With the adoption of the Common Core State Standards for Mathematics 12 years ago, the content of geometric transformations was shifted from high school to grade 8. In our research with middle grades teachers, they often discussed their difficulty in teaching geometric rotations. Therefore, we analyzed 444 middle grade students' responses, across four states, to eight rotation questions from the SMART assessment. The results corroborate teachers' challenges with teaching and student learning of rotations. Results indicate that students have a rigid understanding of angle measure that may impact their understanding of geometric rotations. Although angle measure is introduced in grade 4, we hypothesize that teachers need to provide additional opportunities for students to expand their meaning of angle measure.

Keywords: Geometry and Spatial Reasoning, Curriculum, Assessment, Measurement.

It has been 12 years since many states in the U.S. adopted the *Common Core State Standards for Mathematics* (*CCSSM*, 2010), which shifted mathematics content to different grade levels and connected mathematics content in different ways than was previously done. For example, geometric transformations are now introduced in grade 8 with the purpose to define congruence and similarity, which are concepts that continue to build in high school. The use of geometric transformations to define congruence and similarity was not typically seen in K-12 mathematics curriculum prior to *CCSSM*, yet it is an intuitive way for students to make sense of congruence and similarity (Usiskin, 1972).

For the past five years we researched teachers' curricular reasoning (Dingman et al., 2021), which is teachers' reasoning for the decisions they make related to the teaching and learning of mathematics. We spent time with middle grades mathematics teachers as they prepared and taught lessons in their geometric transformation unit. Many of the middle school teachers reported that rotations were the hardest transformation to teach, often stating: *Rotations are the hardest transformation for students*; *I am not a rotation teacher*; *Rotations are so hard for students*. Although teachers made these statements, we found that teachers seemed to understand and emphasize two important mathematical characteristics of rotations: (1) the center of rotation and (2) the measure of the angle of rotation. We began to consider why teachers thought rotations were such a difficult transformation for students and if students were understanding rotations. To investigate student understanding, we analyzed student responses from an online assessment (https://smartvic.com//smart/index.htm) designed to reveal student mathematical thinking about rotations (Stacey et al., 2013). Our intent was to investigate student understanding of rotations based on the content that was taught in the middle school teachers' classrooms. This report addresses the following research questions:

1. How well do middle school students do on the SMART geometric rotation assessment?
2. What meanings of rotations do middle school students display on the assessment?
3. What unintended meanings may teachers convey to middle school students when teaching rotations?

Theoretical Framework: Mathematical Meanings of Angle

We utilize Thompson's conception of mathematical meanings, which are "... images of the mathematics they teach and intend that students have" (Thompson, 2016, p. 437), to investigate students' understanding of geometric rotations. Teachers plan and enact mathematical lessons with the goal of students understanding specific mathematics content. As teachers enact lessons, students interpret both implicit and explicit actions from the lesson to concur with their current schema (Piaget, 1968). When students become perturbed in their thinking they often adjust their schema, which promotes learning. However, sometimes students interpret implicit actions of the teacher or the task that lead students to adjust their schemas improperly.

Angle measure is a mathematics topic that spans all grade levels. It is introduced in elementary grades and students continue to build on their understanding of angles through college level mathematics courses. Mitchelmore and White (2000) interviewed elementary students to identify how they conceptualized angles in physical settings and how students' conceptualization could progress to understanding abstract angles. Their findings suggest that students' standard angle meanings develop with corner physical angle situations (that show both rays that create the angle). When a turn was used instead, students had difficulty conceptualizing the angle in the situation. Keiser (2004) argues that a static definition "robs students of opportunities to experience angles as rotations that might affect their experiences in trigonometry and other advanced mathematics courses that require some flexibility in this area" (p. 303-304). Moore (2013) argues that teachers and curricula in the United States often define degrees as the standard unit of angle measure and then have students use protractors to measure angles, which may facilitate relating angles measures, "but it fails to address the quantitative structure behind the *process* of determining an angle's measure" (p. 227). Devichi and Munier (2013) found that the word "angle" typically evokes a right angle. The persistent prototypical image of a right angle "opens on the right with arms parallel to the edges of the paper" (p. 3). Browning et al. (2007) adds that "even some adults still struggle with identifying 90º angles that do not have at least one horizontal ray" (p. 286).

When presenting angles beyond 90°, curricula may contribute to a persistent image that assumes specific angle position. A common image students use to identify angles greater than 90° are a 12- hour clock or a compass. With both images one ray of the angle is vertical relative to the paper (i.e.; 0° North, 12 o'clock) and the second ray created by the students is measured clockwise from that initial position. Note that these images maintain the prototypical right angle image. While angles can be measured without one ray being perpendicular to the edge of the paper, are mathematics curricula or teachers providing students with tasks that require them to make sense of angles other than the prototypical right angle image?

Another incomplete meaning of angle is evident when students use measurement tools like protractors. Berry and Wiggins (2001) found that students rely on protractors to measure angles without understanding protractors as measurement tools. The authors' teaching experiment with grade 6 students highlighted how little students understood their standard protractor when asked to generate a nonstandard unit of angle measurement. Hardison and Lee (2020) conducted another teaching experiment with high school and college level students providing them with non-standard protractors and asked them which protractor correctly measured angles in degrees. The students thought that equal changes in angle measurement amounted to equal changes in the linear distance between non-standard protractor units. These students did not demonstrate that equal changes in a circle's circumference signified equal changes in angle measure. It is evident from prior research that K-16 students struggle to conceptually understand angle measurement, which may lead to unproductive meanings that affect their learning of geometric rotations.

Methods

We report on data from 444 middle school students from 13 teachers' classrooms across four states (AR, MI, NV, UT). Students answered an eight-question online formative assessment (http://www.smartvic.com/smart/index.htm) after learning about rotations. The assessment is designed to reveal student mathematical thinking about rotations (Stacey et al., 2013). The questions assess students' understanding of identifying 90° rotations, angle measure based on a given rotation, whether two figures are rotations, and identifying the center of rotation. One question on the assessment had students select a figure and place it so that it represented an image rotated 180°. The assessment contains four attributes of rotations that students should understand after learning about rotations in grade 8: 1) the distance from the center of rotation to any point on the pre-image and image is preserved, 2) identifying the angle measure of rotation from pre-image to image, 3) the orientation of the pre-image and image is preserved, and 4) rotations mean that the pre-image and image are the same size and shape.

Data Analysis

The SMART assessment includes eight questions that reveal student thinking about geometric rotations. First, we analyzed all answer choices for each question to identify common student thinking. We then matched the common student thinking with four conceptions identified by the assessment developers. We created a spreadsheet of all student responses for each question part. Two questions (Q1, Q8) on the assessment had multiple parts, which we scored as separate questions. Q1 has four parts and Q8 has three parts giving a total composite score of 13 points with each question part weighted the same. We then calculated a composite score for each student based on their correct or incorrect answer choices. With these data we then created frequency tables to identify the answer choices that were most prevalent for each question. We also grouped similar questions to identify trends in students' understanding. Finally, we identified different mathematical meanings that students have about rotations based on their answer choices that may not typically be addressed in mathematical tasks students see in their classrooms.

Only one question on the assessment was open-ended. Figure 1 displays the four "E" options students were given for the image. Students selected one image and then placed it on the circle to create an 180° rotation from the pre-image (grey). The variability of responses were first coded for students' selected image and location on the circle. This created 31 distinct student responses, with 30 variations of an incorrect answer. From there, we categorized these incorrect answers into similar meanings. This categorization allowed for trends to be considered across students' varied responses.

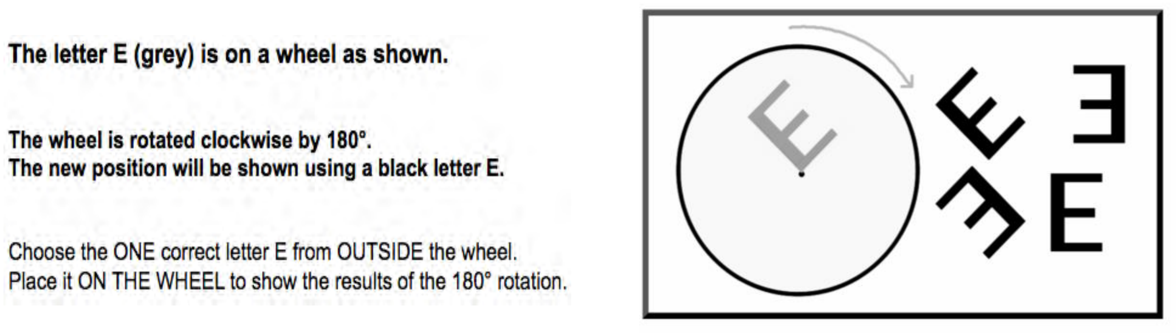

Figure 1: SMART Question 3 (Stacey et al., 2013)

Results

We begin by sharing overall results for the assessment across all students in the study using student composite scores. We then elaborate on the different meanings we found across the students, regardless of their teacher or the state in which they live. Finally, we present findings related to students' mathematical meaning for rotations that teachers should be aware of as they teach topics related to rotations.

Research Question 1

How well do middle school students do on the SMART geometric rotation assessment? The average composite score for all students was 7.73, with a standard deviation of 3.52. This suggests that on average students answered 59% of all questions correctly after being taught about rotations. The percentage of correct answers ranged from 46-74% across the eight questions. Question 1b, which had students identify the amount of rotation between the pre-image and image that was rotated 180° was one of the easiest questions for students as 74% (*n*=321) of all students answered it correctly. Conversely question 8a, which had students determine if the pre-image and image were a rotation or not and if it was a rotation, then students identified the center of rotation was the most difficult for students as only 46% (n=196) of all students answered correctly. From these results on the SMART assessment, we conclude that students held an incomplete meaning of geometric rotations. Therefore, we further analyzed the four attributes of geometric rotations that were challenging for students.

Research Question 2

What meanings of rotations do middle school students display on the assessment? We illustrate middle school students' meanings displayed on the assessment with the results of questions 1, 2, and 3, which are displayed in Figures 1 and 2. The percentage of all students who correctly answered Q1 (parts a-d) completely was 63.6%. The percentage of all students who correctly answered Q2 was 68.7% and for Q3, 62.8%. Student responses to these questions demonstrate their meanings we identified throughout the assessment.

One of the most surprising findings was the difference between students who answered Q1(parts a-d) correctly and those who missed any part of Q1. Students were given the pre-image and had to identify the amount of rotation for the given image (either 45°, 90°, 180°, or 270°). The simplicity of the object (i.e., a circle with a radius) allowed this question to assess students' understanding of angle measure. The results indicate that when students answered all parts of Q1 correctly, they scored significantly higher on the remaining questions ($F = 99.488$, $p \leq 0.001$). Students who answered all parts of Q1 correctly also had a higher composite score on Q2-8 ($\bar{x} = 5.5548$, $\sigma = 2.28444$) than those that answered at least one part of Q1 incorrectly ($\bar{x} = 3.4627$, $\sigma = 2.13336$). This indicates that students who have a productive meaning of angle measure are more likely to understand the concept of rotation.

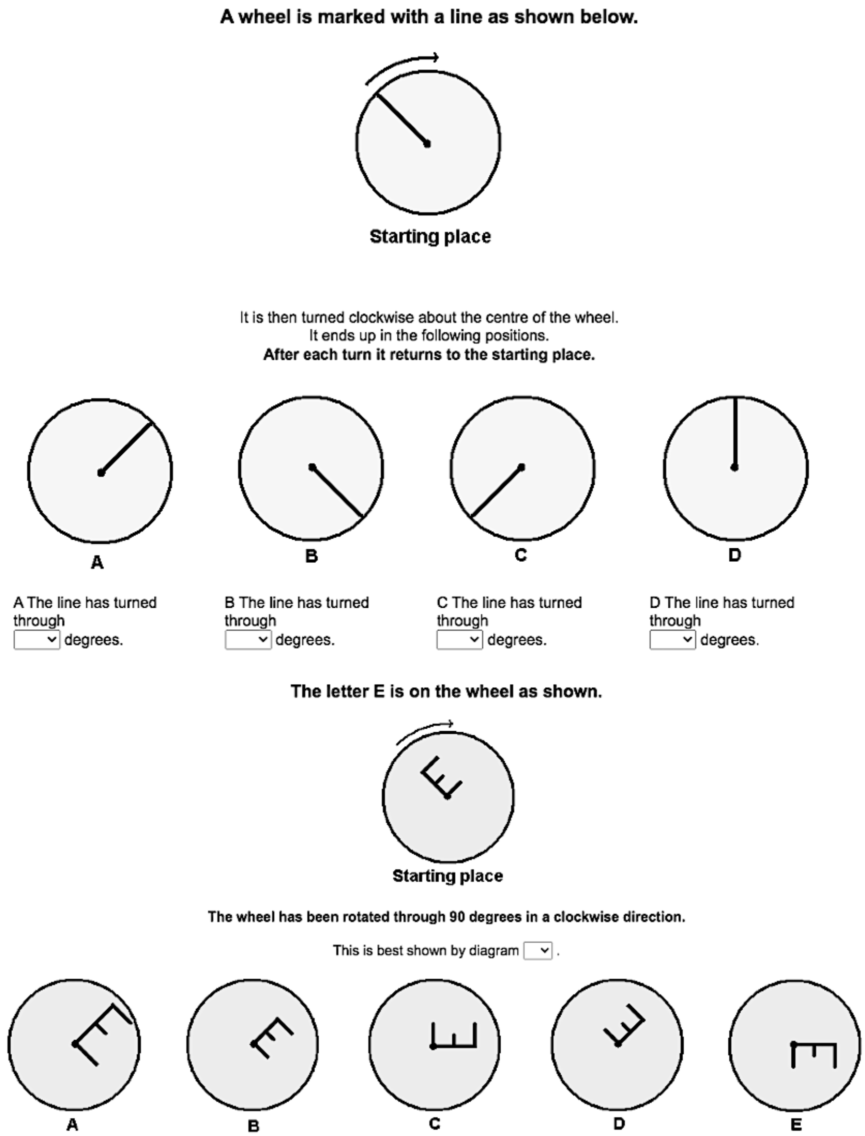

Figure 2: SMART Questions 1 and 2 (Stacey et al., 2013)

In Q2 (see Figure 2, bottom question) students were given a pre-image (the letter "E") and asked to select the image that is rotated 90°. The answer choices targeted different meanings that students form about rotations. Approximately 5.2% (*n*=23) of all students selected answer A that assesses students' meaning that the size of the image stays the same when it is rotated. Approximately 5.4% (*n*=24) of all students responded with answer D that assesses students' meaning of the orientation of an image when rotated. Answers C and E assess students' meaning of a rotation of 90° from the pre-image. Approximately 4.5% (*n*=20) of all students chose answer C; however 16.1% (*n*=71) of all students chose answer E. Among the students that answered Q2 incorrectly, more than half of them chose answers that suggest their meaning of angle measure is not productive. While answer choice E has the image with the proper size and orientation, it is rotated to the 3 o'clock position. From here, we conclude that students were more challenged by distractor answers that showed an incorrect angle measure than answers that showed incorrect orientation or size. We then analyzed student results based upon whether students answered all parts of Q1 correctly. We found that 81% of students who correctly answered all parts of Q1 also got Q2 correct. However, of the students that did not get all parts of Q1 correct, there were only 45% of them that answered Q2 correct. This seems to indicate that students who have a productive meaning of angle measure are more likely to have an understanding of rotations when asked to rotate an object 90° than the students who do not have a productive meaning of angle measure.

Q3 is the open-ended question (see Figure 1). Students were able to place their selected image (of four options with varied slant and orientation) anywhere on the circle to represent a 180° rotation for the pre-image in gray. There was great variety in student responses, which we categorized based on their incorrect answers that were associated with different incomplete meanings of rotations: (1) an orientation meaning, (2) a distance meaning, and (3) an angle measure meaning. A student response was categorized as an incomplete orientation meaning if their chosen image did not preserve orientation of the pre-image. Student responses were categorized as an incomplete distance meaning if their placed image was located away from the given center of rotation (since the pre-image was connected to the center). For incorrect responses in which the students' image is connected to the center of rotation, there may still be an overlooked distance meaning based on their final image location. For a simple categorization, we categorized a student's response as "an incomplete distance meaning" if the image did not touch the center of rotation. Responses were categorized as an incomplete angle measure meaning if their image was not 180° from the pre-image. These were not exclusive groups, so a single student response could be categorized in two or three of the meanings.

Of the students that answered Q3, 7.5% chose an image that suggests an incomplete meaning of orientation. By our categorization of the distance meaning, 11.2% of students responded without attending to distance preservation, indicating an incomplete meaning of distance preservation for rotations. By contrast, 31.9% of students responded with an image placement that suggests an incomplete meaning of angle measure. It seems that students have the most difficulty, of those three attributes of geometric rotations, attending to the angle of rotation.

Research Question 3

What unintended meanings may teachers convey to middle school students' when teaching rotations? Student responses to SMART test Q1, Q2, and Q3 demonstrate implicit student meanings of angle measure and the salience of the prototypical angle position. In these questions, students were asked about a 45°, 90°, and 180° rotation. Students associated an image halfway between the 12 o'clock and 3 o'clock position as a 45° rotation, an image at the 3 o'clock position as a 90° rotation, and an image at the 6 o'clock position as a 180° rotation, regardless of where the pre-image was located.

In Q1, students were given the pre-image and identified the angle of rotation (either 45°, 90°, 180°, or 270°) based on the given image (see Figure 2). Each of the images are shown within a circle with the center of rotation as the center of the circle. If the circle were a clock, the pre-image is located around the 10 o'clock position. When students were shown an image located around the 2 o'clock position, many students indicated that the object had rotated 45° instead of 90°. However, if the pre-image was located around the 12 o'clock or 0° North position, the 45° angle would be accurate. Table 2 summarizes the percent of students who selected the different angle measures for Q1a. For this question, 25.8% of all students indicated that the angle of rotation was 45°. Regardless of the location of the pre-image, these students seem to associate a segment located around the 2 o'clock position with a 45° angle.

Table 1: Question 1 Part A Student Frequencies

Student Response	Percent
45°	25.8
90° (Correct)	71.4
180°	1.4
270°	1.4

Next, in Q2 (see Figure 2), students were given the pre-image of a rotation with the center of rotation and were asked to identify which of five images was a 90° rotation. Table 3 displays the percentage of students who selected the different answer choices. Answer E is particularly popular, which has the image with the correct size and orientation, but incorrect angle measure. However, the distractor showed the image at the 3 o'clock position, 90° from the 12 o'clock position but more than 90° from the pre-image's position. Answer E was chosen by 16.1% of all the students. Of the students who did not answer Q2 correctly , 51.45% (n=139) chose answer E. Answer E also has the image parallel to the bottom of the screen, instead of tilted like the pre-image.

Table 2: Question 2 Student Frequencies

Student Response	Percent
A	5.2
B (Correct)	68.7
C	4.5
D	5.4
E	16.1

Q3 asked students to choose an image from four options and place the image on the given circle to create a 180° rotation from the pre-image (see Figure 1). The image is the same as in Q2, which is the letter "E". About 6.8% (n=30) of all students chose an image that was perpendicular with the bottom of the screen, instead of slanted like the pre-image. Figure 3 shows a few typical student responses that indicate a rigid meaning of angle measure.

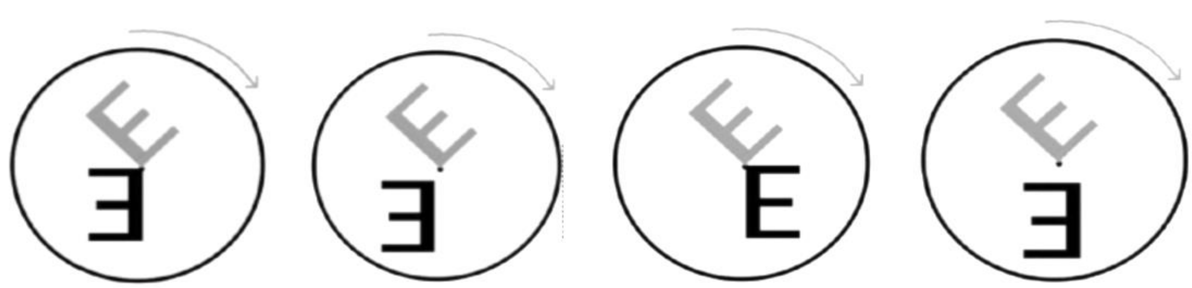

Figure 3: SMART Assessment Q3 sample student responses with 6 o'clock placement

These students did not attend to a 180° rotation from the pre-image, but seem to interpret 180° as the location at the base of a circle. The choice of the upright letter E instead of the slanted letter E shows the comfort students have with objects/images that have a parallel side to the base of the paper or screen.

Students appear to have developed an implicit meaning for angle measurement relating object position to a clock or compass. Perhaps students infer this meaning through their experiences measuring angles. Alternatively, student experiences with geometric rotation may be limited to objects aligned with the x- or y-axes on a Cartesian grid. It appears that teachers must provide students with opportunities to disrupt this implicit meaning.

Implications and Conclusion

Given the results presented on middle school students' understanding, incomplete meanings, and implicit meanings of geometric rotations we recommend teachers explicitly address the meaning of angle measure with students in multiple grades starting at grade 4. The incomplete orientation and distance meanings of rotation may suggest that students are reasoning colloquially with rotations as simply a turn or a flip. Instead, however, the most common incomplete meaning was related to the student's mathematical meanings of angles. It is important that teachers spend more time on having students understand what an angle is measuring and how that measuring unit is different from a linear unit of measure. As can be seen on students' composite scores on the SMART assessment, they are not understanding geometric rotations based on one lesson in grade 8; however, more problematic seems to be students' meanings related to angle measure. These grade 8 students rely on the visual placement of an image to determine the angle measure, rather than the amount of openness of the angle. While this specific meaning of angle measure is introduced in grade 4 of *CCSSM*, we conjecture that teachers and curricula should provide students with opportunities across multiple grades to think about angle measure in this way.

Many of the students in our study displayed a prototypical right angle meaning of angle measure. Students need to be given opportunities to work with angles that are not aligned with the horizontal and vertical axes as well as angles that are not 90° to create dissonance in the students about their own meaning of angle measure. Without students having the opportunity to work with different angle measures they seem to implicitly assume that all angles are the prototypical right angle, which may be reinforcing an unproductive meaning of angle. Without a deeper understanding of angles, students will continue to struggle with the concept of rotations, which may also impact future learning of content for which knowledge of geometric transformations is prerequisite.

Given the centrality of angle in mathematics curricula and scarcity of research in this area, we investigated 64 PTs' assimilatory domains of angularity by analyzing the angles they indicated when presented with four segments mutually sharing an endpoint. In both interview and written settings, we found PTs were more likely to recognize convex angles than reflex angles. Additionally, they were more likely to assimilate disjoint angles than angles formed via additive angular compositions. In particular, we found that PTs were unlikely to recognize full angles or additive compositions involving reflex angles. We consider future directions and implications.

Keywords: Geometry and Spatial Reasoning, Cognition, Preservice Teacher Education

Teachers play a significant role in students' mathematical learning. Therefore, prospective teachers (PTs) enrolled in undergraduate teacher education programs need opportunities to develop strong mathematical content knowledge to support their future teaching (AMTE, 2017). Geometry and Measurement are critical domains of mathematics, and, within these domains, angle and angle measure are pervasive topics throughout mathematics curricula from elementary school through higher education (Barabash, 2017).

Although many researchers have studied and worked to support prospective and practicing teachers' content knowledge related to other quantities (e.g., length, area, and volume), research on teachers' conceptions of angle and angular measure is scarce (Smith & Barrett, 2017). However, we know from the few extant studies in this area that teachers tend to experience challenges when it comes to angle concepts (Smith & Barrett, 2017). Prior to the study of precalculus mathematics, conceiving of angle measures in degrees is particularly important given current conventions and curricular standards. For example, in the Common Core State Standards for Mathematics (CCSSM), angle measure is explicitly introduced in Grade 4:

> An angle is measured with reference to a circle with its center at the common endpoint of the rays, by considering the fraction of the circular arc between the points where the two rays intersect the circle. An angle that turns through 1/360 of a circle is called a "one-degree angle," and can be used to measure angles. (NGA Center and CCSSO, 2010, p. 31)

In subsequent grade levels, robust understandings for angles and their measures are essential for topics including the analysis of geometric figures and relationships, constructions, transformations, proof, and trigonometry. Given this, more research is needed to understand teachers' conceptions of angles and their measures. Working toward this goal, we focus this report on a fundamental question: What angles do prospective teachers recognize when presented with multiple line segments mutually sharing an endpoint? We view this question as fundamental because PTs' conceptions of angles as objects will necessarily impact their understanding of angular measure.

Theoretical Components

The study reported here was informed by principles of quantitative reasoning (Thompson, 1994; 2011). A quantity is an individuals' conception of a measurable attribute of an object or phenomenon. Quantities are conceptual entities existing in the minds of individuals. Quantities vary both within an individual over time and across individuals. Characterizing a quantity involves attending to an individuals' conception of three interrelated components—an object of interest, a particular attribute of the object, and a conceived measurement process (i.e., a quantification). Although all three components are important, we focus primarily on the object of interest in this report. Specifically, we are interested in PTs' conceptions of angles as mathematical objects and variation in these conceptions.

To investigate these conceptions, we leverage a radical constructivist (von Glasersfeld, 1995) perspective. In this perspective, knowledge is not seen in relation to a "true" understanding of the real world (or a mathematical one); instead, knowledge consists of conceptual structures an individual has produced to organize experiential constraints (von Glasersfeld, 1997). Within an individual, conceptual structures are constructed and modified over time, and the structures that persist do so because they remain viable. In other words, the existence of an individual's knowledge implies that the knowledge is useful (for the individual).

Radical constructivists often offer nuanced characterizations of individuals' conceptual structures via scheme theory, which has roots in Piaget's (1970) genetic epistemology. According to von Glasersfeld (1995), schemes consist of three parts (a) an individual's recognition of a prior situation in a present experience, (b) an executable activity associated with the recognized situation, and (c) an expected or beneficial result. In this report, we focus in particular on the first component, which is often referred to as assimilation. Regarding assimilation, von Glasersfeld remarked, "The mind primarily assimilates, that is it perceives and categorizes experience in terms that are already known" (1997, p. 301). Specifically, we are interested in specifying the perceptual material PTs assimilate as angle models. In other words, we are interested in what PTs recognize as angles and the assimilatory operations of recognition, which are crucial steps toward better understanding how individuals quantify angularity.

Methods

The findings reported here come from a larger, design-based research (DBRC, 2003; Cobb et al., 2003) project. In this project, we designed and iteratively refined task-based lessons for elementary and middle-grades PTs enrolled in geometry content courses in order to foster critical ways of reasoning about angularity. For more information on the project and lessons, see Hardison and Lee (2019). In this report, we focus on a single task we used in two different contexts: (a) follow-up interviews conducted approximately one year after eight PTs' enrollment in the course (Method 1) and (b) written responses from 58 different PTs prior to a subsequent implementation of the lessons (Method 2).

Method 1: Follow-up Interviews (Spring & Summer 2020)

In Fall 2018, we implemented task-based lessons with three sections of elementary and middle-grades PTs enrolled in a geometry course. We have argued elsewhere that these lessons were successful in engendering productive quantifications of angularity during the course (Hardison & Lee, 2019). However, we wanted to investigate whether participants sustained these ways of reasoning about angle measure beyond the course. Therefore, we contacted the PTs previously enrolled during Fall 2018 to solicit participants for follow-up interviews. Eight PTs volunteered, and we conducted interviews with these eight participants during Spring and Summer 2020, a little more than one year after the PTs' original enrollment in the course.

Interviews, task, and protocols. The one-on-one, task-based clinical interviews (Clement, 2000; Goldin, 2000) with PTs were semi-structured and conducted by their previous course instructor, which was one of the first two authors. Each interview was approximately 60 minutes in length. Due to restrictions associated with Covid-19, each interview occurred remotely via Zoom. Microsoft OneNote was used to pose tasks and for PTs to record written work. Each interview was video-recorded. Data sources for subsequent analyses included interview recordings, PTs' digitally written work, interview transcripts, and researcher notes. Each interview consisted of 6–8 tasks on angle or angle measure, which were either tasks previously presented during the geometry course, variations on these tasks, or entirely original tasks.

Here, we focus on a single original task, *How Many Angles*, which is shown in Figure 1. We designed this task to investigate what perceptual material PTs would assimilate as an angle as well as the assimilatory domains for angularity (e.g., whether PTs considered reflex angles to be angles in this context). In this task, PTs were asked how many angles they could identify in the provided configuration of line segments. If a PT did not spontaneously draw to indicate the angles they counted, the interviewer asked the PT to indicate the angles they counted using the drawing function. Once a PT committed to a final number of angles, the interviewer pressed by asking whether it would be possible to find any more angles. This aspect of the interview protocol was repeated until the PT indicated it was not possible to find any more angles.

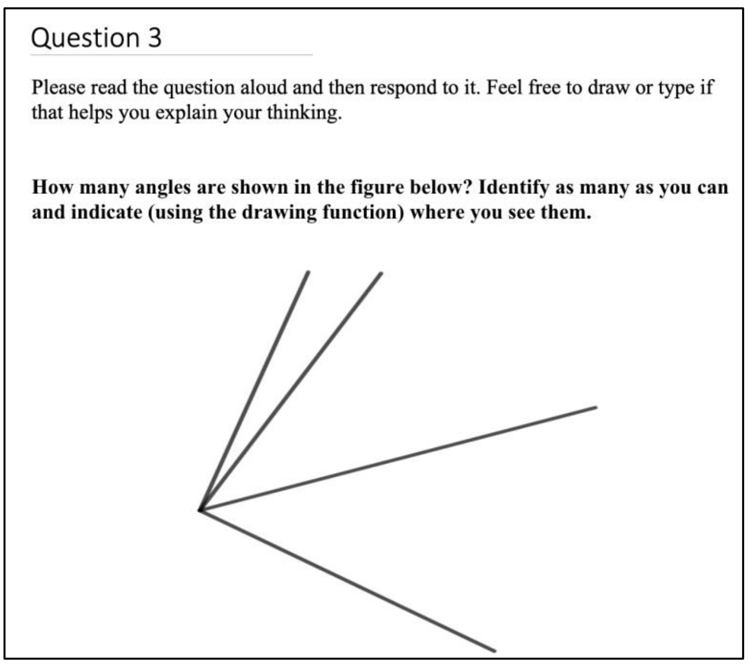

Figure 1: How Many Angles Task

Coding and analysis. Procedures for analyzing the data were established after the interviews were conducted. In order to systematically track the angles PTs identified, we created a reference and notation for the angles participants considered in the interviews (Figure 2). In Figure 2, convex angles are designated C1–C6 and reflex angles R1–R6 with matching enumeration for conjugate angles, (e.g., C6 and R6 are conjugate angles in that they share the same sides but have different interiors). Designations for full, closed, and straight angles were F, O, and S, respectively. We tracked the angles PTs indicated regardless of the indication method. Indication methods included usage of arcs, shading, and labels. As shown in Figure 3, we tracked the angles

PTs identified, the order in which angles were indicated, and the number of angles indicated. If PTs identified more angles after an interviewer press (e.g., "Would it be possible to identify any more?"), we continued additional rounds of coding. Each interview was coded by three of the authors, codes were compared, and discrepancies were discussed until consensus was achieved.

Method 2: Written Responses (Fall 2021)

In Fall 2021, the first author taught two sections of the same geometry content course for elementary and middle-grades PTs. Written data was collected throughout the course from 58 PTs, none of whom were participants in the previous study. The How Many Angles task, with minor modification in phrasing (see Figure 4 below), was posed in a written journal prompt, which PTs submitted electronically, during the second week of class. This occurred prior to any lessons on angle or angle measure. Given the written format of the task, we were limited to the responses PTs submitted. So, in contrast to the interview task, we were unable to request clarification, track the order in which PTs identified angles, or press for finding additional angles. As a consequence, we tracked only the angles PTs indicated and the number of angles reported. These responses were coded by two of the authors, and discrepancies in coding were discussed until resolution was achieved. We noted the angles indicated using the coding shown in Figure 2, with one significant modification described in the paragraph below.

In their written responses, some PTs indicated a pair of sides without clearly indicating an interior (e.g., Figure 4). In these cases, since we were unable to determine whether the PT intended to indicate a convex angle or a reflex angle, we adopted the notation P1–P6 to indicate the pair of sides that was indicated. For example, we coded the response shown in Figure 4 below as "P1, P2, P3, P4, P5, P6" since all six pairs of sides were designated in different colors.

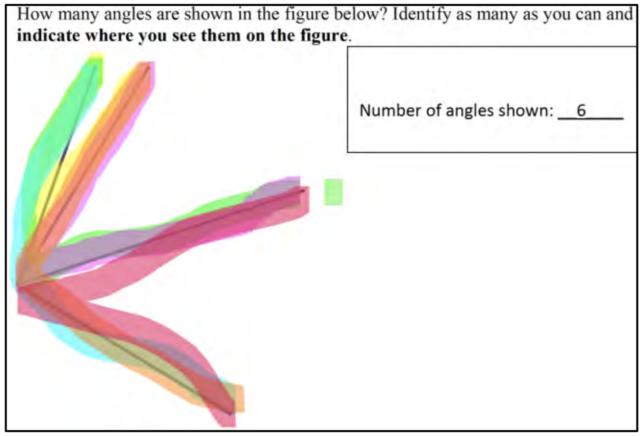

Figure 4: Indicating Pairs of Sides Without Interiors

Findings

We organize the findings in two sections according to the methods described above. We first present findings from follow-up interviews and then present findings from written responses.

Findings from Method 1: Follow-up Interviews (Spring & Summer 2020)

We begin by discussing the angles PTs identified prior to any interviewer press for additional angles (i.e., Round 1). In Round 1, PTs' numbers of stated angles ranged from four to seven, with 50% of the eight PTs indicating six angles were shown in the task (see Table 1).

Table 1: Distribution of Number of Angles Stated in Interviews in Round 1

Number Stated	4	6	7	**Total**
Number of PTs (% of 8 PTs)	2 (25)	4 (50)	2 (25)	58 (100)

The distribution of the angles PTs indicated is shown in Table 2. PTs were more likely to indicate convex angles than reflex angles in Round 1 (100% vs. 38%). Thus, PTs were more likely to assimilate convex angles than reflex angles. Additionally, we noted that disjoint angles (i.e., angles with no perceptual segments penetrating their interiors; C1–C3) were more frequently indicated than composite convex angles (i.e., angles that could be formed through additive compositions of C1–C3, namely C4–C6). Furthermore, the only reflex angle indicated in Round 1 was R6, which was indicated by three PTs. We hypothesize that other reflex angles were not indicated since R6 is the only disjoint reflex angle that might be assimilated without additive composition. Thus, PTs' assimilatory domains for angularity appeared not to spontaneously include additive compositions involving reflex angles (i.e., R1–R5).

Table 2: Angles Indicated by PTs in Round 1 of Interviews

Angle Indicated	C1	C2	C3	C4	C5	C6	R6
Number of PTs (% of 8 PTs)	8 (100)	8 (100)	8 (100)	6 (75)	6 (75)	7 (88)	3 (38)

At the end of Round 1, each PT was pressed by the interviewer for whether it would be possible to find any more angles in the figure. Five of the eight PTs indicated that it was not possible; one subsequently entertained R6 as a possibility and discarded it; leaving only two PTs who ultimately changed their final number of angles after Round 1. We discuss the responses of these two PTs (Lori and Taneem) in further detail in the subsequent sections.

Lori's subsequent rounds. At the conclusion of Round 1, Lori had identified 4 angles (C1–C3 and R6). That is to say, Lori initially assimilated all possible disjoint angles (both reflex and convex). In Round 2, she considered whether additive compositions of angles were permitted:

Lori: If you can use, like any lines, like in any way that you wanted, you know, like I'm not sure if that's allowed, but if you could there's tons of possibilities of angles.

Int: Oh yeah? So, what would, what other possibilities would that introduce if that was allowed?

…

Lori: Okay, does it go from here to here, here to here, this one to here, this one *all the way back around* that'd be 1, 2, 3, 4. And this one would have four – oh, would it be 16?

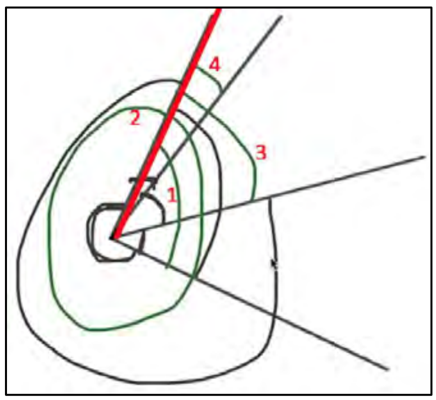

Figure 5: Lori's indication of 4 green angles initiating clockwise from the red segment.

Lori's consideration of using lines "like in any way" indicated that she began to consider all possible pairings of the line segments as a way to determine the number of angles shown. Lori's last line of transcript indicates her picking a single initial segment and considering pairing it with each of the four segments (including the initial segment she selected) and concluding that four possible pairings would be possible. Lori's conclusion that it might be 16 angles was indicative of her awareness that the enumeration of four pairings could be repeated taking any of the four segments as the initial segment. Because Lori's gestures were always enacted in a clockwise fashion from the initial segment, she did not double count any of the 12 convex or reflex angles (i.e., C1–C6, R1–R6). The additional four angles in Lori's final count of 16 were four full angles, each of which went "all the way back around" and initiated at a different segment. Her illustration of the four possible clockwise pairings (in green) with a single initial segment (in red) is shown in Figure 5.

Taneem's subsequent rounds. At the conclusion of Round 1, Taneem had identified 7 angles (C1–C6 and R6). That is to say, Taneem initially assimilated all possible convex angles (disjoint and additive compositions) and the only disjoint reflex angle. In Rounds 2 and 3, she continued considering additive compositions until she had identified all remaining possible reflex angles (i.e., R1–R5) and concluded she saw 12 angles in the task. When pressed again (Round 4), Taneem considered whether full angles should be counted and how many.

Taneem: So, like, if you were just using like this the line [*highlighting a line segment in pink in Figure 6*], I'm thinking about and then, if you just counted that as like, if that was, like the only line here then this would be like a, hold on. [*Drawing the circle in green*] Around there, like a 360-degree angle. I don't know.

Int: Okay. If you, if you counted the one that you just drew, how many would there be then?

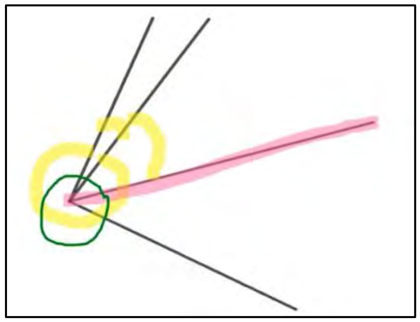

Figure 6: Taneem indicates a full angle initiating and terminating at the pink segment.

Subsequently, Taneem questioned whether each of the four segments could be used in the generation of a distinct full angle remarking, "Well, actually I think that will all be the same for all these lines because they all meet up with the same point. So just be like one more angle possibly…so it'd be like the same 360-degree angle for all of them." Taneem ultimately determined that if she counted full angles, then only one should be counted, bringing her total angle count to 13. Taneem's decision to count only one full angle, rather than four, was rooted in that the four angular candidates shared the same vertex and interior. Ultimately, she decided her final count for angles in the figure was 12 as she did not wish to count any full angles remarking, "So, I'm not sure if that counts an angle because it's like 360-degrees. So, it's like a circle."

Findings from Method 2: Written Responses (Fall 2021)

We now shift our focus to an analysis of 58 PTs written responses to the same task in Fall 2021. In these responses, the number of angles PTs stated ranged from 3 to 12, with a plurality of PTs (47%) stating six angles were shown (Table 3). Only three PTs stated that more than six angles were shown, with two PTs stating 7 shown angles and one PT stating 12.

Table 3: Distribution of Number of Angles Stated for How Many Angles Task (Written)

Number Written	3	4	5	6	7	12	Total
Number of PTs (% of 58 PTs)	14 (24)	11 (19)	3 (5)	27 (47)	2 (3)	1 (2)	58 (100)

Regarding the angles PTs indicated, we begin first by noting two findings different from the interview setting. First, six PTs (10%) stated the number of angles shown but did not indicate any angles on the figure. Second, another nine PTs (16%) did not indicate an interior for any angle. We attribute these findings to a constraint in our second research method, namely that we could not press for clarification in the written setting. An alternative interpretation is that, for some of the PTs, assimilating an angle did not necessarily mean assimilating an angular interior.

We restrict our remaining findings to analyses of the 43 PTs who indicated the interior of at least one angle, either reflex or convex. In other words, we are excluding from subsequent analyses the six PTs who did not indicate any angles on the figure and the nine PTs who indicated only pairs of sides without indicating an interior for any angle. All of the remaining 43 PTs indicated at least one convex angle. In other words, convex angles were in the assimilatory domain of angularity for each of the 43 PTs. As shown in Table 4, all 43 PTs indicated C1, C2, and C3, while only about half of PTs indicated C4, C5, and C6. We attribute these differences in percentages to the disjoint nature of C1–C3 and the composite nature of C4, C5, and C6 in the figure. This indicates additive compositions of convex angles are outside of some PTs' assimilatory domain of angularity.

Table 4: Convex Angles Indicated by PTs (Written)

Convex Angle Indicated	C1	C2	C3	C4	C5	C6
Number of PTs (% of 43 PTs)	43 (100)	43 (100)	43 (100)	21 (49)	22 (51)	23 (53)

Reflex angles were indicated less often than their convex counterparts with only 10 of 43 PTs (23%) indicating a reflex angle. This suggests that reflex angles are outside of the assimilatory domains of the majority of PTs in our study. Moreover, R6 was the only reflex angle indicted by these 10 PTs. In other words, none of the 43 PTs indicated R1, R2, R3, R4, or R5 on the provided figure. We suggest that the disjoint nature of R6 accounts for PTs assimilation of this angle and not R1–R5 since these later angles can be viewed as additive compositions of reflex and convex angles. This suggests that additive compositions involving reflex angles are rare in the assimilatory domains of the PTs we studied. We do note that, as shown in Table 3, one PT stated that 12 angles were shown in the figure, which suggests all 12 possible convex and reflex angles noted in Figure 2; however, this PT was one of the six PTs who did not indicate any angles on their figures. Finally, we note that none of the 58 PTs indicated consideration of closed, straight, or full angles in their responses to this task.

Brief Conclusions and Considerations

In this report, we considered PTs' assimilatory domains of angularity through analyzing the angles they indicated when considering four segments with a mutually shared endpoint. In both interview and written settings, we found PTs were more likely to assimilate convex angles than reflex angles. Additionally, we found PTs were more likely to assimilate disjoint angles than angles formed via additive composition of disjoint angles. In particular, we found that PTs were unlikely to assimilate additive compositions involving reflex angles. Finally, we note that across the 64 PTs from both methods, only two PTs (Lori and Taneem) indicated consideration of a full angle and this consideration was occasioned through interviewer prompts. We also acknowledge that our results only reflect PTs assimilatory domains of angularity for static angle contexts and that dynamic angle models might indicate different assimilatory domains of angularity. Still, these results suggest purposeful interventions targeting angular operations may be necessary to support PTs conceptions of angularity.

As noted at the beginning of this report, angle measurement in degrees is typically introduced in Grade 4 by taking a full angle as a 360-unit composite. Considering the PTs we studied have had 12+ years of experience in school mathematics classrooms, we hypothesize that their assimilatory domains of angularity would tend to exceed those of the students they are to teach. Of course, more research is needed to verify this hypothesis. Nevertheless, given this hypothesis and our finding that PTs tended to assimilate angles in excess of 180° less frequently than the convex counterparts, future research is needed to investigate whether approaches that introduce degrees using other composite units (e.g., a right angle as a 90-unit composite) might better support students in productively quantifying angularity in the context of static angle models.

Block building activities help develop students' spatial reasoning, but few studies focus on the development of block building skills beyond preschool. We worked with four kindergarten, four first grade, and four second grade students to learn more about their Lego block building. We compared students' accuracy, building strategies, and spatial language as they used manuals versus pictures of final Lego structures (presented in color versus grayscale) to build two Lego structures. On the first structure, students using color manuals or pictures had an easier time choosing correct bricks but had difficulty correctly placing them; students using grayscale manuals or pictures had difficulty picking the correct bricks but placed them more accurately. By the second design, students did better with the manuals, regardless of color. Students need more support to use specific spatial language and building with depth versus height.

Keywords: Elementary School Education; Geometry and Spatial Reasoning; Instructional Activities and Practices.

The K-2 mathematics standards in the United States emphasize geometric reasoning, which includes the ability to identify and describe shapes and to create structures by analyzing and predicting the outcome of composing and decomposing shapes (National Governors Association Center for Best Practices & the Council of Chief State School Officers, 2010). Children use geometric reasoning to make sense of the world through multiple practices (Goldenberg & Clements, 2014). The first practice in making sense of the world is classification, which involves children identifying the elements in the environment and establishing relationships among them. Then, children might use spatial relationships, which help identify an object's location relative to reference points by using spatial words (e.g., right, under, top) or numbers (e.g., 3 units away from an object). Another practice to understand the environment is noticing the transformations of objects at various orientations or distances (e.g., symmetry, rotation). Geometric reasoning also entails measuring or counting to identify the relationships between objects in the environment. To identify certain properties of the objects, direct measurements (e.g., length, area, volume), indirect measurements (e.g., comparing an object to another object being measured), or using various units (e.g., one-unit length, block should be placed in the middle) might be utilized (Goldenberg & Clements, 2014).

Play with blocks is a popular early childhood activity that helps children develop a variety of concepts, including geometric and spatial reasoning (Casey et al., 2008; Phelps & Hanline, 1999; Ramani et al., 2014), part-whole relationships (Gura, 1992), and other early mathematics concepts (e.g., aspect of numbers, lines, area surfaces, and volume; Cross et al., 2009; Gura, 1992; see also Kamii et al., 2004). There is also a 3D shape composition learning trajectory (Clements & Sarama, 2009) focused primarily on preschoolers' block-building; however, research on block building beyond the preschool has been limited. Since the development of block-building skills may not be fully established until school age, more research on block-building behaviors after preschool is needed (Tian et al., 2020).

Unstructured (free-play) and structured (guided) block building activities are two pedagogical approaches to building blocks. Unstructured tasks are more open-ended, allowing children to create their own structures without being given specific goals, i.e., "Build the best thing you can with these blocks" (Caldera et al., 1999, p. 860). In structured activities, children, on the other hand, copy and reproduce a specific structure from a design (Caldera et al., 1999; Stiles & Stern, 2009). Structured activities focused on improving skills in sorting and classifying blocks and sometimes focused on "...estimation, measurement, patterning, part-whole relationships, visualization, symmetry, transformation, and balance" (Casey & Bobb, 2003, p. 2). At the preschool level, Verdine et al. (2014) used the Test of Spatial Assembly (TOSA) to measure students' block building accuracy. For these tasks, students must copy a block design (e.g., a three-piece Lego structure). However, Lego sets targeted at students ages 5-8 typically range from having about 50 pieces to multiple hundred pieces, and the features (i.e., use of color, types of pieces, orientation of pieces, placement of pieces) increase in complexity. Therefore, to better understand K-2 students' block building behaviors, we need more investigations into how they coordinate these features and how pictures and manuals can support their efforts.

Framework

Worked examples are an instructional aid for helping students understand challenging concepts. Worked examples show step-by-step solutions to problems that help students understand the problem-solving process (Atkinson et al., 2000; Sweller & Cooper, 1985) while reducing cognitive load (Paas et al., 2003; Sweller et al., 1998). Analyzing worked examples promotes learning in different fields, such as in mathematics (Catrambone, 1998; Congdon et al., 2018; Durkin & Rittle-Johnson, 2012) and programming (Bofferding et al., 2022; Joentausta & Hellas, 2018; Margulieux & Catrambone, 2016). Congdon et al. (2018) investigated first-graders' ability to measure using rulers starting at zero or a whole number. The students' measurement conceptions improved when they analyzed worked examples of taking measurements that were not aligned with the zero point.

Worked examples organized by subgoals, on the other hand, may help students learn since subgoals make problem steps explicit by explaining the purpose of each step and providing clues on how to achieve them (Atkinson et al., 2003; Atkinson & Derry, 2000; Catrambone, 1998). Additionally, students can concentrate on the important components in the worked examples (Margulieux et al., 2016) and engage in more self-explanations (Catrambone, 1998; Renkl & Atkinson, 2002).

Studies of young children's block building provide some insight into factors that children pay attention to (e.g., spatial language, see Bower et al., 2020; Cohen & Emmons, 2017; Pruden & Levine, 2017) or struggle with when recreating block structures (e.g., placement, see Stiles & Stern, 2009; Verdine et al., 2017). For example, Verdine et al. (2014) evaluated 102 children's (38 to 48 months) spatial assembly skills beyond basic building accuracy as they attempted to construct seven models using 2 to 4 Mega Blocks of various sizes and colors. When determining if the children's constructions matched the models, the researchers created a dimensions score. They scored the accuracy of blocks relative to the base block, taking into account the *vertical* location of the blocks, *rotation* of the blocks, and the *translation* or horizontal location of the blocks based on the child placing the blocks on the right studs. Based on children's decreasing dimension scores, they had difficulty coordinating rotation and translation as the number of pieces (e.g., 2 versus 3 pieces) or the spatial complexity (e.g., two blocks sharing the two-studs width of the base) increased.

Other researchers have investigated the language children use as they work with blocks for insight into the factors they find important. Pruden and Levine (2017) investigated boys versus girls' (14-46 months) spatial language in terms of dimensions (e.g., big, little, tall, short), shape terms (e.g., circle, square), and spatial features (e.g., curvy, bent). Compared with girls, boys produced more spatial words in preschool years. On the other hand, Cohen and Emmons (2017) investigated school aged children's (4-12 years) production of spatial language during structured block building activities. Like Pruden and Levine (2017), Cohen and Emmons (2017) identified children's spatial language regarding dimensions (e.g., big, wide, length), shapes (e.g., square), and spatial features (e.g., vertical, flat, curvy, side, corner). Additionally, they identified children's spatial language regarding location/direction referring to relative position of blocks (e.g., high, under, up), orientation/transformation referring to relative orientation or transformation (e.g., rotate, upright, right side up), continuous amount (e.g., a lot, same, half, inch), deictic (e.g., here, there, anywhere), and pattern (e.g., order, next, first, increase)(Cohen & Emmons, 2017). Children were more likely to produce words in the location/direction category than they were in the shape and orientation categories (Cohen & Emmons, 2017).

Current Study

Block features (e.g., length, color, shape, size) contribute to spatial complexity, especially as the number of blocks increases. The preschool studies involved a few bricks (e.g., up to 4, Verdine et al., 2014; up to 8, Stiles & Stern, 2009) and typically focused on children's final structures. Instead, we explored how school-aged children deal with spatial complexity by concentrating on the process, particularly what is easy or difficult for them and what they pay attention to in relation to language while building 30-40 piece Lego structures.

Structured (guided) block building can be interpreted as a form of using worked examples, where the final structure is shown but also includes all information needed to build it (e.g., someone can trace the steps from bottom to top and see the needed pieces). Manuals, such as those included in Lego sets, can be interpreted as a worked example with subgoals, where the final structure is broken down into smaller chunks to help explain how the pieces fit together to make the final structure. Subgoal labels may be of increasing importance as structures increase in size and complexity because they make each step explicit. Likewise, colors might reduce cognitive load when structural complexity increases by helping children distinguish among pieces.

In this study, we explored: How do students' composing of Lego structures compare when they build with manuals of steps versus a picture of the final structures? (a) What spatial language do they use? (b) Which Lego brick features (i.e., location, size, orientation, shape, color) are most difficult to coordinate in their building?

Method

For this study, we analyzed data from four kindergarteners, four first graders, and four second graders in an afterschool program at a Montessori school in the midwestern United States. We tried to strike a balance in regard to students' gender and background. During three sessions of a Lego building project, the students composed, decomposed, and fixed Lego structures. We met with students individually and video recorded them using two cameras to capture the front and back of their Lego structure. Interviewers also asked students questions about where they were looking in the picture or manual as they built, how they knew which brick to use and where to place it. The data for this study comes from the composing portions of the tasks from the project's first two sessions.

In the first session, the students either used a picture (as a worked example) or a step-by-step manual (as a worked example with subgoals) to build a Lego structure (see Table 1). We showed the picture or manual in color to half of the students and in grayscale to the other half. The students built a different Lego structure in the second session but started with half of the structure already built. Students who used a manual in the first session used a picture in the second session (and vice versa). Likewise, students used a color picture or manual in the first session used a grayscale one in the second session (and vice versa).

Table 1: Examples of Pictures and Manuals Used for Each Design

	Design 1	**Design 2**
Order 1	 Example color pictures	 Example grayscale manual steps
Order 2	 Example grayscale pictures	 Example color manual steps
Order 3	 Example color manual steps	 Example grayscale pictures
Order 4	 Example grayscale manual steps	 Example color pictures

Analysis

In order to analyze students' building process, we first recorded the number of differences between students' structures and the given picture or manual. Differences were divided into several categories based on Verdine et al.'s (2014) coding scheme and included students using the wrong brick, including an extra brick, leaving out a brick, placing a brick with an incorrect orientation, and placing a piece with an incorrect left-to-right, forward-to-backward, or vertical placement. We took notes of the specific bricks students had difficulty with in order to identify patterns. Next, we coded the students' building process based on how they used the bricks, pictures, and manuals (see Table 2 for description of codes). During this process, we also took notes of changes students made as they built as well as any help they received from the interviewers.

Table 2: Codes for How Students Composed the Lego Structure

Composing strategy	Description
Resource	Where students referred when building and explaining:
Picture of structure	The composed picture of the structure (solo picture/in manual)
Manual of steps	Steps in manual for how to compose the bricks
Lego structure	Parts of the Lego structure
Turning pieces	Turned the direction of bricks horizontally
Flipping pieces	Turned the direction of bricks vertically
Turning structure	Turned the direction of the Lego structure
Direction	Built the structure from *bottom to top* or *top to bottom*
Symmetric	Built one side and a similar brick on the other side (1 piece, 2 pieces, or 3 pieces at a time)
One side	Built up more than 3 bricks of one side, then did the other side
Lines	Used the lines between bricks on the picture
Counting studs	Counted raised dots on bricks to decide the location or brick

Finally, we used Cohen and Emmons' (2017) classification to code students' spatial language as they built and answered questions about the building of the Lego structures. We did not use their pattern category, but we also included a separate color category given our design focus on the role of color in building (see Table 3). We calculated the percent of students' language for each of the categories to look for trends.

Table 3: Codes for How Students Composed the Lego Structure

Language (Cohen & Emmons, 2017)	**Description**
Dimension	Length and Width: Students reference the brick size using specific numbers (4x2) or in generic terms (e.g., long, big, wide) Height: Students reference the brick's thickness (e.g., thick, thin) or how tall it is.
Shapes	Specific: Students use shape words or names of the bricks (e.g., square, window, flower) Generic: Students refer to the brick using "this" "that" or other generic referents

Location/Direction	Specific: Students use the number of studs on Lego bricks or number of bricks to justify placement Generic: Students refer to locations without using numbers (e.g., on the top, the other side, on the right)
Orientation/ Transformation	Students talk about turning or flipping bricks
Continuous amount	Students use number words to describe number of pieces or the count pieces using numbers
Deictic	Students use generic language (e.g., here, there) to describe brick placement
Spatial features	Students describe the appearance or features of the brick (e.g., sharp, slanted, curved, has a shadow, has an eye) Generic: Students describe the appearance using vague language and actions (e.g., “like this,” “the same,” “looks good”)
Color (we separated this out from spatial features)	Students refer to the color or shading of a brick (e.g., red, darker)

Results

Design One

When building design 1, all students built from the bottom to the top and used the lines between bricks to help guide their building. Further, one student composed several bricks into a substructure on one side before building the same sub-structure on the other side; whereas, the other 11 students built symmetrically (see Figure 1), placing bricks back and forth between sides. Students used more spatial language as their grade level increased, but overall their language was pretty generic. They referred to the bricks in general shape terms (27% of language terms) and often paired it with a continuous amount (e.g., this one, those two; 24% of terms), leading to those categories having the highest percentage. Their language involved specific location terms 11% of the time and general location terms (e.g., “there”) 13% of the time. Overall, students had a median of six differences with the target structure (ranging from 2 to 17) when composing the first Lego structure. Students who used the grayscale picture had a total of 38 differences, those who used the color picture had 21 differences, those who used the color manual had 16 differences, and those who used the grayscale manual had 14 differences. Participants who had the highest numbers of differences left out chunks of the structure (e.g., the window and surrounding pieces or arch and surrounding pieces) and referred to the picture of the final structure.

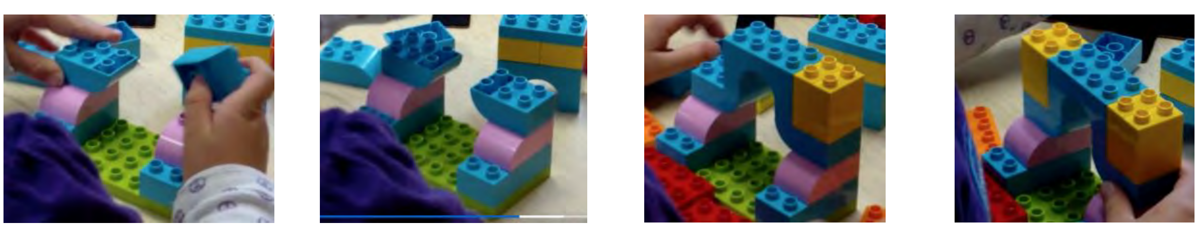

Figure 1: Second Grader Building Symmetrically

Aside from general differences between students who built using the manual versus the picture, there were interesting differences between students who used color pictures or manuals and those who only used grayscale pictures or manuals. Students in the color conditions had more difficulty placing Lego bricks in the correct spots; their typical difficulties in placing the bricks aligned with students not making proper use of the forward/backward dimension (see Figure 2). Students in the grayscale conditions had more difficulty using the correct Lego bricks; their typical difficulties with pieces involved using the incorrect thickness of pieces, regular 2x2 bricks instead of taller 2x1 bricks, or incorrect dimensions (see Figure 3).

Incorrect: red brick does not overhang	Correct overhang for red bricks	Incorrect: window and blue 4x2s set back	Correct placement of window and blue 4x2s

Figure 2: Difficulty with Placing Lego Bricks

Incorrect: 4x2 curved bricks instead of 3x2	Correct use of 3x2 curved bricks	Incorrect: 2 stacked 2x2 bricks on right	Correct use of tall 2x1 bricks on right

Figure 3: Difficulty with Choosing Lego Bricks

Design Two

In general, most students had fewer differences when they completed design 2, which was not surprising since they only had to build half of the structure. Students also did not have much difficulty figuring out where to start from the manual or general picture. They continued to build symmetrically from the bottom up but only eight continued to use the lines between bricks to guide them. As with the first design, they continued to use generic language, referring to bricks in generic ways (21% of language terms) and paired this with continuous amounts (20% of terms). They also continued to refer to locations in generic ways (13% of terms) and increased their focus on the bricks' colors or shading (e.g., darker; 11% of terms). Overall, students had a median of two differences in their final designs (ranging from zero to six difficulties, excluding one kindergartener who left off 10 bricks). Interestingly, there were fewer differences between the color and grayscale conditions with this design. Rather, the biggest difference occurred between students who used a manual (who had a total of six differences in their final structures) versus those who used the picture (who had a total of 29 differences in their final structures). Students' difficulties were similar to those from the first design.

Discussion

Overall, students who built the Lego structures using the manuals had fewer differences than those who built the Lego structures using the pictures. Manuals (a kind of worked example with subgoals) may reduce students' cognitive load by engaging them in more self-explanation (Atkinson et al., 2003; Catrambone, 1998; Renkl & Atkinson, 2002) and helping them focus on transformations (Goldenberg & Clements, 2014). There were benefits and drawbacks to students' building their first design using the *color* picture or manual. These students were largely able to pick out the correct pieces, perhaps aided by the color (see also classification, Goldenberg & Clements, 2014) and a reduction to cognitive load (Atkinson et al., 2000; Paas et al., 2003; Sweller et al., 1998); however, they had difficulty placing them, especially in relation to the forward-backward dimension (see also transformation, Goldenberg & Clements, 2014). One potential reason may be that their focus was more on the correct use of pieces vertically in relation to each other. Students who saw the pictures and manuals in grayscale may have looked more closely at the placement to help them figure out both the pieces involved as well as how to place them because they did not have the color cues. The Lego structures were designed to emphasize the vertical element, so future work could explore if students have similar color-placement difficulty with Lego structures that involve a stronger depth element and little vertical change. Another possible avenue to explore would be to give students manuals where the pieces for the sub-goals are in color but the composed structure is in grayscale. This change might help students find the correct pieces but then encourage them to examine the picture more closely to interpret how to place the pieces. In fact, by design 2, the advantage of having color appeared to wane, and the benefits of the manual, with its sub-goals, took on more importance. Interestingly, students were more likely to use general words than specific words to describe the bricks and their locations, similar to findings from Cohen and Emmons (2017). Therefore, another fruitful avenue may be to help students use specific language when building to determine if that helps them have a better sense of the spatial dimensions in the pictures or manuals.

We argue that playing board games provides crucial experiences for developing logical and spatial reasoning. Drawing on Dewey, growth in spatial and logical reasoning requires the accumulation of sufficient experiences in action. Our design-based research involving Grade 4-6 students playing Qwirkle weekly revealed their significant improvement using three key tile arrangements that contributed to strategic play. These strategies occurred as a result of enacting intertwining spatial and logical reasoning. Both are necessary for flourishing in mathematics.

Keywords: Geometry & Spatial Reasoning; Reasoning & Proof; Elementary School Education; Instructional Activities & Practices.

To disrupt the hegemonic discourse of mathematics class as creating arithmetic fluency, using commercial games holds promise for mathematics learning through playfulness. Spatial reasoning and logical reasoning in abstract strategy games are processes critical for all mathematics learning. Games have long been recommended as a way for students to develop a meaningful understanding of mathematical ideas before they move toward abstractions (Diénès, 1971; Skemp, 1993). Only limited systematic research is published on the use of commercial games for mathematics learning (e.g., Marshall, 2004; McFeetors & Palfy, 2018; Reid, 2002). We argue that playing board games provides crucial experiences for enacting logical and spatial reasoning. Play as learning is devalued in compulsory schooling and contexts to develop reasoning are needed. Mathematical play is a universal cultural activity (Bishop, 1988) and is about the opportunity to flourish (Su, 2020), engage in mathematical thought (Taylor, 2014), actively do mathematics (Vogel, 2013) while finding joy as motivation to continue playing (Gerofsky, 1999). Contexts which promote the development of reasoning are familiar and stimulating in reaching all students – like playing games. Higher achievement in mathematics is correlated to spatial reasoning (Young et al., 2018) and logical reasoning (Nunes et al., 2007).

In this paper, we illustrate the connections of spatial and logical reasoning in the growth of game play strategies in Qwirkle. In particular, we ask: **How does students' play with Qwirkle occasion moments of spatial and logical reasoning that contribute to strategic engagement?** Our aim was to understand ways in which students increase strategies for game play as their spatial and logical understandings of the game evolved.

Theoretical Framework

We ground students' growth of spatial and logical reasoning in Dewey's theory of experience. Dewey (1938/1997) saw experience as the essence of education, where the aim of education is growing. Students learn by (inter)acting in and on the world around them, including both physical and intellectual engagement so that the event is meaningful and leads to growth. Doing is not sufficient for learning to occur, but students transform activity into experience through reflection where they interpretively ascribe meaning to their activity. Learning requires the accumulation of sufficient experiences in action (Kahn et al., 2015; Varela et al., 1991) through curated opportunities to ensure each and every learner can engage in a sufficient set of educative experiences over time (Francis & Kahn, 2021).

We view logical reasoning as a systematic pattern of behaviour (Reid, 2002a) to "develop lines of thinking or argument" (Brodie, 2010, p. 7) that encapsulates both process and product (Jeannotte & Kieran, 2017). As a process, logical reasoning includes specializing, conjecturing, representing, generalizing, investigating, explaining, justifying, refuting, modifying, and convincing (Lannin et al., 2011; Mason et al., 2010; NCTM, 2000). As a product, logical structures include deductive and plausible/inductive (Polya, 1954), analogy and metaphor (English, 1997), abductive (Conner et al., 2014) and transformational (Simon, 1996), to name a few. Students' development of logical reasoning follows a trajectory, moving from analysis of specific cases to systematic generalizations and proof (Stein & Burchartz, 2006; Tall, 2014).

Spatial reasoning involves the capacity to relate to and navigate the world, and the ability to create and mentally manipulate actual and imagined shapes (Cohen & Hegarty, 2012), recognize relations amongst objects (Bruce et al., 2017), manipulate visual patterns (Carroll, 1993), and locate shapes as they move along a path (Newcombe & Frick, 2010). It is about being able to visualize or picture things in the mind's eye and to mentally move objects and shapes in space. Davis et al. (2015) attempted to collect the many competencies and habits associated with spatial reasoning into a model that represents the emergent complexity of spatial reasoning skills as co-evolved and the complementary nature of the mental and physical actions. Spatial reasoning elements include: altering, moving, situating, sensating, interpreting, [de]constructing.

Methods

This paper reports on successive cycles of Qwirkle game play as part of a larger design-based research project (Cobb et al., 2003; McKenney & Reeves, 2012). The research occurred in one elementary school in Calgary (2 teachers and 48 Grade 6 students) and one in Edmonton (4 teachers and 44 Grades 4-6 students). Qwirkle was played weekly in each class for 60 minutes over 4-5 weeks. Weekly sessions included: a class discussion about students' reasoning from the previous week, game play, and students recording their thinking through words and drawings on reflection sheets. Data collected included videos, photos, students' reflection sheets and score sheets, teaching materials, and field notes.

Qwirkle is a tile-laying game of matching six different colors or six different shapes to score points (see ultrabaordgames.com/qwirkle/game-rules.php). Qwirkle has been established as containing mathematical features, namely combinatorics (Britton et al., 2018), visuo-spatial processing (Nyamsuren & Taatgen, 2013), computational thinking (Scirea & Valente, 2020), and executive functioning (Allee-Herndon & Roberts, 2018).

For this report, we limited our analysis to photos, reflection sheets, and field notes generated in three grade 6 classes where Qwirkle was played. We conducted two phases of data analysis. First, our emergent analysis of reflection sheets revealed three types of tile arrangements for game play: 1-line/crane, 2-line/corner, and grid/add-on (see Fig. 1). We coded responses on reflection sheets with the three arrangements and collected examples in images from class game play. Second, we used Davis et al.'s (2015) elements of spatial reasoning and McFeetors and Palfy's (2017) elements of logical reasoning to analyze the students' enactment of spatial and logical reasoning during their game play, as recorded in photos and field notes. For each action or utterance, we coded each manifestation of a spatial and/or logical reasoning element with a corresponding verb (e.g., investigate, conjecture, analyze, convince, integrate, generalize for logical reasoning; e.g., alter, move, situate, sensate, interpret, (de)construct for spatial reasoning).

Figure 1: Strategic Tile Arrangements in Qwirkle

Results

Students' analysis of game boards for tile placements indicated that they were enacting both spatial and logical reasoning (elements indicated in italics, as coded in the data analysis process) in their Qwirkle play. Logical reasoning occurred as students *investigated* possible tile arrangements, *specialized* while considering their hand against the current board, and *analyzed* current and future moves by arranging their hand for maximum points. Spatial elements of *modelling* by *deconstructing* various *paths* and *imagining* how the *paths* could be *reconstructed* by *locating* and *arranging* new tiles informed students' moves.

On the weekly reflection sheet, students were asked to *analyze* a given game board and six-tile hand by *diagramming* their preferred move and *justifying* it. Table 1 shows how quickly students eliminated illegal moves and increased awareness of tile arrangements. In the first week 15% of the students applied the grid on the reflection sheet. By the third week 57% of the students chose to make a grid with the tiles. Awareness of a range of tile arrangements increases the opportunity to make strategic moves. A repeated measures ANOVA (Huck, 2012) reveals that Mauchly's assumption of sphericity was violated $X^2(5) = 14.89$, $p < .05$, therefore the degrees of freedom were corrected using Huynh-Feldt estimates of sphericity ($\varepsilon = .83$). The results show a significant change in means $F(2.69, 89.93) = 23.68$, $p < .05$. A post-hoc linear contrast analysis reveals significant improvement each week $F(1,36) = 41.89$ $p < .05$.

Table 1: Cycle 1 Reflection Sheet Results

	Week 1	Week 2	Week 3	Week 4
Illegal moves	8	3	0	0
1-line / crane	12	23	3	1
2-line / corner	20	4	17	17
Grid / Add-on	7	12	27	26
Total (out of 48)	47	42	47	44

While student analysis on reflections sheets was important for demonstrating reasoning, it was decontextualized from their immediate experience. However, we observed strategic use of the three tile arrangements within the flow of game play. Figure 2 depicts a game in the second class of Cycle 2 with analysis of each move. It is apparent that the two players in this game were able to employ all three tile arrangements throughout the game.

We provide commentary on a few key moves. After Move 8, the two students discussed that no red tiles had been played yet as they *analyzed* the board in hopes of drawing a red clover to complete the first qwirkle of the game (*projecting* and *pathfinding*). In Move 10, Cora's *conjecture* of playing a red clover expressed as "Jackpot!" when she drew the tile resulted in *justification* of her play. The 15-point creation of the red line of circle-rhombus-clover required *intersecting*, *locating*, *composing*, and *modelling* to complete the maximum score compared to any other move possible with the tiles in hand as a corner tile placement. In Move 11, Amy's play of adding the purple line of star-rhombus provided the maximum points of any move possible and she was fortunate to have these tiles in her hand as an add-on tile arrangement. Between Moves 15 and 16, Amy demonstrates an approach to *investigating* (*modelling* with *arranging, locating,*) a tile arrangement to *explain* (*composing* and *pathfinding*) the possible point value with her opponent without revealing the specific tiles before completing her turn. The students *generalized* a tile arrangement when they named the red clover placement in Move 18 as a “corner,” as it became an object of class conversation because a similar play had yielded a double-qwirkle for Amy the previous week as a great payoff of 24 points for one tile played. Amy *convinced* her classmates and it became a coveted board arrangement to set up in advance. While Move 22 also involves the coordination of two lines similar to Move 18, the students were adamant that this was a distinct tile arrangement as they *refuted* a claim of similarity (*composing* and *arranging*). In Move 24 where Amy placed the green line of square-circle at the bottom of the picture to score a qwirkle and two more points. The qwirkle at 12 points is such a large bonus that strategically it may supersede other tile placements that make a board “crowded” as Amy *explained* (*modelling*). We observed a common strategy across students, where they first looked for a qwirkle and then added extra tiles to the line to increase their score on a single turn.

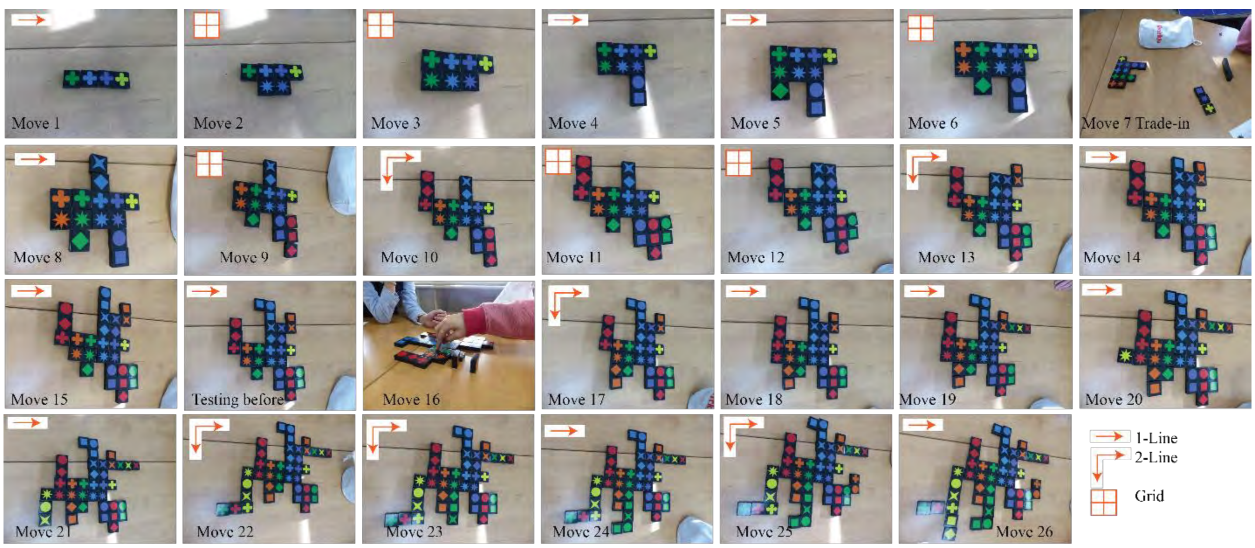

Figure 2: Observing Placements in the Flow of a Game

Discussion

What came as a surprise to us as researchers is how just a few experiences with Qwirkle led to significant gains in strategic play through developing and using a variety of tile arrangements. Over the weeks of Qwirkle play, students were able to analyze the board and make strategic plays to maximize scoring. Knowing the three tile arrangements and having sufficient experiences in playing the game provided more possibilities for strategic game play.

Our study reveals that students were continuously drawing on key components of spatial and logical reasoning. We found it incredibly challenging to tease apart spatial and logical reasoning. In fact, it is not meaningful in understanding students’ actions and mathematical thinking to separate moments of spatial reasoning and logical reasoning. Rather, we see these two specialized types of reasoning as intertwined. We conjecture that these two types of reasoning evolve together. That is, students became more proficient in spatial reasoning as they used processes of logical reasoning, and the converse is the case. We suggest that not only further research needs to be conducted to explore this conjecture, but that teachers are invited to use intertwined spatial and logical reasoning tasks in classrooms. Such tasks invite the complexity of mathematics and simultaneously invite each and every learner into flourishing in mathematics.

This document presents the central aspects for the design of authentic tasks and some results obtained during their implementation, which were applied to a group of six students belonging to the Consejo Nacional de Fomento Educativo (CONAFE) of the state of Puebla. The analysis considered the previous knowledge of the students and their interaction with each of the tasks. The results obtained show that students present misconceptions regarding the relationships between the concepts of area and perimeter and the use of extracurricular knowledge is evidenced when working with authentic tasks assisted by a 3D software.

Keywords: Authentic tasks, extracurricular knowledge, Area and perimeter

En este documento se presentan los aspectos centrales para el diseño de tareas auténticas y algunos resultados obtenidos durante su implementación, las cuales fueron aplicadas a un grupo de seis estudiantes pertenecientes al Consejo Nacional de Fomento Educativo (CONAFE) del estado de Puebla. En el análisis se tuvieron en cuenta los conocimientos previos de los estudiantes y su interacción con cada una de las tareas. Los resultados obtenidos muestran que los estudiantes presentan concepciones erróneas con respecto a las relaciones existentes entre los conceptos de área y perímetro y se evidencia el uso de conocimientos extraescolares cuando se trabajan con tareas auténticas asistidas por un software de realidad virtual.

Palabras clave: Tareas auténticas, Conocimientos extraescolares, Área y Perímetro.

Different researchers, teachers, and educators in mathematics throughout history have shown interest in the teaching and learning processes of mathematics in the classroom. This interest has exposed that some of the contend in geometry are presented as finished products, promoting the memorization of formulas (Araya & Alfaro, 2010).

The area and perimeter are geometric concepts that are presented explicitly and implicitly in many situations of daily life of the students, however, Amadeo and Yáñez (2006) affirm that the students have a confusion between these concepts, due to use of meaningless formulas. Gómez and Reyes (2015) highlight the fact that many of the students perform the proposed exercises in class, ignoring the origin of the algorithms used. In parallel, D'Amore and Fandiño (2007) emphasize that the concepts of area and perimeter of flat figures present from the scientific field some elements in common, but many others are only assumptions created by students and even by the teachers themselves.

However, it should be noted that extracurricular knowledge plays a role of great relevance within the training process of students, because better results are obtained when extracurricular knowledge is integrated with that acquired in the classroom (Schliemann et al., 2002). Similarly, Palm (2009) mentions that great contributions to the field of mathematics education could be generated if authentic word problems can be incorporated into the classroom.

Considering what has been mentioned so far and the fact that one of the places where technology has influenced considerably is in the school and in turn, the work of the teacher (Parra, 2012), this word poses the following research question: What designs of authentic tasks assisted by the Sweet Home 3D software that simulate aspects of students' daily lives under the theoretical approach proposed by Palm and Nyström (2009), promote the learning of the relationships between the concepts of area and perimeter of flat figures?

To answer this question, this study set as a general objective:

- Design authentic tasks assisted by sweet home 3D software that simulate aspects of students' daily lives under the theoretical approach proposed by Palm and Nyström, which promote the learning of the relationships between the concepts of area and perimeter of flat figures.
- To achieve the general objective set, the following specific objectives are proposed:
- Characterize some aspects of the theory of authentic task situations and some mathematical elements, which strengthen the work with the concepts of area and perimeter in extracurricular contexts.
- Articulate the aspects of the theory of authentic task situations and the mathematical elements in the design of authentic situations assisted by the Sweet Home 3D software, which comply with the aspects raised by Palm and Nyström.
- Analyze the data obtained in the implementation of authentic tasks and determine if the students managed to establish the existing relationships between the concepts of area and perimeter.

Theoretical and Referential Framework

Theory of authentic task situations

This is a local theory put forward by Dr. Torulf Palm in 2009. In it, word problems are considered as situations that are real for a group of people who are immersed within the described context and that allow to establish a connection between abstract mathematics and mathematics that are immersed in real life, which can be manipulated to eventually be proposed in the classroom as authentic tasks.

This theory seeks to link extracurricular mathematics with mathematics learned in the classroom through simulations of real-world situations. However, it is to be recognized that not all aspects surrounding a problem situation can be simulated in a word problem. Therefore, Palm and Nyström (2009) present three aspects and two sub-aspects that allow us to identify an authentic task, which are described below:

Event: The statement proposed in the task must be a phenomenon, event or incident that has existed in real life or failing that may occur, in such a way that the student recognizes the situation as an extracurricular environment and allows him to locate himself mentally in that situation.

Question: The questions that arise within the school task must have a close relationship with real life, since within the simulation it is essential to establish a concordance between the questions posed in the school task and the context of the phenomenon or event proposed in the event of the task.

Information/data: When word problems are raised, they not only describe the event, but also provide relevant information that will allow the solution of this, they also have explicitly and / or implicitly the conditions of the problem, the possible models to be built and even the purpose of the situation.

Specificity of the data (sub): In the event proposed in the task, it is not spoken in general terms, but rather, it seeks to give all the specific characteristics of the simulated situation, describing with proper names the people, objects and places that are linked to the situation.

Purpose in the figurative context (sub): The purpose of the task must be clear to the student within the simulated situation as it would be within the real-life situation, since the considerations that the student considers for the solution, will be framed with the purpose of the task.

Mathematical Referent

Fandiño and D'Amore (2009) present in detail the relationships between the concepts of area and perimeter of flat figures, which can be summarized as follows:

1. At parity of sides and perimeter, the one with the largest area is the regular polygon.
2. Among several isoperimetric polygons, the one with the largest area is the polygon with the most sides.
3. Among all isoperimetric figures (figures in general), the circle is the figure that has the largest area.

However, it is necessary to clarify what is meant by area and perimeter in this research and understanding that it is not possible to take for granted the definition of a mathematical object if the preceding elements that allow us to understand its beginning are unknown (Fandiño & D'Amore, 2009).

Perimeter conception: It is called perimeter to the measurement of the contour of a figure, this is measured in linear units which represents a length (for example: m, cm), understanding that the perimeter is different from what is understood by contour or border of a flat figure, since the contour is a closed line, and the perimeter is the measure the same.

Area Conception: The area is a two-dimensional measure accompanied by a conventional measure (for example: m2, cm2), understanding that the area is different from the surface, since the surface is a part of the plane and the area is the measure of said surface, understanding that parallel to the perimeter the area is usually defined as a synonym of surface.

Research Method

This research is qualitative, more specifically it is a descriptive case study. Six students belong to the Consejo Nacional de Fomento Educativo (CONAFE) of the municipality of Tzicatlacoyan in the state of Puebla. The students belong to an agricultural community, which is in the process of expansion, for this reason, in the community there are many houses in the process of construction, an aspect that turns out to be of relevance for the design of authentic tasks, since the students have been involved in the building process.

The study subjects do not have computing devices in their homes and have only made use of two computers installed in the Educational Institution, for this reason their knowledge is basic regarding the use of these devices. Another aspect to highlight is the fact that students only have access to the internet in the Institution since there is no coverage of this service within the community.

For the data collection, the following were used: a test of previous knowledge, which allowed to know if there are erroneous conceptions regarding the relationships between the concepts of area and perimeter; three designs of authentic tasks, which were constructed using their everyday language and situations that occur or came to occur within the Community; housing designs in Sweet Home 3D software, in this software students work on a 2D plane and visualize their effects in a 3D plane, students here can build or rebuild homes; video recordings, which allow the in-depth study of students at the time of the implementation of the tasks; and a semi-structured interview, with this it is possible to know how authentic the task was for the students.

