated drawings with regards to WM and cognitive offloading on college students' understanding of science text. Lin et al. (2017) explored the levels of WM and the cognitive load that students bear when learning college level science material. In their study, three groups of students were instructed to study in particular ways: one group of students was told to create representations of the material being studied, another had a repeated reading method, and the other group simply had to imagine the relationships and reason through ideas in their heads. Evidence supported the conclusion that the study method of using learner-generated drawings facilitated schema construction to integrate prior knowledge with the new information that allows for easier transfer to storage in long term memory instead of simply with their WM. Learners who exhibited a lower prior knowledge of the course content demonstrated a deeper and higher level of understanding through the use of learner-generated drawings. It also found that students bore less of a cognitive load when they were able to draw out and connect their ideas on paper. By being able to draw out the relationships and make proper connections, students were able to offload the information learned during the study rather than attempting to make all of the connections mentally.

Another study explored the components and effects of learner-generated drawing on subsequent testing. During the learning process, internalizing and externalizing the information can be difficult for students to retain, but once this information is offloaded into the environment it is not as difficult to keep track of (Schmidgall et al., 2019). The process of drawing out representations allows learners to engage in generative learning processes. This study found that the students who utilized the drawing methods for studying outperformed those who simply did a summary of the information to study.

Despite the prior work and findings, drawings have received considerably little attention as being a reliable method for offloading cognitive demands on students' WM when they are engaged in mathematical reasoning. The purpose of the present study is to examine the impact of using student generated drawings to offload the cognitive demands of mathematical tasks. Understanding mechanisms underlying the phenomenon of cognitive offloading will help to improve learning conditions for mathematics learners, which addresses one of the major goals of PME-NA. Specifically, we contribute to the existing body of research by answering the following research question: *How do drawings lighten the load of students' working memory when they are engaged in fractions tasks?*

Theoretical Framework

In answering our research question, we adopt a Piagetian perspective on the construction of mathematical knowledge and a neo-Piagetian approach to WM. Following Piaget, we conceptualize mathematics as a coordination of mental actions (e.g., Beth & Piaget, 1966). In the context of fractional knowledge, these actions are well researched (Boyce & Norton, 2016; Hackenberg & Tilemma, 2009; Steffe & Olive, 2010; Steffe, 1991, 1992). The operations most germane to our study include *unitizing* (U_n; taking a collection of n units as a whole), *iterating* (I_n; copying a unit n times to form a new unit), *partitioning* (P_n; breaking a whole into n identical units); *disembedding* (D_n; taking n equal units out of a whole without losing their connection to the whole), and *distributing* ($T_{m:n}$; inserting a collection of m units of a whole into each of the n units of another whole to create a unit of units of units).

Pascual-Leone (1970) proposed a neo-Piagetian characterization of WM through a mental-attentional operator, which is known as M-operator. Its capacity is called M-capacity and represents "the number of separate schemes (i.e., separate chunks of information) on which the subject can operate simultaneously using his mental structures" (p. 302). It has been shown that an average adult's *M*-capacity ranges from 5 to 7, meaning that they can activate 5-7 schemes at once, without offloading cognitive demands onto the environment. In the context of fractional tasks, we hypothesize that WM involves manipulating sequences of actions used to construct and transform units.

Although an average person cannot activate more than 7 schemes during a cognitive task, these schemes differ in complexity and may contain other, "smaller" schemes. In particular, some of the units and unit transformations can be organized within "larger" units coordinating structures (Boyce & Norton, 2016; Hackenberg, 2007; Ulrich, 2016). Consider, for example, the construction of 1/12 as a unit, which has a one-to-twelve relationship to a whole unit. 1/12 may be obtained by partitioning the whole into 12 equal units (see the left part of Figure 1). Vice versa, the whole may be built by the mental action of iterating 1/12 twelve times. In the absence of structures to assimilate multiple levels of units, each unit or unit transformation poses separate demands on a student's WM. However, the whole, the unit fraction, and the mental transformations between them may be chunked into a single cognitive unit, thus reducing cognitive demand of the task from three to one (see the right part of Figure 1).

Figure 1: Units coordinating structures

Our integrated framework explicitly accounts for students' available structures in lightening cognitive load on their WM when solving fractional tasks. However, the increase in the number of units and mental transformations required to operate on may overwhelm one's WM even for students with high WM capacity and advanced level of unit coordination. The utility of drawings in handling the situations of cognitive overload is the primary interest of this study.

Data and Methods

The data used in this paper is part of a larger project aimed to explore behavioral and neurological aspects of mathematical development. Here, we report on video recorded behavioral data and students' written work.

Participants

The participants recruited for this project were pre-service elementary teachers (PSTs) at a large public research university in the southeastern United States, enrolled in one of two sections of Mathematics for Elementary School Teachers, taught by the same instructor. We chose to invite PSTs because they were encouraged to explain and reflect on their reasoning while solving elementary school mathematics tasks. In total, 12 students agreed to participate. In this paper, we report on two of them.

Data Collection and Analysis

Each PST participated in an individual clinical interview (Clement, 2000) with a member of the research team, lasting approximately 75 minutes. The interviews consisted of an assessment of students' available structures (Norton et al., 2015), a WM assessment (backward digit span; Morra, 1994), and a set of fraction tasks (modified from Hackenberg & Tillema, 2009). In this study, we focus on one of those tasks: *Imagine cutting off 1/4 of 5/6 of a cake. So, how much is that of the whole cake?* The analysis of cognitive demands of this task can be found in (Kerrigan et al., 2020).

The participants were given the fraction task verbally and asked to initially solve it without using any figurative materials, so that we could determine the number of units and unit transformations each student could hold in their WM without relying on drawings. The participants were sometimes asked follow-up questions to clarify their reasoning. None of the PSTs were able to properly solve the task mentally. After they attempted to solve the fraction task in their heads, the participants were given the opportunity to use a pen and paper. All interviews were video and audio recorded, and all drawings were captured using LiveScribe pens.

We qualitatively analyzed the behavioral video data, transcripts of students' verbal reasoning, and data collected via LiveScribe pens. We built unit transformation graphs (UTGs; Norton et al., in press) to illustrate the sequences of actions the students' used in attempting to solve the task mentally, and being able to rely on drawings. The comparisons of these graphs helped us to draw inferences about the impact of student generated drawings on cognitive offloading for fraction tasks.

Results

We report on two participants: PST A (with WM capacity of 6, operating at unit coordination stage 3) and PST B (with WM capacity of 7, operating at units coordination stage 2). We decided to choose these two students because both of them were assessed with high WM capacities, made the most progress on the task in the initial phase, and could come up with the correct answer when they were allowed to use drawings. Here, we present our analysis of their reasoning before and after drawing.

PST A Before Drawing

Researcher: This is the next task. Imagine cutting off one fourth of five sixths of a cake. So, how much is that of the cake. First just try to do it in your head then you can draw.

PST A: Ok, so [motions with hands] three fourths of the five sixths.

Researcher: One fourth of five sixths.

PST A: One fourth. One fourth of the five sixths. Ok, so I see six bars, but only five. So, one fourth of one… One fourth of the five sixths… Ok…. So, that would be… [pauses for twenty-six seconds.] Umm… Five… Twenty fourths? But you're not using all six… It's really hard to do in your head. I'm not sure. I'm like really messing up your experiment, I'm sorry.

Researcher: No, this is… I mean this is… We have to have ones where you're…

PST A: Just complete dud. Um, so you have five sixths [Student motions with hands]. And one fourth of that… The fifths don't go in evenly with the fourths. So that's what is confusing to me. Is there some easy way to multiply these? Am I just, am I overlooking something?

Researcher: No.

PST A: Um…

Researcher: Do you want to draw it?

PST A: Yeah.

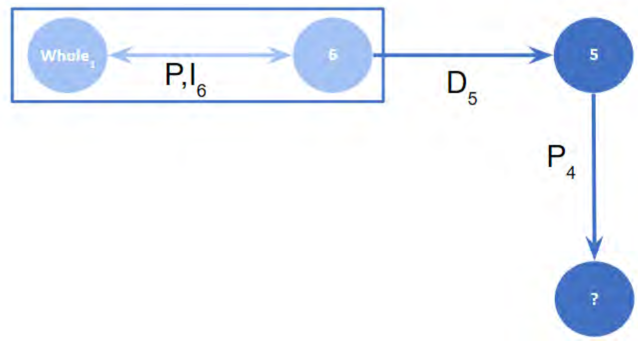

Figure 2: UTG for PST A before drawing.

As evident in UTG (Figure 2), we inferred that PST A used a two-level unit coordinating structure. This means that she could partition the whole into 6 equal parts, while being simultaneously aware of the whole, a piece of the whole, and a 1:6 relationship between them (see the rectangle in Figure 2). Therefore, mental actions of partitioning and iterating, as well as the two quantities they connect, allowed the student to chunk these three units, reducing the cognitive demand of the task by two. She could further disembed 5/6 and attempted to operate on it through partitioning into four parts. However, the latter action led to considerable cognitive overload, which might impede the student's progress on the task.

PST A After Drawing

PST A: [Picks up pen and begins to draw.] So, you have six things… Or six… But you're only using five of them. So, you need one fourth of this.
[Student thinks and draws for fourteen seconds.] Split that into fours.

Researcher: Mhm.

Student: Ok so that means it's one-fourth of that, so… One two three four five. Of the whole thing? No, just five sixths. So, five…

Researcher: Out of the- uh- original cake.

PST A: So, six sixths?

Researcher: Yes.

PST A: So, five out of, five twenty-fourths?

Researcher: Yeah.

PST A: Five twenty-fourths.

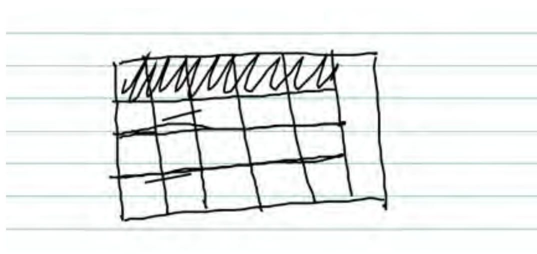

Figure 3: LiveScribe Pen drawing of PST A after drawing.

Being able to draw the problem out allowed PST A to complete the task. The student first drew a whole and split it into six pieces. She then cut each of the five pieces into four parts. After that, she shaded in a fourth from each fifth, as shown in Figure 3. Finally, the participant counted the total number of fours in each sixth to find the total number of pieces to base her shaded portion out of.

PST B Before Drawing

PST B: You're cutting off one fourth of five sixths of a cake?
Researcher: Yes.
PST B: [uses hands to show number of pieces on the desk and begins talking to herself] So, you'd have, so you'd have six pieces…and out of those five…you want to cut off one fourth of that. Um…I guess you would…I mean I guess you could split those five pieces into four and get one of those, but I'm trying to think like numbers-wise what that would...I. well… [pauses for seven seconds] I guess of those five pieces you could…Split them into…Like you could get a…Split them into twenty pieces because five times four is twenty and then, um, you would take one fourth of that… I guess it would be five pieces. Yeah, it would be five pieces of that twenty to find the one fourth of the five sixth. Is that, do I need to explain it more?
Researcher: Okay, uh let's…
PST B: Which would be, do you want me to draw it? [reaches towards paper]
Researcher: Well tell me the final answer and then we can draw it.
PST B: Um, oh gosh it would be… [pauses for four seconds] Splitting twenty, it would be five…Well it would be five twentieths, which would equal one fourth, so like five of those, but then I don't know how to figure that out into sixths. I think that's my…
Researcher: Yeah that's cool, I like the way you're reasoning. Let's draw it, and I think you will figure it out.

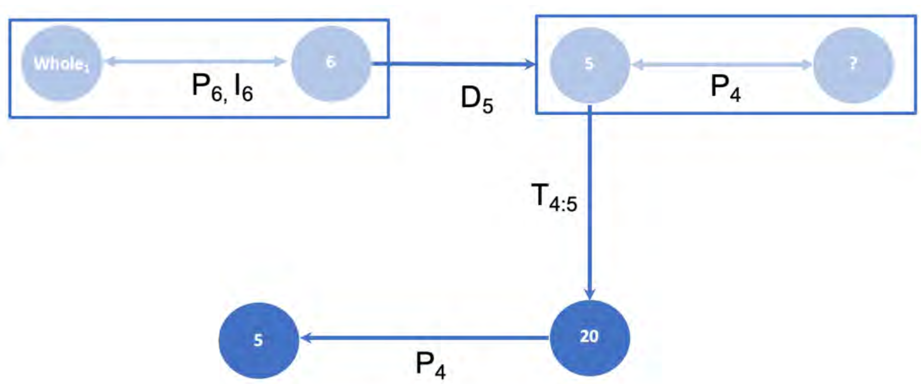

Figure 4: UTG for PST B before drawing.

Similar to PST A, PST B began with the use of a two-level structure to conceptualize 1/6, then disembedded 5 copies of it ("so you'd have six pieces… and out of those five…"), and attempted to split them into four pieces (Figure 4). However, when constructing 1/4 of 5/6, the student lost track of the sixth part making up the whole. She, thus, ended up distributing four parts into each of the 5 pieces, producing 20 parts in total. Taking a quarter out of 20, with no relation to the whole, resulted in her final answer of 5/20, or 1/4.

PST B After Drawing

PST B: Okay, so there's…This and then…Five, and we're trying to find… We have five sixths and we're trying to find one-fourth, and you… [Student works for fifteen seconds.] Okay, wait can I… can I cross this out?

Researcher: Sure. [Student crosses out picture.]

PST B: Okay this is five sixths, we want five of those and then you would, I guess divide…

[Student writes on paper for twenty-four seconds.] So then yeah you would have twenty little pieces and then…One fourth of that…Would just be, one two three four five. [Student marks pieces.] So… so I guess in terms of sixths it would be like…Well, oh wait I guess, wait…In total it would be, twenty-five twenty-fifths…Okay so in terms of six that would be… [Student works for six seconds.] Five…Wait, yeah it would be five twenty-fifths would be one fifth. I don't think that's right.

Researcher: Why don't you think it's right?

PST B: I just think, I just don't think one fourth of… I don't know it just doesn't…

Researcher: How did you get the twenty-five?

PST B: Um, I shaded in… Well I shaded in five of these because that's one fourth of the five sixths, because there are… [Student counts on drawing.] Because that's one fourth of that and then, when you turn the five sixths into terms of…Um…Twentieths, well, then I just… [Student reexamines paper.] …There are actually twenty-four…There's… So, it's out of twenty-four then, I guess, so then it would be, five twenty-fourths.

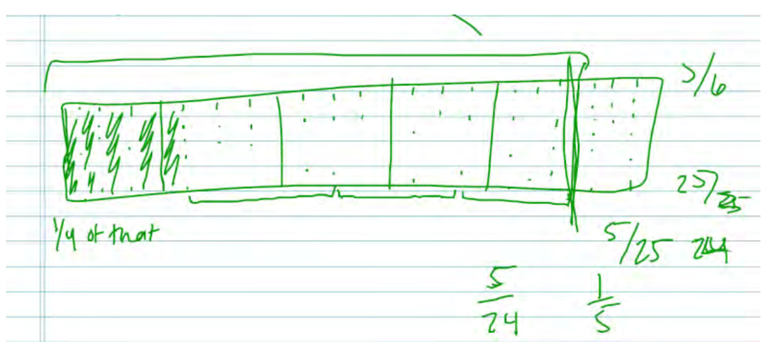

Figure 5: LiveScribe Pen drawing of PST B.

Consistent with her original strategy, the participant partitioned the whole into six pieces and marked off five of them. From there, she went through her previous approach of fourthing 5/6 by dividing each fifth piece into four smaller pieces to make the total of twenty within the fives.

Taking 1/4 of that, the student shaded in five pieces of that twenty, aligning with her previous final answer (Figure 5). However, this time, she was able to refer back to comparing that new piece to the whole cake by dividing the remaining 1/6 into four parts as well and counting the total number of pieces. The ability to draw the problem out and to refer to the depiction allowed PST B to maintain her perspective on the whole without losing the extra 1/6, and eventually come up with the correct answer of 5/24.

Discussion

The partial solutions, presented by our participants before drawing, exhausted their WM capacities. Both of the students employed two-level units coordinating structures, which allowed them to alleviate the cognitive demands on their WM. However, the experienced cognitive demand of the task was too high, leaving no cognitive resources required to complete the task. PST A had potential to make greater progress on the task because she was assessed as having WM capacity of 6 and operating at unit coordination stage 3. Nevertheless, it is known that students do not necessarily construct all possible mental structures by virtue of operating at stage 3 (Izsák, 2008). Similarly, it appears that people do not always use all their available WM resources (Eysenck & Cavo, 1992; Norton et al., in press).

After being able to represent their thought processes pictorially, both students could continue with their original method of solving the problem. Although PST A and PST B produced different drawings, their final thought processes converged (see Figure 6). They both partitioned the whole into 6 pieces, disembedded 5 of them, which constituted a new whole. After that, they distributed 4 pieces into each of the 5 pieces, producing 20 parts, which were further partitioned into 4 parts, arriving at 5 smaller pieces. In order to conceptualize how much of the whole cake these 5 pieces were, the participants had to repeat the process for the remaining 1/6 (indicated by dashed lines, ovals, and cross-hashed circles in Figure 6). Because the first part of the solution was already drawn out, the students could focus on the second part without losing any of the previously obtained information. Thus, the possibility of relying on the picture allowed the participants to save mental resources and eventually come up with the correct answer, as predicted by the prior literature (Kirsch, 2009; Schmidgall et al., 2019).

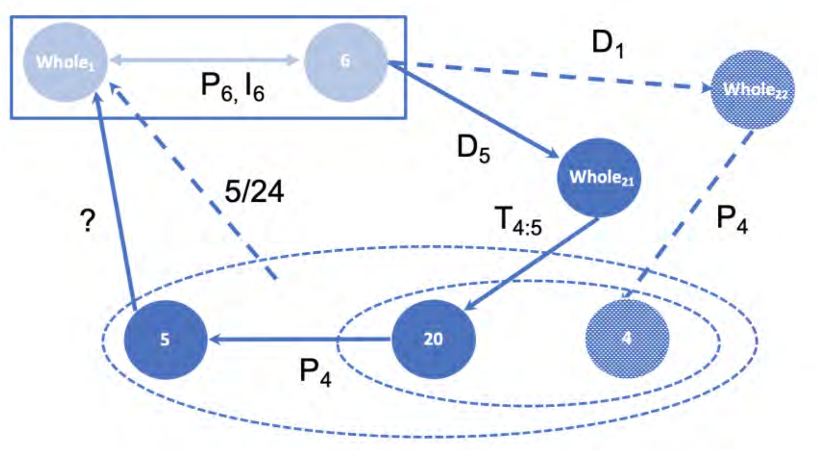

Figure 6: UTG after drawing for both PST A and PST B.

Notably, in absence of other offloading tools, the participants actively produced hand gestures when reasoning through the task. Gesturing was used as a natural method to physically represent some properties of the object of thought and make the task less demanding (e.g., Ping & Goldin-Meadow, 2010; Wagner et al., 2004). However, the use of hand gestures did not help our participants to overcome the experienced cognitive overload. Future research should be conducted to compare the effects of gesturing and drawing on managing the cognitive demands of mathematical tasks.

Research on dyscalculia has focused almost exclusively on elementary-aged students' deficits in speed and accuracy in arithmetic calculation. This case study expands our understanding of dyscalculia by documenting how one college student with dyscalculia understood algebra during a one-on-one design experiment. A detailed case study of 19 video recorded sessions revealed that she relied upon unconventional understandings of algebraic quantities and notation, which led to persistent difficulties. This exploratory case study provides new insights into the character of difficulties that arose and persisted for one student with dyscalculia in the context of algebra and suggests the utility of documenting the persistent understandings that students with dyscalculia rely upon, particularly in understudied mathematical domains, like algebra.

Keywords: Students with Disabilities, Algebra and Algebraic Thinking, Design Experiments

Although many students may have difficulties with mathematics, the 6% of students with dyscalculia (Shalev, 2007) have a neurological difference in how their brains process quantity (Butterworth, 2010). Research on dyscalculia has identified that students have difficulty processing both symbolic (e.g., 5) and pictorial (e.g., *****) representations of quantity (Butterworth, 2010). This neurological difference in number processing may render standard mathematical tools, like symbols or representations, less accessible for students with dyscalculia (Lewis, 2014; 2017). Currently, research on dyscalculia has predominantly focused on elementary-aged students engaged in basic arithmetic (Lewis & Fisher, 2016). It remains largely unknown what kinds of difficulties students may experience when encountering more complex mathematics, like algebra. This is a critical omission because algebraic reasoning is qualitatively different than arithmetic (e.g., Carraher & Schliemann, 2007; Kaput, 2008; Kaput et al., 2008; Kieran, 1992; Stephens et al., 2013), quantities are represented abstractly in a variety of forms (Kaput et al., 2008; Kieran, 1992), and failure to pass algebra can limit students' academic and career opportunities (Adelman, 2006).

Large-scale studies of students with dyscalculia in algebra are not currently feasible because of difficulties in accurately identifying students with dyscalculia. Researchers emphasize the importance of differentiating between students with dyscalculia and students who have mathematical *difficulties* that are due to environmental, language, instructional, or affective factors (Lewis & Fisher, 2016; Mazzocco, 2007; Mazzocco & Myers, 2003). Researchers also argue that it is essential to differentiate students with dyscalculia from other disabilities (e.g., dyslexia) who may struggle with math, because these students have different cognitive profiles (Lyon et al., 2003) and conflating these groups of learners may mask unique characteristics of each (Mazzocco & Myers, 2003). To establish whether students' low mathematics achievement is due to cognitive or noncognitive factors, researchers often use longitudinal designs (e.g., Geary et al., 2012; Mazzocco & Myers, 2003; Mazzocco et al., 2013) or work with adult learners (e.g., Lewis, 2014; Lewis & Lynn, 2018). For example, in the context of fractions, longitudinal research has found that the difficulties experienced by students with dyscalculia are qualitatively different than low achieving students (Mazzocco & Devlin, 2008), and that these difficulties have been found to persist over years (Mazzocco et al., 2013). Detailed analyses of adults with dyscalculia have demonstrated that these difficulties may be due to persistent, unconventional understanding and use of standard mathematical tools, which suggests that all mathematical tools are not equally accessible for students with dyscalculia (Lewis, 2014; 2016; 2017; Lewis et al., 2020). Although both studies of adults with dyscalculia and those with a longitudinal design have identified characteristic patterns of reasoning students with dyscalculia demonstrate in fractions (Lewis 2016; Lewis et al., 2022; Mazzocco et al., 2013), no similar studies have been conducted in algebra.

To extend work on dyscalculia into algebra, we conducted a detailed analysis of an adult learner with dyscalculia ("Melissa") as she engaged in a weekly videorecorded one-on-one design experiment focused on algebra. We adopt an anti-deficit theoretical orientation to disability (Vygotsky 1929/1993), and we identify the understandings she relied upon rather than interpreting her data through a deficit frame. A detailed analysis of 19 weekly hour-long videorecorded sessions suggests that the student relied upon unconventional understandings of algebraic symbols. This exploratory case study provides new insights into the character of difficulties that arose and persisted for one student with dyscalculia in the context of algebra and suggests the utility of documenting the unconventional understandings that students with dyscalculia persistently rely upon.

In this section we review research on algebra teaching and learning which has established both the common misconceptions experienced by all students when learning algebra, as well as instructional approaches intended to address these issues. We then present our theoretical framework – grounded in an anti-deficit Vygotskian framing of disability. We conclude by considering how this framing influenced the design decisions for our one-on-one learning environment.

Prior Research on Algebra

In this study, we aimed to extend research on dyscalculia to the mathematical topic of algebra. Algebra is a particularly appropriate content area to explore dyscalculia because algebra is representationally and conceptually far more complex and abstract than arithmetic (Kaput, 2008). Kaput (2008) defines algebraic reasoning as generalizations within a conventional symbol system and syntactically guided action on those symbols. Because students with dyscalculia have difficulty both using symbols to represent quantities and manipulating those quantities in arithmetic (Piazza et al., 2010) – it is critical that we begin to explore how these difficulties emerge in algebra when symbol use and manipulation is core to the mathematical activity. Fortunately, research with *nondisabled* students offers considerable insight into the nature of common student difficulties and a wealth of instructional approaches for addressing these difficulties (e.g., Carraher & Schlieman, 2007). For example, using real world problems, manipulatives, and two-sided scale models have been recommended to support students' understanding of unknowns, equality, and algebra (e.g., Common Core State Standards, National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; van de Walle et al., 2016). Although common difficulties and effective instructional approaches have been identified for nondisabled students, it is unclear what kinds of unique difficulties students with dyscalculia may experience, as well as which mathematical representations and tools may be inaccessible.

Theoretical Perspective – Reconceptualizing Dyscalculia as Difference

Although dyscalculia is typically conceptualized in terms of cognitive *deficits* (e.g., Geary, 2010), we argue that it is more productive to conceptualize dyscalculia in terms of cognitive *difference.* Our perspective is derived from a Vygotskian perspective of disability (Vygotsky, 1929/1993). Vygotsky argued that mediational signs and tools (e.g., language, symbols), which developed over the course of human history, were often incompatible with the biological development of children with disabilities (Vygotsky, 1929/1993). For example, the mediational tool of *spoken* language is not accessible to a Deaf child, and therefore does not serve the same role in supporting the child's development of language as it would for a hearing child. In the case of students with dyscalculia, it is possible that standard mathematical mediational tools (e.g., numerals, graphs, equations), which support the mathematical development of most students, may be incompatible with how a student with dyscalculia cognitively processes numerical information (e.g., Piazza et al., 2010). Students may have difficulties accessing and using these standard tools and may understand representations and symbols in unconventional ways. Although all students may use standard tools in unconventional ways as they are first learning a topic, we propose that students with dyscalculia may experience *persistent* incommensurability because of the inaccessibility of these mathematical mediators. Therefore, in this study, we identify unconventional use or understanding of standard mathematical tools that persist across problems and contexts – we term these *persistent understandings*.

Disability Through the Lens of a Design Experiment

In this study, we capture the student's attempts to learn during a design experiment (Cobb et al., 2003). A design experiment involves engineering learning environments and systematically studying the forms of learning (Cobb et al., 2003). In this design experiment not only do we capture the student's unconventional understandings as she is engaged in attempts to learn, but we attempt to design instructional approaches which address her difficulties. It is through the iterative cycles of design, enactment, and analysis that we can understand both the student's unconventional understandings and what instructional approaches are accessible for the student. The outcome of this design experiment is not a recommendation for a particular sequence of instructional activities or tools. Instead, the design experiment serves as the context through which we are able to better understand the kinds of inaccessibility this student with dyscalculia experienced in mathematics and what kinds of tools were more accessible. In this paper we focus on identifying the kinds of unconventional understandings of mathematical mediators that the student persistently relied upon during the design experiment (persistent understandings).

Methods

Case Study Participant History

Melissa was a 31-year-old, woman, native English speaker, who identified as half Black and half White. We recruited Melissa from her pre-college mathematics class at community college. All students in the pre-college mathematics class were given a written fractions assessment (Lewis et al., 2022), which has been shown to identify students who demonstrate unconventional understandings, characteristic of dyscalculia (Lewis et al., 2022). Melissa demonstrated unconventional understandings on this assessment and was invited to participate in an interview, formal assessment, and design experiment focused on algebraic concepts. On the Woodcock-Johnson Test of Achievement IV (WJ-IV; Schrank et al., 2014), Melissa composite math score was at the 19th percentile – which is below the 25th percentile – the most commonly used cutoff for determining dyscalculia eligibility (Lewis & Fisher, 2016). An interview revealed that

Melissa had a long history of difficulties with mathematics through school, despite having sufficient resources (e.g., private tutor). She had repeatedly failed pre-college mathematics classes at the community college. She reported doing all her homework and practicing problems “over and over and over again,” but she still struggled to understand the content. She did not pass this class. She explained, “how my mind processes it, is quite different than the average person. It seems easy for other people, but for me you have to explain it in a different way.” She explained that she did well in all her other classes, “it’s just math that gets me.” Given Melissa’s unconventional fraction understandings, low mathematics achievement score, and her history of continued mathematics failure despite sufficient resources, Melissa meets the dyscalculia criteria.

One-on-One Design Experiment

We conducted 19 videotaped design experiment sessions with Melissa. This design experiment involved iterative microcycles of design, enactment, and analysis (Gravemeijer & Cobb, 2006). Each microcycle involved designing and enacting an individual, one-on-one instructional session and then analyzing a video of the session in order to design the subsequent session. The first and third authors participated in the design microcycles and the first author (“Kelly”) was the tutor for all sessions. The goal of these sessions was to identify the ways in which Melissa used mathematical tools in unconventional and problematic ways and to provide Melissa with alternative mediational tools to support her understanding (for more details about this iterative approach to design see Lewis et al., 2020). In designing alternative mathematical mediators we (a) drew upon prior research on the teaching and learning of algebra with nondisabled students (e.g., Kieran, 2007), (b) leveraged instructional recommendations offered by an adult with dyscalculia who developed ways of compensating (Lewis & Lynn, 2018) and (c) built upon Melissa’s intuitive notations about mathematics and what she reported was more or less effective for her. In our design we aimed to provide Melissa with mediators that would help support a conventional understanding of algebra, specifically solving for an unknown, which is a core algebraic concept.

Retrospective Analysis

After the conclusion of data collection, we began our retrospective analysis. We transcribed all video recordings and scanned all written artifacts. We parsed each transcript into individual problem instances, which began with a question and ended with a student answer. The first and second author iteratively reviewed videos of each of the sessions and generated and refined analytic categories that captured the nature of the student’s understanding. We produced operational definitions for persistent understandings, specifying inclusion criteria and identifying prototypical examples of each. Five persistent understandings were related to Melissa’s understanding of algebra (see Lewis et al., 2020 for a description of persistent understandings associated with integer operations). Three coders (first, fourth, and fifth authors) systematically coded each problem instance for correctness, problem type, instructional approach, mediational tools, and any persistent understandings. Each problem instance was coded by at least 2 coders. Reliability for the coding of the 5 algebraic persistent understandings was 95.4%. Any discrepancies in coding were resolved during our weekly research team meetings by rewatching the video and discussing whether there was sufficient evidence to warrant the attribution of that operational definition (for a similar approach see Schoenfeld et al., 1993; Lewis, 2014).

Findings

The detailed analysis of video recordings revealed a collection of five persistent algebraic understandings that reoccurred, were unconventional, and led to difficulties. These persistent understandings were related to (1) the value of unknowns, (2) the equal sign, (3) coefficients, (4) the meaning of “x=”, and (5) the value of zero. We begin by providing a high-level overview of the unconventional understandings and data about their prevalence throughout the sessions, which indicate that these unconventional understandings were often associated with an incorrect answer. We then dive into detail for the first unconventional understanding to demonstrate how this unconventional understanding emerged in the data. We then present a problem instance taken from the first session which shows how multiple unconventional understandings sometimes occurred in tandem and led to significant difficulties.

We identified five persistent unconventional understandings based on the detailed analysis of Melissa’s video recorded data, these include:

1. **Expansive and static view of unknowns** - When working with unknowns/variables, Melissa asserted that any non-numeral symbol (e.g., +, =) was a variable, that x could be different values in the same problem, and that x was a static value equal to 1.
2. **Equal sign as a bridge** - When working with equations, Melissa treated the equal sign as a symbol which indicated the result of a calculation, so she often used intermediate equal signs between solution steps or had equations with more than 1 equal sign. She often made invalid transformations of the equations moving terms from one side to the other across “the bridge”, and did not object to invalid equalities (e.g., -4=5).
3. **Unconventional manipulation of coefficients** - When working with coefficients, Melissa often assumed an additive relationship between the coefficient and the unknown and would subtract the coefficient away from the unknown (e.g., 6x-6=x). At other times, she would resolve coefficients by dividing by the entire term, rather than the coefficient value (e.g., to solve 6x=12, diving by 6x rather than 6).
4. **x = the answer** - When working with unknowns, Melissa understood x to equal the answer, so would often ignore the location of x in an equation and tack “x=” in front of the answer she calculated, regardless of whether it represented the value of the unknown.
5. **Zero is not a value** - When solving algebra problems, Melissa treated the value 0 as if it were not a quantity. At times she treated like any other constant, (subtracting it from both sides of the equation) and at other times she argued that it was not a valid value.

Within these 19 individual sessions, 427 problem instances involved algebra content. Of the 427 problem instances, 186 were coded as incorrect (44%) and 90% of these incorrect answers were associated with an unconventional persistent understanding. Indeed, in problems where Melissa relied upon these unconventional persistent understandings, she often produced an incorrect answer (see Table 1).

Table 1: Prevalence of Persistent Understandings and Correctness of Problem Instances

Persistent Understanding	Number of problem instances	Associated with an incorrect answer
1. Expansive and static view of unknowns	80	80%
2. Equal sign as a bridge	110	59%
3. Unconventional manipulation of coefficients	70	74%
4. x = the answer	46	74%
5. Zero is not a value	13	61%

These five persistent understandings (along with the integer persistent understandings, Lewis et al., 2020) provided a relatively comprehensive explanatory frame for the difficulties that the student experienced. We now provide details for one persistent understanding, to illustrate how this emerged over the course of the sessions.

Persistent Understanding #1 - Expansive and Static View of Unknowns

The first persistent understanding – ***expansive and static view of unknowns*** – involved an unconventional understanding of algebraic unknowns and their values, that was both overly expansive and overly static. Melissa was overly *expansive* in her definition of unknowns, in that she used the term "unknown" or "variable" to refer to any non-numeral mathematical symbol. She explained, "a variable is a… an unknown number," and that a variable could be an "addition or subtraction problem" and then identified a whole range of different mathematical symbols (e.g., $+, \pi, [, x, m, \div, <, =$) as variables. She explained, "[The equal sign] is a variable, as well as an *x* is a variable, or a plus is a variable." In addition to treating all symbols as variables, she was also overly expansive about her understanding of unknowns in that she believed that an unknown (e.g., *x*) could be different values within the same problem (e.g., $2x+4=3x$), and argued that even after solving for x, that that unknown could still be anything.

Although she was often overly expansive in her understanding of unknowns, she also demonstrated a *static* view of unknowns, and often asserted that unknowns were equal to 1. She explained, "The rule of x is 1, that's most common unknown, in other words, for x to be 1." For example, during one session Kelly asked her to write a value that was greater than x. She incorrectly determined that 2 was larger than x and explained, "because I look at x, or a letter, as 1. And 2 is just bigger."

Believing that unknowns were static values equal to 1 was sometimes problematic when she attempted to solve for *x*. For example, when asked to solve $12=x+5$, she replaced the x with a 1 simplifying the equation to 12=6, then divided both sides by 6 to get an answer of 2. Melissa's static understanding of x, being equal to 1, was used in this example to create an invalid equation 12=6. She did not find this to be problematic and continued to procedurally manipulate the values, as if she was still solving for x, determining that the answer was 2.