Results and Conclusions

Initially, a Knowledge Test was presented to the study population, which allowed to identify that the students consider that there is a direct relationship between the concepts of area and perimeter, since, the students consider as true that if you have two iso-perimeter plane figures then these figures are necessarily equi- extensive, in turn, if you have a figure A with a greater perimeter than a figure B, then figure A has a greater area than figure B, it is also possible to identify that within a set of iso-perimeter figures they cannot identify that the figure that has the largest area is the figure with the largest number of sides. All these initial data agree with the assumptions that students can generate, which were raised in D'Amore and Fandiño (2007).

About working with authentic tasks, the students when facing them in one way were able to identify that these contexts emulated in the verbal problem are related to their environment, this aspect allowed them to think about the situation and forget the academic part, seeking to propose solutions that fit their reality. From this application you can rescue the fact that the software allowed them to quickly visualize the present magnitudes of their constructions. The following figure shows some of the students' work:

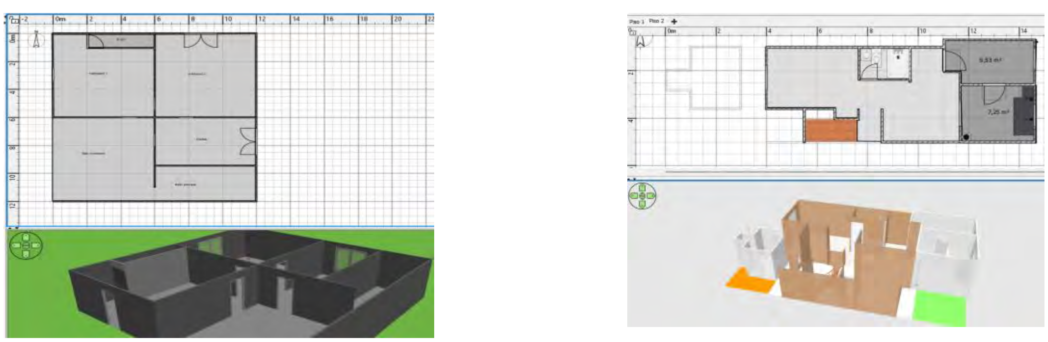

Figure 1. Student design in Sweet Home 3D Software.

This research is still in the process of analyzing the data collected, however, the information analyzed so far shows that working with authentic tasks allows the student to use their extracurricular mathematical knowledge and even their knowledge acquired in the classroom. In addition, these authentic tasks when linked to the use of the software allow the student to think differently than they would in a verbal problem that is worked on pencil and paper, since this software not only allowed them to have a realistic image of the environment that is described in the task, but also, it allows them a quick view of the considerations they come to have as possible solutions.

DEVELOPING A FRAMEWORK FOR CHARACTERIZING STUDENT-CREATED DIAGRAMS IN DGES

Xiangquan Yao
The Pennsylvania State University
xzy73@psu.edu

Dynamic geometry environment (DGE) offers a wide range of tools for its users to create and interact with geometry diagrams. In this paper, I propose a framework to characterize the geometry diagrams learners create in DGEs. This framework considers a learner's approach to creating a geometry diagram (i.e., perceptual-based, measurement-based, construction-based, and transformation-based), the driving force that guides the learner's specific actions in a DGE (i.e., tool-driven, and property-driven), and constraints in the resulting diagram (i.e., drawing, underconstrained, overconstrained, and appropriately constrained). Examples of student work on one geometry construction problem are used to illustrate the use of the framework.

Keywords: Geometry Diagram; Dynamic Geometry Environments; Geometric Construction

Geometry diagrams are a distinct mode of mathematical representation and communication that uses the visual features of specific drawn objects to convey meaning about abstract geometric concepts. Geometry diagrams are both signs that represent abstract geometric concepts and visual images that offer graphical-spatial properties, which can mobilize the perceptual activities of an individual. The duality of geometry diagrams has been discussed by researchers in mathematics education (Fischbein,1993; Laborde,2005). A geometry diagram can be used as a visual representation of a geometric figure, which displays the theoretical properties that define a geometric figure. Meanwhile, a diagram also has other properties that are not necessitated by the defining properties of the geometric figure but rather depend on the spatiographical features of the diagram. Geometry diagrams are thus ambiguous representations of sets of geometric concepts and their relations. The ambiguity of geometry diagrams as a semiotic mode of representation has urged researchers to examine the use of diagrams in teaching and learning geometry (Duval, 1995; Herbst, 2004; Alshwaikh, 2010; Jones, 2013; Dimmel & Herbst, 2015). However, learners' activity of constructing geometry diagrams is less examined. This is probably due to the limited number of tools to create a geometry diagram and the static nature of a geometry diagram in a paper-and-pencil environment. Traditionally, a geometry diagram is created through either freehand drawing or a straightedge-and-compass construction. In both cases, the diagram is static and cannot be manipulated directly.

The appearance of dynamic geometry environments (DGEs) not only allows users to create and then manipulate geometry diagrams with a wide range of tools but also adds a dynamic feature to them. DGEs like the Geometer's Sketchpad (GSP) and GeoGebra contain multiple sets of tools, such as free drawing tools, construction commands, measuring commands, and transformation commands. As a result, a user can create a diagram by using different DGE tools. Moreover, once a DGE diagram is created by a sequence of primitive commands chosen by the user, the diagram can be modified by dragging an element of it while still preserving all the geometric relations used in its construction. Therefore, when a user drags an element of a DGE diagram, it changes according to the geometry of its construction rather than the wishes of the user. In other words, once created, DGE diagrams become quasi-independent from the user and react to manipulations of the users by following the laws of geometry. This separates DGE diagrams from paper-and-pencil diagrams, which are statics and can be slightly distorted by students in order to meet their expectations. The variety of tools and the dynamism in a DGE enrich learners' construction activities. When asked to create a DGE diagram that represents a geometrical object, learners can be guided by different knowledge, take distinctive approaches, and use various tools, which can result in different diagrams. Therefore, it is important to develop a theoretical tool to analyze the different geometry diagrams in DGE that are intended to represent the same geometrical figure. In this paper, I will first present a framework for characterizing geometry diagrams in a DGE and then use the framework to describe some diagrams that students created with GSP. The affordances of the framework will also be discussed.

A Framework for Characterizing Student-Created Diagrams in DGE

The framework was developed based on a review of existing research on learning geometry in DGEs and my teaching and research work in DGEs (Figure 1). In developing the framework, I considered the possible approaches students could take to create a diagram, the driving force that guides students' specific actions in a DGE, and the constraints in the resulting diagram.

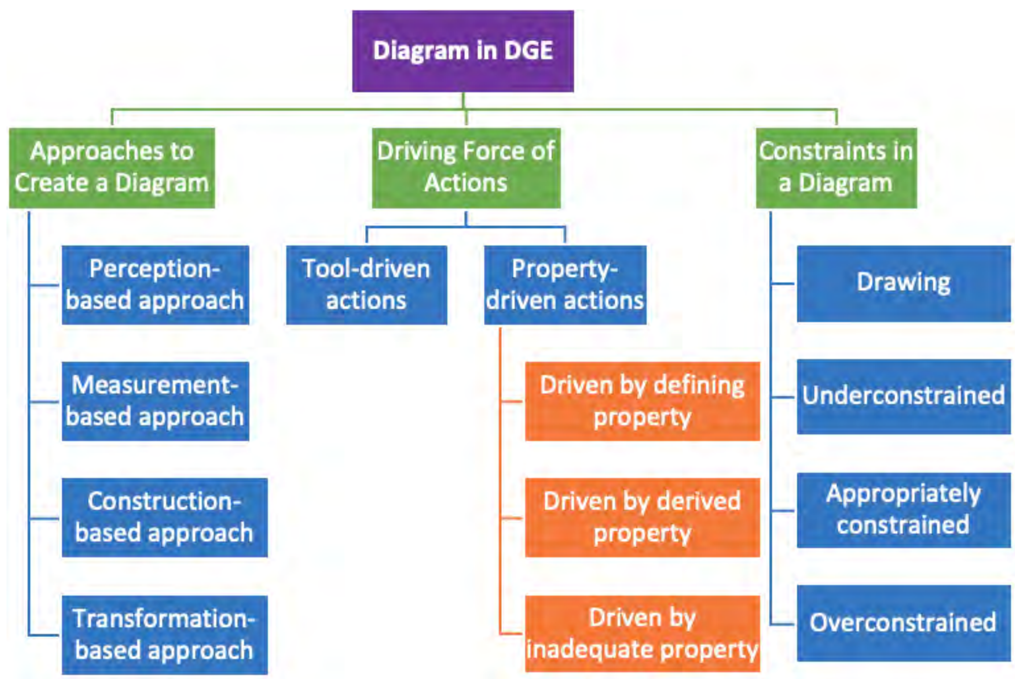

Figure 1: A framework for characterizing student-created diagrams in DGEs

Approaches to Create a Geometry diagram

Dynamic geometry software includes both free drawing tools and construction commands that intend to create a dynamic version of a compass and a straightedge. The accessibility to different sets of tools in a DGE allows learners to take different approaches to create a geometric figure. The preference for drawing over construction for beginning users of dynamic geometry software suggests that visual perception can sometimes dominate diagram creation in a DGE. Moreover, in the process of moving from drawing to construction, learners are likely to develop different construction techniques. Laborde (2005) differentiated between *soft* and *robust* constructions. A robust construction is a construction that passes the "dragging test" and is obtained by using geometrical objects and relationships characterizing the construction. In contrast, a soft construction is a partial construction in which variation is part of the construction itself, and a property becomes evident only at the point at which another property is satisfied. In discussing the validity criterion of constructions in DGEs, Stylianides and Stylianides (2005) identified *measurement constructions* as constructions that pass the “dragging test” but violate the Euclidean construction restrictions because of their use of measurement. Measurement constructions are different from the constructions that are compatible with straightedge-and-compass constructions. The two types of robust constructions suggest two distinct construction approaches in DGEs. Meanwhile, geometric transformations and the invariant properties under them offer a new approach to study geometry opposite to the classical synthetic geometry approach. The transformation commands in DGEs make it easier for learners to construct geometric objects through translation, reflection, rotation, and dilation. For instance, Villiers (2016) used transformation tools in GSP to construct geometric objects when solving the classic treasure-hunt problem and its generalization. Yao (2020) described how one preservice mathematics teacher used the rotation tool in GSP to construct an equilateral triangle with its vertices on three parallel lines.

Based on the above literature, I propose that learners could take at least four approaches to creating a diagram in a DGE. In a *perception-based* approach, a learner relies on visual perception to create the intended diagram. The use of free drawing tools and dragging is prominent in this approach. A learner who takes a *measurement-based* approach relies heavily on numerical measures to create the intended geometric figure. In this approach, the use of visual perception and primitive commands is heavily guided by numerical measures. In a *construction-based* approach, a learner mainly relies on geometric properties and primitive construction commands that are compatible with straightedge and compass to construct the intended geometric figure. A learner who takes a *transformation-based* approach largely relies on properties of transformations and transformation commands in a DGE to construct the intended geometric figure.

Driving Force of Actions

Studying the behaviors students exhibit when working with DGE tools can lead to insights about the appropriateness of their use of those tools and their understanding of geometric ideas. Researchers have observed that some students use technological tools judiciously and some students use technological tools inappropriately (Ball & Stacey, 2005). This indicates that students might use digital tools differently even though they take the same approach to create diagrams in a DGE. Guin and Trouche (1999) used *work method* to characterize students’ behaviors when using technological tools and identified five work methods for students’ use of symbolic calculators: random work method, a mechanical work method, a resourceful work method, a rational work method, and a theoretical work method. These different work methods reveal different roles technological tools and mathematical knowledge can play in students’ mathematical activities. Based on whether students’ actions with technology are guided by mathematics knowledge and their ability to interpret and predict results produced by technology, Hollebrands (2007) described *reactive* and *proactive* strategies as two distinct ways that students interact with tools in a DGE. Students who use a tool reactively perform an action based on what is produced on the computer screen rather than their knowledge of the geometric figure to be constructed. As a result, they might not be able to fully anticipate what may result from their technology-mediated action prior to performing it. In contrast, students who use the tool proactively are guided by their knowledge of the geometric figure to be constructed. They are likely to anticipate specific results of their technology-mediated action.

Based on the above literature, I argue that the dominant force that drives student actions in DGEs can be either the technological tools or knowledge of geometry. In *tool-driven actions*, students are guided by instantaneous feedback from the use of DGE tools rather than their knowledge of the geometric figure to determine their subsequent actions. It is parallel with Guin and Trouche's mechanical work method and Hollebrands' reactive strategy. In *property-driven actions*, students are driven by what they know about the properties of the geometric figure to be constructed and then choose DGE tools to produce these properties. These properties can be visually salient properties that define the geometric figure (e.g., a parallelogram has opposite sides congruent and parallel), less visually salient properties that still define the geometric figure (e.g., diagonals of a parallelogram bisect each other), properties that are derived from the defining properties but not sufficient to define the geometric figure (e.g., two pairs of adjacent angles of a parallelogram are supplementary), or properties that are inadequate or irrelevant to the geometric figure. In other words, students' actions can be driven by defining properties, derived properties, and inadequate or irrelevant properties. Property-driven actions are parallel with Hollebrands' proactive strategy.

Constraints in a Diagram

The dynamism of DGEs has provoked researchers to consider the robustness of a DGE diagram under dragging. Finzer and Benett (1995) established four categories (i.e., drawing, underconstraint, overconstraint, and appropriate constraints) for diagrams built in a DGE and used the case of drawing a parallelogram to exemplify these categories. Scher (2005) applied these four categories to assess squares created in a DGE. In this paper, I define the four categories according to the relationship between a diagram and the theoretical properties that it intends to represent. A *drawing* is a geometric object that perceptually appears to be the intended geometric figure but possesses none of its property under dragging test. It can easily be messed up by dragging. An *underconstrained* diagram is a geometric object that is constructed by using one or more properties that are necessary but not sufficient to define the intended geometric figure. Like a drawing, an under-constrained diagram can appear to be the intended geometric figure but collapse when particular elements are dragged. Laborde (2005) used soft construction to describe this type of geometric figure in a DGE. An *overconstrained* diagram is a geometric object that is constructed by using one or more properties that are sufficient but not necessary to define the intended geometric figure. Since excessive constraints are imposed on it, when dragged, an overconstrained diagram can only generate a subset of all the possible configurations of the intended geometric figure. An *appropriately constrained* diagram is a geometric object that is constructed by using properties that are necessary and sufficient to define the intended geometric figure. Laborde (2005) used robust construction to describe this type of geometric figure in a DGE. When dragged one or more elements of it, a diagram created by a robust construction maintains all of its significant properties and is possible to generate all the possible configurations of the intended geometric figure.

Example of Student-Created Diagrams

To illustrate the affordance of this framework, I will use some geometry diagrams that learners created with GSP when solving the following construction problem:

The center of a circle is accidentally erased, can you find it?

In addition to the above statement, a circle with its center hidden was shown in GSP. These geometry diagrams were collected through a larger research project that used a sequence of task-based interviews to examine the dynamic relationship between instrumented activities and the development of mathematical knowledge in solving geometric construction problems. The participants of this research project were a group of preservice secondary mathematics teachers from a large public university in the United States. All of the participants reported that they had not taken any geometry courses after high school. Before participating in this research project, these preservice teachers (PSTs) had learned how to use the GSP through a course that focused on teaching and learning mathematics with mathematics action technologies. Figure 2 presents a few of the methods that the preservice teachers used to find the center of a circle. The geometry diagrams in these methods are used to illustrate how the framework can be used to characterize student-created diagrams.

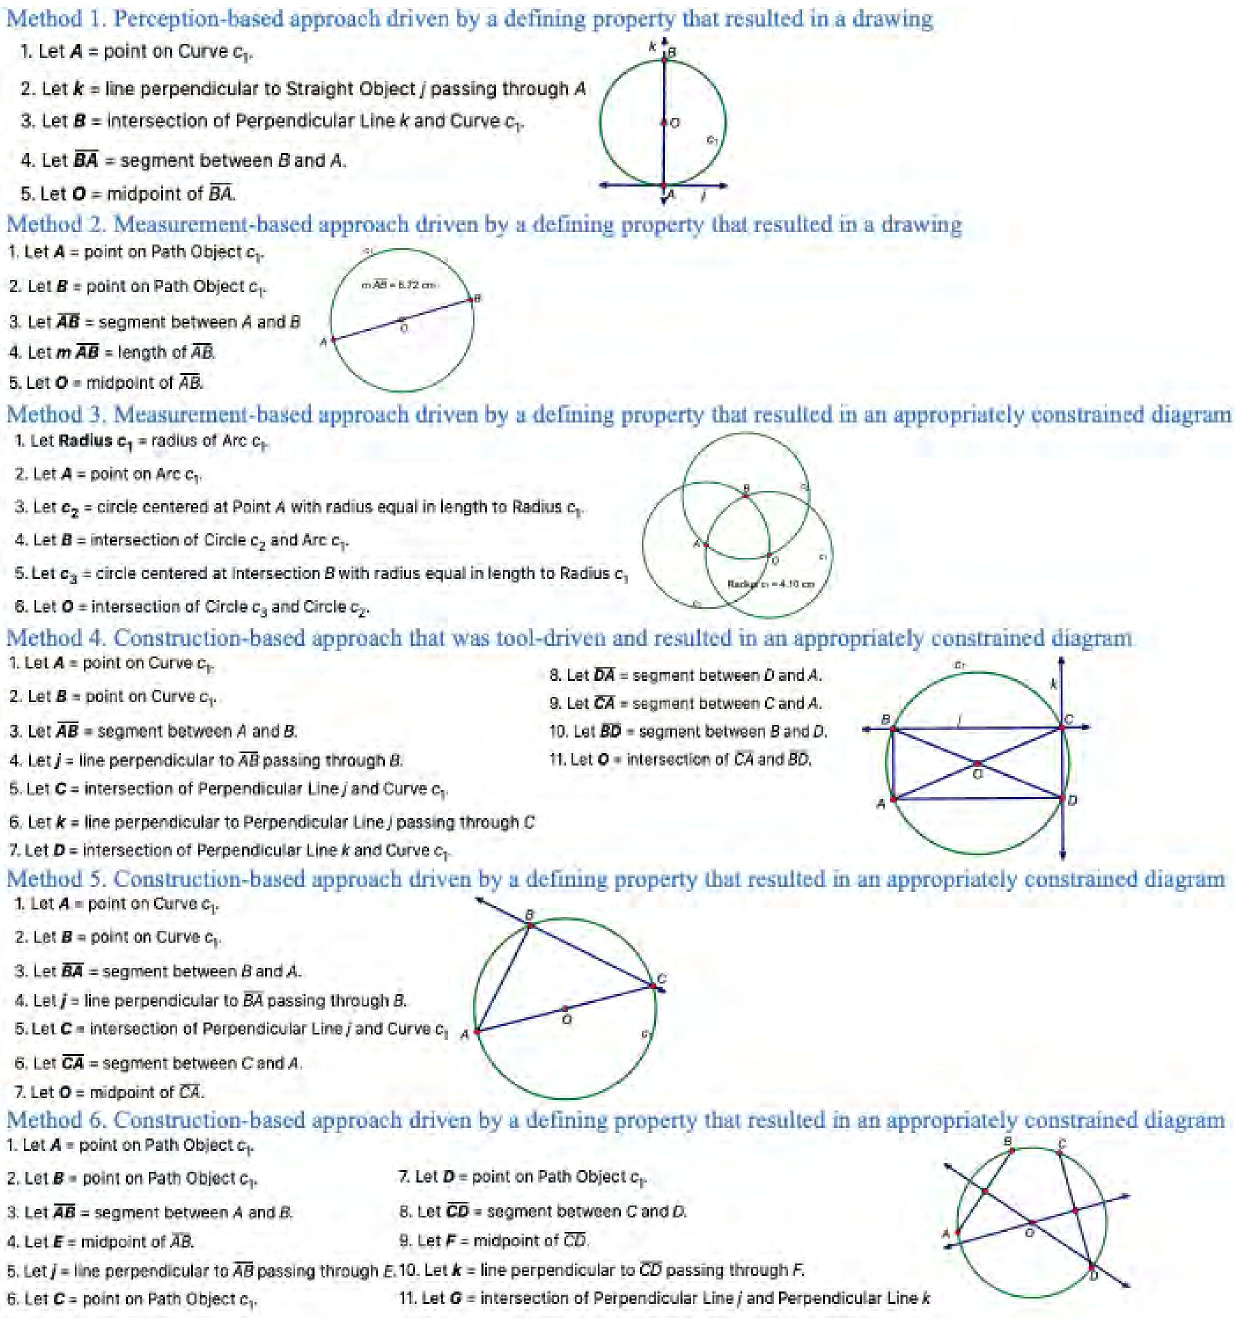

Figure 2: Methods for Finding the Center of a Circle

In Method 1, the PST was guided by the knowledge that the radius of a circle is perpendicular to the tangent line through its endpoint on the circle's circumference. He drew a line j and made it appear to be tangent to the circle through dragging. After marking the “tangent” point A, he constructed a line k perpendicular to line j at point A, which intersects the circle at point B. After creating segment $\overline{AB}$, he found the midpoint of $\overline{AB}$ and claimed that the midpoint was the center of the circle because $\overline{AB}$ was the diameter of the circle. In this method, the PST was guided by a property that could define the center of the circle. However, he relied on perception when creating a tangent line of the circle. Therefore, the diagram in Method 1 can be characterized as a perception-based approach driven by a defining property that resulted in a drawing. In Method 2, knowing that the diameter is the longest chord of a circle, the PST drew a chord, measured its length, and then gradually dragged an endpoint of the chord to make it the longest based on the numerical measure on the screen. After that, he found the midpoint of the chord and claimed that it was the center of the circle. Although guided by a defining property of the center of a circle, he relied on measurement to create the longest chord (i.e., diameter) of the circle. Therefore, the diagram in Method 2 can be characterized as a measurement-based approach driven by a defining property that resulted in a drawing.

In Method 3, the PST was driven by the idea that all points on the circle are equidistant to its center. After measuring the radius of the given circle by using the “Radius” command under the “Measure” menu, she chose a point A on the circle and the length of the radius of the circle to construct a new circle by using the “Circle by Center+Radius” command under the “Construct” menu, intersecting the given circle at point B. Using point B as the center and the length of the radius, she then constructed another circle by using the “Circle by Center+Radius” command again. She claimed that the point of intersection of the two new circles would be the center of the given circle. In this method, the PST was guided by a property that defines the center of the given circle. To use this property, she turned to measurement since the length of the radius of the circle was not given. The method did result in a diagram that passes the dragging test. Therefore, the diagram in Method 3 can be characterized as a measurement-based approach driven by a defining property that resulted in an appropriately constrained diagram.

In Method 4, the PST was initially guided by the idea that a square and its circumscribed circle share the same center. However, she did not know how to inscribe a square in the given circle. As a result, she planned to first make a rectangle and then adjust the side lengths to make it a square. After drawing a chord $\overline{AB}$ of the given circle, she constructed a perpendicular line j of $\overline{AB}$ from point B intersecting the circle at point C, and then a perpendicular line k of j from point C interesting the circle at point D. This resulted in a rectangle $ABCD$. After constructing the diagonals $\overline{AC}$ and $\overline{BD}$, she noticed that the point of intersection of the diagonals of the rectangle seemed to be the center of the circle. While dragging the vertices of the rectangle, she observed that it remained to be the center of the circle. As a result, she claimed that the point intersection of the diagonals of an inscribed rectangle is the center of the circle. In this method, the PST only used construction commands and dragging. Her actions were initially informed by a mathematical idea but then heavily driven by the instantaneous feedback from dragging. The feedback from dragging made her realize that she had already constructed the center of the circle. Therefore, the diagram in Method 4 can be characterized as a construction-based approach that was tool-driven and resulted in an appropriately constrained diagram.

In Method 5, guided by the idea that the hypotenuse of a right triangle inscribed in a circle is the diameter of the circle, the PST decided to inscribe a right triangle in the given circle. He drew a chord $\overline{AB}$ of the circle and then constructed its perpendicular line from an endpoint B of the chord. He then connected the endpoint of the chord and the point of intersection between the perpendicular line and the circle to create a right triangle ABC. He then found the midpoint of the hypotenuse $\overline{AC}$ of the right triangle ABC and claimed that it was the center of the circle. In this method, the PST relied on a property that defines the center of the circle and only used construction commands to locate the center. Therefore, the diagram in Method 5 can be characterized as a construction-based approach driven by a defining property that results in an appropriately constrained diagram. In Method 6, guided by the idea that the perpendicular bisector of a chord of a circle passes through the center of the circle, the PST drew a chord of the circle and constructed its perpendicular bisector by using the “Midpoint” and “Perpendicular Line” commands. Then, she drew another chord and constructed its perpendicular bisector in the same fashion. The point of intersection of the two perpendicular bisectors was marked as the center of the circle. This process of finding the center of the circle shows that the diagram in Method 6 can be characterized as a construction-based approach driven by a defining property that results in an appropriately constrained diagram.

Discussion and Conclusion

In this new framework, I consider learners' approaches to creating a geometry diagram, the mathematical knowledge that guides specific actions, and constraints in the resulting diagram. As a result, it provides a tool to describe geometry diagrams in a DGE that goes beyond any one of the three dimensions in the framework.

In DGEs a solution to a construction problem is often considered valid if the diagram is not possible to be messed up by dragging. In other words, a DGE geometry diagram is appropriately constrained when it passes the “dragging test”. However, the framework in this paper shows that an appropriately constrained diagram can be constructed in different ways. First of all, appropriately constrained diagrams can be created by using a measurement-based approach, a construction-based approach, or a transformation-based approach. For example, in the problem of finding the center of rotation, although both Method 3 and Method 5 produced the exact center of the circle, they took different approaches. While Method 3 relied heavily on measurement tools, Method 5 used construction tools. The existence of different approaches to constructing an appropriately constrained diagram has raised the issue of validity for diagrams in a DGE because the "dragging test" does not distinguish between diagrams involving measurement and diagrams involving only those software tools that are compatible with straightedge and compass. Stylianides and Stylianides (2005) introduced the compatibility criterion, which states that a DGE diagram is valid if and only if it maintains its geometrical properties under dragging and its construction process does not violate the DGE-construction constraints equivalent to those imposed on straightedge-and-compass constructions. The proposed framework can capture the subtle differences among appropriately constrained diagrams that are built upon different approaches.

Moreover, appropriately constrained diagrams can be created based on different geometric knowledge. For example, when finding the center of a circle, both Method 5 and Method 6 took a construction-based approach and yielded a construction for the center of the circle, but the two methods were built on different mathematical ideas. While Method 5 was guided by the idea that the hypotenuse of a right triangle inscribed in a circle is a diameter of the circle, Method 6 was built on the property that the perpendicular bisector of a chord of a circle passes through the center of the circle. The knowledge that is mobilized to create a geometry diagram reveals students’ understanding of the geometric object to be constructed and how it connects with other geometric ideas. The proposed framework affords us to account for the mathematical knowledge mobilized in the diagram construction process.

Appropriately constrained diagrams can also result from actions driven by the instantaneous feedback from the use of construction commands and dragging in DGE. For instance, when finding the center of a circle, although the preservice teacher in Method 4 did not anticipate that the intersection of diagonals of the inscribed rectangle would give the center of the circle, the instantaneous feedback from dragging made her realize that she just constructed the center of the circle. This suggests that an appropriately constrained diagram might not build on a learner's appropriate knowledge of geometry. Rather, it might be created unintentionally by the indirect invariants in DGE (Mariotti, 2014). This is particularly true when a learner is not aware of the invariant relationship resulting from the use of one and more construction commands. The proposed framework can capture this nuance among appropriately constrained diagrams. Meanwhile, teachers may leverage such realizations as opportunities to support the making and proving of conjectures.

The proposed framework also provides a tool to identify methods for creating geometry diagrams that are only possible in DGEs. As shown in Method 2 for finding the center of a circle, an appropriately constrained diagram can be created through a measure-based approach that is driven by a defining property of the intended geometry figure. However, this method is only possible in a DGE because it is impossible to measure the radius of a circle without knowing its center in a paper-and-pencil environment. Indeed, any method that is characterized as a measure-based approach driven by a defining property that results in an appropriately constrained diagram is unique to DGEs. Another unique method in DGEs is dragging an underconstrained diagram to create the intended geometry figure. Barabash (2019) suggested adding dragging as a geometric construction tool in DGE because it is an application of the continuity reasoning and intermediate-value theorem to geometry. In essence, dragging is the continuous variation of one of the parameters of a problem, which is only made possible by dynamic mathematics software.

Creating, interpreting, manipulating, and communicating with geometry diagrams is an important part of geometry learning. Dynamic geometry environment offers a wide range of tools for its users to create and interact with geometry diagrams. This paper proposes a framework to characterize a geometry diagram in a DGE that considers a learner's approach to create the geometry diagram (i.e., perceptual-based, measurement-based, construction-based, or transformation-based), the driving force that guides the learner's specific actions in a DGE (i.e., tool-driven, or property-driven), and constraints in the resulting diagram (i.e., drawing, underconstrained, overconstrained, and appropriately constrained). Examples of student work on a construction problem are presented to illustrate the use of the framework. These examples show that the proposed framework can capture the subtle but important differences among geometry diagrams that learners create in a DGE. The examples also show that the framework can be used to identify methods for creating geometry diagrams that are only possible in DGEs and moments of instrumental synergy.

GEOMETRIC REASONING OF K-5 IN-SERVICE TEACHERS

Teruni Lamberg
University of Nevada, Reno
Terunil@unr.edu

Lynda Wiest
University of Nevada, Reno
wiest@unr.edu

Keywords: Geometry and Spatial Reasoning; Teacher Knowledge

The purpose of this study was to investigate K-5 in-service teachers' geometric reasoning. Twenty teachers completed two types of problem sets. The first consisted of three problems in which participants were to examine three geometric figures, mark which did not belong, and tell why. In the second, participants were to answer five questions on a Venn diagram with three intersecting circles (classify figures in each circle and then draw a figure that would fit into the intersection of all three and one that wouldn't fit into any (with explanation). Developing geometric thinking involves understanding polygons as a class (Battista, 2007; Clements & Battista, 1992). Understanding polygons and relationships among polygons draws on students' ability to recognize and modify relevant attributes of polygons. This process also involves the ability to transform a non-example of a polygon into a polygon (Bernabeu et al., 2021).

Methods

Participants were 20 in-service teachers in a small city in the West. All were engaged in a mathematics professional development project.

We analyzed written work by marking the eight responses for each participant as correct, partially correct, or incorrect and writing notes about possible student thinking. We discussed these until we agreed on our assessments of participant work.

Results & Implications

Influencing factors in participants' work were content knowledge (e.g., knowing specific polygon and angle types), reasoning (ability to identify similarities and differences, to name the most constrictive class describing a set of figures, such as "triangles" versus "polygons," and to interpret a Venn diagram), and visual perception (e.g., noticing key mathematical features without relying on visual impressions, such as having "diagonal sides" or a "short base").

Participants operated at different levels of geometric reasoning (e.g., Pujawan et al., 2020) ranging from use of visual perception to properties of figures to classes of figures (with most falling into the second two categories). Participants who based decisions on properties of figures relied almost entirely on the sides (number and relationship to each other) with little consideration of angles. This points to the importance of that which can be directly observed. This can limit an ability to perceive and examine geometry problems more flexibly and could interfere with reasoning about shapes. Indeed, creativity in perceiving likenesses and differences among figures where several answers were possible was very limited (two examples where this did occur involved two isosceles and one scalene triangle that was noted by almost all participants, albeit worded differently, but one participant identified the scalene as different due to not having line symmetry and another chose the figure that had no obtuse angle). Finally, a key issue noted was lack of language precision (e.g., "straight three-sided shapes" instead of "triangles" and "all have right angles" instead of all have "at least one right angle").

We conclude that teachers need more work with content knowledge, reasoning (visual, oral, textual), and language precision in relation to teaching elementary geometry (e.g., Shockey & Pindiprolu, 2015).

SPATIAL ANXIETY MODERATES THE EFFECT OF SPATIAL ABILITY IN GEOMETRIC REASONING

Kelsey E. Schenck
University of Wisconsin - Madison
keschenck@wisc.edu

Mitchell J. Nathan
University of Wisconsin - Madison
mnathan@wisc.edu

Keywords: Spatial Anxiety, Spatial Ability, Geometry Reasoning

Geometry is a highly spatial domain of mathematics with studies investigating the relationship between spatial skills and geometry from both psychometric accounts (Newcombe, 2013) and domain-centric analyses (Battista et al., 2018). While spatial ability has been linked to general mathematics performance (Newcombe, 2013) and STEM achievement (Shea et al., 2001), little is known about the impact of spatial anxiety on specific domains of mathematics such as geometry. *Spatial anxiety*, a type of domain-specific anxiety, is a relatively new construct linked to spatial ability (Malanchini et al., 2017) and varies considerably among individuals (Lyons et al., 2018). Recently, studies have begun to investigate its links to mathematics (Schenck & Nathan, 2020), but these studies have focused on standardized assessments that encompass various mathematics domains. To the best of our knowledge, no studies have investigated the links between spatial anxiety and geometric reasoning, which drives the research question: What is the relationship between spatial anxiety and geometric reasoning as seen in verbal insight, and transformational proof?

Methods

The dataset includes undergraduate students (N = 94) recruited from a large Midwestern university in the United States. First, participants completed a series of demographic and covariate measures including a truncated spatial ability assessment based on the *Spatial Reasoning Instrument (*Ramful et al., 2017) and the *Novel Spatial Anxiety Scale* (Lyons et al., 2018). Next, participants played an embodied videogame, *The Hidden Village*, in which participants gave a verbal response to the veracity of eight geometry conjectures (Nathan & Swart, 2021). Videos were transcribed verbatim and time stamps were added to split the transcripts into eight conjectures for coding. This segmentation resulted in 752 videos clips to be coded. Verbal insight and transformation proof were given a 0/1 binary code based on the coding scheme developed by Authors (Nathan et al., 2021).

Results and Discussion

For verbal insight, the interaction between spatial ability and spatial anxiety was significantly associated with a decrease in the chance of producing correct verbal insight. Gender and spatial ability scores remained significantly associated with correct verbal insight. The results for the model predicting transformational proof showed that the interaction and spatial anxiety scores were significantly associated with a decrease in the chance producing a transformational proof. Gender and spatial ability scores also remained significantly associated. These results suggest that spatial anxiety may not have a direct effect on geometric reasoning but appears to moderate effect of spatial ability on geometry reasoning. This effect may need to be considered by researchers and educators who are looking to improve students' geometric reasoning.

Colleen Wahl
Alfred University
Wahl@alfred.edu

Chen Lin
University Western Ontario
clin393@uwo.ca

Keywords: Geometry and Spatial Reasoning, Integrated STEM / STEAM, Cognition, Body Movement.

Following the introduction of embodied cognition by Lakoff and Núñez (2000), several studies have expanded body-mind unity in mathematics education (Arzarello & Robutti, 2008; Radford, 2009; Nemirovsky & Ferrara, 2009; Roth, 2010). We desired to investigate mathematical embodied cognition in student's body movements, including choreographic choices based on mathematical ideas, where the students did not share a Science, Technology, Engineering, and Mathematics (STEM) background at their undergraduate level. This study, inspired by the aesthetic geometrical nature of the human movement categorized and perceived in the Laban Movement Analysis tradition (Dörr, 2003; Wahl, 2019). To address this purpose, we suggested the following research question: How do non-STEM background students perceive, demonstrate, leverage, and perform geometrical concepts and patterns in their moving bodies?

Methods

In this exploratory mixed-method study, we offered an elective interdisciplinary undergraduate course called "World of Pattern: Geometry, Body, and Beauty", where eight students are enrolled and the course is co-taught by faculty in STEM Education and Dance, both with unique specialties. For this study, some course experimental activities were developed in the classroom, which consisted of recognizing, planning, drawing, and performing movements. The course is still in process, and we video record and analyze students' body movements, their performances, gestures, and communications. The theoretical lens of perceptuomotor integration (Nemirovsky, Kelton & Rhodehamel, 2013) is used to articulate mathematical embodied communications. The figure below illustrates a portion of the student's planned performance while maintaining an awareness of spatial and geometric patterns and directions, followed by dancing in an octahedron.

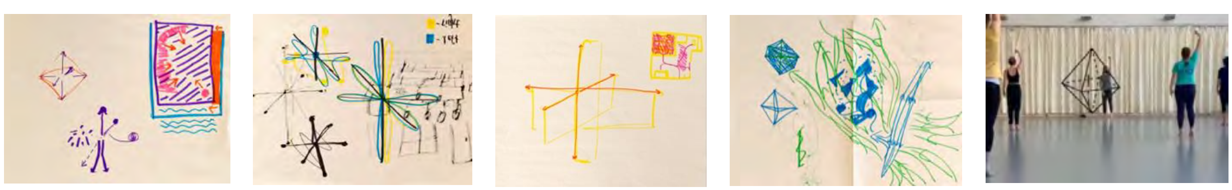

Figure 1 : Geometry is used to communicate, plan, and perform body movements.

Conclusion

The initial analysis of the students' actions and feedback shows the students search for patterns, directions, and dimensions in the space even beyond the obvious primary ones; they also create algorithms, plan, and perform sophisticated 3D geometrical shapes—individually or jointly—and propel themselves through the space in specifically patterned ways. We also found the interdisciplinary approach promoted spatial reasoning skills and awareness, which are vital in both geometry and dance. Furthermore, we saw the emergence of challenging creative ideas based on the concept of interconnectedness between mathematics and art, demonstrating mathematical embodied cognition with implications for both mathematics education and dance.

EXPLORING MEASUREMENT STRATEGIES AMONG NOVICE AND ADVANCED LEARNERS

Hannah Smith
Worcester Polytechnic Inst.
Hsmith2@wpi.edu

Luisa Perez Lacera
Worcester Polytechnic Inst.
lmperezlacera@wpi.edu

Avery Harrison Closser
Worcester Polytechnic Inst.
ahclosser@wpi.edu

Keywords: Geometry and Spatial Reasoning, Instructional Activities and Practices, Measurement.

Accurately measuring and estimating spatial quantities is important for success in and out of school and is contingent on grasping core concepts of measurement (Lehrer, 2003). In particular, *tiling*, or successive measurement without gaps, is critical for measurement (Leher, 2003). The concept of tiling is that measurement must be done from an acute start point such as the edge of an object. The current study explores whether and how elementary and college students use a start-point marker strategy for measurement, as an indicator of their understanding of tiling.

As part of a larger study, we compared the measurement strategies of 15 novice (elementary) and 25 advanced (college) learners (Harrison, 2019). Students were given a basketball, which had a diameter of 9.5 inches, and asked, “Can you estimate the diameter of this sphere?”

Students were provided with a 6- or 12-inch stick to help. Students were video recorded, and researchers coded measurement strategies during problem solving. Here, we analyze whether or not students used a start-point marker strategy, defined as: “the edge of the object lining up with the end of the reference tool” (Harrison, 2019). We compare the use of start-point markers across students’ accuracy on the task by percent error, calculated by subtracting the correct answer from the given answer, dividing it by the correct answer, and retrieving the absolute value. We ask: 1) How often do college and elementary students use a start-point marker measurement strategy? 2) How does using a start-point marker strategy affect measurement accuracy? 3) Does the accuracy differ between college and elementary students?

First, we found that 72% of college and 67% of elementary students used a start-point marker. Second, a 2 (age: college vs. elementary) × 2 (start-point marker: yes or no) ANOVA revealed a significant main effect of age, $F(1,36) = 18.00$, $p < .001$. College students' average percent error ($M = 8.39$, $SD = 5.88$) was significantly lower than elementary students' ($M = 20.71$, $SD = 19.94$). Next, we found a significant main effect of the start-point marker, $F(1,36) = 9.04$, $p = .005$. Those who used a start-point marker ($M = 10.04$, $SD = 9.64$) had a lower percent error than those who did not ($M = 19.9$, $SD = 20.08$). Third, we found a significant Age × Strategy interaction, $F(1,36) = 10.30$, $p = .003$. When participants used a start-point marker, there were no significant differences in accuracy between age ($p = .79$). However, when participants did not use a start-point marker, elementary students had a significantly higher percent error than college students ($p < .001$). There were no differences in percent error between college students based on strategy. However, elementary students who used a start-point marker had a significantly lower percent error than those who did not ($p = .002$).

The results from this study have implications for instruction and practice in classrooms. We found that when novice learners use a start-point marker strategy, they have a much more accurate measurement estimation, adding to the literature on concepts of measurement as a critical component of instruction (Lehrer, 2003). Researchers should expand this work with a larger sample to see if this strategy is successful in other contexts and to identify other successful measurement strategies that might inform classroom practice.

SCALE IT UP? I DO NOT KNOW WHAT THAT MEANS

Lili Zhou
Purdue University
Zhou756@purdue.edu

The concept of *scale/scaling* is important in mathematics as well as in other disciplines and in real life. In mathematics, the concept development of *scale/scaling* derives measurements from qualities and links to spatial reasoning and multiple mathematical topics (e.g., proportion). I observed a group of 8th-grade girls (n=10) completing a scaling task in an afterschool STEM club; the girls were asked to scale the original design by a factor of two. Eighty percent of the girls scaled the original design in one direction or two directions. See Figure 1, the sample of student work showing that she only scaled the original design in one direction.

Initial Design	Student Work	Correct Model
		

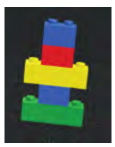

Figure 1. Scaling Task

I interpret this student's work as her having understood the concept of scaling by a factor of two to mean using double the original number of blocks to make the design bigger. She chose to make the design wider, showing her incomplete understanding of the concept of scale/scaling. My observation prompted me to investigate how scale/scaling is described and used in the mathematics curricula, including the official curriculum and the intended curriculum (Remillard & Heck, 2014). Here, I only focus on scale/scaling in the official curriculum (i.e., CCSSM).

Exploring the Concept of Scale in CCSSM

I chose CCSSM because, as an official curriculum, it is widely adopted and greatly influences the intended curriculum (Reys, 2014). Throughout CCSSM, the word *scale* appears nineteen times, *scaled* appears three times, and *scaling* appears twice. These appearances are distributed throughout multiple topics: (a) measurement, in the area of Measurement and Data, CCSSM expects students to use scaled pictures and scaled bars to represent and interpret data; (b) multiplication, in Grade 5, CCSSM expects students to "interpret multiplication as *scaling* (resizing)" (G5, p. 36); (c) drawing, CCSSM expects students to "solve problems involving *scale* drawings of geometric figures" (G7, p. 49); and (d) transformation, in high school geometry, scale is used in similarity, e.g., "…formalizing the similarity ideas of 'same shape' and 'scale factor'…" (HS-G, p. 74).

Conclusion and Discussion

Scale/scaling covers multiple mathematics topics in CCSSM and is used to describe and explain other concepts. However, there is no clear description of *scale/scaling,* and no learning expectations for the development of students' understanding of *scale/scaling*. CCSSM expects students to interpret multiplication as *scaling*, which interprets *scale/scaling* as a linear quantitative concept. Later, in the topic of similarity, *scale/scaling* is presented as both qualitative and quantitative transformation of figures. Given the importance of scale in mathematics and other disciplines (e.g., engineering), I suggest that mathematics curricula present *scale/scaling* as a formal concept, providing a rigorous definition and explicating learning expectations to support the development of understanding.

Chapter 6:
Mathematical Knowledge for Teaching

DEVELOPMENT AND MEASUREMENT OF STATISTICAL KNOWLEDGE FOR TEACHING

We describe novel teacher education curriculum materials designed to develop secondary PSTs' Statistical Knowledge for Teaching (SKT) along with a new test for measuring teachers' SKT. We report PSTs' changes in SKT from learning with the materials in a preliminary study.

Keywords: Teacher Knowledge; Data Analysis and Statistics

Teachers create meaningful student learning opportunities by drawing on a variety of knowledge domains—encompassing not only knowledge of the content to be learned but also additional knowledge connected to the work of teaching (Hill et al., 2008; Shulman, 1986; Thwaites et al., 2011). Assisting preservice teachers (PSTs) in developing this sort of mathematical and statistical knowledge (termed mathematical knowledge for teaching (MKT) and statistical knowledge for teaching (SKT)) is of particular interest to those who teach mathematics and statistics content courses in secondary mathematics teacher preparation programs because we know that there is an association between teachers' MKT/SKT and high quality instruction (Hill et al., 2007). However, there is dissonance between the preparation PSTs are receiving in these courses and the preparation they need to develop MKT/SKT (Goulding et al., 2003). Additionally, understanding how PSTs develop MKT/SKT and how researchers observe and/or measure MKT/SKT is still an open question (Groth, 2017; Silverman & Thompson, 2008; Thwaites et al., 2011). The MODULE(S^2) project works in this space and has created curricular materials that provide opportunities for secondary PSTs to develop MKT and SKT in university algebra, geometry, modeling, and statistics courses. With regard to measures, some tests exist for measuring MKT (e.g., Hill et al., 2007; Mohr-Schroeder et al., 2017), but none exist for measuring secondary (grades 6-12) teachers' SKT. In this brief report, we describe the development of a test we created to assess secondary PSTs' SKT prior to and after learning with MODULE(S^2) materials, and report PSTs' changes in SKT from learning with the statistics MODULE(S^2) materials in a preliminary study.

Just as mathematics and statistics are related yet distinct fields (Cobb & Moore, 1997), MKT and SKT are related yet distinct domains of knowledge (Groth, 2007, 2013). Both MKT and SKT include subject matter knowledge (SMK: understanding the logical necessity of aspects of the content to be taught) and pedagogical content knowledge (PCK: understanding how to make content understandable to students) (Groth, 2013; Hill et al., 2008; Simon, 2006). However, SKT differs from MKT because it contains nonmathematical elements, such as assessing the suitability of statistical questions for the context of a statistical investigation (Groth, 2007). The *MODULE(S^2): Statistics for Secondary Mathematics Teaching* curriculum (Casey et al., 2019) was created to develop PSTs' SKT regarding study design, exploratory data analysis, statistical inference, and association, through enactment of the statistical investigation cycle. The materials align with the content of a modern college introductory statistics course while also preparing PSTs to address the CCSS-M (CCSSI, 2010) statistics standards in their teaching and meeting the recommendations from professional societies (AMTE, 2017; Bargagliotti et al., 2020; Franklin, 2015). Attention is given to developing PSTs' critical statistical literacy (Weiland,

2017) and abilities to implement equitable teaching practices. This is accomplished through a sustained focus on data sets addressing inequities in educational and social contexts, asking PSTs to wrestle with the dissonances that analyses of these data sets illuminate, and prompting PSTs to reflect on how they might teach lessons with their future students to leverage these contexts for learning. Opportunities for PSTs to develop their PCK are integrated throughout the materials, including learning common conceptions of students when learning statistics, responding to student work, constructing lessons, analyzing curriculum standards, and learning how to use statistics to empower action for social change. The materials are organized into three modules that could collectively be taught in a semester course.

SKT Test

We developed a 7-item SKT test along with an accompanying scoring rubric for the MODULE(S^2) project. It is designed to assess secondary teachers' knowledge for teaching the statistics standards in the CCSS-M (CCSSI, 2010). It is aligned with Groth's (2013) conceptualization of SKT, comprehensively assessing SMK and PCK. Its design drew upon previous work to develop SKT assessment items (e.g., Casey et al., 2019; Groth, 2014). Items assessing PCK utilized released student work from LOCUS (n.d.) to document student conceptions of statistics. We piloted and revised the instrument and its accompanying rubric for two years. Revisions focused on improving the clarity of the language as well as the reliability of the scoring. Thus, we used multiple methods to work towards test content validity (AERA et al., 2014) for the use of this SKT test for this study.

The test contains 12 selected response prompts (e.g., multiple choice) and 20 open-ended prompts across the 7 items. The maximum number of points possible on the test is 45. Three of the items, worth a total of 8 points, address SMK. An additional 3 items, totaling 29 points, address PCK. Finally, a single item addresses both SMK (parts i and iii, worth 3 points each) and PCK (part ii, worth 2 points). This item is shown in Figure 1 as a sample.

Imagine you were teaching a high school (non-AP) class and presented the following task to your students:

A simple random sample of 100 high school seniors was selected from a large school district. The gender of each student was recorded, and each student was asked the following questions: 1. Have you ever had a part-time job? 2. If you answered yes to the previous question, was your part-time job in the summer only? Their responses are shown in the table to the right.

Construct a graphical display that represents the association between gender and job experience for the students in the sample.

Job Experience	Gender		
	Male	Female	Total
Never had a part-time job	21	31	52
Had a part-time job during summer only	15	13	28
Had a part-time job but not only during summer	12	8	20
Total	48	52	100

As your students work on the task, you notice a student named Juan has created this graph (shown at the right).

i. Comment on the strengths and weaknesses of this graph.
ii. How would you respond to Juan in order to advance his thinking concerning graphical displays to show association between categorical variables?
iii. Complete the task yourself, creating the best graphical representation for representing the association between gender and job experience.

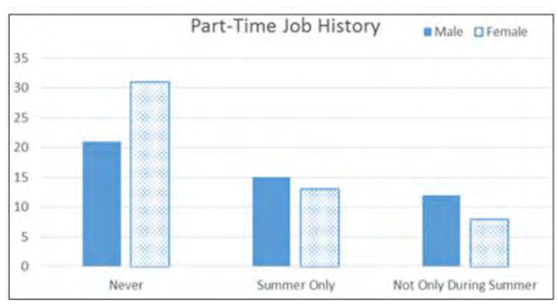

Figure 1: Sample item; parts (i) and (iii) focus on SMK while (ii) focuses on PCK

The scoring rubric for the item in Figure 1 delineates how the points should be awarded for this item. To earn 3 points for part (i), the response needs to include at least one strength and the following two notable weaknesses: (1) there is no label on the vertical axis; and (2) it displays frequencies instead of conditional relative frequencies. Relatedly, when creating the best graphical representation in part (iii), a representation received all three points if it was a segmented bar graph showing percentages conditioned by either categorical variable and there were no flaws in the execution of this representation. The rubric tiered down the point values when some elements were missing. For part (ii), a response received 2 points if it included questions or proposed activities for Juan that addressed either of the notable weaknesses from part (i). A response to part (ii) received 1 point if it accurately gave an explanation about what is incorrect or correct about Juan's graph but did not prompt Juan to think about it himself.

Data Collection and Results

The SKT test was given to PSTs in two statistics-for-teachers classes at separate universities that used the MODULE(S^2) materials in the 2020-21 academic year. It was given at the start of the semester as a pre-test and at the end of the semester as a post-test. It was administered as a take-home test without a time limit. The tests were independently scored by 2 graduate assistants using the scoring rubric, and they reconciled any scoring discrepancies for each item. The sample sizes were 11 on the pre-test and 11 on the post-test; we present results here for the 10 PSTs who submitted both tests.

Figure 2a shows the pre- and post-test scores for PSTs' overall SKT, with line segments linking each PST's pre- and post-test scores.

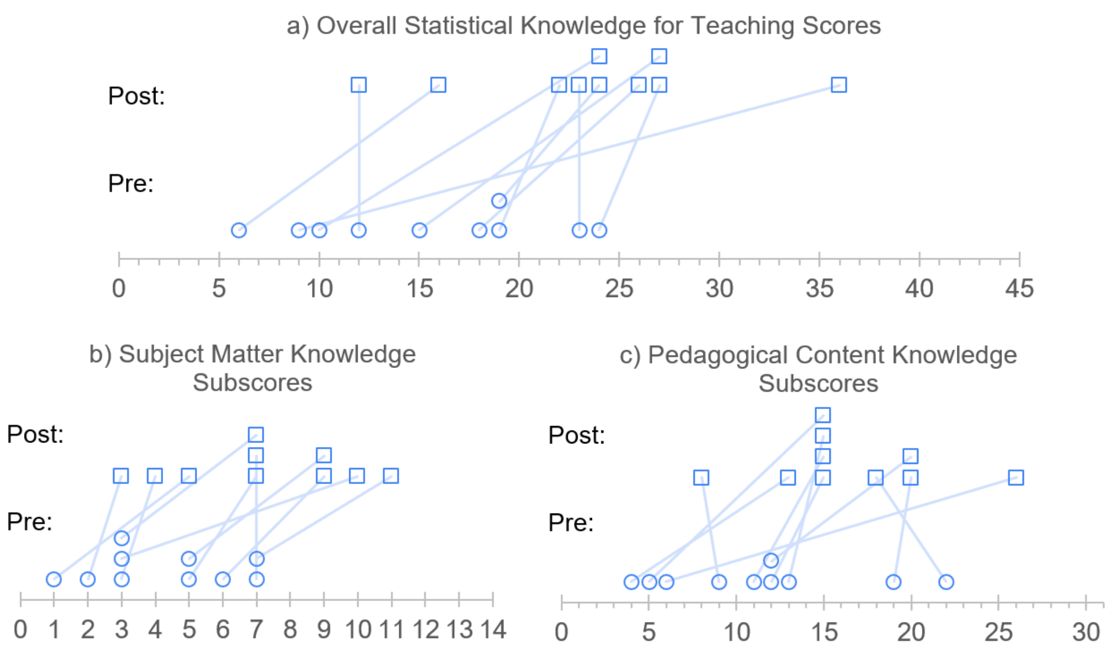

Figure 2: Paired dotplots of pre-test (circles) and post-test (squares) scores. (a) Overall scores, (b) SMK subscores, (c) PCK subscores

We observe a general pattern of increases from pre to post; the mean pre-test and post-test scores were 15.5/45 (34.4%) and 23.7/45 (52.7%), for an average increase of 18.22 percentage points (standard deviation 18.20). This results in a strong effect size, measured as 0.92 by Cohen's d with Hedge's correction. Similar graphs are provided in Figure 2 for SMK (2b) and PCK (2c). These also show that PSTs generally improved from pre- to post-test in both of these areas, some quite substantially. The mean SMK pre-test and post-test subscores were 4.2/14 (30.0%) and 7.2/14 (51.4%), a mean increase of 21.4. The mean PCK pre-test and post-test subscores were 11.3/31 (36.5%) and 16.5/31 (53.2%), a mean increase of 16.8. We concluded that PSTs made similar gains on the SMK and PCK portions of the test. An item-by-item analysis revealed that, on average, the PSTs considerably improved their performance on all items from pre- to post-test and that their mean change was roughly the same for SMK- and PCK-related items overall.

Discussion

The MODULE(S^2) project works to resolve the conflict between the preparation PSTs have historically received in their university content courses and the preparation they need to develop their MKT/SKT. The statistics teacher education curriculum materials made by the MODULE(S^2) project were designed to address this by attending to the development of PSTs' SKT, including SMK and PCK development simultaneously. This preliminary study has provided initial evidence that harmony in developing these aspects of SKT concurrently is possible and productive. Use of the MODULE(S^2) project's materials considerably enhanced PSTs' SKT, including both their SMK and PCK. Additionally, we believe that strong SKT supports teachers to effectively implement data-driven lessons focused on equity. The design of the MODULE(S^2) project's materials to improve PSTs' critical statistical literacy along with evidence from this study that PSTs' SKT improved through their use of the MODULE(S^2) project's materials is promising for the development of teachers who can teach equity-focused statistical lessons. Further research on a larger scale to study the effects of the MODULE(S^2) project's materials on SKT and critical statistical literacy is needed to move to more substantial findings. In addition, further research that explores how PSTs' SKT evolves through use of the MODULE(S^2) project's materials—including features of the materials' implementation that support or inhibit PSTs' SKT development—is recommended.

An additional contribution of this preliminary study is the development of a SKT test for secondary teachers, addressing a longstanding lack of teacher instruments in statistics education (Groth & Meletious-Mavrotheris, 2018). Future projects can conduct large-scale validation studies of the test to work towards establishing more validity evidence for its use in measuring teachers' SKT.

Knowledge of student misunderstanding is a critical aspect of teacher knowledge, with implications for teacher practice and student achievement. However, there is no mechanism describing the progression from how teachers identify student misunderstandings to the types of strategies used when addressing misunderstandings. In this study, we analyze 342 cases of student misunderstandings, underlying rationales, and instructional strategies reported by 153 elementary mathematics teachers. Using fsQCA, we identified pathways showing the conditions that lead to teachers providing instructional responses that target the misunderstanding and/or build students' conceptual understanding. Overall, we found that if teachers provide mathematical rationales to explain why students struggle with a concept/procedure, then their instructional responses help students develop conceptual understanding.

Keywords: teacher knowledge

Many conceptualizations and studies of teacher knowledge place an emphasis on teacher knowledge of students, due to its broad implications for how teachers plan instruction, deliver content, and interact with students (e.g., Hill, Ball, & Schilling, 2008; Shulman, 1986; Carlsen, 1999). A subdomain of teachers' knowledge of students is their knowledge of student misunderstandings (KOSM), a theoretically relevant subdomain which can be traced back to Shulman's (1986) conceptualization of pedagogical content knowledge. Research on teachers' KOSM has shown evidence that there is a positive relationship between teachers' KOSM and student achievement (Sadler et al., 2013; Chen et al., 2020). However, while studies have linked teacher KOSM to student achievement, it is unclear *how* this knowledge plays out in teacher decision-making about instructional strategies. To capture *how* this knowledge plays out, we use a novel research method, *fuzzy set qualitative comparative analysis* (fsQCA; Ragin, 2000, 2008), to begin modeling pathways that link how teachers describe student misunderstandings to the types of instructional decisions they report using to address the misunderstandings.

Sadler et al. (2013), Chen et al. (2020), and Hill and Chin (2018) studied science and mathematics in-service teachers' ability to anticipate the most common distractor for students on multiple-choice items. Sadler et al. (2013) found that science teachers who could identify the misunderstanding through the multiple-choice distractors had larger classroom gains than those teachers who could only identify the correct answer. Chen et al (2020) replicated the previous findings but with biology content rather than physical science. Relatedly, Hill and Chin (2018) noted that although knowledge of student misunderstandings can be difficult to measure, they were able to identify a link between this aspect of mathematics teachers' knowledge and student outcomes. These studies indicate a link between teacher knowledge of misunderstandings, instruction, and student outcomes by way of how teachers identify and address student misunderstandings in conceptual and procedural ways. However, research has yet to identify the mechanism that describes the progression from how teachers are identifying student misunderstandings (procedural, conceptual, or a combination) to the types of strategies used when addressing the student misunderstanding. Thus, the present study aims to understand the association between how teachers think about student misunderstandings and their planned instructional strategies to address the misunderstandings. The research questions were:

What pathways describe how teachers' descriptions and rationales for a misunderstanding are associated with:

1. The type of instructional response (i.e., targeted to build students' conceptual or procedural understanding) they use to address student misunderstandings?
2. Whether the instructional response is specific or not specific to the misunderstanding teachers are aiming to address?
3. Whether the instructional response is or is not both specific and building students conceptual understanding when addressing student misunderstandings?

Conceptual Framework

We use the constructs of procedural and conceptual understanding (or knowledge) to describe the ways teachers identify student misunderstandings and the instructional strategies used to address the misunderstandings. Procedural understanding is commonly defined as an understanding of procedures and carrying them out flexibly and appropriately (Eisenhart et al., 1993; National Research Council, 2001; Rittle-Johnson et al., 2015). For instance, knowing the steps involved adding two fractions with unlike denominators is an indicator of procedural knowledge (i.e., find a common denominator, find equivalent fractions, add across the numerator, keep the denominator the same). Instructional strategies focusing on students' procedural understanding of adding fractions would highlight step-by-step overviews of how to carry out algorithms or ways to remember the steps (i.e., a song or mnemonic device).

Conceptual understanding is commonly defined as an understanding of concepts and the interconnectedness of topics that provide the structure for understanding procedures (Eisenhart et al., 1993; NRC, 2001; Rittle-Johnson et al., 2015). Returning to the fraction addition algorithm, a student with conceptual understanding of adding fractions would show an understanding of ideas such as part-whole relationships and equivalent fractions, as well as the meaning of addition. Instructional strategies supporting students' conceptual understanding of adding fractions would highlight strategies linking the ideas of part-whole relationships, equivalent fractions, and adding fractions.

Methods

This study used data from a sample of 153 elementary mathematics teachers located in Indiana and North Carolina. The teachers completed an online, open-ended survey with three items asking teachers to (1) identify common student misunderstandings related to fraction content, (2) provide a rationale for why students have a given misunderstanding, and (3) report the instructional steps they would take to address the misunderstandings. Since many teachers answered the three survey questions referring to more than one misunderstanding, the dataset was parsed out such that each row contained one misunderstanding and subsequent rational and reported instructional strategies. This means the 153 teachers provided 342 complete cases of a student misunderstanding and the subsequent rationale and instructional decision.

To investigate the links between how teachers describe student misunderstandings and the types of instructional decisions they report using to address the misunderstanding, this study employed fsQCA (Ragin, 2000, 2008). fsQCA views a collection of individual cases through a set-theoretic lens, where Boolean logic is used to look across the cases and identify solution pathways that represent the logical paths linking conditions and outcomes. Using fsQCA to find these solution pathways allows us to describe the ways in which how teachers identify and understand the reasons for a student's misunderstanding leads to the types of instructional strategies they use to address misunderstandings.

For the analysis, each case was coded for three conditions related to how teachers described a misunderstanding. First, whether the student misunderstanding was described as procedural or conceptual in nature (student misunderstanding type). Second, whether the source of the misunderstanding was attributed to students' understanding of procedures or students' underlying thinking about mathematical concepts. Third, whether there was an external factor provided as the source of the misunderstanding (e.g., issues concerning curriculum or home support).

We also coded each case for three outcomes related to the instructional strategies teachers reported using to address the misunderstanding. First, whether the instructional strategy aimed at building students' procedural or conceptual understanding Second, whether the instructional strategy was specific to the misunderstanding or generic. Third, whether the instructional strategy was specific to the misunderstanding and built students' conceptual understanding or not. For an overview of the conditions and outcomes, see Table 1. All coding was completed by two raters who initially coded a small number of cases (10-20) and checked their coding until interrater reliability was >90%. Then, a larger number of cases were coded independently and all disagreements were reconciled.

After coding, we used fsQCA software (Ragin & Davey, 2016) to carry out the quantitative analysis, referred to as a truth table analysis (Ragin, 2008). The truth table analysis identified the combinations of the presence and absence of conditions (pathways) that led to the presence or absence of a given outcome.

Results

We report the eight pathways leading to the four different types of instructional responses (Table 2). Table 2 indicates which combinations of factors were present in how teachers identified student misunderstandings (e.g., procedural versus conceptual) and the underlying rationales for these misunderstandings (e.g., based on students' mathematical or non-mathematical thinking) and the subsequent instructional response.

Due to the limited space, we specifically focus on one pathway that leads to teachers reporting instructional strategies aimed at building students' conceptual understanding. Teachers in Pathway 1 describe the student misunderstandings conceptually *and* provide a mathematical rationale for why the students have the misunderstanding which led to a conceptual instructional response. An example of this pathway is below. The teacher described how students have a misunderstanding about the result of multiplying and dividing fractions because they do not make connections between the meaning of a fraction and the operation.

When you multiply, the number gets bigger and when you divide it gets smaller [referring to whole number operations]. When students move into operations with fractions, their understanding of what a fraction means is lost, and they don't understand why their product is smaller than the factors or the quotient is bigger than the dividend/divisor.

The teacher identified the misunderstanding as a conceptual issue with students' understanding of fractions as different from whole numbers. This teacher later explains the rationale for this confusion could be that students, "miss the understanding that a fraction means that you divide a whole into parts… a number less than one." To address this misunderstanding this teacher:

I have used explicit examples of multiplying by 0 (where the product is 0 - less than the factors), by 1 (where the product is the same as a factor), and by 2 (where the product is greater than the factors) to show students that there is a pattern to the value of the product compared to the factors. When they see that x0 is less than the factors and x1 is equal to a factor, it becomes easier for them to accept that multiplying by a proper fraction will result in a product less than the factors. I continue with multiplying by 1/2 because it's an easy fraction and students typically know that it's the same as dividing by 2, which they know will result in a smaller product. Through targeted examples and a slow approach to looking for patterns, students "get it" and are able to correctly predict whether the product will be smaller or larger than the factors.

By identifying a misunderstanding through conceptual issues, along with a mathematical rationale for the misunderstanding, this teacher is able to provide an instructional approach that uses targeted examples and pattern-making to help students overcome the misunderstanding conceptually.

Overall, across all pathways, it is interesting to note the role of teachers' rationale for student misunderstandings. When teachers are describing strategies that support students' conceptual understanding (Pathway 1, 3), it is important that teachers base the rationale for the misunderstanding on students' mathematical thinking. In contrast, when teachers are not providing specific or conceptually grounded instructional strategies, then they are not providing a mathematical rationale for the misunderstanding (Pathway 4-7).

How teachers interpret the student misunderstandings also seems relevant to their instructional decision. Two of the three pathways leading to a conceptual instructional response include the teacher interpreting the misunderstanding conceptually, whereas two pathways leading to a procedural response include teachers interpreting the misunderstanding procedurally.

Significance of the Study

This study adds depth to the field's understanding of teacher knowledge of student misunderstandings by capturing an initial snapshot of how this knowledge is operationalized in relation to instructional strategies. While student misconceptions are well studied in the literature on teaching and learning, there remains a need to identify how teachers progress from *identifying* misunderstandings to *addressing* them. We found multiple descriptive pathways that highlight the complex ways in which teachers make sense of student misunderstandings in order to address them. Each path is important, but the repeated occurrence of providing a mathematical rationale about the misunderstanding appears to be an important condition to better understand why teachers provide the instructional strategies they use. It is plausible that teachers who have considered what causes common misunderstanding are more able to craft an instructional response that target the conceptual issues rather than simply addressing the procedural components. This suggests that time spent analyzing student responses and discerning why the mistake was made could be a valuable addition to teacher preparation and planning.

Of similar note, is how teachers conceptualize and explain student errors. If teachers explained the misunderstanding procedurally, their response to it was procedural. This is not unexpected, but reestablishes the importance of teachers having a deep conceptual understanding of the content and of their students (Shulman, 1986). Without that conceptual understanding, it is unreasonable to expect a conceptual instructional response, which is what we see in these pathways.

Overall, we find value in the fsQCA methodology to assist in answering questions about the mechanisms describing how and why teachers' make particular instructional decisions. How teachers interpret a misunderstanding (either procedurally or conceptually) and the rationale for the misunderstanding (mathematical or non-mathematical) seem to be key pieces in understanding how teachers choose to respond to student issues.

Table 1: Description of Conditions and Outcomes

Conditions and Outcomes	Description
Conditions	
Students' misunderstanding	Captures the extent to which teachers described student misunderstandings as solely an issue of procedural or conceptual understanding.
Mathematical rationale	Captures the extent to which teachers described the cause of student misunderstandings through students' understanding of procedures or students' underlying thinking about mathematical concepts.
Non-mathematical rationale	Captures instances where teacher provided non-mathematical reasons for student misunderstandings (e.g., issues around curriculum or home-support).
Outcomes	
Instructional strategy aimed at building students' conceptual understanding	Captures the extent to which the strategies teachers reported were supporting students' conceptual understanding of the mathematical concepts underlying the misunderstanding.
Instructional Strategy Specific to Students' Misunderstanding	Captures whether or not the strategy teachers described using specifically addressed the student misunderstanding.
Instructional strategy that is specific to students' misunderstanding and builds students' conceptual understanding	Captures whether or not the strategy teachers described using both specifically addressed the student misunderstanding and supported students in making sense of math concepts.

Table 2: Pathways leading to instructional responses to student misunderstandings

Solution Pathways by Outcome	Conditions: Student Misunderstanding	Conditions: Mathematical Source of Misunderstanding	Conditions: Non-mathematical Source of Misunderstanding	Pathway Consistency and Coverage: Consistency	Pathway Consistency and Coverage: Raw Coverage	Pathway Consistency and Coverage: Unique Coverage
Occurrence of instructional strategies aimed at building students' conceptual understanding						
Pathway 1	•	•		0.773	0.411	0.355
Pathway 2	•		•	0.765	0.149	0.092
Pathway 3		•	•	0.824	0.075	0.019
					Solution Consistency: 0.755 Solution Coverage: 0.523	
Nonoccurrence of instructional strategies aimed at building students' conceptual understanding						
Pathway 4		⊗	⊗	0.703	0.495	0.495
					Solution Consistency: 0.703 Solution Coverage: 0.495	
Nonoccurrence of instructional strategies that are specific to the student misunderstanding						
Pathway 5		⊗	⊗	0.853	0.437	0.097
Pathway 6	⊗	⊗		0.814	0.490	0.151
					Solution Consistency: 0.829 Solution Coverage: 0.588	
Nonoccurrence of instructional strategies that are specific to the student misunderstanding and build students' conceptual understanding						
Pathway 7		⊗		0.923	0.633	0.146
Pathway 8	⊗			0.897	0.650	0.163
					Solution Consistency: 0.895 Solution Coverage: 0.796	

Note: Presence of a condition is indicated with a closed circle (•); absence of a condition is indicated with an open circle with an x (⊗); empty cells indicate that a condition is not part of the recipe and can be present/absent and not impact the outcome.

DEVELOPMENT OF A MATHEMATICS DISCIPLINE-SPECIFIC LANGUAGE SCALE

Alanna Gibbons
Teachers College, Columbia University
ag3729@tc.columbia.edu

Irina Lyublinskaya
Teachers College, Columbia University
il2369@tc.columbia.edu

Existing studies have defined and assessed disciplinary literacy, mathematical literacy, and general academic language. However, there is a need to define and assess mathematics discipline-specific language (MDL), particularly for elementary school teachers. Therefore, the purpose of this study was to develop a research instrument to assess the MDL of elementary school teachers. The final instrument developed through iterative analysis included 20 items on a 4-point Likert-like scale distributed between three distinct MDL categories: technical, symbolic, and visual. Instrument validity was confirmed using Confirmatory Factor Analysis with the set of 211 video recordings and corresponding lesson plans of mathematics lessons taught by pre-service elementary school teachers enrolled in a graduate special education program.

Keywords: Mathematical Knowledge for Teaching, Preservice Teacher Education, Teacher Knowledge

Purpose of the Study

Mathematical literacy is essential for solving problems encountered in today's rapidly evolving world. It is defined as "an individual's capacity to identify and understand the role that mathematics plays in the world, to make well-founded judgments and to use and engage with mathematics in ways that meet the needs of that individual's life as a constructive, concerned, and reflective citizen" (OECD, 2009, p. 14). Mathematically literate students should know how to do mathematics and how to speak the language of mathematics. This is not learned by simply memorizing definitions; but rather, by using the language of mathematics in their learning experiences (Hill, et al, 2008). The Common Core State Standards for Mathematical Practice emphasize the importance of developing mathematical literacy and discipline-specific mathematics language (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010).

Discipline-specific language is defined as "the decontextualized oral and written language used within a specific discipline or profession with specialized vocabulary, syntax, and discourse patterns" (Zhang, 2014, p. 40). Mathematics discipline-specific language (MDL) is different from everyday language (Machaba, 2017). MDL is used to encode information and it allows members of the discipline to communicate in discipline-specific ways (Bernstein, 1996). Examples of MDL include vocabularies, symbols, and notations. A lack of appropriate MDL can hinder student learning and become a source of misconceptions carried over to later mathematics education (Di Domenico, 2014; Köse, 2008). It is vital that attention be given to MDL beginning at the elementary level (Siffrinn & Lew, 2018) since high-quality early mathematics instruction serves as a sound foundation for later learning in mathematics (Darling-Hammond & Bransford, 2005). In order to develop students' MDL, elementary school teachers must be proficient in their own MDL.

Studies that assess teachers' knowledge of MDL have been mostly conducted at the secondary level (Colwell & Gregory, 2016; Di Domenico, 2014; Spires et al., 2018) and in other content areas (Cisco, 2016; Feez & Quinn, 2017; Ruzycki, 2015), but it remains unclear what MDL looks like in the lower grades. Therefore, the purpose of this study was to develop and validate an instrument, titled the Mathematics Discipline-specific Language Scale (MDLS), for assessing the MDL of elementary school teachers. This study was guided by the following research question: What are constructs of MDL for elementary school teachers?

This study addresses the conference themes by resolving the dissonance between what is expected of elementary school teachers' MDL and the lack of the assessment instrument through the process of developing and refining the MDLS.

Literature Review and Theoretical Frameworks

MDL is a major component of disciplinary literacy (McConachie & Petrosky, 2009; Fang, 2012). Analysis of literature on disciplinary literacy theory provided background information on what is known about MDL of elementary school teachers. Disciplinary literacy is defined as "the use of reading, reasoning, investigating, speaking, and writing required to learn and form complex content knowledge appropriate to a particular discipline" (McConachie & Petrosky, 2009, p. 70). Shanahan and Shanahan (2014) proposed that disciplinary literacy should be introduced as early as elementary school. Therefore, elementary school teachers must develop MDL to make their instruction more accessible (Siffrinn & Lew, 2018).

McConachie and Petrosky's (2009) disciplinary literacy framework defined criteria necessary for students to develop discipline-specific literacy in the core subject areas. This framework suggests the following components of literacy: reading, reasoning, investigating, speaking, and writing. Gee (2012) suggested that language incorporates behaving, interacting, thinking, reading, speaking, and writing. Therefore, McConachie and Petrosky's (2009) speaking and writing components of disciplinary literacy can be categorized as language. In this study, McConachie and Petrosky's (2009) framework was adapted to focus solely on the language component of disciplinary literacy for the discipline of mathematics. The discipline of mathematics has a language of its own that is functional for constructing knowledge and reasoning in the subject. Further, Fang (2012) suggested that different language patterns of mathematics can be categorized as technical, symbolic, and visual. Fang (2012) defines technical language as discipline-specific grammatical features, structure, and vocabulary. Symbolic language is represented by mathematical symbols that are used to describe relationships between mathematical objects. Based on topics covered in elementary school mathematics curriculum, the following symbols are learned in grades K-5: basic operations signs, the plus sign ($+$), the minus sign ($-$), the multiplication signs ($\times$, $\cdot$, or $*$), the division signs ($\div$ or $/$), the relation signs ($=, >, <, \geq$, and $\leq$), the fraction notation ($\frac{\square}{\square}$ or $\square/\square$), the place value signs (decimal point . and coma ,), units of measurement signs (feet $'$ and inches $''$), grouping symbols (parentheses, brackets, braces), and money signs (\$ and ¢). Visual language at this level is represented by number lines, number paths, array and area models, strip diagrams, schematic diagrams, drawings, tables, and graphs. These three categories of MDL were used to classify the patterns of MDL in this study.

Theoretical frameworks need to be tested in practice, and in research that is accomplished through development of research instruments that are consistent with the theory. There are various research instruments that assess MDL of teachers (Stanford: Center for Assessment, Learning, & Equity, 2016; Hill, 2010). However, most of these instruments focus on a single aspect of the language. For example, the Teacher Performance Assessment (edTPA) evaluates pre-service teachers' precision in language, where MDL precision is defined as being accurate with definitions and symbols in labeling, measurement, and numerical answers (Stanford: Center for Assessment, Learning, & Equity, 2016). The Mathematical Quality of Instruction (MQI) Coding Tool assesses pre- and in-service teachers' explicitness of mathematical terminology and technical language fluency as part of overall instruction quality rather than focusing specifically on quality of MDL (Hill, 2010). In the MQI, fluency is defined as the density of MDL during periods of teacher talk. The MQI also defines explicitness as teachers' accurate use of technical terms. Further, most research instruments focus on the teacher's ability to support language development of students, rather than assessing the teacher's own MDL. In order to assess the quality of teachers' MDL, this study adapted assessment criteria from edTPA and MQI, e.g., precision, fluency, and explicitness for each language category specifically for the MDL of elementary school teachers.

This study's theoretical framework for the development of the MDLS aligned the three assessment criteria of MDL quality for each of the three language categories (Figure 1).

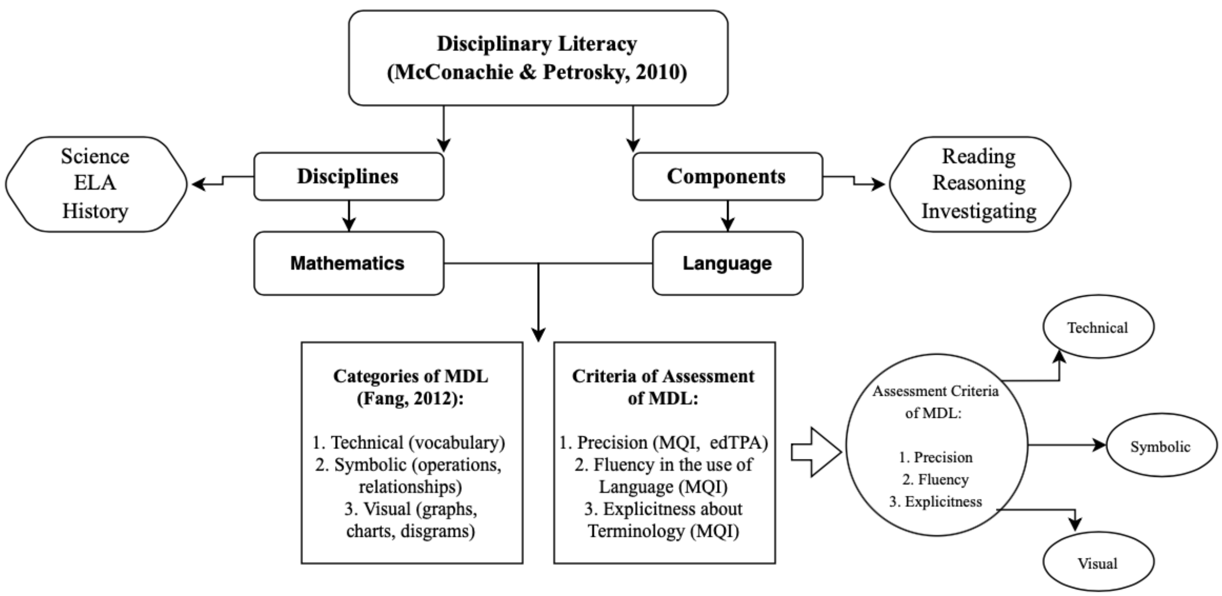

Figure 1: Framework for Development of the MDLS

Methods

Development of MDLS items was guided by the criteria defined by Hathcoat, Sanders, and Gregg (2016). First, category-specific items had to describe directly observed characteristics of MDL in video recordings and corresponding lesson plans. Second, the following practices were used: 1) generating twice as many items as needed, 2) making items simple and specific, and 3) ensuring that items are unidimensional and easy to read.

Explicit phrases that were found in the literature in relation to MDL characteristics were collected and analyzed to generate the preliminary statements for the MDLS items. Further, these statements were revised into performance-based statements. Then, each item was classified into one of the three categories of MDL. A 4-point Likert-like scale (never, rarely, often, always) was used in the MDLS to measure frequency of occurrence for each MDLS item. Iterative process of item revisions at this stage aimed to ensure that each item was observable and independent of others.

The initial version of the MDLS was sent to two mathematics literacy experts to evaluate the content validity. Based on their feedback, wording of several items was revised for clarity. The reliability and construct validity of the MDLS were tested on video recordings and corresponding lesson plans developed by pre-service elementary teachers enrolled in a special education graduate program and collected over the course of six years in grades K-5 mathematics classrooms in urban public schools in Northeast USA.
In order to test inter-rater reliability, two raters were trained to use the MDLS. An initial round of scoring included independent assessment of a set of thirty video recordings and corresponding lesson plans. Pearson correlation analysis was used on this set of scores. Debriefing with the raters was conducted and based on debriefing, additional revisions to wording of items and the structure of Likert-like scale were made. This version of the MDLS was then independently scored by the same two raters on a new set of thirty video recordings and corresponding lesson plans. Inter-rater reliability was tested again using Pearson correlations on this set of scores. Construct validity was tested using a Confirmatory Factor Analysis (CFA). The CFA was conducted in SPSS 28 using varimax rotation with three factors according to the number of categories of MDL defined by the theoretical framework. The goodness-of-fit of this model was tested using SPSS AMOS 28. This procedure led to removal of several items. Internal consistency of the final MDLS was tested using the split-half reliability method in SPSS 28.

Results

Initial MDLS consisted of 27 items, with nine items in each category (Table 1). Based on the feedback from the experts, the wording of three items in technical language (TL4, TL6, and TL8), two items in symbolic language (SL14 and SL17), and all items in visual language was revised for clarity (see Revision 1 in Table 1).

The teacher uses different mathematical models for the same problem.	The teacher uses different mathematical models for the same problem.

The Pearson *r*-values for Revision 1 of MDLS ranged from .63 to .86. All items with *r*-values below .7 were discussed with the raters during debriefing and further revisions were made (see Revision 2 in Table 2). The raters also suggested changing the original 4-point Likert-like scale that was based on frequency of occurrence to a 4-point scale based on quality of MDL (not evident, incorrect, somewhat correct, correct). For the scoring with Revision 2 of MDLS, the Pearson *r*-values ranged from .71 to .89 confirming high inter-rater reliability (Asuero, Sayago, & Gonzalez, 2006). The remaining video recordings and corresponding lesson plans were divided between the raters to complete the scoring using this version of MDLS.

In order to confirm the construct validity of MDLS, CFA on the set of 211 video recordings and corresponding lesson plans was completed in SPSS 28 using principal component analysis extraction method with varimax rotation. Loadings less than .42 were suppressed which is consistent with assumption about significant loadings for this sample size (Guadagnoli & Velicer, 1988). Five items (TL1, TL2, VL19, VL20, and VL24) that did not load to their specific categories were removed.

The goodness-of-fit of this three-factor model was examined using maximum likelihood estimation performed in SPSS AMOS 28. The analysis resulted in a significant chi-square, $\chi^2(206) = 658.0$, $p < .001$. The comparative fit index (CFI = .834) and the Tucker-Lewis index (TLI = .813) were both below the accepted values. In addition, the standardized root mean square residual (SRMR = .082) and the root mean square error for approximation (RMSEA = .102) were higher than acceptable. In order to improve the fit of the model, two items (SL11 and SL17) that had very high modification indices were removed. The final model (Figure 2) resulted in a significant chi-square, 2(167) =368.7, $p < .001$, although this can be sensitive to the sample size.

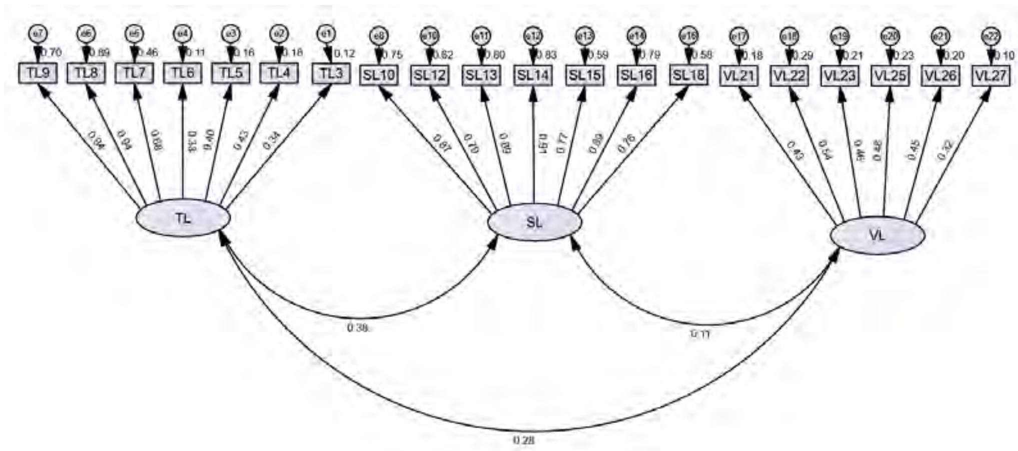

Figure 2: AMOS Path Diagram for a Final 3-factor Model of MDLS

The ratio $\chi^2 / df = 2.208 < 3.0$ indicates a good fit (Kline, 2005). The comparative fit index (CFI = .90) shows relatively good fit and the Tucker-Lewis Index (TLI = .886) is just a little below the acceptable value of .9, which suggests a reasonable fit (Bentler, 1990). Moreover, both SRMR = .047 < .08, and RMSEA = .076 < .08 are acceptable. Based on these indices, the three-factor model has a reasonable fit and CFA procedure confirmed the three factors matching the three theoretical categories of MDL.

The final version of the MDLS consists of 20 items with seven items in technical language and symbolic language categories each, and six items in visual language category (Table 1). Cronbach's alpha was used to test internal consistency of the final scale. The value of alpha for symbolic language subscale (α = .954) is excellent, for the technical language subscale (α = .795) is good, and just a little below acceptable for visual language subscale (α = .594) with very good overall value of 0.897 indicating acceptable internal consistency of the MDLS.

Conclusion

This study developed and validated a quantitative instrument for external assessment of the MDL of elementary school teachers. To the best of our knowledge, this is the first instrument that defines constructs of MDL for elementary school teachers. Another significance of this study is that through validation of MDLS it confirmed three categories of MDL suggested in the theoretical framework by Fang (2012). Thus, this study contributes to the field by bridging the gap between the theoretical definitions of MDL and the practical measurements of MDL in the field. The process of iterative development and analysis of the MDLS items led to the higher clarity of MDL categories and clear distinction between them.

The results of this study have practical implications for teacher education and professional development programs. The MDLS could be used to assess gaps and deficiencies in the MDL of preservice and in-service elementary school teachers and therefore to support their MDL development through focused programs. Further studies are needed to develop better understanding of the visual language category and to analyze how the teachers' MDL influences student learning of mathematics. Although this study made progress in operationalizing different categories of MDL, more work is also needed to operationalize qualities and correctness of MDL. Therefore, future studies will 1) identity levels of the MDLS using the criteria of precision, fluency, and explicitness, and 2) connect these levels to the three categories of MDL.

STRUCTURAL VALIDITY OF 2021 KNOWLEDGE FOR TEACHING EARLY ELEMENTARY MATHEMATICS (K-TEEM): A PSYCHOMETRIC STUDY

Ahmet Guven	Robert C. Schoen	Gizem Solmaz

In this paper, we describe the method and results of our investigation of structural validity of the 2021 Knowledge for Teaching Early Elementary Mathematics test, which measures teachers' mathematical knowledge for teaching at the early elementary level. The 2021 Knowledge for Teaching Early Elementary Mathematics test was used in a long-term, randomized controlled trial of the effect of a Cognitively Guided Instruction professional-development program on teachers, teaching, and students. Our sample includes data collected in spring 2021 from 651 grades K–2 elementary educators in Florida. Exploratory factor analysis and analyses based on classical test theory and item response theory were conducted to examine the psychometric properties of the test. Results of factor analysis suggest a one-factor solution. The marginal reliability for response pattern scores was 0.84, and the test difficulty appears to align well with the levels of mathematical knowledge for teaching of the target population.

Keywords: Assessment, Mathematical Knowledge for Teaching, Measurement, Teacher Knowledge

Introduction

The quality and usefulness of quantitative research rests on high-quality measurement practices (APA, AERA, & NCME, 2014). Hill and Shih (2009) presented a compelling argument for improvements in quantitative research methods in mathematics education. In this paper, we present a method for examining the structural validity (Flake et al., 2017) of the 2021 Knowledge for Teaching Early Elementary Mathematics (K-TEEM), a web-based assessment of mathematical knowledge for teaching (MKT) at the early elementary level (Ball et al., 2008; Schoen et al., 2017; 2019; 2021; 2022a). The intended use of the K-TEEM is to estimate impact of three consecutive years of a professional development program based on Cognitively Guided Instruction (CGI) and to examine the role of MKT as a mediator of the effect of the CGI program on teaching and students. Through this paper, we will describe the process and results of a psychometric analysis of the data from the 2021 Knowledge for Teaching Early Elementary Mathematics (K-TEEM) test.

Methodology

The 2021 K-TEEM test serves as a measure of teacher knowledge in a randomized controlled trial of the CGI program. A previous version of the K-TEEM test, which included 31 items consisting of a combination of open-ended and multiple-choice questions, was used in 2019 and 2020. Based on some concern about potential ceiling effects in 2020, the 2021 version of the K-TEEM included 34 items after adding three items in attempt to improve measurement of teacher ability for those with high levels of MKT. Teachers (n = 651) in the K–2 track of the CGI program (Schoen et al., 2022) completed the web-based assessment (Qualtrics, 2020) in spring 2021. Our sample included teachers, math coaches, and other instructional support personnel, such as interventionists. K-TEEM contains items designed to measure early elementary teachers' knowledge in five subcategories: common content knowledge, specialized content knowledge, knowledge of content and students, knowledge of content and teaching, and knowledge of content and curriculum.

To examine the structural validity of the 2021 KTEEM test, the exploratory factor analysis (EFA) and analyses based on classical test theory (CTT) and item-response theory (IRT) were conducted. We followed these steps in the investigation: 1) initial item analysis, 2) dimensionality, 3) item- and test-level statistics based on the CTT and EFA analyses, 4) reliability, and 5) IRT item calibration and person scoring.

Analysis & Results

In this section, we present the results from dimensionality analysis, initial item analysis, and analyses based on CTT and IRT. For the sake of transparency and scientific rigor, we also share the data, syntax, and output files through Open Science Framework (OSF; Schoen et al., 2022b).

Initial Item Analysis

The EFA was run via Mplus 8.0 (Muthén & Muthén, 1998-2017) using the weighted least square estimation with mean and variance adjusted method with tetrachoric correlations. The structure of the 34-item test was examined by requesting solutions with 1–6 factors. The tetrachoric correlation matrix was also checked to investigate the interrelations among the items. One of the new items was removed before subsequent analyses due to non-significant factor loadings identified through the EFA and negative correlations with the other items. The remaining 33 dichotomously scored items contributed to the final scale for the 2021 K-TEEM.

Dimensionality Analysis & Results

To investigate the dimensionality of the 2021 KTEEM test, we repeated the EFA with the remaining 33 items. Table 1 shows the first six eigenvalues provided in the Mplus EFA output with the corresponding percentages of explained variation for the one-factor model. The largest variation explained by the first factor was 26.51 percent, whereas second largest variation was found to be 5.49 percent. The difference of the Root Mean Square Error of Approximation (RMSEA) values between the 1-factor EFA (Model 1) and the 2-factor EFA (Model 2) can be a supplementary approach used to identify the optimal number of factors to retain. Specifically, if the difference is smaller than a prescribed cut-off value (we used 0.015 for this case), the more parsimonious model is retained. Finch's (2020) study recommended this approach and showed that the RMSEA_0.015 approach performed better than Parallel Analysis when the indicators are categorical with small factor loadings. The difference was calculated to be 0.007 (RMSEA_Model1 = 0.030; RMSEA_Model2 = 0.023), again suggesting the more parsimonious 1-factor model. This result implies that unidimensionality is a reasonable assumption.

Table 1: Eigenvalues Estimated from Mplus and Their Corresponding Percentages of Explained Variation

	Eigenvalue	% Variation explained
1	8.75	26.51
2	1.81	5.49
3	1.59	4.81
4	1.51	4.56
5	1.28	3.87
6	1.21	3.67

Classical Test Theory (CTT) Analysis & Results

After concluding the dimensionality analysis (and removing the item with poor fit), we conducted the CTT analyses using SPSS 26.0 (IBM corp., 2019). Figure 1 shows the distribution of the raw sum scores. The scores ranged from 2 to 33 with a mean of 18.35 and a standard deviation of 6.20. Less than one percent (0.61 percent) of examinees in this sample received a perfect score of 33. Item means (i.e., item difficulties based on the percentages of correctly endorsing an item) ranged from 0.19 to 0.79 with a mean of 0.56 and a standard deviation of 0.17 and were approximately normally distributed. The coefficient alpha (Cronbach, 1951) and standard error of measurement were calculated to be 0.84 and 2.50, respectively.

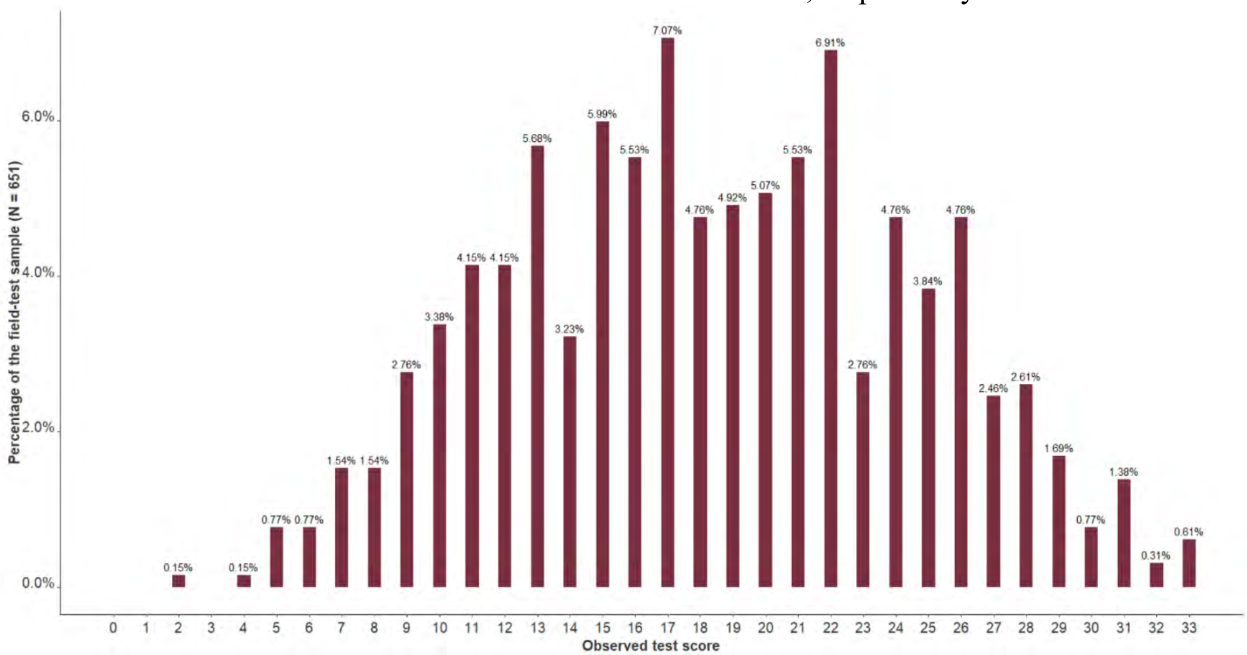

Figure 1. Observed Test Score Distribution for the 33-item 2021 K-TEEM

Item Response Theory (IRT) Analysis & Results

We used flexMIRT 3.6 (Cai, 2020) to perform the IRT analyses. Because the final test consists of 33 dichotomously scored open-ended and multiple-choice items, and the dimensionality analysis suggested one dominant construct underlying the relationships of the items, we fit a unidimensional IRT model to the data. Many cognitive assessments in educational practices involve data with binary scores (i.e., assigning “0” to an incorrect response and “1” to a correct response). Measurement practitioners may consider fitting a three-parameter (3PL) model for multiple-choice items as a way to take a guessing effect into account. However, the optimum number of observations required by a unidimensional three-parameter model is recommended to be at least 1,000 (de Ayala, 2009).

Following this suggestion and based on the fact that our test includes open-ended items as well as multiple-choice items, a unidimensional two-parameter logistic (2PL) model was used to calibrate two items added to the 2019 version of our test. For the other test items, the parameter estimates from the 2019 sample were used as anchor items to vertically link the metrics (Schoen et al., 2021; 2022). This is known as fixed item parameter calibration (FIPC) approach under the common item nonequivalent group test design, which could be used to place scores from the tests of different levels on a common scale (Kolen & Brennan, 2004). The population mean and standard deviation were freely estimated. Results of flexMIRT showed that the model converged successfully. The formula of the 2PL model is shown in Equation 1 according to the parameterization of de Ayala (2009).

$$P_j(\theta) = \frac{\exp[a_j(\theta - b_j)]}{1+\exp[a_j(\theta - b_j)]}, \tag{1}$$

where a_j is the discrimination index of item j ($j = 1, 2, \ldots, J$), b_j is the difficulty index of item j, $P_j(\theta)$ is the probability of correct answer, θ is the person ability.

Figures 2 and 3 display the item-difficulty estimates and item-discrimination estimates of each item. The item difficulty estimates ranged from –2.48 to 1.99 with a mean of –0.20 and a standard deviation of 1.12. The item discrimination estimates ranged from 0.41 to 1.35 with a mean of 0.80 and a standard deviation of 0.39. As seen in the figures, the discrimination estimates of those two items (see the last two items in the graphs below) added to the 2019 version were 0.75 and 1.12, and their difficulty estimates were relatively larger as compared to many items in the test. We note that the difficulties of the test items are heterogeneous, and the difficulty of the test aligns reasonably well with the ability range. The marginal reliability for response pattern scores calculated in flexMIRT was 0.84.

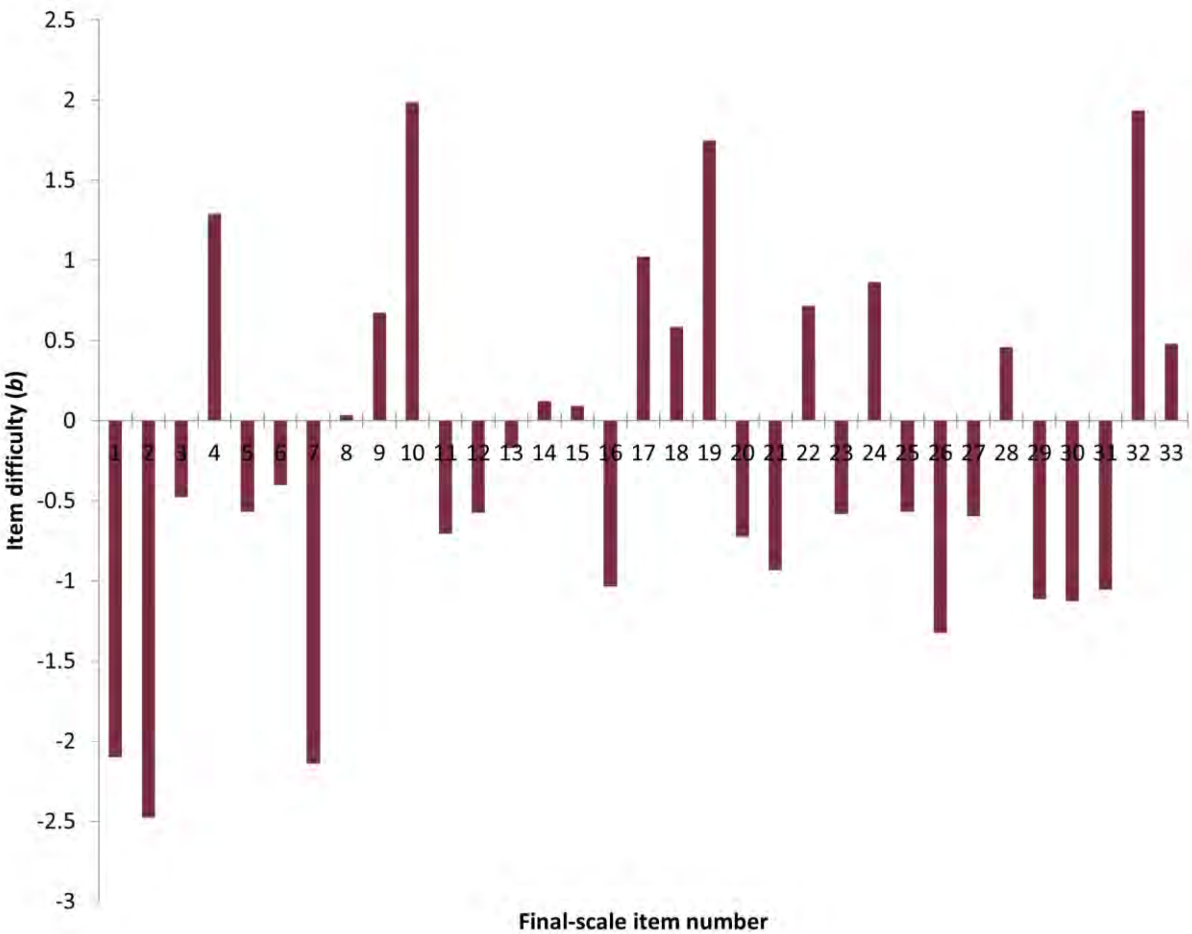

Figure 2. Item-difficulty estimate (b) of each final-test item, presented in sequential order.

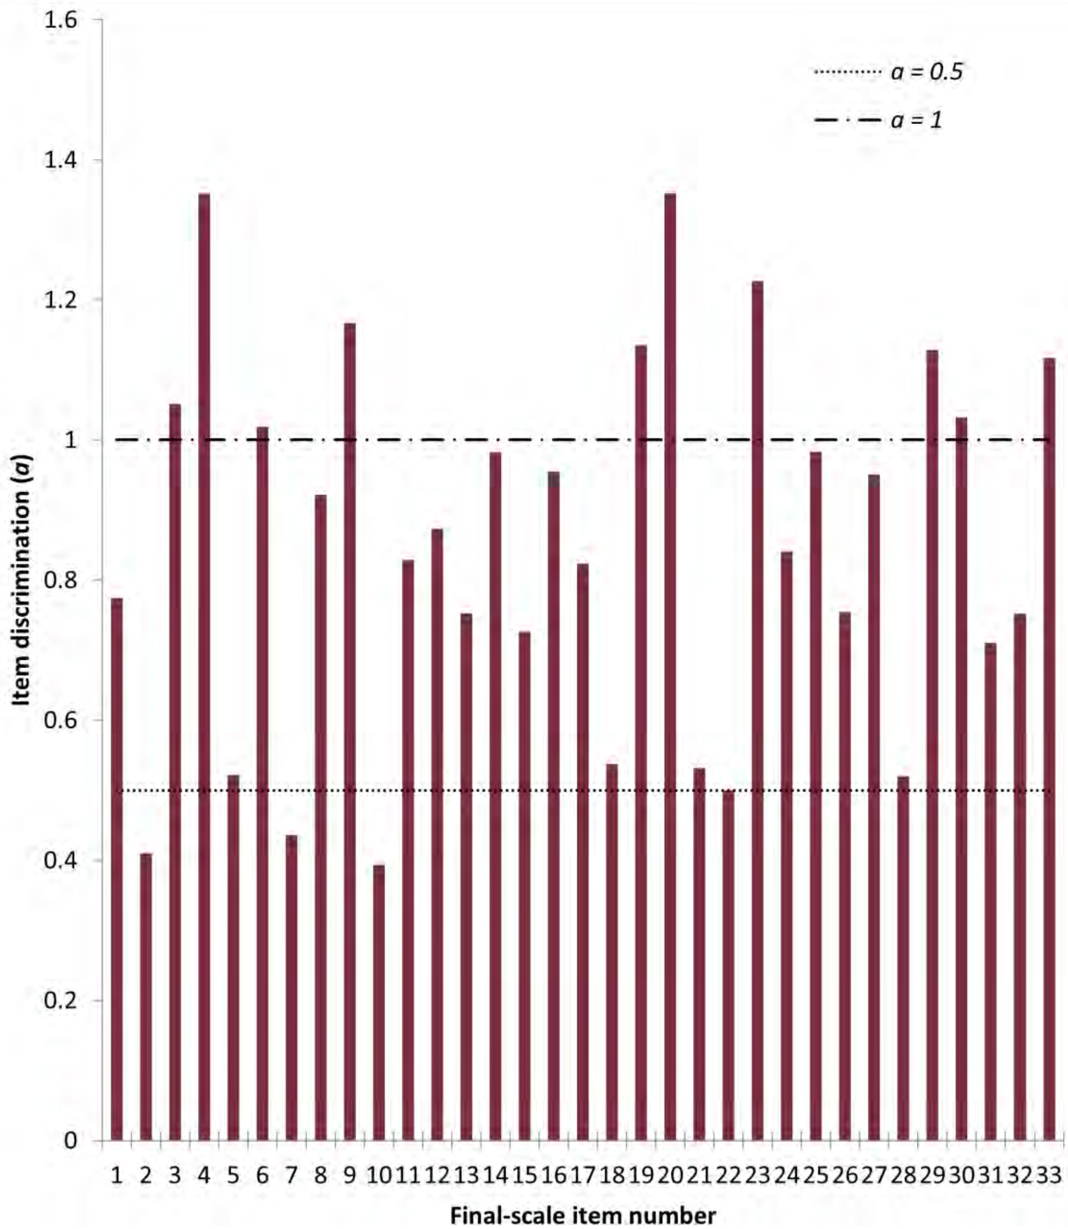

Figure 3. Item-discrimination estimate (b) of each final-test item, presented in sequential order.

Discussion

The 2021 K-TEEM is one of more than a half-dozen test forms in the K-TEEM set of assessments. It is being used in a three-year randomized controlled trial involving teachers in more than 200 schools. It is being used as a baseline measure of teacher MKT and to estimate the effects of a CGI professional-development program on teacher MKT, and as a measure of MKT as a potential mediator of the effect of the CGI professional-development program on teaching and student learning.

Item-level analysis suggested that 33 out of 34 items on the 2021 K-TEEM test form were adequate. Dimensionality analysis demonstrated that one dominant construct (i.e., MKT) described the interrelatedness among the items. The difficulty of the test was reasonably well calibrated to align with the levels of MKT of the target population. Reliability estimates for the observed sum scores and response pattern scores indicated that the test scores may be useful for the planned, subsequent, group-level analyses.

The construct validation process is an ongoing effort of collecting evidence to justify the interpretation and use of test scores. Structural validity is one of the phases of the construct validation process, which investigates the psychometric/measurement properties of an assessment tool. According to Flake, Pek & Hehman (2017), "if the measurement properties of a scale do not replicate, then the replicability of the results from analyses using those measures is suspect (p. 3)". Notably, the best practices for conducting construct validation are to continually collect evidence to support measures underlying the latent construct using rigorous measurement practices. Therefore, the process used for analysis and scoring of the K-TEEM can present a model for researchers in mathematics education to use as they increase the methodological rigor of their measurement practices.

IMPACTO DE LA REFLEXIÓN EN LOS CONOCIMIENTOS DE PROFESORES MIEMBROS DE UNA COMUNIDAD DE APRENDIZAJE

IMPACT OF REFLECTION ON THE KNOWLEDGE OF TEACHERS WHO ARE MEMBERS OF A LEARNING COMMUNITY

UNAM (México)
sandraareli.martinez@cch.unam.mx

Un grupo de profesores de matemáticas de nivel medio superior buscan mejorar su labor docente, para lo cual crean una comunidad profesional de aprendizaje, en dónde los docentes producen de manera colectiva actividades de enseñanza mediante un ciclo reflexivo de varias etapas que llaman 'Enseñanza-Reflexión'. En este reporte se describe cómo se amplía el conocimiento para la enseñanza de las matemáticas durante un ciclo reflexivo sobre la función cuadrática, así como el impacto de la reflexión en el conocimiento de los docentes. Un resultado importante de este trabajo es que el marco de Rowland et al. permite analizar el conocimiento de profesores, que emerge cuando ellos hacen actividades reflexivas en una comunidad profesional de aprendizaje autogestiva.

Palabras clave: Conocimiento matemático para la enseñanza, Función cuadrática, Álgebra y pensamiento algebraico, Desarrollo profesional

Un grupo de profesores de una escuela de nivel medio superior mexicana, se organizaron para diseñar, aplicar y discutir reflexivamente actividades de enseñanza, con el fin de mejorar su labor docente ya que consideran que tienen deficiencias para la enseñanza de las matemáticas, debido a que ninguno de estos docentes tuvo formación inicial para la enseñanza, Sosa y Ribeiro (2014, p. 1) señalan que es una situación muy común en los profesores de ese nivel en México hasta 2014.

Para atenuar sus deficiencias los profesores deciden crear una comunidad profesional de aprendizaje, Sowder (2007, p. 185) la define como una agrupación en la cual se comparten mismos propósitos, generalmente con el entendimiento de que los docentes son responsables unos con otros por lograr sus metas; coordinar sus esfuerzos para asegurar el aprendizaje de los estudiantes, aprender juntos para mejorar su práctica y compartir responsabilidades para la toma de decisiones sobre asuntos pertenecientes a la mencionada comunidad.

Los investigadores acuerdan junto con los profesores implementar una metodología de trabajo dentro de la comunidad en la que se planean, aplican en el aula y se discuten reflexivamente actividades de enseñanza, las cuales están definidas como actividades que facilitan el aprendizaje significativo, de temas específicos de conocimiento conceptual o procedimental, que pueden estimular la investigación aplicada a la enseñanza diaria de las clases (Moreira, 2011).

También determinan que el tema en el que se van a centrar es en la enseñanza de la función cuadrática ya que tiene un lugar relevante en el curriculum, así que a partir de ese momento las actividades de enseñanza que van elaborando se centran en ese tema.

El propósito de este trabajo es mostrar evidencias de que el conocimiento de los profesores para la enseñanza de la función cuadrática puede ampliarse cuando los docentes participan en una comunidad de aprendizaje, y hacen actividades reflexivas en las que producen actividades de enseñanza. Hay una versión previa de esta investigación en Huerta-Vazquez & Figueras (2020).

Se analizan esas evidencias aplicando el trabajo de Kula Ünver (2018) como herramienta de análisis, a partir del marco teórico del Cuarteto del Conocimiento de Rowland, Huckstep y Thwaites (2005).

Con la herramienta teórica antes descrita se busca, además, observar cómo el trabajo reflexivo dentro de la comunidad impacta en el conocimiento de los profesores participantes del colectivo.

El conocimiento del profesor

Shulman (1986, 1987) es de los primeros en centrar la investigación en el conocimiento del profesor en general, proponiendo tres dimensiones: conocimiento del currículo, del contenido de la materia (o del objeto matemático) (subject matter knowledge SMK), y conocimiento pedagógico del contenido (pedagogical content knowledge PCK).

Ball et al. (2008) profundizan el trabajo de (Shulman (1986) y lo adecuan para el profesor de matemáticas el cuál denominan cómo el Conocimiento Matemático del Profesor para su Enseñanza (MKT), que corresponde al conocimiento matemático necesario para la enseñanza de las matemáticas a los estudiantes, y se centran en dos dominios del trabajo de Shulman: el conocimiento del contenido o de la materia (SMK) y el conocimiento pedagógico del contenido (PCK).

Rowland et al. (2005), proponen un marco que también retoma de Shulman (1986), y lo denominan Cuarteto del Conocimiento (KQ del inglés), lo desarrollan inicialmente para describir y analizar las observaciones hechas en el aula. Este marco está divido en cuatro dimensiones:

Fundamentación: La primera tiene sus raíces en la base de los antecedentes y creencias teóricas del profesor. Se refiere a su conocimiento, la comprensión y capacidad a recurrir a lo que se aprendió en etapa de instrucción (escuela, universidad, etc.), incluyendo la educación inicial del profesorado, en preparación (intencionadamente o no) para su papel en el aula.

Transformación: La segunda tiene que ver con el conocimiento en acción demostrado tanto en la planeación de lo que se va a enseñar, como en el mismo acto de enseñar. Al respecto Kula Ünver (2018) señala que este componente se puede visualizar como la transformación del conocimiento del contenido (SMK) en el conocimiento pedagógico del contenido (PCK) de ahí que la transformación requiere del uso de modelos, analogías, ejemplos, ilustraciones, representaciones y demostraciones que puedan construir un puente entre la comprensión de los profesores sobre la materia y la comprensión que se espera que alcancen los alumnos.

Conexión: La tercera combina ciertas elecciones y decisiones que se hacen en partes concretas del contenido matemático. En gran medida, estas reflejan las deliberaciones y decisiones que implican no sólo conocimiento de conexiones estructurales dentro de las matemáticas en sí mismas, sino también el conocimiento de las demandas cognitivas relativas a diferentes temas y tareas.

Contingencia: La cuarta se refiere a la respuesta del profesor a todos los eventos no previstos en el aula durante la planificación. A pesar de tener todo planeado, libro de texto, programa de estudios, secuencia de actividades, etc. las respuestas de los estudiantes son impredecibles, y está probado que la respuesta a estas situaciones es de las tareas más difíciles para los profesores novatos

Kula Ünver (2018) revisa de manera exhaustiva las dimensiones del Cuarteto del Conocimiento (KQ) de Rowland y colaboradores, y concluye que es un marco detallado y exhaustivo para examinar cómo se manifiesta el conocimiento del contenido (SMK) y el conocimiento pedagógico del contenido (PCK) de los profesores de matemáticas en su proceso de enseñanza. Además, encuentra conexiones teóricas en cada una de las dimensiones con el marco teórico del MKT de Ball et al. (2008).

Comunidad Profesional de Aprendizaje en acción

La inspiración para establecer la forma de trabajo en la comunidad fue a partir de la metodología de estudio de lección (lesson study) que en consiste que un grupo de profesores hagan investigación acerca de lo que planifican, enseñan, observan y comparten con el fin de observar lo que pasa en el aula, además tiene también como objetivo la mejora de la práctica educativa. Dicha metodología se aplica en muchos países de diferente forma dependiendo del objetivo (Soto Gómez & Pérez Gómez, 2015); en Lewis et al. (2019, pp. 17–33) se sintetizan varios de estos estudios de lección y se puntualiza que en general están compuestos en cuatro etapas: de estudio de lección, de planificación, de enseñanza y de reflexión.

Basados en lo anterior los investigadores sistematizaron la metodología de trabajo de la Comunidad en un ciclo que llamaron Ciclo de Enseñanza-Reflexión, está dividido en tres etapas.

Primera etapa, planeación /reflexión-colectiva, basado en las ideas de Dewey (1989) se hace una reflexión colectiva de la secuencia para ser ajustada antes de su aplicación por algún profesor, en este momento se hace una re-revisión de los conocimientos matemáticos para la enseñanza, necesarios para la aplicación de la secuencia.

Segunda etapa, puesta-a-prueba/reflexión-individual, en esta fase se desarrolla lo que Schön (1983) llama la reflexión durante la acción, la secuencia se pone a prueba por el docente el cual debe tomar decisiones durante el proceso de enseñanza. Esta etapa es videograbada para que pueda ser analizada

Tercera etapa, análisis-síntesis /reflexión-colectiva es lo que Schön llama la reflexión después de la acción, en este momento - se analizan los videos de las puestas a prueba, los conocimientos que se esperaba que los estudiantes construyeran, de los modos de enseñanza de los profesores, de las dificultades de los estudiantes, de cómo se intentó que las superaran y como resultado del proceso del diseño de la secuencia enriquecida con la experiencia de todos los miembros de la comunidad. Surge una reflexión individual de lo que cada uno de los miembros 'aprendió' durante el ciclo. (Figura 1)

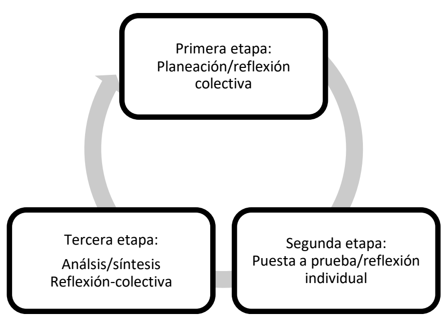

Figura 1: Ciclo de Enseñanza-Reflexión de la comunidad de aprendizaje

El Ciclo de Enseñanza-Reflexión del problema del área mínima de un cuadrilátero

El Ciclo de Enseñanza-Reflexión de la Comunidad para la secuencia didáctica planteada del área mínima de un cuadrilátero se desarrolló de la siguiente manera:

Dado el rectángulo $ABCD$ con base de 6 cm y altura de 4 cm Sea P un punto en el lado $\overline{AB}$, M un punto en el lado BC, N un punto en CD y S un punto en DA, tal que las distancias de BM, CN, DS y AP son iguales. Obtener el área mínima del cuadrilátero que se forma con los puntos P, M, N y S.

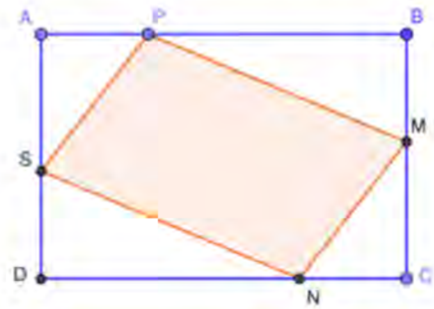

Figura 2: El problema del área mínima del cuadrilátero

1. Etapa 1 *planeación*: la profesora Lola propuso el problema a los docentes de la comunidad y se discutieron los pormenores para usarse en la enseñanza y ella dijo que esta serie de actividades podría ayudar a la enseñanza de la función cuadrática, pues en estas actividades los estudiantes pueden observar tres registros de la función cuadrática: tabular, geométrico y algebraico, además de observar la importancia de obtener los máximos y mínimos de dicha función. Se acordó que la primera clase la aplicaría el profesor Mario y luego el profesor Tadeo.
2. Etapa 2 *puesta-a-prueba*: el profesor Mario aplicó la secuencia en el grupo de Tadeo, esta clase se desarrolló de acuerdo con la planificación de la secuencia didáctica en cuya enseñanza se busca que el alumno haga el tránsito a los distintos registros de la función cuadrática asociada al problema.
3. Etapa 3 *análisis-síntesis*: en el interior de la comunidad se hace una reflexión colectiva usando los videos que se grabaron en la clase de Mario; Lola señaló lo siguiente: Mario no dejó que los estudiantes exploraran la solución al problema por sí mismos, sino que los apresuró a dibujar el rectángulo ABCD, haciendo que la enseñanza fuera muy dirigida. También sugiere que los estudiantes tengan que hacer la actividad de dibujo en parejas de tal manera que uno dibuja y el otro calcula el área para varios valores AP. Tadeo comentó que Mario debió dejar que los alumnos dibujaran el problema para resolverlo y no apresurarlos entre otros comentarios.
4. Etapa 4 *puesta-a-prueba*: el profesor Tadeo aplica la secuencia propuesta en el grupo de Mario, siguiendo el desarrollo de acuerdo con la planificación de la secuencia y toma en cuenta los comentarios de la etapa anterior y de la clase de Mario.
5. Etapa 5 *análisis-síntesis*: los profesores llevan a cabo una nueva reflexión colectiva acerca de la secuencia didáctica en la que resaltan varios aspectos.
   En particular para pasar del *registro verbal al geométrico*: el docente debe escribir el problema en el pizarrón o llevarlo escrito en un papel para que no se pierda tiempo en dictado a los estudiantes. También señalan que los estudiantes deben traducir el texto para hacer el dibujo del rectángulo y del cuadrilátero en su cuaderno y eventualmente algún estudiante pasar al pizarrón a hacerlo. Así también observaron que muchos estudiantes probablemente se van a equivocar al colocar los puntos P, M, N, S como puntos medios del rectángulo $ABCD$ en vez de preservar la igualdad $AP = BM = CN = DS$, así que el profesor que aplique la secuencia debe estar preparado.

Para el *registro tabular* sugieren que los propios alumnos deben proponer diferentes valores de AP para calcular el área del cuadrilátero para que así en el registro gráfico vayan trazando la parábola con los valores que hayan propuesto para AP y así observen cómo el área varía en cada caso.
Para el *registro algebraico* los estudiantes deben generalizar la función cuadrática con base a lo hecho en las actividades anteriores, mientras el docente acompaña a los estudiantes en el proceso para lograr la expresión algebraica esperada. Y para encontrar el área mínima: sería conveniente que usaran los registros tabulares y gráficas, así los estudiantes podrían identificar el área mínima del área $PMNS$ del cuadrilátero, por último, sería conveniente que llevaran la función cuadrática a la forma $y = a(x-h)^2 + k$ donde (h, k) (ver Figura 3 registro algebraico) es el vértice para así interpretar k del vértice, cómo el área mínima del cuadrilátero $PMNS$ pero saben que es probable que no les alcance el tiempo.

La enseñanza de esta secuencia didáctica requiere que haya tránsito entre los registros de representación de la función cuadrática (Figura 3), además estos registros sirven para señalar segmentos útiles para el análisis de cada etapa del Ciclo de Enseñanza-Reflexión.

Registro	Acciones para tener el registro
Verbal Geométrico	Traducir del texto al dibujo geométrico, el problema demanda hacer la conversión del texto al cuadrilátero $PMNS$ y el rectángulo $ABCD$ (Figura 1)
Tabular	Encontrar el área del cuadrilátero cuyos vértices son los puntos $PMNS$ en función de diferentes valores de $\overline{AP}$, para hacer lo siguiente es necesario calcular el área para cada valor propuesto de $\overline{AP}$
Gráfico	Representar la parábola asociada a los valores de la representación tabular, haciendo la conversión de la tabla a la gráfica
Algebraico	Encontrar la expresión algebraica que relaciona el área del cuadrilátero $PMNS$ $A(x)$ en función de valores de $x = AP$ $A(x) = 2x^2 - 10x + 24$ Forma general de la función cuadrática $A(x) = 2(x-2.5)^2 + 11.5$ Ecuación estándar de la parábola vertical

Figura 3: Registros del problema del área mínima del cuadrilátero

Metodología para análisis del Ciclo de Enseñanza-Reflexión del problema

Previamente se describieron las cinco etapas que se desarrollan en el ciclo de Enseñanza-Reflexión, las cinco etapas de dicho ciclo se grabaron en video usando un celular colocado en un tripié fijo, grabando a una resolución *full HD*.

Para las dos etapas de puesta a prueba la cámara fue colocada al fondo del aula de tal manera que el pizarrón fue grabado de manera frontal con el objetivo de captar al profesor y los dichos de los estudiantes. Los nombres de los profesores han sido cambiados por confidencialidad.

Para el caso de las demás etapas la cámara fue colocada al fondo del salón donde se llevaron las actividades de discusión de tal manera que los profesores podían ser grabados al menos en su audio, además se grabaron dos entrevistas individuales tanto de Tadeo como de Mario obteniéndose en total sietes videos para este análisis.

Para el análisis de este Ciclo de Enseñanza, la participación de tres profesores es analizada, Lola la que propone la actividad en la etapa 1, Mario y Tadeo etapa 2 y 4 los que aplican la secuencia en aula, y los tres participan en las etapas 3 y 5.

El software que se usa para el análisis de los datos es el MaxQDA 2020, para codificar y transcribir los videos, y el análisis de los datos obtenidos en la investigación descrita en este artículo, a saber: el Cuarteto del Conocimiento (KQ) de Rowland mediante la interpretación de Kula Ünver (2018) y como complemento de dichas observaciones se utiliza el marco de Ball y colaboradores y las relaciones entre los marcos de Rowland y Ball resumidos en Turner, (2012, p. 257)

Análisis de los datos obtenidos

En todas las etapas podemos encontrar evidencias del conocimiento para enseñanza de la función cuadrática, se muestran algunos ejemplos de momentos donde aparecen indicadores de cada una de las dimensiones del Cuarteto del Conocimiento de Rowland, bajo el lente de Kula Ünver. Las entrevistas ayudan a entender las actuaciones de los profesores en el aula.

En la etapa 1, planeación, Lola propone la secuencia didáctica, ya que la ha aplicado durante varios semestres previos, así que muestra conocimiento de cómo reaccionan los estudiantes ante la secuencia y cómo puede ser implementada, algunos ejemplos se muestran en la Figura 4.

Etapa 01 Planeación Docente: Lola		
Dimensiones (KQ)	Ejemplo	Comentario
Fundamentación	"Esta secuencia se puede usar de 2 formas, se puede usar para iniciar, se propone un problema y los alumnos empiezan a hacer los dibujitos"	Lola ha aplicado varias veces las secuencia así que conoce como van a actuar los estudiantes cuando se les enseña a ellos, se muestra un conocimiento del pedagógico del contenido (PCK) respecto a esta secuencia y los alumnos.
Transformación	"es que los alumnos deben dominar los 3 registros"	Lola sabe que en esta secuencia se hace el tránsito en los tres registros: tabular, gráfico y algebraico. (Aunque le falta especificar los registros verbales y geométricos relativos al problema)
Conexión	"Se puede introducir incluso lo que es dominio y el contradominio. Eso es más ideal como para mate 4".	Lola conoce como en que otras lecciones se puede usar esta secuencia en este caso para la asignatura de matemática IV

Figura 4: Evidencias de las dimensiones del KQ de Rowland en la etapa 1

En la etapa 2 puesta-a-prueba el profesor Mario aplica la secuencia didáctica, al ser una lección nueva para presenta algunas situaciones que no previó, que lo llevan a contingencias, pero logra sortear las dificultades, además muestra conocimiento acerca de la función cuadrática y conceptos asociados como la ecuación cuadrática Figura 5.

Etapa 02 Puesta a prueba Docente: Mario		
Dimensiones (KQ)	Ejemplo	Comentario
Fundamentación Registro Algebraico	Mario explica la diferencia entre ecuación y función cuadrática, igualando el área a la expresión.	Mario explica esa diferencia para hacer notar la variación en la función y lo estático en la ecuación
Transformación Registro Tabular	Pregunta a los estudiantes si se puede tabular con un valor de AP = 4.5 y llegan a la conclusión que no se puede porque un de los lados del rectángulo es de 4 cm. siendo este el valor máximo para tabular.	Mario interroga a los estudiantes con el objetivo de que se den cuenta de los límites de los valores permitidos para el problema,
Conexión Registro Gráfico	Le recuerda a los estudiantes lo visto en el curso de matemáticas I, los conceptos de variable independiente y dependiente para empezar la gráfica de la tabla antes hecha.	Mario presenta conocimiento de la materia (SMK) acerca de estos conceptos relacionados a la definción de función
Contingencia Registro Verbal/Geométrico	Los estudiantes tardan en hacer el dibujo del cuadrilatero PMNS dentro del rectángulo ABCD ya que los alumnos no toman en cuenta que $AP = BM = CN = DS$	En la entrevista el profesor Mario este relata que en esta parte de la secuencia didáctica tuvo muchas dificultades pero considera que logra sortear esta contingencia de tal manera que logra terminar de dar la lección a los alumnos
Etapa 04 Puesta a prueba Docente: Tadeo		
Fundamentación Registro Algebraico	Tadeo espera que los estudiantes coloquen los puntos AP, BM, CN, DS en los puntos medio del rectángulo, así que les pregunta acerca de la igualdad de AP, BM, CN, DS con el fin de que se den cuenta y logren dibujar el cuadralatero esperado, y una alumna se da cuenta y lo dibuja.	Tadeo observó que esta situación fue de contingencia para Mario y lo tomó en cuenta en la planeación de la aplicación de la secuencia
Transformación Registro Gráfico	Los estudiantes afirman que el valor del área mínima es de 12 cm y mediante la interrogación Tadeo los hace ver que el área mínima es de 11.5 cm^2	Tadeo tiene bien claro el rumbo de la secuencia didáctica por lo que sabe hacer las preguntas correctas, de hecho en la entrevista comenta que su estilo de enseñanza busca ser más constructivista que conductista, por eso considera necesario hacer preguntas para que los alumnos entiendan conceptos matemáticos

Figura 5: Evidencias de las dimensiones del KQ de Rowland en la etapa 2 y 4

Dimensiones (KQ), etapa y docentes	Ejemplo	Comentario
Fundamentación Etapa 03 Lola y tadeo	Para Tadeo encontrar el modelo del área para este problema es más que suficiente ya que se cumple con el aprendizaje indicado en el currículum del Colegio donde laboran, y para Lola introducir comentarios no planificados dentro de la secuencia didáctica no es pertinente ya que se pierde tiempo, refiriéndose al comentario que hace Mario en la etapa de anterior acerca de la función y la ecuación cudrática.	En la entrevista Tadeo considera que el introducir el comentario acerca de la función y la ecuación cuadrática es algo valioso para enriquecer esta secuencia
Transformación Etapa 03 Lola	"tú debes de cuestionar a los alumnos de cómo van a resolver el problema, al final algunos de ellos te voy a hacer un dibujo"	Lola se refiere a qué hay que preguntarle a los estudiantes como deben proceder para empezar a resolver este problema, en la medida de lo posible hay que evitar guiarlos de manera 'conductista'
Fundamentación Etapa 05 Lola	Lola considera que sería pertinente agregar a la secuencia la posibilidad de que el alumno encuentre el modelo de área a partir de 3 puntos, ya que en una parábola vertical sólo se necesitan 3 puntos para encontrar la ecuación.	Lola demuestra conocimientos importantes acerca de geometría analítica y la función cuadrática lo que es un claro ejemplo del conocimiento de la materia (SMK)
Conexión Mario	Mario considera que esta secuencia didáctica puede ser utilizada al empezar la unidad relacionada con la función cuadrática o al terminar ya que considera que puede adaptarse a las necesidades del profesor	Mario muestra que conoce el currículum del colegio donde labora ya que sabe al menos para la unidad relacionada a la función cuadrática como esta secuencia puede ser adaptada en cualquiera de los momentos de la enseñanza de dicha unidad.

Figura 6: Evidencias de las dimensiones del KQ de Rowland en la etapa 3 y 5

Etapa 3 análisis-síntesis, en esta etapa se revisa lo hecho por Mario en la etapa anterior, los profesores en particular hacen una crítica a Mario en el sentido de que no les dio tiempo a los alumnos para que pensaran en el problema lo que, a juicio del Lola, no lograron entender el texto del problema de manera correcta Figura 6.

Etapa 4 Puesta a prueba, es en esta etapa que el profesor Tadeo aplica la secuencia en el aula, él tuvo la oportunidad de observar la aplicación del profesor Mario y de estar presente en la etapa 3 donde se hizo una reflexión acerca de lo hecho por el profesor Mario, la actuación del profesor toma en cuenta las sugerencias hechas en la etapa anterior ya que incorpora en su planeación los errores que pudieran tener los estudiantes al resolver el problema.

Etapa 5 análisis-síntesis, en esta etapa se hace una reflexión final acerca de lo hecho por los 2 profesores se llega a varias conclusiones, la primera es que los profesores deben llevar bien planeada la secuencia para evitar problemas en el momento de su aplicación, también los profesores consideran que es necesario que los estudiantes tenga la oportunidad de fallar y que se les dé tiempo para que rectifiquen sus errores y consideran que se podría mejorar la secuencia con el uso de tecnología como GeoGebra o agregar nuevos retos dentro de la secuencia, como el cálculo de los coeficientes usando diferencias finitas.

Discusión de los resultados

El análisis de las evidencias encontradas en este ciclo de Enseñanza-Reflexión muestran que la reflexión de las actuaciones de los profesores al aplicar la secuencia didáctica ayudó a qué situaciones de contingencia como la que le ocurrió a Mario durante la transición del registro verbal al geométrico, se convierta en una situación de fundamentación de Tadeo ya que sabe que los estudiantes fallan al no considerar la anterior igualdad (Figura 6).

También existen situación donde las creencias, se imponen sobre conocimientos para la enseñanza, es el caso de la explicación de la diferencia de la ecuación y función hecha por Mario en la etapa 2 (ver Figura 2) puede ser una pérdida de tiempo ya que no está en la planificación original, pero puede ser considerada valiosa para otro profesor, ver el caso de Lola y Tadeo (Figura 6, Etapa 03, Fundamentación).

Por otro lado, también se muestra que un docente con experiencia, como fue el caso de Lola puede ayudar a mejorar la enseñanza de otros profesores, ya que ella ha enseñado con el problema y ha visto cómo actúan los estudiantes cuando hacen las actividades de la secuencia, pero los demás profesores pueden enriquecer de manera colectiva el conocimiento para la enseñanza a pesar de no conocer la secuencia.

Otro aspecto que debe ser incorporado a las discusiones reflexivas de la comunidad es el hecho de que los profesores podrían involucrarse en el análisis de cada etapa, sobre todo aquellas relacionadas con la aplicación de las actividades didácticas, con el objetivo de que conozcan el marco del Cuarteto del Conocimiento de Rowland, como una manera de hacer mejores reflexiones acerca de su actividad docente.

De manera más global hay que señalar que esta forma de trabajo colectiva y autogestiva puede contribuir a la ampliación del conocimiento de los profesores que participan en una comunidad profesional de aprendizaje, un ejemplo que podemos señalar es el enriquecimiento al conocimiento de los profesores durante las etapas de 3 y 5, donde se dan discusiones en las que se intercambia la experiencia de parte de Lola, las reflexiones en las aplicaciones en aula de parte de Mario y de Tadeo sobre todo cuando Mario experimenta momentos de contingencia que Tadeo aprovecha para incorporar a su fundamentación. Es claro también que evidencias sólidas del crecimiento del conocimiento de los docentes del colectivo solo se podrá observar en periodos largos.

IMPACT OF REFLECTION ON THE KNOWLEDGE OF TEACHERS WHO ARE MEMBERS OF A LEARNING COMMUNITY

A group of high school mathematics teachers seek to improve their teaching work, for which they create a professional learning community, where teachers collectively produce teaching activities through a reflective cycle of several stages that they call 'Teaching-Reflection '. This report describes how knowledge is expanded for teaching mathematics during a reflective cycle on the quadratic function, as well as the impact of reflection on teachers' knowledge. An important result of this work is that the framework of Rowland et al. It allows to analyze the

knowledge of teachers, which emerges when they do reflective activities in a self-managed professional learning community.

WHAT'S IN A NAME? SEEKING GEOMETRY IN GEOMETRIC SEQUENCES

Mathematical terminology is sometimes created according to conventions that are not obvious to students who will use the term. When this is the case, investigating the choice of a name can reveal interesting and unforeseen connections among mathematical topics. In this study, we tasked prospective and practicing teachers to consider: What is geometric about geometric sequences? Participants embedded their explanations within a scripted dialogue between teacher- and student-characters in a mathematics classroom, provided commentary on this dialogue, and expanded on its mathematical content. Participants most often leverage the concept of a geometric mean to explain why geometric sequences are named as such. To capture this informal arguments, we built on the work of Toulmin (1958/2003) to conceptualize and develop the Toulmin-Reversed (Toulmin-R) model.

Keywords: Teacher Knowledge, Communication, Professional Development, Preservice Teacher Education

Introduction

Mathematical communication relies on the use of terms that have a particular meaning within the mathematical register. However, confusion may arise when a learner interprets a mathematical term by referencing the use of that word outside of mathematics. For example, the phrase "only a fraction of students participated in the Olympiad" implies that a "fraction" is a small amount and may interfere with a learner's ability to recognize fractions that are greater than one (Hackenberg, 2007). To indicate such fractions within a mathematical conversation, a particular adjective is chosen: *improper* fractions are fractions greater than one.

Such adjectives often resonate with the intuitive interpretation of the words. Consider for example increasing functions, whose graphical appearance is often exactly in accord with students' preconceived notions of what increasing entails. There are also instances of particular adjectives which may at first seem unrelated to the mathematical object, but which are immediately explained by the associated definition. For example, *rational* numbers are those expressed as ratios (under some constraints).

However, there are examples of adjectives where the choice is somehow puzzling even after learning the corresponding definition. Consider for example a *perfect* number, defined as an integer that is equal to the sum of its factors (excluding itself). It is not immediately obvious why "perfect" is an appropriate adjective to describe this particular property. It is only in light of the fact that perfect numbers are usually considered together with *deficient* (smaller than the sum of its factors) and *abundant* (larger than the sum of its factors) numbers that the choice of adjective is given some context; and even so, the adjectives "sufficient" or "balanced" could be seen as more appropriate than associating the property with perfection.

We acknowledge that mathematical convention, including terminology, is sometimes *arbitrary* in the sense that it cannot be deduced using logical principles (Hewitt, 1999). For example, a student simply cannot deduce the arbitrary fact that circles are agreed to have 360 degrees—they must be told as much by an authority. But as Hewitt illustrates, it is sometimes possible to embed a seemingly arbitrary convention within a historical or mathematical context to justify its use. When introducing degree measure, a teacher may appeal to the Babylonian number system in which the degree originated in order to rationalize our modern conventions. Our study is concerned with similar explanations surrounding the arbitrary use of the adjective “geometric” in connection with a geometric sequence. It is stimulated by a student question, “What is geometric about geometric sequences?”, to which we collected responses from prospective and practicing teachers.

Our investigation addresses the following research question: How do teachers justify a convention of mathematical terminology? In particular, what is the most common argument invoked by teachers to explain the adjective “geometric” in a reference to a geometric sequence?

Background: Toulmin’s Model

Toulmin’s model is comprised of six elements which, when taken in relation to each other, outline the structure of an informal argument. The *data* is an assertion from which follows the truth of the *conclusion* (sometimes called the claim: cf. Inglis et al., 2007; Conner et al., 2014). The degree of confidence with which the arguer believes the conclusion follows from the data is inferred from the use of a *modal qualifier* (e.g., “therefore, it is necessary that…” or “so, it is probably the case that…”). Throughout this report, we refer to the combination of data, claim, and modal qualifier as the core argument.

A lower degree of confidence in the conclusion is often caused by *rebuttals*, the existence of which may be known or only anticipated at the time the argument is made. Rebuttals are statements that present contrary evidence to the conclusion by describing how it may not follow from the data. Conversely, a higher degree of confidence could be the result of a convincing *warrant* and any associated *backing*. A warrant is an attempt to support the relationship between the data and conclusion with reasoning or evidence; a backing statement is further evidence in support of the warrant (Toulmin, 1958/2003). These elements are not considered part of the core argument because an argument need not contain rebuttals, warrants, or backings—on the other hand, it may contain multiple.

In mathematics, informal argumentation often serves as a foundation for, or supplement to, logical proof; as such, Toulmin models can be used to visualize the structure of mathematical activity surrounding more rigorous mathematics. For example, Inglis et al. (2007) examined the work of mathematics graduate students who had been tasked with deciding the truth value of certain mathematical statements; the authors used Toulmin models to coordinate instances of intuitive and inductive reasoning as their participants informally developed the ideas of a rigorous proof. Weber et al. (2008) and Conner et al. (2014) used Toulmin models to analyze whole-class discussions of middle and secondary school mathematics classrooms, respectively. These data were used to illustrate the role of explicit warrants in facilitating learning opportunities (Weber et al., 2008) and to generate a framework that categorizes the ways in which teachers can support collective argumentation (Conner et al., 2014).

In this paper, we extend the use of Toulmin models to a situation in which the conclusion is known, but the data used to reach that conclusion is not. It is certainly true that geometric sequences are named as such—but what set of data and accompanying warrants might have led to that conclusion?

Methods

Participants and Setting

A total of 24 participants (referred to here as T-1 through T-24) took part in the study. Of these, 9 were prospective teachers in the last term of their teacher certification program. At the time of data collection they were enrolled in a course that used mathematical problem solving as a lens through which secondary mathematics could be connected to advanced mathematics. The remaining 15 participants were practicing teachers enrolled in a professional development course that provided them with an opportunity to investigate and extend their own mathematical thinking by focusing on the learning and teaching of mathematics. The practicing teachers held bachelor's degrees in mathematics or science; in the latter case, the degree also included a number of mathematics courses sufficient for teaching certification.

Both populations completed several scripting tasks (see next section) as part of their regular coursework. Their responses to one such task, along with their responses to accompanying discussion prompts, serve as the dataset for this report.

The Task

The data analyzed in this report is based on participants' responses to a *scripting task*. Scripting tasks were initially introduced in mathematics teacher education as *lesson plays*, which were envisioned as a more robust form of lesson planning. In a lesson play, the scriptwriter constructs dialogue that captures key interactions between a teacher and student characters (Zazkis et al., 2009; Zazkis, et al., 2013). More recently, the idea of a lesson play has been extended to the activity of writing an imaginary dialogue between interlocuters in any mathematical context. In this expanded scope, scripting tasks can provide multiple affordances not only for teachers but also teacher educators and researchers.

Scripting tasks often begin with a prompt, which serves as the beginning of a dialogue between the scripted characters. In prior research, prompts have introduced a student error (e.g., Zazkis et al., 2013), a student question (e.g., Bergman et al., in press; Marmur & Zazkis, 2018; Zazkis & Kontorovich, 2016), or a disagreement among students (e.g., Marmur et al., 2020; Zazkis & Zazkis, 2014). The scriptwriter responds to a prompt by continuing the dialogue. These dialogues reveal mathematical understanding and, for teachers, demonstrate "awareness-in-action" (Mason, 1998, p. 255). That is, they show an envisioned response in practice, rather than in theory, to students' errors, queries, or unusual ideas.

Part 1 of the geometric sequence task consists of a scripting task, the prompt for which is seen in Figure 2. We refer to the scripted characters as "teacher-characters" and "student-characters" throughout this report. We refer to participants also as respondents and scriptwriters, interchangeably. In Part 2, participants were asked to explain the actions taken by the characters in the script. This included justifying both the explanation(s) chosen by the teacher-character as well as the responses given by the student-characters. In Part 3, participants were asked to elaborate on how their personal understanding of the mathematics might have differed from what was presented in the script; that is, they were given the opportunity to clarify the mathematics using more formal or advanced language appropriate for a colleague rather than a student.

> You are starting a unit on geometric sequences. After you have provided several examples, you are faced with a student's question.
>
> **Student: What is GEOMETRIC about geometric sequences?**
> **Teacher: What do you mean?**
> **Student: You called these sequences "geometric", but these are just sequences of numbers…**
> **Teacher: …**
>
> YOUR TASK is to develop an imaginary dialogue in which the student question is discussed and to justify your course of action.

Figure 2: The prompt for the geometric sequences task

Data Analysis

Analysis of participants' responses began with reflexive thematic analysis (Braun & Clarke, 2006, 2019; Nowell et al., 2017). First, the research team thoroughly familiarized themselves with the data by reading and rereading both the scripts and the accompanying commentary. The coding process began by identifying and classifying within Part 1 how the teacher-character chose to answer the student-character's initial question from the prompt: "What is geometric about geometric sequences?" Explanations that only appeared in Part 2 or 3 were also identified and classified in the same way. During this process, supplementary codes emerged from the data that captured other common aspects of the participants' submissions. These included: ways in which the teacher-characters' explanations were unsatisfactory, either to a student-character or the scriptwriter themselves; how characters chose to define the adjective "geometric" and what mathematical objects should be described as such; and how comparisons to other types of sequences bolstered or diminished the explanatory power of the teacher-characters' justification. In total, the initial codes and supplementary codes combined to form a preliminary codebook.

Upon review of the submissions, the research team recognized that Toulmin's model of informal argument could capture the scripted dialogue. When a student-character opposed the teacher-character's explanation, we perceived this as voicing a rebuttal. When the dialogue attended to what is or is not geometric, the characters were seen to be establishing a warrant or its associated backing. However, the existing Toulmin model needed modification given that the scripted characters were attempting to find data that supported a forgone conclusion. That is, it is certainly the case that geometric sequences are named as such—but one cannot establish that they "should" be named this way through formal, deductive logic, as one might establish that the square root of 2 is an irrational number. To capture this novel dynamic, we developed the Toulmin-Reversed (Toulmin-R) model pictured in Figure 3. The Toulmin-R model contains the same elements as a Toulmin model but reverses the direction of the arrows within the core argument and draws attention to the fact that the conclusion is already known; instead, the data is the subject of the argument.

The codebook was then reorganized and refined in light of the Toulmin-R model. Finally, the research team created Toulmin-R models to visualize the informal arguments as they were used by participants to answer the student-character's question from the prompt.

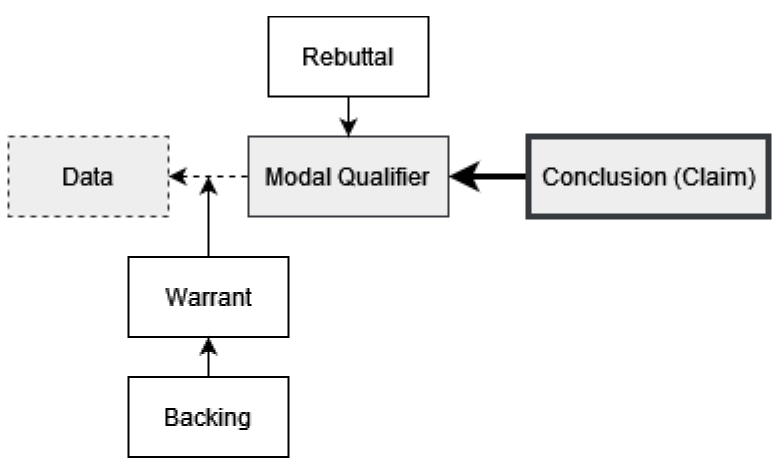

Figure 3: A Toulmin-R diagram template, with the reversed core argument emphasized

Findings

In 13 of the 24 submissions, participants used a connection to the geometric mean as data that could rationalize the naming convention of geometric sequences. This made it the most prevalent source of data employed in arguments.

Scripts that invoked the geometric mean in Part 1 sometimes introduced that concept as an analogue to the arithmetic mean. When this was a purely computational comparison, the student-characters typically responded with skepticism. For example, in T-17's script, an unsatisfied student-character observed that the two means are just "more things called 'arithmetic' and 'geometric' where one's about addition and the other is about multiplication." In these cases the geometric mean was, like the sequence, being introduced and handled entirely with arithmetic—and so its power to explain the choice of "geometric" as an appropriate adjective was limited. A student-character in T-20's script voices this concern explicitly: "If a geometric sequence is geometric because it involves geometric means, then why do we call the geometric mean 'geometric'?"

In response to these student-characters, the teacher-character typically provided one of two geometric explanation that warranted the geometric nature of the mean, and thus, the associated sequence. Both warrants were sometimes accompanied by diagrams, as exemplified in Figure 4.

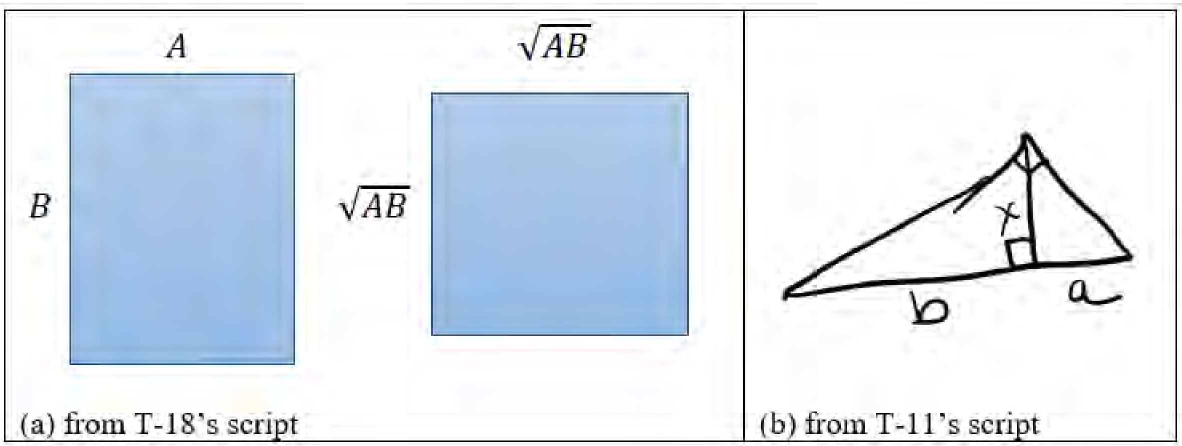

Figure 4: Diagrams used by teacher-characters as warrants

The more common warrant was that if two given numbers were used as the sides of a rectangle, then the geometric mean was the side of a square with the same area as that rectangle. T-18's teacher-character provided the accompanying visualization of this relationship pictured in Figure 4(a). More infrequently, it was explained that the geometric mean could be visualized as the altitude of a right triangle that had been cut into two similar right triangles. The teacher-character in T-11's script drew the diagram seen in Figure 4(b) to illustrate this warrant.

For each of these warrants, an associated backing (sometimes explicit, but usually only implied) was that the polygons in these diagrams were clearly geometric, thereby justifying the use of that adjective for the associated mean and sequence. Figure 5 provides a *composite* Toulmin-R model illustrating these arguments. This model is a composition in the sense that it includes all the rebuttals, warrants, and backings of any submission that argued for the geometric mean as a source of data. We also note that the model in Figure 5 express sequences with notation familiar to a research audience but, as exhibited in the visualizations provided in Figure 4, not typically used by participants in their scripted dialogues.

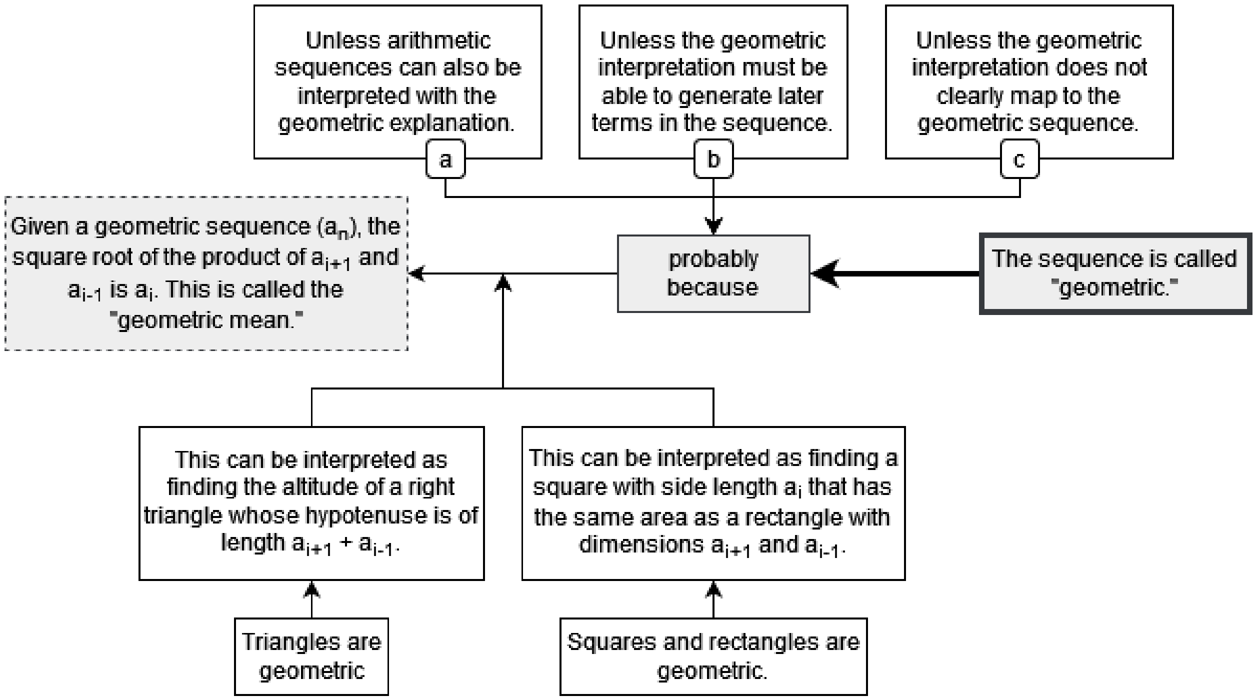

Figure 5: Composite Toulmin-R model featuring geometric mean as a source of data

The selection of the geometric mean as the likely source of data sometimes led to rebuttals, even with the accompanying warrants described above. For example, the teacher-character in T-18's script extended his explanation warranting the geometric nature of the geometric mean to also include a geometric explanation of the arithmetic mean. After drawing the diagram in Figure 4(a), the following dialogue occurs:

Teacher: […] Suppose you have A and B are the lengths of two sides of a rectangle. So the geometric mean $\sqrt{AB}$ is the length of a side of a square having the same area of the rectangle.

Student 1: Okay, then?

Teacher: And the arithmetic mean $\frac{(A+B)}{2}$ is the length of the side of a square having the same perimeter of the rectangle.

Student 1: I still not see your point. Why they are both expressed geometrically?

From Student 1's perspective, accepting the geometric mean explanation as a likely source of data meant that the arithmetic sequence was also similarly geometric. This perspective corresponds to rebuttal-a in Figure 5. Even though the geometric mean does justify that the geometric sequence is in some way geometric, it does not clearly establish why the adjective "geometric" was chosen to apply to one sequence and not the other—thereby calling into question whether it is the correct source of data. Some participants avoided this rebuttal by providing additional historical context. In one such case, T-23's teacher-character explained that "in ancient times" measures of length, such as perimeter, were not considered geometric.

Other rebuttals hinged on the fact that the geometric mean did not immediately lend itself to generating subsequent terms of a geometric sequence, as seen in rebuttal-b in Figure 5. For example, T-17 recognized that the geometric mean could interpolate additional points between two known terms of a geometric sequence, but called into question whether this was a useful property: "Why would we ever be in a position where the nth element is unknown but its 2 neighbours are known?" Similarly, T-14 noted in Part 2 that she was unsatisfied with the geometric mean explanation because it "doesn't nicely describe the progression of numbers […] and it isn't exactly logical what number would come next in the sequence." The characters in T-6's script handled this concern by deriving the common ratio in terms of the geometric mean:

Allen: Uh… A, $\sqrt{AB}$, and B.
Teacher: Exactly! Short rectangle side, then square side, then long rectangle side, which makes A, $\sqrt{AB}$, and B. Now, what's the pattern here? […] To go from A to $\sqrt{AB}$, what do you have to multiply?
Allen: Multiply? Uh… $\sqrt{AB}/A$?
Teacher: Exactly! […] This "pattern" you found is the sequence: the geometric sequence.

Finally, T-11's script contained an example of rebuttal-c in Figure 5. This rebuttal was based on the fact that warranting the geometric mean explanation with a geometric representation actually obscured the underlying sequence. This is illustrated in the following conversation between the characters:

Teacher: […] This is why this progression is called a geometric progression since it's exactly like growing similar triangles.
Student: ………………………….. what is a similar triangle? I forget………………..
Teacher: I'll draw similar triangles for you. Here we have 3 similar triangles: There's the large triangle and the two small triangles.
Student: But where's the geometric sequence?

The visualization drawn by the teacher-character in this excerpt is the right triangle in Figure 4(b). The teacher-character does not answer the student-character's final question in Part 1, but the scriptwriter later explains in Part 3 that she might clarify the construction of this triangle for a mathematically mature colleague.

Discussion

Mathematics teachers must be careful that they do not take language for granted. This is especially true of mathematical names, which are (perhaps naively) expected to encapsulate the essence of the object they denote. An expert in mathematics might take familiar terminology for granted. But before a novice connects mathematical properties to a name, they might associate with it their personal connotations and experiences—which may sometimes cause conflict. It is an awareness of this fact that we hope to explore by assigning the geometric sequences task to teachers.

In analyzing participants' submissions, we considered the following research questions: *How do teachers justify a convention of mathematical terminology? In particular, what is the most common argument invoked by teachers to explain the adjective "geometric" in a reference to a geometric sequence?* Our findings indicate that the most common argument leveraged by teachers to explain why geometric sequences are in fact geometric relies on the relationship between a geometric sequence and the geometric mean. This approach necessitated a warrant justifying that the geometric mean is in fact geometric. Some participants handled this with a geometric diagram: either of a square that preserves the area of a given rectangle, or of a right triangle decomposed into two similar right triangles. In both cases, the fact that these diagrams were made of familiar polygons implied that they were genuinely "geometric."

In addressing our research questions, we considered the ways in which each explanation was considered insufficient to either student-characters or scriptwriters. These observations were captured in the findings as rebuttals. Here, we frame these rebuttals as the inability on the part of the core argument to meet an intellectual need (as in Harel, 2013). Rebuttal-a in Figure 5 does not satisfy the need for *structure*. For student-characters who voiced this rebuttal, the argument from geometric mean did not logically reorganize their understanding of mathematical terminology by meaningfully differentiating between geometric and arithmetic sequences. Rebuttal-b in Figure 5 does not satisfy the need for *computation*. Participants already knew how to compute the next term of a geometric sequence arithmetically by multiplying by the common ratio; the inability of the geometric mean argument to replicate that capability in a geometric context was therefore seen as a shortcoming. Finally, rebuttal-c in Figure 5 captures a need for *communication*. The student-character who voiced this rebuttal could not productively translate between their symbolic understanding of geometric sequences and the visual embedding of that concept in the triangle diagram.

Recasting other elements of an informal argument in light of intellectual need is one direction for future research; for example, how do certain warrants successfully attend to intellectual need? Another direction for additional research is to consider the origin of other mathematical terms. What is linear about linear algebra? What is natural about the natural logarithm? Whether posed to prospective teachers or to other students of mathematics, we anticipate that such questions will provoke meaningful introspection on the nature, structure, and history of the subject. This will, in turn, lead to further exemplification of the role of informal argumentation in mathematical discourse.

Our study contributes to research in mathematics education by developing the Toulmin-R model as a tool for representing informal arguments in which the goal is to establish a likely source of data rather than a meaningful conclusion. We have used this model in the context of explaining mathematical terminology; we suggest it could also be of use when a mathematical effect is observed but its cause is unclear. For example, a novice will eventually prove that the product of any two odd numbers is itself odd. Before their thinking is rigorously expressed by deductive proof, however, the Toulmin-R model might be leveraged to capture their informal arguments as they seek data leading to this conclusion.

This report also contributes to the body of knowledge on methods for mathematics teacher education. In their *Standards for Preparing Teachers of Mathematics*, the Association of Mathematics Teacher Educators recommend that to be “well-prepared,” teachers must “understand that mathematics is a human endeavor” (2017, p. 9). It is empowering for teachers to understand mathematics as the cumulative result of centuries of human effort—even though, as a result, it may sometimes seem disorganized or arbitrary. A well-prepared teacher should recognize that this is not always to the subject’s detriment. It may not be set out clearly why a geometric sequence is geometric, but by attempting to answer the question, teachers are apt to discover unexpected connections between areas of mathematics. Paradoxically, it is often those things that seem inexplicable that ultimately reveal a more cohesive and interrelated subject.

INVENTED STRATEGIES CHANGING TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE

Jana Lunt
Southern Utah University
janalunt@suu.edu

This study investigates how utilizing student-invented strategies in the classroom can inform teachers' pedagogical content knowledge. Two elementary school teachers participated in professional development discussing the benefits of invented strategies. Data was then gathered as the participants implemented this practice in their classrooms. Data was analyzed qualitatively to show the ways in which invented strategies can be useful in a teacher's development of their pedagogical content knowledge, including their Knowledge of Content and Students, Knowledge of Content and Teaching, as well as Knowledge of Content and Curriculum.

Keywords: Teacher Knowledge, Instructional Activities and Practices, Elementary School Education, Curriculum

As one elementary school teacher in this study told me, "In 20 years of teaching I have never come across a math curriculum that encourages teachers to ask students to solve problems with their own invented strategies." In her experience, teaching in three different states, she had not been exposed to the importance of giving students time to develop their own algorithms. After the first day of implementing this practice, I talked with the teacher, expecting to hear validation of the research about students' capacity for thought and their flexibility in their understanding (Carpenter, Franke, Jacobs, Fennema, & Empson, 1998; Chambers, 1996). I was surprised that the conversation centered on what she, as the teacher, had learned. Her understanding of the students, of her own teaching, and of the curriculum changed after watching students invent their own strategies to solve problems.

The teachers in this study reveal how their pedagogical content knowledge (PCK) increased. Some of this growth was pleasing to them. It amplified their current beliefs and ways of thinking. It resonated with past experiences and harmoniously pushed them in ways that excited them. On the other hand, some of this growth was jarring for the teachers to experience. They found this practice confusing, and claimed that it created dissonance between their past teaching practices and what they wanted to accomplish. This study investigates how teachers can increase their PCK directly from observing their students use invented strategies.

Objectives

We know the value of invented strategies for students (Carroll, 1999). In this study I begin to uncover the value of using student-invented strategies for the teachers themselves. My study is exploratory in nature and seeks out possible ways in which teachers can use this practice to change how they see and understand their students, what they teach and how they teach, and how they use the curriculum in their teaching.

Framework

My research uses Deborah Ball's construct of the mathematical knowledge needed for teaching (Ball, Phelps, & Thames, 2008). As Ball illustrates, there are several components of PCK. Knowledge of Content and Students (KCS) is knowledge that involves the dynamic between understanding specific mathematical concepts, and familiarity with students and their thinking about those concepts. This includes knowing student conceptions as well student misconceptions. Teachers need to be able to predict how students will perform on a task, and what students will find challenging, what students will find easy, and what students will find confusing. As students are developing their own concepts, even while those concepts are still incomplete, teachers need to be able to understand the students' language and ideas.

Knowledge of content and teaching (KCT), is knowledge that combines knowing about teaching and knowing about mathematics. Teachers need to understand the architecture of a task and what types of responses will be elicited by the design of the task. Teachers need to know how to sequence particular content for instruction. They need to discern the advantages and disadvantages of different tasks, manipulative, and technologies. When developing content with students, they need to make decisions about which student ideas to pursue, when to pause for clarification, and when to pursue a new avenue.

Knowledge of Content and Curriculum (KCC), the intersection between knowledge of mathematical content and knowledge of the curriculum from which it is taught, is not developed in the literature, but Ball theorizes that KCC is a factor in a teacher's PCK. As Hill suggests, currently KCC is an "interim placement…still in need of revision and refinement…it may run across several categories or be a category of its own" (Hill, Ball, & Schilling, 2008)

My study also relies on the importance of student-invented strategies in the classroom. Carpenter's longitudinal study of invention and understanding in multi-digit addition and subtraction with children shows that students benefit from inventing their own algorithms and strategies in a variety of ways (Carpenter, Franke, Jacobs, Fennema, & Empson, 1998). The authors explain that, in contrast to standard algorithms, invented strategies generally are derived directly from the underlying concepts. Therefore, students who are asked to devise and use their own strategies demonstrate knowledge of underlying concepts before students who relied primarily on standard algorithms. Invented strategies demonstrate a characteristic hallmark of understanding, and children who use them are able to use them flexibly to transfer their use to new situations.

In this study, I helped practicing elementary school teachers understand the benefits of invented strategies. They implemented this practice in their classrooms and, in doing so, they learned more about their students, they discovered benefits of and problems with their teaching methods, and changed their relationship to the curriculum.

Methods

After teaching a series of professional development courses at an elementary school, one second-grade teacher, Julie (all names used are pseudonyms), approached me and asked me to look over the text they were using to "see what was missing." I noticed that student-invented strategies were not addressed in the text, nor in her curriculum. She was very interested in exploring the use of this practice. For the second half of that school year, Julie intermittently gave time to students to try their own strategies before teaching them the standard algorithm. She was impressed with what the students gained from this experience, and I was surprised by and interested in what *she* was learning from the experience. This informal interaction developed into a pilot study. I began observing Julie teach each time she used invented strategies in her class and interviewed her afterwards. There was so much she was learning that we decided to continue the study the following school year and to include other teachers at the school.