In another example, when she solved the problem x+3=8, she correctly determined that x=5, but when Kelly asked her what it meant that x=5 (a standard question), she explained that "one equaled five [*writes 1=5; see Figure 1*] because I see x as 1." In this instance, even though she had just determined that x was equal to 5, her understanding that x=1 emerged. This resulted in her creating an invalid equality 1=5, which she did not find problematic.

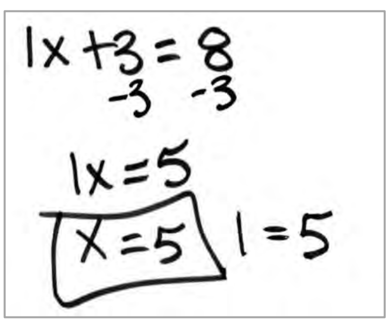

Figure 1. Melissa's written work to solve the problem x+3=8

Both Melissa's understanding of x as a static value, equal to 1, and her overly expansive understanding of unknowns, which involved believing that x could be any value, even after determining the value of x, led to her unconventional use of unknowns and errors across the sessions. This persistent understanding was evident in 80 problem instances across the sessions, and 80% of the time was associated with an incorrect answer. A similar pattern of prevalence and errors were found for the other 4 persistent understandings (see Table 1).

Persistent Understandings Occurring in Tandem

To illustrate how these persistent understandings often appeared together in the same problem, we illustrate how Melissa relied upon several persistent understandings as she solved the problem x/2+7=10. This episode was taken from the first instructional session as Kelly tried to assess her existing strategies for solving for x. The prevalence of these persistent understandings in this first section suggests that Melissa came to this design experiment with these persistent understandings. In Figure 2 we present the student's work, along with the persistent understanding identified and the rationale for that attribution. This example illustrates how Melissa's persistent understandings often occurred together and resulted in difficulties.

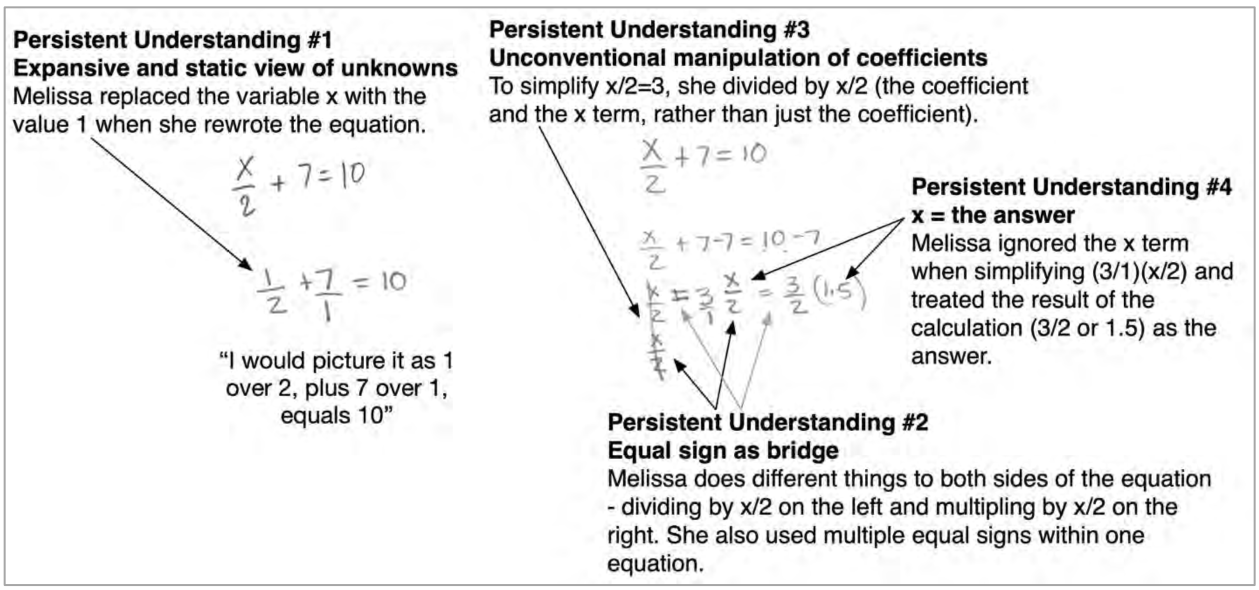

Figure 2. Melissa's written work, and illustration of multiple persistent understandings within one solution process.

Discussion

This detailed case study of Melissa, an adult student with dyscalculia, found that she had persistent unconventional understanding of standard mathematical symbols (e.g., unknowns, the equal sign, coefficients, x=, and zero). Unlike the kinds of difficulties that all students experience when first learning a topic, these unconventional understandings were persistent. We argue that the persistence of these unconventional understandings suggests that these standard mathematical tools – used to represent quantities and relationships between quantities – were at least partially inaccessible to the student. In other work (Lewis et al., in press) we explore how Melissa's persistent understandings interacted with tools specifically designed to provide her with increased access. Here we note that the persistent understandings continued to emerge as Melissa engaged with new tools, but reorientation to the tools enabled Melissa to reason in more conventional ways.

This detailed case study extends prior research on dyscalculia in several important ways. First, this research demonstrates how number processing difficulties found in younger students with dyscalculia (Landerl, 2013; Rousselle & Noël, 2007), occur in older students engaged in algebraic reasoning. Just as prior research has demonstrated that students with dyscalculia are slower and more error prone when asked to compare or manipulate *arithmetic* quantities (e.g., Desoete et al., 2012), Melissa often made errors (44% of algebra problems were incorrect) and she experienced persistent difficulties understanding, comparing, representing, and manipulating *algebraic* quantities. This study, therefore, extends findings that have been documented in students with dyscalculia, and begins to identify how these difficulties would emerge in an algebraic context. This kind of detailed case study can enable researchers to begin to explore mathematical topic domains beyond basic arithmetic, and provides much needed insight into dyscalculia across mathematical topic domains.

Second, this study offers an anti-deficit framing of dyscalculia by providing a detailed depiction of a student engaged in the process of learning and doing mathematics, rather than describing the student's performance from a deficit frame in terms of speed and accuracy. Unlike prior research on dyscalculia which infers learning difficulties based on patterns of errors on outcome measures (e.g., Bouck et al., 2016; Mazzocco et al., 2008), this study explored the student's reasoning underlying these errors. This study documented the ways in which Melissa was understanding, representing, and manipulating quantities, while engaged in problem solving. This anti-deficit framing is critical for making progress in the field towards accurate identification of dyscalculia and offers new avenues to explore for re-mediation.

Future research is needed to determine whether these understandings identified in this study are unique to Melissa, or if they are typical of students with dyscalculia. Building from case study research to large scale studies to examine the prevalence of these characteristics and to develop screening measures to accurately screen for dyscalculia has been demonstrated in the domain of fractions (Lewis et al., 2022).

Conclusion

This exploratory case study provides new insights into the character of difficulties that arose and persisted for one student with dyscalculia in the context of algebra. Findings suggests the utility of documenting the persistent understandings that students with dyscalculia rely upon to understand how dyscalculia may impact students learning of algebra. Beginning to understand dyscalculia in algebra is critical, as algebra often acts as a gate keeper, like it did for Melissa, limiting students' academic and career opportunities.

PROBLEM SOLVING AND PERSEVERANCE IN GEOMETRY: REVELATIONS FROM THINK ALOUDS WITH MIDDLE GRADES STUDENTS

Problem solving is a very important skill for students to learn (e.g., Bonilla-Rius, 2020; NGA, 2010), and part of developing problem solving skills is learning to persevere. One strategy for learning how to persevere is by providing students with materials that allow them the opportunity to engage with challenging problems (e.g., Kapur, 2010; Middleton et al., 2015). This study of the Volume unit of the AC²inG materials analyzes students' strategies for problem solving and persevering. Findings from these think-aloud interviews indicate that different students will utilize one or more methods for solving challenging problems, such as asking clarifying questions, talking themselves through the problem, and attempting various mathematical approaches.

Keywords: Problem solving, middle school education, geometry and spatial reasoning, curriculum

Theoretical Framework

The first Standard for Mathematical Practice outlined in the Common Core State Standards (NGA, 2010) states that students should be able to "make sense of problems and persevere in solving them" (SMP.1). Perseverance and problem solving are also emphasized in standards outside the United States (e.g., Canada (Ontario, 2020); Mexico (Bonilla-Rius, 2020)). The ability to problem solve and persevere are highlighted as part of the skillset required to be successful in our modern society. According to Bonilla-Rius (2020), the recently re-envisioned national standards in Mexico outline eleven skills and characteristics necessary to be a successful citizen in the 21st century, including critical thinking and problem solving.

Students also recognize the importance of perseverance when faced with a challenging problem. When asked what it takes to solve problems, one group of elementary students offered the following responses: "Be open minded."; "Be able to defend your thinking."; and "Don't give up – persevere!" (Costello, 2020). However, while many stakeholders understand the importance of perseverance and problem solving abilities, researchers understand that these crucial skills are not always innate for students and, thus, must be modeled for them (Colgan, 2020). One way to model these skills is through the materials and resources teachers provide for their students (Kapur, 2010; Middleton et al., 2015). Materials that utilize contrasting cases are one such set of resources that provide opportunities for students to practice problem solving (Loibl et al., 2020), an important part of which is persevering.

The Animated Contrasting Cases in Geometry (AC²inG) Materials

The Animated Contrasting Cases in Geometry (AC²inG) project has recently developed a set of materials that utilize contrasting cases to offer middle-grades students the chance to reason about various geometric topics in a relatively novel way. Contrasting cases are materials that present two or more methods for solving the same or similar problems, and research has shown that these types of activities can be effective for developing both procedural fluency and conceptual understanding (Rittle-Johnson & Star, 2009). Covering topics across the CCSS-M

Grade 8 standards, including angles, transformations, the Pythagorean theorem, and volume, the AC^{2}inG materials are organized into four units, each covering one of the aforementioned topics, that include five or six Worked Example Pairs (WEPs) per unit. Each WEP presents students with two fictitious characters' methods for solving a problem and allows students to explore the reasoning of these two characters side by side, providing them the opportunity to compare and contrast each character's method. Furthermore, each WEP consists of five parts: (1) the first character's method alone; (2) the second character's method alone; (3) both methods side by side; (4) a series of discussion questions and practice problems about the concept covered in the WEP; and (5) a Thought Bubble page where one of the characters shares a revelatory idea about the concept. This design presents students with myriad opportunities to critique the reasoning of others (another of the Standards for Mathematical Practice, SMP. 3 (NGA, 2010)) while practicing their problem solving skills and challenging themselves to persevere.

Methods

Due to the constraints of the current pandemic, our team conducted individual think aloud interviews (Piaget, 1976) with 42 students in lieu of piloting these materials in classrooms. In each interview, students worked through one or more of the WEPs from a particular unit while discussing their thoughts about the methods of each character as well as how the students themselves would solve the problems and answer the discussion questions. These interviews were transcribed and independently coded by two members of our research team. After one researcher coded an interview, a second researcher then coded the interview to determine agreement. In the case of disagreements, a third researcher made a final determination about the code(s) in question.

This report focuses on codes from the Volume unit pertaining to students' original geometric thinking, particularly those where students struggled and persevered. The code 'Persevered' was a subcode of the code 'Struggle,' which was used when a student showed us they were having trouble working through a problem. We analyzed quotes tagged with the 'Struggle' code for similarities and differences and realized that, when students were confused, they took one of two possible pathways. First, the student could stop working and give up, an option students exercised approximately one-third of the time. Second, the student could choose to continue working through the problem, an option we observed the other two-thirds of the time and coded as 'Persevered.' These codes were further analyzed for similarities and grouped into two broad approaches, as outlined below.

Findings

Throughout the 14 think alouds covering WEPs from the Volume unit, students worked to solve a variety of problems. Many of these problems caused them to struggle, as indicated by the 41 times we used the code 'Struggle' when analyzing transcripts from this unit. Given that perseverance was observed in eight of the 13 students who completed WEPs from the Volume unit, it is no surprise that this trait manifested itself in several different ways. Primarily, we noticed two broad approaches to persevering when problem solving: (1) the student tried to make sense of the problem; or (2) the student tried to use an alternate strategy.

Making Sense of Problems

Persevering through a challenging problem was seen when students attempted to make sense of the problem before proceeding. They did this in three distinct ways: (1) asked clarifying questions; (2) talked themselves through the problem; and (3) tried to recall something they had previously learned.

Ask clarifying questions. When students encountered difficult problems while working through the materials, one strategy they used to persevere was to ask the researcher clarifying questions about the problem. For example, when posed with the question, "Can two cylinders with different dimensions have the same volume?", one student asked about the word dimensions. "Is that like height or depth or something?" Rather than give up on this problem due to a vocabulary issue, this student chose to ask a clarifying question and was able to craft a cogent, correct response.

Other students asked clarifying questions and were able to correct their misconceptions through the act of asking their question aloud. One WEP prompt asked how much paint is necessary to paint the walls of Rachel's room. Two of her friends, Damien and Sydney, offered to help her solve this problem. Damien used surface area to calculate his answer, and Sydney used volume. One student originally said that volume would be best because "Rachel painted the entire room, and it said that she used [volume]." This student had misassigned Sydney's method to the fictitious character, Rachel, who was the friend in the scenario who needed help. This student asked the researcher to clarify what the question was asking and realized that they had made a mistake when interpreting the methods and solutions. They then changed their answer to surface area, realizing that volume would fill the room with paint.

Talk through the problem. Another strategy students used was to talk themselves through the problem at hand. One student initially struggled to understand the method employed by one of the characters when attempting to find the volume of a cylindrical container. "It seems weird to me," said the student. "I kept running through it. I was wondering why it was like that." Then revelation struck. "Oh wait! I see now. This is B [the area of the base] - you're trying to find the circle." By walking through the problem and provided method several times, this student was able to understand the reasoning of the character in the WEP on their own.

Recall previous learning. A third strategy we observed students using was to dig into their memories to recall concepts and information they had previously learned. Sometimes they were successful in remembering. One student knew that they had learned how to calculate the volume of a cylinder previously and thought their teacher would be "so angry with [them] if [they] forget these things." Consequently, the student tried to think back to their previous work and finally recalled the correct strategy. Another student initially misread a problem about calculating the volume of composite figures and struggled to remember a specific formula before remembering that the figure could be separated into more common figures, the formulas for which the student was able to recall.

Other students attempted to remember what they had learned but were not as successful. One such student stated that they "kind of forgot how to do the area of a cylinder" and cited this as the reason they were confused when trying to reason through the characters' methods. Even though this student could not recall the knowledge necessary to solve the problem, we identified this as perseverance because they attempted and did not give up on the problem until they had attempted several times.

Trying an Alternate Strategy

When students would get stuck in the middle of a problem, we noticed that some of them: (1) tried a different mathematical approach; or (2) took an educated guess.

Tried a new mathematical approach. Students sometimes decided to take a different mathematical approach than the one they originally thought of or tried. One student was confused by a problem that asked them to find the volume of a cylinder if the radius were scaled by a factor of three. The first thing they attempted was to find the height of the cylinder so they could use the volume formula. When they realized the problem did not give them the height, they attempted to plug in what they were given and solve for the height. This strategy was more complex than they were expecting, and even though they did not find the correct answer, they persevered through their selected strategy and found a solution, albeit one that was incorrect.

Took an educated guess. After exhausting other efforts, some students settled on offering a best guess. After talking through the problem of scaling the radius of a cylinder, one student offered an incorrect solution but was able to justify their guess and the steps they took to arrive at their guess. Another student, when trying to use one of the characters' methods to find the volume of a cylinder, admitted that they did not fully understand the fictitious character's method, and while they did not come to the correct solution, they did offer an explanation of their thinking and a guess as to what they thought it might be.

Several times, students initially did not have any idea what to do with a problem, but when the researcher asked what they were thinking, they were able to offer a guess. When thinking about why scaling the radius by some number n causes the volume to scale by n^2, one student tried to reason through the problem, after initially stating that they did not know how to answer it. "Um, I mean, you didn't change the height, I guess, so that's why the volume multiplied. I don't know." Even though this student was not able to completely articulate their thinking, they persevered and demonstrated a preliminary understanding of the relationship between the radius and the volume.

Discussion and Future Research

The math education community places great importance on problem solving and perseverance, as witnessed by the standards we set for our students (e.g., CCSS Standards for Mathematical Practice (NGA, 2010)). These skills are essential in the 21st century (Bonilla-Rius, 2020), and students themselves recognize the importance of persevering when faced with challenging problems (Costello, 2020). In this study, we witnessed students using a variety of problem solving strategies and persevering to overcome questions that caused them confusion. They asked clarifying questions, talked through the problem, dug into their memories, tried multiple strategies, and even took educated guesses when necessary.

The think aloud interviews allowed us to uncover ways in which students persevered when working with middle-grades volume concepts. Future research might analyze what type of materials best encourage students to persevere. It also might be pertinent to compare the students who persevered with those who did not and try to understand the differences between these students.

MATHEMATICS IDENTITY AND GENDER DIFFERENCES IN STEM PERSISTENCE: A LATENT GROWTH CURVE MODEL

Dalton D. Marsh
California State University, San Bernadino
Dalton.Marsh@csusb.edu

Mathematics and science identity has been shown to be a significant factor related to student achievement, course-taking, and college and career choices in STEM. However, less in known about how students' mathematics and science identities change over time and how these changes relate to persistence in STEM programs. This study uses data from three waves of the High School Longitudinal Study of 2009 and latent growth curve modeling to investigate how STEM students' mathematics and science identities change from high school through college. Results show that while male STEM students tend to maintain high levels of mathematics identity throughout, female STEM students' mathematics identity tends to start lower and decline over time.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Gender.

It is well established that despite having similar high school STEM achievement and coursework as their male counterparts, female students are less likely to enter and more likely to leave postsecondary Science Technology, Engineering, and Mathematics (STEM) degree programs (Chen, 2013). To explain women's underrepresentation in STEM, the extant literature points to motivational effects of gender stereotypes and observed female gender disparities in positive self-perceptions about mathematics and science. Such motivational differences are typically examined at fixed time points, however a review by Wang and Degol (2013) argues that more longitudinal research is needed.

One longitudinal study (Wang et al., 2017) employing expectancy-value theory, found that self-perceptions about ability, importance, interest, and usefulness of science tend to decline over secondary school more sharply for girls. These trajectories were linked to lower STEM achievement, course-taking, and career aspirations. More work is needed to see how these effects play out in postsecondary settings. The present study aims to address this gap by examining growth trajectories of two STEM-related self-perceptions that have garnered critical attention recently: mathematics and science identity. Trajectories for these self-perceptions were examined from high school through college and notable gender differences were found that offer explanations for female students' lower interest and persist in STEM.

Theoretical Framework

This study employs expectancy-value theory (Eccles, 2009). In terms of identity, the theory argues that students tend to persist in the achievement-related tasks they view as consistent with their personal and collective identities (i.e., sense of self and sense of belonging to a group). In the context of STEM, this means that students tend to persist in STEM as long as they perceive the activities involved in STEM to be consistent with their view of themselves and others they identify with (e.g., gender and racial groups). Empirical research has agreed, finding that students who form and maintain strong mathematics and science identities persist in STEM degrees and careers (e.g., Aschbacher, Li, & Roth, 2010; McGee, 2015). However, currently most of these studies are small-scale and qualitative. This research aims to address this gap.

Methodology

The present study seeks to answer the following research questions: (1) How do STEM degree pursing students' mathematics and science identities change from high school through college? (2) Do these trajectories differ by gender, race, or first-generation college status?

Data and Sample

To answer these questions the present study employed data from the High School Longitudinal Study of 2009 (HSLS:09; Ingles et al., 2011). HSLS:09 is the most recent in a series of surveys administered by the National Center for Education Statistics (NCES) that follow nationally representative samples of young people as they transition from high school to postsecondary years. The first wave of HSLS:09's data collection began in the fall of 2009 with over 23,000 ninth-graders from 944 public and private schools throughout the United States. Sampling involved a complex, two-stage design in which eligible schools were first randomly selected and then students within those schools were randomly selected (Ingles et al., 2011). The students were followed up in the spring of 2012, when most were in the eleventh grade (Ingles et al., 2014); in 2013, for high school transcripts and postsecondary plans (Ingles et al., 2015); in 2016, when most college-attending students were in their fourth year of college (Duprey et al., 2018); and in 2017, for postsecondary transcripts (Duprey et al., 2020).

The analytic sample consisted of HSLS:09 students who participated in all five rounds of data collection listed above and were enrolled in a STEM degree program according to the 2013 Update (Ingles et al., 2015). Majors considered STEM included computer, physical, and natural sciences; engineering; mathematics and statistics; and military and science technologies or technicians. The resulting sample is then representative of U.S. 2009 ninth graders who pursued STEM degrees after high school.

Dependent Variables

Mathematics and science identity were measured at three timepoints: 9th grade, 11th grade, and in the fourth year of college (Fall 2009, Spring 2012, and Fall 2016). In each of the three waves, two Likert-scale items measured students' mathematics (science) identity: (a) you see yourself as a math (science) person and (b) other people see you as a math (science) person. Items (a) and (b) were combined to form a composite scale via principal components factor analysis. Reliability tests suggested good internal consistency between the items in each scale ($\alpha > .80$). The scales were standardized ($M = 0$, $SD = 1$) over all (STEM and non-STEM) students.

Time-Invariant Predictors

Prior achievement in mathematics was measured using the ninth-grade algebraic reasoning assessment score. The assessment was developed by NCES using an item-response theory (IRT) design. *Prior coursework in mathematics and science* was measured using the highest-level mathematics course and highest-level science course variables gathered from the high school transcript file. The above were each standardized ($M = 0$, $SD = 1$) in the analytic sample. Additional student background variables included student's *gender* (1 = female, 0 = male); *race/ethnicity* (Asian, Black or African American, Hispanic or Latino, Native American, two or more races, and White was used as the reference group); and *first-generation college status* (1 = parents do not have a college degree; 0 = parents have at least an associate's degree).

Estimation

To estimate the mathematics and science identity growth trajectories the researcher used latent growth curve modeling (Byrne, 2011). The analysis was conducted in Mplus 8.4 with the MLR estimator which is robust against non-normality and accounts for missing data (Muthén & Muthén, 1998-2017). Due to the complex sampling design of HSLS:09, a balanced repeated replication (BRR) weighting procedure was employed, and model fit was assessed with the standardized root mean square residual (SRMR) index (Asparouhov & Muthén, 2010, 2018). SRMR values less than .05 and .08 are considered excellent and acceptable fits, respectively (Hu & Bentler, 1999). The HSLS:09 survey weight W5W1W2W3W4PSTRANS was used in combination with its corresponding 200 BRR weights (see Duprey et al., 2020).

Results

The sample of STEM degree pursing students included $N = 1{,}931$ students of which 33.3 percent were female and 66.7 percent male. 6.9 percent of the sample identified as Asian, 8.9 percent as Black or African American, 16.0 percent as Hispanic or Latino, 1.4 percent as Indigenous (Native American, Native Hawaiian, Alaska Native), and 7.5 percent identified with two or more races. 26.5 percent were reported to be first-generation college students.

The growth curve analysis began by estimating the unconditional linear model (intercept, slope, no predictors). The model fit was estimated to be excellent (SRMR = .025). The mathematics curve was estimated to have an intercept of 0.459 ($p < .001$) and a slope value of 0.001 ($p = .788$). The science curve was estimated to have an intercept of 0.489 ($p < .001$) and a slope of 0.006 ($p = .549$). These estimates indicated that STEM degree pursuers on average have about a half of a standard deviation higher sense of mathematics and science identity initially compared to other college students and then maintain these levels of identity throughout high school and college. Quadratic growth curve models (intercept, linear, and quadratic terms) were estimated but the analyses found these models to not fit the data. Therefore, the growth curves were assumed to be linear.

Next, predictors were added, all of which were modeled as time invariant. The model fit test suggested excellent fit (SRMR = .019). The covariate model analysis did not find race/ethnicity or first-generation status to be significant ($p > .05$) predictors on the intercept or slope, suggesting that students' mathematics and science identity growth trajectories did not vary by race, ethnicity, or college generational status. However, there were significant gender effects on the intercept ($p = .007$) and slope ($p = .020$) for mathematics identity but not for science. In the interest of gender differences, Table 1 displays the model estimates for mathematics identity.

Table 1: Parameter Estimates for Latent Growth Curve Model of Mathematics Identity

Predictor	Estimate	*p*-value
Intercept		
Female	–0.193	.007
Asian	–0.182	.182
Black or African American	0.168	.202
Hispanic or Latino	0.077	.514
Indigenous	0.080	.795
Two or more races	–0.209	.134
First-generation to college	0.102	.279
Prior math achievement	0.376	< .001
Prior math coursework	0.107	< .001
Prior science coursework	–0.028	.456
Slope		
Female	–0.030	.020
Asian	–0.001	.960
Black or African American	0.002	.927

Hispanic or Latino	–0.009	.677
Indigenous	–0.021	.640
Two or more races	0.011	.609
First-generation to college	0.007	.719
Prior math achievement	–0.012	.142
Prior math coursework	0.001	.949
Prior science coursework	0.002	.814

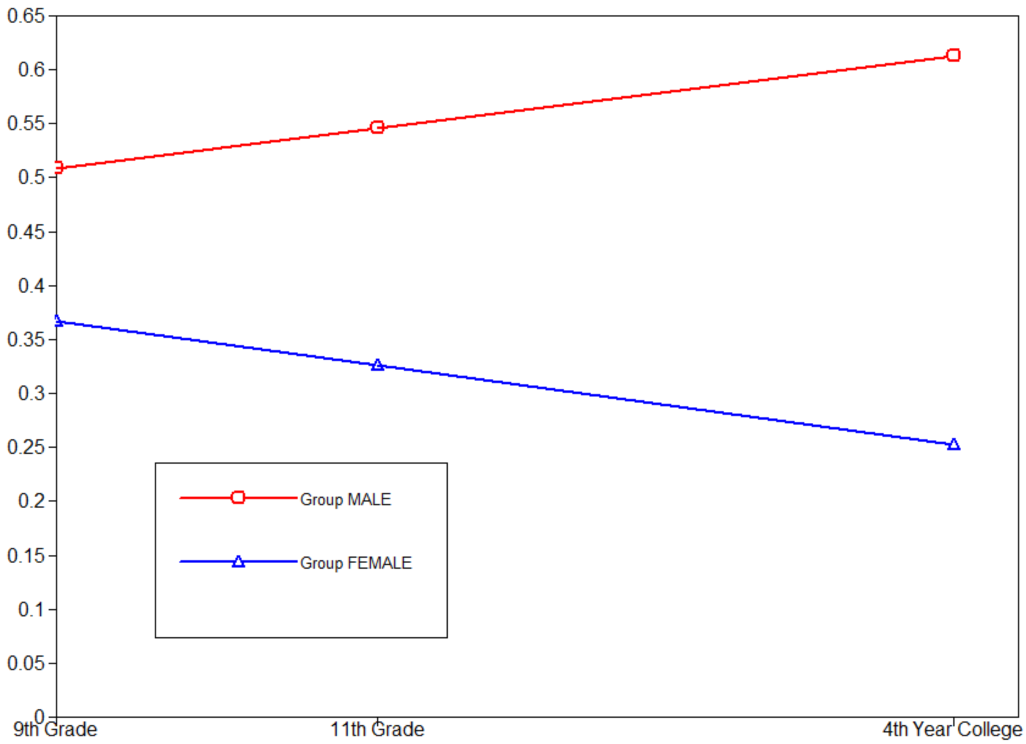

Figure 1: Mean Mathematics Identity Growth Trajectories for Male and Female Students

To further analyze gender differences in mathematics identity growth trajectories, plots were generated of the estimated mean growth curves for each gender group (Figure 1). The estimated mean mathematics identity growth trajectory for male students had an intercept of 0.508 and slope of 0.015 while the mean growth trajectory for female students had an intercept of 0.397 and slope of -0.016. Thus, while male STEM students' mathematics identity started higher and increased over time, female students' identity started lower and decreased, resulting in a further widening of the gender gap in mathematics identity in college.

Discussion

The preliminary results from this study provide large-scale evidence of gender disparities in women's identity as a math or science person that may help to explain why they are less likely to enter and more likely to leave STEM degree programs in the United States. The study is waiting on future data from HSLS:09 to directly link changes in mathematics identity with STEM degree attainment. Other concerns to follow up on include how these results can inform initiatives for broadening participation in STEM and the degree to which this quantitative measure of identity is consistent with other conceptualizations of identity in the literature.

The development of modeling skills in mathematics is essential for individuals to understand, describe, control, and predict phenomena around them. This article describes the results of an investigation to find out how an activity –based on a Models and Modeling Perspective– stimulates the mathematics modeling skills of undergraduate students who are in the first quarter of a business degree. As a result, it was shown that the MEA enabled students to exhibit, develop, and refine different modeling skills, such as: identification of variables, assumptions based on the real-life context, identification of patterns, and construction of mathematical representations.

Keywords: Modeling, higher education, precalculus.

Introduction

The pandemic generated by COVID 19 has highlighted the need for math education researchers and educators to reflect on the knowledge and skills that students must develop to understand, describe, control, and predict phenomena that impact humankind, and that also allows them to make decisions and take actions to relieve negative effects of these phenomena. Some educators suggest teaching strategies based on mathematics modeling that allow students to develop these skills and knowledge, as well as take active part on the solution process of these real-life problems (Lesh, 2010; Sevinc, 2021). Several authors, such as Lesh and Doerr (2003) and English et al. (2020), agree on the need to structure students' experiences in ways that allow them to develop modeling skills. According to Niss et al. (2007), learning to model implies that students develop different skills, such as "ability to identify relevant questions, variables, relations or assumptions in a given real world situation, to translate these into mathematics and to interpret and validate the solution of the resulting mathematical problem in relation to the given situation" (p. 12).

Project GAIMME indicates that "to understand how students grow in their ability to do mathematical modeling is a challenging task. Useful studies of mathematical modeling have been published, but this area has not yet been researched as deeply and systematically as other areas" (Garfunkel & Montgomery, 2019, p. 24). The National Council of Teachers of Mathematics (NCTM, 2018) mentions that mathematical modeling skills are part of modeling cycle processes that involve multiple steps and iterations. However, studies by Montero et al. (2021) and Touchstone (2014) highlight that word problems in math textbooks for higher education students in business careers have a single answer and don't usually foster modeling processes. Therefore, we need to provide learning-teaching opportunities that are purposefully designed for university students in business careers to develop modeling skills to solve real-life problems.

The purpose of this study is to understand how a model-eliciting activity (MEA) can contribute to students in business careers to develop and refine modeling skills. The research question is *What types of modeling skills do undergraduate students in business careers develop when they solve an MEA called Breaking barriers with yogurt investments?*

This research study used Model and Modeling Perspectives (MMP) as proposed by Lesh & Doerr (2003) by focusing on structuring students' experiences that foster the development of modeling skills.

Theoretical Framework

Models and Modeling Perspectives propose the design of model-eliciting activities for students to develop, amplify, and refine their thinking by enhancing math and modeling skills as they solve real-life problems (Lesh & Doerr, 2003). MEAs are situations that are purposefully designed for students to generate models using specific mathematical ideas, and are situated in real-life contexts that are meaningful to students (Aliprantis & Carmona, 2003; Doerr, 2016; Sevinc, 2021). Models are conceived as

> conceptual systems (consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)—perhaps so that the other system can be manipulated or predicted intelligently.
>
> A mathematical model focuses on structural characteristics (rather than, for example, physical or musical characteristics) of the relevant systems. (Lesh & Doerr, 2003, p. 10)

Models reside in the mind and representational media. These representational media can include written symbols, oral communication, diagrams, metaphors, tables, graphs, and algebraic symbols (Lesh & Doerr, 2003; Lesh & Harel, 2003).

Modeling activities based on real-life contexts usually have many possible solutions. They can also involve irrelevant ideas or lack information which creates a need for students to develop modeling processes such as generating assumptions and evaluating situations based on specific contexts (Sevinc & Lesh, 2021). Research studies based on MMP have provided evidence that MEAs promote students' development skills to solve problems related to their professional life in the field of business (Lesh & Yoon, 2007). According to Lesh (2010), MEAs foster students to show their thinking in ways that research can "to investigate the development of important aspects of students' mathematical thinking" (p. 29).

Methodology

We used qualitative methods to conduct this research study involving a total of 13 participants from a group of (male and female) students in their first quarter as freshmen enrolled in a business degree program. Students were registered in an in-person course on mathematics applied to business, which is the first mathematics course students take in the business undergraduate program. The topic on exponential functions had not been covered in this course previous to student participation in this study.

The MEA called Breaking barriers with yogurt investments (Yogurt MEA) was designed in the context of a colony of bacteria and yeast that produce Bulgarian yogurt (Figure 1). This MEA was designed using six principles for the construction of an MEA as proposed by Lesh et al. (2000). The mathematical ideas embedded in the design of the Yogurt MEA are: exponential function, equation, variation, growth, and rate of change. The solution requires that students identify the problem, variables and relationships, relevant assumptions, interpretation, and validation of the solution.

Business-Health Magazine

EL YOGURT ESTÁ ROMPIENDO LAS BARRERAS DE LAS INVERSIONES

LA CRECIENTE POPULARIDAD DEL YOGURT SE HA CONVERTIDO EN UN SALVADOR PARA LAS MAYORES LECHERÍAS. SUS VENTAS SUPERAN LAS VENTAS DE LECHE POR PRIMERA VEZ

El yogurt se está convirtiendo en la "vaca en efectivo" de la industria láctea. De acuerdo con el informe de Mordor Intelligence 2018, se esperan ingresos de $106,400 millones de dólares para el año 2024 (Whitely, 2019). Muchos empresarios están emprendiendo negocios millonarios basados en el proceso de este lácteo.

La revista Forbes de negocios ha nombrado a Hamdi Ulukaya el Steve Jobs del yogurt, ya que su empresa en tan solo cinco años se puede valuar en $1,000 millones de dólares; su empresa es rentable, dominante y crece de forma importante. En estos cinco años la empresa de Ulukaya pasó de tener cinco a 2,000 empleados, convirtiéndose en el número uno del yogurt griego en Estados Unidos.

No solo las empresas de los países del continente americano han tenido estas altas utilidades, en China la creciente popularidad del yogur se ha convertido en un salvador para las mayores lecherías del país.

Las ventas de leche china crecieron sólo un 4% en 2017 en comparación con el año 2016, mientras que las ventas de yogures aumentaron un 18%.

Una de las razones por las cuales la empresa del yogurt está creciendo es debido a los grandes beneficios que tiene este lácteo para el cuerpo humano. Contiene una gran cantidad de calcio, un mineral necesario para dientes y huesos sanos. Sólo una taza proporciona el 49% de las necesidades diarias de calcio; es alto en vitaminas del grupo B, particularmente vitamina B12 y riboflavina, que pueden proteger contra enfermedades del corazón y ciertos defectos congénitos del tubo neural. Una taza también proporciona el 38% de la necesidad diaria de fósforo, 12% de magnesio y 18% de potasio. Estos minerales son esenciales para varios procesos biológicos, como la regulación de la presión arterial, el metabolismo y la salud ósea.

Un problema es que la mayoría de las variedades compradas en las tiendas pierden el grado de calidad por tres principales razones, la calidad de la leche no es buena, contienen sabores, endulzantes, colores artificiales y le adicionan azúcar.