Julie approached all of the other second and third-grade teachers at her school to see if they were interested in participating. Over the summer I met with four teachers to discuss the research regarding invented strategies and the benefits for students. Unfortunately, by the end of the summer two of the teachers had left the school. This was the summer of 2020, and it was unclear if we were going to be able to continue the study at all because of the COVID-19 pandemic. However, this particular school district did teach face-to-face for the 2020-21 academic year. So, although the number of participating teachers was down to just two, these two teachers were still willing to take on this new challenge, in the midst of all of the other pandemic-related difficulties, and learn more about student-invented strategies.

I met with Julie, a second-grade teacher, and Kamila, a third-grade teacher, several times during the summer and at the beginning of the school year to discuss general benefits of invented algorithms. We focused on things teachers should know about the importance of and reasons for employing invented algorithms (Trafton, P., & Thiessen, D., 2004). We also discussed content-specific invented strategies such as children's conceptual structures for addition and subtraction (Fuson, Wearne, Hiebert, Murray, Human, Olivier, & Fennema, 1997; Huinker, Freckman, & Steinmeyer, 2003). The teachers decided, completely on their own, how they would use this knowledge to change and enhance their teaching over the following year. Both teachers decided to use invented strategies before each section that involved a new algorithm.

I observed and took notes during any class time during which teachers were using invented strategies. I made copies of materials used by the teacher, took photographs of board work, and recorded other relevant data including occasional student work. After each observed class, I interviewed the teachers. I audio-recorded those interviews as well as took field notes. The field notes, curricular materials, board work, student work, and teacher interviews were used to analyze how the teachers' PCK was being affected by utilizing student-invented strategies.

The analysis was conducted qualitatively. Learning what the teachers noticed, what surprised them, what they expected, and what changes they made to future lessons due to their findings all provided me with an important avenue for investigating what they were learning. I reviewed the materials looking for patterns, and ultimately found evidence of several developments in the teachers. It was not until after I looked for patterns that I began thinking of the teachers' growth as improving their PCK. This became the avenue for how I grounded by research and began analyzing the data

Results

I discovered ways in which students using invented algorithms informed each aspect of the teachers' PCK. The following paragraphs will highlight some of the ways that teachers experienced change in their Knowledge of Content and Students (KCS), Knowledge of Content and Teaching, (KCT) as well as possibly Knowledge of Content and Curriculum (KCC).

Examples of Change in Teacher's Knowledge of Content and Students

Students as imparters and constructors of knowledge. Because students were given more of a voice in the classroom, teachers were able to get to know their students' capabilities on a deeper level. The teacher, as well as the students, began to see the children as 'imparters of information," according to Julie. Everyone in the classroom saw the students as "capable of knowing and sharing things" and not just the teacher. Julie and Kamila frequently described how they watched the students build confidence as they displayed their thinking to others or made connections to previous strategies. As Julie said, "I'd never asked what they already know. I know much more about that now." The teachers were able to see even their struggling students in a different way, focusing not just on what these students did not understand, but also seeing what they *did* understand. After a day of student-invented strategies Julie reported, "One of my struggling students today was able to solve a subtraction problem on her own today, without having been taught how. I think the flexibility in solving problems in different ways has enabled her to get better at using the strategy that makes most sense to her. Even when posed with the traditional algorithm she uses drawings to help her solve problems and is making great gains. This is so exciting!"

Students spent a lot of time comparing and critiquing other students' strategies. The teachers realized this forced students to explain themselves more clearly and visibly. It encouraged everyone to participate. As Kamila said, "Everyone is working on *something*. No one is just sitting there. They are all willing to come up and share and talk about strategies. They feel successful and proud." Both teachers saw the benefits of students working with partners. They acknowledged that they often used partner-work with reading, but rarely with math. Now they could see how working in partnerships allowed students to help one another, and built confidence and ownership of their work.

Julie used invented strategies in the previous school year, as part of our pilot study. One day after school, one of the students from the previous year approached Julie and asked, "Did you teach them my strategy yet?" Julie did not immediately remember which strategy the student claimed as hers, but the student quickly reminded her. Julie told me, "It made me realize how powerful invented strategies are because kids take ownership of them. They are the constructors of their own knowledge. For her to remember that a year later made quite an impression on me!" The teachers began to look at their students differently: they were now capable of constructing their own knowledge and sharing it with other students.

Student learning styles. The teachers frequently talked about understanding individual students' ways of thinking more clearly. They did not only view their class as a whole, but the teachers could describe each student, what types of strategies each preferred and which strategies posed a struggle. This understanding helped the teachers group students more effectively. Julie described this process:

> After the lesson I sorted the student work into three categories: 1) students who have at least one strategy and were able to solve all of the problems, 2) students who had a start (part of a strategy or a whole strategy, but may have had a misconception or mistakes, and 3) those who don't seem to have any strategies at their disposal. In thinking about these groups of students, it confirmed for me which students have solid strategies and can work independently and most likely transfer these skills. It also showed me which students would benefit from scaffolding…which students need to work with concrete base ten blocks before working with pictures or abstract problems.

Teachers could describe individual students' learning styles after watching them repeatedly invent strategies because they could see which strategies their students relied on, and which strategies the students were using when they made mistakes. As one teacher reported, "When kids get to the standard algorithm they won't use it if they don't understand it. They will fall back on other strategies they have used." The teachers were more aware of how their students thought, how the students could best express themselves, and what tools helped them learn.

Student misconceptions. Julie and Kamila are seasoned teachers, each having taught their grade level for over 20 years. They were both surprised that letting students use invented strategies revealed student misconceptions of which they were previously unaware. For example, many of the strategies in these grades relied on an understanding of place value. But, as some students used their invented strategies, it became clear to the teachers that the students had unanticipated misconceptions about place value. Frequently, these misconceptions surfaced when students were discussing their strategies and they would use words incorrectly, demonstrating to the teachers that the students did not fully understand the math concept behind the words.

The teachers were more informed when words such as “equal” or “whole,” for example, were concepts that needed more instruction. It was also apparent to teachers when students did not understand *why* they were doing certain algorithms. Teachers described identifying a lack of connection between tasks within a unit that was building to a cumulative goal. There were many times when teachers thought the students understood a topic, but recognized that the understanding was not there when the teachers invited the students to build on that topic for the next topic, using student invented-strategies.

Student transfer. The teachers were very concerned about and interested in transfer as they discussed their students with me. Sometimes the teachers saw the students using previous knowledge to solve new problems more than they had expected. They saw invented strategies as a tool that students used to help make connections between different topics. There were also many times when the teachers expressed discouragement that the students were *not* able to build on what they had discussed previously. In some ways, invented strategies left as many questions as answers when it came to students’ ability to transfer knowledge. After a year of using this teaching strategy, the teachers are still interested in invented strategies to investigate transfer.

Examples of Change in Teacher’s Knowledge of Content and Teaching

Assessment. The teachers immediately saw invented strategies as a form of assessment. Julie described using invented strategies, and asking the students to articulate their thinking in writing, as one of the best things she could use to see what her students were understanding. “That was more helpful than seeing the problem and how they solved it,” she explained. Julie now wants to use invented strategies mid-chapter as a formative assessment in her teaching.

Julie and Kamila also found themselves thinking more about assessment in general after using invented strategies. They examined the type of assessments they were using and realized a need for changes. In a conversation with the two teachers they said, “There needs to be some changes on a school level about how students are assessed. There should be more one-on-one assessment with math. We do it with reading; why don’t we do that in math?”

In addition to assessment at the end of, or even during a chapter, the teachers realized invented strategies were an excellent tool to use for pre-assessment. After the very first day that Julie taught with invented strategies she said, “Truly today worked as a pre-assessment and helped me understand what skills my students already have in this arena, as well as helped me identify some action steps for how to address their needs.” The teachers were looking to see how students were able to build on concepts they had learned previously and what new boundaries they could investigate all on their own.

Sometimes the pre-assessment went well and sometimes it did not. When the pre-assessment did not go well, the teachers learned they might need to go back and address concepts from previous lessons. As Kamila described, “If their foundation isn’t there, they can’t see it. They can’t move forward.” Based on how the students performed when trying strategies of their own, the teachers were able to make decisions about the upcoming lessons. The teachers were able to look beyond whether the students performed well or not on the pre-assessment. They were able to decide which concepts they needed to review more, the tasks that would most benefit their students, which students were best suited to work together, and which students needed more instruction.

Manipulatives. At the end of the study, when asking the teachers how they had changed, Kamila expressed that her relationship to manipulatives possibly had changed more than anything else. She said, “I am the type of person that I like to have everything in its place, but now my intention is to have manipulatives accessible so that students can take any tool they feel will help. I already have this math station envisioned in my mind and am so excited about it!” She was looking forward to a time (past the pandemic) when it would be possible to set up a table of manipulatives for students to use at their discretion.

Because of COVID-19, each of Julie’s students had access to their own individual bag of manipulatives that they could use anytime they chose. Even if individualized bags are no longer necessary after the pandemic, Julie plans to continue this practice so that her students have better access to a larger number and a larger variety of manipulatives.

Along with deciding that students need to have more freedom and more choices with manipulatives, teachers were able to tell when, as a classroom, they needed to revert to using a tangible tool instead of proceeding more abstractly. For example, when transitioning from single digit subtraction to double digit subtraction in Julie’s classroom, she noticed that many of the students who tried their version of the traditional algorithm were subtracting the top number from the bottom number. She said this helped her understand that “I need to go back to using blocks and have them see that they cannot subtract in any order.” Using invented strategies helped her see when it would be helpful to revisit using manipulatives.

The teachers also saw how more use of manipulatives changed the students. Julie noticed that her students seemed less intimidated by new problems that had not been explained to them. The students knew they could find a tool that could help them think through the problems. “Everyone has a starting point now,” explained Kamila. The teachers found value in helping students increase their confidence and independence by giving students autonomous access to manipulatives when using invented strategies.

Student-led discussions. According to the teachers, using invented strategies has guided them to a more inquiry-based approach for teaching. Julie learned that getting her students to think deeply about a topic was more easily done as a discussion that was student-led and centered on their own approaches. She realized that when she had been relying on the textbook, the discussions were always teacher-led. She could see that even when the class was not discussing invented strategies, if she wanted deeper thinking, students needed to become more involved. She resolved to plan for times when students would lead the dialogue in all subjects.

Kamila discovered that, when she asked her students a question about their strategy, the students initially would assume that they were wrong. This helped her understand that she was not routinely asking enough questions about how the students were thinking. Both teachers suggested that using invented strategies has taught them to use questioning in a different way. They are more likely to ask questions such as, “What do you already know?” or “What strategy have you used before that could help you?” They describe using these questions as a way to maintain a high cognitive demand in the tasks, allowing students to think more deeply over a longer period of time. In a reflection at the end of the school year Julie said she wants to include “at least three thinking questions in every math class, no matter if it is a textbook lesson or an invented strategy lesson.” Using invented strategies changed her teaching style to include more questioning, which elicited student-led conversations.

Examples of Change in Teacher’s Knowledge of Content and Curriculum

Previous research is unclear about the details of PCK with respect to the teacher’s knowledge of content and curriculum. As I was listening to the teachers talk about their relationship to the textbook and how it was changing, I saw possibilities of how using student-invented strategies could change a teacher’s KCC.

Freedom from the textbook. After using invented strategies, teachers decided that they were relying on the textbook too heavily for their curriculum. According to Kamila, “the Common Core was, at least in part, designed to encourage students to think more critically. But we are still teaching systematically. We give students more freedom in reading. We need to do that more with math.” Both teachers realized this could not be done if they taught straight from the textbook, as they had previously been doing. In a conversation with Kamila, Julie said, “Teachers need to feel enough freedom, and trust themselves enough, to not rely on the text. There needs to be willingness from teachers and administration to supplement the text so kids are getting opportunities to develop conceptual understanding.” She said she felt an expectation to teach with fidelity to the text but that “if we do it with fidelity, we will never create deep thinkers.”

Students need to have an opportunity to select and invent strategies and, in their experience, the text always tells them which strategy to use. The teachers decided that metacognition is not present when students work from their books because students are merely following procedures, compared to using invented strategies which gives students opportunities to think about their thinking. Kamila decided, “teaching the Common core is what we need to do with fidelity, not the textbook.”

Thinking critically while using textbook. Even when using the textbook, teachers realized they need to be thinking more about their pedagogical choices. They realized that they could still facilitate student-led discussions and group work, and start a lesson with invented strategies, while still approaching the lesson from the text. In their opinion, most textbook lessons were not complex enough, so they could incorporate activities such as making an argument and critiquing others’ work using textbook lessons. One of their conclusions at the end of the study, one they had not previously acknowledged, was that they could omit some parts of the units in the curriculum and add in other lessons. Invented strategies helped them feel freer to make pedagogical decisions. They could decide which units needed to be longer or shorter, and use their assessments to guide their practice. They could use modeling, even if it was not an explicit part of the textbook lesson. They learned that they needed to decide how to balance things like invented strategies versus the textbook’s specific algorithms.

The teachers also realized that there were parts of the text they now understood better. By the end of the year, they discovered sections of the text that were intended as inquiry-based class activities, but they were not able to recognize them as such before they started using invented strategies. Kamila described a section in the textbook where the students were asked to write about their thinking. She realized she had not fully utilized that section in previous years, but was now able to see the purpose of the activity. Kamila and Julie both believed that teachers would benefit from professional development regarding textbook use, discussing how to encourage deeper levels of thinking among students and assessing the curriculum as a group.

Discussion

Learning about new ideas and changing teaching practice is both exciting and interesting, as well as difficult and discouraging. Kamila and Julie felt all of these emotions as they were asked to think more critically about their PCK.

Critical Dissonance

It was jarring for the teachers to watch their students fail to see patterns, make connections, or transfer knowledge in unanticipated ways when the teachers asked students to use invented strategies. This practice illuminated problems in ways that were occasionally surprising and disheartening. Teachers sometimes finished a lesson and realized students did not understand the topic to the extent the teachers had supposed. Teachers sometimes realized that they had been using a word or an expression for some time that the students did not actually understand, but the teachers did not discover this until the students tried to employ their own strategies. These realizations were sometimes painful for the teachers, causing teachers to second-guess past lessons, and wondering what they had missed before. The teachers frequently wished that they had more time.

Resonant Harmony

Of course, much of what the teachers learned resonated with them perfectly. Imparting a stronger voice to their students helped the teachers accomplish their goals. Because of COVID-19 each student was given their own set of manipulatives to use. This was a providential turn of events that led to teachers learning that students need better access to manipulatives. It was not a challenging new idea; the teachers already knew the value of manipulatives. However, they learned how to improve the implementation of this idea.

In addition, learning that their students need to work more with others fit perfectly with the teachers' PCK. They were already implementing this practice in other subjects, but they realized that they were not doing it enough in math. These realizations amplified and improved their teaching, helping them push through the pandemic's obstacles to find a better way.

One of the most remarkable things about teachers such as these is their ability to change. These teachers took in new information about PCK and used it to change the experience of their students. Regardless of whether the change in PCK was difficult or easy for them, these teachers knew that it was necessary to improve their teaching. As Julie said, "Invented strategies are a way to open up the dialogue to include more student-directed discussion, to enable teacher reflection and analysis of student work, and to allow students to build on their conceptual understanding. I will include invented strategies in future lessons to ensure more student voice and encourage a more authentic mathematics community."

Limitations

There were many limitations to the study, specifically because of COVID-19. I had four teachers who were excited about participating and were planning on recruiting others in their grade bands before the pandemic hit. Then two of the teachers decided it was a good time to retire from teaching and others realized that, with all the difficulties that were facing them, it was not a good time to be in a study. So only being able to work with two teachers was very limiting.

Additionally, rules for being in classrooms at this time became a lot stricter. Schools were not interested in having more people interact with students and teachers. In fact, the only way I was able to attend the classrooms was to become a teacher aide. I was not able to conduct interviews with or film the students, but I did interact quite a bit with them and even served in other capacities, such as a running reading groups and going on field trips. This was a major reason for shifting the data collecting to only interviews with the teachers. This seemed permissible because the teachers were truly the participants of the study, but videos of the classroom would clearly have been helpful for data analysis.

Response Process Validity (RPV) reflects the degree to which items are interpreted as intended by item developers. In this study, teacher responses to constructed response (CR) items to assess pedagogical content knowledge (PCK) of middle school mathematics teachers were evaluated to determine what types of teacher responses signaled weak RPV. We analyzed 38 CR pilot items on proportional reasoning across up to 13 middle school mathematics teachers per item. By coding teacher responses and using think-alouds, we found teachers' responses deemed indicative of low item RPV often had one of the following characteristics: vague answers, unanticipated assumptions, a focus on unintended topics, and paraphrasing. To develop a diverse pool of items with strong RPV, we suggest it is helpful to be aware of these symptoms, use them to consider how to improve items, and then revise and retest items accordingly.

Keywords: Item development; constructed response; pedagogical content knowledge; response process validity

Purpose of the Study

The mathematics education community has shown a growing interest in mathematics teacher knowledge assessment (e.g., Izsák et al., 2016 and Mosvold & Hoover, 2016). There is still much to do to understand the domain of mathematics teacher knowledge as well as to understand how to best assess this knowledge through a variety of types of scenarios and both CR (constructed response) and SR (selected response) types of items. When creating items for any assessment, one important task in which developers should engage is the determination of whether items exhibit response process validity (RPV). RPV is a measure of whether the person reading the items understands them in a way that is intended by the item developers. Our goal in this study was to determine the reasons PCK items may fail to demonstrate RPV. By being aware of symptoms of low-RPV, item developers can work to improve the assessment items, accordingly. Engaging in the RPV process can allow test developers to move beyond a binary decision to keep an item, or not, and may facilitate the development of assessment items with strong RPV that can also tap more complex, hard to communicate concepts that may take several rounds of revision to build strong RPV. We were guided by the following research question: What characteristics of middle school mathematics teachers' responses to CR PCK assessment items suggest low RPV?

Perspective and Review of Relevant Literature

Effective assessment development requires that relevant content domain (e.g., elements of proportional reasoning) first be successfully identified (Orrill & Cohen, 2016). For example, Hill and colleagues' (2008) efforts to measure mathematical knowledge for teaching, started by defining the knowledge domain they hoped to measure. Defining the knowledge domain is challenging. Rowan et al. (2001) noted, “One difficulty we faced was developing items (and scenarios) that adequately tapped the full range of underlying “abilities” or “levels” of teachers’ content and pedagogical knowledge…” (p. 16). Once the domain has been adequately conceptualized, the work of trying to measure that domain begins with the development of assessment items. Item development is complicated, in part, because the items must invoke the intended knowledge from test takers. This means that a participant needs to understand the question being asked in ways that align to the developer’s intent. Therefore, it is important to determine the RPV of items. RPV has garnered recent attention in STEM education (e.g., Deng et al., 2021; Padilla & Benítez, 2014), and think-alouds is one method used to investigate RPV. Using methods such as think-alouds (Bostic, 2021), researchers sought to determine the match between test developer intent and test taker interpretation and to garner insights into what may be causing any mismatches (e.g., Mo et al., 2021). An area of opportunity is to continue to investigate sources and symptoms of low RPV and to work to hone our RPV research methods, so they lead to diverse items with strong RPV.

Methods

Context and Participants

Participants included a convenience sample of 13 middle school mathematics teachers from across the United States (nine female, four male). All the teachers were given pseudonyms. Assessment items used in this research study came from an assessment development effort seeking to measure mathematics teachers’ content knowledge and PCK about proportional reasoning. The findings reported here are based on an analysis of only PCK items, all of which were constructed response. The items all involved asking teachers about realistic classroom scenarios (i.e., student work and classroom situations) and were based on Kersting and her colleagues’ (Kersting, 2008; Kersting et al., 2012) successful work with similar items. Many of the items included short video clips that the teachers were asked to comment on.

Data Collection and Analysis

The 38 CR assessment items evaluated were spread across five surveys completed online. Depending on their schedule, teachers completed between one and five surveys and typed their responses to items. A follow-up Zoom think-aloud interview was recorded and transcribed. A coding template was developed to facilitate the analysis process that involved three researchers independently reviewing each item to determine, (1) if the item communicated as intended, (2) if the item did not communicate as intended, how had the teacher likely interpreted the item, and (3) if the item did not communicate as intended, characteristics of teachers’ responses that led to this conclusion. Divergent views triggered a review of a teacher’s data until the research team reached a consensus regarding how the assessment item “worked” for that teacher (e.g., did the teacher understand it as intended and did it invoke the kinds of reasoning intended).

Results

Teacher responses that created RPV issues tended to be: vague/overly general, predicated on assumptions, focused on unintended topics, and/or paraphrased information already provided. Below, we expand on our findings for each of these characteristics.

Vague, Overly General Answers

The intent of all CR PCK items was to elicit answers from teachers that provided rich insights into their PCK. Vague, overly general teacher answers to questions were, therefore the antithesis of the types of answers item developers had hoped to solicit, thus, such answered were considered indicative of low item RPV. As an example of one vague response, participants were asked to watch a short video of a 7th-grade classroom discussing proportions. They were then asked, "Would you have led the class discussion in this video clip differently to support the student's understanding of proportional relationships?" If "yes," "explain how you would have led the discussion differently to support student's understanding of proportional relationships." Seven out of 10 teachers' responses to this item were coded as vague/overly general. For example, Christie offered, "…getting input for more than one student and perhaps leading them in a direction to the correct answer using keywords from students." We considered this and other answers like it vague or general because Christie did not reference specific mathematical concepts, and while she mentioned she would look for "keywords," she did not provide detail about which key math words she was looking for or how she could help students make relevant connections among them to support an understanding of proportional relationships. We found vague/overly general responses were often associated with items that: were not specific enough, provided insufficient information, contained distracting elements, and/or did not adequately take the test-takers vantage point into account.

Answering Based on Assumptions

We considered another indicator of low item RPV when teacher responses suggested that teachers made assumptions to answer an item. Assumptions were deemed problematic because if test takers are making different assumptions, they are, in essence, answering different assessment questions. For example, for an item in which teachers were asked to watch a video and comment on a student's understanding, Lydia, noted, "I think it was difficult to understand what he [the student] truly understood…" and Lydia went on to tell us that she "made an assumption about what he was sort of thinking …" In other instances, teacher responses suggested an assumption may have been inadvertently made which altered the question being asked. One such item presented an inverse proportion task (i.e., $y = k/x$), and the student's use of cross multiplication to solve it—a strategy appropriate for solving proportional problems; not inverse proportions—was therefore problematic. Yet, seven out of 10 teachers' answers were predicated on the assumption or assessment that the student's work was correct, when item RPV depended on teachers recognizing the student's work was not correct. In summary, when teacher responses explicitly or implicitly suggested an answer was based on an unanticipated assumption, we considered it a sign of poor RPV. We found teacher responses that were based on assumptions tend to be associated with items that provided insufficient information and/or did not ask specific enough questions.

Focusing on Unintended Topics

We deemed an item to have low RPV if teachers' responses focused on an unintended topic, as this suggested they had interpreted the item quite differently than anticipated by item developers. An item in our research study that resulted in several responses that did not address the intended topic included a graph and table that featured a proportional relationship between mango weight and cost. The item stated, "how could you help students understand how the key characteristics of proportional relationships are demonstrated in both representations?". This item's goal was to solicit PCK regarding helping students build conceptual understanding of proportions across different types of representations. The item's goal was not to tap PCK regarding optimal graph labeling. However, three of nine teachers' answers focused solely on the suboptimal qualities of the graph. For example, Christie noted "you don't see any clear ordered pairs. If it was in units of one on the y axis, I think it would be easier for the students to visualize the proportionality." Emma noted, "we can create ordered pairs: (1,6) (2,12), etc. Then I would place these points on the graph, so they can see that the points all fall on the line on the graph." In our study, we noticed teachers tended to have off-topic responses when an item contained a distracting element, was not specific enough, or did not adequately take the test-takers vantage point into account.

Paraphrasing the Information

Some teachers responded to items by simply paraphrasing information provided to them in the item scenario. No items were written asking participants to summarize the information provided. Instead, all items were designed to solicit PCK specific to a scenario. Hence, we considered paraphrasing a sign of RPV issues. In one example, teachers viewed a video clip in which a student (Evan) explained why he thought two ratios (6/14 and 15/35) were equivalent. Teachers were asked to "Comment on Evan's understanding based on his method, 'If you divide down, you'll get the same answer'." The intent was for teachers to use information about Evan and their own PCK to project what else Evan likely understood. Seven out of 10 teachers' responses did not go beyond paraphrasing Evan's response. For example, Christie noted that Evan "… understands that you can check for equivalent fractions by simplifying them." Similarly, Emma offered, "Evan understands that equivalent ratios will always simplify to the same numbers." In our study, paraphrasing was linked with overly general questions as well as items that did not adequately reflect the test-takers' perspective.

Discussion

Soliciting teacher feedback on assessment items via think-aloud or other relevant methodology is critical for developing items with high RPV. We posit that it is not only important to perform such RPV research to refine a given assessment, but also it is important to share "lessons learned" so that other research teams can benefit from better understanding potential pitfalls. Our findings are situated in one study, and we do not suggest the four response characteristics we found in our study are exhaustive of responses that signal RPV issues. We suggest identifying responses that signal low RPV is most beneficial if it is used to drive subsequent refinement of assessment items. We posit that using RPV as the basis for refinement may allow developers to create assessments that better measure challenging and harder to communicate ideas. We hope by sharing our analysis of "what teachers told us" in our assessment pilot items we will enhance existing knowledge for item development as well as trigger discussion regarding how one's RPV methodology may impact the diversity of assessment items that ultimately result.

TYPES OF MATHEMATICAL REASONING EVIDENCED BY A MIDDLE SCHOOL TEACHER IN PATTERN GENERALIZATION

Karina Nuñez-Gutierrez
Universidad Autónoma de Guerrero
kgutierrez@uagro.mx

Guadalupe Cabañas-Sánchez
Universidad Autónoma de Guerrero
gcabanas@uagro.mx

The objective of this article is to describe types of mathematical reasoning evidenced by a middle school mathematics teacher, when answering two generalization questions in a figural pattern generalization task, related to quadratic sequences. Reasoning is delimited from teacher's arguments, reconstructed from a theoretical-methodological proposal that combines Peirce's definitions with some elements of Toulmin's argumentative model. The results show that the teacher evidenced abductive, inductive, and deductive reasoning, based on cognitive actions such as the decomposition of the figure, strategic counts, recognition of the behavior of the figural pattern, formulation, verification, and validation of conjectures.

Keywords: reasoning, argumentation, figural pattern, teacher.

Introduction

Reasoning is one of the fundamental cognitive processes in teaching and learning mathematics. Organizations such as the National Council of Teachers of Mathematics ([NCTM], 2000) conceive of reasoning as a skill or proficiency that must be developed at all levels. On this regard, teacher assumes an important role to promote it in students through different mathematical experiences in teaching conditions (Brodie, 2010). Research has reported that teacher have limited knowledge both the nature of reasoning and pedagogical knowledge to support development in their students (Clarke et al., 2012). On the other hand, the investigations on mathematical reasoning that have taken as a case study to the preservice teacher and in service have been of an exploratory nature (e.g., Bozkus & Ayvaz, 2018; Mata-Pereira & Ponte, 2017) and teaching proposals to develop it (e.g., Bragg & Herbert, 2018).

The study of mathematical reasoning has focused mainly on the central and classic forms of reasoning: abductive, inductive, and deductive (Arce & Conejo, 2019; Conner et al., 2014; Soler-Álvarez & Manrique, 2014), which, in their most have showed cognitive processes developed by middle school students and future mathematics teachers when solving tasks in arithmetic and geometry context. They connected the structures of Peirce and Toulmin in their analysis to show through the arguments, the reasoning they evidenced when solving them. However, the same has not happened with the study of these forms of reasoning about the in-service mathematics teacher. Patterns are one of the contexts that favor the study of reasoning because it contributes to the formulation and justification of generalizations (e.g., Barbosa & Vale, 2015; Rivera, 2013; Mata-Pereira & Ponte, 2017). Kirwan (2015) states that if students are expected to generalize and justify, then it is important to reflect on teachers' thinking about these concepts. The research is focused in describing the mathematical reasoning that is evidenced a middle school mathematics teacher in the framework of the generalization of quadratic patterns. Patterns are one of the contexts that favor the study of reasoning because it contributes to the formulation and justification of generalizations (e.g., Barbosa & Vale, 2015; Rivera, 2013; Mata-Pereira & Ponte, 2017). The research question of the study is, what types of mathematical reasoning does a mathematics teacher evidence when solving a quadratic pattern generalization task?

Theoretical Framework

Mathematical reasoning

In mathematics education there is no consensus on the definition of mathematical reasoning, because it is a polysemic term that encompasses a wide range of mathematical practices (Conner et al., 2014; Yackel & Hanna,2003). In this research, it is understood as any action or procedure that allows obtaining new information from: a) previous or known information, which corresponds to that provided by a statement as initial hypotheses; b) resolution of a problem or c) that derived from previous knowledge (Saorin et al., 2019; Torregrosa et al., 2010). In addition, it is related to other processes, such as inference, justification, and generalization (McCluskey et al., 2016).

Argumentation and argument

Argumentation is a sequential process that allows conclusions to be inferred from premises, through interactive communication between people (Toulmin, 1958/2003). Mathematical reasoning groups a set of arguments based on a series of propositions that implies a conclusion inferred from the data (Toulmin et al.,1984). The argument is a complex data structure that involves a movement from data (D) to a conclusion (C). The movement of the evidence to the conclusion is the certainty that the argumentative line has been carried out successfully, a movement or connection that is allowed by the warrant (W), which in turn has a backing (B), a modal qualifier (Q) that indicates the degree of strength or probability of the assertion and occasionally, objections or refutations may be presented (R). Toulmin´s model is considered to analyze the content of the arguments (Inglis et al., 2007) (see Figure 1).

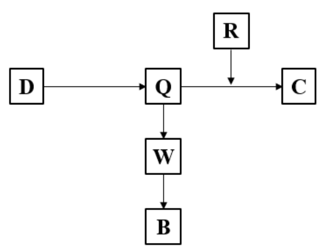

Figure 1: Toulmin's argumentative model (Inglis et al., 2007).

The study of arguments in this research is based on the core of the argumentative Toulmin´s Model (See figure 2). This structure allows to identify the typology or mathematical reasoning.

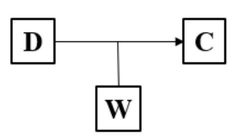

Figure 2: Toulmin's basic argumentative model.

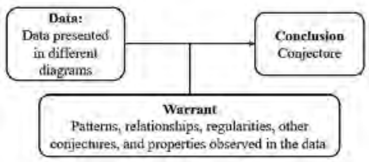
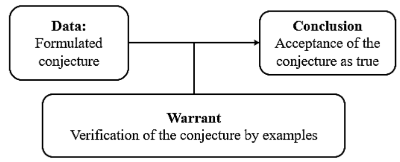
Types of Reasoning

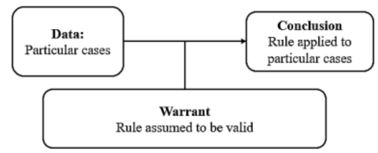
Mathematical reasoning is classified into three types: abductive, inductive, and deductive. *Abduction* and *induction* represent plausible and experimental reasoning, supported by the formulation and verification of conjectures, while *deduction* consists of validating the conjecture to warrant its veracity (Polya, 1966). We are based on the theoretical-methodological proposal of

Soler-Álvarez and Manrique (2014) (see Table 4) for the identification and description of the types of mathematical reasoning.

Table 1: General schemes of the types of mathematical reasoning (Soler-Álvarez & Manríque, 2014).

Abductive	Inductive	Deductive
		






Generalization

When a conjecture expresses a plausible mathematical rule related to all the particular cases and it represents the mathematical pattern, we speak of generalization, which consists of the process of identifying a regular behavior in some particular cases of a sequence, in order to extend that identified regularity and construct an expression or general rule that represents and relates all the terms of the sequence (Radford, 2008).

Method

The research is a qualitative case study (Merriam & Tisdell, 2015). It was developed through a course-workshop (CW) in a virtual setting. Participants were 16 middle school mathematics teachers (MMT) from three Latin American countries. One of these teachers was selected for the analysis of the case study unit with the following criteria: a) to solve seven quadratic pattern generalization tasks and b) to participate in a semi-structured interview. For the purposes of this article, the analysis focuses on one of the tasks (see Table 2).

Tabla 2: Quadratic pattern generalization task.

Task of the points and sides	Characteristic
Considering the figures, answer the following questions and give a detailed argument for your answer. a. Find a general rule for the total number of points in any figure. b. Find a general rule for the total number of sides in any figure. 	Adapted from Rivera (2010). The context of the task is a figural pattern. The explanation of the behavior of the pattern in any of its stages involved the construction of two general rules, one associated with the variable sides and the other with points. Promotes the use of visual strategies.

Data analysis

The data analysis followed three stages: 1) reconstruction of teacher's argument from the task resolution process and the semi-structured interview. Toulmin's argumentative model (1958/2003) was useful in this process, 2) identification and description of the reasoning based on the typology of Soler-Álvarez and Manrique (2014) and 3) triangulation of data from previous stages, with expert researchers in argumentation, generalization and mathematical reasoning.

Results

The results are described by type of reasoning that the MMT evidenced when solving the task, which challenged him to build two general rules, one associated with the points variable and the other with the sides variable. In the construction of the general rule linked to the first type of variable, the teacher evidenced three forms of mathematical reasoning and two for the second.

Abductive reasoning

a) Reasoning in the points variable

In the construction of the general rule associated with the variable points, this way of reasoning appears when the MMT recognizes how it can explain the behavior of the pattern in each figure (see Figure 3). He identifies that the total number of points in the corners is a constant number, eight, that, on the sides, the number of points equals four times the figure number multiplied by three and in the center, it is four times the figure number minus one, squared. This fact constitutes a conjecture, which establishes three actions: a) to decompose the points of each figure in three parts: corners, sides and center, b) to count strategically the points in each of the parts, c) to establish a correspondence relation between the number of points of this decomposition, in relation to each figure.

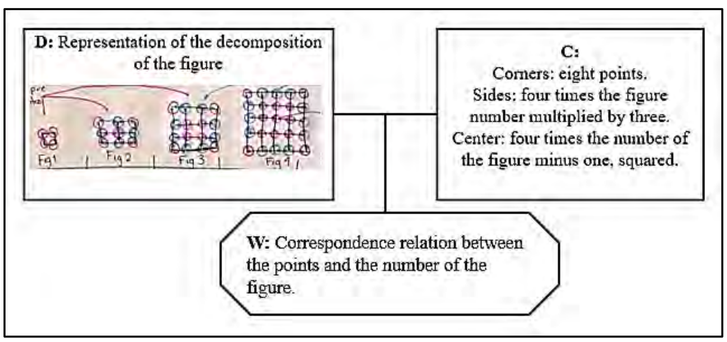


Figure 3: Abductive argument associated with the variable points.

The behavior identified by the teacher regarding the variable points when decomposed it into three parts, represents it through algebraic expressions where the figure number is written down in terms of n (see Table 3). The formulated conjecture is: $8 + 3[4(n - 1) + 4(n - 1)^2]$.

Table 3. Algebraic expressions about the points and the figure number.

Points	*Algebraic expressions*
Corners	8
Sides	$3[4(n-1)]$
Center	$4(n-1)^2$
Total (conjecture)	$8 + 3[4(n-1)] + 4(n-1)^2$

b) Reasoning in the variable sides

In the construction of the general rule associated with the variable sides, the abductive reasoning appears when the MMT recognizes that the increase of this variable from one figure to another has a quadratic type of behavior, that is, the number of the figure squared multiplied by two, plus twice the number of the figure. This fact constitutes a conjecture, which establishes four actions (see Figure 4): a) to count the total number of sides of each figure, b) to establish the first and second differences between the total number of sides of one figure and the next, c) to recognize that the first differences are not constant, and d) that the second differences are constant.

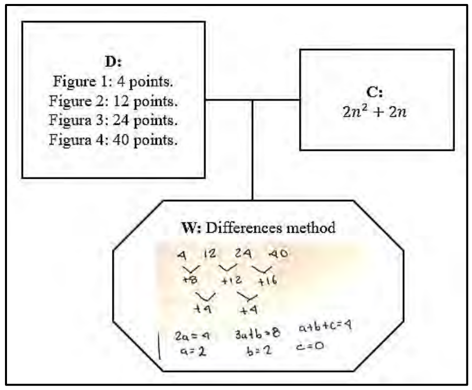

Figure 4: Abductive argument associated with the variable sides.

The behavior identified by the teacher with respect to the variable sides is based on the method of differences, which consists of determining the coefficients of the quadratic sequence. He represents them in terms of n. The formulated conjecture is: $2n^2 + 2n$.

Inductive reasoning

This type of reasoning was identified when the MMT evaluated the conjectures formulated by abduction within the framework of the variables points and sides of the figural pattern. Therefore, he relied on a double-entry table in which he recorded the total points and sides per figure. This evaluation consisted of substituting the total number of points and sides of four figures, from 1 to 4. These data are compared with those obtained by substituting the number of each figure (n) in the algebraic expression that he formulated by abduction (see Figure 5).

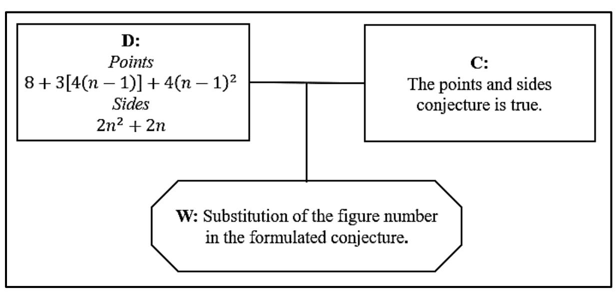

Figure 5: Inductive argument of the MMT in the context of the variables points and sides.

Deductive reasoning

This type of reasoning appears in the MMT when validating the conjecture associated with the points variable, obtaining the general expression. In addition, he used the method of differences to verify the general expression obtained (see Figure 6). The general expression obtained through the difference method is $4n^2 + 4n$, equivalent to $8 + 3[4(n-1)] + 4(n-1)^2$(see Table 3). He realized this by comparing them.

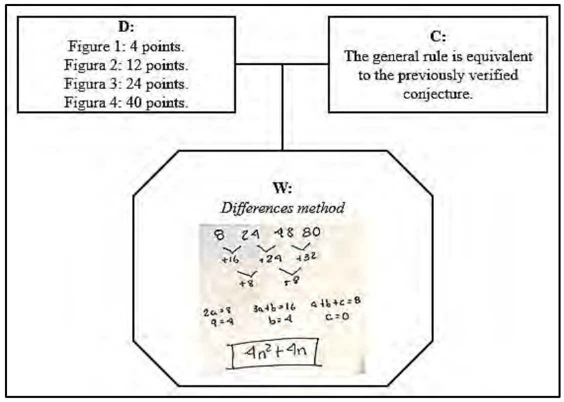

Figure 6: Deductive argument of the MMT on the variable of the points.

Discussion and conclusion

In this paper we described types of mathematical reasoning of a MMT when solving a task of generalization of figural patterns in the context of quadratic sequences. The mathematical reasoning evidenced by the MMT allows characterizing the thought process regulated by mental actions and relating it to the typology of reasoning (abduction, induction, and deduction). The way of reasoning abductively in the MMT begins with the observation of particular cases to formulate a conjecture. Then, inductively, he verifies the conjecture through the particular cases known, in order to verify its veracity. Finally, deductively, he validates the conjecture with known particular cases.

According to the characteristics and demands of the figural task, in the construction of the general rule associated with the points variable, the MMT evidences the three types of reasoning and in the sides variable, it reasoned abductively and inductively. In this sense, it is recognized that the types of mathematical reasoning can be presented in an ideal way and not necessarily in a linear way.

The context of quadratic pattern generalization contributed to the MMT evidencing different actions when solving the task in the figural context (see Table 4).

In the construction of the two rules of thumb in relation to the points and sides variables, the MMT involved his visual skills to recognize the behavior of the pattern. In the analysis of the points variable, the arrangements allowed him to establish correspondence relationships through decompositions of the figure, while for the sides variable, the MMT decided to work with the differences between the total number of points in each figure. According to Rivera (2010), working with figural patterns allows different interpretations of their behavior and the organization or configurations of the objects of some figural patterns are complex to interpret, even when their construction is well defined (Nuñez-Gutierrez & Cabañas-Sánchez, 2020).

In general, it is recognized that teaching experience and professional knowledge about mathematics, supported by the teacher's facts, conceptual images, and beliefs (Lithner, 2006), influence the choice of his strategies to formulate, verify and validate conjectures. Furthermore, it was evidenced that the mathematics teacher does not make his random choice of his actions but is supported by his knowledge of the subject and uses it to respond to the demands of the task, which, for his criteria, is the most accurate and quickest method.

This exploratory study offers a unique qualitative approach to exploring a teacher's knowledge of proportional reasoning and how that knowledge appears in the classroom. Using two theoretical frameworks, Knowledge in Pieces and the Knowledge Quartet, the study analyzes one middle grades teacher's proportional reasoning knowledge in two content interviews as well as in classroom data. Results suggest the teacher has both procedural and conceptual knowledge. Interestingly, the teacher tended to rely on procedural approaches with a preference for efficiency. This was evident across data types. A challenge was coordinating the teacher's understanding with classroom practice and raises questions about needed modifications to the Knowledge Quartet to include approaches to teaching that are less didactic.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge

Purpose

While it is a commonly held belief that a teacher's knowledge of mathematics shapes the instructional opportunities available to students, proving this conjecture is very complicated. Most efforts to date have focused on large scale assessments of teacher knowledge and students' outcomes (e.g., Hill et al., 2005) or more modest efforts using premade tools to assess teachers' practices from a particular lens of practice (e.g., Boston, 2012; Hill et al, 2008). Sometimes these studies also align teacher performance on the assessment of practice to the assessment of knowledge (e.g., Hill et al., 2008). Further, some studies have attempted to determine the relationship of teachers' knowledge to their practice through assessment items designed to engage teachers in life-like scenarios (e.g., Copur-Gencturk, 2015; Kersting et al., 2012)

In contrast to these approaches, we have undertaken to understand how one teacher reasons about proportional situations and how his content knowledge was observable in his classroom teaching using a qualitative approach. That is, we relied on Epistemic Network Analysis (ENA; described below) to build an understanding of the ways in which the teacher could reason about proportions. Then we used the Knowledge Quartet (KQ; described below) to understand how his knowledge was implemented in the classroom. This is a first step for understanding, in fine-grained detail, how teachers' knowledge aligns to their practices. For this exploratory study, we asked: How do we see one teacher's knowledge of proportions in his practice?

Theoretical Framework

We worked from two theoretical frameworks. We used Knowledge in Pieces (KiP; diSessa, 2016; diSessa, Sherin, & Levin, 2006) to understand teacher knowledge of mathematics. KiP posits that knowledge is comprised of fine-grained pieces of understanding connected in a variety of ways. As we learn, we refine those understandings, build on them, and make connections between them to create a rich understanding. Consistent with the research on expertise (Bédard & Chi, 1992; Bransford et al., 1999), KiP considers greater understanding to be characterized by the connections made between the knowledge resources and not just on the number of knowledge resources. Therefore, focusing on the connections between these knowledge resources provides a view into a teacher's knowledge that goes beyond simply understanding the amount of knowledge they have.

For this paper, we specifically relied on coding of one teacher's knowledge that was done as part of a larger project. This coding was done using a framework for the robust understanding of proportions that was created by the larger research team (Weiland et al., 2021). Each utterance of a teacher's response was coded as they thought aloud about mathematics tasks using a binary coding where 1 means they are invoking the knowledge resource in that utterance and 0 means they are not invoking the knowledge resource.

For the teacher interview data, we use ENA (Shaffer et al., 2009) to attend to the connections between knowledge resources that were invoked. ENA presents a mapping of knowledge resources when used in connection with other resources (Figure 1). Each node represents a knowledge resource. The size of the node indicates the relative number of co-occurrences. Thus, a larger node indicates a knowledge resource that co-occurred more frequently in this teacher's interview than a smaller node. The visual map also highlights the strength of the connection with the thickness of the connecting segment showing the relative frequency of pairs of codes co-occurring in the interview. Thus, a darker, thicker line indicates knowledge resources that were used together more than a thinner, paler line. For the purposes of this analysis, we assume that the co-occurrence of codes in an utterance indicates a connection between those codes for the participant. Using KiP and ENA allowed us to create a visual image of the teacher's content knowledge as expressed in two interviews.

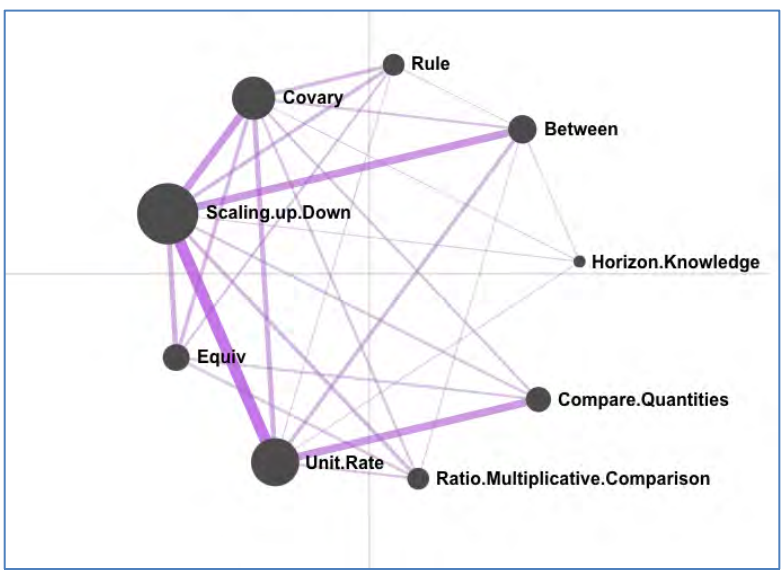

Figure 1: ENA plot of Matt's interview data.

The second theoretical lens upon which we draw is the KQ (e.g., Rowland, 2011; Rowland et al., 2005; Rowland & Turner, 2007; Turner & Rowland, 2011). The KQ is an operationalization of Shulman's (1986) construct of Pedagogical Content Knowledge (PCK). One of the elements that makes the KQ particularly useful and intriguing for our work is that it is a theory of mathematics knowledge *in* teaching, meaning that it is a framework that aims to make sense of that ways that PCK manifests itself in teachers' mathematics teaching. The KQ is divided into four key categories of knowledge: Foundation, Transformation, Connection, and Contingency. By using this framework, we were able to think about the ways in which one teacher's knowledge of mathematics was drawn on throughout his teaching. We were unable to use the same framework across data types. Originally, we intended to use KiP and ENA to look at teacher knowledge in the classroom; however, there was little direct evidence of the teacher's content knowledge during facilitation, in part because this teacher relied on high press questioning (Kazemi & Stipek, 2001) and mathematical argument for instruction more than on direct instruction. Thus, KQ allowed us to consider teacher knowledge (as well as other important categories of teacher knowledge) for the classroom data.

Methods

Participant and Data Collected

In this study, we examine one 7th grade teacher, Matt (pseudonym), as he solved a series of proportional reasoning tasks in two interviews and as he taught his own class proportional reasoning across four lessons. Matt was a white, male teacher who had been teaching mathematics for seven years at the time of data collection. He worked in an urban district where he had been able to "wrap" with his class – thus the 7th grade students we observed him teach were with him for the second year in a row.

Matt completed a paper-based think-aloud protocol using a LiveScribe pen, which allowed us to capture his speech as he wrote on the paper. He also completed one face-to-face clinical interview. Both interviews engaged teachers with a range of proportional reasoning tasks including many novel tasks such as tasks that made use of dynamic representations.

In addition to the two content knowledge interviews, Matt also allowed us to video record his mathematics class and conduct brief interviews with him about those sessions. For this paper, we analyzed four mathematics lessons and three brief teacher interviews focused on those lessons.

Data Analysis

As mentioned above, we used a framework for robust understandings of proportional reasoning to analyze the content interviews. For this paper, we particularly focused on knowledge resources that were focused on key understandings about the structures of proportional situations (e.g., between measure space, covariation, ratio as a multiplicative comparison, and compare quantities) and those that were key solution approaches (e.g., unit rate, equivalent fractions, scaling up or down). We also considered adherence to a given rule and horizon knowledge (Ball et al., 2008), which refers to knowledge that relies on proportional reasoning, but extends beyond what 7th graders typically learn (e.g., slope). See Weiland et al., (2021) for definitions of each knowledge resource code represented in Figure 1.

For classroom video, we trimmed the videos to focus exclusively on the main task of the day, thus cutting the "do now" or any test preparation, etc. Once the video was trimmed, we cut it into three-minute segments. Each segment was coded using the codes set forth by Rowland and Turner (2007), however, we also allowed for emergent codes (Charmaz, 2014). Emergent codes were included when we noticed a trend in Matt's teaching that seemed mathematically important, but not included in the original coding set. We classified the new codes into the original categories based on the original definitions for each category. Each video segment was viewed by at least two researchers. Discussion about codes was brought to the whole team and any points of disagreement were discussed until there was 100% agreement.

We then compared our observations about Matt's classroom teaching to his ENA graph. Noting some important similarities and differences. We then used his classroom interview transcripts to inform our understanding of particular decisions he made about his instruction.

Results

Our results suggest that Matt had both procedural and conceptual understandings of proportional reasoning. In both his own mathematical practice and in his teaching, however, he relied heavily on procedural approaches, with a strong preference for efficient procedures. This was evident in the tasks he used as well as in his interactions with his students. Further, Matt demonstrated a commitment to deep procedural knowledge (Star, 2005) through his use of high press questions and fostering of mathematical argumentation.

In Matt's ENA plot (Figure 1), we can see he relied considerably on scaling and unit rate, which we consider as two approaches for finding solutions to proportional reasoning tasks. We can also see that he used covariation and between measure space reasoning with scaling as well as comparing quantities with unit rate. These codes are all about understanding and applying the structures of proportional situations. That is, covariation, between measure space reasoning, and comparing quantities are all codes that consider the invariant relationship between the two quantities that are being compared in the ratio. Thus, Matt demonstrated both procedural and conceptual knowledge.

In his classroom, Matt gave the students tasks that could be solved with unit rate or scaling up and down. For example, one task asked students to determine how far they would need to run to burn off the calories in a sports drink. He allowed students to solve these any way they wanted, but in whole-class discussion, he highlighted "efficient" approaches. For example, he often asked the students to think about the ways different approaches were the same. And, sometimes, he introduced the idea of efficiency in the discussion. In our interviews with Matt, we learned this was part of his intentional practice. He noted, "The kids all use ratio tables right, that's what they all had coming in, which is fine. They just need to be able to use these other strategies…they need to be able to understand them… I want them to choose one that's efficient." The focus was primarily on making sure students had key solution approaches.

Discussion

This analysis is the first step in our ongoing effort to understand how a teacher's knowledge of proportional reasoning shapes his practice. In this case, we were able to see the teacher has more knowledge resources available to him than we saw him emphasize in his instruction. His decisions about what to emphasize in instruction were deliberate and had a focus on students learning to use more than one method, to focus on efficiency, and to have confidence in their ability to use at least one strategy.

The analysis is interesting because we learned one of the hardest parts of this research is learning how to coordinate the ENA analysis of the teacher's understanding with classroom practices. In this classroom, the struggle was amplified by Matt's lack of use of direct instruction. Thus, we needed understand how he leveraged his mathematics knowledge to ask students questions, to assess their understandings, and to pose rich tasks. Based on our work in this case, we conjecture that the KQ needs to be extended to include less didactic teaching approaches. That said, we also note that the four overarching categories of the KQ do hold up to Matt's teaching style, it is only the code set that needed to be extended.

EXAMINING CHANGES IN PRESERVICE SECONDARY MATHEMATICS TEACHERS' DEFINITIONS OF FUNCTION (FROM PRETEST TO POST-INTERVENTION)

Radhika Pathak Kharel
Illinois State University
rpathak@ilstu.edu

Matthew S. Winsor
Illinois State University
mwinsor@ilstu.edu

This study examined preservice secondary mathematics teachers' (PSTs') definitions of a function and how those definitions changed because of a teaching intervention. Fourteen PSTs in a senior-level content capstone course participated in the study. PSTs' definition of a function before and after the intervention were analyzed using the comparison method. The findings showed that the PSTs struggled to revise their rote-learned definitions of a function to incorporate both definition univalence and arbitrariness in their descriptions of functions. In addition, the findings indicated that PSTs were able to identify whether the given relations or graphs represented a function.

Keywords: Preservice Teachers, Functions, Knowledge

Introduction

The concept of a function is fundamentally important in mathematics, relating to topics including algebraic representations and expressions, dependency, ordered pairs and graphs (Bannister, 2014; Biber & Incikabi, 2016). Indeed, a function has sometimes been described as the most powerful and useful concept in all of mathematics (Bannister, 2014). It is regarded as basic to undergraduate mathematics, (e. g., to calculus) and essential to applying mathematics in many sciences (Oehrtman et al., 2008). Yet, despite the acknowledged importance of functions, teaching functions in a conceptual manner has been found to be challenging for many teachers (Biber & Incikabi, 2016).

Part of the challenge has been to enable learners to arrive at a mathematically acceptable definition of a function. Providing accurate definitions of important mathematical concepts is crucial in teaching and learning mathematics. A student's construction of appropriate definitions is "a mathematical activity of no less importance than other processes such as solving problems, making conjectures, generalizing, specializing, proving, etc., and it is therefore strange that its [importance] has been neglected in most mathematics teaching" (De Villiers, 1998, p. 249).

Researchers noted that preservice teachers should understand univalence and arbitrariness to successfully teach the concept of functions to their future students (Even, 1990, 1993; Haciomeroglu, 2005; Nyikahadzoyi, 2013; Steele et al., 2013; Hatisaru & Erbas, 2017; Viirman, 2014). According to the Common Core State Standards Initiative [CCSSI] (2010), secondary school students should know that a function is a relationship between elements in an "input" set (the "domain") and an "output" set (the "co-domain") which assigns each input element to exactly one output element. This relationship between input and output elements is what determines the *univalent* nature of a function (Even, 1993). Thus, for example, if x and y represent real numbers then the equation $y = x^2$ exhibits univalence because each element x gets assigned to a unique element y. Similarly, functions are arbitrary because, "the elements of the domain and range need not be numbers and that the rule relating them does not have to be described by a regular expression" (Steele et al., 2013, p. 455).

It is well documented that school students' mathematics learning depends on their teachers' mathematical knowledge (Ball & Bass, 2002; Tasdan & Koyunkaya, 2017). As such, it is necessary to develop prospective mathematics teachers' mathematical knowledge. With respect to functions, researchers (Even, 1993; Even and Tirosh, 1995; Hatisaru & Erbas, 2017; Tasdan & Koyunkaya, 2017) found, however, that some preservice teachers have only a partial understanding of functions, which limits their ability to teach functional relationships thoroughly. Helping PSTs understand the concept of functions should be a priority for mathematics teacher educators. Mathematics education researchers are required to examine PSTs' prior knowledge of function concepts, a foundation for constructing a complete understanding of univalence and arbitrariness function. This study, therefore, assesses how PSTs knowledge of function changed, as measured by their definition of function, because of a teaching intervention in a content course for secondary preservice mathematics teachers.

Theoretical Perspective

Shulman (1986) defined *content knowledge* as "…the amount and organization of knowledge per se in the mind of the teacher." When examining different theories of teacher knowledge (e.g., Shulman, 1986, 1987; Hill et al., 2008), content knowledge serves as the anchor for other types of knowledge (e.g., pedagogical knowledge, knowledge of learners). For example, Shulman coined the term pedagogical content knowledge (PCK) (Shulman, 1986). PCK combine the knowledge of content with the knowledge of pedagogy and the knowledge of learners to teach content in the classroom. Without the anchor of content, PCK would not exist. Similarly, with Mathematical Knowledge for Teaching (MKT) (Hill et al., 2008) several subsets of MKT rely on mathematics (e.g., Knowledge of Content and Students (KCS), Knowledge of Content and Teaching (KCT), and the Knowledge of Content and Curriculum (KCC).) A strong anchor of mathematics content knowledge is a starting point to help PSTs build their teaching knowledge. This study examines PSTs' definition of function, which can serve as the foundation for successfully teaching the concept of function to students (Chesler, 2012, Edwards & Ward, 2008; Hill et al., 2008).

Related Literature

Researchers have investigated pre- and in-service teachers' knowledge of mathematical definitions of functions. Chesler (2012) found that most of the PSTs used the definition of functions from several resources such as dictionaries, textbooks, and websites. Chelser noted that some PSTs provided insufficient details about the definition of functions. Nineteen out of 21 students defined functions as relations, rules, mappings, correspondences, or relationships between variables, sets, or inputs/ outputs (Chesler, 2012). Although participants presented correct memorized definitions, intuitive understandings of the concept of functions were usually lacking (Chesler, 2012). Haciomeroglu (2005) observed that PSTs' weak subject matter hindered PSTs from acknowledging misconceptions of their students' mathematical work which caused students to make incorrect mathematical assertions.

Vinner and Dreyfus (1989) investigated junior high teachers and college students' concepts of mathematical functions. Only 82 of the 307 participants in the study noted the univalent nature of a function in their definition. Furthermore, while working on function-related tasks, those 82 candidates exhibited discrepancies in their performance—46 of the 82 did not incorporate any well-defined conception of a function while answering function-related tasks. Linchevsky et al., (1992) reported that only 21of the 82 junior high school mathematics PSTs in the study articulated an understanding of the arbitrary nature of functions.

Purpose

The purpose of this paper is to examine the effect of a teacher intervention aimed at helping PSTs refine their understanding of functions. Chesler (2012) explained that creating appropriate definitions promotes both teachers' and students' understanding of mathematics and helps to deepen teachers' abilities to teach mathematics conceptually. As such, it is imperative for PSTs to develop a clear understanding of definition of function, which will strengthen PSTs' ability to effectively teach the concept of functions.

Research Question

How did PSTs' definition of function change because of a teaching intervention?

Method

Participants

This research was conducted in a large public university in the Midwest region of the United States. Fourteen PSTs (nine female and five male) enrolled in a senior level content capstone course participated in this study. The content capstone course used college-level mathematics to develop a deep and connected understanding of secondary-school concepts such as functions, complex numbers, and polynomials. The instructor's pedagogy emphasized group work, problem solving, connections, justification, and mathematical communication. The aim of the course was to help PSTs conceptually understand both the mathematics of the secondary school and the more nuanced mathematical underpinnings that can aid in the implementation of meaningful instruction. This course was a part of PSTs' degree plan to become secondary mathematics teachers.

Procedures

The PSTs took a pretest on the first day of their course. Post-tests were taken at the end of the unit on functions. For two weeks, PSTs examined the content on functions from Usiskin, Peressini, Marchisotto, & Stanley (2003). Each class lasted 95 minutes and was structured to start with a problem to solve. The problem was designed to lead into the topic of the day as well as to generate discussion. The lesson would then proceed into a variety of planned activities. The end of the study session consisted of completing several problems out of the text, worked as a group. PSTs' solutions were offered and discussed. Finally, a journal prompt was put on the board for PSTs response and homework was assigned.

As the first classroom activity, PSTs were asked to write down their "best" definition of a function. PSTs then shared their definitions of functions with peer groups and were given the opportunity to revise their definitions if needed. The instructor recorded the groups' definition of functions on the board and conducted a discussion comparing the different groups' definitions.

With the groups' definitions of function on the board, the instructor provided circle diagrams (see figure 1) that represented examples and non-examples of functions. The instructor asked PSTs to identify which representations were functions and which were not, based on the groups' definitions of functions. Based on the activity, PSTs were asked to determine the robustness of their definitions of function and make edits if necessary. Finally, the entire class worked to establish a common definition of functions. The instructor helped PSTs recognize the characteristics of univalence and arbitrariness in the circle diagrams presented.

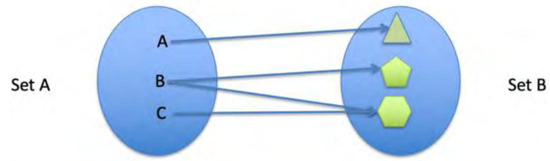

Figure 1: Circle Diagram Representation of Potential Function

In the remaining classes, PSTs examined different characteristics of functions (e.g., one-to-one functions, inverse functions) that were central to high school mathematics. The instructor made every effort to connect the topic of the day to the concepts of univalence and arbitrariness. A post-intervention test was administered to detect change in PSTs' definition of functions and mathematical work about functional relationships.

Research Design

This study was qualitative in nature. The pre- and post-intervention assessments were taken from a larger assessment on functions used by Winsor (2003). For this study, only three tasks were chosen for analysis. The first assessment item asked PSTs to provide a definition of function. The second item asked the PSTs to determine whether a given example was a function or not and to provide justification. The third assessment item showed a representation of function and PSTs were asked whether the item was an example or non-example of a function, and to provide a justification for their answer (see figure 2). All 14 PSTs took both assessments.

Pretest Items:

1. Give a definition of a function.
2. Is this a function? Why or why not?

$$g(x) = \begin{cases} x, \text{if } x \text{ is a rational number} \\ 0, \text{if } x \text{ is an irrational number} \end{cases}$$

3. Do the following ordered pairs describe a function? Why or why not?
   {(1,4), (2,5), (3,9), (4,4)}

Post-Intervention Items:

1. Give a definition of a function.
2. Is this a function? Why or why not?

$$g(x) = \begin{cases} x, \text{if } x \text{ is a rational number} \\ 0, \text{if } x \text{ is an irrational number} \end{cases}$$

3. Does the following table describe a function? Why or why not?

X	12	5	7	9	4	5
Y	5	12	8	4	9	7

Figure 2: Pre and Post Questionnaire for the Tests

A comparative method (Steele et al., 2013) was applied to compare the level of correctness of student responses to all the three tasks on both the pre-and the post-intervention test. Before analyzing the data, a rubric was created, with five different categories being defined for the purpose of analyzing appropriateness of the definitions of functions which would be given. Commonalities of definitions of function found in previous research (Steele et al., 2013) were incorporated in the rubric. PSTs' responses to assessment items two and three were based on the extent to which valid justifications were given. All data were analyzed by the first author and another doctoral student in mathematics education.

The following categories are how PSTs definitions were classified. Special attention was paid to how PSTs addressed arbitrariness and univalence in their definition of functions.

Category 4 Assessment. The definition of function should explicitly refer to both univalence and arbitrariness. For definition of univalence function a statement like– "*y* is a function of *x* when there is a relationship between *x* and *y* such that for every value of *x* there is one and only one corresponding value of *y*" was expected (Steele et al., 2013, p. 461). For arbitrariness, "elements of the domain and range need not be numbers and that the rule relating them does not have to be described by a regular expression" (Steele et al., 2013, p. 455). Definitions that had the same meaning as the definitions found in Steele, but not the same wording also were classified as a "Category 4" response. For example, the letters *x* and *y* could be replaced by identical mathematical terminologies, for instance, input and output, independent variable and dependent variable, domain, and range, etc.

Category 3 Assessment. The definition of a function would include a formal definition of arbitrariness or univalence and informally or intuitively refer to the other concept. For example, a definition might say that each element in the set of baseball stadiums is assigned to the city where it was built. This definition addresses univalence and implicitly hints at arbitrariness.

Category 2 Assessment. The definition of function only focuses on univalence or arbitrariness, but not both. As a sample response for this category is, "a function is any relation such that for every number input into a formula result in exactly one number as an output.

Category 1 Assessment. The definition of function is incomplete. As an example, "Functions map inputs to outputs."

Category 0 Assessment. The PSTs did not give a response or gave a definition which did not include any idea of univalence or arbitrariness. For example, "functions need to be linear relationships."

Findings

Assessment Item 1

The PSTs' responses were categorized based on their descriptions of definitions of functions that they provided for the pre- and post-intervention (see Table 1).

Table 1: Results of Assessment item 1

Categories from the rubric	Number of PSTs responses on the pre-test	Number of PSTs responses on the post- test
0	1	0
1	9	2
2	1	1
3	1	6
4	2	5

The data showed that in both their pre- and post-intervention test responses, some PSTs had difficulty in providing accurate definitions of a function. At the pre-test stage, only two of the 14 participants offered definitions which included detailed information of both the univalent and arbitrary nature of functions explicitly (a rating of 4). Five PSTs received a rating of 4 on the post-test. An example of a definition of function given at the pre-test stage which was classified as Category 4 was "A function is a rule which maps each element of the domain to a unique element in the co-domain." The same participant's definition of function at the post-intervention stage was “A function is a rule which maps every element of a set A (domain) to a unique element in a set B (co-domain)” which was also classified as a *Category 4* response.

Similarly, nine PSTs’ pre-test definitions of functions were categorized as *Category 1, and* two PSTs’ post-intervention definitions of functions were categorized as *Category 1*. At the pre-test stage, one of the participants explained definition of function as “a *relationship where no 2 same x’s are paired with different y’s”* and was assessed as *Category 1*. The same participant posed, *“a relationship where every input has exactly one output*” at the post-intervention test. That definition was classified as a *category 1* response as well.

Some PSTs who struggled to provide adequate definitions at the pre-test stage improved to provide better definitions of functions at the post-intervention stage. In fact, five PSTs’ definitions were deemed to have improved from Category 1 to Category 3 and two from Category 1 to Category 4. Additionally, one participant improved from Category 0 to Category 3, another from Category 3 to Category 4, and another from Category 2 to Category 4. However, one participant’s responses were assessed as decreasing from Category 4 to Category 3. A participant whose responses improved from Category 0 (pre-test) to Category 2 (post-intervention test) wrote, “a function represents an equation/ graph” (at the pre-test stage) and “a function is a domain and range of elements that maps in X (1 2 3) to a unique element in Y (w y z) (at the post-intervention stage).

Assessment for Item 2

This task required PSTs to determine if the given mathematical statement described functions, and to provide justifications for their decisions. The correct response for this question was “yes,” and a justification such as, “there is an assignment of a single value to each number" (Even, 1990, p. 105). Table 2 has a summary of the results. At the pre-test stage, 50 percent of the PSTs gave correct answers and acceptable descriptions. Similarly, at the pre-test stage, two of the 14 participants provided a correct response but did not give an acceptable justification, and five participants responded with an incorrect answer or did not provide a justification. But, at the post-intervention stage, most of them—indeed 13 of the 14, provided correct answers with acceptable justifications.

Table 2: Findings of Assessment for Task 2

Category of Response	Number at Pre-test	Number at Post-test
Participants with correct responses and acceptable justifications	7	13
Participants who gave correct responses without providing appropriate justifications	2	–
Participants with incorrect responses and/or no responses	5	1

Most of the justifications for correct responses of the PSTs were in the form: “Yes, this is a piece-wise function”, or “Yes because ‘it passes the vertical line test.” Justifications that were deemed not correct included “No, several *x* values were mapped to zero” and “No, because these are boundaries.”

Assessment for Item 3

This task included to check whether participants could identify if a set of ordered pairs was a function. Participants were required to explain why they gave their explanations. The correct answer at the pre-test stage was “yes” and at the post-intervention stage, it was “no” (questions of assessment item 3 in the pre-test and post-intervention were little bit different). Table 3 has a summary of the results. At the pre-test stage, eight PSTs gave correct responses and offered valid justifications, and at the post-intervention stage, 13 participants responded with correct answer and valid reasoning. All 14 participants attempted to explain their justifications in both tests, however six of their responses were incorrect at the pre-test stage and one was incorrect at the post-intervention stage.

Table 3: Findings for Assessment for Task 3

Category of Response	**Number at the Pre-Test**	**Number at the post-test**
Correct response and an acceptable justification	8	13
Correct response but no justification	0	0
Incorrect and/or no response	6	1

Some of the PSTs’ responses at the pre-test stage were, “Each x-value in the (x, y) pair maps to one y-value”, “no two same x-values have different y-values". Similarly, some correct responses in the post-intervention test—for which the correct answer was “no,” were, “no, because each x element does not have a unique y element”. Most PSTs appealed to the univalent nature of functions to justify why a set of ordered pairs was or was not a function. Some correct responses at the post-intervention stage were: “No, the following does not pass the vertical line test,” and “No, because there is not a common relation between the x and y coordinates.”

Discussion

This study assessed the quality of PSTs’ definitions of a function at pre-test and post-intervention stages. Analysis of pre-test responses has shown that some of the PSTs did not understand the concept of a function. However, it was also found that although most of the PSTs improved their understanding of the function concept by the post-intervention stage, some of their explanations were still inadequate. This study revealed that at the pretest stage the PSTs focused on the univalent nature of a function. Similarly, studies found that their participants were aware of the univalent nature of functions but did not know about the arbitrary nature of function (Chesler, 2012; Haciomeroglu, 2005). Steele et al., (2013) reported that the *arbitrariness* of a function was not well known by participants in her study, and the same was true for this present study.

Similar trends have been observed in previous research—for example, Even (1993) found that many preservice teachers were not aware of both univalence and arbitrariness. This finding is not surprising given that most of the concept of functions that preservice teachers experience during mathematics classes at school and in undergraduate mathematics programs were presented via graphs and expressions which clearly demonstrate univalence. Unfortunately, arbitrariness is often overlooked in the high school and undergraduate curriculum. Even (1993) further reasoned that the application of the concept of the arbitrariness of a function is found within advanced calculus, which is a part of PSTs' education. Unfortunately, that is not enough for students to reinforce that arbitrariness should be included as a part of the definition of function.

Additionally, an examination of PSTs' data generated by assessment items two and three, revealed that there was significant pre-test to post-intervention improvement so far as clarifying whether the given expressions were or were not functions. After completion of all the three tasks by the PSTs, some of them showed inconsistency in the justifications which they provided with *assessment item 2* and *assessment item 3* in comparison with the definitions of function they provided with *assessment item 1*. Some of their explanations in the second and third assessment items were valid but often their definitions of functions seemed implicit or incomplete. Tabach and Nachlieli (2016) found that although students explicitly expressed the definition of function, some of them were not able to use the definition to identify the mathematical model of a function.

Even (1990) claimed that the mathematical knowledge of the PSTs in her study was "fragile and weak." PSTs did not hold comprehensive and well-articulated definitions of the mathematics which they were going to teach. Even (1993) further elaborated that when the teacher participants in her study were asked to define a function, many of them chose to offer rote definition and did not refer to univalence and arbitrariness because their minds were influenced by the functions with which they had regularly worked on in classes, rather than by the definitions of a function which they had memorized. Wilson (1997) found that although the PSTs' understanding of the concept of function had grown significantly, because of their participation in different types of classroom activities and had been influenced by their involvement in classroom teaching practices, interviews, written work, and observations, they still had limited understandings of functions and, more generally, of mathematics.

Conclusion

Most PSTs referred only to the univalent nature of a function, omitting the arbitrary nature of functions. None of the PSTs mentioned univalence or arbitrariness by their names nor provided any distinct examples of those two aspects. Based on previous research (e.g., by Tabach & Nachlieli, 2016) and the analysis provided in this paper, it appears to be unlikely that the PSTs' concepts of a function will be changed significantly because of participating in a single mathematics course. Shulman's (1987) concept of pedagogical content knowledge which has content as an anchor for a teacher's pedagogical knowledge and knowledge of learners, suggests that if PSTs do not acquire a strong mathematical knowledge of the concept of functions, their future teaching on the concept of functions will be limited. PSTs should have multiple opportunities to study about functions in multiple classes with the aim of helping them develop a clear understanding of the concept of functions. Moreover, it seems as if it is challenging to restructure a PST's definition of functions, which suggests that the concept of functions should be taught more carefully in the high school mathematics courses (Vinner & Dreyfus, 1989). High school students should be given the opportunity to grapple with the concept of function starting in algebra 1.

Teachers' mathematical knowledge is critical for their teaching of mathematics. We investigated whether elementary teachers believe that a unit fraction, $1/n$*, results only from a whole equipartitioned into* n *parts. We adapted Ciosek and Samborska's (2016) Frame Task, presenting a frame consisting of three unequal segmented squared rings, with one squared ring shaded. In semi-structured interviews, 19 teachers engaged the task and reasoned whether the shaded portion equals 1/3 of the frame. Our findings indicate that about three-quarters of the participants believe that either (1) to have one-third of a quantity, a section needs to be one of three parts, or (2) a section cannot be 1/3 of an object if the object is partitioned into three unequal sections. Finally, we hypothesize how an iterative perspective of unit fractions may mitigate against the false beliefs that Ciosek and Samborska (2016) and our study document.*

Keywords: Number Concepts and Operations, Rational Numbers, Teacher Beliefs, Teacher Knowledge

Introduction

Foundational interpretations of what is a fraction are numerous and interwoven. They are pedagogical, historical, mathematical, and neurocognitive (Cuisenaire & Gattegno, 1954; Davydov & Tsvetkovich, 1991; Kieren, 1976, 1980; Matthews & Chesney, 2015). Those interpretations shape how learners perceive a whole or unit and an associated unit fraction, that is, a fraction with 1 as its numerator. Studies illustrate how assigning a unit of measure to a given quantity, or unitizing, is critical for working adeptly with fractions (Lamon, 1996, 2007; Mack, 2001; Olive, 1999; Steffe & Olive, 2010; Van Ness & Alston, 2017a, 2017b, 2017c). To inaugurate students' study of fractions, textbooks and disciplinary policy (Common Core State Standards Initiative, 2010) present the part/whole interpretation. However, research suggests that a fraction's part/whole understanding leads learners to conceive and represent with difficulty fractions greater than a unit or whole (Gabriel et al., 2012, 2013; Mack, 1990; Tzur, 1999; Zhang et al., 2017). To understand further the difficulty of learners to conceive and represent improper fractions, a potentially fruitful line of inquiry concerns investigating how a part/whole interpretation of fractions shapes learners' comprehension of a unit fraction. Exploring an aspect of unit fraction comprehension, Ciosek and Samborska (2016) present a hitherto undocumented belief among elementary to university students, science graduates, and mathematics teachers that a unit fraction, $1/n$, results only from a whole equipartitioned into n parts. Using Ciosek and Samborska's (2016) study instrument, our work extends theirs by examining the related ideas of practicing elementary school teachers. Teachers of those grades are responsible for supporting elementary school students' development of ideas about fractions and their operations. Therefore, understanding teachers' ideas may provide valuable insights into the origins of students' beliefs and indicate percipient ways to challenge and enhance students' fundamental awareness of unit fractions.

Related Literature and Conceptual Framework

Teachers' Mathematical Knowledge

Teachers' mathematical knowledge is critical for teaching mathematics and their students' achievement. Several models have theorized the knowledge that teachers need to teach mathematics effectively. Our study draws from the Mathematics Teacher's Specialised Knowledge (MTSK) model by Carrillo-Yañez et al. (2018). Extending the work of Shulman (1986) and Ball et al. (2008), Carrillo-Yañez et al. (2018) state that teachers' knowledge consists of three major domains: beliefs, pedagogical content knowledge, and mathematical knowledge. Since teachers' beliefs influence teaching practice, MTSK centers the two other domains around teachers' beliefs about mathematics and mathematics teaching and learning. Each of the remaining two domains includes three subdomains. The pedagogical content knowledge domain involves knowledge of features of learning mathematics (KFLM), knowledge of mathematics teaching (KMT), and the knowledge of mathematics learning standards (KMLS). The KFLM subdomain encompasses the features inherent to learning certain mathematical content. The second subdomain, KMT, concerns awareness of mathematical teaching theories, including knowing about activities, strategies, and techniques for teaching specific mathematical content. The last subdomain, KMLS, is the knowledge about mathematical standards and curricula for the content at different levels.

The mathematical knowledge domain includes knowledge of topics (KoT), knowledge of the structure of mathematics (KSM), and knowledge of practices in mathematics (KPM). The KSM subdomain describes teachers' knowledge about the relations among different mathematical ideas. This knowledge influences teachers' decisions when connecting a mathematical topic to previous or future topics. Carrillo-Yañez et al. (2018) define the KPM subdomain as "any mathematical activity carried out systematically, which represents a pillar of mathematical creation and which conforms to a logical basis from which rules can be extracted" (p. 9). This knowledge does not focus on teaching mathematics but on the workings of mathematics such as mathematical demonstrations, justifications, definitions, and making deductions and inductions. Finally, the KoT subdomain describes "*what* and *in what way* the mathematics teacher knows [or may know] the topics they teach" (Carrillo-Yañez et al., 2018, p. 7, original emphasis). An example of this type of knowledge includes concepts, procedures, and theorems.

This study investigates the mathematical knowledge domain and focuses on teachers' KoT. The specific topic of our research concerns teachers' knowledge of the unit fraction concept, its relation to a whole and other parts of the whole. Moreover, regarding elementary school teachers who teach mathematics, this study also seeks to explore Ciosek and Samborska's (2016) hypothesis: "An iterative procedure of dissecting something into n equal parts to constitute a fraction of $1/n$ (as it is defined) may lead to the false belief of the learner of mathematics that if a whole is divided into n unequal parts, none of them can be $1/n$ of its size" (p. 22). Investigating how teachers conceptualize and identify unit fractions is essential since, as Chapman (2014) states, "it is not only important what mathematics teachers know but also how they know it and what they are able to mobilize for teaching" (p. 295).

Unit Fractions

Fractions, one of three representations of rational numbers, have several interpretations. Kieren (1976, 1980) calls them sub-constructs and identifies five: part-whole, quotient, measures, ratios, and operators. These interpretations, Kieren further notes, are united by the act of equipartitioning a whole. "Partitioning is seen here as any general strategy for dividing a given quantity into a given number of 'equal' parts. Thus, it can be seen as important in developing all of the five sub-constructs" (1976, p. 138). In that quote and elsewhere in our text, the term *quantity* means a measurable quality of an object such as its length, area, or volume. Positing partitioning a quantity as the cognitive basis for fraction knowledge has in practice implied that instructionally the part/whole interpretation is the foundational and initial fraction concept. This stance perseveres as curricular policy (Common Core State Standards Initiative, 2010).

This partitioning approach Vergnaud (1983) identifies as the first of two categories of ratios or fractions as comparisons or proportions. The first category he calls inclusive fractions, represented by a whole and a part of it (p out of q) such as this set model statement: Aaliyah ate two-thirds of the cookies. For an area model, one compares pizza slices to the whole pizza. The part/whole interpretation is the ubiquitous basis for initial learning about fractions among students in the United States and elsewhere. The inclusive category is how fractional parts of a whole are understood, including unit fractions. For example, the unit fraction, $1/n$, quantifies the part-whole relationship. It represents one part of the whole's equal parts. Its quantification or magnitude results from equipartitioning a whole and considering the ratio between one part and the whole.

In contrast, Vergnaud (1983) denotes the second category of fraction representations as exclusive. In it, fractions multiplicatively compare two distinct quantities with no inclusion relationship (p to q)—for example, the volume of Karma's luggage is three-fifths of Samir's luggage. The second quantity is the unit to which the first is compared. The quantities are of the same kind (volume) and compare proportionally. As a further instance, Davydov and Tsvetkovich (1991) present this situation: A student compares two distinct objects, sharing length as a common attribute, a ruler to a table's side. To compare the objects, the student assigns a quantity to equal one and measures, actions corresponding to the fraction concept's origin. For example, if n iterations of the student's ruler equal the table's side, and she considers the table the unit, the ruler is one-nth or $1/n$ of the table.

Building on the preceding paragraph's conceptual ideas, we subscribe to a generalized formulation of a unit fraction. A unit fraction, $1/n$, quantifies a particular multiplicative relation between two quantities of the same kind (e.g., lengths, areas, or collections). Specifically, the multiplicative relation is where n iterations of one quantity measure the other quantity considered the unit of measurement. In other words, definitionally, a quantity is $1/n$ of a unit if and only if n iterations of the quantity equal the unit. Though this definition integrates inclusive and exclusive categories of fractions and their corresponding nonsymbolic models, the crucial difference for the two categories is whether the n iterations are internal or external to the unit quantity. In either case, a unit fraction is a unit of a unit or a subunit.

Research evidences learners' movement from inclusive to exclusive fraction representation. This movement is essential for, as Vergnaud (1983) notes, "comparisons and ratios between any two quantities of the same kind are a more powerful model than inclusive fractions, providing a more general foundation for scalar operators or ratios" (p. 164). Hunt et al. (2016) show how tasks for learners with learning disabilities can conceptually prime them to use unit fractions to construct non-unit fractions in and out of equal sharing contexts. Tzur's (1999) study evinces how children nontrivially reorganize their numerical operations with a unit fraction to construct fractions less than or equal to a whole to represent fractional magnitudes greater than a whole.

Other than initiating fraction learning with the part/whole interpretation and its inclusive representations, challenging the settled partitioning perspective of fraction learning, there are instructional research and pedagogical materials that develop fractional knowledge with exclusive models (Cuisenaire & Gattegno, 1954; Davydov & Tsvetkovich, 1991; Dougherty & Simon, 2014; Dougherty & Venenciano, 2007).

Assigning a quantity to equal one or a unit is a mental and bodily act. Lamon (1996) calls the "assignment of a unit of measurement to a given quantity" (p. 170) unitizing. For a given whole or unit, a fraction whose numerator is 1, a unit fraction, is a subunit. From the part/whole perspective, if a whole is partitioned into n equal parts, one part is $1/n$ of the whole. As Ciosek and Samborska's (2016) study suggests, from that statement, learners may incorrectly conclude the statement's converse: If one part of a whole is $1/n$ of it, then the whole is divided into n equal parts. Besides, learners may falsely believe versions of the following two statements:

- If a whole is partitioned into n parts, one part is $1/n$ of the whole.
- If a whole is partitioned into n unequal parts, one cannot equal $1/n$ of the whole.