Por esta razón, algunos negocios están emprendiendo en el sentido de hacer yogurt con características semejantes al yogurt casero que no tiene aditivos ni conservantes, esto permite al producto mantener sus nutrientes y ser un alimento sano para el cuerpo humano.

La empresa familiar "Kéfir healthy", después de leer el artículo pretende lanzar una línea de yogurt casero, que le permita entrar en el mercado. Uno de los principales obstáculos a los cuales se enfrenta es conocer el crecimiento de los búlgaros de leche (Kéfir). La empresa ha recabado algunos datos con un experimento en laboratorio.

Resultados de laboratorio

La empresa necesita conocer el comportamiento de crecimiento de los búlgaros, de tal manera que pueda decidir en qué momento tendrá cantidades suficientes para vender.

Tu equipo es el responsable de proponer a la empresa "Kéfir healthy" una descripción del comportamiento del crecimiento de los búlgaros y, por lo tanto, un procedimiento que le ayude a predecir en qué momento empezar a vender. Escribe una carta a la empresa donde le expliques cómo puede calcular la cantidad de búlgaros (mililitros) en cualquier momento. En tu carta debes incluir los procedimientos matemáticos, de tal manera que puedan utilizarse por cualquier otra empresa.

Figure 1: a) Yogurt MEA Newspaper article y b) Yogurt MEA Problem Situation

For the implementation of the Yogurt MEA, students were organized in five teams: Team 1 [T1] with two members, Team 2 [T2] with three members, Team 3 [T3] with three members, Team 4 [T4] with two members and Team 5 [T5] with three members. The Yogurt MEA was implemented in several phases:

- Phase 1. Warm-up Activity (15 min). Students read page 1 of the MEA (Figure 1a), answered the warm-up activity, and discussed the context in their teams.
- Phase 2. Team Solving the Yogurt MEA (90 min). Students worked in teams to solve the problematic situation in the MEA (Figure 1b includes the QR code with the video students watched). Students used tools such as spread sheets.
- Phase 3. Teams presented their model solutions to the whole class (30 min). Each team presented their solution model and the process they used to construct it. After each presentation, the class had the opportunity to ask questions and provide feedback about the model.

Data collection involved: video recordings of the group discussion about the model-construction processes and presentation of the final solution model; the solution letters written by each team; log notes from class observations; and the electronic files that the students submitted. Data analysis was guided by an MMP, through a qualitative lens considering the iterative modeling process, which included each team's final solution. We documented how students changed, extended, and refined their conceptual system during the solution process and during whole-class presentations and discussion. In particular, the analytical framework we used is supported in the skills as described by Niss et al. (2007), which include: the ability to identify questions, variables, relationships, relevant assumptions in a given real-life situation, interpretation, and validation of a solution.

Results and Discussion

Based on the models built by the students, we identified that the Yogurt MEA elicited modeling abilities, in particular, four: identification of variables, assumptions based on the real-life context, identification of patterns, and construction of mathematical representations (Table 1).

Table 1: Teams' Modeling Abilities

<table>
<tr><th></th><th>Identification of variables</th><th>Assumptions based on the real-life context</th><th>Identification of patterns</th><th>Representations</th></tr>
<tr><td>T1</td><td rowspan="5">They identified the relationship between the variables: amount of kefir grains, time, and temperature.</td><td rowspan="3">Assumption A. The growth of kefir grains (G) depends on the temperature (T) and time (t). The temperature and time are variables.</td><td rowspan="2">They described and predicted the growth of kefir grains. They identified a pattern of weekly cyclical growth.</td><td rowspan="2">They included verbal, tabular, and graphical representations.</td></tr>

Team's Modeling Abilities

Identification of variables. Based on the data provided and the Yogurt MEA video, all the students identified three variables related to the process of kefir grains growth. They focused their attention on the variables: growth, temperature, and time. For instance, team T3 mentioned the following in reference to their data table:

[1] T3: Tenemos, en cuanto a los días, temperatura, mililitros y… esto es la diferencia entre un día y otro en cuanto a mililitros [We have, in relation to days, temperature, milliliters and... this is the difference in milliliters between one day and another].

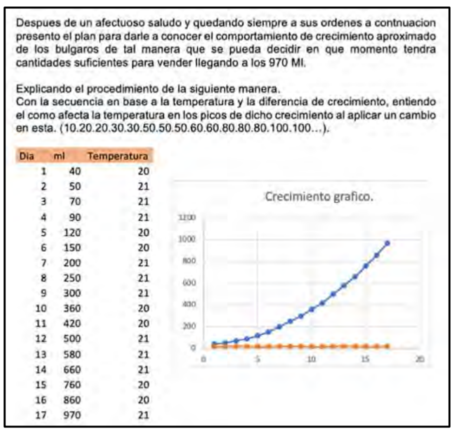
The team T1 indicated the following while they pointed to the column headings of their table (Figure 2a).

[2] T1: Nosotros intentamos resolver esto, primero, con los datos que nos habían dado [para] los primeros siete días. Viendo así, el cambio de temperatura y [cómo] los mililitros cambiaban. [We tried to solve this, first, with the data given for the first seven days. Looking at the temperature change and how the milliliters changed].

After the team's T1 presentation, T2 mentioned that they had found a different relationship among variables.

[3] T2: Yo no estoy de acuerdo… nosotros que también nos basamos en la temperatura y en el porcentaje, nos dimos cuenta que para el día seis, siete el cambio no era de 10 10. Sino se elevaba al doble, pues, de hecho, sacamos como una tablita. [I do not agree… we also considered the temperature and the percentage, and noticed that on day sixth, seventh the change was not 10. Instead, it doubled, and we actually built a table].

[4] T1: Yo también hice esa secuencia [refiriéndose a un modelo inicial que había construido y posteriormente refinó con base en el contexto de la MEA]. [I also created this sequence [referring to an initial model that they initially build and refined later based on the MEA's context].



Despues de un afectuoso saludo y quedando siempre a sus ordenes a contnuacion presento el plan para darle a conocer el comportamiento de crecimiento aproximado de los bulgaros de tal manera que se pueda decidir en que momento tendra cantidades suficientes para vender llegando a los 970 Ml.

Explicando el procedimiento de la siguiente manera.
Con la secuencia en base a la temperatura y la diferencia de crecimiento, entiendo el como afecta la temperatura en los picos de dicho crecimiento al aplicar un cambio en esta. (10.20.20.30.30.50.50.50.60.60.80.80.80.100.100…).

Figure 2: a) T1's Model and b) T4's Model

Discussion. The Yogurt MEA fostered an iterative discussion of the variables related to the kefir grains growth, [3] and [4]. According to Bliss et al. (2014), identification of variables is important because it allows students to determine the factors influencing the phenomenon they are analyzing and "distinguish between independent variables, dependent variables, and model parameters" (p. 7).

Assumptions based on the real-life context. The students built their models by generating assumptions based on the real-life context; they contrasted their procedures with the actual growth of kefir grains and their personal and professional experiences. We identified two types of assumptions.

Assumption A. The initial assumption of teams T1, T2, and T3 was that kefir grains growth (G) depends on the temperature (T) and time (t). They assumed that the temperature and time were independent variables. T2's personal experience allowed them to identify the possibility of additional variables that could influence the growth. The following excerpt illustrates this idea.

[5] T2: Yo, por experiencia que he cultivado muchos búlgaros, lo que platicaba con ellas, al tener siempre la misma temperatura, los búlgaros van reaccionando... lo ideal sería mantener la misma temperatura, para mayor crecimiento. Siento que depende mucho de varios factores. [I, from my experience growing kefir grains, what I was talking with them, because they always keep the same temperature, the kefir grains react… the best scenario would be to maintain the same temperature, for a higher growth. I feel that it depends of multiple factors].

T3 showed the need to investigate the kefir growth to understand the phenomenon and the influence of time and temperature. The students made the following statement:

[6] T3: Primero que nada, no sé si alguno de ustedes investigó un poco sobre este tipo de bacterias. Por medio de la investigación te das cuenta … que van creciendo solas dependiendo de la temperatura y el ambiente, y ese rollo. Se van reproduciendo, una se convierte en dos y así. [First of all, I don't know if any of you investigated about this type of bacteria. Through investigation you realize… that they grow by themselves depending on the temperature and the environment, and all that. They reproduce, one becomes two and so on].

Assumption B. Assuming an entrepreneurial role, Teams T4 and T5 considered a constant temperature based on the MEA context and the precision of industrial refrigerators [9], and they focused on modeling the kefir grains growth depending on time, $\mathrm{G}(t)$. For instance, T5 justified considering a constant temperature by contrasting their mathematical analysis with the factors that influence the growth of kefir grains in real-life.

[7] T5: noté que cuando teníamos una temperatura menor de 20º el porcentaje de crecimiento se reducía, se volvía a elevar cuando la temperatura subía porque es una bacteria. Hace rato lo comentó, el otro Bryan; que al ser una bacteria, el ambiente, la cantidad de proteínas y lo demás que hay alrededor es influyente para que se reproduzcan. Si tienen más temperatura, igual aun no conozco mucho a que temperatura se mueran y demás, pero con los datos que nos dieron, a mayor temperatura o sea 21º se reproducen más, manteniendo el sistema de las bacterias en un estándar. Entonces, mantener una temperatura, sí es posible. Yo dije mantenemos siempre la temperatura, saco un promedio en el porcentaje del crecimiento que me daba de los días de, que teníamos 21º, pues me dio un promedio del 33%. Entonces si yo mantengo siempre mi temperatura a 21º porcentualmente, más menos, voy a tener un crecimiento del 33%. [I noticed that when we had a temperature lower than 20º [C], the growth percentage decreased, it increased again when the temperature rose because it is a bacterium. If they have a higher temperature, I still don't know a lot about the temperature at which they die and so on, but with the data they gave us, the highest the temperature, i.e., 21º they reproduce more, maintaining the system of the bacteria in standard conditions. Then, maintaining the temperature is possible. I said, we always maintain the temperature, I obtain an average of the growth percentage from the days we had 21º C, and I got an average of 33%. Then if I always maintain my temperature at 21º C percentage, more or less, I will have a growth of 33%].

During the questioning phase, team T1 hesitated about the possibility of considering a constant temperature during the kefir grains growth. Based on their experience, T5 replied the following:

[8] T1: Pero está difícil, la temperatura hace un cambio de un día para el otro. [But it is hard, the temperature changes from one day to the next].
[9] T5: sí, pero no es lo mismo el sistema de refrigeración industrial que el de un salón. [yes, but the industrial refrigeration system is not the same as a classroom].

ml	temperatura	%	promedio de crecimiento
40.00	20		
50.00	21	20	33%
70.00	21	40	
90.00	21	40	
60.00	20	30

3,251.43	21	33	
4,324.40	21	33	

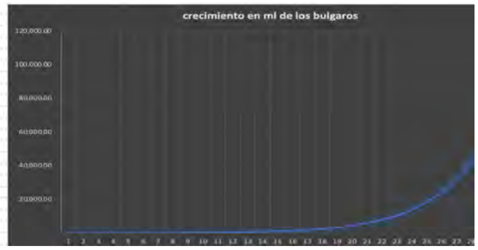

Figure 3: Mathematical Representations Included in T5's Model

Discussion. The fact that the Yogurt MEA includes three variables -time, temperature, and amount of kefir grains that influence their actual growth, allowed students to generate real-life assumptions to model the problematic situation. The whole group discussion created opportunities for students to revise and evaluate their assumptions and models. According to Garfunkel and Montgomery (2019), during the modeling process "we select 'objects' that seem important in the real-world question and identify relations between them. We decided what we will keep and what we will ignore about the objects and their interrelations" (p. 12).

Identification of patterns. The MEA allowed students to exhibit and develop their ability to identify patterns and build various strategies to solve the problem. Teams T1, T2, and T3 identified a "weekly cyclical growth" pattern.

[10] T2: Cada siete días íbamos repitiendo el ciclo, hasta terminar. [Every seventh day, we repeated the cycle until finished].

Team T3 described the kefir grains growth behavior, and teams T1 and T2 predicted the growth behavior in addition to describing it. For instance, the team T1suggested a growth pattern that established a relationship between time and temperature variation (Figure 2a). Even though the mathematical succession T1 developed requires further refinement to predict the growth in a way that is closer to the actual phenomenon, it provided a model to solve the situation.

Team T4 identified a kefir grain growth pattern that was not strongly related to the temperature. They focused on describing and predicting the growth considering the contextual factors. They suggested that the company could use jars to replicate growth whichever number of times was necessary to obtain sufficient kefir grains to produce Yogurt (Figure 2b).

[11] T4: Tomamos el crecimiento del primer día al día siete, y cerramos como semana. Volvimos a empezar en uno. Como al día siguiente teníamos 200, nosotros dividimos, 200 entre 40ml y ya fijamos los cinco frascos (segunda fila, tabla Semana 2, Figura 2b). [We considered the growth from the first to the seventh day, and we finished the week. We started again like in day one. The next day we had like 200, we divided, 200 by 40 ml and then we have five jars (second row, Week 2 table, Figure 2b)].

Team T5 identified an exponential growth pattern. They calculated the daily kefir grains growth and the corresponding percentage. Next, they obtained the average growth percentage considering only the days in which the temperature was 21ºC. The team obtained an average rate of 33% and predicted the growth (Figure 3). The students found a growth pattern that corresponds to the expression.

Discussion: The Yogurt MEA prompted students to organize and systematize information, recognize patterns, build various solution strategies and generate diverse models to estimate the growth. Sevinc and Lesh (2021) discuss that problems in realistic contexts can be solved through various solution strategies and "allow students to make mathematical and contextual inferences, an essential activity for the development of problem-solving competence” (p. 4).

Construction of mathematical representations. Given that the data included in the Yogurt MEA was included in various images embedded in a video (see QR code, Figure 1b), the students had to extract, interpret, organize and create mathematical representations to analyze the kefir grains’ growth. The students used diverse representations in their models. For instance, teams T1, T2, and T5 included verbal, tabular, and graphical (Figures 2 and 3), while teams T3 and T4 included oral and tabular representations in their model. These representations allowed them to describe, explain and estimate when the kefir grain growth was sufficient to start thinking about selling yogurt (Figure 2b). The following excerpt illustrates the way they described it verbally and in their letters:

> [12] T5: En un mes ya tengo un aproximado de 3600 litros que ya los puedo mandar a producción. Porque aquí tengo los mililitros en bacterias, más no tengo la producción en yogurt. [I have approximately 3600 liters in a month that I can send to production. Because this is the milliliters in bacteria, but I do not have the production of yogurt].

Discussion: The Yogurt MEA fostered model-building using diverse representations to explain and describe the kefir grains growth phenomenon. The creation of the models reported by the students revealed their modeling abilities and the knowledge used and developed throughout the problem-solving activity. According to Lesh and Doerr (2003), “meanings associated with a given conceptual system tend to be distributed across a variety of representational media” (p. 12).

Conclusions

The analysis of the results supports the conclusion that the Yogurt MEA has the potential to support the development of diverse modeling abilities. In this study, students developed modeling abilities through model building, team interactions, and whole-group discussion. The abilities reported included: variable identification, assumptions based on the real-life context, identification of patterns, and construction of mathematical representations.

The identification of variables was fostered through the inclusion of three variables in the Yogurt MEA. The students had the opportunity to identify, select and establish relationships among variables to solve the problem. The assumptions based on the real-life context emerged because the Yogurt MEA was situated in a context close to the students. Thus, it fostered opportunities to self-evaluate and contrast models with real-life experiences growing kefir grains. This is consistent with the fact -discussed in the MMP- that the ways of thinking or models built to make sense of situations, requiring realistic decision-making, integrate with frequency ideas from more than one discipline or theory. The teams identified patterns to describe and explain the kefir grains growth and estimate the time to decide when a sufficient amount of kefir grains would be available to start selling yogurt. The teams built mathematical representations to organize data, interpret the situation, identify patterns and explain their model.

We observed students refine their modeling abilities during the MEA solution process, which was mediated by their understanding of the phenomenon, mathematical knowledge, personal and professional experience, and interaction with the environment.

A MATHEMATICS SUPPORT PROGRAM: MODIFICATIONS AND RESPONSES TO THE PANDEMIC

Jenna Tague
Clovis Community College
jenna.tague@cloviscollege.edu

The purpose of this report is to share the facets of a support program set in a mathematics department in a mid-sized comprehensive western university. This is an ongoing project and I use the social community framework (Mondisa & McComb, 2015) to compare the students in the mentoring program to a control group of students. The current results allowed me to examine the effect of the mentoring program on their community of practice during the 2020-2021 Covid-19 pandemic. Results include overall effects of the pandemic on mathematics students, and interventions that could help encourage a sense of belonging through the pandemic environment.

Keywords: Policy, Undergraduate Education, Systemic Change.

The question of how to help support students in mathematics majors remains open (Lisberg & Woods, 2018). Research indicates that through the leaky pipeline, students intending to major in STEM are lost from high school to college (Snyder & Dillow, 2011) and 48% of students leave STEM majors during college (Chen, 2013). STEM majors are particularly vulnerable to attrition in their first year of college (Chen 2009; Higher Education Research Institute 2010). A goal of no attrition is unreasonable; undergraduates should change majors if they would like to. Unfortunately, research indicates that students may leave the major because they do not feel they belong and/or they have a poor instructional interaction (Seymour & Hewitt,1997). Additionally, both people of color and women are more likely to leave mathematics majors than white or male students (e.g. Anderson & Kim 2006; Hill, Corbett, & Rose, 2010; Griffith, 2010). These are stark disparities that indicate a need for more supportive mathematics departments.

I worked with a team of mathematicians to design a mentoring program for mathematics majors at a mid-sized western comprehensive university. The mentoring program was open to all students, but was designed specifically to address issues faced by low-income students, students of color, and female students in our mathematics department. The purpose of this presentation is to describe changes and updates to the mentoring program, and to share the third year of results of what has helped our students, and what did not. The data from the third year was collected in Fall 2020, and as such, is heavily impacted by the Covid-19 pandemic and online learning.

Literature Review

There are two important questions related to designing/studying a mathematics support program: (1) What supports are most helpful for students?, and (2) What measures, quantitative and qualitative, are important for measuring the effectiveness of such a program?

Lisberg and Woods (2018) found four areas of focus when designing support programs for STEM majors: (1) Peer & faculty mentorship, (2) Familiarity with programs & faculty, (3) Student mindset, and (4) Student learning techniques. In the first category, students are paired with a peer or faculty as a mentor; in studies of this model results indicated having mentors help students with the transition into the university community (Mondisa & McComb, 2015) and increased retention rates (Campbell & Campbell, 1997). Familiarity with programs & faculty includes helping demystify the academic structure and increase connections with faculty. Student mindset centers around providing students with evidence that intelligence is not fixed and mistakes are necessary to learning (Dweck 2008) coupled with evidence that academic setbacks can be overcome (Walton & Cohen, 2011). Lastly, student learning techniques provided students with STEM-specific study skills. In their support program, Lisberg and Woods (2018) reported that under-represented minority students in first year mathematics were more likely to pass, and if they did not pass them, were twice as likely to retake them and persist during their first year.

Karp (2011) conducted a metanalysis of non-academic supports and also found four main categories: *social relationships*, *career options*, *college structure*, and *life issues* (italics added for emphasis and to denote each category). *Social relationships* indicated programs that helped to encourage community building amongst students. Providing information about *career options* aided students in connecting their college experiences with long term goals. Similar to Lisberg and Woods (2018), Karp (2011) also found that it is necessary to illuminate the *college structure* for students. Lastly, *life issues* are the most difficult category to provide support for, however, when students were able to connect with resources, they can recover from *life issues* to remain in college. The metanalysis indicated that much of the research relied on Likert-style questions of how helpful students found particular supports, but did not delve into how or why.

Mondisa and McComb (2018) described how the majority of studies of mentorship programs tend to focus on quantitative measures exclusively (i.e. comparisons of students' GPA, attrition rates) while neglecting how these programs affect individual students on a social level. "Evidence is needed identifying what social elements contribute to the positive experiences of program members…and what characteristics may explain differences across member experiences (Mondisa & McComb, 2018, p. 94).

In summary, we designed our program around Karp's (2011) four categories: *social relationships*, *career options*, *college structure*, and *life issues*. We also integrated pieces of Lisberg and Woods (2018) categories in workshops. In creating the research design, we did include quantitative methods of comparison, such as attrition rate, but mainly focus on a qualitative understanding of how the program affects students on a social level.

The Support Program

The study was conducted at a mid-sized western comprehensive university with a student population including 67% first generation students, and 61% Pell-eligible. The overall student population demographics are: 3% African American, 14% Asian (mainly Southeast Asian: Hmong and Cambodian), 49% Hispanic, 6% non-resident students, 3% two or more races, 5% unknown, and 20% white.

Previous research (Tague, 2021) described how focus groups were held and the themes from those were used to reinforce Karp's (2011) four supports: *social relationships*, *career options*, *college structure*, and *life issues*. I worked with a team of three mathematicians, who will be referred to as mentors, to design the support program using research and the focus group data as a guide. The program has been running since Fall 2018 and includes four main facets: scholarships, advising, required office hours/tutoring, and weekly Friday meetings including workshops, problem solving challenges, homework help sessions, and socializing.

Scholarships, weekly meetings, and required office hours are included in the *social relationships* category. Scholarships are included in this category because the tuition support allowed students to work fewer jobs, which provided time for students to build connections. The weekly meetings and office hours were designed to help students build relationships with one another and also with faculty members. Advising and workshops/guest speakers were designed to meet the *career options* category. Workshops (financial aid, health/mental health center, etc.) were designed to help students navigate the *college structure*. *Life issues* are the most difficult to plan for, however, we hoped that providing students with a community and knowledge of resources would protect against this category.

Theoretical Framework and Methods

Mondisa and McComb (2018) proposed using the framework of Social Community as an answer to the gap in qualitative research results from mentoring programs in mathematics. The Social Community framework is designed to measure the effectiveness of the program based on level to which participants feel *connectedness*, *resiliency*, and *communities of practice*. Connectedness is how linked to the program each student feels (in the current study: do you have a mentor?). Resiliency is focused on students' reactions to hardships or challenges (in the current study: what was an obstacle you faced this year, and how did you overcome it?). Lastly communities of practice are "collections of like-minded individuals sharing similar experiences and social resources as they interact with and support each other (Eckert, 2006; Wenger, 2000)" (Mondisa & McComb, 2018, p. 98). An example of a communities of practice question in the current study was: Do you feel like you belong as part of the math department? I adapted the questions from Mondisa and McComb's (2018) work to form interview questions.

Table 1. Participants

	Second Year	Third Year	Total
Scholars	10	6	16
Control Group	9	5	14

The participants are shown in Table 1 according to group and also year at the university. All participants were mathematics majors, the control group was chosen to be the same level in the program, and both groups were majority people of color. All students participated in semi-structured interviews lasting 30 minutes (on average) in October-November of 2020. The audio recordings were transcribed verbatim, organized by question in a spreadsheet, and then coded according to *connectedness*, *resiliency*, and *community of practice* (Mondisa & McComb, 2018).

Results

The results will be presented categorically according to *connectedness*, *resiliency*, and *community of practice* (Mondisa & McComb, 2018).

Connectedness

The Scholars were significantly more likely (χ^2=8.6277; p=0.003) to report feeling connected than the control group. In responding to the question of if they had a mentor, 14 out of 16 (87.5%) of the scholars versus 5 out of 14 (35.7%) control group students cited a faculty member at the university as a mentor. A representative quote from one of the Scholars was: "*She's literally there to help me with whatever I'm there for. And it makes me…even more comfortable now.*" The scholars were also more likely to list one another, or a math student from the same university than someone outside of the university or from a different major. In contrast, the students in the control group did say they had mentors, but they were family members or friends outside of the university. This difference shows that the control group were less connected to members of the mathematics department community than the scholars.

Resiliency

The biggest challenges faced by all of the students were (1) time management, (2) motivation, and (3) social interactions. All three were brought on by the pandemic and the mental health fallout. The time management issue was brought on by lack of structure with not having to be a physical place, causing students from both groups to disrupt their sleep schedules, and procrastinate working on school. The motivation drop was also prevalent in interviews with scholars and control group alike. They articulated that it was difficult to stay motivated when they were going to school and sleeping in the same physical location. Lastly, all of the students were missing social interactions. For the scholars, a bit of the social interactions were eased through the Friday weekly meetings. Many of them said that although they felt forced to meet on a Friday afternoon, they appreciated connecting with one another.

Communities of Practice

To rate the community of practice level for each student, I relied mainly on the following question: Do you feel like you belong in the math department? Out of 16 scholars 14 (87.5%) said they felt like they belonged, and out of 14 of the control group, 10 of them (71.4%) said they felt like they belonged. Thus there was not a statistically significant difference (χ^2=1.2054; p=0.272). However, the reasons given for the sense of belonging were different. The scholars explained that they belonged because of their social connection and network within the department. One scholar commented, "*The whole [scholar] community really helps you feel like you belong…They're very warm, welcoming. [T]here's things that the math department are now doing like they just…did the LGBTQ plus math day*." In contrast, the control group would make statements like, "*Am I smart enough to be here? And then like, after the first test and stuff, I'm like, Oh, yeah.*" This quote indicates that the control group drew their sense of belonging from their understanding of mathematics, which will likely be challenged during this time as a mathematics major.

Conclusions

All of the students expressed resiliency in working through the difficult times of transitioning to online learning and living through a pandemic. The scholars displayed higher levels of connectedness and communities of practice. The findings in the third year are consistent with those from the first and second years of the program (Author, year; Author, year). During the first year, scholars were more comfortable seeking out a faculty member for help with academic or life issues (6 out of 7 versus 1 out of 6). Similarly, in the second year and third years, scholars were more likely to consider a faculty member a mentor and seek them out for help (12 out of 16 versus 3 out of 12; 12 out of 16 versus 5 out of 14). Additionally, the control group students persist in linking their sense of belonging in mathematics with their understanding of mathematics. In contrast, the scholar group links their sense of belonging in mathematics with their relationship with faculty members and social connections amongst the department. It seems that during the pandemic time, even having a one hour meeting each week can help students continue to feel a sense of belonging and community through the difficult issues they face.

Future research reports on the results from the program will be forthcoming, however, pieces of the current model could be implemented to see if the results also hold in different context and if more mathematics departments could be more welcoming and supportive.

Acknowledgments

This research was possible due to NSF grant # 1742236.

IRRELEVANT DETAILS WHEN USING LEGO® BRICKS AS MANIPULATIVES

Alison TELLOS	Helena P. OSANA	Anne LAFAY
Concordia University	Concordia University	Université Savoie Mont Blanc
alison.tellos@mail.concordia.ca	helena.osana@concordia.ca	anne.lafay@univ-smb.fr

The primary aim of the present study was to examine whether the studs on LEGO® bricks act as irrelevant details when solving fraction division problems. We also investigated whether prior knowledge plays a role in the irrelevant details effect and in children's problem-solving strategies. Fifth- and sixth-grade students (N = 38) first completed a fractions test to assess their prior knowledge. A video-recorded lesson then was delivered to all students on how to solve fraction division problems with LEGO® bricks. Most of the participants were not distracted by the studs on the LEGO® bricks when solving fraction division problems on a transfer task. Prior knowledge was related to accuracy on learning and transfer performance, with low prior knowledge students generating less accurate solutions than to high prior knowledge students.

Keywords: Problem Solving, Mathematical Representations, Number Concepts and Operations

Any quick search on the Internet reveals hundreds of webpages and videos that show how to use LEGO® bricks in mathematics instruction (Tellos, 2021). Most of these illustrations target teachers and parents, who are often interested in how to make mathematics fun and interesting. Despite recent research on concrete objects (i.e., manipulatives) and their use in mathematical contexts (e.g., Carbonneau et al., 2013), it remains unclear if and how LEGO® bricks can support children's learning in mathematics.

Our research program focuses on the conditions under which children can learn mathematical concepts and procedures with LEGO® bricks. Recent research has shown that the perceptual features of manipulatives can impact learning in different ways (e.g., Lafay et al., in press; McNeil et al., 2009). LEGO® bricks have perceptual features, too; they are colorful, and the studs (i.e., the bumps that connect the bricks together) add an interesting visual feature. Children may enjoy working with LEGO® bricks because the perceptual features are appealing, but the features may be unrelated to the learning objectives ("irrelevant details"; Mayer et al., 2008), and thus detract from the concepts that the manipulatives are intended to represent (McNeil & Uttal, 2009). Prior domain knowledge has also been found to moderate the irrelevant details effect: Magner et al. (2014) found that students with high geometry knowledge were better able to overcome irrelevant details in geometric illustrations than those with low prior knowledge.

The Present Study

The primary objective of the present study was to explore whether the studs on the LEGO® bricks act as irrelevant details when fifth and sixth graders solve fraction division problems, and if prior knowledge of fractions is related to the irrelevant details effect. Because little is known about children's thinking when they use LEGO® bricks in mathematical contexts, a secondary objective was to document students' responses when using the bricks to solve fraction problems.

In individual online sessions with a researcher, participants completed a fractions test to assess their prior knowledge, followed by a video lesson on how to use LEGO® bricks to represent fractions and solve fraction division problems (e.g., $1/4 \div 1/16$). All examples in the lesson used a 1 x 1 brick (i.e., with one stud) to represent the divisor. Students were shown how to count the number of divisor bricks that could fit on the dividend brick to find the solution.

After the lesson, students solved fraction division problems with computerized images of LEGO® bricks on two tasks, namely learning and transfer (Panels A and B in Figure 1, respectively). On the learning task, only a one-stud divisor could be used to find the correct solution, as shown in the lesson. On the transfer task, the only brick available that would result in the correct solution was a 2 x 1 brick (i.e., with two studs). If participants counted the studs on the transfer task, we could conclude that the studs acted as a detractor from the measurement division concept demonstrated in the lesson. On the other hand, counting the bricks would show that the studs had no negative impact on their understanding of measurement division.

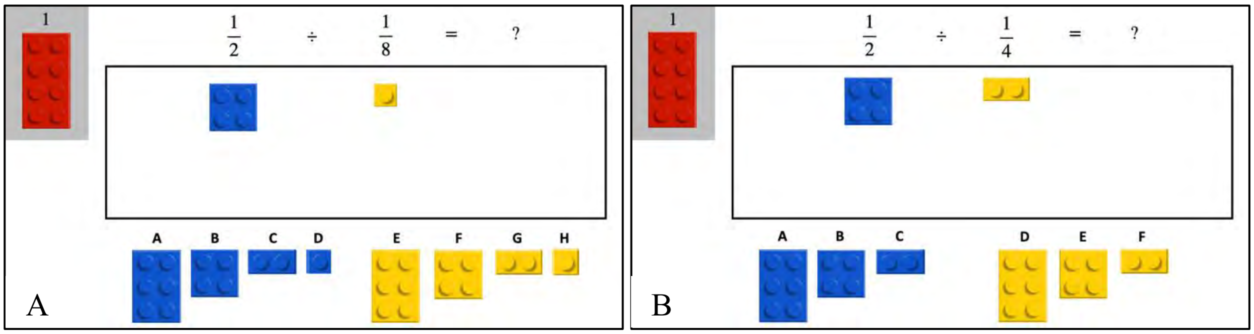

Figure 1: Sample of a Learning Item (Panel A) and a Transfer Item (Panel B)

Two research questions framed the current study: (1) Do the studs act as irrelevant details when solving fraction division problems, and is prior knowledge related to the irrelevant details effect? (2) What is the effect of prior knowledge on performance accuracy, and what is the effect of prior knowledge on the types of responses generated on the learning and transfer tasks?

Method

Participants

Participants were 38 fifth- and sixth-grade students (14 girls; age: M = 11.6 years, SD = .59) from a private French school in a large urban center in Canada.

Measures

Fractions test. The fractions test was a paper-and-pencil test with 8 items based on Saxe et al. (2001). Designed to measure knowledge of fractions concepts, the test required students to represent and estimate fractional quantities depicted in area models, and to solve problems using drawings. A median split was conducted to create low and high prior knowledge groups.

Learning and transfer. All five items on the learning task required the students to use a one-stud brick to find the solution, whereas all five items on the transfer task required a two-stud divisor (see Figure 1). To test the irrelevant details effect, we coded whether the student counted the studs or the bricks on the transfer task. Accuracy scores on each of the learning and transfer tasks were the mean number of correct responses. All online sessions were videorecorded for subsequent coding of the students' use of the LEGO® bricks on the learning and transfer tasks.

Results

Irrelevant Details

Seven students (18.4% of the sample) counted the studs rather than the bricks at least once on the transfer task, evenly distributed across the low- (3 students) and high-knowledge groups (4 students). The same pattern was found using item as the unit of analysis: Of all responses generated on the transfer task, 11.6% involved counting the studs to find the solution; in each prior knowledge group, the same proportion was observed (11.6%). Together, these results show that prior knowledge was not related to whether the students counted the studs or the bricks.

Accuracy and Response Analysis

Accuracy. Means and standard deviations for the accuracy scores are presented in Table 1.

Table 1: Means and Standard Deviations for Accuracy Scores on the Learning and Transfer Tasks by Prior Knowledge

Measure	Learning accuracy			Transfer accuracy		
	n	*M*	*SD*	*n*	*M*	*SD*
Low prior knowledge	19	.67	.25	19	.74	.31
High prior knowledge	19	.90	.14	19	.84	.29

Using students as the unit of analysis, the results showed that there was a main effect of prior knowledge, $F(1, 36) = 5.53$, $p = .02$, with the high prior knowledge group ($M = .87$, $SD = .20$) outperforming the low prior knowledge group ($M = .71$, $SD = .23$). There was no main effect of task type nor a prior knowledge by task type interaction, however. These findings suggest that children with low prior knowledge had less accurate solutions than children with high prior knowledge, regardless of task type.

Response analysis. We conducted a descriptive analysis of the types of responses generated on the learning and transfer tasks to provide additional insight on the reasons for the different accuracy levels observed between the low and high prior knowledge groups. Table 2 shows the number of times each type of response was generated on each task as a function of prior knowledge. On the learning task, participants either used the bricks correctly or chose the wrong brick to represent the dividend fraction. On the transfer task, participants either used the bricks correctly, or committed errors in three categories: (a) chose the wrong dividend brick, (b) counted the studs, or (c) chose the wrong dividend brick and counted the studs.

Table 2: Responses on the Learning and Transfer Tasks by Prior Knowledge ($N = 190$)

	Counted studs		Wrong dividend brick		Wrong dividend brick and counted studs		Correct	
Knowledge group	*n*	%	*n*	%	*n*	%	*n*	%
				Learning				
Low prior knowledge	—	—	29	30.5[a]	—	—	66	69.5[a]
High prior knowledge	—	—	8	8.4[a]	—	—	87	91.6[a]
				Transfer				
Low prior knowledge	7	7.4[a]	13	13.7[a]	4	4.2[a]	71	74.7[a]
High prior knowledge	11	11.6[a]	4	4.2[a]	0	0	80	84.2[a]

Note. Dashes refer to no data recorded. Coding of stud-errors applied only to the transfer task. [a]Percent represents the proportion of responses generated out of the total number of responses in each prior knowledge group ($n = 95$).