The part/whole interpretation of a unit fraction means that if both conditions—n parts and all parts equal—are true for how a unit is partitioned, each part equals $1/n$ of the unit. However, the statement does not imply that a part cannot equal $1/n$ of the unit when the unit is not partitioned into n parts, or the parts are unequal. That is, a part of a unit can equal $1/n$ of it even (a) when the unit is partitioned into n unequal parts or (b) without the unit being partitioned into n parts.

To engage learners' awareness of the meaning and conditions for the existence of unit fractions, educators can develop instructional tasks that challenge potential false beliefs (see, for example, Problems 1 to 6 in Ciosek and Samborska (2016, pp. 30-31)). However, to support the appropriate implementation of those tasks, it is essential to know how elementary school teachers understand the consequences of a fraction's part/whole interpretation for ideas about unit fractions. Then, if needed, teacher educators can support teachers to be aware of what the interpretation means and does not mean about the existence of unit fractions.

Methods

Study Instrument

To explore how elementary school teachers understand unit fractions and, if necessary, support them in educating their awareness of false ideas, we implemented the Frame Task (see Figure 1 below), adopted from the study instrument in Ciosek and Samborska (2016, p. 22). This task reveals participants' unit fraction understanding as one of n equal parts of a whole. It also allows us to examine whether they have the false belief that if a whole is divided into n unequal parts, none of them will equal $1/n$ of the whole.

In Figure 1, the frame consists of three squared annuli or rings—an outer, a middle or shaded, and an inner—each segmented into squares of the same size. Not part of the frame is the unsegmented center square.

Participants and Setting

From a pool of 47 teachers of grades 1 to 5 participating in a larger professional learning project about rational numbers, this study involved 19 of the teachers. They are from a public charter school in the Bronx, New York City, with two locations, which we call B1 and B2. They volunteered to participate in individual interviews, responding to the Frame Task, justifying and illustrating their responses, reacting to challenges to their answers or justifications, examining alternative explanations, and discussing their take-aways from the experience. For the interview, the teachers meet with one of the two first authors for an average of 18.2 minutes during the school day through videoconferencing. All interviews occurred on the same day. So that participating teachers did not receive information in advance about the task and the nature of the interview, we asked each participant not to reveal their experience to their colleagues until the next school day. All participating teachers signed an online informed-consent form, previously approved by the Institutional Review Board of Rutgers University.

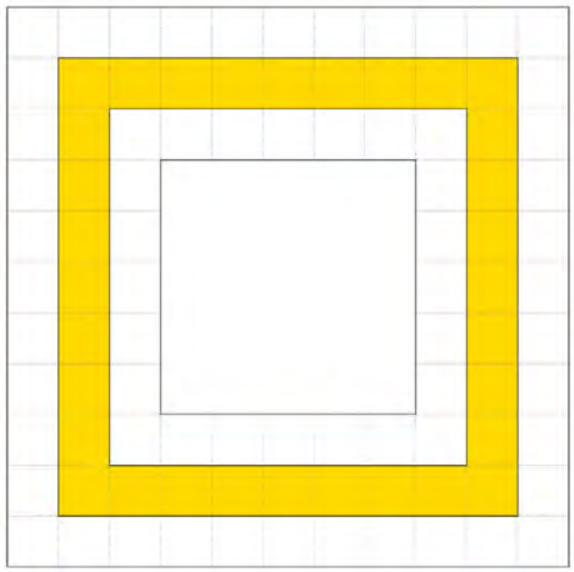

Figure 1: The Frame Task

Data Production

Guided by an interview procedure from Ciosek and Samborska (2016), the current study's two interviewers performed semi-structured interviews (Lune & Berg, 2017). We randomly assigned each participant to one of the two researchers for a specific one-half-hour time slot. Each researcher interviewed teachers from both B1 and B2. At the assigned time, teachers logged into the videoconferencing application, and their interviewer informed them that the session would be videorecorded. In addition, the interviewers confirmed that teachers knew how to use the application's annotation tool to illustrate their work and then shared their screens to display the Frame Task.

After displaying the task, we asked participants to read the question—Is the shaded part $1/3$ of the "frame"—and, for the context, explain their understanding of the word "frame." Their explanation was essential since the word as a noun or verb has several meanings. Furthermore, even when considering a picture frame, the consideration is variable as to which portion of the figure constitutes the frame in question. Once the participant and interviewer agreed that, for the task, the "frame" was the area of the figure surrounding the central large white square, the interviewer asked the participant to respond to the task. A complete response entailed two components: an answer to the task's question and a justification of the answer. Therefore, aside from their answers, we listened to how participants justified them If they did not, we then invited them to do so. If the participants' answers and justifications were correct, we encouraged them to provide an alternative rationale for their answers. If they did not have one, we offered an alternative explanation based on counting or mentally decomposing and recomposing the task's graphical figure.

If participants' answers or justifications were incorrect, we prompted their awareness by offering a monetary scenario that challenged their erroneous reasonings such as whether a unit fraction can only be defined for an equally partitioned object. After participants responded to the challenge and revised their answer or justification, we invited them to provide an alternative rationale for their answer. If they had none, we offered an alternative justification.

Finally, the interview ended with participant and researcher reflections. First, we encouraged participants to reflect on their experience in the interview from the perspectives of mathematics, learning, and teaching. Second, to complement or extend what the participants said, we offered mathematical perspectives to contribute further to their KoT of fractions.

Our mathematical perspectives comprise two considerations. The first KoT idea concerns this statement: If a whole is partitioned into n equal parts, one part is $1/n$ of the whole. This partition or part/whole interpretation of a unit fraction means that if both conditions—n parts and all parts equal—are true for how a unit whole is partitioned, each part equals $1/n$ of the unit. However, the statement does not imply that a part cannot equal $1/n$ of the unit when either the unit is not partitioned into n parts or when the unit's parts are unequal. That is, a part of a unit can equal $1/n$ of it (a) without the unit being partitioned into n parts or (b) even when the unit is partitioned into n unequal parts.

The second KoT consideration we offered pertains to the following generalized interpretation of unit fraction: A quantity is $1/n$ of a unit if and only if n iterations of the quantity equal the unit. We hypothesize that this understanding of a unit fraction, including that it is considered a subunit, emerges naturally from a measuring perspective of fraction knowledge (Powell, 2019b).

Data Analysis

The data consisted of the video recordings of the online interviews, including participants' annotations on a digital version of the Frame Task and transcripts of the videos' audio tracks. To probe the interview data, the authors developed an analysis spreadsheet containing columns for components of the interview and a row for each participant. The columns pertinent to this report captured participants' initial answers, whether their justification was unprompted or prompted and its content, whether the interviewer challenged their answer or explanation and the content of the challenge, the conclusion of how a participant addressed the challenge. In addition, two of the authors independently analyzed the interview data. For their analyses, the inter-rater reliability measure was 93.42% agreement, and the Cohen's Kappa coefficient is 0.858, indicating strong agreement between the two raters (McHugh, 2012).

Results

We report results corresponding to segments of our interview that parallel those Ciosek and Samborska (2016) detailed. Consequently, we do not discuss participants' reflections about alternative explanations for why the frame's yellow-shaded portion is one-third of it that they offered or that we supplied and comments about what they learned from the interview.

A complete response to the Frame Task entails two parts, an answer to the task's question and its justification. However, our data analysis suggests that a small proportion of the participants initially responded correctly to the Frame Task, and most teachers struggled at first to reason correctly about the conditions necessary for a portion of an object to represent a unit fraction.

Participants' initial responses comprised an answer to the question—"Is the shaded part 1/3 of the 'frame?'"—and the reason for their answers. An answer essentially was either "yes" or "no," coupled with a justification. Nevertheless, two participants' initial answers were a version of "Let me check" and ultimately responded "yes." Table 1 contains a tally of participants who provided each of the three initial responses and provides justification examples from teachers, T19, T5, and T3. In Table 1, of the 11 who responded, "yes," about 32 percent or six provided false justifications, noted with the letter "I" next to a paraphrasing of their explanation, and the five others or roughly 26 percent proffered correct reasonings, indicated with the letter "C."

Table 1: Initial responses and examples

Initial Answer	Justification	Count	Example
Yes	(I) The shaded part is one of three parts.	6 (31.6%)	T19: "the shaded area represents one of three parts."
	(C) The number of small shaded squares equals one-third of the total number of squares.	3 (15.8%)	T5: "So, the yellow part of this frame is 32... So, it is one-third of 96."
No	The three parts are not the same size.	8 (42.1%)	T3: "I see three divisions of the frame, but they're not all equal."
Let me check-Yes	The number of shaded squares to the total number of squares is $1/3$.	2 (10.5%)	
	Totals	19 (100%)	

As participants' initial responses, the incorrect to correct responses were 26 percent to 74 percent. Among participants whose initial answer was "yes," we observed false and valid justifications. Six teachers argued incorrectly that the frame's shaded part is $1/3$ of the frame since it is one of three parts. The other three participants reasoned correctly by attending to the number of the shaded squares (32) to the total number of squares (96). The eight teachers who initially answered "no" justified their answers, stating that the three squared rings of the frame are not the same size. The two teachers who first answered some version of "Let me check" compared the number of the shaded squares to the total number of squares in the frame before answering. They inspected the frame, compared the three squared rings, and stated that the shaded part is one-third of the frame. Then, they mentally shifted squares from the frame's outer ring to its inner ring and verified that the shifting resulted in two squared rings that are the same size as the shaded squared ring. For example, one of the "Let-me-check" teachers, T12, reasoned by mentally decomposing and recomposing the outer and inner squared rings to visualize that the average number of small squares is the same for the frame's three squared rings.

For participants who responded incorrectly, we prompted their awareness by offering one of two scenarios that challenged their erroneous reasoning: (a) Suppose you divide $90 into these three parts: $45, $30, and $15. Is any of these 1/3 of $90? or (b) Suppose you divide $90 into these three parts: $40, $35, $15. Is any of the parts 1/3 of $90? We gave the first scenario to participants whose initial answer was "no." We offered the second scenario to participants who answered "yes" but incorrectly justified. In all cases, after we challenged their thinking with a scenario, participants revised either their answer or justification or both and, ultimately, responded correctly based on the portion of the shaded square ring to the total of the three squared rings.

Discussion

A goal of our study was to investigate how elementary teachers who teach mathematics understand how unit fractions are constituted. Specifically, we were interested in knowing whether they believe that a unit fraction, $1/n$, results only from a whole equipartitioned into n parts, as Ciosek and Samborska (2016) documented among a range of elementary to university students, science graduates, and mathematics teachers. Understanding elementary teachers' ideas may provide valuable insights into the origins of students' beliefs. Also, teachers' understanding is associated with the learning opportunities they create for their students (Borko et al., 1992; Fisher, 1988). Furthermore, discerning whether teachers have robust conceptual insights into the unit fraction concept might indicate whether they need support to engage students with counterexamples to challenge mistaken notions.

Our study and Ciosek and Samborska's (2016) results indicate that, respectively, about 75% and 65% of the participants initially harbor incorrect interpretations of how the part/whole perspective defines unit fractions. Specifically, in our study, elementary-grade teachers who teach mathematics believe either (1) for a section of an object to equal one-third of it, the section needs to be one of three parts of the object, or (2) a section cannot be equal to one-third of an object if the object is partitioned into three unequal sections. Notably, when we presented scenarios to challenge their conceptual beliefs, the teachers revised their thinking and responded correctly to the task.

Our investigation suggests that, like teachers, without working through counterexamples, students may develop incorrect conclusions about the constitution of unit fractions such as this idea: The only way to obtain $1/n$ of a given whole is to divide it into n equal parts. Educators will want to challenge and enhance students' fundamental awareness of how unit fractions are constituted.

Earlier in this report, we mentioned the following generalized interpretation of a unit fraction: A quantity is $1/n$ of a unit if and only if n iterations of the quantity equal the unit. From a part/whole perspective, Tzur (1999) analyzes a constructivist teaching experiment to show how children, engaging in an iterative fraction scheme (Olive, 1999), nontrivially reorganize their numerical operations with a unit fraction to construct fractions less than or equal to a whole then later to represent fractional magnitudes greater than a whole. This cognitive feat is noteworthy since the fundamental basis for conceiving of the unit fraction is the equipartitioning of a whole. That criterion causes learners to hesitate iterating a unit fraction beyond the magnitude of the whole (Gabriel et al., 2012, 2013; Mack, 1990; Tzur, 1999; Zhang et al., 2017) and, as the present study and Ciosek and Samborska (2016) show, perceiving a unit fraction among parts of a whole partitioned unequally. To attenuate cognitive obstacles associated with founding fractions on equipartitioning a quantity, we hypothesize that learners' iterative fraction scheme, handling comeasurement units (Olive, 1999), and construction of proper, improper, and mixed numbers may emerge naturally from a measuring perspective of fraction knowledge (Alqahtani & Powell, 2018; Powell, 2019a, 2019b). This perspective defines fractions as ratios that express the multiplicative comparison of two quantities of the same kind. We surmise that working from a measuring perspective, learners spontaneously encounter the meaning of a general fraction, m/n, as an outcome of m iterations of the unit fraction $1/n$. Our research team intends to explore this hypothesis in a future study, challenging the settled partitioning perspective of fraction learning.

PRESERVICE TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING: FOCUS ON LESSON PLANNING AND REFLECTION

Bima Sapkota
Purdue University
bsapkota@purdue.edu

Amanda Huffman
Purdue University
huffma33@purdue.edu

Mathematics teacher educators have suggested that preservice mathematics teachers' (PMTs') practices provide evidence of their Mathematical Knowledge for Teaching (MKT). In an effort to explore connections between MKT and PMTs' practices, we developed a framework that operationalizes Ball et al.'s (2008) six MKT domains in terms of approximations of practice. We then used our framework to investigate which domains were evidenced in eleven PMTs' lesson plans and how PMTs described MKT in their lesson plan reflections. We found Knowledge of Content and Teaching most evidenced and Horizon Content Knowledge least evidenced. Also, PMTs made few instances of Knowledge of Content and Students as they struggled to address students' mathematical thinking in their plans. We propose alternative forms of approximations of practice to optimize PMTs' opportunities to demonstrate and conceptualize MKT.

Keywords: Mathematical knowledge for teaching, Teacher knowledge, Preservice teacher education; Instructional activities and practices

Educators have emphasized that teacher knowledge should be discipline-specific, and evidenced through teacher practices (e.g., Ball et al., 2008; Shulman, 1986; Tchoshanov, 2010). In mathematics education, discipline-specific knowledge is commonly conceptualized as Mathematical Knowledge for Teaching (MKT, Ball et al., 2008), which provides a way to contextualize mathematical knowledge during mathematics teaching (Thomas et al., 2017). Preservice mathematics teachers (PMTs) often engage in approximations of practices (referred to as "approximations") such as peer teaching (Grossman et al., 2009) during their teacher education programs, thus, their MKT could be evidenced in approximations. However, the forms of approximations of practice that are appropriate for PMTs to demonstrate specific aspects of MKT (e.g., anticipating students' mathematical reasoning; formulating meaningful questions to students) are underexplored. In addition, mathematics teacher educators would benefit from opportunities to consider the operationalization of Ball and colleagues' (2008) six MKT domains in terms of associated practices (see the description of the domains in the Perspectives section). In this study, we operationalized MKT domains in terms of peer lesson planning and reflections. First, we synthesized the literature to develop descriptors for the MKT domains. Then, we used this framework to investigate the following questions: (a) How did PMTs demonstrate MKT in their lesson planning? (b) How did PMTs describe the use of MKT domains in their lesson plan reflections? We conceptualized lesson planning (e.g., formulating teacher and student actions) as approximations of practice. As such, PMTs engaged in approximations through peer teaching; thus, the actual practices were altered by changing the context of the practice (i.e., PMTs planned a lesson to implement in a university classroom) and by offering scaffolding such as peer and instructor feedback and a guided lesson plan template (Tyminski et al., 2014).

Perspectives

We framed our study around the concept of discipline-specific knowledge, or MKT, with foundations in Shulman's (1986) interpretation of Pedagogical Content Knowledge (PCK)—

teachers' skills to identify and unpack critical mathematical components that are fundamental for the teaching of mathematics and use those components in a way that are comprehensible to students. PCK was further elaborated by Ball and Bass (2000) and other mathematics educators (e.g., Hill et al., 2005; Wasserman & Stockton, 2013). These educators proposed that teacher knowledge is discipline-specific; suggesting that focusing solely on generic pedagogy, such as classroom management, poses a risk of simplifying the complexities of teaching because generic pedagogy does not include the unique characteristics associated with content or discipline. Moreover, Shulman and recent educators (e.g., Styers et al., 2021) proposed teacher knowledge should be evidenced through their practice as opposed to paper and pencil tests.

Ball et al. (2008) formalized MKT through a framework, which consists of two domains—Subject Matter Knowledge (SMK) and Pedagogical Content Knowledge (PCK), each consisting of three subdomains (referred to as "MKT domains"). SMK consists of the following three subdomains: Common Content Knowledge (CCK), Horizon Content Knowledge (HCK), and Specialized Content Knowledge (SCK). CCK comprises the general mathematical knowledge required to solve mathematics problems. HCK is the knowledge of core disciplinary values and major structures of the discipline. SCK refers to teachers' conceptualization of mathematics in nuanced ways that include mathematical reasoning and multiple mathematical representations. PCK consists of Knowledge of Content and Student (KCS), Knowledge of Content and Teaching (KCT), and Knowledge of Content and Curriculum (KCC). KCS includes the understanding of students' mathematical conceptions and reasoning. KCT includes knowledge of effective mathematics teaching strategies. KCC comprises knowledge of learning goals and horizontal and vertical organizations of mathematics across grade levels. Even though the MKT framework provides a way to unpack MKT in terms of six domains, how these domains are operationalized in PMTs' teaching is still underexplored. In addition, teacher education programs have yet to ensure practices for PMTs to conceptualize and demonstrate MKT (Wasserman et al., 2019); which forms of approximations of practice (our second conceptual framework) are appropriate for PMTs to engage with and demonstrate MKT is still underexplored.

As we worked to operationalize Ball et al.'s (2008) six MTK domains in terms of approximations of practice, we looked at how approximations have been defined in research. Approximations of practice are defined as "opportunities for novices to engage in practices that are more or less proximal to the practices of a profession" (Grossman et al., 2009, p. 2058). Approximations are different from actual practices because they often (a) mimic components of teaching practice, (b) include scaffolding, and (c) do not always replicate the complexities of teaching (Campbell et al., 2020; Janssen et al., 2015; Tyminski et al., 2014). Through approximations, teacher educators focus explicitly on the enactment of teaching and aim to develop skilled teachers (Forzani, 2014; Janssen et al., 2015). By using the concept of approximations, we designed instructional activities that provided PMTs with opportunities to rehearse several practices in a setting different than the actual classroom; PMTs rehearsed peer teaching and received feedback from their instructors and peers to improve their teaching. We explored the explicit connections between MKT and approximations of practice— how MKT domains are operationalized in approximations involving lesson planning and reflections.

Methods

Using a single case-study design (Yin, 2017), we identified the MKT domains associated with teacher and student actions described in the PMTs' lesson plans and lesson plan reflections. We considered all PMTs' lesson plans as one case and investigated all MKT domains demonstrated across all PMTs' lesson plans. This merging of all data into one case was appropriate for our study because we were interested, not in individual PMT's demonstration of the MKT domains, but rather in the total instances of MKT domains in all PMTs' lesson plans and the way they describe MKT domains in their reflections.

Context, Participants, and Instructional Activities

Using convenience sampling (Nielsen, et al., 2017), we recruited 11 secondary PMTs enrolled in a secondary mathematics methods course at a large Midwestern University. The first author was a course instructor and developed and implemented instructional activities based on the fundamental concepts of approximations of practice (Grossman et al., 2009). The PMTs had completed content and general education courses prior to taking this course, but this was their first methods course. During this course, the PMTs planned, reflected on, and implemented lessons with their peers. In the first phase, the PMTs worked with a peer to plan a lesson ("Lesson Plan I") for middle school students using the Connected Mathematics curriculum (Connected Mathematics Project, n.d.). Afterward, they individually reflected on their lesson plans with prompts (e.g., Describe how the examples, strategies, and representations that you have listed in the lesson plan help to build on students' understanding of mathematics). We used González et al. (2020) and Özgün-Koca (2020) to develop prompts. In the second phase, the instructor facilitated a discussion of Ball and colleagues' (2008) MKT framework. In the third phase, PMTs individually planned a lesson ("Lesson Plan II") by adapting activities from the College Preparatory Mathematics curriculum (CPM Educational Program, n.d.). For both lessons, PMTs were provided a lesson plan template, which partitioned the lesson into three sections: Launch (helping students understand the problem setting, the mathematical context, and the challenge), Explore (inviting students to explore mathematical ideas), and Summary (inviting students to present and discuss problem-solving strategies).

Data Collection and Analysis

Our primary data was the PMTs' lesson plans. We used the PMTs' reflections on the lesson plans as an additional data source to understand how and why the PMTs selected certain teacher and student actions. We used content analysis methods (Chi, 1997; Schreier, 2012) to analyze the data. We first synthesized the literature to develop descriptors for the MKT domains (Table 1) and then used these descriptors to code lesson plans and reflections.

Table 1: Descriptors of MKT Domains

MKT Domains and Associated Descriptors/Codes
Common Content Knowledge -CCK (Ball et al., 2008; Baumert et al., 2010)
Define mathematical terms
Unpack mathematics concepts and/or symbols
Solve mathematical problems
Specialized Content Knowledge- SCK (Ding & Heffernan, 2018; Hill et al., 2005; Morris & Hiebert, 2017)
Anticipate alternative representations, provide explanations, evaluate unconventional student solution approaches
Identify multiple representations for mathematics problems or concepts
Offer multiple representations of mathematical solutions
Unpack mathematical concepts and concrete models for justifying standard procedures utilized in the process
Horizon Content Knowledge- HCK (Ribeiro et al., 2013; Wasserman & Stockton, 2013)
Address how a topic is connected with the broader disciplinary territory
Include big mathematical ideas that contribute to the teaching of mathematics topics
Knowledge of Content and Curriculum-KCC (Ball et al., 2008)
Address curricular trajectory

Knowledge of Content and Students-KCS (Hill et al., 2005; Özgün-Koca, 2020; Schilling & Hill, 2007)	
Anticipate the contextual factors that would support (or impede) the development of students' understanding	

MKT Domains and Associated Descriptors/Codes
Anticipate what students are likely to do with a mathematical task and/or concepts
Evaluate the diagnostic potential of tasks or recognize typical student errors
Foresee students' alternative conceptions and plan to address those conceptions
Predict what students will find interesting or motivating or useful
Knowledge of Content and Teaching-KCT (Ding & Heffernan, 2018)
Anticipate an item's difficulty level and plan for mathematical concepts that address rigor demanded by the item
Describe mathematical tasks or procedures that students would be engaged in
Formulate, sequence, pose questions to students
Identify strategies to assess students' mathematical understanding
Identify supplemental resources associated with mathematics topics
Identify what different methods and procedures might afford during instruction
Select and sequence examples or performance tasks that would allow students to understand the topic
Generic-No MKT-domains
Include generic teacher and student actions without referencing mathematics

We also modified the descriptors based on our coding. For example, we identified the code "anticipate the contextual factors that support (or impede) the development of students' understanding" under KCS from PMTs' descriptions of contextual factors associated with students' mathematical understanding. The first author used the data from the pilot study (i.e., four PMTs' lesson plans and their reflections collected in an earlier semester) to test the initial codes and further develop the coding scheme. The first and second author (a mathematics education graduate student and an instructor of the methods course in subsequent semesters) identified new descriptors in the data which we added to the framework. For example, we found that the PMTs planned strategies to assess students' thinking. It was not in the original set of codes, and we added it as a descriptor of KCT because it is related to teachers' knowledge associated with selecting instructional activities to understand students' mathematical thinking.

We coded teacher and student actions described and the assessment strategies noted in the lesson plans; the standards, instructional materials, students' prior knowledge, and vocabulary were articulated while describing the teacher and student actions. For the second data set, we coded all the reflections. We identified each instance in which the MKT domains were evidenced in PMTs' lesson plans as one coding unit. For example, one PMT mentioned that "students also need prior knowledge of probability notation, including that P(x) means that we are looking for the probability of x." We identified this as one coding unit. In addition, we identified instances wherein PMTs described generic teacher and student actions without referencing mathematical content. We added those activities under the new category "Generic-No MKT-domains." In addition, we refined our coding scheme by revising codes. For example, we aimed to distinguish between types of specific questions PMTs planned to pose versus types of tasks PMTs planned to implement while selecting mathematical tasks. Thus, we added the code: "formulate, sequence, and pose questions." We each used the coding scheme to code all lesson plans independently, then discussed our coding processes and codes to resolve any discrepancies. We collaborated to decide which codes or descriptors needed to be added or eliminated.

Findings

We first report the frequency of the MKT domains that appeared in the PMTs' Lesson Plan I and Lesson Plan II. We then elaborate on the context of the frequencies— how we identified these frequencies from PMTs' lesson plans and what these frequencies suggest in terms of

PMTs' MKT; we first report MKT domains that were evidenced the most and the shifts in the frequency from Lesson Plan I to Lesson Plan II. Afterward, we include examples of less evidenced domains in PMTs' lesson plans. We used PMTs' lesson plan reflections to provide the context and description of potential reasons that PMTs included certain activities in their lesson plans. In Table 2, we present the MKT domains that we identified in the PMTs' lesson plans.

Table 2: MKT Domains in PMTs' Lesson Plans

MKT Domains	KCC		KCS		CCK		KCT		HCK		SCK	
Lesson Plan	I	II	I	II	I	II	I	II	I	II	I	II
Total Instances	16	22	14	45	8	7	87	102	4	1	11	21

As indicated in Table 2, KCT was the most highlighted domain in both lesson plans, including 87 instances in Lesson Plan I and 102 instances in Lesson Plan II. KCT was primarily identified when PMTs described the following instructional plans related to teacher actions: (a) selecting and describing mathematical tasks, (b) formulating, sequencing, and posing questions for students, and (c) identifying what different methods or procedures would afford during instruction. PMTs had more instances (102) in their Lesson Plan II associated with teacher actions compared to Lesson Plan I (87 instances), suggesting that PMTs may have begun to think more about mathematics-specific teacher actions. PMTs presented examples of mathematical tasks from textbooks while other times they elaborated on the mathematical tasks from the textbook to describe which mathematical concepts students would be engaged in and which mathematical concepts or procedures that given mathematical tasks would afford. PMTs also discussed how tasks would allow students to engage with certain mathematical concepts. For example, Adam (pseudonym) discussed the following task and procedure in Lesson Plan I:

> This [Factor Game] provides students the chance to improve their understanding of factors. While playing the game, students become familiar with the factors of the numbers from 2 to 30. They also review the multiplication and division of small whole numbers while playing.

In Lesson Plan I, John anticipated that students would be confused by the problems that he planned: "I anticipate that students will have trouble initially figuring out what to do and will tell the students that the solution lies in using the tools they were given, e.g., a ruler and protractor."

In Lesson Plan II, the PMTs began to anticipate students' mathematical thinking; however, their skill of identifying and incorporating students' mathematical thinking was still evolving and they even stated in their reflections they needed to engage with authentic student work. In Lesson Plan I, the PMTs' included generic teacher and student actions (48% of the instances were generic). In Lesson Plan II, PMTs began to include more specific teacher and student actions.

Thus, we identified more instances that were related to both KCT and KCS. For example, Sarah included more specific questions in Lesson Plan II than in Lesson Plan I. In Lesson Plan I, she included the following generic statement: "Pose further questions to keep them thinking and understanding their answers to the questions." In Lesson Plan II, Sarah included specific students' mathematical thinking: "How did you know where to put each variable? If you had a word problem that required three equations, do you think it would be possible to solve that?"

In addition, the PMTs began planning for more mathematics-specific student actions in Lesson Plan II with 45 instances of specific student actions compared to only 14 instances in

Lesson Plan I. Specifically, in Lesson Plan II, the PMTs began describing how their students would be engaged in the mathematical tasks, including how their students might solve mathematical problems or what questions students might ask. For example, Sarah anticipated that her students could have the following response to a task she planned to pose: "[Students] could have an incorrect single equation that doesn't incorporate all the information from the problem." However, many PMTs still included generic teacher and student actions in Lesson Plan II. Some of their generic teacher actions included teacher questioning, division of groups in their classrooms, how students would respond to teacher actions. For example, George and Kate included the following generic student action: "[Students will] discuss the process with peers to gain a better understanding and will respond to teacher prompting to dig deeper and prepare responses for class discussion." PMTs had to use a Lesson Plan template asking them to write teacher and student actions separately. Not surprisingly, KCS was evidenced in the PMTs' descriptions of student actions. However, there were only a few instances wherein PMTs described which mathematical topics students would find interesting, what would be motivating to students, and what kinds of mathematical problems their students might find difficult to understand. For example, Jacob in his Lesson Plan II included the following: "I anticipate there will be questions and confusion. Students in the past have only worked with equations, so they have the tools they just are unaware of how to implement them into solving the problems."

We identified more MKT domains from the Launch and Explore sections of the lesson plans than in their Summaries. In these sections, PMTs described mathematical tasks building on their students' prior knowledge, what the teacher would present to the students, and what actions the teacher and students would perform. We identified only a few instances of the MKT domains in the Summary sections. We noticed that the PMTs struggled to plan for those specific actions because they had to anticipate what their students would explore in the Explore section. As a result, most PMTs planned for generic actions, specifically inviting students to share their ideas. For example, Griffin and Sarah wrote: "Walk around to each group and observe what they are discussing. Pose further questions to keep them thinking. Decide which groups should share."

KCC and CCK were also evidenced in the PMTs' lesson plans. KCC was evidenced when PMTs discussed students' prior mathematical knowledge and how they would build on it in their lessons. For example, in Lesson Plan II, Kate included: "Prior knowledge about calculating area and probability knowledge is needed for this lesson. Students also need prior knowledge of probability notation, including that P(x) means that we are looking for the probability of x." CCK was evidenced when PMTs presented the specific definitions or solution methods. For example, in her Lesson Plan I, Kiara included her plan for defining a *factor of a number*: "Teacher will review what a factor of a number is by reminding them that it can be thought of as both the numbers multiplied to get a product and the divisor of a number." This quote indicates Kate's knowledge of MKT in the CCK domain as she defined factors.

In their reflections, PMTs mostly described KCT, including which mathematical tasks their students were engaged in. For example, in Lesson Plan II reflection, Kate noted:

> I think she wanted the students to think of solutions on their own because there were several ways for the students to solve the problems. Through the student presentations, other students were able to discover different strategies so that they could figure out which method works best for them or what they understand the most.

In this reflection, the notion of students sharing multiple strategies and different thinking allows the teacher to assess their students' understanding, one descriptor of KCT. In Tania's

Lesson Plan II reflection, another code of the KCT domain, “Identify what different methods and procedures might afford during instruction,” was referenced:

> I encourage each activity to involve some sort of discussion with their peer, and the activities themselves are asking the students to present the information in different ways, which is allowing the students to enhance their conceptual understanding of the material.

While this reflection could be seen as more generic, the mentioning of “enhance their conceptual understanding of the material” points to understanding how students' conceptual knowledge of simplifying exponential expressions was important.

From Table 2, we also notice that there were only a few instances of HCK (four instances in Lesson Plan I and one instance in Lesson Plan II). Recall that HCK includes logical connections of mathematics topics within broader mathematical disciplines when presenting big mathematical ideas. Thus, this domain could have been evidenced when the PMTs presented instructional strategies in a way that made connections with advanced mathematical topics. For example, in the following excerpt, Sarah used her knowledge of “transitivity” to plan her lesson: “If we know that t is equal to two different things, does that mean those two things are equal to each other? (transitivity).”

In addition, SCK, KCC, and CCK were less evidenced in the PMTs’ lesson plans. SCK was evidenced in instances where the PMTs were able to offer alternative mathematics solution strategies, multiple mathematical representations, and concepts needed to understand mathematics. For example, Jacob, in Lesson Plan II, mentioned:

> You are looking for something a little bit bigger but will fit in your TV cabinet and you only know the width and height of the TV cabinet. When you get to the store, they do not list the Width and Height of the TVs, instead, they only have the diagonal. What are some possible ways that you could find out the size of the TV you need?

Here, Jacob presented his mathematics task, and it included a real-world problem. Tayra planned to address students' conceptions in Lesson Plan II: “If the students aren’t understanding conceptually, then I’ll spend more time individually with the students and track specifically what things they’re finding difficult to understand.” Later, while reflecting on the lesson plan, Tayra mentioned that she anticipated the task to be difficult for students; however, she did not explain how: “we anticipated this task being difficult for many. It involves students to get creative and think outside the classroom.” This finding suggested that while PMTs had generic explanations of what their students might find confusing, there were fewer instances wherein PMTs mentioned which mathematical concepts students might find interesting and their anticipation of students’ alternative problem-solving strategies (e.g., patterns of student errors).

In their reflections, PMTs noted that they did not anticipate students’ mathematical thinking because they wanted to have flexibility about how to modify students’ task-solving strategies during lesson plan implementation. For example, Kate reflected that she did not try to anticipate students’ thinking because she planned to be open to students’ ideas: “I do not feel like we tried to anticipate a lot because I did not want to get caught up in what I think the students will answer so that I am more flexible for when they do not answer the way someone typically would.” This finding suggests that PMTs need more opportunities to explore students’ authentic work. KCC was evidenced when PMTs described how they built their plans on students’ prior knowledge. For example, Jacob planned for addressing students’ prior knowledge: “While this is a new chapter, this lesson relates back to measurements, triangles and shapes, and heights and areas.”

Discussion and Implications

Our findings indicated that KCS and KCT were the primary MKT domains identified from PMTs' explanations of teacher and student actions. We identified two possible reasons associated with this finding. First, due to the lesson plan template, the PMTs demonstrated some domains more than others. For example, the template did not include an obvious place for PMTs to demonstrate HCK. Each PMT discussed CCK (i.e., addressing students' prior knowledge). Given that the lesson plan template explicitly included the prompts about students' prior knowledge, each PMT included at least one instructional activity that described how they would address students' prior knowledge. Also, the lesson plan template had prompts for the PMTs to describe teacher and student actions and not many options to demonstrate how their advanced mathematical knowledge connected with the teacher and student actions, which could be a reason we identified less evidence of HCK.

Second, when the PMTs had to explain student actions, they demonstrated fewer instances related to mathematics-specific student actions. PMTs noted they could not plan for student actions because they had not had a chance to work with specific students in the field. We identified that our approximations of practice (i.e., peer teaching, reflections) did not contain students' authentic work. To address this limitation, incorporating authentic student work prior to lesson planning could evoke PMTs' conceptions about mathematics-specific student work. Moreover, engaging PMTs with the research about students' possible mathematical thinking and rehearsing how to respond to students' mathematical thinking could be a way to cultivate PMTs' skills to plan for activities to address students' mathematical reasoning. Analysis of student work could assist PMTs in identifying activities to understand and develop students' mathematical reasoning (Álvarez et al., 2020). We propose authentic forms of approximations wherein PMTs first read and discuss students' potential mathematical reasoning, then engage with students' authentic work in some form. Afterward, they will have opportunities to plan instructional activities to develop students' mathematical understanding of a certain topic, including possible ways to address students' existing conceptions. Finally, PMTs could implement those strategies with their peers first and with real students later during their field experiences.

We found minimal instances associated with SCK, indicating alternative representations of mathematics topics and contextual factors associated with the given mathematics topics were less discussed. Prior research suggested textbooks played a significant role to enhance PMTs' MKT; for example, textbooks predominantly promoted CCK (Atanga, 2021). Given that the textbooks that PMTs used in our study focused on conceptual understanding, our findings do not align with Atanga's findings. Thus, exploring the explicit connections between how MKT domains in PMTs' lesson plans were influenced by the textbook should be a question for further research. In addition to textbook content, a section in the lesson plan template about the contextual factors and alternative representations of mathematics could help PMTs explore, demonstrate, and conceptualize how mathematics topics relate to other concepts and real-life.

Our study has implications for mathematics teacher educators and is connected with the conference theme of Critical Dissonance and Resonant Harmony. As opposed to assessing teacher knowledge through paper and pencil tests to identify what teachers know versus do not know, we invite educators to critically reflect on approximations of practice so PMTs have the opportunity to explore how they can contextualize their advanced mathematical knowledge during mathematics teaching. Our MKT domain descriptors provide a way to design instructional activities that engage PMTs in both teacher knowledge and practices.

Over the past two decades, the landscape of research on mathematics teacher educators (MTE) has grown considerably. One particular area of interest has focused on the knowledge needed by MTEs for their work with preservice K-8 teachers (PTs). In an effort to understand this varied landscape, we conducted an extensive review of research on frameworks of MTE knowledge. This report explores the theoretical underpinnings of MTE knowledge and highlights similarities and differences among theoretical frameworks. By mapping the terrain of research on MTEs' knowledge, our goal is to identify aspects of MTE knowledge to inform the types of research that may be needed for its further development.

Keywords: teacher educators, teacher knowledge, mathematical knowledge for teaching

The issues of what mathematics teachers need to know (Ball et al., 2008; AMTE, 2017; CBMS, 2012) and how to prepare prospective teachers (PTs) as part of teacher preparation programs (e.g., Adler, 2010; Grossman et al., 2009; Dinham, 2013) have become a central focus in both research and policy arenas in many countries. The term Mathematics Teacher Educators (MTEs) refers to individuals who work with PTs in a variety of contexts to develop and improve the teaching of mathematics (Jaworski, 2008a), including mathematicians, graduate students, mathematics education researchers, and classroom teachers. As such, these individuals play a critical role in the mathematical preparation of PTs.

Over the past two decades, the landscape of research on MTEs has grown considerably. In an effort to understand this varied landscape, the authors conducted an extensive review of research on the nature of MTE knowledge. This paper reports the theoretical underpinnings of the existing frameworks for MTE knowledge identified in this review. We focus on MTEs who work with elementary teachers because of the currently limited number of studies focused exclusively on MTEs who teach secondary coursework. Much of the extant research on MTEs draws on the construct of mathematical knowledge for teaching (MKT; Ball et al., 2008), a model of teacher knowledge that is grounded in elementary school teaching. As such, research on MTEs is largely focused on MTEs who teach elementary PTs. We sought to answer the question: What frameworks for teacher knowledge are leveraged in conceptualizing MTE knowledge, and in what ways?

Conceptual Framework

Conceptualizing MTE Knowledge

Broadly defined, *knowledge* is the information and skills that teachers develop through experience and education. Researchers have long recognized the tension that exists for teachers between their general content-specific knowledge, developed in teacher education programs, and the *craft* knowledge that is developed through teaching practice (Shulman, 1986; Leinhardt et al., 1991). *Practice* refers to the things that teachers do consistently in their work with students (Lampert, 2010). Craft knowledge, for example, includes "know-how for teaching based on past experiences, empirical data, and well-reasoned arguments and predictions" (Hiebert & Morris, 2009, p. 476), the knowledge that is developed through experience working with students. Like others (Cochran-Smith & Lytle, 1999; Ball & Bass, 2000), we argue that teacher knowledge is intimately related to teaching practice – teachers' knowledge is further developed and enhanced over time as they teach.

Mathematical Knowledge for Teaching Teachers

Shulman (1986) introduced the term *pedagogical content knowledge* (PCK), which linked knowledge of teaching pedagogy with knowledge of the specific content being taught. Since then, a great deal of research has focused on identifying the knowledge needed for teaching mathematics (e.g., Ball et al., 2008; Davis & Simmt, 2006; Leinhardt et al., 1991; Ma, 1999; Rowand et al., 2005). Many of these studies argue that teachers need to understand the mathematics in the curriculum they teach in deep and connected ways that are specific to the needs of teachers. When combined with PCK, this knowledge base is commonly referred to as *mathematical knowledge for teaching* (MKT) (e.g., Ball et al., 2008).

Building on MKT research (Shulman, 1986; Davis & Simmt, 2006; Leinhardt et al., 1991; Ma, 1999), central to this review is an assumption that the knowledge needed by MTEs for their work with teachers differs from the knowledge needed by teachers for working with students. Researchers generally agree that the work of MTEs involves working with PTs and/or practicing teachers to develop their MKT (Jaworski, 2008a). As there is considerable diversity in the nature of MTEs' work, the range of expertise shared by MTEs is similarly diverse, involving varying levels of mathematical expertise, pedagogical expertise, and/or expertise derived from their experiences as teachers (Bergsten & Grëvholm, 2008). However, in addition to developing new content knowledge, MTEs need to help PTs' understand the ways in which the concepts they are learning connect to their future teaching of students. This requires MTEs to also understand what is involved in teaching mathematics to students. To simultaneously enhance different levels of PTs' awareness (as learners and future teachers), work that is different from what teachers do with students, MTEs need *mathematical knowledge for teaching teachers* (MKTT).

Method

Literature Search

We conducted a literature search using ERIC and Dissertation Abstracts using the following search terms: (1) *mathematics teacher educator(s)* AND *knowledge,* (2) *mathematics* AND *teacher educator* AND *knowledge*, (3) *teacher trainer* AND *knowledge*, and (4) *mathematics* AND *teacher trainer*. We also searched edited books and book series that were cited in many of the articles we reviewed, recent special issues of peer-reviewed journals, and conference proceedings of the Research in Undergraduate Mathematics Education (RUME) annual meetings, as these were not captured in the ERIC search results. The search covered articles written in English and published in peer-reviewed scientific journals or conference proceedings, as well as dissertations. Hereafter we use the term "articles" to refer to the resulting set of scientific studies, books, book chapters, dissertations, and conference proceedings. Because Shulman's seminal article about teacher knowledge was published in 1986 (Shulman, 1986) and the majority of the research on MTEs emerged in the early 2000s, we confined the search to 1986-2021. The literature search and initial review of abstracts for studies of MTE knowledge or its development (beyond just implications for MTE knowledge) resulted in 87 articles (including 6 dissertations). We then divided up the articles and individually reviewed each one in its entirety, summarizing each in terms of research goals, method(s), research questions, researcher's role, and findings, resulting in a final tally of 15 articles that proposed different frameworks for conceptualizing and characterizing MTE knowledge. Of these, we categorized 10 as proposing Complete Frameworks for MTE Knowledge and five as proposing Components of a Framework for MTE Knowledge. Additionally, we found one paper (Goos, 2009) that proposed a framework for *analyzing* MTE knowledge, which we will not discuss in this review.

Results: Frameworks for MTE Knowledge

Complete Frameworks for MTE Knowledge

We begin with Mason (1998) who presented one of the earliest frameworks for MTE knowledge. In particular, Mason conceptualized MTE knowledge not as different types of knowledge, but rather as different levels of awareness. Mason identified the key notions underlying teaching practice as the nature of awareness and the structure of attention (which encompasses the locus, focus, and form of attention moment by moment). Teaching teachers involves the refinement and development of a complex of awareness on all three levels, and this is manifested in alterations to the structure of attention. He proposed three levels of awareness: (a) *awareness-in-action* involves an awareness of one's actions and own learning, i.e., the development of one's knowledge of mathematical content; (b) *awareness-in-discipline* includes an awareness of one's awareness-in-action, i.e., the development of one's mathematical knowledge needed for teaching so that they can develop others' knowledge of mathematical content; and (c) *awareness-in-counsel* encompasses an awareness of how to develop awareness-in-discipline in others, i.e., the development of one's knowledge for teaching teachers so that they can develop other's mathematical knowledge for teaching. In this way, each level of awareness encompasses all prior levels. For Mason, MTEs develop awareness-in-discipline in PTs, as opposed to just awareness-in-action. Mason points to the unique nature of MTE knowledge and the ways in which it builds on, but is different from, teacher knowledge. His work provided a foundation for much of the research on MTE knowledge that followed.

Zaslavsky and Leikin (2004) expanded Jaworski's (1992) model for the practice of teaching mathematics to better understand the practice of teaching mathematics teachers. Jaworski's (1992) model, known as the "teaching triad of mathematics teachers," highlights the interactions among three important components of teaching: *challenging content for students* (mathematics), *the management of students' learning*, and *sensitivity to students*. Zaslavsky and Leikin created analogous terms for knowledge important to the teaching of teachers: *challenging content for mathematics teachers*, *the management of mathematics teachers' learning*, and *sensitivity to mathematics teachers*. In developing their "teaching triad of MTEs," Zaslavsky and Leikin considered Jaworski's "teaching triad for mathematics teachers" to be a subdomain of MTE knowledge, contained within the component of *challenging content for mathematics teachers*.

Similarly, Perks and Prestage (2008), reflecting on their work with PTs and their experiences as teachers themselves, proposed the "teacher-educator knowledge tetrahedron," positioning their entire "teacher knowledge tetrahedron" framework (Prestage & Perks, 1999) as a subdomain of MTE knowledge. Both frameworks highlight the interactions among four aspects of classroom practice: *teacher knowledge*, *professional traditions*, *practical wisdom, and learner knowledge*. However, in the teacher-educator knowledge tetrahedron, the learners in question are PTs and the teachers in question are MTEs. For Perks and Prestage, teacher-educator knowledge refers to the knowledge MTEs develop over time as they teach PTs; professional traditions refer to knowledge of teacher preparation coursework and research on mathematics teacher education; practical wisdom refers to the tasks and activities used with PTs; and, learner knowledge refers to the content that PTs need to understand. Notably, the teacher knowledge tetrahedron (Prestage & Perks, 1999) is entirely contained within the learner knowledge portion of their teacher-educator knowledge tetrahedron.

Reflecting on her work as an MTE, Chauvot (2009) conceptualized MKTT as consisting of different subdomains that encompass the varied responsibilities of a teacher educator who works with PTs. Specifically, she constructed a knowledge map consisting of subject matter content knowledge, PCK, and curricular knowledge that parallel knowledge domains for teachers described by Shulman (1986), as well as subsequent research on teacher knowledge (e.g., Ball et al., 2008). Chauvot's model expanded upon Shulman's work by placing all three of his domains of knowledge for teaching within the *subject matter content knowledge* of MTEs. She also extended several of the domains identified by Ball and colleagues (2008) and described how they are relevant to her work as a MTE-researcher (MTE-R), including knowledge of how to develop PTs' specialized and PCK and knowledge of how to engage PTs with content in ways that are connected to teaching. Chauvot also included the notion of *knowledge of context*, describing this knowledge subdomain for MTEs as including an understanding of contextual factors affecting the teachers with whom they work, e.g., standards and policies for teacher preparation programs, state teacher certification, and national accreditation. Like others, Chauvot's framework includes a teacher knowledge framework as one of the subdomains of MTE knowledge.

Shaughnessy and colleagues (2016) expanded upon the *instructional triangle* suggested by Cohen and colleagues (2003) by positioning the instructional triangle for teacher knowledge (i.e., interactions among teachers, students, and content) as the content knowledge needed by MTEs. Furthermore, they proposed analogous subdomains of MTE knowledge that parallel those of the MKT framework offered by Ball and colleagues (2008), arguing that MKT is a subdomain of MTE knowledge. These subdomains include *MTE common content knowledge* (e.g., knowledge of how to explain multi-digit subtraction that allows PTs to engage in this instructional practice); *MTE knowledge of content and students* (e.g., knowledge of common errors that PTs tend to make when engaging in instructional practices like regrouping using base-10 blocks); and *MTE knowledge of content and teaching* (e.g., knowledge of the types of tasks, representations, etc., that are useful in helping PTs learn an aspect of mathematics teaching).

Hauk and colleagues (2017) also expanded upon the MKT framework offered by Ball and colleagues (2008) in their conceptualization of MTE Knowledge, which they call Mathematical Knowledge for Teaching Future Teachers (MKT-FT). They argued that akin to the ways in which teachers require specialized mathematical knowledge for teaching students, MTEs require specialized knowledge specific to helping PTs develop MKT. The "subject matter" for MKT-FT is a combination of mathematics and mathematics education, as they conceptualize MKT becoming MTEs' common content knowledge. They then propose a framework for MKT-FT PCK, which builds upon a framework for teacher PCK proposed by Hauk and colleagues (2014). By adding a fourth domain, *knowledge of discourses*, connected to each of the three components of PCK in the framework offered by Ball and colleagues (2008), this model for teacher PCK becomes a tetrahedron with vertices that represent anticipatory, curricular, and implementation thinking. Hauk and colleagues (2017) expanded this tetrahedron model for teacher PCK to create an analogous tetrahedron to model MTE PCK, where the subdomain of knowledge of content and students for MTEs contains the entire framework for teacher PCK. The authors describe this subdomain as including knowledge of how to support PTs' development of MKT, as well as knowledge of how to engage PTs in learning to unpack mathematical ideas in ways needed for teaching students. Hauk and colleagues concluded by illustrating ways in which MTEs have used the MKT-FT framework in designing and implementing teaching-related tasks with PTs.

The conceptualization of MKTT that we have proposed (Castro Superfine et al., 2020; Olanoff et al., 2018; Welder et al., 2017) similarly extends from and is connected to the domains of MKT (Ball et al., 2008). We posit that akin to how MKT is composed of subject matter knowledge and PCK, MKTT is composed of subject matter knowledge for MTEs (including MKT) and PCK for MTEs (for facilitating PTs' learning of MKT). We conceptualize MTE-subject matter knowledge as being composed of three subdomains analogous to those comprising subject matter for teachers: *MTE common content knowledge* (which includes the entire framework for MKT), *MTE specialized content knowledge* (mathematical content knowledge that is specific to developing PTs' MKT), and *knowledge at the mathematical horizon for PTs*. We conceptualize MTE-PCK as being composed of three subdomains analogous to those comprising PCK for teachers: *knowledge of content and PTs* (i.e., MTE-knowledge of content and students), *knowledge of content and teaching PTs* (i.e., MTE-knowledge of content and teaching), and *knowledge of curriculum for PTs* (i.e., MTE-knowledge of curriculum). Our conceptualization of MKTT consists of not only the mathematical knowledge needed by teachers but also specialized knowledge of content that is unique to teaching PTs and knowledge of how to facilitate PT learning (i.e., relearning (Castro Superfine et al., 2020)). Like Beswick and Chapman (2012), we consider MKTT to be an elaborated extension of teacher knowledge that also includes domains of MTE knowledge that are characteristically different from teacher knowledge.

The most recently offered framework for MTE knowledge was published in a chapter of a book on the learning and development of MTEs edited by Goos and Beswick in 2021. Based on a review of research with and about mathematics teachers, Escudero-Avila and colleagues (2021) constructed a framework for MTE knowledge composed of seven subdomains, the last three of which the authors consider to be aspects of MTE PCK: 1) *mathematical knowledge*, which includes both knowledge of mathematics and MKT, 2) *knowledge about teachers' PCK*, which includes theories of teaching, key features in learning mathematics, and learning standards, 3) *knowledge about mathematics teaching practices and skills*, 4) *knowledge about professional identity*, 5) *knowledge of the features of the professional development of mathematics teachers*, 6) *knowledge of teaching the content of initial mathematics teacher education programmes*, and 7) *knowledge of the standards of mathematics teacher education programmes*.

In contrast to all of the frameworks discussed above, in the concluding chapter of a volume on MTE knowledge and practice that she edited, Jaworski (2008b) suggested that there are aspects of teacher knowledge that are unique to teachers, just as there are aspects of MTE knowledge that are unique to MTEs. In doing so, she conceptualized the relationship between MTE knowledge and teacher knowledge using a Venn diagram. Similar to Chavout (2009), Jaworski posits that unique to MTE knowledge is the professional and research literature related to mathematics teaching and learning, including knowledge of theories of learning and teaching and knowledge of methodologies of research focused on learning and teaching in educational systems. MTEs utilize their knowledge of methodologies used to study teaching and learning in schools as they work with PTs both in and out of school settings. According to Jaworski, knowledge unique to the needs of teachers, and not necessarily needed by MTEs, includes knowledge of school contexts and elementary mathematics curricula.

Components of a Framework for MTE Knowledge

Five articles do not include complete frameworks for MTE knowledge, but rather, they present components of a framework. Building on Shulman's (1986) subdomain curricular knowledge, in particular, Chauvot (2008) characterized what such knowledge entails for MTEs. Relevant to this review, she identified four components of curriculum knowledge for MTEs based on her experiences as an MTE and as a mathematics education researcher. These components include (a) *knowledge of programs and materials* (e.g., different models for teacher preparation, textbooks, and materials for use in courses for PTs), (b) *knowledge of indications and contraindications of curricula* (e.g., use of curricula or program materials in particular circumstances and effectiveness of curriculum programs), (c) *lateral curriculum knowledge* (e.g., knowledge of other courses PTs are enrolled in), and (d) *vertical curriculum knowledge* (e.g., knowledge of coursework that precedes and follows current courses in which PTs' are enrolled). Chauvot concluded by highlighting the use of MTE curricular knowledge in current studies of MTEs' professional learning, arguing for the centrality of curricular knowledge in MTEs' work.

In their studies of an MTE's practice, Chick and Beswick (2013; 2017) proposed a framework for the subdomain of MTE PCK, building their descriptions of PCK for MTEs from descriptions of the PCK teachers require. Analyzing the teaching practice of the first author, Chick and Beswick identified several components of MTE PCK, including knowledge of examples, curriculum, student thinking, and common misconceptions, among others. Using vignettes of practice from the first author's practice, they provided evidence of the existence of the various components, illustrating ways in which such knowledge is leveraged as an MTE teaches PTs. For each component, they identified ways in which such components of MTE knowledge are similar to and different from teachers' knowledge.

Olanoff (2011) used observations of and interviews with three MTEs teaching fraction multiplication and division concepts, to identify several components of MKTT. Unlike other authors, Olanoff examines the components of the domain of MKTT, with a particular focus on the knowledge components leveraged while teaching a particular concept to PTs. These components include knowledge of (a) multiple representations of the topics, how the representations relate to other topics, and which representations best support PTs in making connections, (b) how to set specific goals for student learning, and (c) how to design and use assessments effectively. Like Chick and Beswick (2013; 2017), Olanoff provided evidence of the existence of MTE knowledge components that are unique to MTEs.

Felton-Koestler (2020) proposed a framework for *knowledge for sociopolitical mathematics teaching* (KSMT), knowledge that teachers at all levels, including teacher preparation, need for addressing issues of equity and social justice by what he calls *mathematizing sociopolitical issues*. This framework extends MKT, which he uses as a blanket term to address the specialized knowledge for teachers and MTEs, to include knowledge of sociopolitical issues and knowledge of sociopolitical curriculum. To have and develop KSMT, teachers and MTEs must be aware of current sociopolitical issues and be able to turn a critical lens on how they are presented in the general discourse. This work goes beyond just understanding the effects of individual biases on current events to include institutional and structural forms of oppression. Although this framework is generalized to both teachers and MTEs, Felton-Koestler does identify a need for future work to address differences in KSMT for teachers and MTEs. Regardless of these potential differences, it is noteworthy to consider KSMT as a component of MTE knowledge.

Discussion

There is general consensus within the teacher education community that the knowledge MTEs require in their work with PTs includes not only the knowledge teachers need to know but also unique elaborations of that knowledge. In fact, many of the articles we reviewed conceptualize MTE knowledge as an extension of teacher knowledge. That is, these frameworks not only position teacher knowledge as a subdomain of MTE knowledge but also partition MTE knowledge into subdomains similar to those found in frameworks for teacher knowledge. In our previous work (Castro Superfine et al., 2020; Olanoff et al., 2018; Welder et al., 2017), similar to Hauk and colleagues (2017), we propose a fractalization metaphor to describe the ways in which various articles conceptualize MTE knowledge as the visualizations of many of these frameworks resemble part of a fractal. We use the term *fractalization* to refer to the process by which one component or subdomain is entirely contained within a larger subdomain, where the larger subdomain is analogous in structure to the smaller one. In many instances, a teacher knowledge framework becomes the content knowledge subdomain of a framework for the knowledge needed by MTEs. We refer to this fractalization metaphor throughout the discussion.

Three main themes emerged from our review of frameworks for MTE knowledge. First, many of these frameworks build on existing frameworks for teacher knowledge, and in many instances, represent fractalizations of teacher knowledge frameworks (e.g., teaching triad (Cohen et al., 2003), instructional triangle (Jaworski, 1992), teacher knowledge tetrahedron (Prestage & Perks, 1999)). Therefore, many frameworks for MTE knowledge included a teacher knowledge framework in its entirety as one of its subdomains. Only Jaworkski (2008b) proposed a Venn Diagram to suggest that teachers require additional knowledge (e.g., school context, elementary curriculum) not needed by MTEs in their work with PTs. Furthermore, researchers conceptualized certain subdomains (and related components) of MTE knowledge as being "meta" forms of analogous teacher knowledge subdomains (e.g., Chauvot, 2009; Hauk et al., 2017; Perks & Prestage, 2008; Zaslavsky & Leikin, 2004). For example, similar to Shaughnessy and colleagues (2016), we (Castro Superfine et al., 2020; Olanoff et al., 2018; Welder et al., 2017) have proposed MTE knowledge subdomains analogous to the MKT framework from Ball and colleagues (2008). These include MTE common content knowledge (which contains MKT), MTE knowledge of content and students, and MTE knowledge of content and teaching. In other words, as teachers of teachers, MTEs require similar types of knowledge needed by teachers, but MTEs need knowledge of these subdomains in ways that are specific to teaching PTs. Thus, we posit that fractalization can be a useful metaphor for conceptualizing MTE knowledge.

Second, despite some overall similarities, there are important differences in the subdomains of the frameworks we reviewed. Broadly speaking, all of the knowledge frameworks in our review include some or all of four main subdomains representing extensions of teacher knowledge domains (e.g., Ball et al., 2008; Shulman, 1986): knowledge of content, knowledge of curriculum and context, knowledge of PTs, and knowledge of ways of supporting PT learning. However, some frameworks included subdomains unique to MTEs, such as Zaslavsky and Leikin's (2004) sensitivity to mathematics teachers (PTs). Considering the uniqueness of PTs as a population of learners, this knowledge includes understanding that PTs often enter teacher preparation programs with limited conceptual understandings of mathematics. As such, the work for MTEs is to support PTs' relearning of mathematics, which involves PTs ultimately reconstructing their previously developed knowledge of mathematics (Author 2020; Zazkis, 2011). Further, Chauvot (2009) included MTEs' knowledge of mathematics education research as part of the knowledge needed to effectively prepare PTs. In fact, Chauvot posited that knowledge of research in mathematics education underlies all other knowledge subdomains MTEs require in their work with PTs (e.g., knowing the research on how children learn can inform MTEs' content course design). This subdomain echoes other researchers who describe conducting research in mathematics teacher education as a form of professional learning (e.g., Rowland et al., 2014). Notably, these different subdomains are unique to MTEs and arguably do not have analogous subdomains in a teacher knowledge framework. In addition, there are important differences in the grain size at which researchers conceptualized MTE knowledge. While the majority only identified subdomain levels using the four main subdomains described above, a few deconstructed their subdomains into components. For example, Chauvot (2008) described components of MTE curricular knowledge (e.g., lateral and vertical curricular knowledge); whereas we (e.g., Castro Superfine et al., 2020) specified components of MTEs' content-specific knowledge (e.g., specialized content knowledge, knowledge of content and teaching). Such variation is indicative of the fragmented research landscape on MTE knowledge.

A third theme that emerged is the process by which MTE knowledge has been conceptualized, which has largely been from a knowledge-in-practice perspective. Through an analysis of various artifacts of practice and reflections on MTEs' work with PTs, researchers applying a knowledge-in-practice perspective to the work of MTEs highlight the types of knowledge leveraged as they teach PTs, reinforcing the dynamic relationship between knowledge and practice. A majority of articles on MTE knowledge describe a self-study process wherein one or more authors reflect on and describe the types of knowledge they leveraged in their work with PTs (e.g., Masingila et al., 2018; Muir et al., 2017; Zazkis & Mamolo, 2018). Such a process is productive for understanding the types of resources (e.g., experiences, beliefs, knowledge) that impact MTEs' practice to support drawing on different types of knowledge in light of their expertise. However, more work needs to be done to explicate the analytic processes taken in research on MTE knowledge so that others can employ similar methods and contribute to the growing knowledge base on MTEs. Moreover, while self-studies (i.e., research *by* MTEs) provide unique insights into the nature of MTE knowledge, the research base would be strengthened by research *on* MTEs to corroborate and further specify the various MTE knowledge subdomains and components.

The goal of this review was to explore the theoretical underpinnings of the existing frameworks for MTE knowledge. We find that MTE knowledge frameworks that are fractalized versions of teacher knowledge frameworks tend to miss the same aspects of MTE knowledge that are missing from teacher knowledge frameworks. For example, Felton-Koestler's (2020) KSMT framework addresses MTE's knowledge of equity, a domain that does not explicitly appear in any of the fractalized frameworks. Additionally, none of the frameworks discussed the need for MTEs to be knowledgeable of classroom technologies. The COVID-19 pandemic and subsequent shifts to online courses demonstrated the need for MTEs to have knowledge of relevant technological tools, not only for their practices as teacher educators but also for preparing PTs to use such tools in their future classrooms. There exists a corpus of literature on *technological pedagogical and content knowledge* (TPACK) for mathematics teachers (e.g., Kohler & Mishra, 2009), but this work has not yet been integrated into frameworks for MTE knowledge. To address some of these missing aspects and further build a mutually agreed-upon knowledge base for MTEs, researchers might analyze MTEs' reflections of their teaching practices to understand their knowledge-in-practice and the types of knowledge MTEs draw on in their work with PTs. Such a knowledge base could inform the design and implementation of opportunities to improve the preparation and professional development of MTEs.

This study presents an extension of the validity argument for the PCK-Fractions measure. PCK-Fractions is designed to assess the effectiveness of professional experiences in facilitating teachers' pedagogical content knowledge (PCK) for children's fraction reasoning in grades 3-5. We examined data across 101 participants from two Midwest universities including non-education majors, education majors, and education majors with grade 3 to 5 math field experiences. Results provide additional validity evidence for the PCK-Fractions. Namely, evidence indicates differences in scores between groups of participants—preservice teachers grade 3 to 5 field experience had higher scores than those without, and all preservice teachers had higher scores than non-education majors.

Keywords: Mathematical Knowledge for Teaching; Rational Number.

Introduction

Mathematical knowledge for teaching (MKT) is a practice-based theory that investigates the nature of professional knowledge of mathematics that teachers use to make effective instructional decisions to help students' learning (Ball & Bass, 2002, Ball, Thames, & Phelp, 2008). MKT as a theory and set of constructs has been largely developed and disseminated with quantitative assessments across mathematics content. For instance, many scholars designed different kinds of MKT assessments in geometry, rational numbers, and number sense from grades K to 12 (Herbst & Kosko, 2014; Hill et al., 2008; Kazemi & Rafiepour,2018; Khakasa & Berger, 2016). MKT includes two primary domains of content knowledge (CK) and pedagogical content knowledge (PCK). While both domains are considered vital to effective teaching, most MKT assessments either target teachers' CK explicitly (Lo & Luo; 2012), or include both CK and PCK in the same assessment (Depaepe et al., 2015). There has been little attention to designing MKT assessments that focus on PCK as a domain worthy of investigation on its own (Copur-Gencturk et al., 2019; Hill et al., 2008; Zolfaghari et al., 2021). Rather, by incorporating PCK assessments within efforts to develop CK measures, many items designated as 'PCK items' have later been found to assess CK instead (Copur-Gencturk et al., 2019; Hill et al., 2008). This led to Zolfaghari et al. (2021) focusing on a PCK exclusive measure for fractions. Piloting items with a focus on the 'task of teaching' of assessing children's fraction reasoning resulted in a more accurate representation of the domain.

The current study is our continued effort to validate our framework for how PCK for Fractions develops, and our associated construct map for the PCK-Fractions measure (Zolfaghari et al., 2020, 2021). In this validation process, we hypothesize that PCK develops in a particular way that is useful in designing items of varying difficulty – described as *construct maps* within validity argument literature. We also found that exposure to coursework and field experience had a positive association with PCK scores. However, there was a need to better examine this phenomenon with a larger sample. Given prior results (Zolfaghari et al., 2020; 2021), we conjecture individuals' experiences inform the development of their PCK. In particular, we sought to understand the degree to which majoring in teacher education and having certain forms of field experience affected PCK for fractions.

Theoretical Framework

MKT is "the mathematical knowledge used to carry out the work of teaching mathematics" (Hill et al., 2005, p.373). It involves abilities such as analyzing and interpreting students' reasonings and determining the related materials and information based on that. Mastering these skills promotes good instruction and, as a result, effective mathematics learning for students. The emphasis on knowledge of teaching a subject was primarily introduced by Shulman (1986) as PCK. Later, Ball and colleagues applied Shulman's theory to mathematics, thus framing MKT (Ball et al., 2008). MKT contains two primary domains of CK and PCK, with each of these domains consisting of several subconstructs (Hill et al., 2008b). To explore teachers' MKT, various assessments were designed within several mathematical topics, including geometry (Herbst & Kosko, 2014), rational numbers (Kazemi & Rafiepour, 2018), multiple mathematical topics at the secondary level (Khakasa & Berger, 2016) and elementary level (Hill et al., 2008), statistic subject (Siswono et al., 2018), and so forth. These various scholars explored several components of MKT, with many finding that MKT scores aligned with teachers' professional experience (Herbst & Kosko, 2014) and effective instruction (Hill et al., 2008).

MKT is professional knowledge; thus, various forms of professionalized experience have been found to affect and/or facilitate MKT. For instance, in examining the effect of types of experiences on teachers' MKT, Hill (2010) found characteristics such as grade taught, math content course, years of experiences, and math self-concept associated with teachers' MKT. Although these associations vary in terms of their strengths. Jakobsen et al. (2011) noted the grade level at which the teachers taught was related to their MKT scores. Similarly, in the study of mathematic teachers grade 3-7, Copur-Gencturk (2020) found that teachers with experiences teaching higher grades had stronger MKT scores. However, the number of years of mathematics teaching had a weak associate with teachers' MKT scores.

Research on MKT for fractions typically includes both domains of CK and PCK (Depaepe et al., 2015; Tirosh, 2000; Trobst et al., 2018). For instance, in studying PSTs' knowledge of teaching fractions, Tirosh (2000) found that most PSTs know how to solve fraction division (CK) but are unable to explain children's strategy or misconception (PCK). Similarly, examining secondary and elementary preservice teachers, Depaepe et al. (2015) noticed that PSTs with significant differences in demonstrated CK did not demonstrate differences in their PCK. A common premise across such studies is that CK is a prerequisite for higher PCK. Indeed, in describing PCK applied to assessing a student's error, Hill et al. (2008) noted that "teachers must be able to examine and interpret the mathematics behind student errors prior to invoking knowledge of how students went astray" (p. 390). Yet, Trobst et al. (2018) found that PSTs were able to increase their PCK despite limited CK. Coupled with Depaepe et al.'s (2015) findings of no statistical relationship between the constructs, there appears to be inconsistent evidence towards the common stance that CK is a prerequisite for PCK.

To be clear, there is a large body of evidence that supports a relationship between CK and PCK (Agathangelou & Charalambous, 2020; Depaepe et al., 2015; Hill et al., 2008). However, various findings in reports such as those described in the prior paragraph should not be disregarded. We believe the inconsistent findings in the literature point to an issue noticed by Hill et al. (2008) and expanded upon by Copur-Gencturk et al. (2019): development of PCK measures has focused more on CK than PCK and the resulting assessments have led to conflicting reports and an incomplete understanding of PCK as a theoretical construct. For this reason, PCK-Fractions was designed exclusively to focus on PCK (Zolfaghari et al., 2020; 2021), with an initial focus on the PCK sub-domain of knowledge of content and students (KCS). This targeted focus allowed us to decrease the risk to validity in designing unintended items that might measure CK instead of PCK.

Measuring PCK-Fractions

The intended purpose, or use, of the PCK-Fractions measure is to assess the effectiveness of professional experiences in promoting or facilitating teachers' PCK for upper elementary fractions concepts. The present version of PCK-Fractions focuses on the KCS domain, and represents one of several studies that collectively construct a validity argument for PCK-Fractions (Zolfaghari et al., 2020; 2021). Hill et al. (2008) define KCS as "used in tasks of teaching that involve attending to both specific content and something particular about learners" (p. 375). *Tasks of teaching* are the fundamental means Ball and colleagues have designed items for MKT, focusing on what a teacher must do in a specific aspect of the profession. For KCS, we focused on assessing children's reasoning as the task of teaching for fractions. Zolfaghari et al. (2021) initially adapted the sequence children learn certain fraction concepts but found that "student actions being assessed [were] a better explainer of why certain items have different difficulties" (p. 241). Table 1 presents a construct map developed from the initial pilot data (Zolfaghari et al., 2020; 2021). At Level 1, teachers are able to assess how children partition, fragment, or fair share fractional parts. At Level 2, teachers assess whether and how children coordinate parts to whole. Specifically, children may or may not have developed part-whole reasoning, but a teacher is able to distinguish between children's actions demonstrating such reasoning or not. Level 3 demonstrates an ability to assess how children compare and use different fractions. Level 4 focuses on a teachers' ability to assess how children coordinate non-unit fractions with the whole – actions often demonstrated in fraction multiplication and division.

Table 1: Construct map for PCK-Fractions.

Level	Description
Level 1	Assess children's creation and/or use of fractional parts.
Level 2	Assess children's coordination of parts and of the whole.
Level 3	Assess children's creation and use of non-unit fractions & comparison of fractions.
Level 4	Assess children's coordination of non-unit fractions with the whole & comparison of fractions and wholes.

Key in understanding the role of the construct map presented in Table 1 is that it is child-focused, not task-focused. Rather, a teachers' ability to assess children's reasoning begins with a focus on the child. As an example, consider item F44 in Figure 1. The mathematical task at-hand is fraction addition that requires the child to convert to a common denominator to obtain a correct answer. However, that's not what this child does. Rather, Tim counts the total shaded and unshaded and draws a representation illustrating that total. Thus, Tim is coordinating parts of the fraction, but without maintaining the whole. A teacher correctly assessing Tim's reasoning is, therefore, at Level 2 or higher. This focus on the student's reasoning within a mathematical task was key in aligning items with the construct map (Table 1). Additionally, all PCK-Fraction items were designed as multiple choice. Most items followed a common template in wording, as evidenced in responses for F44 (Figure 1). Specifically, response options were adapted from fraction diagnostic literature written for teachers (i.e., Battista, 2012; Hackenberg et al., 2016) and were listed in order of lower to higher level reasoning evidenced by the student depicted in the prompt. This design was purposeful, as prior data collection suggested randomization of such levels and changes in language decreased consistency in responses across items (Zolfaghari et al., 2020; 2021).

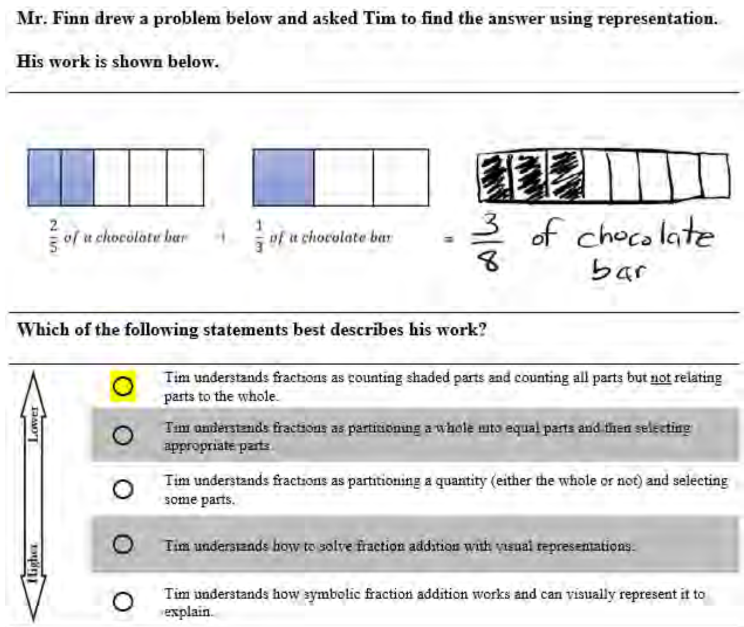

Figure 1: Example item (F44) from PCK-Fractions with correct response highlighted.

As noted previously, the present study is one of several papers that present evidence towards a validity argument for PCK-Fractions (Zolfaghari et al., 2020; 2021). Validity arguments consist of various claims regarding the validity of a measure, and evidence that warrants such claims (Kane, 2012). Further, such arguments are conveyed through “the accumulation of evidence from various sources for claims” (Krupa et al., 2019, p. 11) and “should occur over several studies in order to provide adequate warrants for claim of inference for a measure” (Kosko, 2019, p. 19). Prior validity evidence for PCK-Fractions suggests a unidimensional construct that aligns with the construct map presented in Table 1 (Zolfaghari et al., 2021). There is evidence that exposure to mathematics methods coursework facilitates PCK-Fractions, but prior samples also represented skew relative to higher scorers (Zolfaghari et al., 2020; 2021). Rather, Zolfaghari et al. (2021) identified a need for sampling participants with a much wider range of ability to better support the validity argument for PCK-Fractions. The present study focused efforts at recruiting a sample we believed would have a wider range in ability, but in doing so we also sought to align this range in ability with the construct map itself. Rather, we sought to better understand how participants with little to no exposure to teaching (outside of once being an elementary student) and those with more experience in such contexts would respond to our items. In doing so, we also sought to understand how responses aligned with our construct map. These efforts fulfill the purpose of the study which is to understand the effect of different types of professional experience on the PCK-Fractions measure by investigating the validity argument process. Particularly, we addressed the following research question:

How does the construct map for revised PCK-Fractions measure align with validity evidence for individuals with different professional teaching experiences?

Method

Participants included 101 undergraduate students enrolled in two Midwest universities. To ensure a sample with a wider range of PCK-Fraction scores, both high and low, we recruited undergraduate students enrolled in a Marketing 101 course (*n*=39) who were not, had not, and did not plan to major in education. Non-education majors primarily included financing, marketing, fashion design, and business. We also recruited participants from 36 early childhood (certification preK to grade 5) and 26 middle childhood majors (certification grades 4-8) across both universities (*n*=62). Because grades 3-5 (the focus grade band for PCK-Fractions) was included in the teacher licensure for both majors, these participants were asked to report whether, and in which grade levels, they had field experience. This resulted in 21 education majors reporting having grades 3-5 field experiences that included teaching mathematics (20.8% of total sample). Across the entire sample, almost all participants self-identified as white (97%). Also, 79.2 % of the participants self-identified as female, 18.8 % male and 2% nonbinary.

Measure

As previously described, PCK-Fractions items were designed to measure teachers' PCK for grades 3-5 students' fraction reasoning. Prior versions of the PCK-Fractions measure included 15 questions, which included several 'multiple-response' items that allowed participants to select 'all that apply' (Zolfaghari et al., 2020). However, following the pilot of the measure, such items were either revised into multiple-choice items or removed to reduce variance in response data. Previous Rasch modeling of the PCK-Fractions measure indicated sufficient item reliability of .90, but less than ideal person reliability of .41 (Zolfaghari et al., 2021). A primary reason identified for the poor person reliability was a negative skew in participants' scores with "75.3% of participants having a score above 0.00, or average ability" (p. 238). The current version of the measure includes 19 multiple-choice items (see Figure 1 for an example item). As noted earlier, these items were revised to further improve item reliability, reduce variance in responses, and better align theoretically to the improved construct map. Responses were all coded dichotomously (0 = incorrect, 1 = correct) for Rasch modeling.

Analysis and Findings

This paper examined validity evidence for revised PCK-Fractions and its construct by adopting the *Standards for Educational and Psychological Testing* (AERA et al., 2014) and building upon the prior validity evidence for PCK-Fractions measure (Zolfaghari et al., 2020; 2021). For the present study, we focused particular on validity evidence related to response processes andinternal structure. Evidence towards *response processes* focuses on how participant responses correspond with the intended theoretical design of the items. Evidence towards *internal structure* was used to provide study how response processes correspond to the conceptual framework for the revised PCK-Fractions' measure. The Rasch analysis and the data from one-way ANOVA allowed us to seek the validity evidence for revised PCK-Fractions as well as how participants' different level of experiences related their scores in PCK construct map.

Rasch Modeling

Rasch modeling was conducted to examine internal structure validities for PCK-Fraction assessment. Namely, we used item and person reliability aligned with unidimensionality and fit statistics to examine the validity of survey (AERA et al., 2014). The initial item analysis indicated the acceptable item reliability of .95, which exceeded the acceptable threshold of .90 (Linacre, 2021). Likewise, the item separation index showed a sufficient value of 4.23 (above 2.0 implies a good differentiation of item difficulty). In particular, this item separation value (4.23), indicates the items can be differentiated into four different tiers, which coincidentally aligns with the four levels of construct map (see Table 1). This result suggests that the hierarchy of difficulty of the items for PCK-Fractions would remain constant for different samples in similar contexts. Additional psychometric results from the average mean square for item infit (MNSQ= 1.00, Z=.00) and outfit (MNSQ= 1.01, Z= .10) provide another indicator that the data fit the model. These findings suggested that our revised PCK-Fractions measure represents a significantly wider range of item difficulties than the initial PCK-Fractions—improving from an item reliability of .90 and item separation of .30 (Zolfaghari et al., 2021) to item reliability of .95 and item separation of 4.23. Collectively, these results provide validity evidence that the measure is aligned to the construct map in Table 1.

Despite otherwise ideal psychometric data, the person reliability estimated for participants was .42 which is lower than the acceptable threshold of near or above .80. Further analysis showed that, although the person reliability was low, the average mean square for person infit (MNSQ= .99, Z=.00) and outfit (MNSQ= .99, Z= .00) aligned with Rasch Model expectation. This indicated that all participants' responses to the items behaved as expected (Bond & Fox, 2015). Two potential reasons for a low person reliability are: 1) the spread of item difficulty is too narrow or 2) the ability range of participants assessed is too narrow. In order to examine these issues, the Wright Map was investigated (see Figure 2). As indicated in the Wright Map, items are almost evenly distributed between -2.00 and 2.00 logits. Recalling that item reliability and separation index values were both ideal, this data suggests that the spread of item difficulty was not too narrow. Thus, we further examined the second most common reason for low person reliability.

Mean scores for participants were near the model average score of 0.00 (M = -.14, SD = .65), which did not clearly indicate an issue with skew in responses. To better understand whether, or how, the range of participants may have been too narrow, we visually examined the Wright Map, but distinguished participants into three groups: non-education majors, education majors without grades 3-5 experience, and education majors with grades 3-5 experience. We also juxtaposed a Box-and-Whisker plot to help explore such patterns. Notably, the third quartile is relatively smaller than the fourth quartile, suggesting some skew in the upper half of scores. In particular, this data suggests a need for more participants with higher scores to improve person reliability. The Wright Map in Figure 2 suggests that a targeted sampling of participants with grades 3-5 experience may be warranted in this regard. To test this conjecture, we compared the person reliability of the Rasch model ran with and without participants having grades 3-5 experience. Notably, excluding such participants reduced person reliability from .42 to .37. Note this reduction is not due to sample size but is due to a lower variance in scores. Thus, despite a sample of 101 participants with what visually appears to be a normal distribution (see Figure 2), results suggest a need for more teachers with grades 3-5 experience for our sample to be representative enough to reliably measure PCK across samples.