Using item as the unit of analysis, almost a third of the responses in the low prior knowledge group consisted of choosing the wrong dividend brick on the learning task, whereas under 10%

involved this error in the high knowledge group, $\chi^2(1, N = 190) = 14.8$, $p < .001$. On the transfer task, the data show that the proportion of items completed by participants with low and high prior knowledge also differed by response type, $\chi^2(3, N = 190) = 10.19$, $p = .02$. Participants with high prior knowledge used the bricks appropriately 84.2% of the time, whereas participants with low prior knowledge did so 74.7% of the time. In addition, participants with low prior knowledge chose the wrong dividend brick on 17.9% of all responses on the transfer task, whereas participants with high prior knowledge generated this error 4.2% of the time. Also, the data in Table 2 show that students in the low-knowledge group used the wrong dividend brick — an error that we had not anticipated — more often than counting the studs (17.9% vs. 11.6%).

Discussion

The present study was the first step in our research program to explore the effects of LEGO® bricks in mathematics learning. Contrary to our prediction, the results revealed that most of the students solved the fraction division problems on the transfer task by counting the number of bricks, and not the studs, that fit on the dividend brick. This finding could suggest that the studs on LEGO® bricks did not distract the students from learning the conceptual underpinnings of fraction division. Alternatively, other factors, including those related to the instruction that was delivered, may account for the apparent absence of the irrelevant details effect. Anecdotal evidence from the students' work on the learning and transfer tasks revealed that some repeated the instructions from the video lesson out loud to themselves (e.g., "Now, I have to count how many one-eighths are in one half"). Thus, how the conceptual underpinnings of fraction operations are emphasized in instruction and its relation to the irrelevant details effect, is a consideration for future research. Moreover, students with different degrees of prior knowledge may react differently to the perceptual features of LEGO® bricks under different instructional conditions. Finally, concrete LEGO® bricks should be used in future studies. Embodied cognition would imply that physically interacting with the bricks would generate different, and perhaps more pedagogically meaningful, results than working with images of the same objects.

The positive relations observed between prior knowledge and problem solving points to the importance of fundamental fractions concepts when learning about fraction division. In the present study, accuracy suffered in the low prior knowledge group primarily because they used the incorrect brick to represent the dividend fraction. This implies that teachers may wish to first emphasize the conceptual foundations of fractions and how they can be represented with manipulatives, to prepare students to learn new fraction operations with manipulatives.

THE USE OF SELF-REGULATION STRATEGIES IN FIRST-SEMESTER CALCULUS: THE CASE OF SUNNY

Kyle Turner
University of Texas at Arlington
kyle.turner2@mavs.uta.edu

James A. M. Álvarez
University of Texas at Arlington
james.alvarez@uta.edu

This case study explores self-regulation strategies used by Sunny, a high-achieving first-semester freshman student in calculus and aims to identify how she uses self-regulation strategies while in the course. Individual and group interviews were analyzed using categories of self-regulation strategies previously identified in the research literature. Findings suggest that Sunny's specific self-regulation habits for mathematics centered on mastering course concepts and shifted from focusing on memorization to focusing on understanding. This provides leverage for continued efforts to help foster productive self-regulation strategies for success in first-semester calculus.

Keywords: Calculus, Self-Regulation Strategies, Mathematics Self-Efficacy

While transitioning into a college mathematics course, undergraduate freshmen often face challenges related to their mathematics background, mathematics self-efficacy, and study habits (Hernandez-Martinez et al., 2011 and Seymour & Hunter, 2019). To address these challenges students can use self-regulation strategies to promote academic success (Zimmerman & Pons, 1986). Self-regulation strategies in mathematics can be defined as those actions that are used to overcome some obstacle when working on tasks associated with a mathematics classroom, whether in a specific problem context or in a more general response to tests and grades. High failure rates in college calculus in the United States (Rasmussen et al., 2019, Bressoud et al., 2015, Seymour & Hunter, 2019) make it critically important to explore ways to increase success rates in this gateway course to mathematics-based disciplines. This includes exploring not only the mathematical understandings that support success in calculus (see Carlson et al., 2010, Carlson et al., 2015, and Thompson & Harel, 2021), but also the self-regulation strategies employed by successful calculus students. This case study presents data analysis on a high-achieving freshman calculus student, Sunny, and the self-regulation strategies she used in a first-semester college calculus course. We explore the research question: In what ways do successful first-semester freshman use self-regulation strategies in a first-semester calculus course?

Conceptual Framework

Zimmerman and Pons (1986) produced several categories of strategies primarily used by high achieving students from a middle-class suburban high school, where high achieving was based off test scores, GPA, and teacher and counselor recommendations. The categories they found are as follows: seeking information, keeping records and monitoring, organizing and transforming information, seeking teacher assistance, seeking peer assistance, seeking adult assistance, and self-evaluating. They highlight that as students use these strategies, further instruction could improve the use of strategies and inform students of available strategies.

Wolters (1998) identified 14 separate categories of self-regulation strategies: performance goals, extrinsic rewards, task value, interest, mastery goals, efficacy, cognition, help seeking, environment, attention, willpower, emotion, other motivation, and other. These strategies were identified from open-response questionnaires administered to groups of psychology students at a large midwestern university. Wolters collected survey data from 115 college students which focused on how they would respond to different academic scenarios, gauging what motivational or self-regulatory strategies were used. Focusing on mathematics, Johns' (2020) study centered on the self-regulation strategies of 424 consenting first-semester calculus students and tested whether there were differences relating to gender and academic achievement. She found that high achievers both reported greater intrinsic motivation, task value, and self-efficacy than low achievers. High achievers also reported greater use of self-regulation strategies. From this, Johns found a correlation with the use of self-regulation strategies with student achievement.

How self-regulation strategies are used and developed by undergraduates in mathematics courses has not been widely discussed especially within this transition. Gueudet (2008) outlined several of the challenges that arise during the transition to tertiary school, especially related to individual, social, and institutional phenomena. For the individual phenomena, Gueudet describes that undergraduates beginning the transition often lack flexibility of switching between different thinking modes, such as practical and theoretical thinking. Sonnert et al. (2020) found that high school preparation was a significant factor on retention and performance for first-year students, but as the distance from high school grows the influences lessens. Though for those first-year students it was preparation in mathematics, and to a lesser extent attitudes about mathematics, which had the largest impact on performance in a calculus class. This is attributed to the highly cumulative nature of mathematics as calculus relies on earlier concepts.

Methods and Data Collection

This case study focuses on a set of five interviews and an initial questionnaire for a first-semester calculus student, Sunny. Sunny was one of six undergraduate calculus students who participated in five interviews throughout the Fall 2021 15-week semester. The study occurred at a large, urban research university in the Southwestern United States. All first-semester calculus courses meet two (for 80-minute lecture periods) or three (for 50-minute lecture periods) times a week for lecture. Two additional weekly 50-minute meetings enable students to engage in a collaborative lab activity facilitated by the instructor and graduate teaching assistant (GTA) for one class meeting and traditional recitation activities facilitated by the GTA during the other meeting. Each of the courses have departmentally coordinated exams written by the course instructors, these exams are typically offered the fourth full week of the semester, the ninth full week of the semester, and the final exam during the last week of the semester. Of the five interviews, two individual interviews occurred within a week of the first midterm and within a week of the final exam. These interviews lasted 20-30 minutes and focused on students' mathematics background, self-efficacy, and identity as well as differences between their experiences in high school and college mathematics. The other three interviews were task-based group interviews, lasting 50 minutes to an hour, occurring a week before each midterm and the final exam. Each task-based interview involved at most three participants examining the past three group activities given in the collaborative lab periods. Students provided information about how they worked as a group during those lab periods and worked a specific problem from each lab during the interview to demonstrate their processes. In the second task-based interview, students provided information about specific self-regulation strategies used in this course after being shown a list of strategies derived from Zimmerman and Pons (1986) and Wolters (1998).

Initial surveys were sent to thirteen first-semester calculus sections which included approximately 800 students. Of those invited, 193 students completed the initial survey which included background information, the Motivated Strategies for Learning Questionnaire (MSLQ) (Pintrich et al. 1991), a survey to measure mathematical identity (Kaspersen, 2016), select questions from the Factors Influencing College Success in Mathematics (Sonnert & Sadler, 2020), and a survey to measure the sources of self-efficacy (Usher & Pajares, 2009). To obtain an interview pool of first-time first-semester freshmen with differing measures of self-efficacy, mathematics identity, and self-regulation strategy usage on the initial survey, 38 of the students were invited to participate in a sequence of five interviews. Of these, seven accepted and began the interview sequence, with one student dropping out after the third interview.

A case study methodology was chosen to explore individual experiences of undergraduates' transitions to college mathematics and their uses of self-regulation strategies. A mix of qualitative data from the interviews and quantitative data from the initial surveys was used to get a vivid picture of the students' transition. For each interview an audiovisual recording was made and transcribed verbatim by the researcher. Participants were given pseudonyms. Coding identified self-regulation strategies using codes from categorizations by Zimmerman and Pons (1986) and statements related to mathematics identity, self-efficacy, and differences between high school and college mathematics experiences.

Results

Sunny was a first-year calculus student majoring in computer science. From the initial surveys collected, she scored above average for both mathematics identity and mathematics self-efficacy and reported moderate to high use of the self-regulation strategies identified on the MSLQ. Her high scores related to time and effort spent studying for a course. In particular, her highest score related to the belief that the effort given to learn course material will result in positive outcomes. Her responses from the initial survey also indicated that she used cognitive strategies to study for course material in the following ways: memorizing course material; elaborating material by connecting past ideas from the course to integrate and connect new information; and actively organizing information to understand the main concepts of the course. From both the individual and task-based group interviews we see instances of Sunny using these skills and considering how these skills aid in her understanding of the course material.

In her first individual interview, Sunny reported she had taken Advanced Placement Calculus BC in high school. Although she received an A in the high school course, she felt she did not learn as much as she needed to learn, citing the course's online format due to the COVID-19 pandemic as the reason she did not master the material. She further explained that she did not feel prepared for her current calculus course because she "didn't completely understand everything, I got kind of an idea of how things work…" but now she "can go back and really understand what's happening in the equations." From the five interviews, we noted that Sunny's view that the course was an opportunity to master the material served as a primary motivator in how she studied for exams and solved mathematics tasks. In the second individual interview Sunny reported a change in strategies, rather than relying on memorizing material she found it helpful to be shown how to derive certain formulas, citing the formulas for the derivatives of inverse trigonometric functions specifically. She conveyed that she felt "more confident now, cause [sic] I feel like I understand more… and if I see something I can actually derive it instead of just having to memorize it." She attributed the memorization method as a strategy shown in high school, while the university course required a deeper understanding of the concepts.

Across each of the three task-based interviews Sunny reported that while she worked on the collaborative lab activities, she found it helpful for each member of the group to work independently until they were stumped before turning to collaborate with another group member. She found this helpful as it allowed her to work through each problem and also get help. Since all group members were also working the same problem, she could "check and see where you did [the problem] wrong." This contrasted with her initial attitude of working mathematics tasks independently primarily, stating that that by working the problems herself "it helps [her] understand [the problem] more." When looking at specific tasks, Sunny often relied on organizing and transforming the problem into something more easily understood. For example, when shown the problem in Figure 1 below, Sunny first used a strategy that involved sketching the graphs of the functions as prompted by the problem, but then took the problem further by determining another set of functions that have the same behavior, presenting the piecewise function shown in Figure 2. Furthermore, Sunny is setting goals to master the content and leverages having successfully demonstrated the concept to extend the problem to functions with other attributes, in this case looking at finite discontinuities rather than infinite discontinuities.

Is it possible that $\lim_{x\to a} f(x)$ does not exist and $\lim_{x\to a} g(x)$ does not exist, but $\lim_{x\to a}[f(x)+g(x)]$ does exist? Consider the functions $f(x)=\frac{1}{x}$ and $g(x)=-\frac{1}{x}$.

a. Sketch the graphs of $f(x)$ and $g(x)$ and find their limits (if they exist) as x approaches zero.

b. Sketch the graph of $[f(x)+g(x)]$ and find $\lim_{x\to 0}[f(x)+g(x)]$.

Figure 1: Lab Activity 2 Problem 2

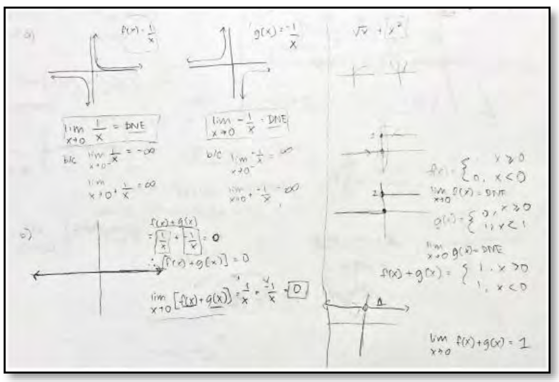

Figure 2: Sunny's written work for Lab Activity 2 Problem 2

Discussion

Sunny had a strong mathematics background, a positive mathematics identity, and valued prolonged effort to master mathematics concepts. These somewhat ideal attributes supported her demonstrated methods and strategies typically used by successful mathematics students. Sunny's intrinsic motivation for mastering the course content and enhancing her proficiency in the course content aligned with Johns' (2020) findings that high-achieving students often exhibit greater use of intrinsic motivation. However, by identifying her self-regulation habits, including reflecting on notes taken, identifying alternative methods for solving problems, creating goals for mastering the material that focused on deeper understanding rather than memorization, this informs mathematics-specific self-regulation strategies for promoting academic success for students transitioning to university mathematics courses. While some of these strategies may relate to mathematical problem solving capacity (see Alvarez, et al., 2019), these findings support the importance of incorporating self-regulation strategies in tandem with foundational mathematics concepts in the teaching and learning of calculus. Further research is needed to examine how calculus instructors can foster their students' development of these strategies.

CHANGING FIRST-YEAR MATHEMATICS STUDENTS' PERSPECTIVES: COMMUNITY, AFFECT, AND ASSESSMENT

Karina Uhing	Keith Gallagher	Nicole Infante

Student experiences in first-year mathematics (FYM) courses are crucial to their success in college. In recent years, there has been a push to improve FYM courses by centering and engaging students. The purpose of this study is to examine how students perceive their experiences with active learning and standards-based grading in FYM courses. In this paper, we present our analysis from end-of-semester Mathographies written by students who were enrolled in FYM courses in Fall 2021. We discuss three preliminary findings: community, affect, and assessment. We compare these findings to a framework relating to students' experiences with active learning and provide questions for future exploration.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Assessment, Instructional Vision, Undergraduate Education

Students' experiences in mathematics courses are a crucial part of their academic success in college (Adelman, 2006). In recent years, there has been a push to improve students' experiences in first-year mathematics (FYM) courses by increasing the use of evidence-based instructional practices (Abell et al., 2017; Smith et al., 2021; CBMS, 2016; PCAST, 2012). In this paper, we present preliminary findings on students' self-reported perceptions of their mathematics experiences after participating in FYM courses at the University of Nebraska at Omaha (UNO), a large metropolitan university. The Mathematics Department at UNO was recently tasked with redesigning the entire FYM program due to high failure rates. At UNO, "first-year mathematics" refers to any course below a standard Calculus 1 course. To support this initiative, the Mathematics Department hired a Director of FYM (Author 3) to oversee these courses. Following the Director's vision and with the support of upper administration, the Mathematics Department hired 10 additional faculty members (including Authors 1 and 2) to redesign and teach FYM courses.

The primary focus of our efforts was to transition our FYM courses from an emporium model (Twigg, 2011; Webel, Krupa, & McManus, 2017) to a more "traditional" classroom model. Our vision for these courses was to use evidence-based student-centered teaching practices to engage students in the learning process. (Henceforth, we use the term "active learning" to encompass this idea. A brief literature review of active learning is provided below.) We began redesigning two courses, Intermediate Algebra and College Algebra, in Summer 2021 and piloted our changes in Fall 2021. Data for this study come from the final assignment in these redesigned courses. Class sections were capped at 40 students, and every section was assigned a full-time faculty member, a graduate teaching assistant, and an undergraduate learning assistant to help facilitate learning. Faculty worked together along with the Director of FYM to develop curricular materials. Both courses were coordinated and used the same instructional materials and assessments. Our overall goal in implementing these changes was to help our students develop a growth mindset towards learning mathematics (Dweck, 2006).

Our course redesign involved two major components: 1) implementing active learning and 2) using standards-based grading. Active learning is a ubiquitous term in education. While several definitions of active learning exist, it is commonly used as an "umbrella term to communicate an alternative to lecture" (Lombardi et al., 2021, p. 9). For this paper, we adopt Theobald, et al.'s (2020) definition of active learning: "any approach that engages students in the learning process through in-class activities, with an emphasis on higher-order thinking and group work" (p. 6480). In addition to implementing active learning, we also used standards-based grading to assess student learning (Elsinger & Lewis, 2019; Lewis, 2020). Under this grading system, students had multiple opportunities to demonstrate skill on content standards, which we called learning outcomes, throughout the semester. After redesigning these courses, we sought to gather feedback about students' experiences in them to inform future work. The central research question guiding our study is: How do students perceive their experiences with active learning and standards-based grading in a first-year mathematics course?

Theoretical Framework

In this paper, we build on a framework that describes how students experience active learning (Uhing et al., 2021). This model was developed in the context of the SEMINAL project, a large study examining departmental change efforts to incorporate more active learning in first-year college mathematics courses. The model consists of five overarching themes relating to students' classroom experiences: student-to-student interactions, relationships with instructors, course format, assessment, and students' affective experiences. These themes were originally developed by looking at broad, open-ended survey response questions across students at multiple institutions taking a variety of precalculus and calculus courses. In our study, we used this framework in our analysis to examine written student reflections to a specific set of questions dealing with their mathematical experiences in a particular course. Our findings expand on this framework to further characterize students' experiences in first year mathematics courses.

Methods

The data in this study come from students at UNO who were enrolled in Intermediate Algebra and College Algebra during the Fall 2021 semester. Data were collected from all students who submitted a "Mathography" assignment at the end of the semester (228 submissions from College Algebra and 241 from Intermediate Algebra). For this assignment, students responded to a set of questions that had them reflect on their mathematical experiences. These prompts were adapted from Drake (2006). For example, students were asked to describe both a "high point" and a "low point" that they had experienced in Intermediate Algebra or College Algebra. They were also asked more general questions such as "What do you think it takes for a student to be good in math?". To analyze the data, we read through a subset of excerpts (54 from college algebra and 77 from intermediate algebra) and developed a list of preliminary codes using the themes from our theoretical framework as a guide. We then read back through these excerpts and systematically applied the codes. We are currently in the process of refining our codebook and analyzing the entire collection of Mathographies. We present our initial findings from the Mathographies below.

Findings

Five initial themes emerged from the data: community, affect, assessment, engagement, and personal growth. We discuss the first three themes below. In our discussion, we highlight connections between these themes and our theoretical framework.

Community

Several students commented on classroom community and culture. Students valued working in groups and getting to talk with their peers. One student said, “I liked working in groups and talking through things with my group and conversing with my peers.” Another student reflected, “I think in math it's very important to talk to others and not try to do everything on your own. I learned a lot better by asking my group questions and asking them for help when I needed it.” Overall, students appreciated the ability to work with their classmates because they liked hearing other students’ ideas and helping each other learn.

In addition to working with their peers, students commented on their relationships with instructors and the overall experience of feeling included in a community. One student explained, “The teacher helped me so much compared to other teachers, who just told me I should drop their class. It felt a lot more inclusive and much more like a community of students and teachers rather than a lecture.” Another student shared a similar comment about the classroom environment: “I always felt welcome in class. There was never a time I felt uncomfortable while I was learning. I think you should try and keep the positivity in the classroom, it really helps a learning environment in my opinion.” This sense of community helped students feel comfortable interacting with others in the classroom and is closely related to students’ affective experiences.

Affect

Affect was another significant theme that was present in several excerpts. Many students wrote about their emotions and how their experiences in these courses helped them enjoy mathematics and become more confident in their mathematical abilities. As one student wrote, “I really enjoyed my time in this class. It made me remember the fun of math.” Another student commented, “After taking [this course], I feel a lot more confident in my abilities.” For some students, the experience was transformative as explained by the student below:

> Besides learning the concepts, I got a new perspective on math. Prior to the class, I did not like math. I wanted to major in computer science but felt discouraged by the amount of math courses needed. All of that changed after [taking this course]. I found myself enjoying math. I changed my perspective of myself from not being a math person, to being one. I am no longer discouraged when I think of future math courses. I am excited!

While the majority of excerpts relating to affect involved positive emotions, there were a few students who expressed negative sentiments towards mathematics. However, these excerpts often had a “silver lining” to them. For example, one student commented, “I still do not like math, its [sic] something that I will never get fond of. Compared to my other classes I did enjoy the way it was taught.” Another student conveyed a similar message, “I’ve never been a fan of math. [...] Mostly, in part because I’m bad at it, but this class made it easier to learn.” These quotes show that even though students may have had positive experiences in their mathematics class, these experiences were not always powerful enough to make them “enjoy” mathematics.

Assessment

When discussing their experiences in these courses, students often commented on assessment methods. To help students develop growth-oriented mindsets, we implemented standards-based grading, which most students had never experienced. While some students were confused or skeptical about it at first, many of them discussed how they felt less stressed about assessment and more focused on their learning. One student commented, “I liked how for our ‘tests’ we were able to attempt to get a [learning outcome] as many times as we needed before the end of the year. It made the class a lot less stressful.” Another student shared a similar sentiment:

> The [assessments] really helped me realize that if I can't get something on the first, second, or even third try, I can always try again and not get penalized. This also really helped me feel more relaxed while I studied for the [assessments] because I wasn't constantly in fear that if I do badly on a test, my entire grade will plummet like in past math classes I've taken.

Overall, students appreciated the opportunity to progress on learning outcomes over the course of the semester and felt like they were able to focus on understanding the material rather than "earning a good letter grade".

Discussion

Many of our themes aligned with those found in the SEMINAL student experiences framework (Uhing, 2021). In this section, we discuss similarities between our findings and this framework, discuss implications of our research, and propose some ideas for future work.

In our analysis, we found that it was helpful to combine student-to-student interactions and relationships with instructors into a single theme: community. While the original student experiences framework separated these two themes, we discovered that the types of interactions that students experienced led several of them to comment about how they felt "included" and unafraid to participate in the mathematical community. It was through these interactions with peers and instructors that the classroom community and culture emerged. Thus, we felt compelled to encompass student-to-student interactions and relationships with instructors under the larger theme of community.

Our findings also paralleled the affective dimension of the student experiences framework. Students wrote about both positive and negative emotions associated with their learning experiences. From the excerpts we analyzed, students were, as a whole, more positive about their experiences in these redesigned first-year mathematics courses, although analysis on the entire data set is still ongoing. This finding reinforces the notion that affect is ever present in the classroom and can have a huge impact on student learning (Hannula, 2006).

Finally, as in the student experiences framework, assessment practices were a central focus for many students. Our findings suggest that the standards-based grading system helped (at least some) students focus less on grades and more on their learning. Compared to assessment theme discussed in the original framework, students seemed to have a more positive outlook on assessment practices, although several offered suggestions for how to improve specific class assignments.

Overall, our findings align well with the SEMINAL student experiences framework. One strength of our work is that it draws on student responses to a focused set of questions about specific FYM courses, rather than broad, open-ended survey questions. Our study also highlights areas that are important to examine, as both researchers and educators: the themes that emerged from the data come from experiences that students have deemed important enough to share in response to the Mathography prompts. Our findings suggest that teachers should incorporate learning opportunities that foster a sense of community in the classroom, attend to student affect, and consider alternative grading strategies that promote growth-oriented mindsets.

As we continue to analyze our data, we expect to find additional ways to expand the original framework. In particular, we pose the following questions for further exploration: What additional insights can be gained from analyzing students' perceptions of their classroom experiences? How do these insights further inform the student experiences framework? Through our work in answering these questions, we will better understand how to create a classroom environment that promotes success for all students taking FYM courses.

THE SPATIAL STRUCTURE OF HUNDREDS CHARTS

Hundreds charts are an essential tool for teachers in the mathematics classroom. The present study investigated the effects of spatial configuration in hundreds charts on children's place-value knowledge and their strategies for solving arithmetic word problems. Kindergarten and first-grade students were assigned to three instructional conditions in which they worked with a researcher to solve arithmetic problems. The charts in the conditions differed by spatial configuration. Results showed that the children improved their place-value knowledge and were more likely to use strategies based on place-value concepts when the numbers in the chart increased from top to bottom than when the numbers increased from bottom to top.

Keywords: Problem Solving, Mathematical Representations, Number Concepts and Operations

Visual representations are often used in elementary school classrooms to illustrate abstract concepts (Schraw et al., 2013). The hundreds chart is an example of a visual representation that teachers often use to teach concepts such as counting, arithmetic, and place value. These 10 x 10 grids contain the numbers from 1 to 100 (or sometimes from 0 to 99) in increasing order. A "top-down" arrangement puts the lowest numbers in the top row, with the numbers increasing with downward movement by rows in the chart. Another variation of the chart (i.e., "bottom-up") is inversely configured, with lower numbers at the bottom and larger ones at the top.

Previous research indicates that the spatial configurations of instructional materials impact how children learn and think about number. Board games that display numbers in linear arrangements provide better support for the development of children's number magnitude than games with circular arrangements (Siegler & Ramani, 2009). Moreover, Navarrete et al. (2018) found that when preschoolers viewed numbers in a linear arrangement that increased from left to right, their performance on an estimation task improved relative to those who saw the same numbers arranged from right to left. Findings from both studies can be explained using processes of analogical reasoning: Mappings made between the spatial configuration of the materials and the desired mental representation (i.e., the mental number line) supported children's numerical performance. Further, the more the structural features in the materials are highlighted, the more likely the target mental representations will be constructed (Gentner et al., 2007).

No systematic studies have been conducted to test the spatial structure of hundreds charts, however. Some anecdotal observations have suggested that moving down in the chart when the numbers increase can be confusing to children ("When we put more milk in the carton, it goes down. When we take milk out, it goes up," Bay-Williams & Fletcher, 2017 p. e3; see also Cobb, 1995). On the one hand, the upward movement in a bottom-up hundreds chart corresponds to increases in quantity, which can be mapped onto observations in the real world (e.g., water filling a glass) through the "up is more" relation. On the other hand, the fact that most young children are learning to read text in a top-to-bottom direction also provides a rationale to expect that a top-down hundreds chart may best support children's number knowledge.

Present Study

The objective of the present study was to study the effects of different spatial configurations on children's place-value knowledge and problem-solving strategies. Children were randomly assigned to one of three instructional conditions that differed by the spatial configuration of the hundreds chart used to solve arithmetic word problems. After the intervention, children completed a learning and transfer task to document their strategies for solving problems using the chart. A test of place-value knowledge was administered before and after the intervention.

We asked two research questions: (1) Does the spatial structure of the hundreds chart have an effect on children's place-value knowledge and the strategies they use when using the chart to solve arithmetic word problems? (2) Does an explicit visual analogy of the "up is more" relation provide additional benefits to their place-value knowledge and problem-solving strategies?

Method

Participants

Data were collected through online interviews with kindergarten and first-grade students in Canada and the US (N = 47; 23 boys; age: M = 81.6 months, SD = 5.9). Conditions did not differ by age, $F(2, 44) = .68$, $p = .51$; grade, $\chi^2(2) = 0.68$, $p = .71$; or gender, $\chi^2(2) = 1.08$, $p = .58$.

Instructional Intervention

In individual online sessions, a researcher showed the children how to use the Virtual Hundreds Chart (VHC; Osana et al., 2021) to solve Join Result Unknown word problems (Carpenter et al., 2014; sample problem in Figure 1). Children in the top-down condition (n = 15) worked with a hundreds chart in which the smallest numbers were in the top row and increased in value with downward movement in the chart. Children in the bottom-up (n = 16) and explicit analogy (n = 16) conditions worked with a bottom-up hundreds chart, in which the numbers increased with upward movement in the chart. The strategy demonstrated in all three conditions consisted of moving up (or down, depending on condition) the number of rows that matched the tens in the second addend and then right within the rows for the ones in the second addend.

In the explicit analogy condition, the instructional intervention included an additional visual cue to highlight the structure of number in the bottom-up hundreds chart. The visual cue was a cylinder that filled with water as the first addend in the problem increased by the second.

Measures

Place-value knowledge. Place-value knowledge was assessed at pre- and posttest using the Picture Place Value Task (PicPVT; Osana & Lafay, 2019), a judgment task designed to assess whether children understand that a digit in a numeral represents a quantity that is determined by its position. A double-digit numeral with one of the digits underlined was presented on a screen. Groups of dots were presented below the numeral and children judged whether the representation correctly matched the underlined digit. Scores were the mean number of correct responses.

Strategy use. The children's movements in the chart were videorecorded to document their problem-solving strategies using the VHC. They solved six Join Result Unknown problems (as in Figure 1) on a learning task and four Separate Result Unknown problems on a transfer task (e.g., There were 48 cars in a parking lot. 30 cars drove away. How many cars were left?), which required moving by tens in the chart in the opposite direction as was shown in the instruction. Mental computation strategies (i.e., no use of the chart) were not coded.

All strategies that were coded as mathematically appropriate involved moving vertically or horizontally in the chart in directions that were consistent with its structure. Movements were further coded as either (a) moving by tens: vertically for tens and horizontally for ones, or (b) moving by ones: horizontally by ones only. The moving by tens strategy demonstrated greater knowledge of place value and numeration concepts than the moving by ones strategy (Carpenter et al., 2014; Fuson, 1990). Errors such as starting on the wrong value in the chart or providing solutions that were off by one (either by one ten when moving by tens, or by one unit when moving by ones) were forgiven. Mathematically inappropriate strategies involved errors such as moving in the wrong direction (i.e., inconsistent with the structure of the chart); moving horizontally for the tens digit; and adding only the value of one digit. Provided no mathematical errors occurred, students were not penalized for strategies that started with the second number in the problem on either the learning or transfer task (e.g., for the problem in Figure 1, starting on 38 and moving 51 spaces to land on 89).

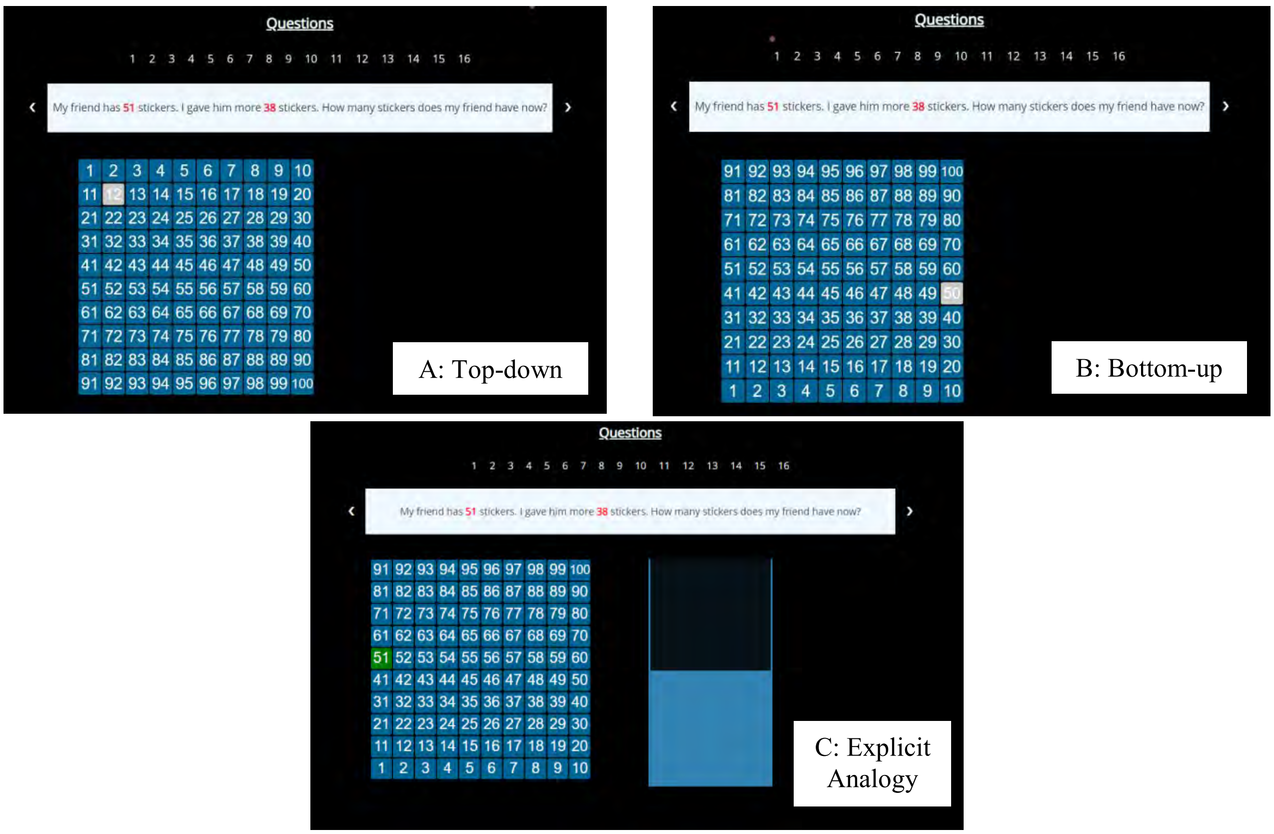

Figure 1: VHC Used in Top Down (A), Bottom Up (B), and Explicit Analogy (C) Conditions

Results

A one-way analysis of covariance (ANCOVA) was performed using PicPVT scores at posttest as the dependent measure, condition as the between groups factor, and PicPVT pretest scores as the covariate. A main effect of condition was found, $F(2, 41) = 3.68$, $p = .03$. Least Significant Difference post hoc comparisons indicated that the top-down condition ($M_{adj} = .83$; $SE = .03$) outperformed both the bottom-up ($M_{adj} = .74$; $SE = .03$) and explicit analogy ($M_{adj} = .73$; $SE = .03$) conditions (*p*s < .05), with no difference between the latter two groups.

Table 1 presents the frequency that each strategy was used as a function of condition. Using item as the unit of analysis, a significant association was found between strategy type and condition on the learning, $\chi^2(4) = 21.1$, $p < .001$, and transfer tasks, $\chi^2(4) = 18.5$, $p < .001$. A larger proportion of the strategies in the top-down condition involved moving by tens (85.6% on the learning and 82.0% on the transfer task) than in the bottom-up (55.8% and 42.0% on each task, respectively) and explicit-analogy (68.8% on each task) conditions.

Table 1: Frequency of Strategy Types on Learning and Transfer within Condition

Strategy	Condition					
	Top down		Bottom up		Explicit analogy	
	n	%	n	%	n	%
			Learning (n = 240)			
Moving tens	71	85.6	43	55.8	55	68.8
Moving ones	7	8.4	10	13.0	12	15.0
Mathematically inappropriate	5	6.0	24	31.2	13	16.2
			Transfer (n = 151)			
Moving tens	41	82.0	21	42.0	35	68.6
Moving ones	2	4.0	9	18.0	6	11.8
Mathematically inappropriate	7	14.0	20	40.0	10	19.6

Note. Data were missing on 20 items on the learning task and 12 items on the transfer task.