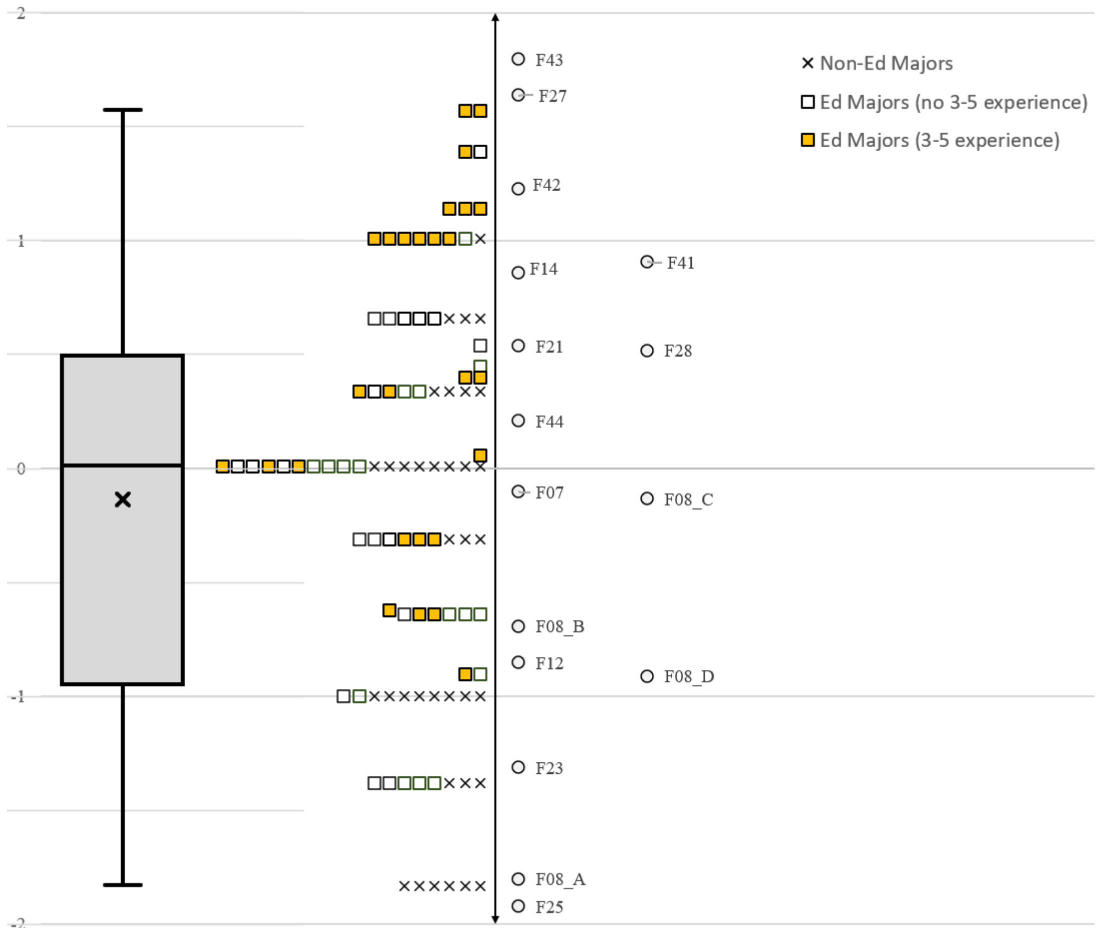

Figure 2: Wright Map for PCK-Fraction measure

ANOVA

The use of a one-way between subjects' analysis of variance (ANOVA) provided evidence to our claim in which differences in PCK scores are associated with participants' professional experiences. We compared Rasch PCK scores of non-education majors, education majors without grades 3-5 field experience, and education majors with such experience. Results from ANOVA found that there was a statistically significant difference between the three groups [F (2, 94) = 11.320, $p < 0.001$]. A Tukey HSD post hoc analysis indicates a statistically significant difference ($p < 0.001$) between the education majors with grade 3-5 experience ($M = 0.16$, $SD = 0.62$) and non-education majors ($M = -0.65$, $SD = 0.74$), as well as statistically significant difference ($p = 0.034$) between education majors with experience and education majors without grades 3-5 field experience ($M = -0.27$, $SD = 0.63$). Comparatively, the Tukey HSD post hoc analysis did not detect a statistically significant difference between non-education majors and education majors without 3-5 experience ($p = .057$). However, non-education majors did have lower PCK-Fraction scores than education majors without grades 3-5 experience, and the p-value was marginally non-significant at the .05 level. A slightly larger sample may have yielded a statistically significant result. Results indicate that differences in PCK-Fractions scores is associated with participants' experience with grades 3-5 students. However, the content and quality of such field experiences were not examined, and further investigation is warranted.

Discussion

This study explored differences in participants' PCK-Fractions scores considering varying professional experiences. Results suggest participants with field experience (particularly with grades 3-5) demonstrated higher PCK scores for fractions than participants without. Additionally, while marginally not statistically significant at the .05 level, education majors tended to have higher PCK scores than non-education majors. Prior studies indicated the importance of teachers having different types of professional experiences including coursework, higher CK, and experience teaching specific grade levels (Agathangelou & Charalambous, 2020; Copur-Gencturk, 2021; Hill, 2010). Our results support some of this prior literature (Copur-Gencturk, 2021; Hill, 2010) as we observed that PSTs' PCK may benefit from having upper elementary field experience. To our knowledge, this paper is the first to compare PCK scores of education and non-education majors. Although it is difficult to distinguish how much upper-elementary field experience may have interacted with some of our participants' coursework, there does appear to be some benefit to pedagogy courses prior to such field experience with education majors lacking grades 3-5 field having much higher PCK scores (M = -.27), than non-education majors (M = -.65).

Results from our psychometric analysis provided strong validity evidence that the PCK-Fractions measure is aligned well with our construct map (see Table 1). Recall that this version of our construct map was a result from analysis in our pilot study (Zolfaghari et al., 2021). Thus, in finding that items designed at specific levels appeared to ordinally fall in the sequence they were designed (see Figure 2), and that our item separation statistic allows for distinguishing four levels of items, we believe there is strong validity evidence for our construct map. This set of findings is non-trivial, as PCK in general is undertheorized. By successfully designing items as child-centered and not task-centered, we believe this study provides guidance to those constructing PCK measures in similar or other domains. Further, the construct map itself provides a framework for examining PSTs' PCK for fractions with or without our PCK-Fractions measure. For example, a PST's explanation of a child's mathematics when viewing a video of their own teaching could be examined in relation to the construct map in Table 1. Such research is needed to further theorize PCK for fractions, as well as other mathematical domains.

The validity evidence from the present study supports and expands that of the initial validation process for PCK-Fractions (Zolfaghari et al., 2020; 2021). Specifically, validity evidence suggests the items in the PCK-Fractions measure are strong and do not appear to need any further revision currently. However, there is a need to sample a wider range of teachers with varying levels of upper-elementary experience. This may include inservice teachers, as well as PSTs' with said experience. Future research in this area may also consider teachers' professional beliefs and other facets.

Keywords: Mathematical knowledge for Teaching, Teacher Knowledge

Purposes of the Study

The question of what knowledge is needed for teaching mathematics has been studied over the last three decades in the community of mathematics researchers and educators. Extensive theoretical and empirical studies have been conducted in this area. However, there is limited systemic review identifying the trends of topics. This study proposes to use a natural language processing method to identify the "unseen" patterns of the topics emerged in all relevant articles published over the last three decades. This study aims to gain insights on what topics get more attention and which other topics are relatively neglected. This study also aims to suggest what areas need to be studied more in mathematics teachers' knowledge to ensure promoting access and attainment in learning mathematics.

Theoretical Framework

This study was built on the theory of mathematics teachers' knowledge (Ball, Thames, & Phelps, 2008; Davis & Simmit, 2006; Peng, 2007; Rowland, Huckstep & Thwaites, 2005; Carrillo-Yañez et al, 2018) that identified the components of it. The previous studies had proposed a slightly different, but similar framework of mathematics teachers' knowledge including subject matter knowledge and pedagogical content knowledge. These studies provided information on the nature of mathematics teachers' knowledge, which helped us to interpret the topics detected by automatic computation.

Methods

This study analyzed the abstracts of 3,485 scholarly articles published in peer-reviewed journals. The quantity of data is the largest in the literature review of mathematics teachers' knowledge within our search scope. Topic modeling was used as an analytical method for this study. Particularly, Latent Dirichlet Allocation (LDA) has been used as a tool for topic modeling.

Results and Implications

Using the topic modeling techniques, eleven underlying topics were found in the articles. The most popular topic was the professional development of mathematics teachers followed by pedagogical content knowledge and students' mathematical understanding. Second, sociocultural context knowledge in teaching mathematics emerged as one topic, which has not been proposed as the component of mathematics teachers' knowledge. Third, the topics were consistent in their popularity over time, which indicates interest in one topic can be quite perpetuating. This study suggests that more diverse topics need to be studied in mathematics teachers' knowledge.

Keywords: Mathematical Knowledge for Teaching, Professional Development, Teacher Knowledge

Here it is presented part of the results of an exploratory study on the application of advanced mathematics topics in the professional development of in-service secondary school teachers. The germ of this work was born during the international conference "Connections between Advanced and Secondary Mathematics: Exploring the Impact of Abstract Algebra on the Teaching and Learning of Secondary Mathematics" (CASM Conference), which took place on May 20-22, 2019, funded by the NSCF-IUSE of the USA. Part of the information shared there was the MET II report. This report stated that courses for teachers should contain content that examines high school mathematics from an advanced standpoint throughout their courses and not just as a capstone. Secondary teacher's educators, therefore, following the MET II recommendations, should be interested in generating explicit connections between advanced and secondary mathematics to support or enhance teacher's teaching.

Following this line of thought, we have then applied variation theory (Koichu et al, 2016; Leung, 2012; Marton, 2015) for setting up a four-month online course for professional development of secondary teachers. The content of learning we have chosen was how to find the general solution to Diophantine equations (see Cárdenas et al, 1988; Guelfond, 1981), a topic of superior (or abstract) algebra that immediately could be connected to solving linear (and quadratic) equations in integers, a topic of secondary mathematics. Diophantine equations is a topic mathematically interesting because to find their general solution all basic properties of integers enter in play This topic could be considered as an introduction to Numbers' Theory.

In this work we were interested in exploring how we could use variation theory to approach finding the general solution of Diophantine equations in a teacher professional development course, and how this approach could be reflected in secondary teachers' practice. In other words, what would be possible connections, established by participant teachers, between the general solution of Diophantine equations and the mathematics to be taught in high school?

Some Results

We observed three different connections between the general solution of Diophantine equations and the math participants taught in high school, namely: 1) Transforming fractions from improper to continuum; 2) Getting a general formula to solve linear Diophantine equations using the Euclid's Algorithm; 3) Getting a general formula to solve Diophantine equations of second degree. That evidenced participants' pedagogical content knowledge in teaching (see Petrou & Goldin, 2011), in this case associated with the topic studied.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Research Methods

One of the challenges for researchers interested in studying teachers' mathematical knowledge is characterizing that knowledge in a way that allows it to be visible in practice. Some high-profile projects have attempted to create instruments for this (e.g., IQA (Boston, 2012)) and researchers in the United States have considered a variety of ways to apply the "egg" proposed by Ball and colleagues (Ball et al., 2008; Hill et al., 2008). Another approach has been proposed by Rowland and his colleagues (Rowland, 2013; Rowland et al., 2005; Rowland & Turner, 2007; Turner & Rowland, 2011) who have developed a framework called the Knowledge Quartet (KQ) for characterizing teacher knowledge by organizing observable activities into four discrete categories: Foundation, Transformation, Connection, and Contingency.

The developers of the KQ have provided numerous codes that emerged through their work with preservice teachers in the United Kingdom. The codes are all observable behaviors that fit into one of the four categories. For example, "Identifying Errors" is one way a teacher may demonstrate Foundation knowledge or "Making Connections between Procedures" can demonstrate Connection knowledge.

In our work, we were interested in understanding how one seventh grade teacher, Matt (pseudonym), applied his content knowledge of proportional reasoning in four video recorded lessons. We adopted the KQ for this analysis. However, as we began to apply the KQ, we began to understand that it was developed for a different teaching and learning context than we saw in Matt's classroom. To this end, we created additional codes, situating them within the four knowledge categories by using the definitions provided by Rowland and his colleagues (Rowland & Turner, 2007).

In this poster, we will present the original KQ code set in addition to the added codes necessary to make sense of Matt's knowledge in his classroom teaching. We will also include discussion of the original codes that were cut from our analysis and those that were merged. Examples from the data will be included to illustrate the needs for these changes. We discuss the implications which consider the extent to which the mathematical knowledge teachers need for teaching is culturally grounded. A teacher who does not demonstrate proficiency with the original KQ codes may have other proficiencies valued by the math education community that may not be captured by the KQ.

Chapter 7:

Mathematical Processes and Practices

TRANSITION FROM PROBLEM SOLVING TO MODELING IN STUDENTS IN HONDURAS

Noé Fernando Aguilar Perdomo
Cinvestav-IPN
noe.aguilar@cinvestav.mx

Claudia Margarita Acuña Soto
Cinvestav-IPN
claudiamargarita_as@hotmail.com

In the present work, we propose to investigate which elements of problem solving could allow the transition to mathematical modeling. The study involved two students from Honduras with standard instruction in problem solving, where one of them has participated in mathematical Olympiads. We consider that the detection and organization of information, the explanation of the results, and the validation processes could be points of contact between these positions and that their adequate management would allow the transition between them. We found that the students were good problem solvers, but only with the support of the researcher did they develop activities of analysis, validation, and determination of the conditions of the problem to achieve school modeling.

Keywords: Problem solving, modeling, metacognition.

Introduction

In the Republic of Honduras, since 2003, mathematics education has been implemented under the problem-solving approach. At the same time, current trends point to the importance of students giving meaning to contextual problems that could enrich their perception of the usefulness of mathematics and that can be used in everyday life, positions that have been part of what has been called school modeling.

Thus, we face Honduran students with a background in problem solving but will soon have to move towards the modeling perspective, which we must prevent.

The essential background for this research considers the formulations of Polya (1989) and Schoenfeld (1985) on problem solving, as well as the positions of educational organizations such as PISA (2015), which establish the objectives and conditions of this position. We also identified that currently, institutions realize that the use and detection of the appropriate strategy are relevant for teaching mathematics. Still, it is necessary to contextualize the problems. We find this phenomenon more clearly in the PISA (2015) position. Over time, they have developed an interest in including skills that traditionally are not considered part of problem solving, which is the basis of their approach. Now they tend to get the benefits that can be obtained from them, for example, when students realize that a problem is associated with specific strategies, where the need to interpret them may arise, in addition to giving a solution which would be bringing them closer to the interests of modeling.

To establish the character and depth of the contents treated in problem solving, we analyzed the official textbooks of Honduras to identify 1. The perspective present in them, and 2. The skills developed based on these materials, so we can say that students in Honduras, from the use of these textbooks, have had some experiences that would allow them to address the problems making use of: 1. The detection of the aspects that are relevant to the task, 2. The approach and identification of the adequate strategies for solving the problems, 3. The organization of the information, and 4. To a lesser extent, the acquisition of tools related to the processes of validation and generalization, aspects that we consider particularly useful for the creation of models.

Referential Framework

In Schoenfeld's (1985) proposal, we identify the dimension called *control*, which refers to the student's ability to realize whether his strategy is going in the right direction and explain his results. Both points could place the student in the metacognition field, which is also related to "monitoring and control" (Schoenfeld, 2016, p.2), where, if the student takes control of his solution process, he can develop an overview of the activities and conditions of the problem, which allows him to increase his chances to solve it correctly.

In our work, by including the development of metacognitive processes, we intend to promote a possible and slight change in the paradigm of problem solving. The object of study is no longer focused solely on recognizing and using strategies to solve problems. Still, it is required to identify the conditions under which it is possible to solve them.

To achieve this paradigm shift, aspects related to decision-making and the interpretation of the problem can be incorporated, including identifying the specific conditions of the problem. If we add to this the realistic contextual component, we would be approaching the field of school mathematical modeling since: "Mathematical models appear when there is a need to answer specific questions in real situations, when decisions need to be made or when it is imperative to make predictions related to natural and social phenomena" (Trigueros, 2009, p. 76).

In this paper, we will consider modeling from a cognitive perspective. In particular, "they foreground how students' thinking leads to modeling while serving as a basis for pedagogical or curricular goals" (Czocher, 2018, p.138).

Students' thinking can be abstracted and illustrated through the structures known as modeling cycles, which establish the nodal points of the process. We will use the proposal of Blum and Borromeo Ferri (2009), which is susceptible, in our understanding, to be used both in problem solving and modeling and which is proposed from four activities: 1. understanding task, 2. Establishing model, 3. using mathematics, and 4. explaining result.

This proposal does not state validation activities; however, these are presented through the cycle iteration, which indicates that it requires validation to be restarted. In addition, when the student can explain his results, he is also developing validation activities.

To achieve this paradigm shift in problem solving, we consider the need to focus on two essential factors 1. The development of metacognitive aspects promotes a reflection on the conditions under which the problem can be solved, and 2. The teacher's role enables a greater understanding of the relationships and implications of the problem, which has as a starting point a recognition of the contextual conditions, which could result in a transition from one position to another.

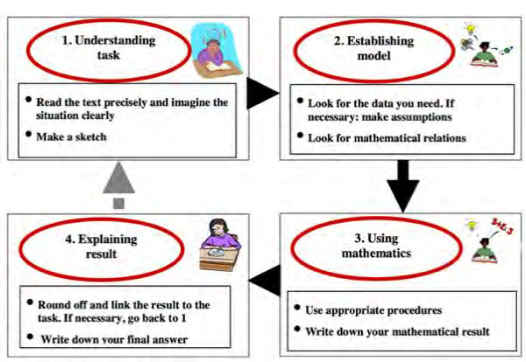

Figure 1: Blum and Borromeo Ferri's Modeling Cycle (2009, p.54)

So, if we consider the definition of modeling competence as a starting point to introduce its teaching, in this case, the one proposed by Niss et al. (2007) that refers to:

> the ability to identify relevant questions, variables, relations or assumptions in a given real world situation, to translate these into mathematics and to interpret and validate the solution of the resulting mathematical problem in relation to the given situation, as well as the ability to analyse or compare given models (p.12)

We are interested in analyzing how metacognitive aspects could promote some of the minimum requirements to develop modeling activities.

Methodology

We developed a qualitative interpretative study to find out how the competencies and skills in problem solving taught, both school and extra-school in Honduras, could serve as a basis for introducing school mathematical modeling and how the transition process from one didactic proposal to the other. Our research hypothesis is that both students who have had regular instruction and those who have acquired additional instruction on problem solving can transition to a didactic proposal based on modeling through relevant problems and collaborative work with the teacher that support the use of metacognitive processes.

The study was conducted in the context of the COVID-19 pandemic in 2021. Two Honduran students of academic excellence participated in the study, both were in the ninth grade at the time of the investigation, and both were 15 years old. Student 1 (E1) has experience in mathematics Olympiads, while student 2 (E2) does not have this experience.

The study was based on 1. The students solved an online questionnaire individually on the GeoGebra platform, which included open-ended questions and the filling in of tables, and 2. From the questionnaire, we detected the level of development of problem-solving skills through four problems, and both students showed: detection of relevant aspects in the problem, organization of information, use of appropriate strategies, as well as good management of the mathematics to solve them.

In the interview-intervention, we asked the students about their procedures and results to deepen the answers to the questionnaire. Also, we took advantage of the incomplete or incorrect questions to understand how the students faced the challenges posed by the tasks, to provoke a metacognitive type of work to observe the possibility of expanding their perception of the requirements of the problem and thus be able to support them in the development of the proposed activities.

Metacognitive reflection in these activities has two functions: The first goes toward explaining the procedure, which can provoke students a need for certainty about the arguments they offer when communicating their solution. The second they can be developed by the need for validation.

In the following section, we will present the analysis and discussion of the data obtained from 1. the answers presented in the questionnaire, 2. the video of the interview-interventions, and 3. the audio of their transcripts.

Results

In the following, we present the results of our study on the points that could enable the transition from problem solving to modeling. This discussion is organized into two moments. In the first, which is before the interview-intervention, we will identify the problem-solving skills possessed by the students and the type of production they carry out individually. In the second moment, we will establish the important elements identified by the interview-intervention to know how the collaborative production with the researcher brought the students closer to modeling.

We will present the results related to activity 2 of the questionnaire since we consider that it recovers the work done by the students, which is shown below:

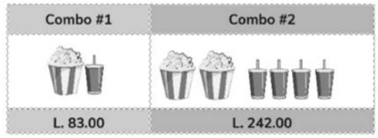

Figure 2: Activity 2

Before the interview-intervention

At this point, we were interested in the problem-solving skills used by the students to solve the activity individually. The following table shows the students' answers to question 1 of activity 2.

Table 1: Answers to question 1 of Activity 2

E1	Tarea 23: Pregunta 1 Explore la imagen y comente sus observaciones: Combo #1: Se observa una caja de palomitas y refresco Combo #2: Se observa dos cajas de palomitas y cuatro refrescos. (El doble de la caja de palomitas del combo #1 y el cuádruple del refresco del combo #1)
E2	Tarea 23: Pregunta 1 Explore la imagen y comente sus observaciones: En el combo 1 nos venden 1 caja de palomitas y 1 refresco por L. 83. En el combo 2 nos venden 2 cajas de palomitas y 4 refrescos por L. 242.

We can observe that E1 recognizes proportionality relationships between the objects that appear in the combos but do not find the total value of each one because it is probably not important to do so for her, at that moment of the solution. While E2 focuses on the composition of the combos, and she gets all the numerical information. We can say that both students detect the relevant information of the situation, but with different approaches, which seem to be directly linked to the possible strategies they will use. This will be reflected in the way they establish the data, which we show below:

Table 2: Answers to question 2 of Activity 2

E1	Tarea 24: Pregunta 2 ¿Qué datos se ofrecen en la figura? Por una caja de palomitas y por un refresco el precio es de L. 83 y por dos cajas de palomitas y por cuatro refrescos el precio es de L. 242
E2	Tarea 24: Pregunta 2 ¿Qué datos se ofrecen en la figura? X= Cantidad de refrescos Y= Cantidad de palomitas x+y=83 2xr+4y=242

The purpose of this question is to know how the students organize the information provided by the problem. In this task, E1 describes the composition of the combos incorporating the numerical relations that appear in the problem. Still, she does not yet show the elements that allow us to know which strategy she will use. However, in answer to question 1, she identified compensation relations between the elements of the combos. On the other hand, E2 expresses his strategy by organizing the information using a system of linear equations.

After retrieving the relevant information from the problem, in questions 1 and 2, students could be able to find the value of a box of popcorn and soft drink in questions 3 and 4. This is shown in Figure 3.

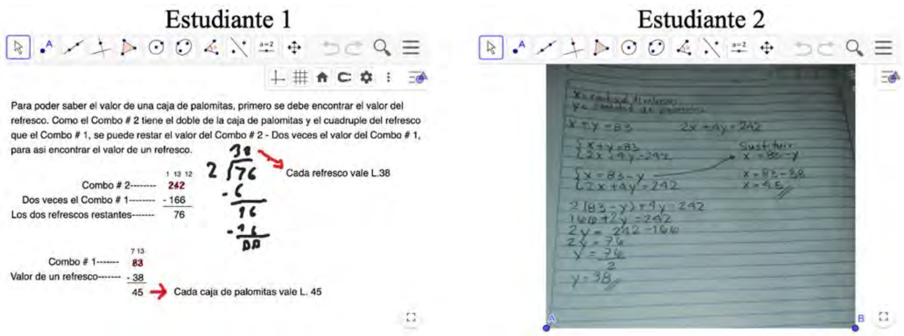

Figure 3: Solution to Activity 2 (questions 3 and 4)

The students' backgrounds explain the difference in the approaches used. When E1 identifies the comparison relationship by compensation, she recognizes a heuristic that consists of duplicating combo #1 to obtain combo #2, realizing that in doing this, there will be a surplus; in this case, it is two sodas. He refers to: "the value of Combo #2 - Twice the value of Combo #1, to find the value of one soda". This recognition allows him to solve the activity using a strategy that is not emphasized in the curriculum and is more typical of a mathematical Olympiad.

On the other hand, in work done by E2, we recognize the use of a strategy emphasized in the curriculum, which is to construct a system of linear equations. Still , she does not adequately label the variables when she applies, which does not allow her to find the correct values. This aspect does not have repercussions on the choice of the strategy, but it does have implications in the results, a situation that is taken up and discussed in the interview.

With question 5, we aimed to identify the metacognition activities that students might be performing, and that relate to the suggestions they would make to another student to solve this activity:

Table 3: Answers to question 5 of Activity 2

E1	Tarea 29: Pregunta 5 Si tuviera que explicar este problema a otro estudiante, ¿Qué sugerencias le daría para que pueda resolverlo? Que primero debe encontrar el valor del refresco y luego el valor de la caja de palomitas.
E2	Tarea 29: Pregunta 5 Si tuviera que explicar este problema a otro estudiante, ¿Qué sugerencias le daría para que pueda resolverlo? Le diría que usara un sistema de ecuaciones de 2 variables para resolver el problema, ya que en esta situación es la mejor forma de hacerlo y que lo resuelva por cualquiera de los métodos, ya sea sustitución o eliminación.

At this stage and before the interview, the suggestion offered by E1 does not give the key elements for another person to solve the problem using her strategy, which seems to show a tendency to make use of a self-explanation since for her, these elements are already codified and therefore should be understood by others. For her part, E2 proposes a method to solve the problem by formulating a system of linear equations but does not explain how to construct the equations from which the solution is obtained. Both explanations lack the important points that could help another person replicate their strategies, which shows us that they could not do metacognitive work on their solutions.

The questionnaire results show that the student's previous experiences condition the type of approach to the proposed problems. E1, having a background in mathematical Olympiads, uses ways of thinking such as compensation strategies that allow her to understand and solve the problem. E2, on the other hand, has only as a resource the elements that have been offered to her through regular instruction. This aspect limits her strategies, but she manages to operate them correctly.

In addition, we identified that the students possess skills related to detecting the relevant information of the problem and its organization. Still, we observed that individually they are not showing the use of metacognitive processes associated with explaining procedures and results.

Analysis of the interview-intervention

Next, to promote reflection, we will address the results from the intervention-interviews we conducted with the students, based on the incomplete or incorrect answers to activity 2 of the questionnaire. In particular, our focus will be on identifying the activities that could be recognized as an approach to modeling and showing how the researcher promoted the need for the development of metacognitive processes that would allow them to reflect on their productions.

In the following excerpt, which corresponds to the discussion of activity 2, E1 is asked to explain *what it is like to complete?* to which she responds:

(161) **E1:** That is to say, the value, well, ... of a box of popcorn, that by doubling it I have two boxes of popcorn and the soft drinks, ... I would subtract two soft drinks from the combo, the combo is multiplied twice, to go like, I do not know how to explain it, sometimes I do not understand my logic, but sometimes I find myself thinking like this
(162) **I:** I understand it; we are doing well.
(163) **E1:** So, to more or less complete, what it was, more or less, to achieve an equality between combo 1 and combo 2.
(164) **I:** Ok, you say you duplicated combo 1 and compared it to combo 2.
(165) **E1:** Yes, and when I subtracted it, I was left with the two soft drinks.
(166) **I:** ou had the soft drinks left, so by subtracting it, you could get what...?
(167) **E1:** The value of one soda, because I only had two sodas left and the answer I had would be to divide it by 2, because they were the two sodas I had leftover.
(168) **I:** Ok, Excellent, divide by two because they were the two sodas you had leftover. So, ... now knowing that, ... how would you tell a classmate of yours? Can you think of this, how would you do it? What things would you ask him to think about so he could solve the activity?
(169) **E1:** Let him look, ... try to compare combo 1 with combo 2, so that he can see a relationship between them and make a shorter procedure, try to duplicate combo 1 in order to find the quantity.
(170) **I:** What quantity?
(171) **E1:** The one for soda ... for the case I used that, first in order to find the popcorn value, I first had to find the soda value.

From the above, we note that E1 realizes that: explaining his procedure can be a complex task *(line 163 - E1)* that involves ordering his ideas so that they can be conveyed clearly. From the questions posed by the researcher: (could you get what ... What things would you ask him to think about so that he can solve the activity? ... What amount?) he pushes E1 to clarify his ideas and be able to explain his approach. Through a continuous dialogue with the teacher, this type of approach allows students to develop a self-demand on their production, where they could establish a mental schema that serves them to order their ideas and explain their procedures and approach.

When we discussed this activity with E2, the following question was posed to her: *what elements of the problem allowed her to think of a system of equations?* she responded:

(106) **E2:** I realized (that) we could make a system of 2-variable equations and solve it fast…
(107) **E2:** I noticed that, ... to begin with ... that there were two situations ... two different situations, but involving the same variables. So, if we organize by variables, we have x on one side and y on the other, then x could represent one of the things they sell us, in this case, the popcorn, as I put it there, and the other would be the amount of soft drinks ... because they are selling us a certain amount of each thing for a specific price. So, I came ... so, I saw that you could make two ... two different equations and make them into a system.

In the dialogue we show, we observe that E2 already recognizes a solution strategy, which is curricular emphasized; this gives him a lot of confidence about the approach he uses to solve the problem since he has used it before and knows that it works.

When the researcher asks E2 to explain the strategy she used to solve the activity, she has a moment of doubt. In the course of her explanation, she realizes that she had not constructed the equations according to the labels she had chosen for the variables *(line 150 - E2)*, as we see in the following dialogue:

(150) **E2:** But... now I have a doubt; I don't know if I solved it right because it says that 38 would be the price of popcorn because... I think that the... the equations that I did were correct, which would be $x + y = 83$ and we have that x is the amount of soft drinks, one soft drink and one popcorn, it is the first one. The second one is $2x + 4y = 242$. It would be the one in the second combo, 2... x... so, there's the mistake.
(151) **I:** But how could we correct that mistake?
(152) **E2:** This would be $4x + 2y$

The uncertainty in E2's explanation produced the need to verify the procedures used, allowing him to have an approach consistent with the initial interpretation *(line 152 - E2).*

From this, we can say that: placing students in a situation where they must explain their procedures could provoke the need to perform validation tasks to obtain answers that are consistent with their strategies and activity conducive to working with models that seek to justify the structure of the problem.

In addition, we can say that the teacher, from the development of metacognitive processes and the questions that the teacher asks, can propitiate in the students a dialogue that allows them to overcome their particular zone of proximal development, encouraging the creation of adequate mental schemes to use the necessary resources and order their ideas through the suggestion of explaining their procedures and approaches, realizing that, in some cases, they can perform validation tasks that go beyond verifying their immediate results, which could help them to improve the solution of problems and provide a broader view of the variety of problems that can be solved with the resources present, which can then be applied to the model idea from the point of view of its general structure.

Conclusions

As shown in the study, we identified that metacognitive reflection was fulfilling two functions, one as a means of explanation of the solution and the other as a validation resource, which allowed the students to identify the conditions under which the proposed problem was solved.

In some cases, certainty about a method may cause the student to resist change or to make his strategy explicit, as happened in the case of E2, who developed an internal dialogue to establish a finer validation process than the one initially developed because the error he presented was exclusively in the process of constructing the equations and in the consistency of the labels he used for the variables and not in the approach, since it was correct.

Finally, in this work, we can say that the skills related to the detection of relevant information and the organization of this, as points of contact between these proposals, can be used as a necessary condition to bring students closer to modeling, which allows the researcher to take advantage of these resources of the students to promote metacognitive processes, which allowed them to be able to analyze and explain their solution and strategy in an orderly manner, as well as to identify the conditions under which the problem was solved, which are activities that go beyond the objectives of problem solving, and that in particular would be approaching the interests of modeling, in an elementary approximation.

TRÁNSITO DESDE LA RESOLUCIÓN DE PROBLEMAS HASTA LA MODELIZACIÓN EN ESTUDIANTES DE HONDURAS

TRANSITION FROM PROBLEM SOLVING TO MODELING IN STUDENTS IN HONDURAS

En el presente trabajo se plantea investigar cuáles elementos de la resolución de problemas podrían permitir el tránsito hacia la modelización matemática. En el estudio participaron dos estudiantes de Honduras con instrucción estándar en resolución de problemas, donde una de ellas ha participado en olimpiadas matemáticas. Consideramos que la detección y organización de la información, la explicación de los resultados y los procesos de validación podrían ser puntos de contacto entre estas posturas y que su adecuado manejo permitiría el tránsito entre ellas. Encontramos que las estudiantes se manejan bien en resolución de problemas, pero que sólo con el apoyo del investigador desarrollaron actividades de análisis, validación y la determinación de las condiciones del problema para lograr la modelización.

Palabras clave: Resolución de problemas, modelado, metacognición.

Introducción

En la República de Honduras, desde el año 2003 se ha venido implementado la educación matemática bajo el enfoque de resolución de problemas. Mientras que las tendencias actuales, señalan la importancia de que los estudiantes den sentido a los problemas llamados *contextuales* que podrían enriquecer su percepción sobre la utilidad de la matemática y que pueden usarse en la vida cotidiana, posturas que han sido parte de lo que se ha dado en llamar *modelización*.

De esta manera, nos encontramos frente a estudiantes hondureños que poseen los antecedentes de la resolución de problemas, pero que pronto deberán transitar hacia la perspectiva que se apoya en la modelización, situación que debemos prevenir.

Los antecedentes básicos para esta investigación consideran las formulaciones de Polya (1989) y Schoenfeld (1985) sobre la resolución de problemas, así como las posturas de organizaciones educativas como PISA (2015), que establecen los objetivos y las condiciones de esta postura. También identificamos que actualmente las instituciones se percatan de que: no sólo el uso y detección de la estrategia adecuada es relevante para la enseñanza de la matemática, sino que es necesario contextualizar los problemas. Este fenómeno lo encontramos más claramente en la postura de PISA (2015), dónde a través del tiempo han desarrollado un interés por incluir habilidades que tradicionalmente no se consideran parte de la resolución de problemas, que es la base de su aproximación y ahora se inclinan por los beneficios que se pueden obtener de esta ampliación, por ejemplo, cuando los estudiantes se dan cuenta de que una problemática está asociada a ciertas estrategias, donde puede surgir la necesidad para interpretarlas, además de darle solución, lo que estaría acercándolos a los intereses de la modelización.

Para establecer el carácter y profundidad de los contenidos tratados en la resolución de problemas, analizamos los libros de texto oficiales de Honduras, para identificar 1. La perspectiva presente en ellos y 2. Las habilidades desarrolladas con base en esos materiales, por lo que podemos decir que los estudiantes de Honduras, a partir del uso de estos libros de texto han tenido algunas experiencias que les permitirían abordar los problemas haciendo uso de: 1. La detección de los aspectos que son relevantes para la tarea, 2. El planteamiento e identificación de las estrategias idóneas para la solución de los problemas, 3. La organización de la información y 4. En menor medida la adquisición de herramientas relacionadas con los procesos de validación y generalización, aspectos que consideramos particularmente provechosos para la creación de modelos.

Marco Referencial

En la propuesta de Schoenfeld (1985) identificamos la dimensión llamada de *control*, la cual hace referencia a las habilidades del estudiante para: darse cuenta de que su estrategia va en la dirección correcta o no y poder explicar sus resultados. Ambos puntos podrían colocar al estudiante en el terreno de la metacognición, que también se relaciona con el "seguimiento y control" (Schoenfeld, 2016, p.2), en dónde, si el estudiante toma el control de su proceso de solución, puede desarrollar una visión general de las actividades y las condiciones del problema, lo que le permite aumentar sus posibilidades para resolverlo adecuadamente.

En nuestro trabajo, al incluir el desarrollo de procesos metacognitivos, pretendemos propiciar un posible y ligero cambio en el paradigma de la resolución de problemas, en dónde el objeto de estudio ya no se centra únicamente en el reconocimiento y uso de las estrategias para resolver los problemas, sino que se requiere de identificar las condiciones bajo las cuales es posible resolverlos.

Para lograr este cambio de paradigma, se pueden incorporar aspectos que se relacionen con la toma de decisiones y la interpretación de la problemática, que incluye identificar las condiciones específicas de ésta y si a esto le sumamos el componente contextual realista, estaríamos acercándonos al terreno de la modelización matemática escolar, debido a que: “Los modelos matemáticos aparecen cuando se tiene la necesidad de responder preguntas específicas en situaciones reales, cuando se requiere tomar decisiones o cuando es imperativo hacer predicciones relacionadas con fenómenos naturales y sociales” (Trigueros, 2009, p. 76).

En este trabajo vamos a considerar la modelización desde una perspectiva cognitiva, porque en particular: “ponen en primer plano la forma en que el pensamiento de los estudiantes conduce al modelo, al tiempo que sirven de base para los objetivos pedagógicos o curriculares” (Czocher, 2018, p.138).

El pensamiento de los estudiantes puede abstraerse e ilustrarse a través de las estructuras conocidas como ciclos de modelización, que establecen los puntos nodales del proceso. En particular, vamos a utilizar la propuesta de Blum y Borromeo Ferri (2009), la que es susceptible, a nuestro entender, de ser usada tanto en la resolución de problemas como en la modelización y que se plantea a partir de cuatro actividades: 1. Entendiendo la tarea, 2. Estableciendo el modelo, 3. Usando matemáticas y 4. Explicando los resultados.

Esta propuesta no declara actividades de validación, sin embargo, éstas se presentan por medio de la iteración del ciclo, lo cual indica que requiere de la validación para ser reiniciadas. Además, cuándo el estudiante está en condiciones de poder explicar sus resultados, también está desarrollando actividades de validación.

Para poder lograr este cambio de paradigma en la resolución de problemas, consideramos la necesidad de centrarse en dos factores esenciales: 1. El desarrollo de los aspectos metacognitivos, que promuevan una reflexión sobre las condiciones bajo las cuales el problema puede ser resuelto y 2. El papel del profesor, que posibilita un mayor entendimiento de las relaciones e implicaciones del problema, lo que tiene como punto de inicio un reconocimiento de las condiciones contextuales, lo que podría dar como resultado una transición de una postura a otra.

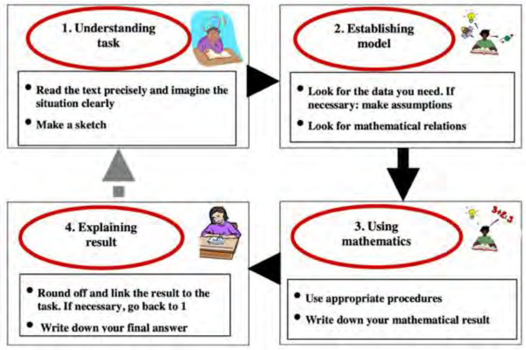

Figura 1: Ciclo de Modelización de Blum y Borromeo Ferri (2009, p.54)

De manera que, si consideramos a la definición de la competencia de la modelización como punto de partida para introducir su enseñanza, en este caso la propuesta por Niss et al. (2007) que se refiera a:

> La habilidad para identificar las cuestiones, variables, relaciones o supuestos relevantes en una situación del mundo real, traducirlos a las matemáticas e interpretar y validar la solución del problema matemático resultante en relación con la situación dada, así como la capacidad de analizar o comparar modelos. (p.12)

Por ello, estamos interesados en analizar cómo los aspectos metacognitivos podrían estar promoviendo algunos de los requisitos mínimos para desarrollar actividades de modelización.

Metodología

Desarrollamos un estudio cualitativo interpretativo para conocer la forma cómo las competencias y habilidades sobre resolución de problemas impartidas, tanto curricularmente como extra curricularmente en Honduras, podrían servir como base para una introducción de la modelización matemática escolar y cómo es el proceso de tránsito desde una propuesta didáctica a la otra. Nuestra hipótesis de investigación es que tanto los estudiantes que han tenido instrucción regular, así como los que han adquirido una adicional sobre resolución de problemas, están en condiciones de transitar a una propuesta didáctica basada en la modelización, a través de problemas pertinentes y un trabajo colaborativo con el profesor que favorezca el uso de los procesos metacognitivos.

El estudio se realizó en el marco de la pandemia por COVID-19 en el 2021. Participaron dos estudiantes hondureñas de excelencia académica, que al momento de la investigación cursaban el noveno grado y ambas tenían 15 años. La estudiante 1 (E1), cuenta con experiencia en olimpiadas de matemáticas, mientras que la estudiante 2 (E2) no tiene esta experiencia.

El estudio se apoyó en: 1. Un cuestionario en línea que las estudiantes resolvieron de manera individual en la plataforma de GeoGebra y que consideró preguntas abiertas y llenado de tablas, y 2. En una entrevista-intervención en línea, luego de haber resuelto el cuestionario.

A partir del cuestionario, detectamos el nivel de desarrollo de las habilidades sobre resolución de problemas a través de cuatro problemas y ambas estudiantes mostraron: detección de los aspectos relevantes en el problema, organización de la información, uso de estrategias adecuadas, así como del buen manejo de la matemática necesaria para resolverlos.

En la entrevista-intervención, preguntamos a las estudiantes sobre sus procedimientos y resultados, para profundizar en las respuestas del cuestionario. También, se aprovecharon las preguntas incompletas o incorrectas, para conocer cómo las estudiantes enfrentaron los retos que les plantearon las tareas, de manera que se provocara un trabajo de tipo metacognitivo para observar la posibilidad de ampliar su percepción sobre los requisitos del problema y así poder apoyarlas en el desarrollo de las actividades propuestas.

La reflexión metacognitiva en estas actividades tiene dos funciones: La primera va en la dirección de lograr una explicación del procedimiento, lo puede provocar en los estudiantes una necesidad de certeza sobre los argumentos que ofrecen cuando comunican su solución y la segunda puede ser desarrollada por la necesidad de la validación.

En el siguiente apartado, presentaremos el análisis y la discusión de los datos que se obtuvieron a partir de: 1. Las respuestas presentadas en el cuestionario, 2. El video de las entrevistas-intervención y 3. La transcripción del audio de estas.

Resultados

A continuación, presentamos los resultados de nuestro estudio sobre los elementos que podrían posibilitar el tránsito desde la resolución de problemas hacia la modelización. Esta discusión se organiza en dos momentos. En el primero, que es previo a la entrevista-intervención, identificaremos: las habilidades sobre resolución de problemas que poseen las estudiantes y el tipo de producción que realizan de manera individual. En el segundo momento, estableceremos los elementos importantes identificados en la entrevista-intervención, para conocer de qué manera la producción conjunta con el investigador acercó a las estudiantes a la modelización.

Presentaremos los resultados relativos a la actividad 2 del cuestionario, ya que consideramos que, recupera de maneral, el trabajo realizado por las estudiantes, la que mostramos enseguida:

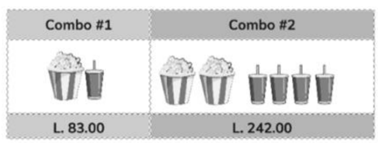

Figura 2: Actividad 2

Previo a la entrevista-intervención

En este momento nos interesa conocer las habilidades sobre resolución de problemas que utilizan las estudiantes para resolver la actividad de manera individual. En la siguiente tabla presentamos las respuestas de las estudiantes a la pregunta 1 de la actividad 2.

Tabla 1: Respuestas de la pregunta 1 de la Actividad 2

E1	Tarea 23: Pregunta 1 Explore la imagen y comente sus observaciones: Combo #1: Se observa una caja de palomitas y refresco Combo #2: Se observa dos cajas de palomitas y cuatro refrescos. (El doble de la caja de palomitas del combo #1 y el cuádruple del refresco del combo #1)
E2	Tarea 23: Pregunta 1 Explore la imagen y comente sus observaciones: En el combo 1 nos venden 1 caja de palomitas y 1 refresco por L. 83. En el combo 2 nos venden 2 cajas de palomitas y 4 refrescos por L. 242.

Podemos observar que E1 reconoce relaciones de proporcionalidad entre los objetos que aparecen en los combos, pero no rescata el valor total de cada uno, porque para ella en ese momento de la solución probablemente no sea importante hacerlo. Mientras que E2 se enfoca en la composición de los combos y extrae toda la información numérica. Podemos decir que ambas estudiantes detectan la información relevante de la situación, pero con enfoques distintos, lo que parece estar ligado directamente con las posibles estrategias que utilizarán. Esto se verá reflejado en la manera cómo establecen los datos, lo que mostramos enseguida:

Tabla 2: Respuestas de la pregunta 2 de la Actividad 2

E1	Tarea 24: Pregunta 2 ¿Qué datos se ofrecen en la figura? Por una caja de palomitas y por un refresco el precio es de L. 83 y por dos cajas de palomitas y por cuatro refrescos el precio es de L. 242
E2	Tarea 24: Pregunta 2 ¿Qué datos se ofrecen en la figura? X= Cantidad de refrescos Y= Cantidad de palomitas x+y=83 2xr+4y=242

Con esta pregunta se pretende conocer cómo las estudiantes organizan la información que ofrece el problema. En esta tarea, E1 describe la composición de los combos incorporando las relaciones numéricas que aparecen en el problema, pero aún no muestra los elementos que nos permitan conocer cuál es la estrategia que utilizará, aunque en la respuesta a la pregunta 1 identificó relaciones de compensación entre los objetos de los combos. Por su parte, E2 deja expresada su estrategia al organizar la información utilizando un sistema de ecuaciones lineales.

Después de recuperar la información relevante del problema, en las preguntas 1 y 2, las estudiantes podrían estar en condiciones de encontrar el valor de una caja de palomitas y de un refresco, preguntas 3 y 4. Lo que mostramos en la figura 3.

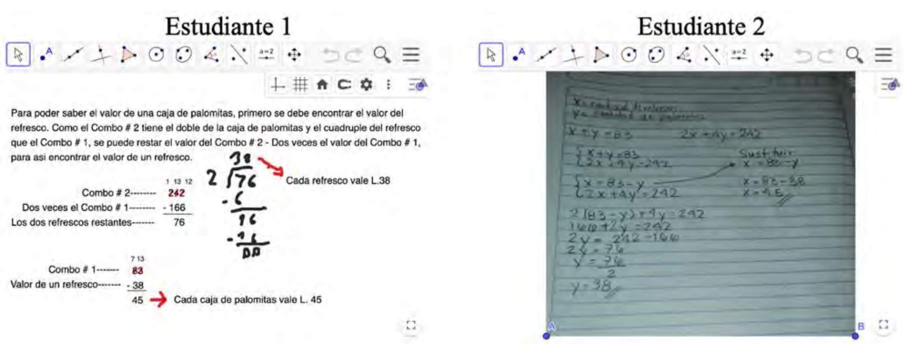

Figura 3: Solución de la Actividad 2 (preguntas 3 y 4)

Los antecedentes de las estudiantes explican la diferencia de los enfoques utilizados. Cuando E1 identifica la relación de comparación por compensación, reconoce una heurística que consiste en duplicar el combo #1 para obtener el combo #2, dándose cuenta de que al hacer esto habrá un excedente, en este caso son dos refrescos. En sus palabras se refiere a: “el valor del Combo #2 – Dos veces el valor del Combo #1, para así encontrar el valor de un refresco”. Este reconocimiento le permite resolver la actividad utilizando una estrategia que no es enfatizada curricularmente y es más propio de una olimpiada matemática.

Por otra parte, en el trabajo que realiza E2 reconocemos el uso de una estrategia que es enfatizada curricularmente, esta es construir un sistema de ecuaciones lineales, pero cuando la aplica no etiqueta adecuadamente las variables y esto no le permitió encontrar los valores correctos. Este aspecto no tiene repercusión en la elección de la estrategia, pero si en los resultados, situación que se retoma y discute en la entrevista.

Con la pregunta 5, pretendíamos identificar las actividades de metacognición que podrían estar realizando las estudiantes y que se relaciona con las sugerencias que le harían a otro estudiante para resolver esta actividad:

Tabla 3: Respuestas de la pregunta 5 de la Actividad 2

E1	Tarea 29: Pregunta 5 Si tuviera que explicar este problema a otro estudiante, ¿Qué sugerencias le daría para que pueda resolverlo? Que primero debe encontrar el valor del refresco y luego el valor de la caja de palomitas.
E2	Tarea 29: Pregunta 5 Si tuviera que explicar este problema a otro estudiante, ¿Qué sugerencias le daría para que pueda resolverlo? Le diría que usara un sistema de ecuaciones de 2 variables para resolver el problema, ya que en esta situación es la mejor forma de hacerlo y que lo resuelva por cualquiera de los métodos, ya sea sustitución o eliminación.

En esta etapa y previo a la entrevista, la sugerencia que ofrece E1 no proporciona los elementos claves para que otra persona pueda resolver el problema utilizando su estrategia, lo que pareciera mostrar una tendencia a hacer uso de una auto explicación, ya que para ella estos elementos ya están codificados y por tanto deberían ser entendidos por los demás. Por su parte, E2 propone un método para resolver el problema formulando un sistema de ecuaciones lineales, pero no explica cómo construir las ecuaciones de las que se obtiene la solución. Ambas explicaciones carecen de los puntos importantes que podrían ayudar a otra persona a replicar sus estrategias, lo que nos muestra que no estaban en condiciones de hacer un trabajo metacognitivo sobre sus soluciones.

Los resultados del cuestionario muestran que las experiencias previas de las estudiantes condicionan el tipo de acercamiento a los problemas propuestos. E1, al tener antecedentes en olimpiadas matemáticas usa formas de pensamiento como las estrategias de compensación que le permiten entender y resolver el problema. Por su parte E2, al poseer como único recurso los elementos que se le han ofrecido a través de una instrucción regular, sus estrategias están limitadas por este aspecto, pero logra ponerlos en funcionamiento correctamente.

Además, identificamos que las estudiantes poseen habilidades relacionadas con la detección de la información relevante del problema y con la organización de esta, pero observamos que de manera individual no están mostrando un uso de procesos metacognitivos, en lo relacionado con la explicación de los procedimientos y los resultados.

Análisis de la entrevista-intervención

A continuación, abordaremos los resultados obtenidos de las entrevistas-intervención que realizamos con las estudiantes, las que se apoyaron en las respuestas incompletas o incorrectas de la actividad 2 del cuestionario, para promover una reflexión. En particular, nuestro foco de atención estará en identificar las actividades que podrían ser reconocidas como un acercamiento a la modelización, además de mostrar cómo el investigador promovió la necesidad del desarrollo de procesos metacognitivos que les permitieran reflexionar sobre sus producciones.

En el siguiente fragmento, que corresponde a la discusión de la actividad 2, se le pide a E1 que explique *¿cómo es eso de completar?,* a lo que ella responde:

(172) **E1:** Es decir, el valor, pues, … de una caja de palomitas, que al duplicarlo ya me quedan dos cajas de palomitas y los refrescos, … me restarían dos refrescos del combo, se multiplica dos veces el combo, para ir como, no sé cómo explicarlo, a veces no entiendo a mi lógica, pero a veces me resulta pensar así

(173) **I:** Yo la entiendo, vamos bien.
(174) **E1:** Entonces, para completar más o menos, lo que era, más o menos, para lograr una igualdad entre el combo 1 y el combo 2.
(175) **I:** Ok, Usted dice que duplicó el combo 1 y lo comparó con el combo 2.
(176) **E1:** Sí y al restarlo, me quedaron los dos refrescos.
(177) **I:** Le quedaban los refrescos, entonces al restarlo, ¿usted podría obtener qué…?
(178) **E1:** El valor de un refresco, porque a lo que queda como al restarle, ya solo me quedaron dos refrescos y la respuesta que tenía sería dividirla entre 2, porque eran los dos refrescos que me sobraban.
(179) **I:** Ok, Excelente, divide entre 2 porque eran los dos refrescos que le sobraban. Entonces, … ahora ya sabiendo eso, … ¿cómo le diría a un compañero suyo? Puedes pensar en esto, ¿cómo lo haría? ¿En qué cosas le pediría que piense él para que pueda resolver la actividad?
(180) **E1:** Que mire, … que intente comparar el combo 1 con el combo 2, para que pueda ver una relación entre el y hacer un procedimiento un poco ya más corto, intentar ya duplicar el combo 1 para poder encontrar ya la cantidad.
(181) **I:** ¿Cual cantidad?
(182) **E1:** La de los refrescos … para el caso que yo utilicé que, primero para poder encontrar el valor de las palomitas, primero tuve que encontrar el valor de refresco.

De lo anterior, observamos que E1 se da cuenta de que: explicar su procedimiento puede ser una tarea compleja *(línea 163 - E1)* que implica ordenar sus ideas de manera que puedan ser transmitidas con claridad. A partir de las preguntas planteadas por el investigador: (¿podría obtener qué … ¿En qué cosas le pediría que piense él para que pueda resolver la actividad? … ¿Cual cantidad?) empuja a E1 para que pueda aclarar sus ideas y sea capaz de poder explicar su enfoque. Este tipo de acercamientos, a través de un diálogo continuo con el profesor permite que los estudiantes desarrollen una autoexigencia sobre su producción, dónde podrían establecer un esquema mental que les sirva para ordenar sus ideas y explicar sus procedimientos y enfoque.

Cuando discutimos esta actividad con E2, se le planteó la siguiente pregunta: *¿qué elementos del problema le permitieron pensar en un sistema de ecuaciones?* ella respondió:

(108) **E2:** Me di cuenta (de) que podíamos hacer un sistema de ecuaciones de 2 variables y resolverlo rápido…
(109) **E2:** Me fijé que, … para empezar… que había dos situaciones… dos situaciones diferentes, pero que implicaban las mismas variables. Entonces, si nos organizamos por variables, tenemos a x por un lado y a y por el otro, entonces x podría representar una de las cosas que nos venden, en este caso, las palomitas, así como lo puse ahí y el otro sería la cantidad de refrescos … porque nos están vendiendo una cantidad determinada de cada cosa por un precio específico. Entonces, llegué … entonces, vi que se podían hacer dos… dos ecuaciones distintas y hacerlas en un sistema.

En el diálogo que mostramos, observamos que E2 ya reconoce una estrategia de solución, la que es enfatizada curricularmente, esto le proporciona mucha seguridad sobre el enfoque que utiliza para resolver el problema, ya que anteriormente lo ha utilizado y sabe que funciona.

Cuando el investigador le pide a E2 que explique la estrategia que utilizó para resolver la actividad, ella tiene un momento de duda y en el transcurso de su explicación, se da cuenta de que no había construido las ecuaciones en función de las etiquetas que había elegido para las variables *(línea 150 – E2)*, como vemos en el siguiente diálogo:

(153) **E2:** Pero… ahora sí tengo una duda, no sé si lo resolví bien porque, es que dice que 38 vendría siendo el precio de las palomitas porque… creo que las… las ecuaciones que hice si estaban bien, que serían $x + y = 83$ y tenemos que x son la cantidad de refrescos, un refresco y una palomita, es la primera. La segunda es $2x + 4y = 242$. Estaría siendo la del segundo combo, 2… x… así, ahí está el error
(154) **I:** Pero ¿cómo podríamos corregir ese error?
(155) **E2:** Sería $4x + 2y$

La incertidumbre en la explicación de E2 produjo la necesidad de verificar los procedimientos usados, permitiéndole tener un planteamiento consistente con la interpretación inicial *(línea 152 – E2)*.

De esto, podemos decir qué: colocar a los estudiantes en la situación donde deben de explicar sus procedimientos, podría provocar en ellos la necesidad de realizar tareas de validación para obtener respuestas que sean consistentes con sus estrategias, actividad propicia para el trabajo con modelos que pretenden justificar la estructura del problema.

Además, podemos decir que el profesor, a partir del desarrollo de procesos metacognitivos y de las preguntas que realiza, puede propiciar en los estudiantes un diálogo que les permita superar su zona de desarrollo próximo particular, propiciando la creación de esquemas mentales adecuados para usar los recursos necesarios y ordenar sus ideas a través de la sugerencia de explicar sus procedimientos y enfoques, dándose cuenta de que, en algunos casos pueden realizar tareas de validación que van más allá de verificar sus resultados inmediatos, las que podrían ayudarles a mejorar la solución de los problemas y proporcionar una mirada más amplia sobre la variedad de problemas que se resuelven con los recursos presentes, lo que luego puede ser aplicado a la idea de modelo desde el punto de vista de su estructura general.

Conclusiones

Cómo se muestra en el estudio, identificamos que la reflexión metacognitiva estuvo cumpliendo dos funciones, una como medio de explicación de la solución y la otra como recurso de validación, lo que permitió que las estudiantes pudieran identificar las condiciones bajo las cuales fue resuelto el problema propuesto.

En algunos casos, la certeza sobre un método puede provocar que el estudiante se resista al cambio o a dar una explicitación de su estrategia, como sucedió en el caso de E2, quien desarrolló un diálogo interno para establecer un proceso de validación más fino que el desarrollado inicialmente, debido a que el error que presentó se encontraba exclusivamente en el proceso de construcción de las ecuaciones y en la consistencia de las etiquetas que utilizó para las variables y no en el enfoque, ya que era correcto.

Finalmente, en este trabajo podemos decir que las habilidades relacionadas con la detección de la información relevante y la organización de esta, como puntos de contacto entre estas propuestas, puede usarse como una condición necesaria para acercar a los estudiantes a la modelización, lo que permitió al investigador aprovechar estos recursos de las estudiantes para promover procesos metacognitivos, lo que les permitió poder analizar y explicar ordenadamente su solución y estrategia, así como identificar las condiciones bajo las cuales se resolvía el problema, que son actividades que van más allá de los objetivos de la resolución de problemas, y que en particular estarían acercándose a los intereses de la modelización, en una aproximación elemental.

USING STRUCTURE TO FIND THE DISTANCE ON AN EMPTY NUMBER LINE

Laura Bofferding

Looking for and making use of structure along with using the mathematical tools (i.e., number line) are important mathematical practices. In this paper, we explore 32 first-grade and 36 third-grade students' noticing and making use of the structure of two identical number lines when determining the distance of a bunny's jumps. The number lines represented a distance from 11 to 27, and students could choose to jump to 20 (nearest multiple of ten), 21 (adding ten), or 15 (nearest multiple of five). Choosing 21 (distance of 10) was the most frequent choice, and overall, 71% of third graders' and 17% of first graders' attempts showed a correct distance. However, less than one-third of students made connections between their two number lines and noticed their structure. This study informs the importance of number combination knowledge and highlighting structure in order to leverage efficient addition strategies.

Keywords: Number Concepts and Operations, Elementary School Education, Problem Solving

An important feature of number lines is that they are continuous representations of numbers that can represent distances. Although object-based interpretations of quantity are prevalent when students first work with addition, connecting addition on number lines to distance is also important (National Research Council [NRC], 2001). Counting jumps can help children bridge between discrete situations and using distance, but they need to pay attention to the length of the jumps. In other words, students need to attend to structure, particularly that distance units can be combined or partitioned into larger or smaller units (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA & CCSSO], 2010; NRC, 2001). When adding on number lines, some students might count tick marks instead of spaces, resulting in answers that are off by one (Ernest, 1985). Students might also count the number of jumps they take (or distance units they use), regardless of the distance of their jumps (or units; e.g., Saxe et al., 2010).

Number lines can serve as important tools for helping students visualize and advance their thinking (i.e., moving from a model of thinking to a model for thinking; Gravemeijer, 1999; Klein et al., 1998) around addition (and other) problems, and can also reveal important connections between addition and measurement (NRC, 2001). Number lines align well with students' counting strategies but also allow for more sophisticated jump strategies (Bobis, 2007; Klein et al., 1998). Further, multiple number lines can help students notice different combinations of jumps to get to the same number (e.g., see work on contrasting cases; Schwartz et al., 2016), highlighting the structure of numbers. Looking for and making use of structure are characteristics of mathematically proficient students (NGA & CCSOO, 2010); "when young students use the relationships in and among mathematical content and processes, they advance their knowledge of mathematics and extend their ability to apply concepts and skill more effectively" (National Council of Teachers of Mathematics, 2000, p. 132). For this study, we explore to what extent first and third graders notice and use the structure of two number lines (representing the same distance from 11 to 27) to solve a missing addend problem.

Theoretical Framework

In terms of finding the difference (or distance) between two numbers, missing addend problems (e.g., 2 + __ = 5) can support a counting up strategy, which is often easier for students than counting down for corresponding subtraction problems (Fuson & Fuson, 1992). When finding the distance between two points on a number line, the distance can be broken up in ways that support students' number sense (Cain et al., 2020). Therefore, when trying to find a missing addend, students might use different addition strategies. Two important addition strategies for students to learn are making 10's and adding on 10's. For example, if a student starts at 11 and is trying to figure out the distance to 27, they might use an *add tens* strategy (e.g., Fuson et al., 1997) to get to 21 and then know that they need six more to get to 27, resulting in a distance (or missing addend) of 16. On the other hand, they might use a *make ten* strategy (e.g., Fuson et al., 1997) by adding 9 to get 20 and then know they need seven more to get to 27, resulting in the same distance of 16. Less efficient strategies involve counting on from 11 by ones or drawing out jumps to represent the addends and counting the total (Fuson et al., 1997; Murata, 2004). Overall, students will use more efficient strategies as they become more comfortable with place value and as students receive support for using tens-based strategies (Fuson et al., 1997; Murata, 2004).

Exploring how distances can be broken up in multiple ways can help students notice patterns and structure in numbers, such as with the compensation strategy or different combinations of numbers (see Bobis & Bobis, 2005). Take for instance a ten frame filled with seven yellow circles and three red circles to show 7 + 3 = 10. If one yellow circle is flipped over to become a red circle (showing 6 + 4 = 10), students may notice that having one fewer yellow circle means one more red. Likewise, when jumping to ten on a number line, a jump of six is one less than seven, so the second jump of four is one more than a jump of three. During a number string math routine, teachers illustrate students' strategies on a series of empty number lines, which could highlight how different sized jumps can lead to the same endpoints (Lambert et al., 2017). However, students may not pay attention to relations among jumps if they are not the ones they might make themselves. Having students try different jumps themselves might help them notice the structure of the jumps or use the structure of one to solve the other. In this study, we presented students with two number lines showing the same distance but asked them to break up the distance by making jumps in two different ways (i.e., creating two addition problems with the same answer). Through this task we hoped to gain insight into the following research questions: How do first and third graders make sense of the distance between numbers on number lines? (a) Are students more likely to jump to the nearest ten, make a jump of ten, or make a five? (b) How do students determine the distances of their jumps? (c) To what extent do they notice and use structure between the number lines in determining distances?

Methods

Participants and Design

Participants included 32 first and 36 third graders from a public suburban elementary school in the midwestern US who completed the target item. The data from this paper came from a larger set of items exploring the relation between students' explanations and debugging in programming and mathematics. This paper focuses on a mathematical explanation item that specifically targeted students' noticing of the common structure between distances on two number lines. Although the first graders had likely been exposed to number lines, they were not a regular part of their instruction. We only presented the target numbers on the number lines, making them similar to students' use of empty number lines. Empty number lines only show the numbers being used (as opposed to labeling all whole numbers, for example), which reduces their passive use (Klein et al., 1998) and can also make it easier for students to focus on the length of the jumps rather than just the number of jumps. Although we did not ask students to identify differences, we structured the two parts of the item to implicitly highlight a contrast in jumps on a number line as students solved each part (see Figure 1). During individual, video-recorded interviews, we read the instructions to the students and helped record their jumps and answers.

2a. The bunny starts at 11, jumps to one apple, and then jumps to get to the carrot at 27. Which apple do you want to jump to? How far is it to the apple? How far is it from the apple to the carrot? How far did the bunny go from 11 to 27?

2b. Now which apple do you want the bunny to jump to? How far is it to the apple? How far is it from the apple to the carrot? How far did the bunny go from 11 to 27?

2c. Which way is better? Explain.

Figure 1. Mathematical Explanation Item - Bunny Hops (11 + __+ __ = 27)

Analysis

First, we recorded which apple they jumped to for their first (Figure 1, 2a) and second choices (Figure 1, 2b) to determine if they were more likely to *choose 20* (the nearest ten), *choose 21* (a jump of ten), or *choose 15* (the nearest multiple of five). Then, we analyzed students' distance strategies and noted their use of structure.

Finding the distances. For each sub-item (2a and 2b in Figure 1), we coded their strategies for how they determined the length of each distance: (1) first jump from 11 to the apple, (2) second jump from the apple to 27, and (3) total. We coded students' strategies as *known fact* if they answered quickly and were correct; we used *guessing* if they answered quickly but were incorrect. The guessing strategies included answers that were close to the correct distances, answers that were wildly off, and answers that resulted from students concatenating the numerals from the jumps (e.g., saying the jump from 11 to 20 is 1120). *Counting* strategies included counting in their head, counting all, or counting on, which often involved finger motions, drawing marks, or mouthed counting words. A couple students subtracted by counting or added in chunks to find the distances, which we also classified under counting. After students found the distances on both number lines, we asked them which way they thought was better.

Noticing and using structure. Across the two sub-items, we coded their strategies as using structure if they used knowledge of the other sub-item to determine the length of a jump (i.e., through compensation) or the total distance (i.e., indicated the answer would be the same because the rabbit starts and ends at the same points). If students' answers to the two sub-items did not align, we took this as further evidence that they did not notice the common structure between the two number lines.

Results

Both first and third graders were least likely to choose 15 for their combined choices (the higher percentage on first graders' first choice appeared to be for 15 because it was the first option for where to jump). First graders were most likely to choose 21 (a jump of ten) first, followed by 20 (a jump to the nearest ten); whereas, third graders were slightly more likely to choose 20 first then 21 (see Table 1).

Table 1: Number of Students' First and Second Choice for Where to Jump

	Choose 15	**Choose 20**	**Choose 21**
First choice			
First grade (*n*=32)	34% (*n*=11)	22% (*n*=7)	44% (*n*=14)
Third grade (*n*=36)	19% (*n*=7)	33% (*n*=12)	47% (*n*=17)
Second choice			
First grade (*n*=32)	13% (*n*=4)	44% (*n*=14)	44% (*n*=14)
Third grade (*n*=36)	17% (*n*=6)	53% (*n*=19)	31% (*n*=11)
Choices Combined			
First grade (*n*=32)	47% (*n*=15)	66% (*n*=21)	88% (*n*=28)
Third grade (*n*=36)	36% (*n*=13)	86% (*n*=31)	78% (*n*=28)

Twenty-eight students (nine first and 19 third graders) indicated that choosing 21 first was better than their other choices because it was faster, or they indicated that the addition problem 10 + 6 was easier to solve than 9 + 7 or 4 + 12. A few students chose 21 as their favorite choice based on the jumping-bunny context. For example, one student said, "Because you use a lot of energy and then just slow down," hinting that the bunny would be tired after the first jump and would want a smaller jump. Choosing 20 first (i.e., making a ten) was a favorite of 17 students (eight first and nine third graders) who thought the numbers were easier or indicated that they liked jumping closer to the middle of the number line. Two of these students (one first and one third grader) also referred to the context and explained why choosing 21 was not good, "Because I think of this [pointing to the jump from 10 to 21], I don't think anyone can jump ten meters (third grader)" and "You don't have a lot of energy, so you go a little [each time] (first grader)."

Finding the Distances

Regardless of their first jump, third graders correctly found the distance from 11 to 27 on 71% of their attempts across both sub-items, and first graders correctly found the distance on 17% of their attempts across both sub-items (see Table 2).

Table 2: Percent of Students Showing the Correct Distances on Both Sub-items

Bunny's first jump	**First jump** (from 11 to chosen apple)	**Second jump (**from chosen apple to 27)	**Total** (overall distance from 11 to 27)
Chooses 15			
First grade (*n*=15)	33% (*n*=5)	27% (*n*=4)	13% (*n*=2)
Third grade (*n*=11)	82% (*n*=9)	64% (*n*=7)	73% (*n*=8)
Chooses 20			
First grade (*n*=21)	19% (*n*=4)	24% (*n*=5)	24% (*n*=5)

Third grade (*n*=31)	71% (*n*=22)	81% (*n*=25)	68% (*n*=21)
Chooses 21			
First grade (*n*=28)	21% (*n*=6)	32% (*n*=9)	14% (*n*=4)
Third grade (*n*=28)	82% (*n*=23)	89% (*n*=25)	75% (*n*=21)

For first graders, finding the distance of smaller jumps was easier (i.e., jump from 11 to 15 and from 21 to 27, compared to 11 to 27; see Table 2). Interestingly, when first graders chose 20 first, they were slightly more likely to find the total distance correctly than when choosing 15 or 21. Although third graders also did well on the small jumps, they had high performance when jumping ten (i.e., jumping from 11 to 21) and jumping from a ten (i.e., jumping from 20 to 27), suggesting they were better able to make use of place value (see Table 3).

Table 3: Percent of Students' Strategies When Finding Distances for Jumps and Total

	Strategy			
	Guess	**Known Fact**	**Counting**	**Using Structure**
Choosing 15 first				
First grade (*n=15)*	33% (15/45 times [a])	11% (5/45 times)	40% (18/45 times)	2% (1/45 times)
Third grade (*n*=11)	26% (10/39 times)	36% (14/39 times)	36% (14/39 times)	3% (1/39 times)
Choosing 20 first				
First grade (*n*=21)	57% (36/63 times)	10% (6/63 times)	22% (14/63 times)	0% (0/63 times)
Third grade (*n*=31)	25% (23/93 times)	49% (46/93 times)	23% (21/93 times)	5% (5/93 times)
Choosing 21 first				
First grade (*n*=28)	55% (49/84 times)	11% (9/84 times)	17% (14/84 times)	2% (2/84 times)
Third grade (*n*=28)	13% (11/84 times)	57% (48/84 times)	23% (19/84 times)	7% (6/84 times)

[a] For each sub-item, we coded three strategies per person. A total of 15 first graders chose to jump to 15 first, so there were 15 * 3 = 45 possible times for them to use a strategy.

Students often provided their answers quickly. In the case of the first graders, over 75% of their quick answers (i.e., known facts and guessing) aligned with them incorrectly guessing what the answer would be.

Guessing. Third graders were more accurate but still incorrectly guessed between 19%-42% of the time out of their quick answers. Students' guesses sometimes indicated a focus on the endpoints of the jumps. For example, one third grader, when asked how long the jump from 11 to

21 is, said it was 21, even though he determined the following jump from 21 to 27 was six. One first grader concatenated the labeled points on the number; for example, when determining the distance from 11 to 20, he indicated the distance was "eleven twenty" or 1120. Another first grader added up the labeled numbers, getting 11 + 15 = 26 for the distance from 11 to 20 and then he took that 26 + 20 + 21 to get the distance from 20 to 27.

Aside from endpoints, some students focused on the number of jumps rather than the distance of the jumps. In fact, several students at both grade levels interpreted each jump as a unit of movement rather than a distance. When asked what the distances from 11 to 21 and 21 to 27 were, a third grader replied, "One and one." Likewise, he indicated that the total distance jumped was "Two." Using the apples as his unit of distance, another third grader (like many first graders) said the distance from 11 to 21 was "two" and from 21 to 27 was "one." When asked what the total distance was, he said, "Three" and then counted the three apples to double check.

Known facts. First graders did not show much difference in their use of known facts across their attempts, suggesting the number choices did not affect them much. When identifying the length of the jump from 20 to 27, a first grader indicated that it was seven because it was "twenty and seven more" to 27. Third graders, on the other hand, were noticeably more likely to use known facts when jumping ten or making a multiple of ten than when jumping to and from 15.

Counting. Students were mostly likely to count if they chose 15 first compared to choosing 20 or 21; however, of the 18 times first graders counted, only five times (28%) were correct (five additional attempts were off by one). Third graders were more successful; of the 14 times they counted, nine times (64%) were correct (and three were off by one). Several students miscounted when trying to find the distance between two numbers or adding two jumps. For example, one third grader counted the distance from 15 to 27 as 13. Another third grader raised fingers to count from 15 to 27. At the end of her count she had two fingers up (after counting fingers on both hands), forgot how many hands she had counted before that, and reported the distance as 17 instead of 12. Interestingly, when jumping to 20, another third grader used subtraction (i.e., solved 20 - 11), and one added up in chunks (11 + 4 = 15 and 15 + 5 = 20).

Using structure. Only three first graders (9%) and eleven third graders (31%) explicitly referred (with or without prompting) to using the structure of one number line to help them solve one or more of the distances in the other number line. On the first sub-item, a third grader identified the jump from 11 to 21 as a jump of 10 and from 21 to 27 as a jump of 6. When determining the length of the jump from 11 to 20 on the next sub-item, he said, "That's obvious, nine, since you're just removing one from [that first jump]." Completing the same items in reverse order, a first grader found the distance from 11 to 20 as 9 on the first sub-item. On the next sub-item, when determining the distance from 11 to 21 as 10, she said, "Last time there was nine, and there was just one more." When another third grader went to find the total distance on the second sub-item, he said that he started to add the two jumps and then realized he could just use the ones from the first sub-item. Six additional first graders and five additional third graders noticed the totals were the same after answering or had reactions, such as laughing and quickly answering, that implied they noticed that the total distances were the same.

Discussion

Students' more frequent choice to the jump of ten or to the next multiple of ten and their greater accuracy when doing so, reinforces the importance of helping students make use of 10-based reasoning (Fuson et al., 1992; Murata, 2004). Students were also more likely to notice the structure between the number lines if they chose those jumps. However, fewer than one-third of students used the common structure of the number lines to help them solve the problems, suggesting an increased need to focus on the connections among number combinations. Three factors appeared to detract students' attention to the structure. First, the context may have been distracting for some students. For students who did not think it was feasible for a bunny to jump a certain distance, comparing distances between the two number lines may not have been likely. Interestingly, some students who talked about one choice being better than another did talk about jumps being longer or shorter, suggesting they did notice the differences between number lines to some extent and reinforcing that some contexts may work for some students and not for others. Second, and related to the first, the number line model was unfamiliar to some students, or they focused on the number of jumps instead of the distance of the jumps.

While we maintain that the number line is an important model for students to interpret, we could explore additional ways of presenting the distances (perhaps as bars stretching from one point to the next instead of jumps) to support learners who are less familiar with these models. Third, the difficulty of the numbers played a role in students' attention to the structure. Students (typically third graders) with strong number sense did not necessarily benefit from noticing structure among the jumps; on the other hand, students (such as most of the first graders) who used more on guessing or had inaccurate counting were not likely to notice the structure. Therefore, to help students notice structure the specific numbers in the items need to be chosen carefully. For example, the first graders might have been more successful if the bunny was starting at 1 and jumping to either 5, 10, or 11 before jumping to 15. That said, encouraging reflection on the visuals of the jumps did promote some students' curiosity about the relations between the two sub-items.

Even if they did not use the structure of one number line to interpret distances on the second number line, students' use of known facts without explanation provides some evidence that they noticed structure within the numbers presented (i.e., adding a ten or making a ten). Regarding those who did notice structure, their answers suggest that pairing problems with number lines in this way could help students check and reason about the accuracy of their answers and could help students think about the relation between number combinations, especially if paired with discussion. Helping them make connections about common distances on the number line could later support a focus on distance when using rulers.

Interest-driven activities, such as mathematical play, can support student agency, motivation, and engagement, and can foster dispositions that reflect authentic disciplinary engagement. However, the bulk of research on mathematical play investigates the mathematics that emerges in young children's natural play or in informal spaces such as video games. We introduce the term "playful math" to highlight the potential of playifying classroom-based activities, and we explore the nature of students' activity when engaged in playful math tasks in a teaching experiment. Our findings show that playful math tasks increased students' agency, authority, investment, and goal selection, as well as encouraged the development of creative, challenging ideas. We present a case of two students' playful engagement in the form of an Explore-Strategize Cycle and discuss implications of playful math for student engagement.

Keywords: Algebra and Algebraic Thinking, Cognition, Problem-Based Learning

Motivation and engagement are critical factors in supporting students' abilities to understand and persist in mathematics (e.g., Durksen et al., 2017). Students' experiences of self-efficacy can foster motivation, which in turn can predict persistence in STEM fields (Simon et al., 2015). There remain, however, ongoing challenges with student motivation and engagement in mathematics (Martin & Marsh, 2006). These challenges are particularly salient in algebra, which represents a critical transition to secondary mathematics, and can act as a gatekeeper, with algebra performance often serving as the main criterion to determine a student's readiness for more advanced courses (Riegle-Crumb, 2006).

One contributing factor to these challenges is that the mathematics taught in algebra can emphasize routinized procedures, resulting in students reporting decreased motivation and engagement (Herzig, 2004). In contrast, focus on interest-driven activities such as mathematical play invites student agency and can increase equitable access to algebra (Widman et al., 2019). In fact, much of authentic disciplinary engagement involves many of the same features as play (Gresalfi et al., 2018; Jasien & Horn, 2018), and professional mathematicians have been shown to engage in mathematical play as part of their disciplinary practice (Lockhart, 2009).

Mathematical play has the potential to support a productive environment for conjecturing and exploring by centering student voices and by offering opportunities to investigate novel ideas (Gresalfi et al., 2018). It can also offer important engagement, motivation, and conceptual benefits, with studies suggesting positive effects for enjoyment, attitudes, and learning outcomes (e.g., Barab et al., 2010; Plass et al., 2013; Wager & Parks, 2014). However, the bulk of existing research on mathematical play is situated either in early childhood learning, or in informal spaces such as video games. Mathematical play can certainly occur in classroom settings, but less is understood about how to incorporate play into the school mathematics that students and teachers navigate in classroom settings, particularly for adolescents. Therefore, this study investigates what occurs when incorporating play-based elements in algebra problem-solving tasks. We use the term "playful math", rather than "mathematical play", to highlight the potential of "playifying" classroom mathematical activity. In particular, we address the following research questions: (1) What characterizes students' mathematical activity when investigating rates of change within play-based activities? (2) How does playifying mathematical tasks affect the nature of students' engagement, if at all?

Background Literature: The Potential Benefits of Playful Math

Mathematics is an area for which interest-driven engagement is not always a consideration in pedagogical design, and yet, focus on interest-driven activities can invite student agency and create spaces for students to bring in more of their whole identities (Widman et al., 2019). Playful math can offer multiple points of access into mathematical ideas, providing opportunities for students to create new challenges for themselves and experiment with ideas that go beyond familiar operations and connections (Featherstone, 2000). Playful engagement can also free students from the stigma of traditional assessment, encouraging a disposition of exploration and innovation (Barab et al., 2010). Research investigating children's and adolescents' playful math suggests both affective and conceptual benefits. Playful math has been shown to support increased enjoyment (Plass et al., 2013), increased engagement (Barab et al., 2010), positive social interaction and communication (Edo et al., 2009), and to engender positive attitudes towards mathematics (Holton et al., 2001). Playful math has also been shown to offer some cognitive benefits, supporting children's geometric thinking (Levine et al., 2005), spatial skills (Casey et al., 2008; Levine et al., 2012), and number development and numeracy (Siegler & Ramani, 2008; Wang & Hung, 2010). Some studies even suggest increased learning efficacy in play-based environments (Barab & Gresalif, 2010; Bodrova, 2008).

Some benefits afforded by play may occur because playful math offers avenues for students to "conjecture and explore in disciplinarily authentic ways" (Jasien & Horn, 2018, p. 624). In fact, there are a number of features of play that mirror the forms of engagement seen in the work of mathematicians, including open exploration, the use of imagination, being voluntary, being ordered and rule governed, and exercising personal agency to determine and pursue goals (Gresalfi et al., 2018; Featherstone, 2000). These parallels point to the importance of intellectual play in learning mathematics, and suggest a need for research examining ways to make mathematics tasks more playful. In particular, the field needs more research exploring playful math with older students in middle-school, high-school, and college, particularly in terms of incorporating playful elements into classroom mathematics in critical domains such as algebra.

Theoretical Frameworks: Defining Playful Math and Quantitative Reasoning

Definitions of mathematical play vary, but all emphasize students' agency in exploration, self-selection of goals, and self-direction in how to accomplish them (Jasien & Horn, 2018). For instance, Williams-Pierce (2019) defines mathematical play as "voluntary engagement in cycles of mathematical hypotheses with occurrences of failure" (p. 591), and Holton et al. (2001) describe mathematical play as the playful exploration that emerges when learners find themselves in mathematical contexts with an open goal. One challenge in characterizing play is that it describes both a form of activity (such as playing a video game) and a stance or orientation towards an activity (Malaby, 2009). We address the second aspect to define playful math as a particular form of engagement in mathematics, one that entails (a) agency in exploration, (b) self-selection or investment in mathematical goals, (c) self-direction in goal accomplishment, and (d) a state of immersion and/or enjoyment.

For the purposes of this study, we leveraged situations involving covarying quantities that students can manipulate and investigate in order to reason flexibly about function as a representation of dynamically changing events (Carlson et al., 2002). By quantities, we mean schemes composed of a person's conception of an object or event, such as a rectangle; a quality of the object or event, such as the rectangle's length or area; an appropriate unit, such as centimeters or square centimeters; and a process for assigning a numerical value to the quality (Thompson, 1994). By covariation, we refer to the visualization of two quantities' values simultaneously, uniting the quantities' magnitudes in order to understand that at every instance, both quantities have a corresponding value (Saldanha & Thompson, 1998; Thompson & Carlson, 2017). Researchers argue that students naturally attend to coordinated changes (e.g., Blanton & Kaput, 2011), which is supported by studies showing that students typically first analyze functional situations from a coordinated change perspective (e.g., Confrey & Smith, 1995; Madison et al., 2015). Furthermore, we hypothesized that the visualization opportunities afforded by a covariation approach could potentially support the type of open exploration and agency that occurs in playful engagement. As we describe in the next section, we built on students' natural ways of reasoning to modify a set of existing covariation activities in order to playify them.

Methods

Setting and Participants

We conducted two teaching experiments (TEs) (Steffe & Thompson, 2000), which both met weekly for 60-75 minutes a session for 5 consecutive weeks. The first author was the teacher-researcher (TR). Both teaching experiments were video and audio recorded, with the exception of Day 2 for each, when a technical error prevented video recording. After each session, we collected all student written work. The first teaching experiment was a paired TE with two rising 7th-grade students, Stewie and GJ. The second TE was with three participants, Artemis (a rising 7th-grade student) and Apollo and Francis (rising 6th grade students). (Participants chose their own pseudonyms.) Due to schooling interruptions from Covid-19, the students' experiences with graphing and functions was largely limited to plotting points. The rising 7th graders also had some experience with graphing lines, but none of the students had experienced a unit on linear functions. For the purposes of this paper, we report on data from the first TE with Stewie and GJ.

Task Design Principles

Our aim was to playify existing covariation problems in order to investigate students' mathematical activity when exploring rates of change within play-based tasks. By "playify", we mean increasing the potential for playful math engagement, while also acknowledging that a task cannot dictate how students will engage with it. We drew on a set of established research-based activities to support understanding of linear and quadratic growth with continuously covarying quantities (Ellis et al., 2020; Matthews & Ellis, 2018). In these activities, students investigate dynamically growing shapes, determining the rate of change of a shape's area compared to its changing length as it sweeps out from left to right, and then graph that relationship (Figure 1).

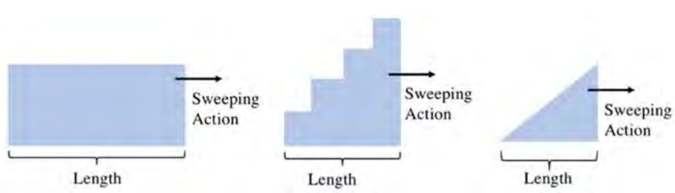

Figure 1: Growing Rectangle, Stairstep, and Triangle

We followed four design principles to playify the tasks (Plaxco et al., 2021): (1) allow for free exploration within constraints; (2) allow the student to act as both designer and player; (3) engender anticipating within the task; and (4) provide a method for authentic feedback. These led to the *Guess My Shape* activity, in which the students created secret shapes of their choice (design principles #1, #2), constructed graphs comparing length and area (design principles #2, #3), and then challenged one another or the TR to determine the shape based on the graph alone (design principles #2, #3, #4). We hypothesized that the playified tasks would encourage playful engagement, without assuming that they would guarantee such engagement.

For Session 1, we only used the extant covariation tasks (Figure 1), which we call standard tasks. For Sessions 2 - 5, we used both the standard tasks and the playified tasks. For each of those sessions, we spent the first two-thirds of the session working with the standard tasks and the last one-third implementing the playified tasks. Figure 2 shows an example of the types of shapes the students encountered and their associated graphs.

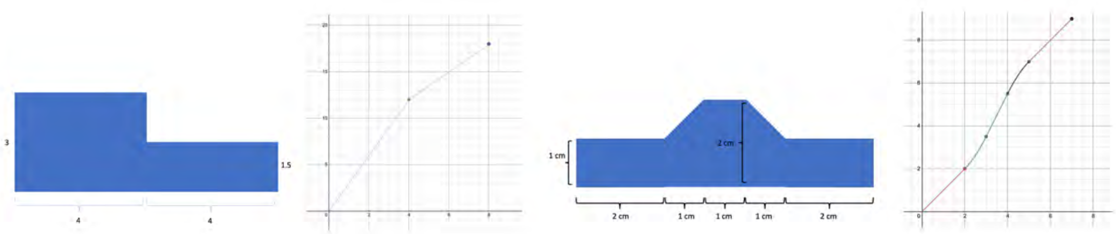

Figure 2: Shapes and associated length-area graphs

Analysis

We employed retrospective analysis (Steffe & Thompson, 2000) in order to characterize the students' conceptions throughout the teaching experiment. We first transcribed each session and then produced a set of enhanced transcripts that included verbal utterances, images of student work, and descriptions of non-verbal actions. We then analyzed the data with two lenses. With the first lens, we identified students' conceptions of graphs, covariation, and rates of change, drawing on Thompson and Carlson's (2017) framework of variational and covariational reasoning, Ellis et al.'s (in press) conceptual acts for constructing linear and quadratic growth through covariation, and Moore and colleagues' graphing actions (Liang & Moore, 2020; Moore et al., 2019; Tasova & Moore, 2020). With the second lens, we identified aspects of playful mathematics, relying on a combination of a priori codes from our definition of playful math, as well as emergent codes that occurred during the coding process through the constant comparative method (Strauss & Corbin, 1990). For the purposes of this paper, we focus on the analysis conducted through the second lens of playful math, and we describe those codes in the next section. The first three authors coded each transcript independently, and then the project team met weekly to refine and adjust codes and resolve discrepancies; this iterative process continued through eight rounds of code adjustments, until all codes had stabilized.

Results: The Explore / Strategize Cycle

Recall that our second research question considered whether and how playifying tasks may affect the nature of students' mathematical engagement. In addressing this question, we turned to our playful math codes to assess whether there was any difference in code frequencies across the two task types. We developed six playful math codes: (a) self-selection or investment in mathematical goals, (b) agency in exploration, (c) investment and/or enjoyment, (d) taking on authority, (e) creative / unusual, and (f) harder math. The first three codes were drawn from our definition of mathematical play. *Self-selection of goals* occurred when students chose their own goals or showed evidence of being invested in a goal. *Agency in exploration* refers to instances of students demonstrating agency in how they explored a task or its goals, and *investment and/or enjoyment* occurred when students showed evidence of investment or immersion, and/or demonstrated enjoyment of their activity. The remaining three codes were emergent. *Taking on authority* refers to instances of students demonstrating mathematical authority with a task or in their engagement with the TR. *Creative/unusual* applies when students have developed an idea, representation, or task that we perceived as creative or novel, and *harder math* occurred when students created a goal or task that introduced challenging mathematics that surpassed the TR's intended set of topics or concepts.

Across the five sessions we implemented 18 standard and 5 playified tasks. In our initial rounds of coding, we applied the relevant code any time we observed a student demonstrating evidence of playful engagement, resulting in a total of 130 code occurrences. We then revisited the codes to determine how many times they occurred during the standard tasks compared to the playified math tasks. We found that our first three codes occurred across both tasks, but with greater frequency in the playified tasks, supporting our hypothesis that the playified tasks would in fact elicit more playful engagement. The last three codes only occurred during playified tasks (Figure 3). The difference in code frequencies is striking given that 78% of the tasks enacted during the teaching experiment were standard tasks.

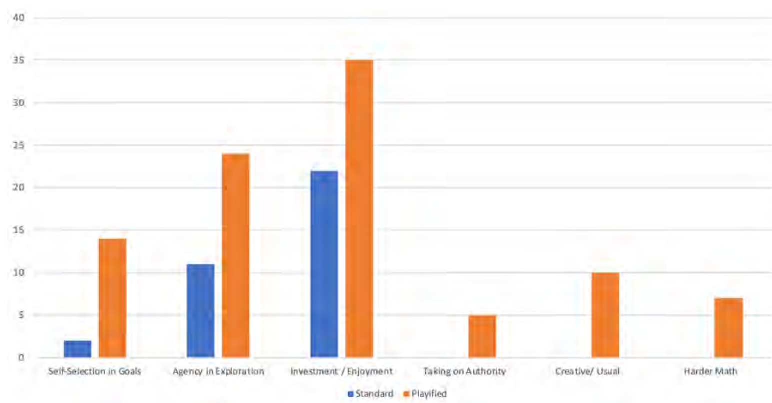

Figure 3: Playful math codes across standard and playified tasks

The difference in code frequencies led us to consider in more detail the nature of students' activity within the playified tasks, addressing our first research question. We found that during those tasks, the students demonstrated a novel form of engagement, which we call the *Explore-Strategize Cycle* (Figure 4). Within this cycle, students shift back and forth between exploration and strategizing. Exploration occurs when students either (a) engage in an action with little or no anticipation of an associated outcome, or (b) notice properties of outcomes and wonder about the connection between those outcomes and the actions that led to them. For example, in the Guess My Shape game, students engaged in exploration when they invented new shapes or when they plotted points arbitrarily to try to develop an unusual graph. In contrast, strategizing occurs when students engage in actions tied to an anticipated outcome. This could include modifying a shape to create a graph that will have a specific property, such as symmetry, or recognizing that a particular shape will be difficult to graph. Once we identified the Explore-Strategize Cycle in students' activity, we revisited the entire data corpus to determine whether this cycle occurred across both task types. We found no instances of the cycle in the standard tasks; instead, during those tasks, students engaged in repeated acts of strategizing but without associated exploration.

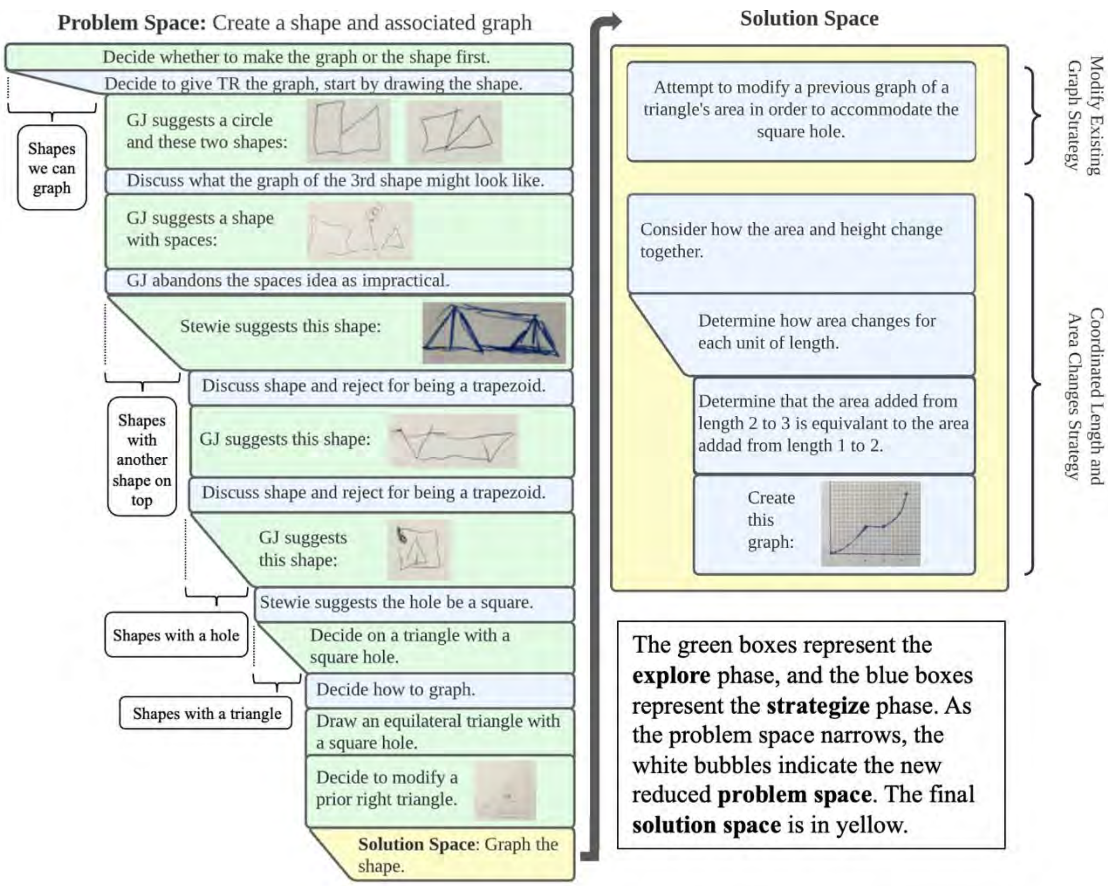

Figure 4: The Explore-Strategize Cycle for A Triangle with a Square Hole

In order to exemplify the nature of students' playful engagement, we present one Explore-Strategize cycle, in which Stewie and GJ collaborated on the Guess My Shape game to create a task that would stump the TR. Within any cycle, there are both problem spaces and solution spaces. As students engage in exploring and strategizing, they narrow the problem space. For instance, when playing Guess My Shape, the set of possible problems are determined by the shapes that the students draw and graph. As they consider what shape to create and how to graph it, they progressively narrow the problem space by exploring characteristics of their invented shape (such as symmetry, the inclusion of a hole, and so forth), or by strategically selecting aspects of the graph or shape to examine. In doing so, the students exclude shapes that do not meet the desired criteria. This can be seen in Figure 4 in the narrowing of the initial problem space, "create a shape and associated graph", down to the final problem they chose to solve, "graph the area and length of this right triangle with a square hole". Once the students have narrowed down to the final problem, they shift into the solution space.

As GJ and Stewie narrowed the problem space, they set implicit and explicit goals to guide their actions. The first decision they had to make was whether to start with a shape or a graph. Stewie suggested that they begin with the graph, "because that would be harder", but GJ wanted to begin by drawing the shape. Together, the students had an implicit goal of creating a shape that was both feasible for them to construct and still challenging for the TR. Stewie strategically negotiated these goals by suggesting that they create the shape first but give the TR the graph. In doing so, he anticipated that determining the shape from the graph would be more difficult than determining the graph from the shape. From this strategizing action, the students have now narrowed the problem space to shapes within their ability to graph.

GJ and Stewie then began to explore a series of potential shapes. Each time, their exploration phase was followed by a strategizing phase in which they tried to anticipate what the associated area-length graph would be. During this process, they rejected multiple shapes as being too difficult to graph, including a circle, composite shapes, and shapes with spaces. They also rejected shapes as being too simple, such as composite shapes that would have area-length graphs identical to trapezoids. GJ then suggested a square with a triangular hole. However, in shifting to considering the associated graph (strategizing phase), the students decided that it would be easier to graph a shape with a square hole. They then explored a triangle shape with a square hole, and then when strategizing how to graph it, anticipated that they could create a graph by partitioning their chosen shape into squares. In exploring final shape options, GJ and Stewie settled on a right triangle, similar to a prior shape they had graphed, but this time with a square hole.

Once the students reached the solution space, they used two different strategies. Their first strategy was to modify a prior graph they had made of a similar triangle without a hole. Stewie said, referring to the constantly-increasing area, "It's going to be a curved line the whole way, and the triangle, but then, what do you do?" Stewie was anticipating that the graph would look different where the hole occurred, but he trailed off, becoming uncertain about how to account for the hole. He then shifted to the second strategy, suggesting that they consider how the area and length change together. In doing so, he quantified the length and area segments, writing "4 in." for both the length and the height of the triangle. He then suggested they determine the area and its change for each unit of length: "At the first point, it was half, all right. For the second one, was one and a half." As he spoke, Stewie began to graph a curve for the first two points. In determining the area from $x = 2$ in. to $x = 3$ in., the portion of the triangle with a 1-in.^{2} hole, both students decided that the area added would be the same as the area added for the prior increment, from $x = 1$ in. to x = 2 in:

Stewie:	So, third one is the same as the second one pretty much.
GJ:	It is.
Stewie:	So, so it would just be like, here. [Draws a horizontal line segment.]

Stewie and GJ anticipated, incorrectly, that the graph would be horizontal if the amount of area added from $x = 2$ to $x = 3$ was the same as the amount of area added from $x = 1$ to $x = 2$. They were correct that the amount of area added was the same across the two increments, but they conflated total accumulated area with added area. When next considering the final increment, from $x = 3$ in. to x = 4 in., Stewie returned to a curve, recognizing that the amount of area constantly increased throughout the increment. It was later in their conversation with the TR that the students realized that the portion of the graph from $x = 2$ in. to $x = 3$ in. would be another curve, rather than a horizontal line segment.

The students demonstrated all six playful math codes during this Explore/Strategize Cycle. They self-selected multiple goals in deciding what types of shapes to pursue, and they also demonstrated agency in exploring those shapes and their associated graphs, freely shifting across different potential shapes. In suggesting novel shapes such as circles, composite shapes, and shapes with spaces and holes, the students demonstrated ideas that were creative and unusual; many of their shapes were markedly different from those that had been previously introduced.

Furthermore, their decision to introduce a hole was not only creative, it also represented a new challenge (harder math), one that took the TR by surprise and brought up a set of mathematical ideas that the TR had not anticipated addressing. In particular, once holes are allowed, area-length graphs no longer uniquely determine a shape, which raises new questions about the set of shapes with holes that can be determined by an area-length graph.

The students also demonstrated immersion, investment, and enjoyment in the task. Their engagement was sustained; they spent 27 minutes on this task alone, and they considered and abandoned many shapes before ultimately settling on a final version. When bringing the TR in to determine the shape from their graph, they actually changed their minds about the accuracy of their graph in the moment. In doing so, the students decided to send the TR away again so that they could re-evaluate. Stewie told the TR, "I think I have an idea. I'm, I'm not totally confident. Yeah, go away." In this moment, the students evidenced investment in their graph, as well as mathematical authority, deciding not only what the graph should be, but also dictating how the process of sharing their work should proceed.

Discussion

Playifying tasks did result in more playful engagement during those tasks; in fact, three forms of playful engagement (taking on authority, creative / unusual, and harder math) occurred only during the playified tasks. However, we still found evidence of playful engagement in the standard tasks, which underscores that playful math as a construct describes a form of engagement, rather than a type of task. Furthermore, although we only observed explore-strategize cycles during the playified tasks, this may be due to the fact that the playified tasks were also more open-ended tasks. More research is needed to tease out the effects of playifying tasks that begin as open-ended tasks. The presence of playful engagement across all tasks suggests that playifying mathematics might support a more playful disposition in general. In our data, we found that one form of playful engagement, investment and/or enjoyment, increased throughout the sessions (occurring six times across the first two days, compared to 34 times on the last two days). It may be that sustained engagement in playful math supported students' increased investment in subsequent tasks, regardless of their form.

One affordance of playful math is that it has the potential to center student voices, particularly those voices less likely to be taken up in more traditional classroom settings. Two of our design principles were particularly important in this role: allow free exploration within constraints, and allow the student to act as both player and designer. By shifting the student's role to designer and encouraging exploration in designing, we opened a space for students to introduce their own ideas in ways that were less constrained by pre-determined topics. Their resulting ideas were novel, creative, and mathematically challenging, and the students demonstrated autonomy and authority. We know that mathematicians, in their own disciplinary practice, also experience this type of autonomy and shift back and forth between exploration and strategizing in a manner similar to what we observed in our Explore / Strategize Cycles (e.g., Lockwood et al., 2016). By playifying mathematics, we set up spaces for more students to adopt productive mathematical dispositions. But more importantly, playful math has the potential to increase overall engagement and enjoyment of mathematics, particularly for students who may not experience traditional mathematics as engaging or enjoyable.

“THIS ONE IS THAT”: A SEMIOTIC LENS ON QUANTITATIVE REASONING

Allison L. Gantt	Teo Paoletti	Steven Greenstein
University of Delaware	University of Delaware	Montclair State University
agantt@udel.edu	teop@udel.edu	greensteins@montclair.edu

Despite significant research exploring students' quantitative reasoning, few studies have explored the semiotic processes that mediate its development. In this report, we present a case study to show how one student constructed a semiotic chain for a quantity as he worked with a mathematical task. Importantly, we connect frameworks for quantitative reasoning and semiotics to make sense of this process. Our findings show how our case student constructed a sign for a chunk of change in a triangle to support his later construction of the quantity of amount of change of area. We also describe how the case student leveraged these signs to bolster his development of the quantity of total area. We emphasize the role of artifacts, such as physical manipulatives, a digital applet, and a diagram, in this process. Finally, we discuss the implications of this analysis for future studies that explore students' constructions of quantity.

Keywords: Algebra and Algebraic Thinking, Cognition, Mathematical Representations

Students' construction of quantities is a non-trivial process (Smith & Thompson, 2008; Thompson, 2011). According to Thompson (2011), “Too often quantities, such as area and volume, are taken as obvious, and hence there is no attention given to students' construction of quantity through the dialectic object-attribute-quantification” (p. 34). In this paper, we seek to investigate this dialectic by bridging two perspectives—namely, quantitative reasoning and semiotics. Specifically, we investigate the following research question: *What can a semiotics lens reveal about a learner's constructions of quantities?*

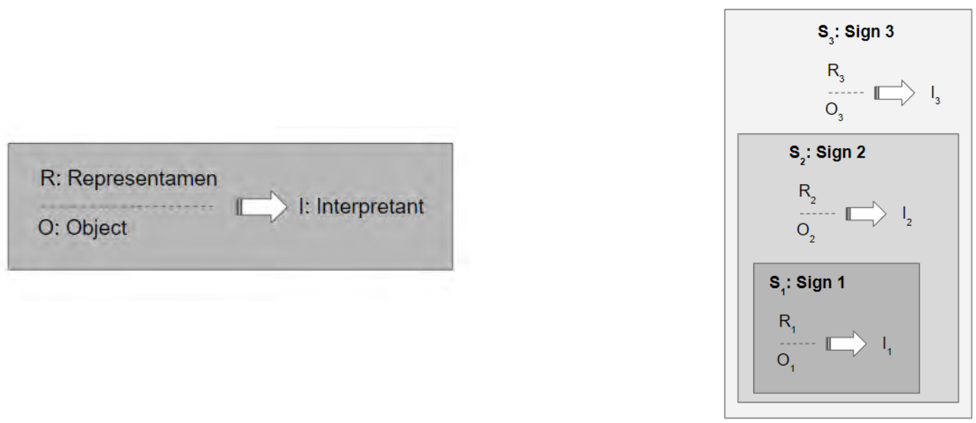
In this report, we first briefly present the frameworks of quantitative reasoning and semiotics, with attention to the ways we intend to use these perspectives concurrently. Then, we describe the method and findings from a revelatory case study (Yin, 2018) of one student's construction of a semiotic chain related to the quantity of an *amount of change* in a dynamic task. We discuss the implications of these findings for researchers and practitioners intending to support students to engage in quantitative reasoning.

Quantitative Reasoning and Semiotics

We follow Smith and Thompson (2008) in conceptualizing quantities as mental constructions of measurable attributes of objects or phenomena. Quantities establish the “conceptual content” (Smith & Thompson, 2008, p. 10) students may represent mathematically (Paoletti & Moore, 2017; Thompson, 1994). Quantitative reasoning, then, entails constructing and reasoning about relationships between conceived quantities.

Individuals can conceive of a quantity that changes its measure (or *varies*). Consider, for instance, the quantity of changing area in a growing triangle (https://ggbm.at/t6d63cun). An individual may develop a smooth image of change for the area of the triangle such that it “[takes] on values in the continuous, experiential flow of time,” (Castillo-Garsow et al., 2013, p. 34). For instance, they can imagine an animation of the triangle growing continuously. An individual may also develop a chunky image of change, entailing a visualization of completed intervals without attending to variations within an interval. For example, one can imagine the triangle's growth in snapshots over time. Although both smooth and chunky images are important for students to develop, chunky images of change can also enable the conceptualization of another important quantity—an *amount of change* (hereafter AoC) between intervals (Carlson et al., 2002). Researchers have highlighted the importance of students' constructing amounts of change, for example, to differentiate between linear and non-linear growth (Paoletti & Vishnubhotla, in press), conceive of rates of change (Carlson et al., 2002), and represent quadratic (Wilkie, 2019, 2021) and trigonometric (Moore, 2014) relationships.

Given the importance of imagery in conceptualizations of quantity, we conjecture that one's mental representations necessarily meditate a student's quantity construction and corresponding meanings. Presmeg's (2006) model for semiotics in mathematics education (adapted from Peirce, 1998) provides a way to describe this process. Presmeg argued that connecting ideas in mathematics involves the negotiation of *signs*, which is the focus of semiotics. Learners construct signs as they strive to make sense of relationships between representations and their associated objects, ultimately developing interpretations for the object and representation. Presmeg follows Peirce (1998) in identifying signs as composed of these three components—*object*, *representamen* (or representation), and *interpretant* (or interpretation)—which operate together in triadic relationship as meaning is negotiated. Figure 1a shows a model for a sign.



(a) (b)

Figure 1: (a) The triadic relationship of a sign (Peirce, 1998) and (b) the process of semiotic chaining (Presmeg, 2006).

To illustrate and define these terms, consider an animation of a continuously growing triangle. One may conceive of the changing triangle (i.e., the *object*, or what a sign could stand for) and construct this object in conjunction with a mental image of the changing triangle (i.e., their *representamen* of the object, or the perceivable part of a sign). In the process of relating object and representamen, they can interpret the changing triangle in relation to a quantifiable attribute such as its area. This would be regarded as an *interpretant* for the individual, which explains the relationship they constructed between the object and the representamen. This process of arriving at an interpretant is an act of *meaning making* for the individual.

As individuals continue to engage with new ideas, they can call to mind their previous signs (i.e., triads of object-representamen-interpretant) and construct new ones. Once established, the whole of a sign can be regarded as an object onto which new representations and meanings can be built (e.g., Sfard, 1991). Presmeg (2006) refers to this process as *semiotic chaining*, whereby previous signs are nested within a new sign which "comprises everything in the entire chain to that point" (p. 169). Semiotic chains can thus explain how learners' meanings are enriched as they continuously connect the signs they make. We present a recreated visual of Presmeg's conceptualization of this process in Figure 1b.

As suggested in our example, objects, representations, and interpretations may be motivated by the artifacts with which one engages (e.g., animations, diagrams, manipulatives). As learners interact with and reconcile their interpretations of multiple artifacts, each artifact can add nuance to associated signs the learner possesses (Radford, 2010). Maffia and Maracci (2019) define this process as *semiotic interference*, which is "an enhancing of signs emerging from the contexts of use of different artifacts and referring one to the other" (p. 3-58). That is, as a learner engages a new artifact, they may translate their interpretations of "old" signs from one context in relation to new ones in another, furthering the development of meanings associated with the sign. In this way, semiotic interference describes how signs become decontextualized and generalized, and thereby more meaningful.

Method

We present a revelatory case study (Yin, 2018) to elucidate how one student's quantitative reasoning developed through a process of semiotic chaining and semiotic inference. The case study was drawn from a larger teaching experiment (Steffe & Thompson, 2000), where a pair of students engaged several tasks designed to elicit and support their covariational reasoning, detailed in Paoletti and Vishnubhotla (in press). We chose to focus on the case of a single student's activity in the beginning stages of one such task, as this account revealed how artifacts played a role in his development of meanings for a quantity via semiotic chaining.

Participant, Context, and Task

Our case student, Vicente, attended sixth grade at a public middle school in the Northeastern United States at the time of data collection. He engaged with the tasks of the teaching experiment with a partner, Lajos. One teacher-researcher (TR, second author on this paper) conducted the teaching experiment with the two students over 12 sessions.

The students engaged the *Growing Triangle Task*, which asked them to consider the relationship between the length of the base segment and area of a growing triangle, presented to them through a dynamic applet (seen in Figure 2a). The ultimate goal of the *Growing Triangle Task* was for students to graph the covariational relationship between these two quantities. However, in the three 40-minute sessions that Vicente and Lajos spent working through the task, only about half of the time involved graphing activity. The TR first sought to develop students' meanings for key quantities in the scenario (e.g., base segment length, total area, AoC of area). We focus this report on Vicente's pre-graphical work as it allows us to provide evidence of his process of semiotic chaining as he constructed the AoC of area.

To support the goals of developing meanings for situational quantities, the TR designed multiple artifacts to mediate students' engagement with the task. Students had access to a digital applet that could change to display the triangle's growth as smooth or chunky (Figure 2a). They also had access to physical manipulatives of instantiations of the growing triangle (Figure 2b) as well as trapezoidal pieces intended to represent the quantity of AoC of area between instantiations (Figure 2c). We note that, in addition to these prepared artifacts, the students and TR also generated artifacts (e.g., diagrams) in the moment to support their work.

Data Collection and Analysis

We audio- and video-recorded Vicente and Lajos's activity using a free-standing camera and screen capturing software. We also collected and scanned written activity from each session. We then transcribed the recordings, including verbal utterances, gestures, and the artifacts students engaged (both prepared and actor-generated) to support our investigation of the artifacts' mediating role in Vicente's construction of quantity.

As we began to respond to our research question through our analysis of the data, we identified transcript segments of interest and the emerging meanings associated with them. First, to ensure we captured Vicente's activity and signs related to AoC of area in their context, we organized our transcript into analytical units bounded by the TR's central prompts (e.g., "How are they changing together?"). Then, through open and axial analysis (Corbin & Strauss, 2015), we examined the data for the types of meanings and related signs Vicente expressed around AoC. After this process, we analyzed each segment to consider how Vicente used or referenced artifacts in his expressions of meanings, allowing us to conjecture the occurrence of semiotic interference. We used these analyses to create models of Vicente's semiotic chain related to AoC of area in connection with his engagement with artifacts. Throughout the analysis we maintained a chain of evidence connecting our findings to data to establish trustworthiness (Yin, 2018).

Results

In this section, we highlight the development of Vicente's semiotic chain involving the quantity AoC of area in the *Growing Triangle Task*. Vicente began his activity conceptualizing a chunk of change in the triangle (Sign 1). He built upon this sign to later elaborate this object as a quantity—an AoC of area (Sign 2). Finally, we show how Vicente connected these objects in his elaboration of the total area of the triangle (Sign 3). Throughout, Vicente's activity promoted semiotic interference across artifacts, which functioned to trigger, enhance, and connect signs in his semiotic chain.

Sign 1: Chunk of Change in Triangle

The activity we present in this section shows how Vicente developed a sign for *chunk of change* in the triangle. This involved his understanding that a chunk could be added after an iteration of each triangle to reach the next (e.g., move from TA1 to TA2 in Figure 2b). This interpretant emerged through Vicente's active meaning making as he negotiated the relationship between the growing triangle (an object) and the chunked compositions he came to see in that triangle (his representamen). Vicente enhanced his meanings for this sign through semiotic interference as he shifted across digital applet and physical manipulative artifacts.

To begin the *Growing Triangle Task*, the TR displayed the initial applet (smoothly and then in chunks) to Vicente and Lajos. We posit Vicente established the growing triangle as a dynamically growing object in the context of the digital applet. Furthermore, the chunky representation introduced the possibility for Vicente to conceptualize another object—namely a chunk of change.

The TR next introduced a new artifactual context to the students through physical manipulatives. He stacked two triangle manipulatives (e.g., TA1 and TA2 in Figure 2b) on top of one another (see Figure 3a) and asked Vicente, “Alright so I’m going from this one [*taps the smaller triangle*] to this one [*taps the larger triangle*]. How much has the area changed by?” Initially, Vicente responded attempting to determine a value: “Maybe by 2…like 2 of these [*taps smaller triangle twice*].” To explore how Vicente was mentally representing a change in the triangle, the TR prompted Vicente to color in “how much the area changed by from the first to the second.” Vicente proceeded to shade the darker area in Figure 3a. For Vicente, this was an instance of semiotic interference; he reinterpreted his growing triangle object and representation of a chunked composition from the digital applet to the context of the physical manipulatives.

(a) (b) (c)

Figure 3: Displays of *Growing Triangle Task* in Vicente’s construction of chunk of change.

Next, the TR prompted Vicente to consider his change in area meaning in the digital applet. The TR displayed the applet in chunks, showing the smallest triangle and then its second iteration (producing the same visual as Figure 3a, on a computer screen). He asked Vicente about “what shows the change in area,” and Vicente again pointed to the grey area in Figure 3a. Given the digital applet’s unique affordance for introducing a growing triangle object, we conjecture that this action may have supported Vicente to connect his representation of the chunked composition of the growing triangle with a notion of dynamic change.

Indeed, Vicente’s subsequent activity indicated that he was beginning to develop a meaning for this change as a chunk added to previous instantiations of the triangle. Importantly, this became salient when the TR prompted him to again revisit the physical manipulatives, furthering the semiotic interference. The TR asked Vicente, “Do you see any pattern… with respect to how the changes in area are growing?” The TR arranged overlapping triangle manipulatives (e.g., TA1, TA2 and TA3 in Figure 2b) in a display like Figure 3b. Vicente’s explanation suggests that chunks of change emerged through additive operations. He stated:

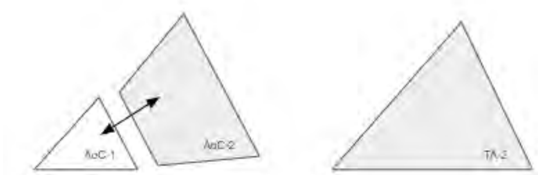
> I think that it’s just, copying off each other… you can see if you counted like it, this [*points to the darkest grey area in Figure 3b*], this would be a bigger one, so you can just add it over [*gestures back toward smallest triangle in Figure 3b*].

As Vicente finished his explanation alluding to meanings for addition, Lajos picked up a new manipulative piece—a trapezoid, as shown in Figure 2c—and placed it against the longest side of the current display of stacked triangles. Vicente explained to the TR, “You can just add another one of the same size… you can kind of add that like there [in Figure 3c].” This interaction shows how the introduction of this new artifact (a trapezoidal manipulative) coincided with even greater emphasis on addition in Vicente’s language about the chunk of change. Taken together, this suggests that semiotic interference (across the digital applet, physical triangle manipulatives, and physical trapezoidal manipulatives) supported Vicente’s development of a sign for a chunk of change in the triangle: that is, a chunk of change had become a new object that could be added after an iteration of each triangle to reach the next.

Sign 2: Amount of Change (AoC) of Area

As described above, Vicente had an interest in numerically describing the magnitude of the chunk of change object he was forming once he first characterized the object (e.g., "Maybe [the area changed] by 2 [of the smallest triangles]"). At the end of the first session, the pair returned to the physical manipulatives, stacking copies of the smallest triangle on top of the trapezoidal pieces (now representing chunks of change) to measure the chunks. They recorded their findings in a diagram (Figure 4a). Thus, Vicente established two artifacts that later became central to his semiotic interference in the development of an AoC of area in his semiotic chain: the physical manipulatives (both triangular and trapezoidal) and the diagram.

(a)



(b)

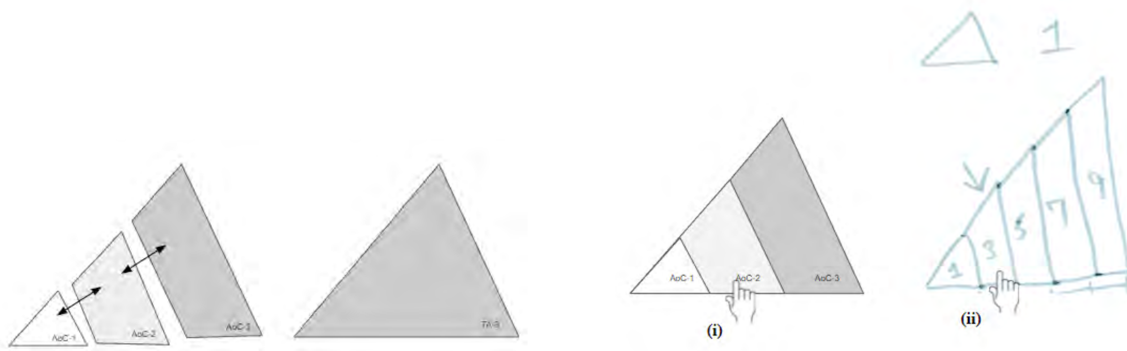
Figure 4: Displays of *Growing Triangle Task* in Vicente's construction of AoC of area.

When the pair of students returned for the second day of the *Growing Triangle Task*, the TR intended to have them to renegotiate their sign for an AoC of area, and he employed both the physical and diagrammatic artifacts to do so. First, referring to their diagram (Figure 4a) the TR asked, "What were these numbers representing, what were you talking about with these?" As Vicente swiped his finger over each corresponding trapezoidal component in the diagram, he described that "in here you could fit 3, then here you could fit 5, then here you could 7… [of] the little triangles." We interpret that Vicente understood the numeric values as representing measures of AoC of area in terms of the first triangle (e.g., AoC 1 in Figure 2c). Moreover, the diagrammatic artifact provided a recorded, concretized representation of chunks of change and their values he could draw upon in the construction of his sign for AoC of area.

The TR, however, encouraged Vicente to extend his meanings back again to the physical manipulative context of the scenario. The manipulative context was important in Vicente's sign for AoC of area due to its previous interference with the digital applet. Arranging the shapes as in Figure 4b, the TR asked Vicente, "So when you say what fits 3 of what?" Vicente at first picked up the larger triangle (i.e., TA2 in Figure 2b) and attempted to arrange copies of the smallest triangle on top. However, he quickly decided "not this one," picked up the trapezoidal piece (i.e., AoC2 in Figure 2c), and began to arrange the small triangles on top of there. He was able to fit 3 small triangles and affirmed, "Yeah, this one." We note that Vicente's activity was effortful, indicative of the semiotic interference involved in his meaning making for AoC that extended across diagrammatic and manipulative contexts. Collectively, Vicente's negotiations across artifacts indicate the development of a new sign in his semiotic chain: an AoC of area. For him, the AoC of area was an object with magnitude that could be determined using the small triangle's area as a unit, establishing a quantity constructed from his sign for a chunk of change.

Sign 3: Total Area of the Triangle

Vicente's chaining of signs for chunks of change and AoC of area supported him in developing new meanings for a related object: total area in the growing triangle. As described in the previous section, the TR had now re-introduced total area manipulatives of the growing triangle (e.g., TA3 in Figure 2b). In this interaction, the TR arranged trapezoids and a triangle piece on the table in front of the two students (see Figure 5a). He asked the pair, "This [smallest triangle] is 1; how big is that [*gesturing to large triangle displayed in Figure 5a*]?"



(a) (b)

Figure 5: Displays of *Growing Triangle Task* in Vicente's construction with total area.

Vicente explained his reasoning to Lajos in a way that first expressed a meaning for the relationship he understood to exist between the largest triangle and trapezoidal pieces in the arrangement of Figure 5a. He argued that "this [*tapping on the largest triangle in Figure 5a*] is the same as that [*gesturing to the trapezoids pushed together in Figure 5a*]." He then picked up the largest triangle piece and placed it on top of the trapezoidal arrangement to show it "fits in perfectly." We note Vicente's argument established a sign for total area as an object related to artifacts that had established his sign for AoC, suggesting a new link in his semiotic chain.

Vicente's next statements demonstrated the salience of his sign for AoC of area as he found a measurement of total area. At first, he gestured to each progressively larger trapezoid in the manipulatives, declaring that they had values of 3 and 5, respectively. When explaining to Lajos, he revealed how his own meanings for the AoC object had been supported through the semiotic chaining he had established with the diagrammatic artifact. Specifically, Vicente explained, "this one [*pointing to manipulatives as in Figure 5b(i)*] is that [*pointing to diagram as in Figure 5b(ii)*], so you can fit 3 [small triangles] in there." Here, Vicente directly related the area of the trapezoidal physical manipulatives to the areas noted in their diagram.

Finally, Vicente called upon his initial interpretations of chunks of change to determine the total area of the triangle. He concluded that "1 plus 3 is 4, and then… 4 plus 5 is 9," identifying that 9 would be the total area of the given triangle. We note that, in this explanation, Vicente does not express his conclusion for total area as simply an addition of consecutive bands in the composite triangle (that is, 1 + 3 + 5 = 9). Instead, Vicente considers each intermediate total area in a way that might reflect an AoC of area as adding on to previous total areas in each step (i.e., 1 + 3 = 4, then 4 + 5 = 9). This further suggests the critical role of Vicente's previously constructed signs in his reasoning. Viewing Vicente's argument holistically, AoC of area (which was based on his sign for chunk of change) formed the basis of his exploration of magnitude with a related quantity (and sign) of total area. We summarize our hypothesis about Vicente's enacted semiotic chain in Figure 6. This figure shows the process by which his sign (1) for a chunk of change in the triangle became an object for his sign (2) AoC of area, and then these subsequently became objects for a sign (3) for total area of the triangle.

Conclusion and Discussion

In this paper, we brought together quantitative reasoning and semiotics frameworks to present a case study that highlighted the emergence of a semiotic chain (Presmeg, 2006) of a student's construction of quantity through his engagement with multiple artifacts. Specifically, we anchored our analysis in Vicente's development of signs related to the quantity of AoC of area. This included his initial constructions of a chunk of change in the triangle and his later connection to the total area of the triangle. Moreover, our evidence showed the processes of semiotic interference (Maffia & Maracci, 2019) that account for the enhancement of Vicente's signs (e.g., building a sign for the quantity of AoC of area by connecting notation in a diagram to his work with physical manipulatives). Addressing our research question, a semiotic lens on Vicente's quantitative reasoning helped us to make sense of the mediated processes that supported him as he developed associated meanings in conjunction with his representational activity through both the processes of semiotic interference and semiotic chaining.

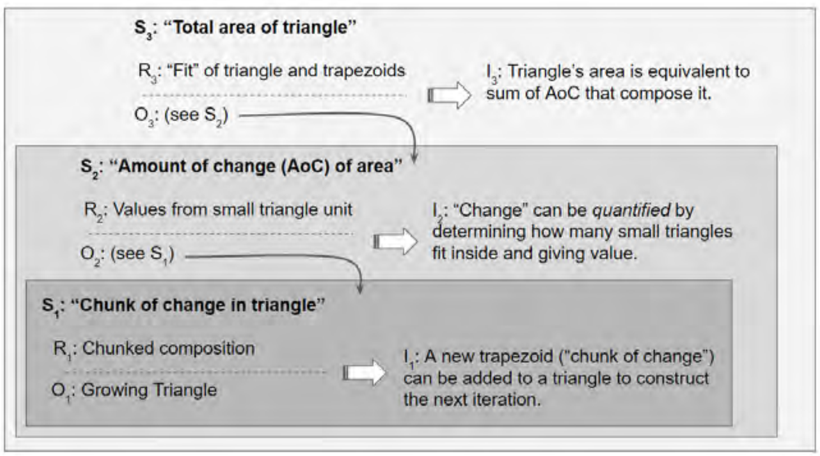


Figure 6: Model of Vicente's construction of a semiotic chain involving AoC of area

By identifying and describing the signs Vicente related to his sign for AoC of area, we charted how conceptualization of this specific quantity may develop. These findings suggest that scaffolded engagement with multiple artifacts such as applets, manipulatives, and diagrams may support learners' development of AoC in other types of tasks, particularly those involving non-linear relationships (e.g., Wilkie, 2021). They may also suggest features that could be productive to investigate beyond the scope of AoC (e.g., a quantity's relationship within and across other quantities), thus contributing to new potential lines of inquiry in the field of quantitative reasoning (e.g., Smith & Thompson, 2008).

Although not described in this paper, we also note that Vicente's signs relating to AoC of area in the *Growing Triangle Task* did not end with the semiotic chain in Figure 6. In fact, he continued to engage with these signs and construct more sophisticated meanings as he interacted with new artifacts (e.g., constructing and interpreting graphs) and as he anticipated smooth change in area (see Paoletti & Vishnubhotla, in press). By maintaining a semiotic lens on Vicente's activity, this work has offered new understandings of students' images and meanings for changing quantities (Carlson et al., 2002; Castillo-Garsow et al., 2013). Through a combined focus on quantities, artifacts, and the meaning-making process that relates them, we intend for this work to open new directions for research into how multiple artifacts can support students' conceptions of quantity.

PROBLEM SOLVING WITH UNDERSTANDING

Siqi Huang
University of California, Berkeley
shuang123@berkeley.edu

It is not well understood when, how, or why students seek a deep understanding of the underlying mathematics relevant to the problems they try to solve. This study of five pairs of UC Berkeley students (undergraduate n=4, graduate n=6) solving challenging mathematics problems indicated consequential differences in the degree to which they worked to understand underlying principles. Drawing on Hiebert and Carpenter's (1992) framework on understanding and Schoenfeld's (2010) model of decision making, I developed an observation system with a coding scheme to investigate students' orientations with respect to deep understanding. Preliminary results show that the system captures students' divergent choices of moves and illuminates aspects of their understanding-related orientations that are not otherwise evident. This approach holds further potential as both a teaching and a learning tool in mathematics classrooms.

Keywords: Problem Solving; Mathematical Processes and Practices; Measurement

Helping students understand is one of the most important goals in mathematics education (Sierpinska, 1994; Duffin & Simpson, 2000; Common Core State Standards, 2010), as is problem solving (NCTM, 1980, 2014; Schoenfeld, 1992). Literature shows that understanding can be viewed as recognizing relationships and making connections between pieces of information (Davis, 1984; Greeno, 1977; Hiebert, 1986; Michener, 1978). According to Hiebert and Carpenter's (1992) Representation and Connection framework, the degree of understanding is determined by the number, accuracy, and strength of connections, and that a richly connected network allows students to draw on and apply knowledge flexibly (Hiebert et al., 1997). But understanding "is not an all or none phenomenon" (Hiebert & Carpenter, 1992, p. 69); it can be rather limited if only some of the potentially-related ideas are connected, and that a deep understanding necessarily implies students' rich, accurate, and robust networks of connections.

For the purpose of this study, I define problems as unfamiliar, perplexing, and challenging tasks that one attempts to solve; they should be distinguished from routine exercises of which one knows the solution or with which one practices what has just been taught. Building on Schoenfeld's (1985) framework of *what* and *how* factors affect problem-solving outcomes, this study contributes to the understanding of *when*, *how*, and *why* students seek a deep understanding of the underlying principles when they solve challenging mathematics problems. It might seem obvious that students should always try to understand the problem and the underlying mathematics when they solve a problem; yet according to my data, that practice does not seem natural — in fact, the first principle in Pólya's (1945) groundbreaking book *How to solve it* is to understand the problem. Drawing from Schoenfeld's model of how people think and act in goal-oriented activities (2010), I hypothesize that an underlying major factor in successful problem solving is the extent to which students are oriented towards deep understanding. The main goal of this paper is to build an observation system with a coding scheme that captures students' choices of moves and that sheds some light on their hidden orientations with respect to deep understanding.

Methods

Think-aloud protocols (Schoenfeld, 1985; Leighton, 2017) were the main data sources. Five self-selected pairs of friends (defined by feeling comfortable discussing math together) from UC Berkeley participated in my study: two pairs were STEM undergraduates and three pairs were Education Ph.D. students. The pairs participated in the study sequentially at a reserved conference room at UC Berkeley, where I emphasized that the correctness of their solution was of no interest to the study; their thinking process was what mattered. To ease their anxiety, I gave them some warm-up exercises to practice thinking aloud and I stressed that the problem required nothing more than high-school knowledge. When they felt ready, I handed out the problem sheet with scratch paper and stood behind their seats to focus my camera on their writing. After each pair finished, I collected their writing artifacts and transcribed the videos. The problem-solving time ranged from 18 minutes to 77 minutes, with a median of 28 minutes.

Problem-Solving Task. A teacher wrote a large number on the board and asked her 30 students to tell about the divisors of the number. The 1^{st} student said, "The number is divisible by 2." The 2^{nd} student said, "The number is divisible by 3." The 3^{rd} student said, "the number is divisible by 4." ... The 30^{th} student said, "The number is divisible by 31." The teacher then commented that exactly two students, who spoke consecutively, were wrong. Who was wrong?

The Observation System. The goal of the observation system was to highlight *when* and *how* students showed evidence of working to develop a deep understanding of the underlying mathematics when they solved the given problem. In formulating the system, I reviewed the videos, developed transcripts, identified emerging themes, applied preliminary codes to the transcripts, and repeatedly reflected and revised the system. As shown in Figure 1, the current version highlights four different aspects of the students' orientations with respect to deep understanding: Examine the Problem Statement (ES); Examine the Proposed Ideas (EI); Suggest Solving with Multiple Approaches (MA); and Problematize the Ongoing Work (PW). Figure 2 provides descriptions and examples for each of the four dimensions of the observation system.

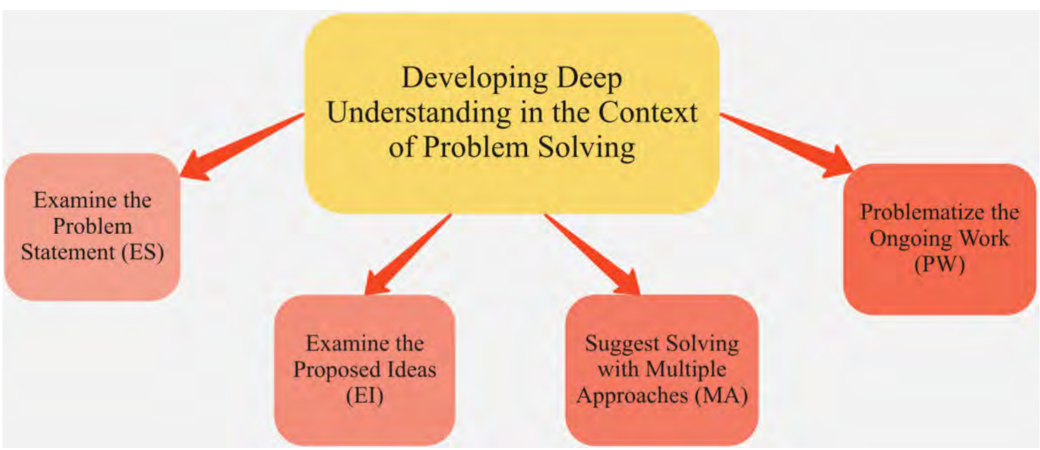

Figure 1: Observation System

Dimension	Description	Examples
ES: Examine the Problem Statement	Clarify, reread, or rephrase the problem statement.	(Pair #3) E: The teacher then commented that exactly two students, exactly, that means all the other students were right?
EI: Examine the Proposed Ideas	Explicitly engage with partners' proposed ideas by (a) rephrasing what has just been said, (b)	(Pair #2) S: I think that we *can*, because we use the 5 and the 4 thing. J: Okay, so we have to *choose* a pair that doesn't overlap.

	using their own reasoning to justify their partners' ideas, (c) suggesting immediate consequences, or (d) asking follow-up questions that probe for further clarification or justification.	(Pair #2) J: We can cross out 21. S: Oh yea, cuz 21, I mean this is the same as 3 and 7, yeah. (Pair #4) N: 7, 14. And every... You are cross[ing] out every single... (Pair #3) E: Do you do 20 to 25, I'll do 26 to 31? L: Do we, what do we do with the numbers? (Pair #2) S: Wait, hold on a second, tell me why? Cuz I thought 27 was a candidate.
MA: Suggest Solving with Multiple Approaches	Explicitly suggest solving the problem in more than one way.	(Pair #2) S: So... Err, let's do... We can maybe just solve using both ways. We can do your way first, and then if we have time, we can do my way.
PW: Problematize the Ongoing Work	Make problems of their ongoing work; suggest doing something more than finding the answer.	(Pair #2) S: Yea I think it is [the answer], but I think we should just spend more time talking about why it is that 16, like why it is that the logic does work for 24 but doesn't work for 16...

Figure 2: Coding Scheme

Results & Analysis

Figure 3 summarizes (ES) when and how many times each pair examined the problem statement, (EI) how many times each pair examined the proposed ideas, (MA) how many times each pair suggested solving with multiple approaches, and (PW) how many times each pair problematized their ongoing work.

Pair	ES (Red arrows show when participants examined the problem)	EI	MA	PW
#1		19	1	1
#2		34	1	2
#3		11	0	0
#4		16	0	0
#5		0	0	0

Figure 3: Results

Examine Problem Statement (ES) & Proposed Ideas (EI). Every pair examined the problem statement at some point. However, only pair #2 examined the problem constraints to their satisfaction at the beginning — all other pairs went back and clarified the problem setup in the middle of their problem-solving process. Every pair except pair #5 examined the proposed ideas; one possible explanation is that a participant in pair #5 simply pursued his approach without any serious consultation with his partner, despite his partner showing clear evidence of not being able to follow along. Unfortunately, the acts of ignorance and of murmuring without communication seemed to result in an unproductive joint problem-solving space and even the failure in pair #5's problem solving.

Suggest Multiple Approaches (MA) & Problematize Ongoing Work (PW). Only pairs #1 and #2 showed evidence of attempting to solve in more than one way and problematizing established ideas or solutions; the other three pairs did not. Why did some students *want* to spend time doing extra things that were not expected from them and that would not earn them any external rewards, while others did not? It seemed plausible that their dominant goals were different: Some might aim for making more connections and developing a deeper understanding of the underlying principles, while others might have a stronger answer-getting motivation. On the assumption that orientations fundamentally shape the way students engage with problems, investigating the extent to which they work to develop a deep understanding sheds light on *what* and h*ow much* they gain from their problem-solving process.

Discussion

Pairs #1 and #2 showed much evidence along all four dimensions, suggesting that they were very likely to have a strong orientation towards deep understanding. This aligns well with my observation that they appeared to care much about connecting various ideas and developing deeper understandings of the underlying principles. In contrast, pair #5 showed evidence of only examining the problem statement. To the extent that the four proposed dimensions are sufficient to capture students' attitudes, this result suggests that pair #5 were likely to have a weak orientation towards deep understanding. Pairs #3 and #4 seemed to be intermediate cases, showing evidence along the first two dimensions (only).

These results give rise to clear profiles of the students' orientations with respect to deep understanding, and appear to capture meaningful differences among groups that also align with my impressions as an observer. While much research is needed to test, refine, and problematize the proposed system, there is reason to believe that this is a step forward into highlighting and investing students' understanding-related orientations in problem solving. Of course, some may argue that showing no evidence of exploring different approaches under this laboratory setting may not imply that the students were not oriented towards deep understanding; it could simply be that they were not aware of this expectation — and I agree. But what if we are in a classroom with a norm of challenging oneself to look for alternative solutions and respectfully discussing different approaches with others? The proposed observation system holds great potential as a teaching tool for teachers to diagnose students' current states of orientations and model desirable problem-solving behaviors, and as a learning tool for students to self-evaluate and self-guide their development of productive mathematical practices.

MANIPULATIVES, AFFORDANCE AND THE LEARNING OF FRACTION: THE TWELFTH TASK

MATÉRIEL DE MANIPULATION, AFFORDANCE ET APPRENTISSAGE DES FRACTIONS: LA TÂCHE DOUZIÈME

Doris Jeannotte	Claudia Corriveau
UQAM	Université Laval
jeannotte.doris@uqam.ca	claudia.corriveau@fse.ulaval.ca

This study investigates the use of manipulatives by elementary students working on a fraction task. Extending previous work on the role played by the manipulatives in students' activity, we aim at describing how the choices made for the task design disrupt students' activity, creating opportunities to learn. The theoretical underpinnings allow envisioning the students' activity through the concept of routine and the manipulatives through the concept of affordance. The analysis of the students' mathematical activity allows us to better understand how manipulatives can serve as breaching elements, leading students to modify their mathematical activity, and thus, creating opportunities to learn.

Keywords: Elementary School Education, Rational Numbers, Instructional Activities and Practices, Mathematical Representation

In this paper, we draw on our previous research (Jeannotte & Corriveau, 2020; Corriveau et al, forthcoming) about the role played by manipulatives in students' activity when solving arithmetical tasks. More specifically, we are studying the relation between didactic choices linked to manipulatives and the students' mathematical activities in a task about fractions. We aim to describe how those choices disrupt students' activity, creating opportunities to learn. To do so, we first describe why it is still important to research the use of manipulative in mathematics classrooms. We then define mathematical activity from a commognitive perspective. The concepts of routines and affordance are theoretically explicated to frame our methodological and analytical work. The result section presents the main routines that emerged from our analysis of a mathematical task called the "Twelfth task". We illustrate with examples how those routines are bound to the manipulatives used in this specific task and how different didactic choices may create different opportunities to learn.

Manipulatives and Mathematical Learning

The use of manipulatives for teaching arithmetic at the elementary level is encouraged and even prescribed by several curricula around the world (OCDE, 2019). Thus, it is often seen as an efficient teaching practice and is rarely questioned (authors, 2020). In particular, the learning of fractions, considered as one of the most difficult areas in elementary school mathematics, seems to benefit from this use (Carbonneau et al., 2013). However, research on manipulatives mainly focuses on whether manipulatives support student achievement in mathematics (e.g., Moyer, 2001), without articulating the uses of manipulatives and the different choices made when designing the educational setting. Some research sheds light to a certain extent on some didactic variables. For example, the use of familiar manipulatives may mislead students (McNeil & Jarvin, 2007) or, for the same task, two different manipulatives can lead students to engage in different mathematical activities (Authors, 2020). Familiarity and types of manipulatives are two examples of variables among others that can shape the students' mathematical activity. In this paper, we present a fraction task that students solve using pattern blocks. We aim to show how different choices, especially the choice of limiting the number of Pattern blocks available to students, introduce breaching elements that can disrupt the students' activity and thus create opportunities to learn.

Conceptual Framework

From a commognitive point of view, mathematics is defined as a particular form of communication, with its vocabulary, its visual mediators, its distinct routines, and its narratives generally accepted by a mathematical community (Sfard, 2008). By positioning ourselves in this sociocultural and non-mentalist perspective, manipulatives, and therefore their use, become part of the mathematical activity developed in the culture of the classroom. The use of manipulatives, when defined in commognitive terms, is viewed as participation in the mathematical discourse of the classroom through the manipulation of physical apparatus. In other words, using manipulatives is not a concrete version of mathematical activity, but a mathematical activity with its specific vocabulary, visual mediators, and narratives generally accepted by the classroom. For example, we often hear students say, "I am breaking down the tens into units" (referring to base-ten blocks) instead of "I am dividing the tens into units."

The Concept of Routine

Sfard (2008) defines a mathematical routine as a repetitive pattern of discourse discernable by the vocabulary and visual mediator used, and the narratives produced. Moreover, a routine is linked to the concept of 'task situation.' A task situation is "any setting in which a person considers herself bound to act—to do something" (Lavie et al., 2019, p. 159). For example, a 4th-grade student may refer to number fact to calculate mentally twelve divided by three to answer the question: "What is the third of twelve?". Another may draw a rectangle, divide the rectangle into four horizontal lines and three vertical lines to form twelve equal parts, and color four of them. Thus, "a routine performed in a given task situation by a given person *is the task, as seen by the performer, together with the procedure she executed to perform the task*" (Lavie et al., 2019, p. 161, italic added). Manipulatives can play distinct roles in routines. We can recognize manipulatives through vocabulary. Indeed, when using Pattern blocks, students will refer to a kind of block by its color or its shape. We can also observe students act upon the manipulatives, by moving them, stacking them, regrouping them in certain ways. Manipulatives can also play the role of visual mediator, representing mathematical objects.

Learning is defined as a change of discourse, and more specifically as a change of routine (Lavie et al., 2019). Discourse, therefore, progresses in an individualization-(re)communication direction (i.e., learning) through changes in routines, thus in vocabulary, visual mediators, and accepted narratives, what Lavie et al. (2019) name routinization. Therefore, because we aim to describe how manipulatives can create opportunities to learn, we are particularly interested in moments when routines seem disrupted, i.e., when students are bound to act differently.

The Concept of Affordances

We call affordances the relational properties of an object within a certain environment that are bonded to certain actions. "An affordance relates attributes of something in the environment to an interactive activity by an agent who has some ability, and an ability relates attributes of an agent to an interactive activity with something in the environment that has some affordance" (Greeno, 1994, p. 338). For example, a pen will generally be seen as an object to write with, but it could be seen as a tool to unlock a door. For some people with long and thick hair, it could be seen as an object to tie hair. Thus, "[w]hether or not the affordance is perceived or attended to will change as the need of the observer changes, but being invariant, it is always there to be perceived" (Gibson, 1977, as cited in Brown et al., 2004, p. 120).

In a given task situation, the use of manipulatives by students generates different affordances. In other words, the affordance realized in a task situation relies not only on the tool itself but rather on the interactions between the manipulatives, the students, and the teachers, in a particular educational setting (Drijvers, 2003, in Brown et al., 2004).

To try to disrupt students' routine, we can play with didactic variables to subtly change the affordance, thus the task situation by adding some breaching elements. Didactic variables are parameters, linked to the design of a teaching situation, which can vary according to the teacher's choices, and which can lead to a change in the students' mathematical activity (Brousseau, 1981). The concept of breaching (from ethnomethodology) refers to a subtle breakage of what is familiar. By varying several aspects related to the use of manipulatives, it is possible to place students in conditions familiar enough for them to engage in a task but sufficiently unfamiliar that it resonates as a conflictual use of the manipulatives. In a way, it plays into how students perceive the affordances of the manipulative and leads them to explicit their usual routines and renew them.

Methodology

In collaboration with teachers from grades 4 to 6, we created a task (titled "Twelfth") that aims to develop different routines to represent and compare fractions using Pattern blocks. Pattern blocks were familiar manipulatives for the students as they already had worked with them before the experimentation. We experimented "Twelfth" into two fourth-, two fifth-, and one sixth-grade classes of about twenty students each. The task was implemented with different choices according to teachers' rationales (mainly based on students' abilities and familiarity with fractions) during a 60-minute period.

The Task "Twelfth" and the Didactic Choices

"Twelfth" is, at first sight, a common task in which students are asked to represent a certain fraction with pattern blocks. We chose to place students in pairs. Each pair received a kit of limited Pattern blocks (Figure 1) and were asked to do several subtasks. These can be divided into three categories:

1. The given fraction is a twelfth and students must represent a third (the piece representing one-twelfth varies): e.g., the green triangle (blue rhombus, red trapezoid, etc.) is worth 1/12, we want 1/3 of the same whole.
2. The given fraction is one-twelfth and students must represent other varied fractions (unit and non-unit): e.g., the blue rhombus is worth 1/12, we want 1/24 of the same whole; the red trapezoid is worth 1/12, we want 5/6 of the same whole.
3. The given fraction varies, and students must represent varied fractions: e.g., the yellow hexagon is worth 2/5, we want 1/15 of the same whole.

Figure 1: kit of pattern blocks available to each pair of students

The subtasks were projected on the whiteboard, one or two at a time. There was a whole class discussion after each subtask. In the two 4th grade classes, the students were allowed to use scrap paper to take notes. In one 5th grade class, the students were not allowed to use any paper at all. In the two other classes (5^{th} and 6^{th} grade), the students were given a document to work on. On each sheet, they had two subtasks with a space to draw and record their answers.

Data Analysis

In each class, a camera with a primary focus on the front of the class filmed the whole group and other cameras filmed pairs of students with a primary focus on their hands (10 in 4th grade, 14 in 5th grade, and 7 in 6th grade). For this paper, we focus our analysis on the resolution of the first subtask by the students working in pairs: "Find what is 1/3 of a whole, if the triangle is 1/12." Following Powell, Francisco, and Maher (2003), each video excerpt was watched multiple times and described; critical events were identified. We transcribed, coded, constructed the storyline, and composed the narratives. Descriptions of the videos and codes helped us compose the narrative to report the results. Conversely, composing the narrative forced us to revisit some critical events. Critical events are moments when students' routines seem disrupted, i.e., when they seemed to doubt, when the routine implemented did not lead to solving the task and was challenged by someone, or when they suddenly changed their routines.

Routines and Affordances

By analyzing the data, we were able to highlight three intertwined routines that could be linked to the interpretation of the subtask: 1) 'comparing-and-naming', 2) 'forming and partitioning' a whole, and 3) 'covering'. Those routines had distinct functions throughout the resolution of the task but were all bound to certain affordances of the manipulatives in this specific setting.

The Routine of Comparing-and-Naming

Several pairs used a routine we called "comparing-and-naming" at different moments during their resolution. They attributed a name to each kind of block, or group of blocks by comparing pieces and relying on number facts. Some used fraction-names (e.g., a hexagon is ½ [of the whole], or a rhombus is 1/3 [of a hexagon]) and other whole number names (e.g., a rhombus is 2 [triangles]). Adam and Phil, a pair of 4^{th} graders in Heloise's class, help us illustrate how this "comparing-and-naming" routine was bound to the manipulatives, the didactic variables, and the students' discourse. Right at the beginning, Adam associated some blocks with a fraction-name by referring to the given value of different blocks: "yellow is ½ because 6+6", "red is ¼ because it's half of the half." Like 1/3, those unit fractions are familiar to the students as they start working with them in 1^{st} grade. However, because of our didactic choices, it was impossible to associate one and only one block to 1/3. Indeed, 6 triangles are equivalent to a hexagon and a hexagon to two trapezoids, but 4 triangles could not be replaced by a single block. Phil proposed to name the rhombus 1/3 of a hexagon. This proposition combined with the accepted narrative that the whole was not the hexagon led them to realize that more than one piece was requisite. If we had chosen 1/6 as the given value of the triangle, their routine could have led them to solve the subtask. Here, the given value combined with how the Patterns blocks are designed created a need to change the routine, and thus created an opportunity to develop a new discourse about fractions, that is to accept a visual mediator of a unit fraction composed of more than one piece, a necessary narrative to solve this task.

The Routine of Forming-Then-Partitioning a Whole

The routine of forming-then-partitioning a whole appeared in three different variations linked to the function of the routine: solving the subtask, validating the calculation, and justifying the answer prompted by a request from an adult or a peer. This routine was recognizable by the action of composing a whole with a certain number of blocks followed by its partitioning in a certain number of equivalent (mostly identical) groups. In a way, this routine was the expected one. Indeed, the curriculum (MEQ, 2001) prescribes the learning of fractions through manipulatives and schemas use. Thus, we expected them to use this routine. The blocks available to students for this first subtask allowed them to compose a whole, but not with twelve identical blocks, leading to the impossibility to partition it into three identical groups of four triangles. Figure 2 presents possibilities of different wholes with their partitioning. Except for the last example (Figure 2d) where each group is formed of one rhombus and two triangles, the students needed to form three equivalent but not identical groups. The shape of the groups is the same, but neither the orientation nor the kind of blocks (colors and shapes) are the same.

Figure 2: Partitioning of the whole with three equivalent groups

Solving the subtask. John and Owen, a pair of 5th graders in Christophe's class, engaged in the routine of forming-then partitioning the whole to solve the task, after reformulating the question as "1/3 of twelve is what?":

Owen: We say the whole is that [taking one hexagon in his hand]
John: No, this is six! […]
Owen: Oh, ok, so how many there are [counting the triangles]. Ok, six, so this [pointing a hexagon] is six. So, that [sliding two hexagons on the side], means, it's our whole. And this [sliding a triangle beside the two hexagons, Figure 3a] is one-twelfth.
John: No! This [the triangle] is one-sixth. We have to find out the half of it. Impossible... Oh, wait, wait, I know what it is! Look, [regrouping six triangles]
Owen: it's the half.
John: [regrouping a hexagon to the six triangles]. This is twelve. So, this [separating one triangle, Figure 3b] is one-twelfth.
Owen: It's what I've been saying since earlier!
John: we've found the twelfth, we have to divide by four... by three. [Separating 3 triangles from the whole and covering it with a trapezoid, Figure 3c].

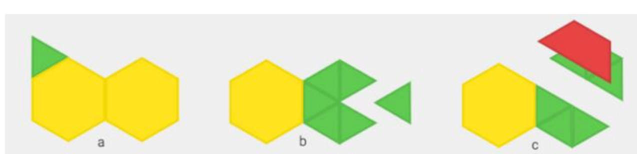

Figure 3: Forming-then-Partitioning a Whole

In this short excerpt, we observe how Owen and John struggle to make sense of all the information with the manipulatives at their disposition, juggling between one hexagon as the whole/one triangle as one-sixth and two hexagons as the whole/one triangle as one-twelfth, suggesting that the routine of "naming" interfered with the routine of "forming-then-partitioning" the whole. Moreover, after convincing themselves that they succeeded at representing the whole, they intended to partition it. But the interpretation of the division led them to the wrong partitioning.

Validating. Some pairs used manipulatives to validate an answer obtained through calculation. Indeed, some students interpreted the task as one of mental calculation. At some point, usually early in the resolution, they calculated 12 divided by 3 or searched for the number that multiplied by 3 gave 12. Tim and Nick, two 5th graders, used this method. Tim seemed to calculate mentally and then added two rhombi on top of the two hexagons. Nick wanted to validate. To do so, he counted "one-third, two-thirds, and three-thirds" pointing with his fingers holding imaginary blocks over the whole but without moving any pieces. Tim and Nick were able to perceive the twelve triangles inside the two hexagons and the three groups formed of four triangles. The Pattern Blocks design facilitated this identification for Tim and Nick.

Justifying the answer. Adults and peers sometimes challenged an answer by asking why it was the good one. Tim and Nick had already found the solution through calculation and validated through forming-then-partitioning the whole. When an adult asked them to explain their solution, they argued that one-twelfth means there are twelve triangles in the whole. "The third of twelve is four." Therefore, the answer is four triangles. Their explanation relied on calculation, but they also overlaid four triangles on top of the two hexagons (see Figure 4). They answered that four triangles "fit" three times in two hexagons. They completed their justification by effectively making three-thirds "fit" on top of the two hexagons pointing fingers to show the three distinct groups as Nick did when validating the answer earlier. For Tim and Nick, a calculation was not an acceptable justification. They used the manipulative to visually back their claim in the context of the task, showing the whole, the part, and the fact that it fits three times.

If the students did not use the wanted whole, the teacher could use the manipulatives to challenge not only the answer but the students' routines. For example, Mike and Edith, two 5th graders, attributed the name 1/3 to the hexagon and then formed a whole with three of them. Incidentally, they had placed the manipulatives as positioned in figure 1 in front of them when they received the bag, the three hexagons were a bit separate from the other blocks. They reproduced three hexagons on a sheet of paper and wrote 1/3 in one of them. An adult asked them to explain their answer: "[After they answer that 1/3 was a hexagon]. Ok, if this [showing a triangle] is one twelfth, can you show me the whole in which this triangle represents one twelfth?" By reintroducing the triangle and its value in the conversation, the students were able to determine the wanted whole [two hexagons] and modified their routine accordingly:

Mike: Look, it can be those two [touching two rhombi]
Edith: Ha, yes, it works... mmm, but you cannot split it in three.
…
Mike: Yes, look in this [taking the two hexagons], there are six like that [covering the hexagons with two rhombi]
Edith: but we are looking for the third
Mike: exactly! [splitting the whole in three by pointing rhythmically]

After the adult intervention, Mike and Edith were able to modify their routine by using new visual mediators (the whole and the part) that considered the given value of the triangle (one-twelfth) and Mike convinced Edith that two rhombi were an adequate answer by simulating a partitioning through gesture.

The (Sub)-Routine of Covering.

As illustrated in the examples presented above, we observed students in each grade using a "covering routine" (see Figure 4). This routine has at least two functions. First, it allows comparing blocks or groups of blocks to determine that they fit exactly on top of each other. For example, by covering the trapezoid with three triangles, we can figure out that a trapezoid is equivalent to three triangles. However, as said before, it was impossible to cover two hexagons with twelve triangles, forcing students to rely on imaginary blocks, as Tim and Nick did, or to use equivalent combinations as in Figure 2. The breaching element brought to bear by the limited manipulatives pushed the students to slightly modify their routine.

Second, it allows showing not only the part representing one-third but the whole in which it represents one-third. This second function was used more in 5th and 6th-grade classes, leading us to hypothesize that it was part of the classes' discursive rules, i.e., that, in those specific classes, students were expected to justify their answers. Indeed, to be able to judge the validity of the answer, you need to refer to the whole.

Figure 4: Example of an answer obtained through the covering routine

Interpretations

Through the lens of routine and affordance, we aim to describe how different choices disrupt students' activity, creating opportunities to learn. The analysis exposes how the students' mathematical activity is bound to the manipulatives used in this task and how different didactic choices may create different opportunities to learn. First, we hypothesize that the manipulatives led students to different routines than a paper-and-pencil task would. With no manipulatives, students may have reproduced the triangle twelve times (as a set or a whole) and circled four of them, or circled three groups of four. The comparing-and-naming nor the covering routine would have been needed.

Second, the limited quantity of pattern blocks is an important breaching element that created different opportunities to learn, here, through three routines. In this task situation, students were bound to represent different fractions with manipulatives. They could have represented the given fraction, the whole, the sought fraction, or other specific fractions. The 'representation-able' quality of the manipulative is linked to one of the main affordances. Indeed, the diverse ways that pattern blocks can be used as visual mediators are specific to this type of manipulatives, leading to breaches of routines.

A first breach was observed when students were not able to associate one-third to only one block, this permitted us to note a breach in their routine of 'comparing-and-naming'. This choice of limiting the blocks used created an opportunity to enrich visual mediators associated with unit fractions and to challenge the rule that "a unit fraction should be represented by one and only one block." A second breach was observed for the routine of 'forming-then-partitioning' a whole. Students could not represent the whole with twelve triangles. They had to adapt their routine. One way to do so was to use two hexagons. This breaching element led to work on equivalent surfaces. The third breach is also linked to this routine and to the importance of equivalence. Indeed, using only one kind of block to represent a fraction was a common routine for students.

The limited manipulatives introduced a breaching element that created opportunities to develop new narratives about partitioning a whole, focusing on equivalence rather than on the identity of the parts. A fourth breach was observed when students lost sight of the given value one-twelfth, leading them to associate the whole with one or three hexagons. In both cases, the manipulatives available led to the perception of a whole partitioned into three identical parts. Clearly for some students, in this task situation, one-third was associated with the narrative "one of three identical parts." Thus, they were looking for a whole constituted of three identical parts.

Even though it was not the focus, this analysis also put to light other affordances linked to the qualities of the manipulative. The 'representation-able' quality of the manipulatives did not only depend on the number of blocks available but on the design of the pattern blocks. Indeed, depending on the fraction given, Pattern blocks do not allow the representation of any fractions. A second affordance can be linked to the "move-able" quality of manipulatives. Students can move the blocks, stack them, group them, separate them. This quality helps students perceive and validate the equivalence of distinct groups, an element that cannot be avoided in this task partly because the manipulatives are limited. A third affordance can be linked to the "communication-able" quality of Pattern Blocks. Indeed, these manipulatives are tied to certain keywords as each piece has a specific color and a specific form. Other layers of analysis are required to push further the interpretation here.

Conclusion

The limited manipulatives, as a breaching element, created opportunities to learn by introducing nuances in what is mathematically important when working with fractions (e.g., the use of identical parts when partitioning a whole to represent a fraction is not necessary, the use of equivalent parts is). The didactic choices made helped us identify shared narratives and routines in those specific communities of students and how those choices created opportunities to learn, i.e., created changes in routine. Referring to Nachlieli and Tabach (2019), we could define those opportunities to learn as exploration-requiring opportunities to learn, i.e., to complete the task or meet the teacher's expectations, students cannot apply an already familiar single procedure. They needed to create a new combination of actions, a new routine. While Nachlieli and Tabach (2019) linked the creation of those opportunities to the kind of question asked (e.g., presenting request with words like what, why, find, explain), we add that those breaching elements can also play a key role.

Those findings also point out some implications for the classroom. Because breaching elements are possible only when disrupting familiar ways of doing (Corriveau, 2013), introducing such elements in tasks is not trivial. To go further than the question of whether to use manipulatives or not, one must attend to the implicit culture of the class. In other words, it is to be able to realize what is usually taken for granted and articulate it with the targeted mathematical learning to make clever didactic choices. It also brings us back to the fact that the use of manipulatives is not a magic solution (Ball, 1992).

STEM UNDERGRADUATES' STRUCTURAL CONCEPTION OF RATE OF CHANGE

Using data from teaching experiments and theories from quantitative reasoning, we built second-order accounts of students' mathematics with regards to how they conceived rate of change through operating on existing quantities. In this report, we explain three different ways STEM undergraduates structurally conceive rate of change as they constructed mathematical models for real-world scenarios.

Keywords: Quantitative Reasoning, Mathematical Modeling, Rate of Change

Understanding *rate of change* (RoC) is central to the understanding of mathematical concepts such as the fundamental theorem of calculus (Thompson, 1994b; Thompson, 2008), derivative (Zandieh, 2000), limits and function (Tall, 1986), and differential equations. Beyond mathematical concepts, an understanding of RoC is necessary to model dynamic situations (e.g., Arleback et al, 2013; Ellis, 2007). Generally, the main goal of studies surrounding RoC is to understand students' mathematical conceptions of RoC. That is, the field is reporting accounts of students' understanding of RoC as they are working on tasks that help them to understand RoC as a mathematical concept. We still need an account of how students are conceiving RoC as they are developing mathematical models for real world scenarios that aren't necessarily set out teach the concept of RoC. This is important because educators of the field will get an idea of how students apply their understanding of RoC into practice. Accordingly, we ask: how do STEM undergraduates conceive RoC while constructing mathematical models for real-world scenarios?

Theoretical Framing and Background

Our research lies within the cognitive perspective of mathematical modeling (Kaiser, 2017). In this perspective, mathematical modeling is the cognitive processes involved in constructing a mathematical model for real-world scenarios. We define a mathematical model to be a representation of the relations among conceived quantities.

A *quantity* is a mental construct of a measurable attribute of an object. It consists of three inter-dependent entities: an object, a measurable attribute, and a *quantification*. Quantification involves conceiving a measurable attribute of an object and a unit of measure and forming a proportional relationship between an attribute's measure and the unit of measure (Thompson, 2011). Quantification takes place in the mind of an individual and we can only use an individual's externalized actions to infer whether she has quantified an attribute. Czocher & Hardison (2021) presented eight quantification criteria that can be taken as indication that a student has conceived measurement process for a measurable attribute of an object.

Quantitative reasoning is the mental operations involved in conceiving a situation through quantities and relation among those conceived quantities (Thompson, 2011). A relation among conceived quantities is established through operation on quantities. Thompson (1994) defines *quantitative operation* as the "mental operation by which one conceives a new quantity in relation to one or more already-conceived quantities" (p.10). As a result of a quantitative operation a *relationship* is created: the quantities operated upon along with the quantitative operation are in relation to the result of operating (Thompson, 1994). Examples of quantitative operations include combining two quantities additively or multiplicatively and comparing two quantities additively or multiplicatively. A *quantitative structure* is a network of quantitative relationships (Thompson, 1990).

Reasoning about quantities may also entail reasoning about how the quantities can vary. While *variational reasoning* involves reasoning about varying quantities independently (Thompson & Carlson, 2017), *co-variational reasoning* involves "coordinating two varying quantities while attending to the ways in which they change in relation to each other" (Carlson et al, 2002, p.354). Scholars have extended the work of covariational reasoning to *multivariational reasoning*, which is reasoning about more than two quantities changing in conjunction with each other (Jones 2018; Jones & Jeppson,2020). Recently, Ellis et al (2020) defined *scaling continuous covariation* as "imagining the continuum as infinitely zoomable, couple with the understanding that one can re-scale to any arbitrarily small increment for x and coordinate that scaling with associated values for y" (p. 88). When an individual engages in covariational reasoning she constructs a *multiplicative object* in her mind. Constructing a multiplicative object entails coupling of two quantities (Saldanha & Thompson, 1998) that yields a new conceptual object "formed by mentally uniting the attributes of two quantities, so that the new conceptual object is simultaneously one and the other" (Thompson & Carlson, 2017, p. 433). For example, the rate at which the size of a bank account changes with respect to time is a multiplicative object that may be formed by coupling *change in size of the account* and the *length of time elapsed*.

Many scholars have posited ways in which students may develop a conceptual understanding of RoC based on *rates*. For example, using a quantitative reasoning orientation, Thompson (1994a) defined *rate* as a reflectively abstracted constant ratio, where a ratio is a result of comparing two quantities multiplicatively. Thompson (1994b) argued that developing images of rate starts with student imagining a change in some quantity, next coordinating the changes two quantities, and finally developing images of the two quantities covarying so that they remain in constant ratio. Confrey & Smith (1994) used a covariational reasoning approach as a way to learn the concept of function through exploring the concept of RoC. They discovered that students employed three different ways to describe RoC in the context of cell splitting: an additive RoC, a multiplicative RoC, and a 'proportional new to old' RoC. Through these investigations, they proposed an analytic approach to RoC as a "unit per unit comparison" (p. 37) where a unit is a "invariant relationship between a successor and its predecessor" (p. 142), as means to instill a multiplicative unit approach viewing RoC for exponential functions. Johnson (2015) investigated how students quantify *rate* through "forming and interpreting relationship between varying quantities" (p. 66). Johnson discovered that students quantified rate by associating amounts of change in extensive quantities, using a single extensive quantity that represents an association of two quantities, and coordination of intensive and extensive quantity through the quantitative operations *coordination* and *comparison*. Through *coordination,* rate is quantified as an intensive quantity and through *comparison,* rate is quantified as an extensive quantity. While Johnson reported distinct ways students quantify RoC, it excludes ways in which students may conceive RoC that do not necessarily involve quantitative operations as how Thompson defined. We postulate one such operation in this report.

Borrowing ideas from the aforementioned constructs we define *structural conception* of *RoC* as conceiving RoC as a measurable attribute of an object through forming a relation among constituent quantities (i.e., operating on quantities). We use the term *operating on quantities* to include Thompson's quantitative operations, mental operations involved in reasoning about varying quantities, and other operations on quantities that could yield a new quantity. The research question addressed in this report is: In what ways do STEM undergraduates structurally conceive RoC while constructing mathematical models for real-world scenarios?

Methods

We present data from a pair of 10hr individual teaching experiments (Steffe & Thompson, 2000) conducted with undergraduate STEM majors at a large university. The overall goal of the teaching experiment was to investigate how students conceive real-world situations through quantities and relations among quantities. Our students, Szeth and Pai were both enrolled in differential equations at the time of the interviews. Throughout the teaching experiment, Pai and Szeth worked on 9 and 10 tasks, respectively, that were based on real-world scenarios. In this report we present data from the *CI8 Account Task* and *The Cats & Birds Task*. We focus on these tasks because they exemplify how Pai and Szeth operated differently on similar quantities, that they had previously constructed, to conceive RoC.

CI8 Account: The competing Amtrak Trust has introduced a modification to City bank's SI8, which they call the CI8 account. Like the SI8 account, the CI8 earns 8% of the "initial investment". However, at the end of each year Amtrak Trust recalculates the "initial investment" of the CI8 account to include all the interest that the customer has earned up to that point. Create an expression that gives the value of the CI8 account at any time t (Castillo-Garsow, 2010).

Cats & Birds: Cats, our most popular pet, are becoming our most embattled. A national debate has simmered since a 2013 study by the Smithsonian's Migratory Bird Center and the U.S. Fish and Wildlife Service concluded that cats kill up to 3.7 billion birds and 20.7 billion small mammals annually in the United States. The study blamed feral "unowned" cats but noted that their domestic peers "still cause substantial wildlife mortality" (Raasch,2013). Consider a backyard habitat, where cats are the natural predators of birds. Model the rate of decrease of the population of birds due to predation by cats.