Discussion

As expected, the children's knowledge of place-value was dependent on the spatial structure of the chart they used to solve arithmetic word problems, as was the extent to which their strategies appropriately applied number concepts. Despite its misalignment with the "up is more" relation, the top-down configuration produced the largest benefits in performance. The instruction in the top-down condition involved movements that matched the direction in which words are read in text (i.e., left to right and down). Such movements may have freed cognitive resources to attend to the instruction, thereby facilitating the application of number concepts on the learning and transfer tasks. Alternatively, the benefits of the top-down chart may have been due to classroom exposure, a potential confound to be addressed in future research.

The effectiveness of the top-down chart may in part explain why the visual cue of a cylinder filling with water did not have the anticipated instructional effects: It explicitly highlighted the bottom-up structure, which by itself was relatively less effective. All the same, the cue may have had some instructional effect, as the children exposed to it made use of the "moving by tens" strategy more often than the children in the bottom-up condition. Although our conclusions are preliminary, the results nevertheless imply that teachers should attend to the ways students interact with the spatial configurations of mathematical representations.

SECONDARY STUDENTS' AGENCY IN MATHEMATICS CLASSROOMS

Mitchelle M. Wambua
University of Missouri-Columbia
mwambua@mail.missouri.edu

Engaging students in ways that promote their agency in mathematics classrooms is seen by many scholars as pertinent in nurturing meaningful, enjoyable, and equitable learning opportunities for the students. Yet, whether teachers value and support students' mathematical agency is as important as how they do so. This study uses teacher questionnaire to investigate how secondary mathematics teachers think about students' agency and the forms of agency their students exercise in class. Results indicate that students exercise different types of agency depending on how the classroom authority is distributed.

Keywords: Classroom Discourse; Teacher Beliefs; High School Education; Equity, Inclusion, and Diversity.

Within mathematics education, there has long been a focus on the need for teachers to engage students in ways that promote the students' agency and position them in authority during mathematics classroom learning. Professional organizations (e.g., National Council of Teachers of Mathematics, 2000), policymakers (e.g., National Governors Association & Council of Chief State School Officers, 2010), as well as scholars (e.g., Bieda & Staples, 2020; Wilson & Lloyd, 2000) have underscored the need to build and sustain students' mathematical agency. Mathematical agency refers to one's belief that they can generate valid mathematical ideas and engage in a meaningful practice of doing mathematics (Bieda & Staples, 2020; Ruef, 2021). Bieda and Staples add that for students to exercise their mathematical agency, their teachers should provide them with the opportunities to do so. Mathematics teachers can promote students' agency within their classrooms through practices like having them share ideas and methods that steer class discussions, engaging them in constructing arguments, justifying their thinking, and critiquing/assessing their peers' work (Amit & Fried, 2015; Bishop et.al., 2021). Scholars see these practices as pertinent in nurturing meaningful and enjoyable student learning, encouraging more equitable learning opportunities for students, and building students' curiosity and willingness to take up more learning opportunities.

The goal of this study was to investigate where secondary mathematics stand on this issue of promoting students' mathematical agency. Specifically, the study attended to how teachers think about students' mathematical agency, and how they support students' agency in their self-reported classroom practices. Understanding teachers' thinking and practices related to student agency is an important step toward supporting them in improving their practice.

Theoretical Framing

As mathematics teachers and students engage with each other during classroom learning, they participate in social practices wherein norms and obligations for what counts as mathematical competence are developed and negotiated (Cobb et. al., 2009; Langer-Osuna, 2016). Inherent in these norms and obligations are negotiations around the kinds of agency that students can bring to bear. Cobb and colleagues have delineated between two forms of agency (i.e., disciplinary and conceptual) that students can legitimately exercise in their classrooms. *Disciplinary agency* involves student performing mathematical practices that have already been established by the teacher, while *conceptual agency* involves students having the freedom to choose among mathematical practices and to make connections among mathematical concepts and principles beyond those taught directly by the teacher.

Students' mathematical agency is closely linked with the distribution of classroom authority (Cobb et. al., 2009). Classroom authority refers to the shifting dynamics around who has the legitimacy to lead classroom interactions (Amit & Fried, 2015; Pace & Hemmings, 2007) and determine the validity of mathematics concepts (Cobb et. al., 2009; Langer-Osuna, 2016). In Mathematics classroom, authority may be distributed solely to the teacher, with the teacher being the only one responsible for determining the correctness of mathematics concepts and deciding which ideas the class will engage with. Alternatively, authority may be distributed to the whole classroom community, with the teacher and students jointly determining the concepts to focus on and the validity of those math concepts. The types of agency that students exercise in math classrooms often depends on how authority is distributed in the classroom. That is, whether the teacher is the sole authority and students are obligated to just follow the teacher's lead, or there is shared authority between the teacher and students and hence students are invited to take lead in classroom learning (e.g., by devising solution strategies). This study draws on Cobb and colleagues' characterizations of student agency and classroom distribution of authority, and is guided by the question: *According to secondary mathematics teachers, what kinds of agency do students exercise in their mathematics classroom?*

Method

Study Context and Participants

This study is situated within an ongoing, exploratory study aimed at understanding and documenting how teachers view and support students' mathematical agency and authority. The participants are practicing secondary mathematics teachers working at various schools throughout the United States and who are all enrolled in a Mathematics Education master's program at a university in the midwestern United States. Practicing teachers were chosen as the target group because the goal is to investigate both the teachers' thinking and classroom actions related to students' mathematical agency and authority. Moreover, these teachers have taken at least two mathematics education courses within their program that urge them to reflect on various ways of meaningfully engaging their students mathematically, and hence this study would act as one avenue for this kind of reflection.

Data Sources and Analysis

For this study, the researcher focused on data from a teacher questionnaire. The questionnaire had a mixture of open-ended and closed-format questions related to students' mathematical agency. The analysis reported here is from 15 teacher responses. These teachers vary in their professional experience (i.e., from 1 year to 10 years of teaching), but are primarily white females (n=13) who are currently teaching Algebra and/or geometry to 9 - 12th grade students.

Data analysis was done in two phases. Phase one involved reading the teachers' responses and applying broad codes to any segments and response choices related to students' mathematical agency and classroom authority, alongside noting who the teachers highlighted as the authority in those instances. Phase two involved qualitative coding based on Cobb and colleagues' (2009) interpretive framework for student agency and classroom distribution of authority. These codes are described briefly below:

Table 1: Coding Categories

Category	Description
Authority figure	Identifies who takes the lead in classroom activities and determines the validity of math ideas. This could either be the teacher, students, or both.
Student agency	*Conceptual agency* – relates to if and how students choose solution methods, justify their work, assess their peers' work, and make mathematical connections.
	Disciplinary agency – relates to if and how students use established solution methods and follow teacher-led activities.

Findings

Most of the teachers expressed that they are the main authority in their math classrooms, with a few of them illustrating that they give their students minimal opportunities to share in the classroom authority. As a result of the teachers being the primary authority, students mostly exercise disciplinary agency, although there were some instances where teachers depicted that their students get opportunities to exercise some forms of conceptual agency.

Students' Agency when Teachers are the Main Classroom Authority

More than half of the teachers reported that the authority of leading the class in engaging with both new and known math concepts was distributed mainly to them. The teachers were responsible for delivering all lesson concepts and determining the methods for solving tasks. For example, one teacher said the following about her roles in a typical class:

> I review the assignment from the previous lesson then do notes over our new topic in a discussion style where I demonstrate to the students [how to solve] various examples.

This teacher, as well as several others saw themselves as the sole authority in reminding students how solve tasks from previous topics as well as "demonstrating" the solution methods for tasks from new topics. The teachers also took the lead in determining which tasks the classroom community would solve and in conveying the concepts required to solve new tasks. They reported that they usually "select tasks from the textbook, online materials or [personally] create them" without involving their students in task selection.

Teachers who saw themselves as the main classroom authority cited that their students exercise *disciplinary agency*. According to the teachers, students are obligated to "take notes" and "ask questions" during class to make sure they understand the concepts and can "apply [the concepts] correctly." Additionally, students are obligated to solve tasks using clearly established strategies. One teacher specified that she is currently teaching systems of equations and her students are expected to "solve these equations using the substitution, elimination, graphical and matrix methods." These student roles reveal a disciplinary agency of keenly following teacher-led activities and reproducing solution strategies as dictated by the teacher.

Students' Agency in Classrooms with Shared Authority

Although most of the teachers reported that they were the main classroom authority, a few of them highlighted that they provide opportunities for shared authority. For example, some teachers said that they engage students in critiquing and verbally assessing the validity of their peers' math solutions whenever the students share their work publicly during whole class discussions. One teacher added that when students publicly share their solutions, she invites all students to "recognize the different strategies … and make connections" between the strategies.

Other teachers expressed that even though their students treat them as the primary source/author of knowledge, they would like the students to view themselves and their peers as legitimate resources for learning mathematics. Although all the teachers reported that whenever their students encounter challenges while solving problems they always ask the teacher for help, a few teachers said that they wish that wasn't the norm. These teachers added that they preferred that students look at their notes and/or consult their peers. These teacher preferences show that they believe in their students' ability and authority to navigate math challenges without always relying on the teacher.

Teachers who stated that they share classroom authority with students expressed that their students exercise different types of mathematical agency. Some of the teachers highlighted that their students have the freedom to choose which strategy to use when solving math tasks. One teacher added that she encourages her students to "choose from multiple solution paths instead of having them pigeonholed into a specific strategy." These student choices relate to *conceptual agency* in the interpretive framework. Other teachers mentioned that their students exercise conceptual agency by performing classroom roles like explaining their thinking, "making connections between concepts" and assessing their peers' work (see above).

However, some of the teachers who expressed that they share classroom authority with students cited ideals related to *disciplinary agency* when describing what it means for a student to be good at math. For example, one of them said that a mathematically competent student should "be able to use the rules, procedures and proofs that I taught them efficiently in order to get the right answer." In this case, the teacher alluded that their standard for a mathematically competent student comprises a student who gets valid answers by recalling and reproducing the "rules" and "procedures" that the teacher taught.

Discussion and Conclusion

The goal for this study was to elicit how secondary mathematics teachers think about students' mathematical agency and the forms of agency their students exercise during classroom practices. Knowing the reality of what is happening in classes is helpful for scholars who want to work with teachers to improve their practice and student learning. Even though the teachers participating in this study were actively being taught (in their masters' program) the need to meaningfully engage their students by sharing classroom authority with them and positioning them as competent math learners, the teachers primarily employed teacher-centered practices in their classrooms. Consequently, their students exercise disciplinary agency, mostly appealing to teacher-led practices and reproducing teacher-taught solution strategies. There were however a few teachers who made attempts at sharing classroom authority and allowing their students to exercise the conceptual agency of selecting appropriate solution strategies, validating mathematical solutions, and making connections between multiple concepts. Interestingly, even these few teachers demonstrated a tendency to still expect their students to perform roles relating to disciplinary agency. These findings imply that teachers need more support beyond advanced university teaching for them productively engage their students in meaningful ways.

MIDDLE SCHOOL STUDENTS' TYPES OF MATHEMATICAL PERSONIFICATIONS

Nicole M. Wessman-Enzinger
George Fox University
nenzinger@georgefox.edu

Clara Stilwell
George Fox University
cstilwell18@georgefox.edu

Unpacking middle school students' mathematical relationships is important as a step towards improving mathematical relationships. In this study, 500 middle school students drew personifications of mathematics. We examined these personifications of mathematics for insight into their relationships with mathematics. Using constant comparative methods, we present various ways the middle school students personified mathematics. Negative relationships were personified with terrible beasts, abusers, authoritarians, and pests/nuisances. Positive relationships were personified with best friends and nature. Some personifications supported both positive and negative relationships or were neutral relationships. Reflecting on these personifications point to components of positive relationships with mathematics that we should support and confronts ways we may be perpetuating negative relationships with mathematics.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Middle School Education

All mathematical learners deserve the opportunity to see themselves as "good at math" (Ruef et al., 2020; Wickstrom & Gregson, 2017). Having a positive relationship with mathematics is a component of developing a positive mathematical identity. Students have both relationships *with* and *in* mathematics (Hunter & Anthony, 2011); these relationships influence identities (Black et al., 2009). Relationships *with mathematics* impact equity, access, and empowerment (Smith et al., 2017) in thinking and learning. Students enjoy mathematics more (Parks, 2020) and engage in the deep work of mathematics (Smith et al., 2017) if they have positive relationships with mathematics. Exploring what the elements of positive relationships with mathematics entail will provide insight into how to support students in healthy mathematical relationships.

Students enter middle schools where math is "tracked," which can have negative impacts on their identities (National Council of Teachers of Mathematics, 2018). Mathematics has the potential to be a challenging adventure that opens doors to their future (Stinson, 2004). But, students may not see themselves as mathematicians (Wickstrom & Gregson, 2017) and that impacts their mathematical relationships and identities. Although we suspect that some middle school students have negative relationships with mathematics, we need to understand the challenges in students' mathematical relationships in order to meet students where they are at. Insight into the challenges of mathematical relationships, can provide perspective into how we may transform negative mathematical relationships.

Purpose

Although teachers and researchers might inherently understand that middle schoolers have negative relationships with math, we do not fully understand the complexities that are included within those mathematical relationships with middle school students. We sought to understand middle school students' relationships with mathematics. The research question that guided our work is:

What types of mathematical personifications did our middle schoolers create?

Describing the nuances of the different types of personifications will provide insight into the mathematical relationships and experiences we need to change, enhance, or continue supporting.

Theoretical Perspective: Narrative Theory

Relationships, in general, are complex, and even positive relationships have a slew of emotions that come with that relationship. Having a positive relationship with mathematics does not mean that there will not be elements of frustration or struggle. In fact, we know that productive struggle is a critical attribute of doing mathematics deeply (Baker et al., 2020; National Council of Teachers of Mathematics, 2014). But, the relationship we hope students have with mathematics is not toxic or abusive. Yet, prior studies that have used personification tasks have revealed that university students describe their relationships with mathematics as toxic or abusive (Ruef, 2020; Zazkis 2015). Prior studies have also shown that personification tasks are better than "draw a mathematician" tasks alone (Picker & Berry, 2000; Zazkis, 2015). We extend this prior research further by examining the ways that middle school students personify mathematics. Through personifications, we have some insight into the narrative of their experiences (Langer-Osuna & Esmonde, 2017). Indeed, it is human nature to personify things. Three personifications present in the literature, created by preservice teachers, are: terrible beast, (former) best friend, and lover (Zazkis, 2015; Zazkis & Mamolo, 2016). The terrible beast relationship is equated to fear and repulsion. While the best friend, or even former friendship, or lover are relationships that can be translated to a level of comfortability and enjoyment, even if former, of mathematics. These types of personifications can provide insight into mathematical relationships and we entered our study expecting to see these personifications from middle schoolers as well.

Qualitative Methods

Participants and Data Collection

During Spring 2019, 505 middle schoolers (grades 6–8) volunteered to participate in the study and completed a personification of math task. At the time of data collection, the participants attended a middle school with students that scored in the 37th percentile in the state for mathematics.

The personification task included three different parts modified from (Ruef, 2020; Zazkis, 2015; Zazkis & Mamolo, 2016): (1) a picture of how they personify math and describe it; (2) a paragraph about who math is to them; and (3) a conversation with math. Of the 505 middle school participants, some of the responses were blank or illegible, leaving exactly 500 of the responses for analysis.

Data Analysis

The unit of analysis included the collective responses to the personification task—the drawing, description of drawing, and a written conversation with math. Sometimes students only had a drawing or a drawing and description, but no conversation with math. We used whatever they provided as the unit of analysis to help understand the personification.

The first pass of the data analysis entailed: (a) taking notes about each drawing and (b) coding the relationship with the Zazkis and Mamolo framework (2016): terrible beast, lover, (former) best friend. Using constant comparative methods (Merrriam, 1998), we went through each piece of data and negotiated what relationship was personified. We did about two passes of the data. First, we began with examining between 20-50 pieces of data at a time, iteratively meeting and comparing, and discussing if these themes aligned with our data. Second, we adjusted the themes—modifying the descriptions from Zazkis and Mamolo (2016) and adding categogies as needed. Third, we went through our data again with our new framework. This was a lengthy iterative process with the 500 pieces of data, but it spurred conversations about the themes and development of descriptions of our drawings.

In this research report, we present our modifications the Zazkis and Mamolo framework that fit the data for middle schoolers. For example, none of our participants personified their mathematical relationship with lovers as Zazkis and Mamolo described. Perhaps this is due to the age of our participants or their mathematical experiences. On the other hand, our participants emphasized authoritarians (e.g., drawings of mean teachers), pests, and nature which are were not highlighted in prior work. Therefore, for the results section of this research report, we describe the different personifications and how they relate to students' mathematical relationships.

Different Types of Mathematical Relationships

Negative Relationships

The middle schoolers personified negative relationships in mathematics with terrible beasts, authoritarians, abusers, and pest/nuisances.

The terrible beast. The terrible beast personifications included monsters, devils, or other terrifying animals (see Figure 1). Consistent with the Zazkis and Mamolo (2016) framework, the beast relationship showed fear or repulsion. When including beasts, students shared two dichotomous perspectives. One perspective with the beast included elements of consistent failure and defeat. The other perspective included elements of conquering math or beating "the beast." Figure 1 on the left shows a monster leaning over a student calling her stupid, dumb, and wrong. There is a sense of defeat in the student's face. However, in the second example in the middle of Figure 1, the student is trying to have some power and ability to fight back. The figure on the right, is a fetus that has a snake-like tongue, red eyes, and two sets of sharp teeth.

Figure 1: Terrible Beast Personifications

The authoritarian. The authoritarian personifications showed someone or something exerting power and control. This authority figure seems related to a beast relationship; but the authoritarian relationship differed from the terrible beast because the focus is on power and control and may not be a beast. Some drawings, for example, included stern or angry teachers. This is a theme that we added to the Zazkis and Mamolo (2016) framework. In Figure 2 math is illustrated as authoritarian that has all the control by putting the student in prison (math class). Freedom is outside of math class. In this example, the student wrote about how they desire to have more freedom within math class. In Figure 2 there is a student slumped and labeled with a depression; another student seems to be looking out of math class to freedom. The middle schooler wrote, "It's like a slap in the face every day. Math puts me in prison only [letting] me look at freedom."

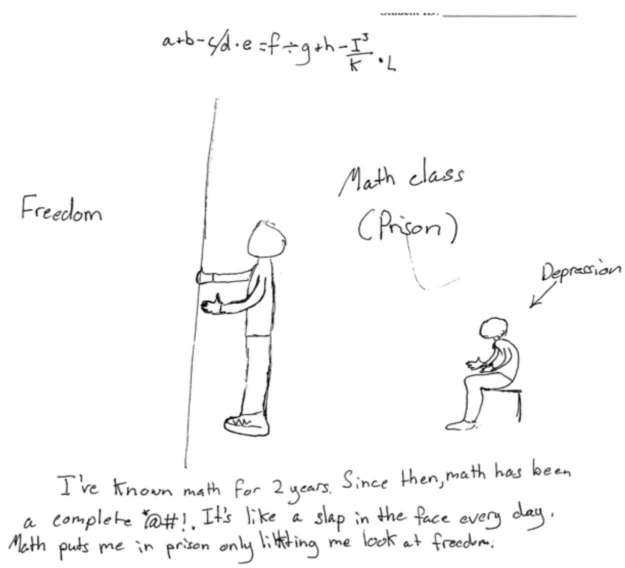

Figure 2: Authoritarian Personification

The abuser. With the abuser personification, the personifications included evidence of emotional or physical trauma. This is similar to the authoritarian relationship in that there is no power and control; however, the abuser relationship is an extreme version of an authoritarian with extreme emotions and/or trauma involved in this relationship. Although trauma and abuse in math is evidenced in the literature (e.g., Ruef et al., 2020), we made it a distinct category based on the amount of clear abuse that differed from a fantastical beast drawing (e.g., drawings of torture chambers). Within the abuser personifications, there are themes of hopelessness and cycles of abuse. Most of the abuser personifications in our study were incredibly graphic in ways that made us uncomfortable and reluctant to place in a proceeding. We selected Figure as a personification of abuser that "hit(s) kids with a ruler" as our example. Most of the personifications were more intense than this.

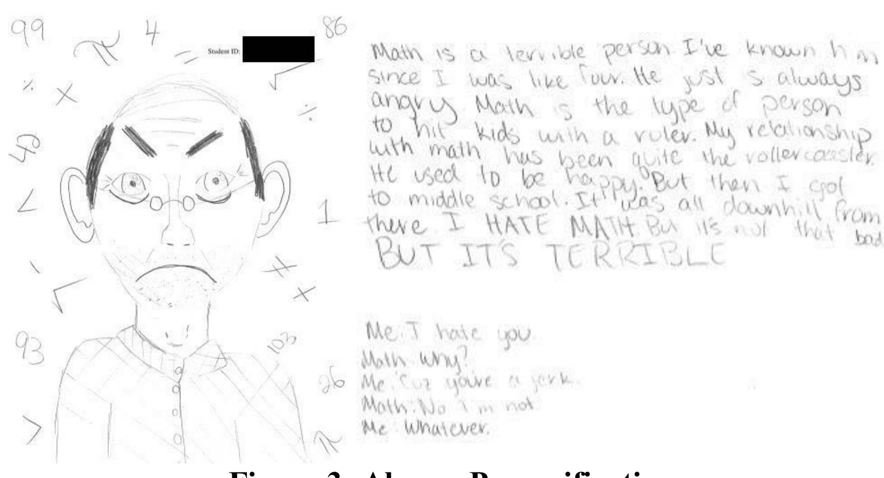

Figure 3: Abuser Personification

The pest/nuisance. Students that drew math as a pest often describe math as something that is intentionally annoying highlighted a pest/nuisance personification of mathematics. A pest is typically irritating or an inconvenience. These inconveniences can look like losing your keys or a skunk making you smell. It can also look like either doing math or smelling something gross. Figure 4 highlights a pesky macaw stealing keys form a student.

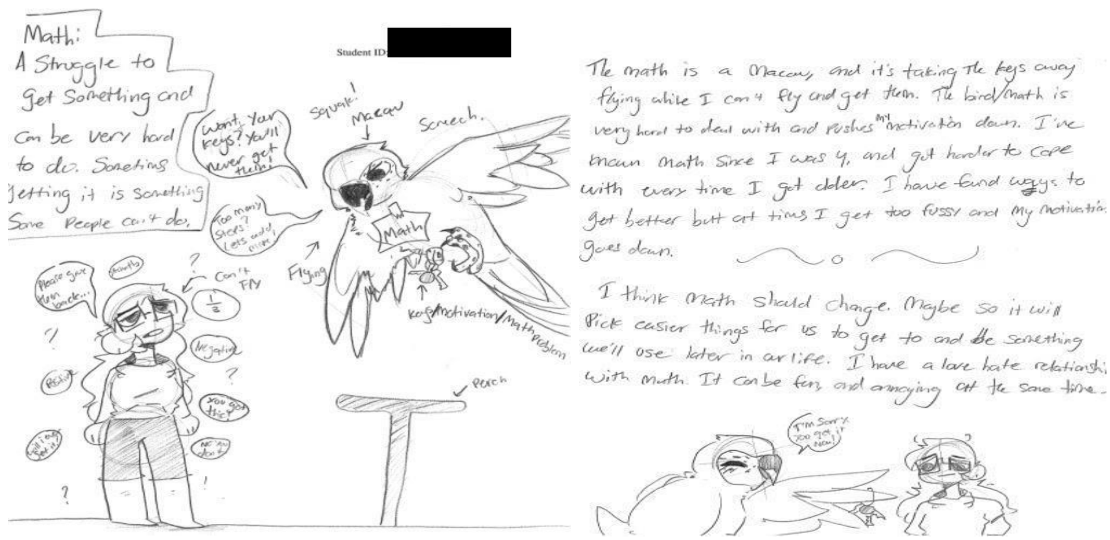

Figure 4: Pest/Nuisance Personification

This is a category that we added to the Zazkis and Mamolo (2016) framework of personifications.

Positive Relationships

The middle schoolers personified positive relationships in mathematics with best friends and nature.

The best friend. Students personified mathematics as a best friend. Zazkis and Mamolo (2016) described how math was personified as both a lover and also a (former) best friend. We did not see lovers as a theme; instead, there was an abundance of math personified as a best friend. The best friend personifications showed themes of comfortability and enjoyment of mathematics. The students described their friend as someone that you can do many things with, including but not limited to: playing games, going to the store with, and even being a helpful resource. This did not mean that the students did not think that mathematics had flaws. In Figure 5, the student described math as someone that is shy but kind. The student described her best friend as "She might be challenging to understand at first, you might have to tell her to slow down, and take a step back, but she will be with you through thick and thin." The student wants to be friends with math for as long as they can—It will be a useful asset all through life." This student highlighted that they are not a stranger to the challenges of mathematics, but it is worth the struggle.

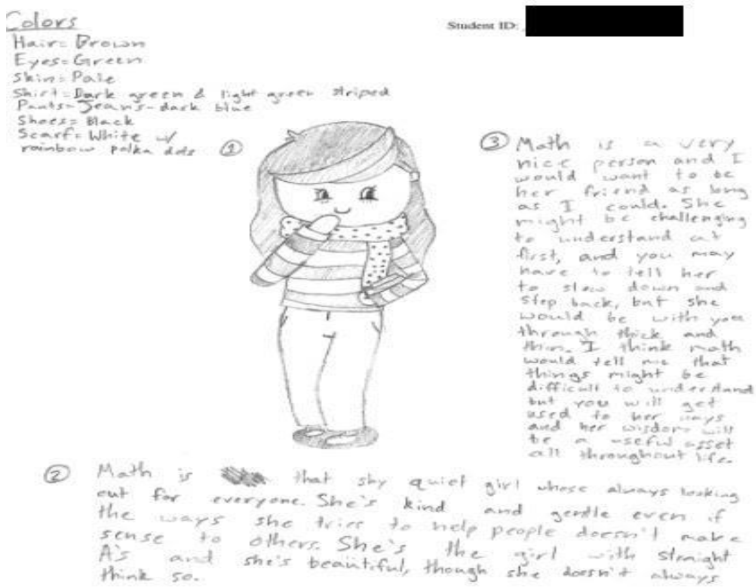

Figure 5: The Best Friend Personification

Nature. The students also personified mathematics with nature. These personifications described the push and pull of nature, how sometimes nature is beautiful and sometimes it is a challenge. Nature is beautiful and to be enjoyed, but also can be harmful and dangerous. We added this type of personification to the Zazkis and Mamolo (2016) framework. As the transcript below states, "math starts out looking like tangled videos with thorns like a rose bush, but after you get to know math and understand it, it can look like simple, harmless flowers."

Figure 6: Nature Personification

Both Positive/Negative Relationship or Neutral Relationships

The middle schoolers personified relationships in mathematics that could be considered both positive and negative or neutral with former friends and cartoons.

The former friend. Consistent with Zazkis and Mamolo's (2016), the students personified mathematics as a former friend. Figure 7 highlights a variety of emotions and types of relationships, both an abusive relationship and a former friend are illustrated. This is a reminder that sometimes relationships can be more than one thing. Emotions and relationships are complex in general and that does not exclude mathematics. This means that these classifications can overlap. Figure 7 shows some fingers that have various faces (e.g., smiles, frowns), indicating evidence of both positive and negative relationships. For example, in the transcript the relationship is described as "love/hate." The student described math as "fun," but math says things like "you ruin my life."

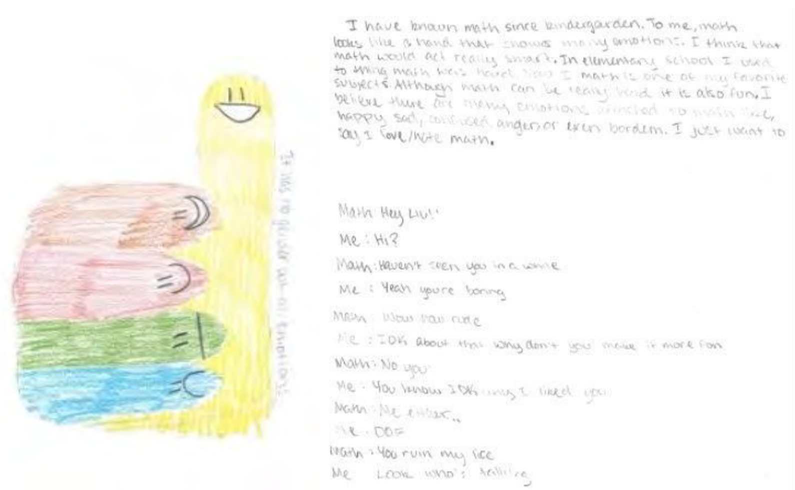

Figure 7: Former Friend Personification

The mathematical cartoons. We also added the mathematical cartoon personification to the Zazkis and Mamolo (2016) framework. Our students personified mathematics as cartoon mathematical symbols or objects, sometimes with no transcript or unemotional transcript. We struggled with determining what type of mathematical relationship was depicted. Although the drawing on the left in Figure 8 describes math as nice and funny, the cartoon depicted does not show much more emotion. The figure on the right says that "math likes to annoy kids," which is slightly negative, but the drawing itself is neutral. For the mathematical cartoon personifications, the drawings looked neutral, but if text was included, there was more insight the relationship with mathematics.

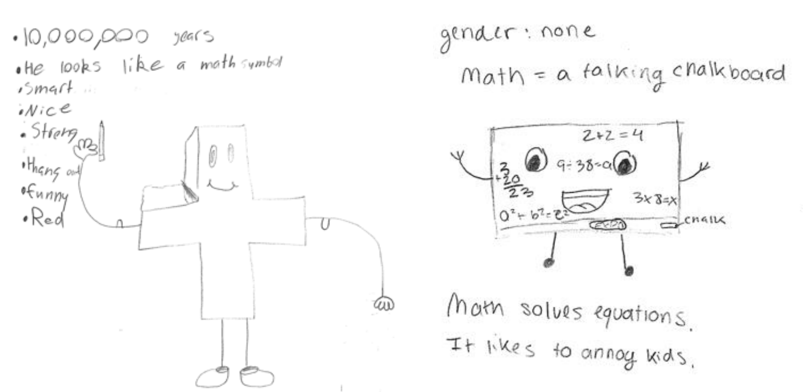

Figure 8: Cartoon/ Personification

Discussion

Unpacking middle schooler's personifications of mathematics is one aspect that makes this study significant. Prior studies on personifications of mathematics have been done with preservice teachers (Zazkis, 2015; Zazkis & Mamolo, 2016). This study extends this work to middle school students, which is important for understanding relationships with mathematics. Further, we describe additional personifications of mathematics (e.g., pests, nature).

Positive relationships in mathematics can lead to students pursuing careers in STEM. We want all students to have a positive relationship with mathematics and to see themselves as young mathematicians, especially those that have been traditionally underrepresented in STEM (Wickstrom & Gregson, 2017). Understanding and describing mathematical relationships helps researchers and educators support more positive relationships with mathematics. In this study, positive relationships were illustrated in personifications of mathematics as bests friends and in nature. The nature personification highlights the beauty and complexity of mathematics. The best friend personification illustrates someone that you spend extended, enjoyable time with. When we think about those personification, in what ways do we support our students in befriending mathematics or seeing the nature in mathematics?

Similarly, understanding the depth of negative relationships in the person is also important for supporting transformation in mathematical experiences of our students. If we understand what is negative about the relationship, then researchers and educators can work together towards specific changes. Negative relationships in this study were personified as mathematics as terrible beasts, authoritarians, abusers, and pest/nuisances. In what ways do we perpetuate these personifications in school mathematics?

Acknowledgments

We would like to thank the Paul K. Richter Memorial Fund and the Evalyn E.C. Richter Memorial Fund, distributed by the Bank of America, for funding this work.

"I'M ONLY SIX.": EXPLORING YOUNG CHILDREN'S MATHEMATICS IDENTITY DEVELOPMENT

Mari Altshuler
University of Illinois Urbana-Champaign
mshuler@illinois.edu

Keywords: Affect, Emotions, Beliefs, and Attitudes, Early Childhood Education, Elementary School Education

When Reese and I had our first conversation over Zoom, she was just a few days from finishing Kindergarten, and she knew she had a lot of learning ahead of her. I asked if she expected to keep learning math as she got older, and she said, "I'm still learning math. I'm only six." Reese's reminder of her age was apropos because the literature exploring mathematics identity has focused on older students. Though previous research has revealed mechanisms that lead to negative relationships with mathematics for middle and high school students, including narrow pedagogies (e.g. Boaler & Greeno, 2000) and cultural and gender biases (e.g. Shah, 2017; Langer-Osuna, 2011), there is little related research with young children.

In this study, I looked at patterns in the literature that illustrate relationships between classroom features and students' mathematics identities, and I explored the applicability of these patterns with children in early elementary school. Specifically, I asked, what dimensions of young students' relationships with mathematics are relevant to understanding their emerging mathematics identities? And, what features of mathematics learning environments are supportive of young students forming positive relationships with the discipline of mathematics? The data for this study come from a larger project that took place between the spring and fall of 2020 with 30 young students and their caregivers from the Chicagoland area. The students began the study in either kindergarten, first, or second grade, and I conducted three interviews over Zoom with each student. Our conversations focused on students' experiences learning mathematics and their feelings towards mathematics within and outside of school, now and into the future.

Through qualitative analysis of the student interview transcripts, I compared this study's data to the mathematics identity development patterns identified in the work of Boaler & Greeno (2000), Cobb et al. (2009), and Nasir & Hand (2008). Together, their work explored mathematics identity from a variety of angles and highlighted a range of important and overlapping classroom features that impact students' developing mathematics identities including students' access to meaningful learning, the types of agency students experience, how authority in the classroom is allocated, and whether students have opportunities to express themselves. I found that whether students felt successful and whether students saw mathematics as a part of their futures were not suitable metrics for understanding young students' emerging mathematics identities. Rather, it was more meaningful to look closely at the combination of whether students enjoyed mathematics and whether they knowingly engaged in mathematics in their own time outside of school as a way to understand their relationships with the discipline. In addition, though experiencing classroom environments as collaborative and being granted access to mathematics as a meaningful and expansive domain have been documented to support older students' positive mathematics identities, for young learners those conditions were either less common or more difficult to perceive or articulate. In contrast, whether students felt that they had conceptual agency in their mathematics learning experiences and whether they perceived opportunities for self-expression appeared impactful across the Kindergarten through second grade participants in this study. This has implications for mathematics identity research and for classroom educators looking to ensure that more of their young students form positive relationships with mathematics.

There is no doubt that the shifts to virtual and hybrid models of instruction due to the pandemic have impacted learning for k-12 students. Many of the impacts of these changes are measurable through quantitative data such as reading levels or assessments scores (Dorn et. al, 2020). Other impacts are not as easily observed through traditional school measures. For example, the psychological impact of learning in isolation, may become evident in concerns related to mental and emotional health (Hertz & Barrios, 2021). Using similar periods of student separation from school such as summer break (Kuhfield & Tarasawa, 2020), research can begin to give some sense of how to best serve students post pandemic. However, there is no true comparison to draw from that accurately compares to what students are currently experiencing. To be best prepared to address student needs, we would be well served to better understand how students are currently reacting to their pandemic educational experience.

In this study we explore the way in which pandemic related educational changes have impacted how students perceive themselves as mathematicians. The lens used to describe approach to doing mathematics is observable actions that indicate either a positive, neutral, or negative perception of themselves as doers of mathematics. We are utilizing the observations of practicing veteran teachers as our primary lens of observation of student behavior. We interviewed 14 teachers, seven 3rd grade and seven 6th grades to be able to compare any similarities and differences observed between elementary and middle grades students. Results from the study will provide insight into the ways in which students perceptions may have been impacted from pandemic shifts in instruction, but also suggest ways in which teachers' expectations have shifted as well.

Keywords: Integrated STEAM, Computational Thinking, Culturally Relevant Pedagogy

This poster focuses on a project that sought to build on family stories to support children's integrated learning of mathematics and computational thinking. The research conducted analyzed observational notes of the family workshop sessions, student presentations, and families' dioramas in order to identify and understand opportunities to learn about mathematics and computational learning that were co-constructed in the informal learning space. Analyses indicate that the family stories provided a purpose for learning how to code and for unpacking the code of others. Further, the family stories integrated with coding provided a hybrid space that supported community and voice while learning about mathematics and computational thinking.

Family Stories as Starting Points for Integrated Learning

In this project, we sought to answer the question of how to make mathematics and computational thinking meaningful to children and their families. We worked with families as part of a six-session coding workshop, initially conducted in a face-to-face format and then transitioning to a virtual format. Sessions 1 and 2 focused on an introduction to coding through the use of hands-on activities and picture that helped to unpack common coding terms (e.g. algorithm, loop, etc.). Sessions 3 and 4 introduced Scratch to families, and sessions 5 and 6 focused on families coding and adding robotics to their dioramas which featured a scene from their stories. Our approach was inspired by the *Techtales* curriculum. In this analysis, we draw on sociocultural perspectives that view learning as involving shifts in participation reflected in individuals' experiences and changes in trajectory (Nasir, 2012).

Analysis and Insights Gained

We drew on observational notes from each workshop session, the written artifacts, pictures of the dioramas, and children's presentations of their dioramas. We analyzed the notes for critical incidents in which both coding and families were discussed and examined common themes across these occurrences. Our findings indicate two themes in the critical incidents: First, when families discussed coding, they also included aspects of the story the majority of the time. Second, the families talked about the robotics features in relation to the purpose it served in telling the story. Third, the children were able to unpack and explain the code that was used. This research has implications for how we leverage family practices and identities in designing instruction.

INVESTIGATION OF MATHEMATICAL MINDSET, IDENTITY, AND SELF-EFFICACY OF COLLEGE STUDENTS

Yolanda G. Rush
Illinois State University
ygrush@ilstu.edu

Amanda L. Cullen
Illinois State University
almille@ilstu.edu

Keywords: Affect, Attitudes, and Beliefs.

Mathematical identity, mindset, and self-efficacy play a vital role in the success of students at the college level. These noncognitive components aid students in their ability to overcome setbacks (Center for Community College Student Engagement, CCCSE, 2019). The Center for Community College Student Engagement (2019) report recommends that community colleges should teach students the research behind growth mindset and improve student strategies on overcoming setbacks. Other studies have shown that students at 4-year institutions benefit from knowledge of productive mindsets especially minority students (Aronson et al., 2001; Hwang et al., 2019). Although some college students may benefit from a mindset intervention, how do we identify students who may benefit from this intervention? The purpose of the study was to determine if mathematical mindset, mathematical identity, or mathematical self-efficacy differ significantly among college students when looking at high school mathematics course history, race, gender, or 2- or 4-year institution enrollment, and which factors are helpful in identifying students who may benefit from a mindset intervention.

For this quantitative research study, a mass email was sent to students, through list serves from professors, instructors, college administrators or institution's marketing department. Over 500 college students participated in an online survey. The survey was comprised of demographic variables: gender, race, 2- or 4-year institution, and high school mathematics course history. There were three groups of questions that measured students' mathematical mindset, identity, and self-efficacy beliefs. Multiple independent sample *t*-tests were used to determine if there was a significant mean difference in student mathematical mindset score, mathematical identity score, and self-efficacy beliefs score across gender, race, and 2- or 4-year institution. A univariate ANOVA analysis was used to determine if mathematical mindset, identity, or self-efficacy differed significantly among college students when looking at high school mathematics course history (i.e., Algebra I, Geometry, and Algebra II) and grade level in which course was taken (e.g., before high school, Grades 9–12, does not apply).

The results showed: (1) significant differences in mathematical mindset, identity, and self-efficacy when considering grade level that Algebra I was taken; (2) significant differences in mathematical identity and self-efficacy when considering gender; (3) significant differences in mathematical mindset when considering race; and (4) significant differences among students' mathematical mindset when considering students who attended 2- vs. 4-year institution. Results confirm the CCCSE (2019) report recommendations that community colleges may need to teach their students the research behind growth mindset. Although the grade Algebra I was taken and current institution (i.e., 2 or 4-year) could be indicators, more research may be needed to determine additional factors important in identifying participants for a mindset intervention.

GLOBAL AND TASK-SPECIFIC MATHEMATICS SELF-EFFICACY AND PERFORMANCE: A QUALITATIVE STUDY IN INTERMEDIATE COLLEGE ALGEBRA

Bridgette E. Russell
Central Michigan University
buse1b@cmich.edu

Christine M. Phelps-Gregory
Central Michigan University
phelp1cm@cmich.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Algebra and Algebraic Thinking; Undergraduate Education

Mathematics self-efficacy (MSE) is defined as students' beliefs about their ability to learn and be successful in mathematics (Bandura, 1986). Self-efficacy can be measured globally (e.g., I am good at math) or locally for a specific task (e.g., I will be successful in solving this problem) (Pajares & Miller, 1995). MSE is important because it can predict future academic and career achievement, effort, and success on difficult tasks (Betz & Hackett, 1983; Hackett & Betz, 1989; Holenstein et al., 2021; Usher et al., 2018). However, sometimes there can be a mismatch between students' self-efficacy and their performance, which we will call *incongruous mathematics self-efficacy* (IMSE) (Schraw, 1995; Sheldrake, 2016). IMSE and the effect of IMSE on math performance and perseverance are not well understood.

Research Question, Design, and Analysis

This poster presents results from a pilot study in which students' global and task-specific MSE were compared to their performance on related mathematics exercises. This work adds to existing research about IMSE (Champion, 2010; Schraw, 1995; Sheldrake, 2016) by taking a qualitative look comparing students' efficacy and performance. Students (n = 24) in an intermediate algebra course were invited to take a global MSE survey. To allow for comparisons, five participants with a range of global MSE (low, average, and high) were then selected for additional interviews. As part of the interviews, participants were also asked about task-specific MSE and were asked to solve three exercises, two purely algebraic and one word problem, chosen directly from course material. Analysis focused on participants' global and task-specific MSE as well as comparing these to their performance on the exercises. A future full study will seek to build on these results by using a larger sample to examine students' global and task-specific self-efficacy in relation to their course performance.

Findings and Implications

Results show participants' global MSE was aligned with their performance on the three mathematical exercises. In particular, students with higher global MSE solved more problems successfully than students with lower global MSE. This aligns with previous research suggesting MSE can predict academic success on difficult tasks (Hackett & Betz, 1989; Holenstein et al., 2021). However, instances of incongruous task-specific MSE were identified for four of the five participants. For example, on the word problem, Gabrielle rated the problem as difficult and expressed low confidence in her work but was one of only two participants who solved the problem correctly. Also, interestingly, instances of task-specific under-confidence were identified in students with high global MSE and instances of task-specific over-confidence were identified in students with average or low MSE, building on the work of Champion (2010). Overall, these results, with richer qualitative data we will share in the poster, suggest that the relationship between MSE and performance is complex.

"I AM PETRIFIED. EVERYONE SEEMS SO MUCH MORE KNOWLEDGEABLE THAN ME." – UNDERGRADUATE REASEARCH PERSPECTIVES

James C. Willingham
James Madison University
willinjc@jmu.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Equity, Inclusion, and Diversity; Informal Education; Undergraduate Education

The National Science Foundation's Research Experience for Undergraduates (REU) is a staple effort to increase the participation of underrepresented groups in advanced math, science, and engineering careers (Beninson, Koski, Villa, Faram, & O'Connor, 2011), expending close to $90 million yearly to support these efforts (Singer, 2019). However, many REU participants experience dissonance, as despite their high achievement and selection to competitive REUs, they lack an internal sense of success or belonging. This *imposter phenomenon* (Clance & Imes, 1978) is notoriously detrimental among women, and underrepresented racial, ethnic, and religious minorities (Chrousos & Mentis, 2020). With this background in mind, I consider how participants in a mathematics REU describe their experiences and the aspects of these programs that they find to best support their success.

The conceptual framing of this study is based on considering the value created by participants in the networks and communities (Wenger, Trayner, & de Laat, 2011) in which they experience situated learning (Lave & Wenger, 1991). In this context, a *network* is viewed as the relationships, interactions, and connections among the members of a *community* which is formed from a shared identity around a common set of challenges. As the primary recipients of value in this system are the participants, the emphasis of this framing is exploring the personal and shared narratives of this group in terms of their accounts of what has occurred and their common goals for the group.

To consider these narratives, I employed an embedded single-case design (Yin, 2014) to follow the experiences of five mathematics-REU participants across two eight-week research projects at a large mid-Atlantic university. I performed a simple time series analysis (Yin, 2014) across these eight weeks, codifying the participants experiences and aspirations through multiple interviews, weekly journals, and email exchanges.

The preliminary results of my analysis reveal a common anxiety among the participants, well characterized by one young woman's initial concern that, "Honestly, I am petrified. Everyone seems so much more knowledgeable than me." However, over the course of the project, she and other participants provide rich details of the specific activities that led them to individual and group success. This transition to more productive dispositions occurred through opportunities for sustained and substantial individual contributions to the groups' research, personal interactions with the faculty and other students involved in the project, and the recognition that, "Sometimes you don't know what exactly you are doing, you second guess yourself and don't feel confident. You have to be ok with asking for help and conversing with your peers so you understand."

Teaching Practice and Classroom Activity

THE ROLE OF A BOUNDARY OBJECT IN A STUDY OF MIDDLE GRADES MATHEMATICS INSTRUCTION

Angela R. Crawford
Boise State University
angelacrawford1@boisestate.edu

Michele Carney
Boise State University
michelecarney@boisestate.edu

Joe Champion
Boise State University
joechampion@boisestate.edu

Megan Schmidt
Boise State University
meganschmidt@boisestate.edu

This report is about how a group of U.S. teachers (N =98) and researchers used a boundary object in a collective study of grades 6-8 mathematics instruction. The focus is the teachers' engagement with a framework for effective instructional practices. Using qualitative content analysis of teachers' responses to use of the framework, we assessed its implementability and usefulness while supporting shared understandings of effective mathematics instruction. We found the framework supported shared understanding and implementation across varied contexts and was viewed as useful for meeting teachers' instructional and professional goals. Constraints were related to ambiguity around understanding and use of instructional practices related to student struggle. These findings demonstrate how a brief researcher-designed framework can serve as a bridge between teachers and researchers, meeting the professional goals of both.

Keywords: Middle School Education, Professional Development, Instructional Activities and Practices.

Our research is set in U.S. public middle schools, places where dissonance is a daily part of life (especially in band classrooms). In mathematics classrooms, students and teachers need to blend their often wildly different interests and goals to make the shared time together meaningful and mutually enriching. Nurturing harmony in these classrooms can be challenging, but it is a necessary condition for thriving mathematics education. Meanwhile, as researchers of effective mathematics instruction in the middle grades, we face an additional layer of dissonance. We come from a research culture and aim to build transferable knowledge of "what works", while our collaborating teachers are mostly focused on tuning their individual classroom practice to meet the needs of their students and schools. This study is about one way we have tried to orchestrate harmony in that context.

We are conducting a large-scale grant-funded study of sequences of mathematics instructional strategies within a teacher-researcher partnership (Kieran et al., 2012; Koichu & Pinto, 2018). Our project hinges on a guiding framework that effectively supports shared understandings, implementability, and motivation. While we aim to help teachers understand and use the framework, we take an explicitly asset-based approach to the work. As researchers, we know about effective instruction as described in the literature, and our collaborating teachers know about effectively working with students in their contexts. These ways of knowing about mathematics instruction introduce a "boundary" (Wenger, 1998), a useful analytic concept for studying teacher-researcher partnerships because it reflects the dissonances in our perspectives and goals while describing how learning may take place across the boundary (Akkerman & Bakker, 2011). The tool that has served as a boundary object (Star, 2010) for bridging our ways of knowing about mathematics instruction is a framework.

Theoretical Framework

EAC/SOS framework

We see our framework as the centerpiece of our work to learn alongside teachers about what works in their contexts. Based on decades of research addressing effective mathematics instruction, the Explicit Attention to Concepts (EAC) and Students Opportunity to Struggle (SOS) constructs were described by Hiebert and Grouws (2007) as primary clusters of instructional practices with robust evidence for supporting students' conceptual understanding of mathematics. Stein et al. (2017) subsequently operationalized the constructs, finding further evidence of the practices for supporting high student achievement on assessments of both procedural and conceptual knowledge in mathematics.

We developed a two-page practice guide for teachers to support the enactment of EAC and SOS in their classrooms (see Figure 1; Champion et al., 2020). The artifact presents three *features* for each construct. The features that characterize EAC instruction are (a) a focus on concepts, (b) making concepts explicit and public, and (c) emphasizing connections. The features that characterize SOS instruction are (a) a focus on sense-making, (b) application of sustained mental effort, and (c) engagement with important mathematics. The *constructs* and *features* are meant to broadly describe effective practice, but the guide also includes examples at a finer grain size. Each construct lists four instructional *strategies* with two accompanying *routines*, which more explicitly detail what enactment could look like in the classroom. Lastly, each strategy is annotated with potential instructional *tools* that teachers could use to support the enactment.

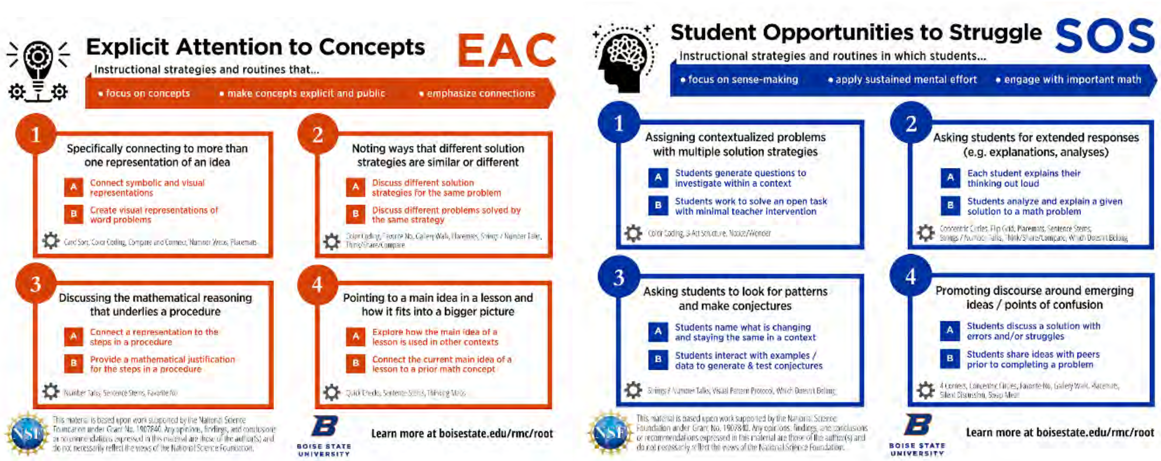

Figure 1: EAC/SOS Guide to Instructional Practices for Improving Math Achievement

EAC/SOS Framework as a Boundary Object

Our project is a boundary encounter between two communities of practice, mathematics education researchers and teachers, who are working toward a common goal of building useful knowledge for both communities (Wenger, 1998). Within boundary encounters, boundary objects are "things" (either physical or conceptual) that act as a bridge between communities (Star, 2010). As a bridge, a boundary object should be accessible to multiple perspectives, allowing shared meanings to be negotiated (Akkerman & Bakker, 2011; Star, 2010). In an investigation of a boundary object in teacher professional development, Edgington et al. (2016) found their framework was used by teachers in both expected and unexpected ways, suggesting opportunities for researcher learning through investigations of teachers' meanings around the boundary object. As researchers, our goal was to communicate research at a boundary while valuing collaborating teachers' expertise, so we identified teachers' interpretations of the boundary object as pivotal. Our guiding research question was, "To what extent does the EAC/SOS framework function well as a boundary object with middle school mathematics teachers, supporting shared understandings of effective mathematics instruction while being adaptable in teachers' diverse contexts?"

Method

Our study centers collaborating teachers' perspectives of the EAC/SOS framework. We used qualitative content analysis, which involves interpreting meaning from text, to understand teachers' feedback on their engagement with the framework across the first year of our partnership.

Participants

The participants in this study are Grades 6-8 mathematics teachers from 34 schools within 22 school districts in the western United States ($N = 98$). All teachers were working in public schools. Nearly all worked in brick-and-mortar schools, though one teacher worked for a virtual public charter school. Teachers' mathematics instruction often spanned multiple grades (49 taught Grade 6, 44 taught Grade 7, and 44 taught Grade 8) and courses (37 taught one course, 48 taught two courses, and 12 taught three or more courses). The teachers worked in a variety of school settings, both in terms of students' socio-economic status (mean eligibility for federal free or reduced school lunch was 58%, $SD = 21\%$) and locale type (31% rural, 69% suburban or small city). Teacher demographics indicated substantial variability in mathematics teaching experience (mean = 9.8 years, $SD = 7.4$, Range = 1 to 32), and they primarily self-identified as female (77%) and white (96%). Teachers' highest academic degree was typically a bachelor's degree (57%), though 40% held a master's degree, and 2% held an Ed.S.

EAC/SOS Guide & Professional Development Modules

The framework was enacted by inviting teachers to engage with the two-page guide and three supporting professional development modules. The first two modules were in-person and synchronous and, due to the COVID-19 pandemic, a third module was online and asynchronous. The focus of Module 1 was an orientation to the research project and the EAC/SOS framework. Modules 2 and 3 focused more deeply on EAC and SOS strategies, respectively. The in-person meetings gathered all teachers together for 4 hours on Saturday mornings. The asynchronous modules integrated online tools in the form of virtual bulletin boards, an interactive mathematics activity builder, and a video-based interaction platform.

Data Sources

We used extant data that was collected across the first year of the project to inform decisions about upcoming modules or engage teachers in exploring ideas (Table 1). These data were collected via graphic organizers and online forms. Questions asked of teachers varied each time, depending upon what information was desired to inform upcoming professional development sessions.

Data Analysis

We applied a three-level analysis (Simon, 2019). At the first level, we worked with the teachers' responses as raw data. We tabulated frequency counts for strategy and routine choices and coded textual data, guided by the research purpose and using constant comparison (Corbin & Strauss, 2008). To verify the trustworthiness of our coding at this level of analysis, we checked the comparability of coding within Data Source 3 (DS3, see Table 1). Two researchers applied open coding to half of the responses, and the team then discussed the codes and established a coding dictionary. To check for reliability of coding, two researchers used the coding dictionary and coded data in DS5. We compared the frequency with which codes were applied to responses; average exact agreement across codes was 68% and within 2 agreement was 91%. Disagreements were reconciled, and definitions were refined. Using this refined coding scheme, a single researcher conducted the remaining analyses and summarized each data source. These summaries described the context of the data (what the teachers were responding to and why), provided tables with frequencies of applied codes, and exemplar responses for frequent codes.

The second level of analysis identified themes across the summaries with reference to the original data as needed. Two researchers engaged in this process independently, and the full research team then compared the themes, discussing similarities and differences. A third researcher then compiled the results of the discussion into a final set of claims related to the research purpose. In the third level of analysis, we applied abductive reasoning to the second level claims to identify inferences which, if true, would account for the data (Simon, 2019). The goal is to consider the claims with the intention of contributing useful postulations that apply beyond the scope of this particular study. These inferences therefore inform our understanding of the success of the framework as a boundary object in a teacher-research partnership.

Table 1: Summary of Data Sources

Data Source ID	Module	Data Source	Content	# of Responses
DS1	1	Comfort-Frequency Notes	Compare comfort-frequency of strategy implementation to a peer	85
DS2	1	Implementation Cycle 1 Plans	Choose a strategy to try out in classroom and explain why it was chosen	94
DS3	1	Implementation Cycle 1 Reflection	Indicate what strategy was tried and what went well and what was difficult.	98
DS4	2	Implementation Cycle 2 Plans	Choose an EAC strategy to try out in classroom and explain why it was chosen	94
DS5	2	Implementation Cycle 2 Reflection	Indicate what EAC strategy was tried and reflect on how it went	93
DS6	3	SOS Impressions	Read a description of SOS, comment on using SOS in classrooms	89
DS7	3	SOS Strategy Identification	Watch a video, identify strategies and teacher moves to support struggle	97
DS8	3	Implementation Cycle 3 Plans	Choose and SOS strategy to try out in classroom and explain why it was chosen	83

Findings

This study investigated teachers' responses to determine the extent to which the framework supports a shared understanding of research-supported instructional practices and the extent to which teachers view the framework as implementable and useful.

Understandings about EAC and SOS

We looked for evidence of teachers' understandings of the framework across their reasons for selecting strategies. These data sources were coded for degree of alignment with our understandings as researchers. Coding categories were: aligned (described key features of the construct), partially aligned (described strategy without language related to key features), unaligned (confused the constructs or added unintended ideas), or unclear (e.g., "it fits my curriculum"). Figure 2 shows the respective percentage of responses in each category across the three modules. The majority of responses, 70% and above, were aligned or partially aligned. We believe this degree of alignment early in our project indicates success of the framework for supporting shared understandings. However, we note that the degree to which shared understandings were established was stronger for EAC than SOS. This discrepancy is also evident from DS7 in which we asked teachers to watch and respond to videos of a teacher implementing SOS strategies, from which only 39% of responses were coded as aligned, while 59% of responses were coded as partially aligned.

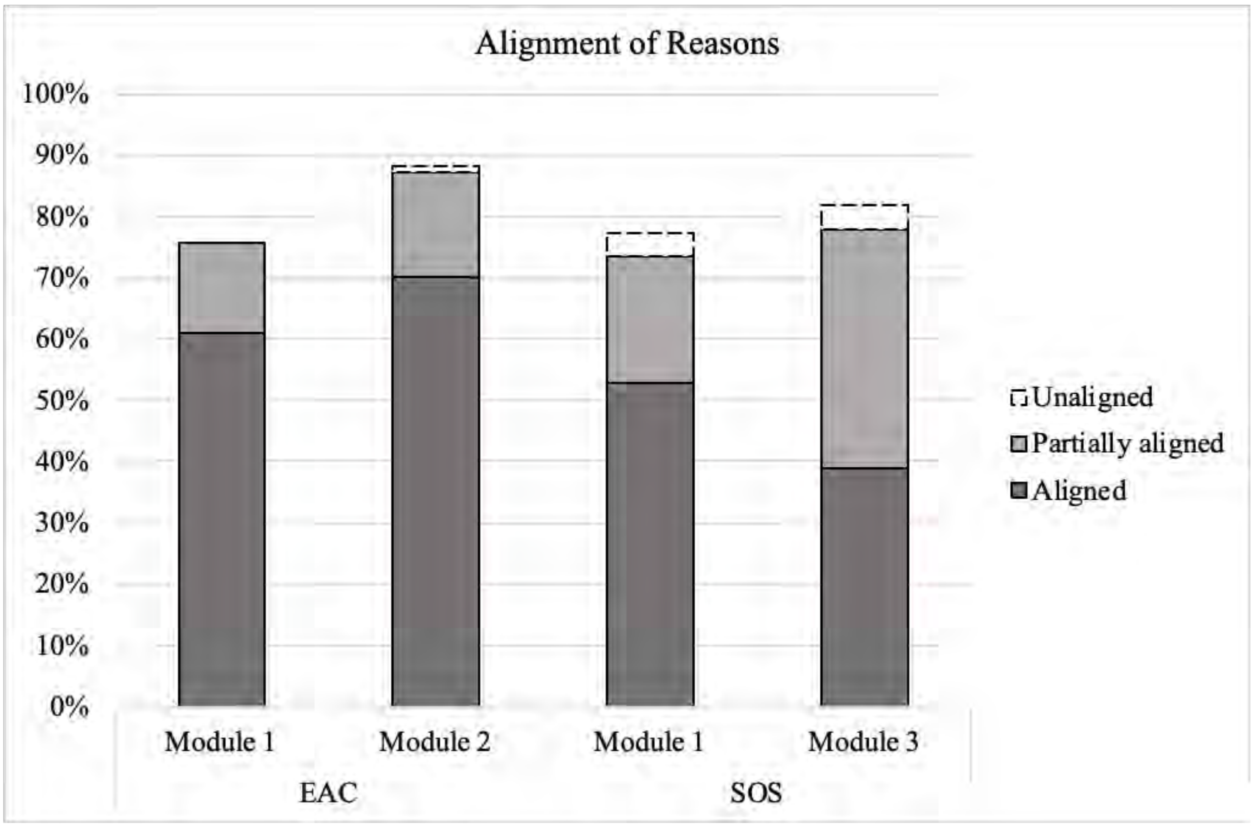

Figure 2: Alignment of Reasons for Strategy Choice to Researchers' Intended Meanings

Teaching Context

We wanted to determine to what extent the framework was viewed by teachers as implementable in their contexts. We found the framework offered options that were taken up by teachers across these contexts, and we found teachers preferred different strategies based on their experience, interests, and school or district context. Teachers' reasons for selecting strategies (Figure 3) indicated contextual factors such as the needs of their students, aligning with curriculum or learning goals, and teachers' experience or interests. When we asked teachers to rate EAC and SOS based on their comfort and frequency of use, and then comment on similarities and differences to the ratings of another teacher (DS1), 62% of comments related specifically to choices based on teaching context, including curriculum, working environment, years of experience, and teachers' individual personalities.

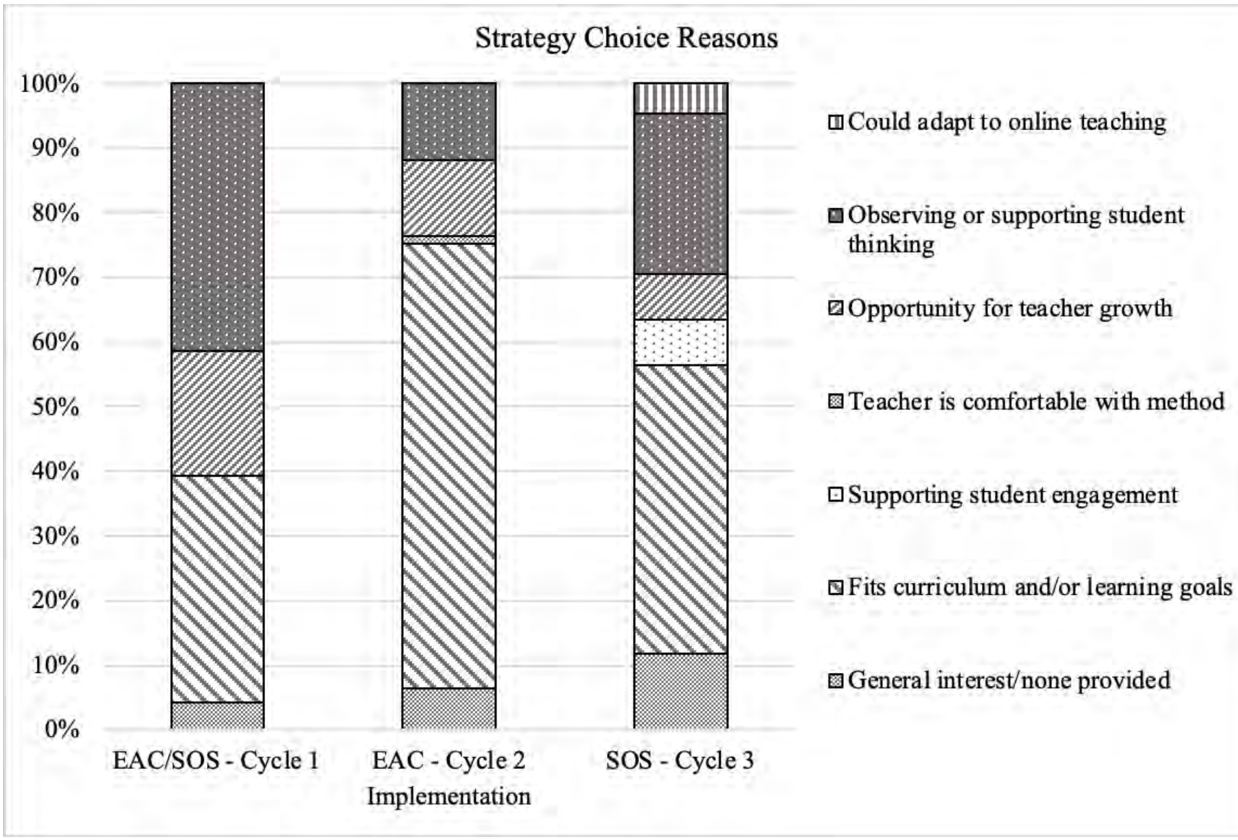

Figure 3: Themes Identified in Reasons for Strategy Choice

Despite evidence that teachers identified adaptable options in the framework, some data indicated a perception that SOS may not be successful with some students. After implementation cycle 1 (DS3), teachers reflected on the benefits and challenges of the experience. The primary difficulty related to SOS was "student engagement" which accounted for 61% of the SOS responses. A response that suggests SOS may not be successful with some students was, "It was very difficult to engage the students who struggle in math….A lot of scaffolding and accommodating was needed." Also, DS6 asked teachers to comment on a reading about the meaning of productive struggle, and 22% of the comments focused on the challenge of using SOS with some students. A characteristic response was, "With productive struggle it never really feels like they are learning anything, especially without teachers teaching step by step. Students definitely give up when they don't understand something, so how can they productively struggle if they keep giving up?"

Opportunities for Teacher and Student Learning

In support of implementation, we hoped teachers would interpret the framework as useful and motivating for innovating their professional practice. We found teachers described its usefulness in terms of offering opportunities for teacher and student learning. We identified the theme of opportunity for learning as reasons for selecting a strategy across all three cycles of implementation (see Figure 3). An example of a response that fell under this theme is a teacher's explanation for choosing an SOS strategy, "I believe that I guide my students too much to the answer, and give them too much information, which gives away the Ah Ha moments. I want to work on allowing the students to explore more of the problem without just giving them their answers" (DS2). In addition to identifying this theme in reasons for strategy choices, we identified this theme in 20% of teachers' reflections on implementation cycle 1 (DS3) and 17% during cycle 2 (DS5).

A number of teachers interpreted the strategies as opportunities to facilitate learning by focusing on student thinking. As seen in Figure 3, we identified the theme of "observing or supporting student thinking" in 41% of reasons for selecting a strategy in the first implementation cycle, 11% in the second, and 25% in the third. An example of a response that supports this claim is related to the SOS strategy of promoting discourse among students around emerging ideas, "Want to see if it will help with further understanding the concepts amongst the kids" (DS8). We also identified this theme in teachers' reflections. "Students learned" and "students were engaged" accounted for 88% of the descriptions of what went well after implementation cycle 1 (DS3) and 37% after implementation cycle 2 (DS5).

Discussion

This study aimed to understand the EAC/SOS framework as a boundary object bridging two communities of practice. We believe that this investigation of the boundary object can offer guidance to others involved in similar projects that involve communicating across such boundaries. We found the framework, by and large, supported shared understandings. We also found that teachers could identify appealing options and meaningful benefits from the framework, indicating they viewed it as implementable and useful. Despite the indications of shared understandings and positive reception of the framework, there are some challenges around the meaning and implementability of SOS. One potential contributing factor for this is the possibility that teachers who are accustomed to 'traditional' mathematics instruction may find EAC more accessible than the more student-centered 'reform-oriented' instruction associated with SOS. Researchers working with teachers to study SOS may need to provide additional experiences and resources for implementation. Teachers' context may be important, as well as teachers' beliefs about their students' abilities to learn through productive struggle.

Implications

Based on our findings, we offer some provisional recommendations for teacher-researcher partnerships to study mathematics instruction:

- Expect some aspects of the research lens you are using to be easily understood and translated by practitioners, while it may be more difficult to form shared understanding around others.
- Use cycles of data collection to monitor teachers' perceptions and implementation results, and adjust the planned meetings between each cycle.
- Give teachers an overview of the theory and research underpinning the project, and then ask teachers what information they need to translate this to their practice (e.g., video examples, curricular materials, rehearsals).
- Be mindful of teachers' context and beliefs. Provide multiple entry points, choices for teachers with different contexts, and be aware the assumptions and expectations of teachers may or may not align to those of the researchers.

Conclusion

To achieve harmony between our goals for learning “what works” in a broad sense and teachers’ goals of fine-tuning their individual classroom practice, we investigated the EAC/SOS framework as a boundary object. We centered teachers’ voices and found evidence in their responses that the framework supported shared understandings, strong implementability, and the usefulness of the framework across varying teaching contexts. These affordances are signs that the framework provides entry points for engaging teachers in professional learning around these constructs. However, we also found constraints of the framework, particularly around SOS. The constraints indicate specific ways to better support teachers’ understanding and implementation of SOS, and the study findings indicate several ways to scaffold teacher-researcher partnerships in order to build meaningful knowledge of effective mathematics instruction.

Research processes are often messy and include tensions that are unnamed in the final products. In our attempt to update and generalize a framework used to examine teachers' support for collective argumentation in mathematics education classrooms to examining teachers' work in interdisciplinary STEM contexts, we have experienced significant linguistic tensions because of the context-dependent nature of language. We aim to acknowledge the difficulty of generalizing research beyond the mathematics education community, describe our attempts to resolve the problem we face, and discuss potential conclusions pertaining to the feasibility of generalizing frameworks beyond mathematics education.

Keywords: Classroom Discourse; Integrated STEM/STEAM; Research Methods

Background

In 2019, Eric Siy asked the mathematics education community to reveal their work to cultivate a healthier and more rigorous culture of research. Siy argued that one way to expose the messiness of research was to make our processes products. In response to his call, our team has decided to openly share a present, messy tension in our research process. By disclosing our present dilemma to the community for outside opinion and critique, we aim to practice academic humility and make our process a product.

The current tension emerged out of our attempt to update and extend the Teacher Support for Collective Argumentation (TSCA) framework (Conner et al., 2014) that was originally developed to understand and describe how secondary mathematics teachers support collective argumentation. We define collective argumentation as teachers and students working together to establish a claim and provide evidence to support it. The original framework described teachers' support of collective argumentation as (a) directly providing a claim, data, or a warrant, (b) prompting a student's contribution of argument components with a question, or (c) responding to a student's contribution. These three descriptions of teacher support for collective argumentation simplify to three categories: direct contributions, questions, and other supportive actions.

Given the utility of the original framework, we (a group of mathematics education, science education, and engineering education researchers) attempted to update and extend the framework to other STEM+C settings/classrooms. Our updates include specific kinds of questions within each broader category of question. For example, Table 1 shows a few of the kinds of questions originally conceptualized. In the updated framework, we want to potentially include additional kinds of questions as well as examples from multiple disciplines.

Table 1: Working Descriptions of Selected Types of Questions in New TSCA Framework

Category of Question	Description
Requesting a factual answer: Asks students to provide a mathematical fact	*Identification*: choose from a set of options, identify something *Observation*: describe what happened or is happening.
Requesting a method: Asks students to demonstrate or describe how they did something	*Describe a method*: state how they did, would, or could do something
Requesting an idea: Asks students to compare, coordinate, or generate mathematical ideas	*Conjecture*: put forward a prediction, suggestion, or other idea

Note. This table is adapted from the original TSCA framework (Conner et al., 2014, p. 419)

However, in our attempt to update and generalize the framework for use in other contexts, we experienced significant linguistic tensions. The complexity of meaning and the context-dependent nature of language pose severe challenges for crafting the framework for use beyond mathematics education. In this brief research report, we aim to acknowledge the difficulty of generalizing research beyond the mathematics education community, describe our attempts to resolve the problem we face, and discuss potential conclusions pertaining to the feasibility of generalizing frameworks beyond mathematics education.

Theoretical Framework

Ludwig Wittgenstein, in his *Philosophical Investigations* (1953/1958), sought to dismantle theories of language that were referential, representational, and ostensive at their core. A referential view of language is where words directly refer to objects and, consequently, a word has a referential meaning. Wittgenstein wanted readers to break free from the idea that there could be a unitary account of language (Grayling, 1988). Rather than an all-encompassing theory, Wittgenstein proposed the concept of language-games. Wittgenstein's concept of language-game was meant to emphasize that language is not independent from context nor is it referencing some outer reality. Rather, Wittgenstein (1953/1958) described language-games as "meant to bring into prominence the fact that the speaking of language is part of an activity, or of a form of life" (§23). Grayling (1988), expounding on Wittgenstein's phrase "form of life," wrote,

> Language is not something complete and autonomous which can be investigated independently of other considerations, for language is woven into all human activities and behaviour, and accordingly our many different uses of it are given content and significance by our practical affairs, our work, our dealings with one another and with the world we inhabit—a language, in short, is part of the fabric of an inclusive 'form of life.' (p. 67)

Through his exploration of concepts like "language-games" and "form of life," Wittgenstein sought to reinforce his main point: the meaning of language is largely found in its *use* in humans' embodied activities and social practices (i.e., in various language-games). Hence Wittgenstein wrote, "the meaning of a word is its use in the language" (§43). Given Wittgenstein's ideas about language and meaning, we should not be surprised that the same word is used across various

STEM+C disciplines with different meanings. Furthermore, a word's meaning may not be easily disentangled from its disciplinary use and the associated embodied practices and contexts.

Methods

The data for the larger project consist of many hours of video from elementary teachers' instruction in which they integrated coding with mathematics, science, literacy, and social studies lessons. To examine the teachers' use of argumentation and support of students' arguments across disciplines, episodes of argumentation were identified, verbatim transcripts were prepared, diagrams of arguments were constructed, and teachers' actions supporting the argumentation were identified according to the methods described in Conner et al. (2014).

Our research team met for multiple hours each week to analyze and discuss our coding of teachers' supportive actions with respect to the original framework. In the summer of 2021, a member of the research team highlighted a prominent linguistic tension about the use of codes within two categories (requesting a method and requesting an idea) in the framework. Subsequently, the use of two additional words was identified as problematic. Our team regularly debated how to use the framework in light of these tensions for the subsequent months. Multiple times, we attempted to settle the debate and move forward by adopting specific meanings for the words. However, further analysis caused additional complications of meanings, and more linguistic tensions were identified. In the most recent attempt to settle various meanings, all team members were asked to submit their own working definition of four contentious terms and to describe the types of practices and activities that are associated with the words within their home discipline.

Results

Table 2 shows four debated words and their meanings (derived from combining provided definitions) within each field. Each of these words was used as a kind of question in the evolving TSCA framework.

Table 2: The Meaning of Words in Different Fields

	Science	Engineering	Mathematics	Statistics
Conjecture	Guess, prediction, or tentative solution; cannot be positively justified; distinct from hypothesis	Idea or hypothesis that is tested out	Prediction, reasoned guess, or proposal of a method for a problem [a]; do not have a proof	Alternative hypothesis or claim related to a research question
Method	Systematic approach to answering a question; process or technique used to find a solution to a problem [a]	Process or technique to transform an idea into a physical reality	Abstract sequence of actions or steps used to solve a problem [a], prove something, or achieve something	Technique to collect data; statistical investigative cycle; statistical approach to solving a problem[a]
Identification	Categorizing or classifying an object into pre-	Pointing out attributes that define	Determine/select what thing (object, drawing, etc.) has a	Not applicable

	established categories based on observable characteristics	something such as a design problem[a] or a design solution	certain characteristic	
Observation	Method of data collection through one's senses and scientific tools; necessarily an interpretation in light of a theory	Assembling facts from what one can see or notice	Statement noting something's (object, drawing, etc.) characteristics	A single measurement of a variable; recognizing trends or patterns in data or a graph

[a] The word "problem" provides another layer of difficulty; the types of problems imagined by scientists, engineers, mathematicians, and statisticians are different.

Discussion and Continuing Dilemmas

Given these words have loaded meanings that are discipline-dependent, our team identified three potential options. First, we could concede and conclude that there is no opportunity to generalize this framework across disciplines—even in related STEM disciplines. Second, we could carefully choose words that are not loaded with meaning in multiple disciplines. This option poses two difficulties: (a) words that do not have discipline-related meanings can often have colloquial meanings and (b) by attempting to avoid discipline-related meanings, we may choose a watered-down word that does not sufficiently communicate the type of question the teacher used. Finally, we could use the words that we currently have in the framework and accept that they will cause friction for some of the disciplines.

As we explored these three options, our team was pushed to re-examine the original purposes of the project. Given our aim of helping STEM teachers support collective argumentation, we believe it is worth attempting to generalize the TSCA framework, and if possible, to use words that would be understandable across disciplines. In our attempt to pursue the second option, we concluded that, by replacing the word "Observation" with the word "Description," we could communicate our intended meaning and avoid discipline-specific meanings. However, we have not come to a consensus on "Conjecture," "Method," and "Identification."

This constructive work across disciplines required researchers to adapt and adopt new meanings for words—meanings that can cause friction with the discipline-specific meanings. Addressing this dilemma has required group members to intentionally learn more about the meanings and uses of words across disciplines, highlighting the epistemic and linguistic differences between related disciplines. This calls into question the ease with which teachers can engage in integrative STEM instruction and suggests the need for intentionality in building theory across disciplines.

The more researchers understand the subtleties of teaching practices that productively use student thinking, the better we can support teachers to develop these teaching practices. In this paper, we report the results of an exploration into how secondary mathematics teachers' use of public records appeared to support or inhibit their efforts to conduct a sense-making discussion around a particular student contribution. We use cognitive load theory to frame two broad ways teachers used public records—manipulating and referencing—to support establishing and maintaining students' thinking as objects in sense-making discussions.

Keywords: Classroom Discourse; Instructional Activities and Practices.

Recommendations for mathematics teaching address the importance of using student thinking during whole class discussions as well as propose teaching practices that one may use to prepare for and facilitate whole class discussions (e.g., National Council of Mathematics Teachers, 2014). In our work, we study a particular teaching practice—a practice that takes advantage of instances of high leverage student thinking (Leatham et al., 2015) by making those instances of student thinking the object of whole-class sense making discussions (Van Zoest et al., 2016). As we studied teachers leading class discussions surrounding high leverage instances, we noticed variation in their use of public records of the initial student's thinking and subsequent discussion. This variation suggested that purposeful use of a public record—a physical representation that holds some degree of permanence and is visually accessible to all participants simultaneously—had the potential to play an important role in supporting the desired practice. The use of a public record as a support aligns with the tenets of cognitive load theory (Swellers, 1988; Swellers et al., 2011), which suggest that if the load for remembering other students' contributions during sense making discussions is lightened, then students can focus more on the sense-making actions they are being asked to carry out. A written representation of students' contributions can thus lighten this load. In this paper we report the results of our initial investigation into *how* teachers create and use public records of an initial student's mathematical contribution and subsequent discussion. These results provide insight into the ways public records can support teachers leading class discussions surrounding high leverage instances of student thinking.

Teachers' use of publicly accessible media (e.g., blackboards, white boards, etc.) is a common and widely accepted practice for sharing student contributions as well as mathematical content (Villareal & Borba, 2010). Additionally, some research has found that teachers' effective use of public records of student mathematical thinking corresponded with an increased level of student mathematical activity during whole class discussions (Koehne et al., 2020). However, few studies have explicitly addressed how teachers use public records of student thinking during class mathematical discussions. Knowing *what* from a student's contribution gets captured and *how* it gets recorded is important since public records of student thinking provide permanence to student thinking, which can help maintain continuity during collaborative inquiry (Staples, 2007). Knowing more about how teachers use verbal and physical actions to reference and add to a public record can help researchers learn how teachers support students to engage with each other's ideas, a practice that has been linked to mathematical achievement (e.g., Webb et al., 2014). With respect to our research, knowing more about teachers' use of public records enables us to better understand how teachers effectively use student thinking during whole class sense making discussions. This understanding is important because there is evidence that teaching practices that use student thinking can be challenging to enact (e.g., Simpson & Haltiwanger, 2017; Peterson & Leatham, 2009). The more researchers understand the subtleties of teaching practices that productively use student thinking, such as creating and using public records, the better we can support teachers to develop these teaching practices.

Theoretical Framework

Our work focuses on understanding how mathematics teachers take advantage of teachable moments. We refer to these moments as **M**athematically significant pedagogical **O**pportunities to build on **S**tudent **T**hinking (MOSTs) (Leatham et al, 2015). Taking full advantage of MOSTs, what we refer to as the teaching practice of *building on a MOST* (or just *building*), is engaging the class in making sense of the MOST to better understand the mathematics of the MOST. As described elsewhere (Van Zoest et al., 2016), building consists of four elements:

- Establish: Make the MOST a clear object.
- Grapple Toss: Offer the MOST to the class with parameters that put them in a sense- making situation.
- Conduct: Conduct a whole-class discussion in which students collaboratively make sense of the MOST.
- Make Explicit: Facilitate the extraction and articulation of the mathematics of the MOST.

As can be seen from this description of building, the original student contribution—the MOST—needs to become a clear object and remain the object of consideration by the class throughout a sense-making discussion. Thus, in our work we focus on a *public record of a student's mathematical contribution and the class discussion of that contribution* (henceforth referred to as *public record*). Because of the central role of the student contribution to building, it seems reasonable to suppose that the way the public record of that contribution is created and used could help to facilitate (or possibly end up hindering) this discussion. One reason to suspect public records are an affordance when teachers are building comes from appealing to cognitive load theory.

Cognitive load theory (Swellers, 1988; Swellers et al., 2011) is a learning and instructional theory grounded on two types of memory —*long term* and *working*. Long term memory is the structure that serves as a person's permanent storage of information and is potentially unlimited in capacity. Working memory is the structure that processes incoming information in conjunction with information drawn from long-term memory. Working memory is very limited in capacity with regard to the amount of information processed and the duration that the information is held.

Given these limitations, learning and instruction impose *cognitive loads* of varying degrees on working memory. *Intrinsic load* is the load imposed by the basic structure of the information that is germane to learning. The other load is an *extraneous load* that is imposed by the instructional materials and activities in which the learner engages with the information. Since the extraneous load is not germane to learning and is typically under the control of a teacher, a goal of instructional design is to reduce the extraneous cognitive load so that a greater percentage of working memory resources can handle the intrinsic load. Extraneous load can occur when students try to hold information from one source while searching for and processing information from a separate source (Swellers et al., 2011). Teachers can help reduce the cognitive load by integrating the separate sources of information when the information needs to be considered simultaneously (Swellers et al., 2011). Additionally, researchers (e.g., Mousavi et al., 1995) have found that when a visual display is paired with speech during instruction, cognitive load can be reduced for students by drawing their attention to relevant pieces of the display that coordinate with referents in speech. Teacher use of public records has the potential to reduce extraneous load in such ways during whole-class sense making discussions, which would allow a greater percentage of working memory resources to be devoted to the intrinsic load imposed by the sense making activity.

In this paper, we address the following research question: How can teachers use public records of a MOST and of the subsequent discussion surrounding the MOST to support elements of the teaching practice of building on MOSTs?

Methods

This study is part of a larger project that included a data set of video-recordings of mathematics lessons from 6-12th grade teacher-researchers who endeavored to enact the teaching practice of building. The participants were selected because they expressed an interest in and a desire to know more about the productive use of student mathematical thinking. After receiving professional development related to building, the participants used mini-tasks designed to elicit anticipated MOSTs and then built on those MOSTs. For this study, we analyzed 27 lessons where a public record was used as part of the building practice.

We identified each time a public record was created in each lesson and then made note of whenever a change was made to the public record (e.g., an idea was added, circled, erased, etc). We refer to this creating and editing as *manipulating* the public record. After tracking how public records changed, we identified each instance of a teacher *referencing* the public record by identifying physical and verbal actions related to or directed at the public record. Physical actions include specific and general gestures that draw attention to parts of or the whole public record. Verbal actions include speech that draws attention to the public record in some way or implies the use or discussion of what was captured on the public record. Physical actions were captured using codes that determined whether gestures or looks were towards specific or general parts of the public record; codes for verbal actions included naming, pronoun, and repeat. Each enactment was coded individually by at least three researchers and then collaboratively reconciled.

Finally, we examined the collections of manipulating and referencing codes across enactments for each building practice element (Establish, Grapple Toss, Conduct, Make Explicit). Specifically, our analysis aimed at describing ways the teachers' use of public records appeared to support or inhibit the use of student thinking within each element of building. This study can thus best be characterized as theorizing grounded in data.

Results

These results are organized by building element and describe the primary ways that teachers' manipulating or referencing of public records support the practice of building on MOSTs.

Using a Public Record to Support the Establish Element of Building

During the Establish element of building a teacher establishes (a) the precision of the MOST, ensuring that the MOST is clear enough for the class to engage with it; (b) the MOST as an object that can be identifiable throughout the sense making discussion; and (c) that the students have an intellectual need to engage with the MOST. (See Van Zoest et al., 2022 for further details about Establish and the other elements of building.) As described below, manipulating the public record has substantial potential to support establishing the precision of the MOST.

Manipulating the public record. In order to build on a MOST, a teacher first needs to create a foundation for a sense making discussion; creating a public record that clearly and completely captures the MOST helps to create this foundation. A teacher's honing of a student's contribution is important for creating a clear and complete public record. One form of honing is the teacher's use of symbols to represent connections students are making among mathematical ideas, such as drawing arrows that indicate a relationship among two entities rather than a written description of the relationship. Another form of honing involves a teacher capturing the essence of a student contribution while not recording it word-for-word, leaving off extraneous information or extra verbiage. Honing may help decrease cognitive load for students, as they would not have to attend to a word-for-word re-presentation of the student's contribution and try to carry out this honing themselves. Additionally, the public record needs to be created on the board space in a location that is visible for all to see, clearly separated from other information with room for additions, and that will not need to be removed as the discussion progresses since we want the MOST to be the object of the discussion. In each case, these manipulating actions support the work of establishing the MOST in preparation for the next element of building—Grapple Toss.

Referencing the public record. While referencing was not a primary use of the public record during Establish, our analysis did reveal some ways referencing may support this element of building. Teachers verbally referencing the public record with a name or label (e.g., this claim, this argument) contributes to making the MOST an object, because the name or label gives the MOST an identity that can be referenced in the public record throughout the discussion. Providing the MOST such an identity during the Establish element reduces the extraneous load for students during later elements of building because they need only remember the name or label and the location of the MOST in the public record as opposed to remembering the entire MOST throughout the discussion. Also, teachers often pointed at specific pieces of the public record as they wrote in order to confirm that what they were writing aligned with a student's thinking.

Using a Public Record to Support the Grapple Toss Element of Building

There are two critical aspects to the Grapple Toss element of building: a clearly established object that is offered to the class (the established MOST), and an action (on that object) that puts the students into a sense-making situation. As described below, referencing the public record has the potential to help students attend to both of these aspects.

Manipulating the public record. A major goal of manipulating the public record during the Establish element is to allow teachers to avoid most manipulation during the Grapple Toss element. That said, a subtle way manipulating can help emphasize the MOST as an object during Grapple Toss is a teacher circling, drawing a box, or underlining the MOST in the public record

The teachers emphasizing the MOST in such a way can serve as a permanent gesture, similar to referencing.

Referencing the public record. A teacher's referencing of the public record during a Grapple Toss orients students to the details of the established object without the teacher having to repeat or revoice the MOST in its entirety. For example, a teacher could ask, "I want you to think about what Elisa has said. What do you find mathematically compelling or conflicting about this claim? *[pointing to a public record of the established MOST]*." Because the MOST is captured in the public record, the object can be referred to succinctly with "this claim" thus allowing the emphasis to be the sense making action. Referencing the public record in this way coordinates a visual mode of communication with the auditory mode of communication, thus potentially reducing the extraneous load of attending to the details of the MOST so that working memory resources can be devoted to the sense making action in the Grapple Toss question.

Using a Public Record to Support the Conduct Element of Building

After the established MOST has been tossed to the students, a teacher conducts a discussion that engages students in making sense of the MOST. As students offer additional contributions during this discussion, a teacher puts unrelated contributions aside, establishes contributions related to the MOST, and invites students to use related contributions to further their sense making of the MOST. As described below, both manipulating and referencing the public record can support these aspects of the Conduct element of building.

Manipulating the public record. As students offer their contributions during a discussion, the teacher may add other contributions related to the original contribution, the MOST, to the public record. When adding these related contributions, a teacher needs to attend to similar actions to those described in the Establish section above. In addition, teachers should consider the organization among contributions. This organization helps to support students in making connections between the new contribution and previous contributions. Parallelism, placement, and particularization are three important considerations for this public record organization. *Parallelism* (similar structuring) among the contributions may help the class make connections between those contributions. For example, the public record in Figure 1a has a variety of symbols and structure for the calculations that may lead to difficulties when comparing. By contrast, each student contribution in Figure 1b has been structured in the same way, potentially scaffolding student attention to their similarities and differences. The *placement* of additional contributions in relation to the original contribution can also support comparisons between contributions. For example, in Figure 1a it would likely take some effort for students to identify which of the contributions align with the MOST and which contributions do not. In Figure 1b, the contribution that agreed with the original MOST was vertically aligned below the MOST in a column on the left, while contradictory contributions were placed together in a column on the right. Teachers also may consider *particularizing* the contributions (e.g., drawing lines, using specific colors, assigning labels) to help distinguish the contributions. For example, in Figure 1a, it is difficult to identify when one contribution ends and another begins. However, in Figure 1b, each student's contribution is color coded differently, and each column of contributions is labeled with a "yes" or "no" so that students understand which contributions support or contradict the original. Also, within each contribution the initial and final prices are underlined to highlight the comparison each individual student's contribution is making. A well organized public record that addresses these considerations has the potential to reduce the extraneous cognitive load for students by integrating and aligning objects so that students' working memory resources can be allocated to processes germane to sense-making.

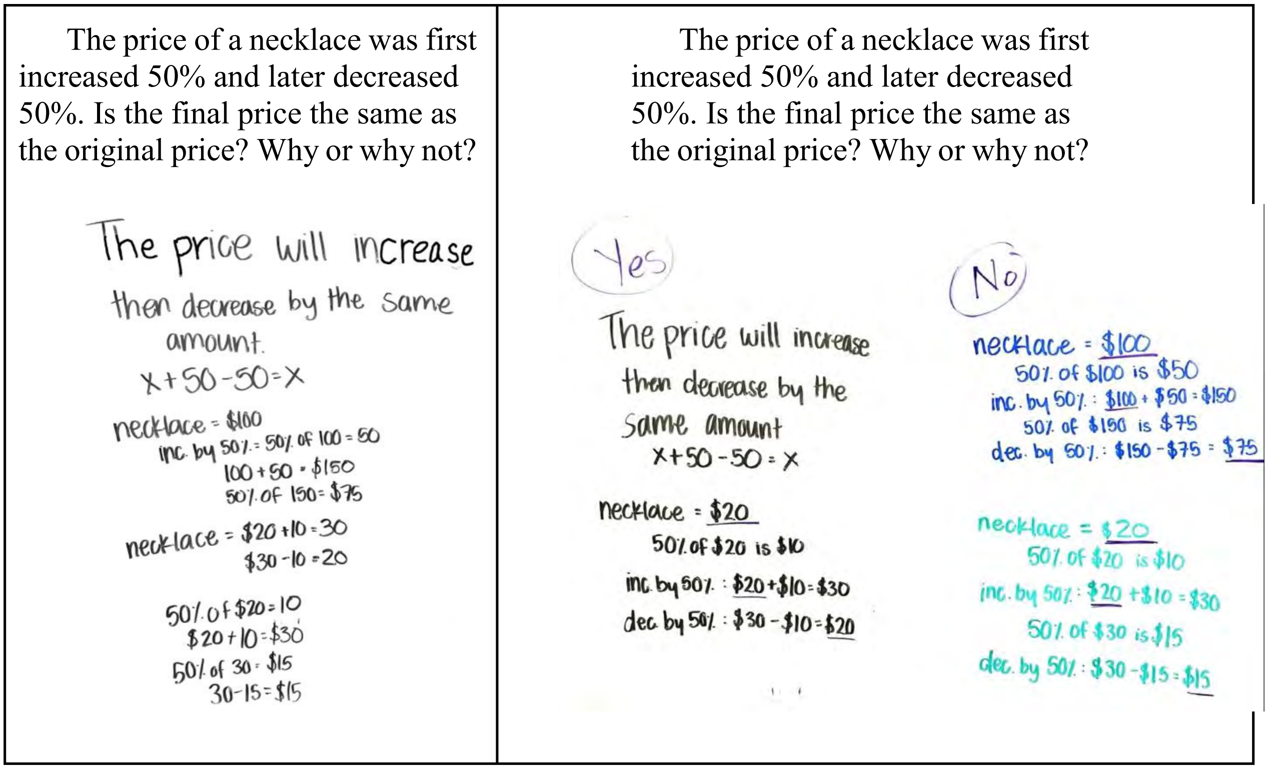

Figure 1: Public Record of MOST and Related Contributions During Conduct

Referencing the public record. One important part of conducting a sense-making discussion surrounding a MOST involves helping students to connect related student contributions (that have been established) to the MOST. Hence, a connecting move requires that both the MOST and a related student contribution be established as the object of the move. In addition, the move requires an action describing or requesting the nature of the connection that students are to make. Similar to referencing the public record during Grapple Toss, referencing to support connecting gives the action more prominence in the teacher's speech. However, because a teacher needs to reference two contributions in the public record, specific pointing gestures or verbal cues corresponding with the MOST and the related contribution become important, particularly because the public record may contain more information than these two contributions. For example, a teacher who asks, "How do you reconcile these two statements?" could use pointing gestures to make clear the objects in the public record that the class needs to reconcile. Differently, a teacher who asks, "How does this claim disprove Jaden's conjecture?" could use a pointing gesture to identify "this claim" in the public record, but the verbal naming "Jaden's conjecture" to identify the second contribution. This type of referencing reduces the cognitive load for students by clarifying the ambiguity of the referent for "this claim" and allowing the main focus to be on the requested reconcile action.

Another important part of using MOST related contributions is summarizing several established contributions so that they can be considered concurrently (i.e., synthesizing). A teacher's referencing supports the synthesis of student contributions to be connected by re-presenting the details of the contributions and helping students track those contributions in the public record. The public record provides permanence for student contributions so that teachers can use pointing gestures to support the class with attending to the details of multiple contributions. Supplementing speech with the use of the public record helps reduce the cognitive load of processing the sometimes lengthy details of contributions. Additionally, specific pointing gestures can clarify what piece of the public record corresponds with the teacher's speech. Such gestures reduce the cognitive load for students as they are directed to a specific piece of the public record and do not have to visually search for it on their own.

If a student shares a contribution during a discussion that is not related to the MOST, referencing the public record can help recenter the MOST as the focus of the discussion. In our research, we often found students responding to a Grapple Toss question with their own solutions to a task or their ways of thinking about an idea that was unrelated to or far from the focus of the MOST. Teachers can refocus students by gesturing at the MOST in the public record and telling students to focus on this idea, or referencing the MOST by its name while asking a student how their contribution is related to the MOST. Alternatively, teachers can use the same physical and verbal referencing of the MOST in the public record while reminding the class that the discussion is currently about making sense of the MOST.

Using the Public Record to Support the Make Explicit Element of Building

In the final element of building the teacher ensures that (a) the class agrees that the issue related to the MOST has been resolved, and (b) the mathematics of the MOST—the mathematical ideas that have emerged from making sense of the MOST—is explicitly articulated. We describe below how referencing can support resolving the MOST.

Manipulating the public record. In our data, teachers often did not manipulate the public record during Make Explicit since the ideas they wanted to discuss were already established, and connections and resolutions were made explicit throughout the discussion. However, we did see some manipulating that seemed to support Make Explicit. Editing the originally established MOST may further support students understanding the resolution of the MOST. Also, capturing the mathematics of the MOST succinctly may be important if the ideas will be used beyond the discussion of the MOST.

Referencing the public record. A teacher may reference the public record to emphasize the MOST as the object of a check-in question similar to the way referencing was used during Grapple Toss and Connect. For example, a teacher may ask, "Given our discussion for the past few minutes, how are you all thinking about our original argument? [gestures to the established MOST]." Another way a teacher may use referencing during Make Explicit is pointing to pieces of the public record that orient students to the details of ideas and connections said throughout the discussion that contribute to resolving the MOST.

Discussion and Conclusion

We reported the primary ways that a teacher's manipulating and referencing actions have the potential to support a teacher's productive use of student mathematical thinking when enacting the teaching practice of building on MOSTs. We begin the discussion by comparing and contrasting how manipulating and referencing actions play out across the four elements of building and conclude by reflecting on how these findings relate to the literature, particularly to cognitive load theory.

Although we described ways manipulating can support all elements of building, we see manipulating having a primary role during Establish and Conduct to provide permanence to student thinking shared in discussions. Manipulating that highlights pieces of the public record may occur during Grapple Toss or Make Explicit, but would be minimal as compared to altering contributions that would leave objects in the public record less clear for students. With respect to referencing, the combination and specificity of referencing actions often contributed to the extent to which these actions supported or hindered the building practice. Teachers clearly drew attention to particular contributions in the public record during Conduct with specific pointing gestures or using locator words (e.g., the upper right argument in blue). However, when teachers used vague pronouns (e.g., this calculation, that number) without pointing gestures to reference to a piece of a public record during conduct, the referent for the pronouns would likely be unknown for students.

There are at least two ways that teacher use of public records has the potential to reduce extraneous cognitive load imposed by split sources of information (Sweller et al., 2011) that inevitably occurs as a teacher builds on a MOST. First, sense making discussions require students to attend to a variety of information that is shared at different points in time and by different members of the class. Displaying (manipulating) the information in the public record can reduce the extraneous load imposed by having to remember the MOST and MOST-related contributions for the length of the discussion. Second, the public record may serve to reduce the extraneous load of attending to or searching for objects in the teacher's speech. During building, a teacher requests or positions students to engage in sense making actions with the MOST and MOST-related contributions. The teacher can reference these objects in the public record as opposed to revoicing or repeating them in their entirety, which has the potential to allow a greater percentage of working memory resources to be devoted to the load that is germane to the sense making of the mathematics of the MOST.

Our findings as to how manipulating and referencing can support elements of building extends the work of others investigating teacher use of student thinking to lead meaningful whole class discussions. Placement, parallelism, and particularization provide considerations for teachers manipulating and structuring public records that clearly and completely display student thinking during a sense-making discussion. These considerations offer insight as to how public records can be used to establish common ground, which is important for sustaining continuity of discussions on student thinking (Staples, 2007). During Grapple Toss, Conduct, and Make Explicit, referencing the public record can help support students' engagement with the details of each other's contributions. Referencing the public record in a Grapple Toss question or a request to connect ideas during Conduct can orient students to the specific objects with which they are to engage in sense making actions. This referencing provides insight into how teachers can use the public record as a resource to help students engage with the details of each other's thinking during whole class discussions, which can be key for students' mathematical learning (Webb et al., 2014).

COLLEGE INSTRUCTORS' PERCEPTIONS OF BARRIERS & DRIVERS THAT IMPACT THE IMPLEMENTATION OF ACTIVE LEARNING

Jessica Gehrtz	Stephen Lee	Priya V. Prasad
UT San Antonio	UT San Antonio	UT San Antonio
Jessica.Gehrtz@utsa.edu	Stephen.Lee@utsa.edu	Priya.Prasad@utsa.edu

College mathematics instruction that leverages evidence-based instructional practices, such as productive group work, can lead to many positive outcomes for students. In order to support instructors in adopting more evidence-based instructional practices, it is important to understand what barriers and drivers can impact their decision to implement such practices. In this study, we interviewed four introductory mathematics instructors teaching the same course in order to understand, in context, what aspects served as barriers and drivers. Transcripts were analyzed using thematic analysis. Initial results highlight how course coordination and weekly project meetings served as drivers, and the impact of the pandemic was seen as both a driver and a barrier to implementing evidence-based instructional practices.

Keywords: Instructional Activities & Practices, Undergraduate Education, Faculty Perceptions

Instruction that actively engages students in their learning has been shown to have many positive outcomes for students. Specifically, research at the college level has revealed that this type of instruction can increase student learning and students' conceptual understandings, as well as reduce achievement gaps (e.g., Freeman et al., 2014; Kogan & Laursen, 2014; Theobald et al., 2020). As such, there have been numerous calls to increase student engagement in college mathematics classrooms (CBMS, 2016; PCAST, 2012). Yet, didactic lecture still remains the most prominent form of instruction (Stains et al., 2018). To support college instructors in adopting more evidence-based instructional practices (EBIPs) that actively engage students, it is important to understand, both locally and globally, what barriers might be getting in the way of instructors' implementation of these strategies. It is also important to understand what drivers, aspects that mitigate barriers, foster instructional change and the adoption of EBIPs.

Previous research has examined various aspects that can impact an instructor's decision to implement EBIPs (e.g., Apkarian et al., 2021; Henderson & Dancy, 2007; Shadle et al., 2017). Although this work has helped to identify barriers, drivers, and individual or situational characteristics that may come into play, more work needs to be done to understand how institutions, departments, and individual mathematics educators can encourage the adoption of EBIPs by college mathematics instructors. Further, in order to foster instructional change locally, by mitigating barriers and leveraging drivers that have the most impact, it may be important to examine instructors' thinking about EBIPs at one's local institution (Henderson et al., 2011). As such, our work seeks to understand how college instructors at one institution think about the implementation of EBIPs in their classes. Specifically, we aim to answer the research question: What do college mathematics instructors consider to be barriers and drivers for implementing practices that engage students in active learning in their teaching?

Theoretical Framework Guiding Our Research

We examine our research question in the context of a larger project focused on transforming the teaching of introductory mathematics at one institution. The theoretical underpinning of this project is the Ethic of Practicality proposed by Doyle and Ponder (1977). This framework describes instructional change as a matter of how practical instructors find the proposed changes.

The Ethic of Practicality consists of three components: (1) *congruence* (compatibility with the instructor's classroom, setting, and instructional goals), (2) *instrumentality* (clearly articulated procedures for ease of implementation in the instructor's classroom), and (3) *cost* (potential benefits outweigh the effort and other costs of implementation). Motivated by this framing, we structured the project to maximize congruence and instrumentality and minimize cost for instructors. Specifically, instructor-participants were given a course release to make time for participation in the project, and the facilitators guided participants in implementing the Continuous Improvement (CI) model for instructional improvement (Berk & Hiebert, 2009), in a manner reminiscent of lesson study cycles (Dick et al., 2022). In CI, participants identify two or three different mathematical concepts and implemented the following cycle each semester: (1) design a task that targets a particular mathematical concept; (2) develop hypotheses about anticipated student responses; (3) collect data in the form of student work and classroom recordings, then analyze the data for evidence of the desired student learning outcomes; and (4) reflect on their own and their colleagues' instructional decisions in the implementation of the task, and revise the task as appropriate. In this way, instructors retain control of the congruence and instrumentality of the resources and materials that they themselves produce.

Methods

Participants were four fixed-term faculty teaching an introductory mathematics course at the same institution. Two participants, Shay and Nicholas (pseudonyms), were experienced instructors who had taught the course multiple times and served as course coordinators, and two participants, Alex and Ivy, were in their first semester teaching the course at this institution.

For this proposal, we focus on data collected in a 60-minute semi-structured interview with each of the instructors during the first semester of this larger project on instructional improvement. The interview protocol included questions to elicit details about each instructor's experience teaching, what a typical class period looked like, how their instruction has changed over time (if at all), and what factors supported or hindered them in implementing EBIPs (e.g., active learning activities). Interviews were transcribed verbatim. To answer our research question, we used thematic analysis of the transcripts to identify instructor reported barriers and drivers to implementing EBIPs (Braun & Clarke, 2006). We coded segments from the interviews, using the 18 barriers (e.g., Time Constraints) and 15 drivers (e.g., Aligns with existing resources) identified by Shadle et al. (2017) as a priori codes. We then created additional codes when instructors described barriers or drivers that were not represented in Shadle et al.'s (2017) findings.

Results

In this section, we describe two drivers, course coordination and weekly CI project meetings, that impacted all four participants decisions to implement EBIPs. We also discuss the impact of the COVID-19 pandemic, which was identified by participants as both a barrier and a driver to implementing EBIPs. In our talk, we will share additional barriers and drivers that arose in our data, including those that align with Shadle et al.'s (2017) findings.

Drivers to Implementing EBIPs: Course Coordination & CI Project Meetings

Course coordination played an important role in creating an environment that fostered the implementation of EBIPs. The course coordinators (Nicholas and Shay) created the course structure, outlining activities that would be done during class and building the homework sets and lecture videos that could be used to support students' learning outside of class. Ivy discussed how she appreciated having someone with departmental and course-specific knowledge in this role, especially when there was disagreement amongst the instructors. She said:

> So having somebody there that I know has the broader perspective … You've got to have somebody that's taking that leadership role and putting stuff into practice and saying this is the way it's going to be. But they have been extremely open with input.

Ivy also emphasized, in this quote and throughout the interview, that she appreciated how the coordinators took instructors' ideas as input when making decisions that impacted the entire instructional team.

All four instructors also emphasized that the resources that were created and made available as part of the course coordination contributed to their decision to implement more EBIPs in their teaching, which was also identified as a driver in Shadle et al.'s (2017) work (i.e., Aligns with Existing Resources). Ivy emphasized how these available resources prompted her to incorporate activities she had never quite been comfortable with implementing before. She said,

> I've got all these resources. My experience was lecture, and now I get to try the things I've always wanted to try. So I'm loving it. I love the activities. And I'll be honest, at the start of the semester I was like, 'Oh, we're going to do this now?' Because I didn't know how powerful it was. … It's just cool to see everything that we can do with [the activities], and it really helps the students understand.

These resources were initially created by the course coordinators, but as the semester progressed, other instructors began to add to this shared repository of course resources.

Weekly project meetings, which focused on developing materials as part of the CI cycle, also served as a driver for instructor implementation of EBIPs. These meetings created time and space for instructors to talk about best practices and pedagogy as they developed class activities. Notably, these meetings were separate from course coordination meetings (where the focus was primarily on logistics such as upcoming assessments, content, or due dates). All instructors shared how these weekly meetings were important for developing and implementing activities that centered student thinking, with the meetings also serving as a space for collaboration and as a form of accountability to ensure progress on shared objectives. Nicholas said,

> I think a lot of it's the kind of dedicated collaboration time. … It's kind of nice to just sit around for an hour and be like, 'What do you think about this? And how would you approach this? And how would you do that?'

Additionally, these weekly project meetings also created space for the facilitators to share related educational research as the instructors expressed an interest in learning more about EBIPs. As such, opportunities for professional development arose organically during these meetings.

COVID-19: Both a Barrier and Driver to Implementing EBIPs

Instructors discussed the impact of the COVID-19 pandemic both as a barrier and as a driver for implementing more EBIPs in their classes. On one hand, Shay described COVID as a driver because it challenged instructors to think carefully about how they were presenting material when the course modality shifted to online. Shay said,

> The idea that COVID kind of opened your [eyes] - you have to look for other ways to be able to present material to them. And so, oh! We'll make these videos. … Why can't we just make the video and they can watch it on their own time, and then come in and then do this

> [activity]? … I want them to - instead of just sitting there blankly looking at me while I'm talking - being able to interact.

This quote highlights the way that the pandemic enabled her to try new things in her class because she realized that she could create videos covering the content she would normally lecture on for students to watch on their own time. This freed up time during class for students to engage in activities and interact with one another.

Another instructor, Alex, pointed to how the COVID-19 pandemic was a barrier for him incorporating more EBIPs. He described how it was challenging to facilitate student discussions in breakout rooms on Zoom because he could not listen in on student discussions as easily. He felt as if there was not the same collaboration and excitement that happens in the classroom when one can hear other groups discussing and laughing together during student work time. Even when courses shifted back to being in-person, the pandemic continued to impact student interactions. Alex said:

> But on the very first day [of being back in person], some students are acting like everything's normal and sitting together, but others are sitting really far away, wearing their masks. And I'm not going to tell them [to get into a group]. … So that's brought me to where I'm a little bit less sure about how it can operate right now.

Discussion

In this study, instructors identified many of the same barriers to implementing EBIPs that were reported by Shadle et al. (2017). However, most of the drivers that were identified in our work differed from those raised in that study. This could be because Shadle et al. (2017) focused on faculty's perceptions of what "will help make change occur" (p. 10), whereas our study sought instructors' reflections as they were in the midst of a project designed to promote instructional change. Nonetheless, we do see some alignment between the drivers identified in both studies. Specifically, we see the drivers of course coordination and the weekly CI project meetings as aligning with the driver "Encourages collaboration and shared objectives" identified by Shadle et al. Critically, Shadle et al. describe this driver as an outcome of "increased emphasis on teaching and student success" (2017, p. 6), whereas in our work course coordination actually served to enable instructors in their adoption of EBIPs. Other recent research has also highlighted the important role course coordinators can play as change agents and drivers for instructional change (Williams et al., 2021). Two years before the start of this project, the mathematics department had embarked on a campaign for improved coordination and alignment across multi-section courses. This required instructors to meet and discuss their goals for and their teaching of the course, increasing collaboration. Then when course coordinators started experimenting with incorporating active learning in their own teaching, this led to the creation of a course structure that fostered the inclusion of more EBIPs.

As shown by the preliminary results of this study, the disruptions to university teaching that resulted from the COVID-19 pandemic complicated instructors' use of EBIPs in the expected ways (e.g. complicating the use of small-group work when social distancing was also encouraged during in-person classes), but they also provided instructors with opportunities to rethink their beliefs about their role in the classroom. As this project progresses, we anticipate that instructors will continue to interrogate their previous assumptions about mathematics teaching and learning.

This study shares two frameworks for analyzing teacher actions that support students in generalizing and examines how those frameworks align with teacher questioning. One classroom teaching episode focused on the mathematical activity of generalizing is shared to illustrate effective generalizing promoting practices. We found several patterns of productive and unproductive generalizing promoting actions and questioning. Repeating generalizing promoting actions in succession were needed to produce student generalizations. Priming actions that set up for later generalizing promoting were helpful when students struggled to identify and state generalizations. Connection questions promoted generalizing, but justification and concept questions did not. Further research will explore the additional strategies to support teachers in fostering student-created generalizations.

Keywords: Instructional Activities and Practices, Classroom Discourse, Algebra and Algebraic Thinking

The mathematical practice of generalizing, identifying a relationship to describe multiple examples or instances of a phenomenon, is fundamental to learning in mathematics (Carraher & Schliemann, 2002; Kaput, 1999) and engages students in algebraic thinking (Blanton et al. 2011; Kieran et al. 2016), which requires students identify, investigate, and represent relationships. Understanding how to support students in developing, articulating, and refining generalizations is critical to mathematics teaching and learning. Teacher questioning plays a pivotal role in fostering students' generalizations, especially when students' reasoning does not lead to formal general statements (Radford, 2010). However, research on teacher questioning and generalizing remains distinct. This study is aimed at better understanding the relationship between teacher questioning and students generalizing. We describe our questioning framework and its relationship to two frameworks for analyzing actions to promote generalizing. We address how a high school mathematics teacher's questioning aligns with her actions to foster students generalizing and describe the patterns in student-teacher interactions that promoted student-created generalizations.

Literature

Generalizing skills contribute to algebraic understanding (Carpenter & Franke, 2001) and are identified as a key mathematical practice across all math content domains in the Common Core State Standards (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Here, we adopt Kaput's (1999) definition of generalization as "lifting" and communicating reasoning to a level where the focus is no longer on a particular instance but rather on patterns and relationships of those instances. A formal generalization is the product of the mental activity of generalizing (Font & Contreras, 2008). In generalizing students must recognize quantities that vary and remain constant and represent these relationships using symbols or words. When students move to generalizing symbolically without having adequate time to understand and reason about quantities and their relationships in a variety of contexts beforehand, they can become dependent on procedures (Kieran, 2007). Teachers value, and thus place an instructional focus on, formal algebra such as symbols, notations, and procedures (Nathan & Koedinger, 2000). A focus on procedural approaches to algebra can obscure attention to engaging students in mathematical practices such as generalizing that build a conceptual understanding of mathematics. Given student difficulties in generalizing (e.g., Blanton & Kaput, 2002; Lannin, 2005; Lee & Wheeler, 1987; Stacey, 1989; Stacey & MacGregor, 1997), students' failure to justify generalizations (Breiteig & Grevholm 2006), and secondary math teachers' challenges in responding productively to student generalizations (Demonty et al., 2018), determining what instructional actions promote generalizing activities is warranted.

Ellis (2007) proposed an actor-oriented generalization taxonomy that consists of generalizing actions, which include students' activities while generalizing and their statements of generalization. To better understand the classroom interactions and discourse that promote generalizing actions, we use a modified version (Strachota, 2020) of Ellis' (2011) generalizing-promoting actions (GPAs) and Strachota's (2020) priming actions (PAs). Priming actions set the stage for more explicit attention to generalizing; they prepare students to build on an idea or refer to an idea later. Generalizing promoting actions, on the other hand, prompt immediate activities that have the potential to produce generalizations. Priming can include making the critical ideas of an individual public to the work of the class, making evident tools needed for generalizing, asking students to consider ideas or examine specific key examples, or setting up to extend an idea later. For example, a teacher who introduces *x* to represent a varying quantity in a pattern or who displays similar expressions for comparison is using a priming action, *reviewing a critical tool* and *constructing searchable and related situations*, respectively. Generalizing promoting requires students to identify a relationship, state a generalization, extend beyond cases available to them, or justify a general statement. For example, prompting students to describe a pattern algebraically is a generalizing promoting action that *encourages reflection*. Table 1 illustrate the codes we used for priming and generalizing promoting actions (Ellis, 2011; Strachota, 2020).

Table 1: Priming Actions and Generalizing-Promoting Actions

Priming Actions (PAs)[1]	
Naming a phenomenon, clarifying critical terms and tools	"Offering a common way to reference a phenomenon or emphasizing the meaning of a critical term or tool."
Constructing or encouraging constructing searchable and relatable situations	"Creating or identifying situations or objects that can be used for searching or relating. Situations that can be used for searching or relating involve particular instances or objects that students can identify as similar."
Constructing extendable situations	"Identifying situations or objects that can be used for extending. Extending involves applying a phenomenon to a larger range of cases than from which it originated."
Generalizing-Promoting Actions (GPAs)[2]	
Encouraging relating and searching	"Prompting the formation of an association between two or more entities; prompting the search for a pattern or stable relationship."

Encouraging Extending	"Prompting the expansion beyond the case at hand."
Encouraging Reflection	"Prompting the creation of a verbal or algebraic description of a pattern, rule, or phenomenon."
Encouraging Justification	"Encouraging a student to reflect more deeply on a generalization or an idea by requesting an explanation or a justification. Includes asking students to clarify a generalization, describe its origins, or explain why it makes sense."

[1]These categories and descriptions are from Strachota (2020, p. 7).
[2]These categories and descriptions are from Ellis (2011, p. 316). We adapted encouraging relating and searching, following Strachota (2020), by combining these into one category.

Teachers often struggle with asking 'good' questions that are cognitively demanding, involve higher-order thinking, and follow up on student input and explanations (Boaler & Brodie, 2004; Franke et al., 2009). In addition to asking good questions, teachers must be able to effectively interpret and make sense of students' questions during class to use student thinking to move the mathematics of a lesson forward (Hufferd-Ackles et al., 2004). The follow-up questions teachers ask after hearing student thinking are of critical importance. Franke et al. (2009) found that students benefited most when teachers asked a probing sequence of specific questions. This process of probing helped teachers better understand student thinking, helped the students who were responding to teacher questions to solidify their ideas and thinking, and helped other students connect ideas to their own thinking and address misconceptions. When a teacher asked only one question, they were often not able to obtain enough information to understand the student's thinking. Boaler and Brodie (2004) concluded that it is important for teachers to ask higher-order types of questions, so students have more opportunities to engage meaningfully with mathematics in ways that go beyond performing procedures. The finalized questioning framework used in this study is based on Boaler and Brodie (2004), Hallman-Thrasher & Spangler (2020), and Chen (2021) shown in Table 2 and described in the methods section.

Table 2: Question Types to Support Generalizing

Definition of Question Type	Example
Rhetorical	
Does not generate responses (teacher answers them or does not provide time for students to answer)	"Everyone else get that? Yeah? Ok."
Gathering Information	
Requires only a single short answer	"How many flowers are in step 5?"
Concept	
Attends students to underlying mathematical relationships and meanings	(No example from data)
Strategy	
Elicits descriptions of students' strategies, solutions, or procedures	"Do you want to come up here and show how you got that?"
Clarification	
Clarifies student input that has been shared or is known	"So, these would be the step numbers?"
Connection	
Seeks a connection across ideas, representations, or strategies	"Which part [of the picture] would be x?"

Justification	
Defends the appropriateness of a particular strategy, augmenting with connections that validate reasoning.	"Why does this [expression] not work [for other cases]?"
Extending Thinking	
Extends to examples beyond what is available or to examples where similar ideas could be used	"What about the 10th step?"

Adapted from Boaler and Brodie (2004) and Chen (2021).

Methods

The participant for this study was Ms. Patton, a teacher candidate enrolled in a one-year master's program with licensure for individuals with STEM degrees. She had earned an undergraduate degree in mathematics the previous year. At the time of data collection, she was in the Fall semester of a year-long teaching placement in an Algebra II classroom and enrolled in her only mathematics teaching methods course. In this lesson, Ms. Patton was supported by Mr. Dayton, her experienced mentor teacher. For this study, Ms. Patton planned, taught, and reflected on her video data from two episodes of teaching a pattern task with grades 9-10 students as part of an assignment for her mathematics teaching methods course. By pattern task we mean, a visual representation of objects that grows over instances of time (Figure 1). The data analyzed for this paper is the video recording of Ms. Patton's teaching where the most student-created generalizations were shared. In methods class, Ms. Patton first engaged in completing pattern tasks as a learner and analyzing videos of other teachers using pattern tasks. We carefully structured her planning for this task to attend to teacher questioning to elicit, understand, and make connections to student thinking.

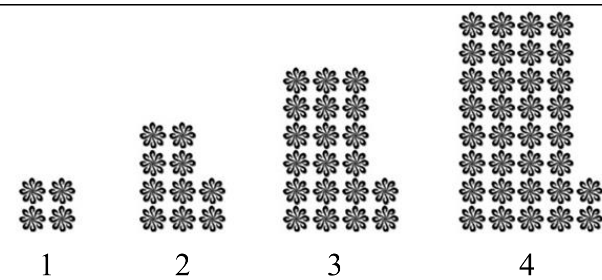

Figure 1. Ms. Patton's Pattern Task (Nguyen, 2020).

For our initial analysis, we coded the video data of teaching in 15-second segments using two established frameworks for generalizing (Table 1, Ellis, 2011; Strachota, 2020). Next, to capture teacher moves we modified Boaler and Brodie's (2004) question types. The question types (Boaler & Brodie, 2004) did not align well with the specific nature of supporting students in the creation of generalizations. Not all of the question types were applicable for this study and some were not sufficiently specific. None of the lessons we reviewed involved linking to concepts outside of mathematics so "linking and applying" and "establishing context" questions were not used. The "orienting and focusing" questions were not adequately specific, so we defined other categories that helped us classify the strategies a teacher would use to orient or focus (e.g., clarifying or justifying questions). "Probing" questions did not describe all the different ways a teacher might follow up on student thinking. We drew on Hallman-Thrasher & Spangler's (2020) broad categories of questions to develop a more comprehensive list which we compared against Chen (2021) to search for overlaps, gaps, and types needing more or less specificity. For example, Chen's (2021) "elicit thinking questions" were broken into strategy and concept questions in a new framework (Table 2). To establish a more descriptive framework specific to the evaluation of questioning that supports generalization, we also used thematic coding (Saldana, 2013) to identify questioning types not addressed by our existing frameworks. We defined a new question type "rhetorical" for questions that did not require a response or served as a means to garner attention to a thought, such as, "Does that make sense to everybody?" We also carefully considered what counted as a question: statements that functioned a question (e.g., "Find all the expressions you can for step 5") counted as questions, as did the questions that were not answered or were not intended to be answered (e.g., "You said that was *x*, right?"). To more closely examine the nuanced turns in conversation, we re-coded the data line-by-line for generalizing promoting actions, priming actions, student generalizations, and questioning with our revised framework for questioning. Interrater reliability was established by having all four researchers review and code all data. When disagreements arose, we discussed them using the frameworks to reach consensus (Syed & Nelson, 2015).

To better understand how the conversation developed over the course of the lesson, we divided the 45-minute lesson transcript into 13 blocks with each block representing a different instructional goal (e.g., launching the task, generating expressions for a particular step, applying a numeric expression for one step to a different step). We identified which blocks of conversation were productive for producing student generalizations. We wrote a description for each block and examined it in order to isolate characteristics of instruction that supported generalizing. We examined the coded data to identify patterns that signaled productive and unproductive questioning strategies and teacher moves to develop students' generalizations.

Results

We focus our results on Ms. Patton's most productive lesson; the one that included the most student-created generalizations. From our blocked classroom interactions, those producing at least one student generalization were identified as productive. Blocks that did not produce a student generalization were considered either missed opportunities for having had the potential to produce a student-created generalization or unrelated when the purpose of the interaction was not directly related to generalizing (e.g., clarifying directions, checking in with a small group). Students shared 13 generalizations spread over 7 productive blocks. Three blocks were unrelated to generalizing and three blocks were missed opportunities for generalizing. Table 3 shows which questioning types were used with priming actions (PAs) and generalizing promoting actions (GPAs). Ms. Patton relied primarily on connection, clarification, and extending thinking questions to develop generalizing actions. Two PAs did not involve questioning and eight GPAs did not involve questioning. Priming was associated with gathering information, clarification, strategy, and connection questions, whereas generalizing promoting incorporated all question types, relying most heavily on connection and extending thinking questions.

Particular types of questioning were more or less helpful for engaging students in conversations related to generalizing. Ms. Patton's use of connection, clarification, and rhetorical questions exceeded all other questioning types. She repeatedly used connection questions when encouraging students to relate between figural and algebraic representations of the pattern. When she asked, "Which part [of the picture] would be *x*?" her focus on a specific part of an expression prompted students to discover that the width of the large rectangle was the same as the step number. All of the connection questions she posed, were priming or generalizing promoting.

Ms. Patton used clarifying questions to have students further explain terminology or ideas and in doing so students revised an idea or stated it more precisely. For example, in prompting students to unpack an expression related to viewing the pattern as two equal-sized squares, Ms. Patton prompted, “Now what were you saying about perfect squares?” Clarifying questions often served to provide an opportunity for students to repeat an important point to which Ms. Patton wanted the class to attend. Clarifying questions, though important to understanding student thinking, did not consistently relate to generalizing; only 8 of her 17 clarifying questions functioned as priming or generalizing promoting actions.

Table 3: Alignment of Question Types, Priming, and Generalizing-Promoting Actions

Question Types	Priming Actions	Generalizing Promoting	Total Questions
Rhetorical	---	4	10
Gathering Information	1	1	5
Strategy	3	2	7
Clarification	4	4	17
Concept	---	---	---
Justification	---	3	3
Connection	4	13	17
Extending Thinking	---	5	6

Ms. Patton used rhetorical questions to state generalizations; the four teacher-stated generalizations were shared in the form of a rhetorical question. She did not, however, provide an opportunity for students to respond to these rhetorical questions. For example, she revoiced a generalization saying, “Does everyone see how he got that? For every picture you have this two right here [the constant two flowers on the rightmost column in each image] and then across [the width of the rectangle] is just the step number plus one.” This question had the potential to ensure that all students attended to and understood a key generalization shared earlier. However, by not providing students an opportunity to agree or disagree and justify their decisions she limited students’ opportunities to actively engage with another’s ideas.

Other questioning types, while not as prevalent as connection, clarification, and rhetorical, were more consistently associated with generalizing promoting. Extending thinking and justifying questions nearly always functioned as generalizing promoting actions. Extending thinking questions and justifying questions did not immediately lead to student generalizations. They always required follow-up supporting questions. Though justifying questions were not used often, they were effective at promoting generalizations. For example, Ms. Patton asked, “Why wouldn’t it work for say step number 3?” and followed with strategy, clarification, justification, and connection questions before a student correctly generalized that an expression for the pattern in step 4 would not work for any other step of the pattern. Justification questions, while present in this lesson, were less than we might have expected and may have established a tendency not to justify claims which could have limited opportunities for students to discover, refine, and state generalizations. We also noted that Ms. Patton did not use concept questions which may have contributed to the missed opportunities for students’ generalizing. By not consistently making underlying concepts and justifications evident, Ms. Patton may have focused more on what strategies were developed and less than the underlying structure that would have supported students in making their own generalizations.

Ms. Patton often used clarification, justification, and connection questions to make students’ generalizations accessible to the whole class. In clarifying to *encourage reflection*, she revoiced a student idea and pressed for detail that prompted a student to state a generalization more precisely; in connecting she *encouraged relating and searching*. Justifying questions such as "Why wouldn't that work for step 3?' served to *encourage justification* and in response a student produced a new general statement about how the formula could not extend to all instances of the pattern. To *encourage extending*, she repeatedly asked students to consider cases beyond those shared and to apply ideas developed from one step of the pattern to earlier or later steps.

Within each productive block we looked at the sequence and density of priming and generalizing promoting actions to identify patterns of actions that were productive towards producing student-created generalizations. One productive pattern for producing student generalizations was using repeated instances of generalization promoting over a short duration. The first such productive block included three GPAs (*encouraging extending*, *encouraging extending*, *encouraging justification*) over a one-minute time span. The questioning types that were used to accomplish these actions varied. She first gathered information and extended thinking to *encourage extending*, and then followed with a strategy question to *encourage justification*. By *encouraging extending* twice with two different question types, she first elicited the information she needed to build on in order to extend and justify. A student was then able to provide a general description of the pattern's structure. Ms. Patton also used repeated GPAs to shift students' attention to articulate a complete version of their generalizations.

A second related pattern, not consistently productive, but which Ms. Patton consistently employed, was to immediately follow every student generalization with another generalizing promoting action. For example, she followed the productive block described above with another GPA to build on that student's thinking by asking the class to translate the student's description into a generalized formula. These GPAs following a student generalization were productive in developing a new generalization when they took the form of a clarifying, connection, or justification question and functioned as *encouraging reflection*, *encouraging relating and searching*, or *encouraging justifying*. They were not productive when the teacher and students focused on different perspectives. Ms. Patton used a connection question, "How could we get it to be minus 6 in terms of x?" followed by a rhetorical question, "[x] Plus 2. Will that work?.. Distribute….Not quite, right?" as generalizing promoting actions to *encourage reflection* to generalize missing flowers in terms of step number. Yet, because students did not approach the problem from a 'what's missing' perspective, they did not readily generalize this strategy.

Within blocks that we labeled a missed opportunity, we identified a third pattern. This pattern involved a failure to use priming and generalizing promoting actions together to build towards a conclusion. When an initial PA or GPA failed to produce a student generalization, Ms. Patton abandoned the line of questioning. For example, Ms. Patton asked students to apply their numeric expressions created for step 4 to the first step of the pattern. Because the general structure is not evident in the first step of the pattern, students had trouble applying their formulas and because she failed to use generalizing promoting and priming together students could not meaningfully respond to this prompt.

A fourth pattern resulted from a missed opportunity where repeated GPAs produced no student generalizations. To scaffold students' thinking, Ms. Patton employed repeated priming before returning to GPAs to produce a student generalization. For example, over a two-minute span she used nine GPAs to try to help students develop a generalization for the number of missing flowers in the rightmost column. Students were able to recognize that she was looking for the missing flowers but were unable to make any general claims about the structure of the missing flowers relative to the full picture. Ms. Patton then used PAs to *construct and search for* *relatable situations.* Aware of the “tricky” part of representing missing flowers algebraically, she primed students by asking for clarification about the missing flowers. She continued priming by noting that there were 6, then 4, then 2 missing flowers (working backwards through the steps), and primed again to prompt students about the goal “We need to have something minus 6 and we need to end up with 2*n* squared plus 2, right? Cause right now we have…” [teacher draws attention to current representation prompting students to complete her sentence]. With this groundwork laid she used GPAs of *encouraging reflection and justification* which prompted students to state incorrect generalizations of the 6 missing flowers in step 4 and then to identify that those generalizations did not work for other steps of the pattern. A student generalized why the expression did not work and then Ms. Patton again primed to build on this idea. Finally, her mentor, Mr. Dayton used a connection question as a GPA to help students notice the connection between the missing flowers and the height of the rectangle. This lengthy exchange spanned three blocks and demonstrates how Ms. Patton’s and Mr. Dayton’s repeated questioning led to student generalizations for the blank spot of missing flowers.

Conclusion

We set out to determine what teacher moves were most productive in promoting students’ generalizing through a close examination of line-by-line student-teacher interactions situated within blocks of classroom dialogue with common purposes. It is not surprising that extending thinking questions and justifying questions aligned with generalizing promoting actions of *encouraging extending* and *encouraging justification,* respectively. However, it is surprising that these actions did not consistently produce student generalizations. Other questioning types (connection, clarification, and strategy) aligned with generalizing promoting and priming actions and, when used in particular patterns of promoting and priming, did lead to student-created generalizations. Our results confirmed the benefits of using connection questions to relate visual, numerical, and algebraic representations and to help students identify and articulate generalizations. Clarifying questions often provided an opportunity for students to repeat an important point critical to precisely state a generalization. Results also point to the difficulty of using justification and concept questions to promote generalizing even when teachers have expressly prepared to use these types of questions. Though justifying was used less than we expected, when employed it resulted in a generalizing promoting action each time.

There is not a one-to-one relationship between questioning and generalizing promoting or priming. A variety of questioning types served as priming and generalizing promoting actions. We expected to see a linear sequence beginning with teacher priming and generalizing promoting actions followed by student generalizations. But, in fact, generalizing promoting actions did not always lead to student generalizations; patterns leading to student generalizations were more complex. Repeated generalizing promoting actions and priming in conjunction with generalizing promoting were needed to produce a student generalization. When generalizing promoting actions did not produce student generalizations, priming followed by additional generalizing promoting was helpful. In this lesson, as with any lesson, questioning occurs in response to student contributions making the planning of all questioning challenging. Accepting this fact means that for questioning to support students in creating generalizations, teachers must possess the ability to respond in the moment with questioning and generalizing promoting moves that are likely to be productive. We suggest that this method of examining common pathways that lead students to generalize can be applied in other lessons to further develop suggestions for teachers as they work to support students as they develop their own generalizations.

TEACHERS' MOTIVATIONS FOR AND ENACTMENTS OF AMBITIOUS MATHEMATICS TEACHING: THE CASE OF "ROUGH DRAFT MATH"

Amanda Jansen
University of Delaware
jansen@udel.edu

Crystal Collier
University of Delaware
crystalc@udel.edu

The purpose of this study was to characterize variations in how teachers enacted an approach to ambitious mathematics teaching: "rough draft math." We also examined teachers' motivations for their enactments. Thirty-two teachers from five states in the U.S.A. were recruited to participate in interviews based on recommendations from leaders of book studies focusing on this teaching practice. All participants enacted "rough draft math" by intentionally building their classroom culture to welcome students' draft thinking to achieve the goal of promoting students' productive dispositions. However, additional variations in enactments drew attention to potential tensions between multiple goals of ambitious mathematics teaching (empowering students and learning through revising). Findings suggest insights for supporting teachers' learning to teach ambitiously; findings also contribute to a knowledge base for teaching.

Keywords: Instructional Activities and Practices; Affect, Emotion, Beliefs, and Attitudes

Ambitious mathematics teaching, according to Anthony and colleagues (2015) "involves skilled ways of eliciting and responding to each and every student in the class so that they learn worthwhile mathematics and come to view themselves as competent mathematicians" (p. 46). During ambitious mathematics instruction, students engage in discourse to learn mathematics and develop positive identities. Additionally, "the motivation to do things differently is as important as knowledge and skill to creating consistently ambitious practice" (Lampert et al., 2013, p. 227). To understand how to support mathematics teachers with learning to enact ambitious mathematics instruction, investigating variations in teachers' efforts to teach ambitiously, and their motivations to do so, can provide insight.

One approach to ambitious mathematics instruction involves inviting students to publicly share their in-progress or unfinished thinking, workshopping those ideas, and explicitly inviting students to revise their thinking – engaging students in *rough draft math* (Jansen, 2020; Jansen, Cooper, Vascellaro, & Wandless, 2016). Teaching mathematics through inviting drafts and revising is a complex activity. To do this work, teachers need facility with eliciting and responding to students' thinking (e.g, Fraivillig et al., 1999). It is not easy to listen to one another (teacher-student, student-to-student, student-teacher) in ways that lead to learning for students and the teacher during a mathematics lesson (Hintz et al., 2018). Building on students' thinking (Leatham et al., 2015) so that revising takes place is demanding work. It may be challenging in-the-moment to recognize strengths (Jilk, 2016) in students' draft thinking and manage classroom interactions to position students' contributions as valuable for their peers' learning (Wood, 2013).

The purpose of this study is to document variations of enactments of an ambitious teaching practice, "*rough draft math*," to contribute to building a knowledge base for teaching (c.f., Hiebert et al., 2002). Researchers can contribute toward building a knowledge base for teaching by documenting practitioners' work in a public, sharable manner so that more educators can learn from teaching practice. Given that incorporating rough drafts and revising in math class involves a range of practices, from creating a classroom culture where drafts are welcome to explicitly structuring revision experiences that move students' thinking forward (Jansen, 2020), there are many entry points into "rough draft math" that can be documented and understood.

Variations in Enactments and Teachers' Motivations

Ambitious teaching practices have interdependent but different goals. Consider scientific inquiry: this teaching practice has multiple goals, such as making sense of phenomena (constructing claims or explanations), articulating understandings (presenting arguments), and persuading others (critiquing, evaluating, and defending arguments) (Berland & Reiser, 2011). Similarly, "rough draft math" has multiple goals: making sense of mathematics, articulating understandings (drafting ideas), improving one's understanding (revising drafts), and promoting students' agency so that they see themselves as capable of knowing and doing mathematics. These multiple goals illustrate complexity and provide opportunities for tensions.

Berland and Reiser (2011) discuss that a complex and ambitious teaching practice, such as scientific inquiry, can vary in enactment in different ways, in part due to these multiple goals. Teachers could emphasize some goals more than others. Some goals might be adopted selectively, and other goals might be set aside. Efforts to achieve certain goals might take place more consistently. In scientific inquiry, this might look like one classroom of students learning to competitively persuade each other while another classroom of students learns to seek to understand one another's thinking (Berland, 2011). What do these variations of enactment look like in mathematics classrooms where teachers incorporate "rough draft math" and why might they occur?

Motivation can be understood through multiple perspectives, including goal-orientation theory and the role of interest. Goal orientation theory attempts to explain how and why people try to reach certain objectives (Kaplan & Maehr, 2006). Motivation can look like meaningful engagement with a practice, and such engagement develops, in part, through cultivating interest (Renninger & Hidi, 2015). Teachers with greater interest are likely to continue to enact a practice about which they have learned (Ginsberg & Wlodkowski, 2019), particularly if they see the practice as positively meeting the needs of their students (Appova & Arbaugh, 2017). However, their enactments could differ depending on the goals they seek to achieve.

In this study, we seek to understand the enactments of teachers who have expressed an interest in enacting "rough draft math," as well as the goals they sought to achieve when enacting it. This study addresses the following research questions: Among teachers with expressed interests in enacting "rough draft math," how do teachers define "rough draft math"? How do these teachers' self-reported enactments of "rough draft math" vary by their motivations?

Methods

Data Collection

We interviewed 32 mathematics teachers from five states in the U.S.A. Teachers were recruited for this study among those who had participated in book study groups to discuss *Rough Draft Math* (Jansen, 2020). Participating teachers were recommended by mathematics coaches or professional development leaders who had facilitated a book study. Additional participants were recruited through Twitter and invited to participate if they had read the book on their own and were attempting to enact relevant instructional practices in their classrooms. Teachers in this sample taught in grades K-12, from first grade through AP Calculus.

Prior to the interview, participating teachers were asked to send, via email, a digital artifact that provided an example of how they incorporated rough drafts and revising into their instruction. The artifact provided context for participants' descriptions of their enactments. Examples of artifacts included the following: web links to Desmos activities, slide decks used during lessons, handouts of mathematics tasks, sample student work that demonstrated students' initial drafts and revisions of their thinking, videos of classroom activities, assessments with directions, and photographs of students collaborating.

Interviews lasted between 35 and 60 minutes, and all interviews were conducted via video call, one-on-one. Interview questions included the following: If you were to tell a colleague about "rough draft math," how would you explain it to them? What can you tell me about this artifact? Tell me the story of this artifact. Why did you decide to do this in your classroom? What happened in your classroom? How is this artifact an example of "rough draft math"? Participants chose their own pseudonyms. All interviews were audio recorded and transcribed.

Data Analysis

Data analysis was conducted by both authors. In our first phase of analysis, we wrote analytic memos for each participant (Saldaña, 2013). In each memo, we described our conjectures for that teachers' thinking based on our initial listening to the interview and editing of the transcript. For the next phase of analysis, we used an exploratory process to inductively create descriptive codes (Saldaña, 2013) based on teachers' talk. We then created descriptive codes for two categories: (a) motivations to enact (or functions for) "rough draft math" and (b) enactments (forms) of "rough draft math." We identified the motivations that teachers described in relation to the artifact they shared. Although teachers described other ways of enacting "rough draft math" in their practice, in addition to the artifact, we assumed that the artifact represented an important part of their teaching practice, from their perspective. The second level of analysis involved frequency coding. We assessed whether, among the motivations reported for enacting instruction aligned with the shared artifact, any of the motivations were repeated throughout the interview and how often they were repeated. Repetition of an idea signals a level of importance to the speaker or an effort to emphasize an idea in their spoken talk (Tannen, 1989).

Results

Below, we illustrate three types of motivations that teachers in this sample expressed as functions for enacting "rough draft math," along with the enactments they described as forms for achieving these motivations. However, before we describe these motivations and enactments, we share teachers' definitions for "rough draft math." These definitions illustrate that teachers could think about rough drafting and revising in mathematics in a variety of ways, which then implies that they could have different motivations to enact "rough draft math."

Rough Draft Math: Teachers' Definitions

When teachers explained "rough draft math," they described components such as, (a) eliciting initial *drafts* of students' thinking, (b) providing students with opportunities to *revise* their thinking, often after some form of (c) *collaboration* with peers, and then (d) inviting students to *reflect* on their growth in their thinking and understanding. When asked to explain what "rough draft math" meant to a colleague, Ms. Dougherty said,

> …it's simply your first draft of thinking, if you're just initially starting out your thinking. You haven't really shared those thoughts with anybody. You haven't revised any of your thinking yet. It's just your first draft… then from there we build on that, and we use our rough draft to help build that understanding to make it stronger and understand where we came from along the way.

In Ms. Dougherty's explanation, she addressed all four components, highlighting the process of first drafts in students' thinking. She alluded to revising when she spoke about needing to "build" on the first draft "to make it stronger." Her explanation included an implicit reference to collective, collaborative work when she shifted to using a "we" pronoun. She suggested incorporating reflection on growth in thinking by saying, "understand where we came from along the way."

However, not every teacher mentioned all four components in their definitions, which suggests that, among some teachers, a subset of components of "rough draft math" resonated more than others. Ms. Briggs emphasized the process of iteratively drafting and collaborating in her explanation when she said, "I would say that it's thinking of math of less like a finished product and more like something you're continuously working on together."
Ms. Kakkar emphasized the process of revising in her explanation.

> For me, when I've heard about rough draft and when we had worked with [math coach] and talked about it, the first thought, to be honest, that was, yes, it should be in math. The rough draft particularly did not come into my mind at first, but since you know how in ELA teachers talk … this makes perfect sense in math, too… you do trials and errors and estimation and all, seeing the patterns, a couple of factors combined together to actually reach out to an answer… It has to be rough draft. It has to be multiple trials. It has to be multiple revising through your work rather than just, okay, here is my answer.

Mr. Vandelay highlighted reflecting on growth and humanizing mathematics learning in his explanation.