The interviews were retrospectively analyzed to construct second-order accounts (Steffe & Thompson, 2000) of students' reasonings via inferences made from students' observable activities such as verbal descriptions, language, written work, discourse, and gestures. The retrospective analysis consisted of multiple passes of through the data to arrive at examples that illustrate the different ways Szeth and Pai structurally conceived RoC. First, we watched the videos in MAXQDA in chronological order and paraphrased each interview by chunks. Next, we created accounts of students' mathematics and the reasons they attributed to their mathematics. Next, we went over the accounts we created and the videos at the same time and refined our accounts by adding details using quantitative and covariational reasoning lenses. We credited a student to have instantiated a quantity if we were able to infer from his reasonings that he had conceived an object, attribute, and a measurement process for the attribute. As evidence of student to have conceived a measurement process, we checked if at least one of the quantifications criteria (see Czocher&Hardison, 2021) was met. We used segments of transcripts, where the students engaged in quantitative reasoning along with inscriptions and gestures as evidence for our claims. Next, from these accounts, we selected instances where the students engaged in conceiving RoC. Next, while watching the videos and going over our accounts of students' RoC, we further refined our accounts by adding details of how Pai and Szeth operated on constituent quantities to form a relation in order to conceive RoC. Next, we went through our accounts of Pai's and Szeth's conception of RoC and observed any patterns, in terms of operation on constituent quantities, that were consistent throughout the sessions. We made note of them by summarizing the pattern. We watched the videos in their entirety again and made sure all of the different ways of conceiving RoC were recorded and refined our second-order accounts by seeking clarification on utterance and gestures to support our claims on Pai's and Szeth's structural conception of RoC. We present some of these second-order accounts below.

Findings

Pai and Szeth structurally conceived RoC in the following ways: (1) as how quickly change is happening, (2) as a multiplicative object, (3) as the derivative, (4) as the net change during a time interval, and (5) as the additive comparison of rate of increase and rate of decrease. Due to space constraints, we share examples only for (1)-(3).

Rate of Change as How Quickly Change is Happening

In the CI8 Account task**,** Szeth constructed the following models for the value of the account at the end of 1st, 2nd, and nth years: $S_1 = \frac{8}{100} \cdot S_0 \cdot t + S_0$; $S_2 = \frac{8}{100} \cdot S_1 \cdot t + S_1$;$S_n = \frac{8}{100} \cdot S_{n-1} \cdot t + S_{n-1}$, where t is the length of the compounding period. We then started to discuss how the account would grow when the compounding periods gets smaller. Szeth reasoned:

> Szeth: gut reaction is it [rate] should increase faster because the compounding is more frequent. Then giving it some thought, I'd agree. If we did one month, make this calculation [Figure 1], it's slightly less than like a year, but you're doing that calculation 12 times over the year. Yeah, yeah, if you decrease the time interval, your rate should increase quicker … I mean, the final amount of money in the account should increase quicker, which I guess means that our rate would be of a greater value over a shorter interval. Yeah, that makes sense.

In the excerpt above Szeth was coordinating three inter-dependent quantities: the length of the time interval, the amount of money in the account, and the rate at which the account grows. Through coordinating the length of the time interval with the rate at which the account grows, Szeth was engaging in *scaling continuous co-variation*. When asked to elaborate further, Szeth coordinated the value of the account for compounding periods 1 year and 1 month (Figure 1). He started with \$500 and showed how the value of the account would increase each compounding period when the length of the compounding period is 1 year. He indicated that the increase in the account's value would be the *difference* between the sizes of the account for consecutive years. Next, he considered the increase in the size of the account when the compounding periods are of length 1 month. He reasoned: "Then actually they should all be the same numbers, but the point being that's one year… But that's one month" (Figure 1). Here Szeth is *comparing* the values of the account for compounding periods of different lengths to discuss how quickly the value of the account changes. We infer that, for Szeth, a bank account in which the size of the account changes over a small time period grows at a greater rate over time than one for which the same change in the size of the account happens over a larger time period. In this scenario, Szeth constructed a mental image of how quickly the size of the account changes in order to reason about the rate at which the account would grow.

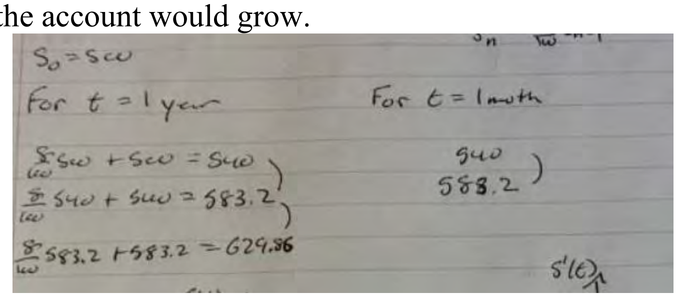

Figure 1: Szeth evaluates the size of the account for different compounding periods

Rate of Change as a Multiplicative Object

In the CI8 Account Task, Pai constructed the following models to indicate the size of the account at the end of 1, 2, and 3 years: $S_1 = S_0 + 0.08(S_0)(t)$; $S_2 = S_1 + 0.08(S_1)(t)$; $S_3 = S_2 + 0.08(S_2)(t)$, were $t = 1$ year. He drew the graph in Figure 2, and we proceeded have a discussion on how during each year the account grows linearly at a rate proportional to the size of the account at the beginning of that year.

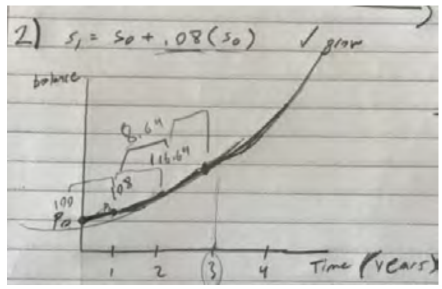

Figure 2. Pai's graph of account value vs time in years

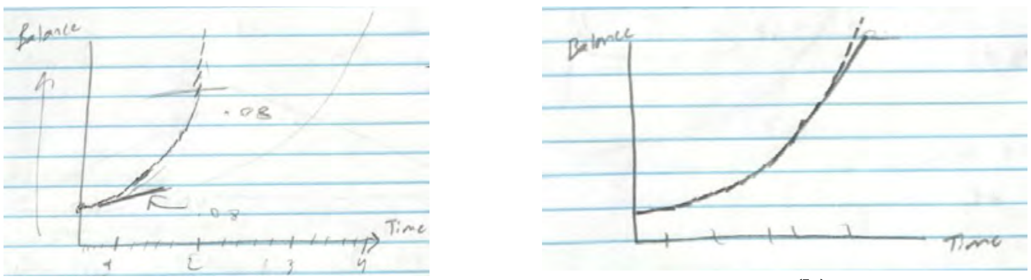
We asked Pai if his expression for S_i would work for any time period of length Δt and not just $t = 1$ year. Pai indicated that it would work as long as all of the S_i's are the account's value at the beginning of each of the compounding period. He rewrote the expression as $S = S_0 + (0.08)(S_0)(\Delta t)$, where Δt was the length of the compounding period and S_0 was the size of the account at the beginning of the compounding period. We asked him to interpret his graph as Δt gets smaller. For example, when we discussed the possibility of having four compounding periods instead of one in a year, Pai gave the following reasoning:

> Pai: "It would change, not the overall direction, but it would change the number of straight pegs, I guess, straight increases, because there's now 16 compounded periods in our time period [4 years]. So it'd be more round, but still not perfectly round, but it'd be my thinking of a circle, circle has infinite edges. It would be like that [tracing a curve along his graph (Figure 3b)] …that's what it would be. It'd be more like a curve"

In the above excerpt, Pai was thinking of the graph taking a curve like shape as Δt becomes smaller and smaller. We next asked Pai the effect smaller Δts would have on the RoC of the account's value, specifically its proportional relationship with the money at the beginning of the compounding period. During this discussion Pai reasoned:

> Pai: That should be proportional still. It's still proportional, but time is increasing so much that, or so fast, or the compounded periods are so small that it's going to change instantly…Like S is going to change. Like S_0 is going to be extremely different than the first... S_0 without… a very shortchange… like a very rapid change. It's still proportional to what was initially there, which just happening much, much faster because the t is much smaller than when we started"

Pai thought the rate at which the account's value changes would still be proportional to the account's value at the beginning of the compounding period. However, this time, he argued that the account's value at the beginning of the compounding period would change rapidly because Δt was much smaller. Pai was *coordinating* the quantities Δt, RoC of the account's value, and account's value at the beginning of the compounding period. We interpret Pai's reasoning as indicative of Pai imagining the quantities change in the size of the account and Δt to be happening simultaneously. We infer that Pai formed a multiplicative object of (change in size of the account, length of time elapsed). We also infer that Pai's formation of a multiplicative object had consequences beyond enabling him to coordinate the quantities change in size of the account and time taken for the change. He also used this imagery to help him in reasoning about the rate at which the size of the account changes. This was further evidenced when we asked him to write an expression for the RoC of the size of the account. Pai wrote $\frac{dS}{dt} = 0.08(S_0)$, where S_0 is the starting value at any compounding period. He reasoned as "[S_0] is just any starting period. Not just the literal start, but any starting period of these pegs, as t [Δt] gets smaller, it's 0.08 of that starting period, so the derivative will change."



(a) (b)

Figure 3: Pai's graph for as Balance vs time as Δt gets smaller

Rate of Change as the Derivative

In the Cats & Birds task, Pai and Szeth both conceived RoC as a measurable attribute that can be measured by taking the derivative of the function. For example, both Pai and Szeth conceived RoC of the bird population due to cats as a measurable attribute that could be measured by taking the derivative of the function bird population at time t.

Taking the derivative. Szeth arrived at the expression the $I(t) = \alpha \cdot \beta \cdot C(t) \cdot B(t)$ as the number of birds killed due to cat-bird interactions. We asked he could use the expression to model the rate of decrease of bird population due to predation by cats. Szeth Solved the above expression for $B(t)$ as $B(t) = \frac{I(t)}{\alpha \cdot \beta \cdot C(t)}$. Since he intended model the rate of decrease of the bird population, he mentioned that he first wanted to isolate $B(t)$ from the expression and thus solved for it. Szeth said, to find the rate he "would take the derivative [of $B(t)$]". Even though we had asked him to construct an expression for the rate of decrease of bird population due to just cats, Szeth tried to evaluate $B'(t)$, which the RoC of bird population due to all causes, and not just cats - a different attribute of the object bird population. Szeth proceeded with taking the derivative of $B(t)$ using the quotient rule.

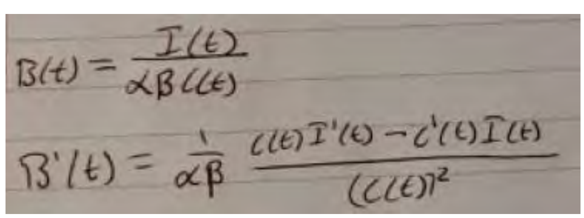


Figure 4: Szeth takes the derivative of B(t)

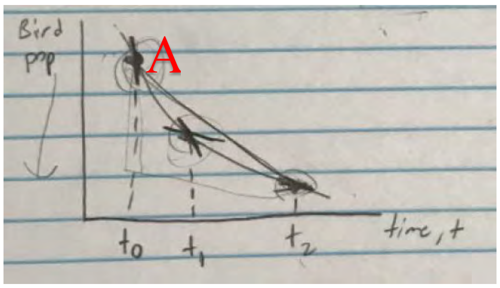
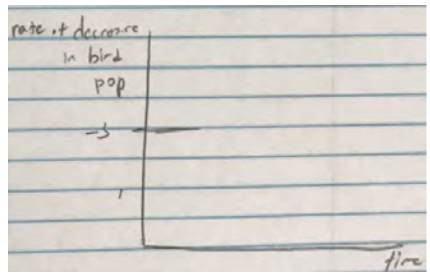
Imagining the slope of the tangent. In the Cats & Birds Task, After Pai constructed an expression for "the number of bird-cat interaction that resulted in a kill" (which for Pai, is also the “number of birds dead at time t”) as $f_k(t) = [\alpha B(t)C(t)]\beta$, we asked what the rate of decrease of the bird population due to cat predation be. Pai’s first reaction to this prompt was to draw a graph of bird population vs time [Figure 5]., where he *grossly coordinated* the quantities the population of bird and time.



(a)



(b)

Figure 5: (a) bird population vs time and (b) rate of decrease of bird population vs time

According to the graph above, for Pai, as time goes on, the bird population decreases due to cat predation. After drawing the graph Pai reasoned:

> Pai: I think this question is trying to plot the function for the derivative of my model, because it wants the rate of decrease. I think we're asking for decrease in bird pop would be the y axis…over time t. The rate would be whatever this slope is [pointing at A], called, I don't know. Negative three. It would be like that [Figure 5b].

We infer that Pai is imagining the slope of the tangent line at different points in time ($t = t_0, t = t_1, t = t_2$), would give him the rate of decrease of bird due to cat predation. Here Pai, like Szeth, conceives the RoC of bird population due to cats by considering the derivative of the bird population. However, he wasn’t very certain what the outcome of evaluating the slope of the tangent at different points in time would look like. Since Pai needed a “a model for the derivative” he thought $f_k'(t)$ would represent the tangent lines in figure 5a. He proceeded to take the derivative of $f_k(t)$ using the product rule and arrived at $f_k{}'(t) = \beta\alpha[B'(t)C(t) - B(t)C'(t)]$. However, he expressed that the result didn’t make sense to him. When asked why it didn’t make sense, Pai reasoned:

> Pai: $B(t)$ is birds at time t. I don't really know what $B'(t)$ would be. The change in birds at time t? The increase or decrease of their population? That's just a fact of, for bird, $B'(t)$, the birds, for that specific case, it would just be change in the natural bird population, not due to cats killing them? Because the bird population is changing, decreasing, because cats are constant killing them. I guess birds are also just die. They're birds... So, B' would be that change. Cats too, cats get run over and whatever, so it would be the change in their population [pointing at $C'(t)$].

We believe the biggest reason it wasn’t making any sense to him was because he wasn’t sure how to distinguish among the quantities $f_k'(t)$ and $B'(t)$.While reasoning out loud, he settled on $f_k'(t)$ as the rate of decrease of bird population due to predation by cats which he expressed in terms of $B'(t)$, where he attributed $B'(t)$ as change in bird population due to all causes. Even though f_k, for Pai, was “number of birds dead at time t”, Pai’s conception of RoC as a derivative was so strong, he overlooked the attribute $f_k{}'$ would be measuring.

Discussion

We presented three examples of differing ways that Pai and Szeth structurally conceived RoC in terms of operating on constituent quantities. Conceiving RoC as how quickly change is happening entails considering the differences in consecutive amount-values and coordinating it with the amount of time it took for the change to happen. Conceiving RoC as a multiplicative object entail uniting the attributes of two quantities so that their chnages both happen simultaneously. In both Pai's and Szeth's cases, conceiving RoC in these manners arose while they were both grappling with the thought: *How would the account grow as the compounding periods get smaller?* However, the ways in which they chose to operate on existing quantities differed. In Szeth's case, he first engaged in the *additive comparison* of the quantities amount of money at $t + 1$ and amount of money at t, and next considered how long it took for the change to happen. In Pai's case, he *coordinated* the change in the amount of money in the account and length of time duration for the change and envisioned those changes to be happening at the same time.

Conceiving RoC as a derivative entails considering the derivative of a function as a measurable attribute of an object. This way of conceiving the RoC is different from the first two examples presented here (and ways (4) and (5) not exemplified in this report). This is because envisioning the derivative or constructing an image of a derivative may or may not fall within the scope of quantitative operation. A derivative may be attributed as a quantitative operation if the meaning student has for derivative entailed the coordination of two quantities. For both students, there was no clear evidence that taking the derivative or envisioning the slope of the tangent carried situationally relevant quantitative meaning. Conceiving of RoC as the derivative might limit a modeler in terms of what he can model. For both students, the phrase RoC acted as a cue to take the derivative, dropping the situationally relevant meaning the derivative being taken on was measuring. Both Szeth and Pai, produced quantities that weren't measuring the attribute that was in question: *RoC of bird population due to cats*. However, for both students, considering derivative resulted in a quantified attribute, namely, the bird population. That is, Both Pai and Szeth conceived RoC as a measurable attribute that can be measured by considering the derivative with respect to time of the function bird population.

By adhering to the definition of quantitative operation and quantitative relation, instances like these, where a student may or may not have quantitative meanings for RoC as a derivative, would be missed. In our data, we found instances where the operation performed does not have clear evidence of a quantitative operation (as defined above), but the outcome of the operation is clearly a new quantity. We ask, *where ought these borderline instances be placed?* We do believe that even though taking the derivative in and of itself may not be credited as a quantitative operation, envisioning the derivative as yielding a new quantity is an image that is prevalent in undergraduate learners and the result of that action is often times useful for mathematical modeling. For example, in a simple interest context, Pai took the derivative of the size of the account at time t to describe the behavior of the growth of the account. Although the field has reported on students' conception of derivative through lenses of quantitative reasoning and covariational reasoning, we still need research on what it means when a student takes a derivative, as a procedure, through a quantity-oriented lens.

UNDERGRADUATE PERSPECTIVES ON THE NATURE OF MATHEMATICS THAT ARISE THROUGH EXPLORATION OF UNSOLVED CONJECTURES

Jeffrey Pair
California State University Long Beach
Jeffrey.Pair@csulb.edu

Gabe Calva
California State University Long Beach
Gabe.Calva@student.csulb.edu

We report on a research study conducted within a transition-to-proof course for mathematics majors at a large public university. Within the course, students explored famously unproven conjectures and reflected on how their perspectives of mathematics changed through this exploration (if at all). In this report we share students' takeaways from the project. For instance, some students experienced mathematics as a creative subject for the first time, as they tried their own methods to solve the conjectures; other students reflected on developing a greater understanding of the behind the scenes work of mathematicians that goes into mathematical creation. We also report on the subjective emotional experiences of the students, which ranged from frustration from being unable to find patterns to enjoyable exploration.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Reasoning and Proof; Undergraduate Education

Within mathematics education scholarship, authors have lamented that students do not experience mathematics in ways similar to those experienced by practicing mathematicians (Boaler 2015; Lampert, 1990; Lockhart, 2009; Hersh, 1997). After describing the creative activity of research mathematicians, Boaler (2016) wrote, "I strongly believe that if school math classrooms presented the true nature of the discipline, we would not have this nationwide dislike of math and widespread math underachievement" (pp. 22-23). What can a mathematics instructor do so that students understand the nature of the discipline of mathematics that Boaler refers to?

If mathematics classrooms are to provide a space for students to experience mathematics in ways similar to mathematicians, then mathematics teacher education programs must provide space for future teachers to experience mathematics in novel ways. But curriculum change is a slow-moving process—the curriculum of the undergraduate mathematics major has remained relatively constant for decades. Mathematics majors frequently take Calculus, Introduction-to-Proof, Number Theory, Geometry, Abstract Algebra, Analysis, etc… How can we improve mathematics instruction in these existing courses so that future teachers are better prepared to support their students in engaging in authentic mathematical practices? One approach that has been used in content courses is to design novel curriculum so that future teachers can collaboratively develop their mathematical knowledge for teaching (Lischka, Lai, Strayer, & Anhalt, 2020). These approaches have been successful in courses for geometry, algebra, statistics, and modeling. But what about traditional proof courses? Inquiry-based and collaborative pedagogical approaches within proof courses are another way to provide future teachers opportunities to experience mathematics in ways more aligned to the discipline (Bleiler-Baxter & Pair 2017, Bleiler-Baxter, Pair, & Reed 2021, Pair & Calva, 2021). In this paper we report on a new approach aimed at enriching students' perspectives of mathematics within a transition-to-proof course—engaging students in the exploration of unsolved mathematical conjectures.

Purpose

Our goal for this research project was to engage students in a novel activity—the exploration of unsolved mathematical conjectures. Unbeknownst to the general human population, mathematics is a dynamic field in which new results are constantly being discovered and reported (Pair, 2017). Unanswered questions and unsolved problems drive mathematical research. Two such unsolved problems, the Twin Primes Conjecture and the Collatz Conjecture have remained unsolved for decades (Bairrington & Okano, 2019; Rezgui, 2017). Our goal with this project was to expose these conjectures to students and provide them the opportunity to develop their own methods to try and prove the conjectures and then reflect on what they learned about mathematics through the activity. Our hypothesis was that engaging in these activities would provide the undergraduates novel opportunities to enrich their perspectives on the nature of mathematics. Our research question is: How are students' perspectives on the nature of mathematics enriched through their exploration of unsolved conjectures (if at all)?

Theoretical Perspective

We designed the study and corresponding unsolved conjectures project in efforts to promote the humanistic vision of mathematics as captured by the four characteristics of mathematics as expressed in the *IDEA* Framework for the Nature of Mathematics (Pair, 2017). This framework was developed through a dissertation study that involved immersive experiences in mathematics (collaboration with a research mathematician, teaching a transition-to-proof course). The purpose of the framework is to provide a list of possible goals for students' understandings of the nature of mathematics. This framework posits that, in order for students to possess a refined humanistic view of mathematics, they should understand that:

I - Mathematical ideas are part of our *I*dentity.
D - Mathematical knowledge is *D*ynamic and ever-changing.
E - Doing mathematics involves an *E*motional *E*xploration of ideas.
A - Mathematical knowledge is socially validated through *A*rgumentation.

In order to foster an understanding of these characteristics of mathematics, students must be engaged in learning activities for which these characteristics of mathematics become apparent. We hypothesized that by engaging in an activity that research mathematicians also engage in (trying to prove an unsolved conjecture), students would have the opportunity to reflect on mathematics in ways that align with these four characteristics.

Methods

Participants, Context and Data Collection

The research took place at a large public university in the United States. The university is a Hispanic-serving institution, and has very diverse student body. This diversity is represented in the students who participated in this study, which was approved by our university's institutional review board. Participants included volunteers enrolled in a transition-to-proof course. There were 16 female participants and 9 male participants. All names in this paper are pseudonyms.

As an added component of the course, students kept a mathematician's notebook in which they were scaffolded into exploring unsolved conjectures and reflecting on the process. These notebooks served as the primary source of data for the project. This exploration was conducted through several assignments over the course of the semester. For the first assignment, students reflected on questions such as 1) What is mathematics all about? And 2) What is mathematical proof and how is it used by mathematicians? Students were then introduced to both the Twin Primes Conjectures and the Collatz Conjectures. After doing some relatively simple explorations, they described how the assignment was similar to or different from their previous mathematical activity. For subsequent assignments, students were assigned to research teams to work on either conjecture according to their preferences. For the second assignment, students were scaffolded into relatively difficult tasks to explore the conjectures—for instance looking for patterns in the twin primes or Collatz sequences; or articulating what it would mean to attempt a proof by contradiction to prove the conjectures. For the third assignment, students invented their own methods and approaches to try and solve the conjectures; there was then time for in-class sharing of approaches and methods. For the fourth and final assignment, students continued to use their own invented approaches to try and prove the conjectures; they also watched videos in which mathematicians described their own work on the conjectures; and finally, they reflected upon the process—this reflection included revisiting the questions: 1) What is mathematics all about? And 2) What is mathematical proof and how is it used by mathematicians? Additionally, students also responded to two more questions: 3) How has your thinking regarding mathematics and mathematical proof developed and changed during this semester? Which changes were the result of studying the Twin Primes and Collatz conjectures? And 4) What were the challenges and successes of your experience with mathematical research this semester?

Data Analysis

The researchers analyzed the notebooks through a thematic analysis process (Ryan & Bernard, 2003). This analysis process took place through two main stages. During the first stage, two researchers individually read through each participants' notebook, one at a time, making note of 1) Student quotations that aligned with the nature of mathematics as expressed in the IDEA framework[1]; 2) Evidence of change in perceptions of the nature of mathematics; 3) Other substantial reflections about mathematics and the research process; 4) Interesting mathematical ideas. Subsequently, the researcher's discussed their findings from each notebook, describing their observations. After this task was completed for the individual student notebooks, each researcher created a holistic summary of what they saw as the major trends in student reflections. The researchers also used student quotations as evidence for the trends they observed. This process resulted in a list of several recurring themes in student reflections (e.g. seeing mathematics creatively for the first time; frustration in being unable to find patterns). During the second stage of analysis, the researchers took the list of recurring themes developed in phase 1, and then reviewed each notebook again, making note of which ideas were expressed by each individual student. We then tallied these recurrences, resulting in a quantitative summary of the ideas expressed by the students. For a more detailed description of the methodology, see (Pair & Calva, 2021).

Results

Overall, we found that exploring conjectures provided an opportunity for students to experience and see mathematics in new ways. Students recognized that they had the opportunity to engage in a process similar to mathematicians, and felt they had a better understanding of the process of how mathematical knowledge is developed. They also experienced first-hand the emotional aspects of mathematics, and recorded a wide variety of emotions from frustration to joy. We now present our results, generally organized according to the four categories of the IDEA Framework.

[1] We also used de Villiers (1990) roles of proof framework in our analysis. Those results are shared in (Pair & Calva, 2020).

Identity

In terms of identity, Figure 1 shows the tallies of students whose notebook reflections expressed related ideas. We identified ten total students whose reflections showed that they either took ownership of their ideas using personal (I/my) language, showed that they grew in their own mathematical identity, or identified with mathematicians to a greater degree than they did before (the total is more than ten as some students were categorized in more than one category).

Identity	10 (total)
Take owernship of ideas (using I/my language)	9
Grew in own mathematical identity (right major choice).	4
Identify with mathematicians	4

Figure 1: Recurring Themes Related to Identity

For instance, we can see that Isabella uses the language "my work" and "things I figured out" in this excerpt from her notebook as she references a concept she invented, "pink numbers":

> Overall, I liked this process of communicating with the class and working together. I got excited when I figured 'the first pink number' out […] I'm even more excited to figure stuff out, or simply just share my work with my classmates. My most important work are on pages 12 and 18 because they show the 2 things I figured out.

See Figure 2 for an image that shows an excerpt from Isabella's work that she referred to:

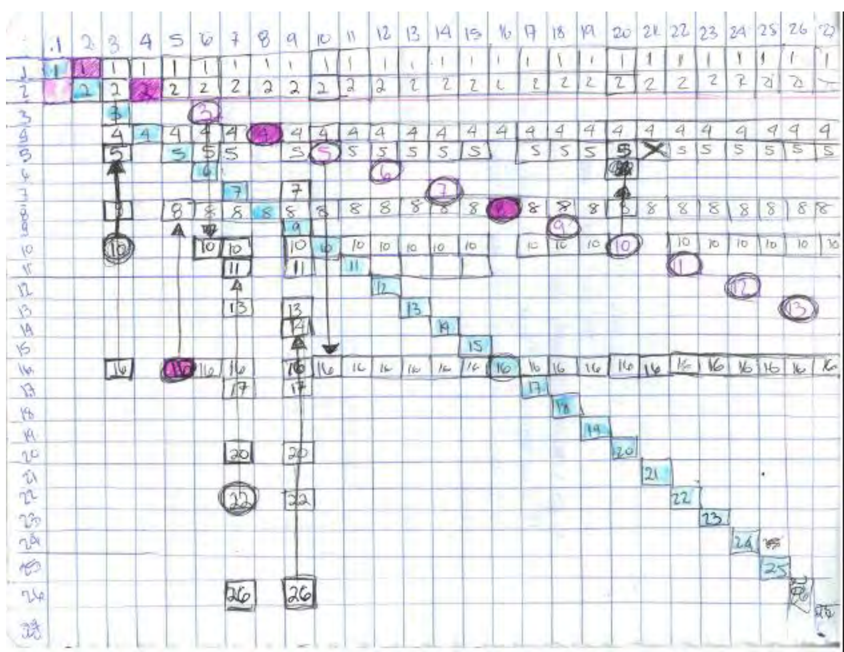

Figure 2: Excerpt from Isabella's Notebook

Four students grew in their mathematical identity as the conjecture exploration helped them see that they enjoyed proofs and/or mathematical research. For instance, Brent wrote,

> This notebook assignment has made me realize that even the simplest arithmetic can lead to problems that even modern mathematics isn't ready for. But it's also grown my passion for

> proofs and the subject itself. I want to dive deeper into this and see what I can learn! Oh, it also made me realize that I made the right choice in majoring in math since I love proofs so much ☺.

Four students wrote that they believed the assignment helped them to identify with mathematicians as they got to engage in the same activities as mathematicians. Vincent wrote,

> I had a lot of fun working on this second assignment because we are working on an unsolved proof like many other mathematicians. It is pretty cool to try and give one's own spin and perspective on the twin primes conjecture and if not prove it, at least come to the understanding of the conjecture and have some hands-on experience.

Dynamic

In terms of the dynamic nature of mathematical knowledge, see Figure 2 for the tallies of how many students reflected upon a particular theme. We found that eleven students either described how they learned about conjectures for the first time, understood better how mathematical knowledge is built, conjectured that new mathematics may be required to solve conjectures, and/or referenced discovery (some students were identified for more than one category).

Dynamic	11 (total)
Learning about conjectures for first time	5
Described building up of knowledge in mathematics	5
Believed new mathematics required to solve conjectures	4
Reference Discovery	6

Figure 3: Recurring Themes Related to Dynamic Nature of Mathematics

Vanessa and at least four other students learned about conjectures for the first time through the assignments. Early in the semester she wrote, "I enjoyed learning about conjectures. I didn't know what conjectures were, but now I do." Near the end of the semester, after watching a video of a mathematician describing their work on their conjectures, Vanessa wrote "Mathematicians use these proofs to help prove other conjectures. As Maynard's proof was influenced by Zhang's proof. Eventually, Maynard's proof will be used to help prove other conjectures."

We found that four students hypothesized that new mathematics may be required to solve the conjectures. Lorenzo wrote, "The Collatz conjecture is unprovable… for now. There has to be some future mathematics that will prove it. However right now, in 2019, the Collatz conjecture remains unsolved." Five students referenced mathematical discovery in their final reflections. Daniel concluded, "Proofs are used by mathematicians to assist them in creating other proofs to eventually have a breakthrough that is groundbreaking in mathematics as well as the world."

Emotional Exploration

Almost every student in the course reflected on significant aspects of mathematical exploration. Five students experienced mathematics creatively for the first time and seven recognized the need to think outside the box in exploring the conjecture. Eight students reflected that the process allowed them to get a glimpse of the discipline of mathematics and what goes into the making of mathematics. Students also described a range of emotions from frustration to joy. We found that five students described frustrations but no positive emotions, 9 students described both frustration and positive emotions, whereas seven students described only positive emotions. See Figure 4 for a summary of themes related to exploration (some students were counted for multiple categories).

Exploration	24 (total)
View of Math as creative	5
Need to think outside the box or think critically	7
Looking at conjecture from different perspectives	5
Getting a glimpse of the discipline.	8
Contrasted conjectures with prior math experiences	11
Frustrated	14
Enjoyed/Excited/rewarding (positive emotions)	16

Figure 4: Recurring Themes Related to Exploration

Students were frustrated when they could not find patterns, or when they were at a loss for how to proceed in working on the conjectures. For example, consider this excerpt from Charity: "I feel lost. Working on this assignment feels like a road with no end. I don't feel confident in what I'm doing unlike when I'm working on what we're working on in class." Other students described similar challenges, as the assignment was different from their previous mathematical experiences. Cassandra found that she needed to look at math more creatively to meet the challenge of the assignment.

> My experience working on this conjecture thus far has been challenging. It is difficult to shift how you approach mathematics from just learning and applying formulas and theorems that define what you do to then try and figure it out yourself. This has made me look at math more creatively than I have before. This conjecture has also made me try and see more patterns in number sequences and how they relate to one another.

After a period of frustration, most students productively engaged in the conjecture by trying a variety of approaches. The quote from Carlos below illustrates how he found enjoyment in the experience and also developed a new perspective on mathematics.

> For the most part, I was able to get a solid foundation about number theory, primes, "3n+1" and all its uses, and also going down the rabbit hole of several given solutions on Collatz or twin primes. This assignment was fun. Really fun. Being able to think of math in a more analytical sense was like a breath of fresh air. Being able to break down, and to be able to show each part of a statement to be true or false. It's kind of eye opening that this is how to "read math" and "talk math."

In addition to considering how to read and talk math, other students described how they got a picture of what goes into the making of mathematical knowledge. Jennifer wrote,

> This assignment was very interesting to me because it had me learn more about why Collatz sequences have not been proven yet. This was a different experience for me compared to my prior mathematical experiences because usually I work with problems that have already been proven. So it was definitely interesting getting a glimpse of what professional mathematicians struggle with when trying to prove something for its first time.

Argumentation

While we have evidence that students had opportunities to enrich their perspectives on the nature of mathematics in ways that aligned with the first three categories of the IDEA framework, we did not find much evidence that students reflected on the fourth category—argumentation. Perhaps this is because the students only had one day in class for in-person sharing of our findings related to the conjecture. That day was a show and tell experience rather than a critiquing experience—the students did not have the opportunity for social validation of mathematical knowledge through the conjecture assignment.

Discussion

We are encouraged by the results of our study. We have some evidence that providing students a scaffolded opportunity to explore unsolved conjectures, and time to reflect on this activity, is a productive means to enrich students mathematical experiences/perspectives. While we chose the Twin Primes and Collatz conjectures due to our familiarity with them, we believe that any accessible conjecture could be used fruitfully with undergraduate students. This activity was implemented in a transition-to-proof course, but a similar activity could be used as a project in courses on analysis, number theory, abstract algebra, etc… It is especially important for future teachers in such courses to have opportunities to experience mathematics in non-traditional, collaborative activities that more closely align with the work of practicing mathematicians. By doing so, they will be better positioned to provide their future students with opportunities for authentic mathematical practice.

In this exploratory study, we used the IDEA framework as a conceptual framework in data analysis for the first time. In our analysis, we carefully looked for student reflections that expressed ideas that aligned with the categories of the IDEA framework. This was a lengthy qualitative process. Future studies may improve upon this methodology, perhaps creating quantitative assessments that can be used to measure the changes in students' perspectives of the nature of mathematics through novel classroom interventions.

We note that of the four categories in the IDEA framework, students had the opportunity to learn about each aspect of the nature of mathematics except that mathematics is socially validated through *A*rgumentation. Future research studies are needed to discover classroom interventions that help students experience and understand this aspect of the nature of mathematics.

JUSTIFICATIONS STUDENTS USE WHEN WRITING AN EQUATION DURING A MODELING TASK

Elizabeth Roan
Texas State University
eaw109@txstate.edu

Jennifer Czocher
Texas State University
czocher.1@txstate.edu

Literature typically describes mathematization, the process of transforming a real-world situation into a mathematical model, in terms of desirable actions and behaviors students exhibit. We attended to STEM undergraduate students' quantitative reasoning as they derived equations. Analysis of the meanings they held for arithmetic operations ($+, -, \cdot, \div$) *provided insight into how participants expressed real-world relationships among entities with arithmetic relationships among values. We extend the findings from K-12 literature (e.g., using multiplication to instantiate a rate) to STEM undergraduates and found evidence of new ways of justifying the usage of arithmetic operations (e.g., using multiplication to instantiate an amount).*

Keywords: Modeling, Undergraduate Education, Mathematical Representations

Mathematical modeling (hereon called modeling) provides a venue within which to promote STEM education, a stance taken by the US government (Committee on STEM Education, 2018, p. 17; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), and researchers alike. Modeling is typically defined as the cyclical process of taking a real-world phenomenon, transforming that phenomenon into a mathematical representation (called mathematizing), working with that mathematical representation, and interpreting that work back into the real-world. The idea to use modeling activities to enrich STEM education is well established. Modeling helps students develop general competences and attitudes towards creative problem-solving while building feelings of self-reliance and competence, prepare to live and act as informed socially conscious citizens, use math to describe extra-mathematical situations, see a richer more comprehensive picture of mathematics, and acquire, learn, and keep mathematical concepts by providing motivation for and relevance of mathematical studies (Blum & Niss, 1991).

Literature on modeling competencies, and specifically mathematizing, typically frame the research as identifying some sort of "blockage" or that an action associated with a competency was "difficult" to perform (Brahmia, 2014; Galbraith & Stillman, 2006; Jankvist & Niss, 2020; Stillman & Brown, 2014). While these descriptive actions are an important step in fully understanding the complexity of mathematizing, we do not yet know why certain actions, such as writing an equation, is difficult for students. In particular, it is often unclear how or why a participant chooses to represent a real-world relationship with a given arithmetic operation ($+, -, \cdot, \div$). Understanding the justifications students use when writing down their equations will inform facilitator scaffolding of mathematizing and may also provide insight into when and how students ensure their resulting equations are adequate. We target this one aspect of mathematizing in order to make strides towards developing rich, empirically- and theoretically-grounded descriptions of students' mathematical reasoning during mathematizing.

Theoretical Framework

Previous studies have indicated that quantitative reasoning promotes building of models (Ellis, 2007; Ellis, Ozgur, Kulow, Williams, & Amidon, 2012; Mkhatshwa, 2020) and is a lens with which to understand STEM undergraduates' reasoning while mathematizing during a modeling task (Carlson, Larsen, & Lesh, 2003; Czocher & Hardison, 2021; Larson, 2013). Czocher and Hardison (2019, 2021) reported findings of a task-based interview with a participant working on a modeling problem. Their retrospective analysis documented how the participant's model changed through the course of the interview by attending to quantities imposed onto the task situation, the relationships among those quantities, mathematical inscriptions, and changes to each of those elements. An interesting implication of this analysis is that the models that students could potentially make during a modeling task depend on (and are constrained by), the quantities the participant imposes onto the situation. Given the arguments and implications of the literature above, it is appropriate to use quantitative reasoning as a lens to study students' reasoning while mathematizing.

In the remainder of this section, we put together the theoretical constructs from quantitative reasoning in order to describe the justifications students used for certain arithmetic operations $(+, -, \cdot, \div)$ when writing an equation during a modeling task. "Quantitative reasoning is the analysis of a situation into a quantitative structure- a network of quantities and quantitative relationships" (Thompson, 1993). A quantity is a mental construct, whose creation is (often) effortful (Thompson, 2011). That effort is characterized by the act of someone conceptualizing an object that has some attribute and intending to measure that attribute. (Thompson & Carlson, 2017, p. 425). This means a quantity is a triple consisting of an object, attribute, and quantification (Thompson, 2011). Quantification in this instance means to conceptualize some object with an attribute that has a measure, and that measure has a proportional relationship with its unit (Thompson, 2011). Further, quantification can be operationalized as the set of operations an individual could enact on the attribute (Hardison, 2019). According to Ellis (2007), length, area, volume, cardinality, speed, temperature, and density are all attributes of some object that can undergo quantification. A quantity is made from an individual's conceptions of objects within the situation, rather than the objects or situations themselves (Ellis, 2007), further, each individual could quantify an attribute using differing sets of operations, therefore a quantity is idiosyncratic to the individual. Because a quantity is idiosyncratic to the individual, quantities are (cognitively) distinct from (mathematical) variables.

A quantitative operation is a conceptual operation where an individual creates a new quantity in relation to one (or more) already created quantities (Ellis, 2007; Thompson, 2011). Enacting a quantitative operation upon two quantities can be thought of as composing or combining two quantities (which could be denoted through arithmetic operations) to yield the new one. Thompson (2011) outlined the arithmetic operations associated with the quantitative operation as seen in his data with students k-12, see **Error! Reference source not found.**1.

Table 1 Arithmetic operations done to construct a new quantity (Thompson, 2011, p. 43).

Structure	Arithmetic Operation to Evaluate the Resultant Quantity
A quantity is the result of an additive combination of two quantities	Addition
A quantity is the result of an additive comparison of two quantities	Subtraction
A quantity is the result of a multiplicative combination of two quantities	Multiplication
A quantity is the result of a multiplicative comparison of two quantities	Division
A quantity is the result of an instantiation of rate	Multiplication
A quantity is the result of a composition of ratios	Multiplication

The left side of Table 1 describes the type of relationships between two quantities that results in a new quantity. In other words, this left-hand side is the schema of action used to apply arithmetic operations to symbols that represent quantities. A schema of action is an organized pattern of thoughts or behaviors (actions) that can be applied to different cognitive objects in different situations (Nunes & Bryant, 2021). For example, in k-12 literature, two schemas of action for addition are: putting together (i.e., quantity is the result of additive combination), and part-whole relations (i.e., a comparison of two quantities) (Nunes & Bryant, 2021). Additionally, a schema of action for multiplicative relationships could be a one-to-many correspondence for quantities with a fixed ratio relationship (i.e., a multiplicative combination of two quantities). There might be other schemas of action participants are using to apply structure to a real-world phenomenon. Structure here is defined to be the schema of action, and the arithmetic operations are the result of the imposition of the schema of action in the mathematical representation.

Research has shown that some schemas of action are not advantageous for combining quantities. As pointed out by Schwartz (1988), the notion of multiplication being a one-to-many correspondence does not work for cases such as (miles/hours * hours = miles), because iterating the relationship between miles and hours "number of hours times" cannot be done. Similarly, Brahmia (2014) argued that students who conceptualize multiplication as repeated addition are not prepared to conceptually understand products of quantities. Additionally, students who see division only as an operation that creates parts from a whole do not have the mental operations available to conceptualize ratio quantities (e.g., density, velocity). That is, students being able to effectively construct quantities in applied contexts must have strong conceptualizations of multiplication and division that differ from the schema of action of "repeated addition" and "creating parts from a whole" (Brahmia, 2014).

In order to describe the justifications participants hold for the equations they write down, we address the question: *What schema of action do STEM undergraduates use to justify their choices of arithmetic operations while mathematizing during a modeling task?*

Methods

This study was part of a larger study of facilitator scaffolding moves that foster participants' modeling competencies. For the present study, 11 STEM undergraduates participated in sets of individual cognitive task-based interviews through Zoom. Each participant saw at least six tasks over ten sessions. The tasks were modeling problems designed to scaffold participants' modeling activities by attending to quantitative reasoning and appealing to similarities in structures. We report findings from three participants' work on the *Cats and Birds* task (see below). Pattern, Neturo, and Khriss were all enrolled in, or had already taken, differential equations (DE) at the time. Pattern majored in civil engineering while both Neturo and Khriss majored in physics with a minor in mathematics. These three participants were chosen from the larger study to showcase schema of action that differ from those described in previous literature.

> *Cats & Birds.* Cats, our most popular pet, are becoming our most embattled. A national debate has simmered since a 2013 study by the Smithsonian's Migratory Bird Center and the U.S. Fish and Wildlife Service (Raasch, 2013) concluded that cats kill up to 3.7 billion birds and 20.7 billion small mammals annually in the United States. The study blamed feral "unowned" cats but noted that their domestic peers "still cause substantial wildlife mortality." In this problem, we will build a model (step-by-step) that predicts the species' population dynamics, considering the interaction of the two species.

In this task, participants were asked to consider a back-yard habitat where birds are the primary prey for cats. The participants were then asked a series of questions with the aim of having them write an equation for the instantaneous rate of change of the bird and cat population. Here we report the students' work to build a differential equation of the bird population due only to cat predation. It is appropriate to study students' mathematization while modeling in dynamic tasks like Cats and Birds because dynamic tasks elicit dynamic reasoning, which is connected to quantitative reasoning (Keene, 2007).

Data were analyzed in four phases. First, the transcripts and written work were segmented according to changes in discussion topic (e.g, the interviewer asked a new question). Second, we identified the quantities the participant imposed onto the task scenario by describing the object, attribute and how the participant exhibited quantification for that attribute according to the quantification criteria developed by Czocher and Hardison (2021). In phase three, we noted instances of arithmetic operations used on the quantities the participant constructed and documented the participants' reason (or inferred reason when the participant's reason was not stated) for using that specific arithmetic operation and if the instance is a quantitative operation, that is, the arithmetic operation is done to create a new quantity. In phase four, we compared the reason we inferred the participant was using to the schema of action documented in Thompson (2011) and Nunes and Bryant (2021) and noted if the schema of action matched previous literature or was not present in previous literature. For example, Neturo stated that he used multiplication because one cat will meet many birds. Neturo's explanation was comparable to a one-to-many correspondence as described by Brahmia (2014) and Nunes and Bryant (2021).

Results

We report the schema of action participants employed when expressing arithmetic operations with the quantities they imposed onto the Cats and Birds task as they built their model for the rate of change of the bird population due only to cat predation. According to our theoretical perspective, arithmetic operations are the result of imposing the schema of action in the mathematical representation and thus tell us how the participant was justifying (either explicitly or implicitly) their usage of arithmetic operations. First, we provide an overview of all of the inferred schema of action exhibited by our participants in Table 2. This table reports the quantities the participant combined, the resultant quantity, the inferred schema of action, and if this schema of action was present or not present in previous literature.

Table 2 Schema of action exhibited by all three participants

Quantity 1	Quantity 2	Resultant quantity	Schema of action	In previous literature?
Number of birds at time t	Number of cats at time t	Number of total possible cat-bird interactions that could occur in the back yard habitat.	Multiplication- One-to-many correspondence (Brahmia, 2014; Nunes and Bryant, 2021,)	Yes
Rate of encounters between cats and birds per time interval	Number of total possible cat-bird interactions	Number of encounters per unit time	Multiplication- Instantiation of a rate. (Thompson, 2011)	Yes
Percentage of encounters that are realized	Number of total possible cat-bird interactions	Number of encounters that are realized	Multiplication- Subsetting	No
Number of encounters that result in a death	Duration of time	Number of birds that die during Δt	Multiplication- Instantiation of an amount.	No
Total accumulated dead birds during a time segment	Total number of observations of the population made during a time segment	Average change in the bird population	Division - Separating into equal parts. (Brahmia, 2014)	Yes
Change in the bird population due to cats	Number of birds that die during Δt	Change in the bird population due to cats per change in time	Division - Evaluate a quantity that is an operand of a quantitative operation. (Thompson, 2011)	Yes
Number of birds present at the beginning of a time segment Δt	Number of birds at the end of a time segment Δt	Change in the bird population due to cats	Subtraction - Additive comparison between two quantities (Thompson, 2011)	Yes

Quantity 1	Quantity 2	Resultant quantity	Schema of action	In previous literature?
Number of lethal encounters between a cat and a bird on day t_1	Number of lethal encounters between a cat and a bird on day t_n	Total accumulated dead birds during a time segment	Addition - Additive combination of multiple quantities	No

Overall, our participants did exhibit schema of action described in previous literature. This indicates that schemas of action present in k-12 literature are also exhibited by undergraduate STEM students. We next illustrate the three schemas of action not present in the previous literature.

Schema of action not present in the literature

Additively combining multiple quantities. Khriss was asked how he could model the decrease in the bird population due to cats during some arbitrary passage of time $\Delta\tau$. Khriss initally reponded by writing down the symbol Σ, indicating he was thinking of constructing some form of summation. The interviewer suggested he find the decrease in the bird population due to cats after five days, instead of an arbitrary duration of time. In Khriss' reasoning, the number of birds dying each day was variable. He used $LE(t)$ to represent the number of lethal encounters between a cat and a bird at a specific time t. In response to the prompt, Khriss wrote $\int_0^5 LE(t)dt$, denoting summation. Khriss understood the decrease in bird population during five days as an accumulation of the non-constant values of the number of lethal encountes on a specific day. Khriss used this schema of action again when he was asked to consider the average rate of change of the bird population during some number of days D. In reponce to this, Khriss labeled multiple instances of time that the number of lethal encounters were recorded that occured during the number of days D. He labeld these instances of time $t_1, t_2, t_3, \dots, t_n$. Khriss then added the number of lethal encounters for each day to yeild the total accumulated dead birds during some number of days D. The equation written for this calculation was $\sum_{t=1}^{n} LE(t)$. A snapshot of Khriss's work is provided to showcase how Khriss thought of this sumation (see Figure 1), and below we provide a quote of Khriss explaning his summation.

Khriss: So during a segment of time D, to find an average I guess we would need multiple readings of what the population is throughout that time. I guess we could we use t_1, t_2, t_3, t_n. Yeah, I guess that would be it. Just to make sure what question I'm answering here, I have lethal encounters at time t adding up all of those for each different t all the way to my last t and dividing that by the number of measurements gives me an average. So that gives me my average number of dead birds within t.

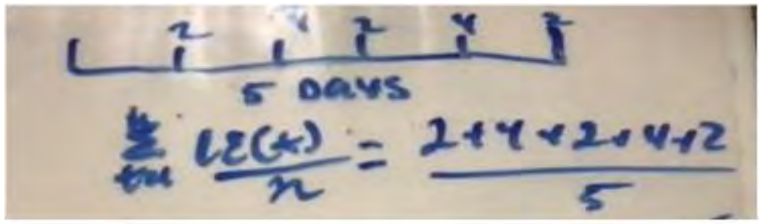

Figure 1: Average change in bird population over five days according to Khriss.

His schema of action for both of these instances was additively combining multiple quantities to arrive at a new quantity. The schema of action described in Thompson (2011) occurs strictly between two quantities. Because Khriss is adding more than one quantity at a time, Khriss' schema of action is different. We infer that Khriss' schema of action is a step up in complexity from the schema described in Thomspon (2011), because Khriss is able to implicetly construct each measure of dead birds between $LE(t_1)$ and $LE(t_n)$ in order to combine an unknown number of quantites additevely.

Multiplication for subsetting. Pattern had previously constructed a quantity that represented the number of total encounters, which is calculated by $B(t) \cdot C(t)$. In order to account for the fact that not all birds encounter all cats, he constructed two new quantities. The first quantity represented the percentage of encounters that are realized, labeled α, and the second quantity represented the number of encounters that are realized, calculated by $\alpha \cdot C(t) \cdot B(t)$. Pattern said that he multiplied α and $C(t) \cdot B(t)$ to take a percentage of the total possible encounters, indicating the schema of action for this instance of multiplication was different than a one-to-many correspondence, and was more like subsetting from a larger amount.

> Pattern: Okay. So now that we have a percentage, then you just do $C(t)$ times $B(t)$ times α equals encounters. Because you're going to take… So this is the total possible encounters that could possibly happen if perfect conditions are met for each cat to meet each bird, and then you're going to take a percentage of that total, and that would be your total...

Multiplication for instantiating an amount. Pattern had previously constructed a quantity that represents the number of birds that have died, calculated by $\beta \cdot C(t) \cdot B(t)$. Pattern then constructed a new quantity that represented the number of birds that die during Δt, labeled D_t, which was calculated by $\left(C(t) \cdot B(t)\right) \cdot \beta \cdot \Delta t$. Pattern multiplied the amount of birds that have died, which he did not view as connected to any specific duration of time, by some duration of time to yield the number of birds that have died during Δt. The schema of action used for multiplication was combining two quantities, however this was not a one-to-many correspondence and was also different from the subsetting schema of action. We infer that Pattern was multiplying by Δt in order to instantiate the number of birds that have died specifically during Δt. Pattern did not evidence multiplying a rate and a duration of time to yield an amount (per-time rate $\cdot\ \Delta t =$ amount) because Pattern did not associate a duration of time with $\beta \cdot C(t) \cdot B(t)$. For Pattern, the quantity calculated by $\beta \cdot C(t) \cdot B(t)$ was an amount, not a rate. The quote below shows Pattern explaining that multiplying by Δt transforms $\beta \cdot C(t) \cdot B(t)$ into the quantity that represents mortality (the number of birds that die) during Δt,

> Pattern: I honestly just know that I have to add [append] this Δt, and it kind of makes sense in my head because this mortality doesn't have a specific time attached to it. It (referring to $C(t) \cdot B(t)$) has already the t, but that's just telling you the amount of cats and birds at that time. It doesn't tell you how much time has passed. So if you multiply all of that by

this number (pointing at Δt),… this is time that has passed….It's not encounters anymore, now it's.. What this is telling me the mortality during Δt.

Discussion

Collectively, our participants exhibited schema of action discussed previously in the literature. Pattern constructed a quantity by additively comparing between two quantities. Khriss used division when finding the average by separating a quantity into equal parts. Pattern and Khriss used division to evaluate a quantity that is an operand of a quantitative operation. Neturo, Pattern, and Khriss used multiplication to combine to quantities in a one-to-many correspondence fashion. Lastly, Khriss used multiplication to instantiate a rate. All of these schemas of action are documented in previous literature (Brahmia, 2014; Nunes & Bryant, 2021; Thompson, 2011). Our participants also exhibited schema of action not present in the previous literature. Khriss used addition to additively combine multiple quantities instead of just two quantities. Neturo used a minus sign to indicate a negative magnitude for a quantity. Khriss showcased a new schema of action where he simultaneously additively combined multiple quantities in order to arrive at a new quantity. Khriss' schema of action is a step up in complexity from the schema described in Thompson (2011) because Thompson's definition is restricted to combining two quantities and Khriss is implicitly combining an unknown number of quantities. Pattern constructed a quantity that indicated a fraction or percentage and then multiplied by a quantity that represents an amount to gain some fraction of the original quantity. This schema of action does resemble the schema of action described in Thompson (2011) as a multiplicative combination of two quantities, however the schema of action for multiplication was different from a "one-to-many" correspondence described by Brahmia (2014) and Nunes and Bryant (2021). Pattern used multiplication in order to take a subset from a larger whole. Lastly, Pattern exhibited a new schema of action where multiplication was used to combine two quantities in order to instantiate an amount.

Overall, our results document justifications STEM undergraduates used when carrying out arithmetic operations ($+, -, \cdot, \div$) on the quantities while mathematizing that were not previously in the literature. We extended what is known about schema of action present in k-12 literature by confirming the presence of schema of action already described, and by introducing three new schemas of action. We postulate that these new schemas of action were observable because our participants are working on a modeling task focused on a predator-prey relationship. This conjecture is based on findings that the models participants make depend on (and are constrained by), the quantities the participant imposes onto the situation (Czocher & Hardison, 2019, 2021), which inherently impacts the types of relationships the participants were able to express using arithmetic operations. Attending to these new schemas of action reveals how students are expressing real-world relationships among entities with arithmetic relationships among quantities, specifically in a predator-prey context. We speculate additional schema of actions could be observed for arithmetic operations in other task scenarios that call for advanced mathematics. Once we know more about the justifications students use when utilizing arithmetic operations, we can then design task and scaffolding moves that directly address, preempt, or build upon, those justifications.

Acknowledgments

Research that will be reported in this paper is supported by National Science Foundation Grant No. 1750813 with Dr. Jennifer Czocher as principal investigator.

EXAMINING HOW UNDERGRADUATE STUDENTS DESCRIBE THE STANDARDS FOR MATHEMATICAL PRACTICE

Elyssa Stoddard

Rebekah Elliott
Oregon State University
rebekah.elliott@oregonstate.edu

While the Common Core State Standards for Mathematical Practice are a focal point of K-12 mathematics education, there is limited research examining how future teachers' (e.g., undergraduate students, teacher candidates) develop their conceptions of these standards. We investigate how opportunities within a mathematics-focused bridge course within a teacher education program provided opportunities for undergraduate students to develop their conceptions of the Standards for Mathematical Practice. Specifically, we explore how undergraduate students drew upon the Common Core provided descriptions to describe key practice ideas. This study contributes to the scholarship on mathematics teacher education and how teacher educators can support students in developing their understanding of mathematical practice.

Keywords: mathematical practices, mathematics teacher education

The Common Core State Standards for Mathematical Practice (SMPs) describe eight ways of thinking and doing mathematics that parallel the ways that mathematicians engage with mathematics (National Governors Association for Best Practices, 2010). These standards reflect a broader goal in K-12 mathematics education focused on moving beyond K-12 learners *acquiring* mathematical content knowledge, towards developing learners capable of actively *doing* something with mathematics (Kilpatrick et al., 2001; National Council of Teachers of Mathematics, 2018). Implicit in the creation and adoption of the SMPs is the assumption that if K-12 learners are to develop these skills and ways of thinking, their mathematics teachers should provide appropriate opportunities and support to develop and engage in these practices.

Initial teacher education offers a space where mathematics teacher educators can provide opportunities for undergraduate students to develop their conceptions about the SMPs including what they are (Bostic & Matney, 2014; Kruse et al., 2017), what doing an SMP looks like (Max & Welder, 2020), and how to support K-12 learners in doing them as well (Cheng, 2017; Gurl et al., 2016). While there are studies of how initial teacher education provides opportunities for undergraduate students to develop their conceptions of the SMPs, these studies are limited and there remain questions regarding these opportunities. In particular, because of the limited literature, it is unclear how different initial teacher education contexts (e.g., content courses, methods courses, bridge courses, student teaching) provide opportunities for undergraduate students to develop their conceptions of the SMPs. Understanding the differences, affordances, and limitations of the opportunities in these contexts is essential if teacher educators are to effectively support (future) teachers in providing K-12 learners with the appropriate opportunities and supports.

This paper shares how a mathematics-focused bridge course within a teacher education program provided opportunities for undergraduate students (hereto called 'students') to develop their conceptions of the SMPs. We discuss how students described the SMPs, including what ideas from the Common Core SMP descriptions students attended to in their own descriptions. We then discuss questions for further research based on these findings. We add to the scholarship on mathematics teacher education and how teacher educators can support their students in building their understanding of mathematical practices.

Framework

To understand how a bridge course provided opportunities for students to develop their conceptions of the SMPs, this study draws upon situative perspectives on learning (Greeno, 1998; Peressini et al., 2004) and sensible belief systems (Hoyles, 1992; Leatham, 2006). Specifically, these perspectives are used to examine how course learning opportunities supported the development of students' knowledge and beliefs about the SMPs. The following sections provide an overview of situative perspectives on learning, including situated knowledge and beliefs, as well as the notion of sensible belief systems.

Situative perspectives on learning

Situative perspectives conceptualize learning as both a social and individual process (Greeno, 1998; Peressini et al., 2004). Learning is social because one learns by actively participating within a context, and through this participation comes to learn the knowledge and accepted social practices of that context. Learning is also an individual process because it is changes in how an individual participates that indicate learning, as one's actions begin to reflect the accepted ways of participating in a given context. Scholars such as Putnum and Borko have argued that due to the variety of contexts within which initial teacher education occurs (e.g., content courses, methods courses, bridge courses, student teaching), applying a situative perspective to teacher education of offers a way of, "disentangling – without isolating - the complex contributions of these various contexts to novice teachers' development" (2000, p. 71).

In addition to knowledge, teachers' beliefs are also situated (Green, 1971; Hoyles, 1992; Leatham, 2006). In particular, the idea of *clustering* describes how beliefs can be connected to or isolated from one another based on the clusters within which they are held (Green, 1971), with clusters being based on the contexts within which the beliefs were formed. The idea of clustering is essential to making sense of beliefs because it describes how someone may hold beliefs that appear contradictory because they are held in different clusters. This clustering allows for the contextualization of beliefs where "a person may believe one thing in one instance and the opposite in another" (Leatham, 2006, p. 95) In other words, beliefs, like knowledge, are situated.

Sensible Systems of Beliefs

Due to the situated nature of beliefs, Leatham (2006) argues that how teachers' beliefs (and actions) are positioned in the literature needs to shift. He argues that if beliefs are situated then teachers' beliefs and actions are sensible with respect to the context within which they are working. Furthermore, any perceived 'inconsistencies' between teachers' beliefs and actions are indications that there are *other* beliefs at play in that particular context that are taking precedent over others; these beliefs may be held consciously or unconsciously and may be difficult for teachers to articulate. However, regardless of whether a belief is made explicit or not, teachers' actions are "fundamentally sensible" (Hoyles, 1992, p. 37) with respect to their beliefs.

Applying a sensible systems lens to teachers' beliefs pushes researchers to better understand the beliefs that are actually influencing teachers' actions rather than what we want to be the influence (Leatham, 2006). By understanding the actual influences on teachers' actions, teacher educators can better provide opportunities for students in teacher education courses to explore their beliefs, as well as provide learning opportunities that can shape students' beliefs so that what is sensible reflects the broader goals of K-12 mathematics education policy.

Conceptions

Finally, while knowledge and beliefs can be discussed separately, some scholars use the notion of conceptions to capture knowledge and beliefs together (Lesseig & Hine, 2021; Philipp, 2007; Thompson, 1992). This is because while knowledge and beliefs can be considered two distinct ways of knowing (beliefs are held with varying degrees of conviction while knowledge is held with certainty), distinguishing between them can be difficult. For example, the level of conviction with which one holds beliefs and knowledge can vary between people (Philipp, 2007). Moreover, what is considered knowledge to one person may be belief for another. Therefore, this study uses the notion of conception to capture students' knowledge and beliefs about the SMPs without trying to disentangle them. More specifically, this study investigates how a bridge course within a teacher education program provided opportunities for undergraduate students to develop their conceptions of the SMPs.

Context and Methods

Data for this study were collected from two sections of a mathematics-focused bridge course focused on familiarizing undergraduate students interested in becoming teachers with K-12 mathematics education policy. In five two-week modules, students in this course were introduced to the Common Core SMPs and content standards (NGA, 2010), the five strands of mathematical proficiency (Kilpatrick et al., 2001), and other key instructional ideas such as multiple representations or classroom discourse (see Table 1). To support students' developing understanding of the SMPs, the course provided opportunities for students to solve mathematical tasks, analyze their own mathematical work and the work of others for evidence of the SMPs, and reflect on their growing understanding of the SMPs and their relation to other course topics. Through activities such as these, course learning opportunities acted as a *bridge* between students thinking about *mathematics* and thinking about *teaching and learning mathematics*.

Table 1: Bridge Course Module Overview

Module	SMP	Course Topic	Strand of Proficiency
1	CCSSM & SMP Overview	Mathematical Identity	Productive Disposition
2	SMP 2: Reasoning SMP 6: Precision	Multiple Representations	Conceptual Understanding
3	SMP 7: Structure SMP 8: Repeated reasoning	Discourse	Procedural Fluency
4	SMP 3: Argumentation SMP 5: Tools	Justification	Adaptive Reasoning
5	SMP 1: Problem-solving SMP 4: Modeling	Cognitive Demand	Strategic Competence

Eight students consented to participate from the two sections of the course. Section one took place online, asynchronously during Winter 2021, with two of 12 enrolled students consenting to participate; Section two took place online, synchronously during Spring 2021 with six of 35 enrolled students consenting to participate. Of the eight participants, two expressed interest in becoming secondary mathematics teachers, five in becoming elementary teachers, and one a K-12 guidance counselor; one student was employed as an elementary classroom assistant while another was completing their elementary student teaching practicum. While limited, the consenting students capture the range of backgrounds and interests enrolled in this course.

Methodology

The primary data sources for this study are two course assignments, one completed at the end of module 3 and another completed at the end of module 5 (*n=16*; two per student); these assignments were a part of the course and would have been completed irrespective of the study. Through assignment prompts, students were asked to describe and provide evidence of their developing understanding of the SMPs including a) how they would describe key SMP ideas, b) why the SMPs are important, c) connections between the SMPs and other course topics, d) examples of how they saw themselves or others doing the SMPs when completing mathematical tasks, e) how class activities have shifted their understanding of the SMPs, and f) remaining questions they had about the SMPs.

To analyze these data, we first read through all student assignments and segmented the data by structural codes that corresponded to the assignment prompts (Saldaña, 2013). This first phase of segmenting and coding indicated that of the assignment prompts, students most frequently provided *descriptions* of key SMP ideas (65 of 231 coded segments). Based on these frequencies, second phase coding focused on the *description* text segments identified in phase one. Second phase coding used Toulmin's model of argumentation (1958) and an adaptation of Nardi et al.'s (2012) classification of warrants to capture the sources students drew upon when describing the SMPs. Due to space, we only provide a brief overview of these frameworks and how they guided analysis; more detail will be provided in our presentation.

Briefly, Toulmin's model (1958) identifies six different components of an argument: 1) a *conclusion/claim*, 2) the *data* upon which the conclusion is based, 3) the *warrant* that connects the conclusion to the data, 4) a *backing* that further supports the warrant through additional reasoning or evidence, 5) *qualifiers* to express one's confidence in the argument, and 6) *rebuttals* that address possible exceptions or refutations to the argument. While many scholars have used Toulmin's model to analyze teachers' and students' mathematical and pedagogical arguments (Krummheuer, 2015; Steele, 2005; Yackel, 2001, 2002), this model also has limitations. In particular, while Toulmin offers a way to make sense of an argument's *structure*, it does not offer a way to make sense of an argument's *quality*. To address this, scholars have proposed classifying warrants to identify the sources of influence one may draw upon when making and supporting an argument (Freeman, 2005; Nardi et al., 2012). For example, Nardi and colleagues (2012) offer seven different types of warrants mathematics educators use in their arguments: 1) *a priori epistemological*, 2) *a priori pedagogical*, 3) *institutional curricular*, 4) *institutional epistemological*, 5) *empirical personal*, 6) *empirical professiona*l, and 7) *evaluative*. These categories capture the scope of influences on mathematics teachers' arguments including their own personal or professional experiences (*empirical*), personal views or beliefs (*evaluative*), curricular resources (*institutional curricular*), shared disciplinary practices (*institutional epistemological*), and established definitions and pedagogical principles (*a priori epistemological* and *pedagogical*).

This study uses an adaptation of Nardi et al's (2012) warrant classification to which we added *policy* classifications to capture the influence of the CCSSM content standards (*policy-content*) and SMP descriptions (*policy – SMP*) (NGA, 2010), and the strands of mathematical proficiency (*policy – strand*) (Kilpatrick et al., 2001). These additional classifications were created to explicitly capture students' attention to different K-12 mathematics education policies, as well as recognize the ongoing debate about the eight SMPs in the literature. Specifically, scholars have argued the SMPs provide an inaccurate picture of mathematical practices due to the methods used to identify them (e.g., self-reported autobiographical data) or because the wide range of practices used by mathematicians cannot be captured in such a small number of standards (Moschkovich, 2013; Weber et al., 2020). Therefore, while *institutional epistemological* warrants refer to shared disciplinary practices, we determined it would be inappropriate to classify the SMPs as 'shared' due to the ongoing debate and created this new categorization. In using this adapted categorization of warrants to analyze students' SMP descriptions, our analysis allowed us to see which sources students were drawing upon as they described the SMPs, including how they related to course learning opportunities and resources.

Findings and Discussion

Within the 65 text segments coded as *description* during first-phase coding, second-phase codes were applied to 165 smaller segments, with each segment representing a different idea within students' SMP descriptions. As illustrated in Table 2, the CCSSM SMP descriptions were overwhelmingly the most frequent influence on students' SMP descriptions (*policy – SMP*; *n=114*). As almost 70% of text segments were coded in this category, further analysis focused on which components or ideas from the CCSSM students drew upon in their descriptions.

Table 2: Frequency of Second-Level Code Application

Influence	Frequency
Policy – SMP	*114*
Institutional Curricular	32
Institutional Epistemological	7
Evaluative	7
A priori Pedagogical	3
Policy – Content	1
Empirical Personal	1

Influence of the CCSSM

Overall, students attended to a range of different ideas from the CCSSM when describing the SMPs, ranging from four different ideas for SMP 5: Tools to 15 different ideas for SMP 3: Argumentation. Closer analysis indicates that how students attended to these ideas differed across SMPs. Specifically, students' descriptions of SMP 1: Problem-solving and SMP 4: Modeling focused on the overarching idea(s) of the SMP, with less attention given to specific actions related to doing the SMP. Alternatively, students' descriptions of SMP 3: Argumentation and SMP 6: Precision focused on one particular way of doing these SMPs, even though the CCSSM describes each of these SMPs as involving multiple actions. Finally, descriptions of the remaining four SMPs generally focused on a smaller range of ideas, including overarching idea(s) as well as specific actions for doing the SMPs.

Overarching idea(s)

Table 3 illustrates the different ideas from the CCSSM descriptions of SMP 1: Problem-solving and SMP 4: Modeling that were attended to in students' descriptions. For SMP 1: Problem-solving, students most frequently attended to the overarching ideas of *make sense of problems* (*n=7*) and *planning* (*n=7*). The CCSSM description also includes *how* one may do this sense making, such as *creating representations, considering analogous problems*, or *looking for entry points,* however, these actions were some of the ideas least frequently included in students' descriptions. This is similar to students' descriptions of SMP 4: Modeling which primarily focused on the overarching idea of *connecting math and the real world* (*n=9*), including *solving real world problems* (*n=7*) and *using math in real world contexts* (*n=2*). However, as with problem-solving, students attended less to the actions involved in carrying out this overarching idea, such as *making assumptions* or *identifying important quantities*. Taken together, these findings suggest students' conceptions of SMPs 1 and 4 are largely focused on the overarching idea(s) of these SMPs, with less focus on specific actions involved in doing them.

Table 3: Ideas from the CCSSM included in students' SMP 1 and SMP 4 descriptions

SMP 1: Problem-solving		**SMP 4: Modeling**	
Make sense of problems	7	Connecting math & the real world	9
Planning	7	Solve real world problems	7
Evaluate own work	6	Apply or use math in real-world contexts	2
Revise/change plan	3	Create representation	3
Create representation	2	Make assumptions	2
Look for entry points	1	Interpret results with respect to context	1
Analogous problems	1	Identify quantities	1
Persevere	1	Make sense of relationships to draw conclusions	1
		Example of modeling	1

Specific actions

Students' descriptions of SMP 3: Argumentation and SMP 6: Precision primarily focused on *particular ways of doing* each of these SMPs. For example, the CCSSM describes SMP 3 as the ability to "construct viable arguments and critique the reasoning of others" (NGA, 2010). In other words, argumentation in mathematics includes both "give and take" where one builds and shares an argument but also makes sense of the arguments of others. From Table 4 we can see that students primarily focused on the "give" aspect of doing SMP 3, largely describing SMP 3 as justifying one's own solution and communicating that solution or justification to others; listening to, discussing, and critiquing the arguments of others were some of the least frequently raised ideas. Overall, these findings illustrate how students generally described SMP 3: Argumentation as one-directional, focusing on students constructing and sharing their own arguments.

Students' descriptions of SMP 6: Precision also focused on a particular way of doing this SMP. Students primarily described SMP 6 as precision with respect to communication, both in general and how definitions, mathematical language, labels, and calculations can support communication (see Table 4). Precise communication, including the formulation of clear explanations and use of definitions, are explicitly included in the CCSSM SMP 6 description. Interestingly, the CCSSM also describes SMP 6 as the ability to "calculate accurately and efficiently, express numerical answers with a degree of precision appropriate for the context of the problem" (NGA, 2010). Despite this explicit attention to precise calculations, only two students referred to calculations in their descriptions, with one student including accurate calculations as a *component of* communication. Furthermore, no students touched on the notion of the appropriateness of precision for the context of the problem. These findings suggest that students' conceptions of SMP 6 are largely focused on precision with respect to communication *about* mathematics, with less attention to precision when carrying out mathematical calculations or processes.

Table 4: Ideas from the CCSSM included in students' SMP 3 and SMP 6 descriptions

SMP 3: Argumentation		SMP 6: Precision	
Communicate solution or justification to others	11	Communication	14
Grade-level appropriateness of arguments	6	Definitions	4
Justify	4	Mathematical language	3
Example of engagement	3	Explain reasoning	3
Concrete referents	2	Examine claims	1
Create diagrams	1	Correct calculations	1
Listen to other	3	Units	1
Identify mistakes/flaws	2	General	1
Critique others' ideas, solutions, or justifications	2	Label graphs	2
Compare arguments	1	Units	2
Ask clarifying questions	1	Correct calculations/answer	1
Make conjectures	1	Clear work	1
Discuss others' solutions or justifications	1	Contextual meaning	1
Use definitions and established information	1		
Analyze problem	1		
Respond to others	1		

Remaining SMPs

Students' descriptions of SMP 2: Reasoning, SMP 5: Tools, SMP 7: Structure, and SMP 8: Repeated reasoning included both overarching ideas and actions related to doing each SMP; these descriptions also generally focused on a smaller range of ideas overall. For example, while the average number of different SMP ideas raised throughout students' assignments for SMPs 1, 3, 4, and 6 was 9, students raised an average of 4.75 different ideas for SMPs 2, 5, 7, and 8.

When describing SMP 2: Reasoning, students' descriptions included multiple ideas from the CCSSM including: contextualizing, decontextualizing, reasoning about quantitative relationships, and creating representations. Similarly, students' descriptions of SMP 5: Tools included both the ability to use tools and the ability to determine which tools are available and appropriate for a given problem, with each of these ideas occurring almost equally in students' descriptions (see Table 5).

As previously discussed, students sometimes focused on a particular action in their descriptions even if multiple actions were included in the SMP title itself (e.g., SMP 3: Constructing **and** critiquing arguments). Interestingly, this was not the case for SMP 7: Structure or SMP 8: Repeated reasoning, which both include looking for *and* making use of structure/ repeated reasoning. While the "look for" aspect of SMPs 7 and 8 was the most frequently raised by students (see Table 5), students included how to "make use" almost as frequently. For example, students' descriptions of SMP 7: Structure included *identifying underlying structures* *and patterns (n=5)* and how to make use of this structure via the *(de)composition* of mathematical objects almost equally *(n=4)*. This is similar to students' descriptions of SMP 8: Repeated reasoning which focused on *identifying patterns and repetition (n=10)*, as well as how to use that repetition to *generalize (n=6)* and *determine shortcuts (n=2)*.

Table 5: Ideas from the CCSSM included in students' SMP 2, SMP 5, SMP 7, and SMP 8 descriptions

SMP 2: Reasoning		**SMP 5: Tools**	
Decontextualize	4	Use tools	6
Contextualize	3	Identify appropriate tools	5
Make sense of quantitative relationships	3	Examples of tools	4
Create representations	3	Purpose of tools	2
Units	1		
Flexible use of operations	1		
SMP 7: Structure		**SMP 8: Repeated reasoning**	
Identify underlying structures or patterns	5	Identify patterns/repetition	10
Examples of using structure	5	Generalize	6
(De)composition	4	Reasonableness of results	3
Shift perspectives	2	Examples of looking for or using repeated reasoning	2
		Determining shortcuts	2

Interestingly, while students' descriptions of both SMP 7: Structure and SMP 8: Repeated reasoning included the idea of patterns, the word 'pattern' is only included in the CCSSM description for SMP 7; SMP 8 refers to noticing repeated calculations or regularity. Therefore, while students' descriptions suggest the CCSSM helped students understand what making use of structure and repeated reasoning entails, the frequent use of the word 'pattern' to describe both does raise questions about the similarity between SMPs 7 and 8.

Conclusion

This study explores how a mathematics-focused bridge course provided opportunities for undergraduate students to develop their conceptions of the SMPs. The influence of the CCSSM on students' descriptions suggests that course opportunities to read and discuss the CCSSM SMP descriptions supported students in developing their SMP conceptions. Furthermore, the ideas that students *did* include provides insight into which ideas students are holding onto and can act as a foundation upon which to build in future learning opportunities. In doing so, we hope this study will inform future research examining how different teacher education contexts provide learning opportunities for students to develop their SMP conceptions, as well as how later learning opportunities can build off conceptions established in previous courses.

In this paper, we offer a novel framework for analyzing the Opportunities for Reasoning-and-Proving (ORP) in mathematical tasks. By drawing upon some tenets of the commognitive framework, we conceptualize learning and teaching mathematics via reasoning and proving both as enacting reasoning processes (e.g., conjecturing, justifying) in the curricular-based mathematical discourse and as participation in the meta-discourse about proof, which is focused on the aspects of deductive reasoning. By cluster analysis performed on 106 tasks designed by prospective secondary teachers, we identify four types of tasks corresponding to four types of ORP: limited ORP, curricular-based reasoning ORP, logic related ORP, and fully integrated ORP. We discuss these ORP and the contribution of this framework in light of preparing beginning teachers to integrate reasoning and proving in secondary mathematics classrooms.

Keywords: Reasoning and Proof, Instructional Activities and Practices, Classroom Discourse, Preservice Teacher Education

Introduction

Reasoning and proving are mathematical *processes* such as identifying patterns, generalizing, conjecturing, and justifying, which are at the heart of mathematics (Ellis et al., 2012; Jeannotte & Kieran, 2017; Stylianides, 2008). The role of reasoning and proving in mathematics classrooms is to support students' sense-making and meaningful learning of mathematics (Hanna & deVillers, 2012; NGA & CCSSO, 2010; NCTM, 2009; 2014). This emphasis is embodied in the notion of Proof-Based Teaching (Reid, 2011) and in Buchbinder & McCrone's (in press) Teaching Mathematics via Reasoning and Proving (TMvRP) framework. The three guiding principles of TMvRP are: (a) integration of reasoning and proving within the mathematics curriculum; (b) emphasis on deductive reasoning for producing and validating mathematical results, and (c) use of precise mathematical language but within the conceptual reach of the students. These principles seem straightforward but require operationalizing. For example, how can reasoning and proving be integrated within the curriculum? And how an emphasis on deductive reasoning can look like in student learning? In particular, teaching mathematics via reasoning and proving requires instructional materials and tasks enabling teachers to engage students with reasoning and proving. Mathematical tasks constitute one of the main sources of student learning (Watson & Ohtani 2015). Teachers design learning opportunities for students by choosing, adapting, or creating mathematical tasks (Brown, 2009; Remillard, 2005), therefore opportunities for students to engage with reasoning and proving vary across tasks. This leads to a question: How can a task's potential for engaging students with reasoning and proving be assessed and characterized? Studies that examined the opportunities for reasoning and proving in tasks tend to focus on the processes students can enact while engaging with the task, such as identifying patterns or making conjectures (Davis, 2012; Thompson et al., 2012). Jeannotte and Kieran (2017) systematized these mathematical reasoning processes (e.g., generalizing, validating, proving) into a taxonomy, carefully defining each concept. However, when considering *how* students engage with such processes, research has identified persistent difficulties in understanding and applying deductive reasoning, which often deviates from reasoning outside mathematics (Harel & Sowder, 2007; Stylianides et al. 2017). Thus, it is important for teachers to expose students to deductive reasoning. This entails a different genre of mathematical tasks, whose learning opportunities for reasoning and proving are not captured by Jeannotte and Kieran's (2017) framework. This different genre of tasks aligns with the Pedagogical Framework for Teaching Proof proposed by Cirillo and May (2020), which delineates logic-related processes that focus on the nature of proof, its structure, rules of logic, the structure of theorems and their use.

These two frameworks provide valuable but different insights into important aspects of teaching mathematics via reasoning and proving, yet there seems to be no unified framework. Our objectives in this paper are two-fold. First, we offer a novel framework for analyzing, classifying, and characterizing tasks and the *Opportunities for Reasoning-and-Proving (OPR)* embedded in them. We rely on the tenets of the commognitive perspective (Sfard, 2008) to combine into a unifying *ORP Task Analysis Framework* the mathematical reasoning processes described by Jeannotte and Kieran (2017), and the logical aspects of deductive reasoning offered by Cirillo and May (2020). The discursive perspective of commognition allows characterizing ORP embedded in a task by identifying the type of discourse to which a task belongs: curricular-based mathematical discourse or meta-discourse about proof. Second, we illustrate the utility of *ORP Task Analysis Framework* by analyzing a corpus of tasks designed by prospective secondary teachers (PSTs) enrolled in a capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020a). We show the variation in ORP afforded by different types of tasks and discuss its potential application to broader contexts.

The Opportunities for Reasoning-and-Proving (ORP) Task Analysis Framework

The commognitive framework views learning as participating in discourse while learners communicate about objects (Sfard, 2008). Working within the commognitive perspective, Jeannotte and Kieran (2017) developed a conceptual model of mathematical reasoning for school mathematics. The model describes nine *mathematical reasoning processes* such as identifying a pattern, generalizing, conjecturing, justifying, validating, and proving. These meta-discursive processes "derive narratives about mathematical objects or relations by exploring the relations between objects" (Jeannotte & Kieran, 2017, p. 9). For example, generalizing is "a process that infers narratives about a set of mathematical objects or a relation between objects of the set from a subset of this set" (Jeannotte & Kieran, 2017, p. 9). The mathematical reasoning processes can be enacted on mathematical objects (e.g., numbers, equations, geometric figures, etc.), which are at the core of various mathematical discourses. For example, tasks in which students are asked to solve an equation and explain their answer focus on *algebraic expression* mathematical object and thus belong to the discourse on algebra (Caspi & Sfard, 2012). The object at the core of a task can be identified by examining what the task is about and what the task asks to find. As students engage with the task they operate on mathematical objects and enact different types of processes (routines in Sfard's terms), which are the "patterns of action that appear when people participate in discourse" (Lavie & Sfard, 2019, p. 6). For example, in the discourse on algebra, students formalize, distribute and group like terms. Identifying the objects at the core of a task and the processes students can enact while engaging with the task, can determine the discourses to which the task belongs. In this paper we define *curricular-based mathematical discourse* as a discourse that focuses on curricular-based mathematical objects. Students participating in a curricular-based mathematical discourse can engage with reasoning and proving by enacting mathematical reasoning processes (e.g., conjecturing, justifying, validating) on the curricular-based mathematical objects, such as linear functions or complementary angles.

However, there are other ways to provide students ORP. Justifying, validating, and other mathematical reasoning processes are rooted in deductive reasoning, which poses multiple difficulties to students (Stylianides et al., 2017). Therefore, it is important to provide students with opportunities to engage with the important elements of deductive reasoning such as analyzing the structure of a theorem or a conjecture, or discussing the generality of proof. These can involve activities such as identifying the hypothesis and the conclusion of a conditional statement, writing the converse of a conditional statement, and identifying or constructing counterexamples (Buchbinder & McCrone, 2020b; Cirillo & May, 2020). Such logic-related processes are not captured by Jeannotte and Kieran's model of reasoning processes since they are not directly related to the deriving of a new mathematical narrative about mathematical objects. Rather, these logic-related processes are enacted on logic-related objects such as conditional statements that are at the core of what we define as *meta-discourse about proof.*

The object at the core of the task and the processes students can enact while engaging with the task determine the type of discourse the task belongs to. By drawing upon the discourses to which the tasks belong, we conceptualize the ORP provided by the task. These ORP can be embedded in the meta-discourse about proof, where students can enact logic-related processes on logic-related objects, or in the curricular-based mathematical discourse, where students can enact mathematical reasoning processes. This classification is illustrated in Figure 1, which summarizes the *ORP Task Analysis Framework*.

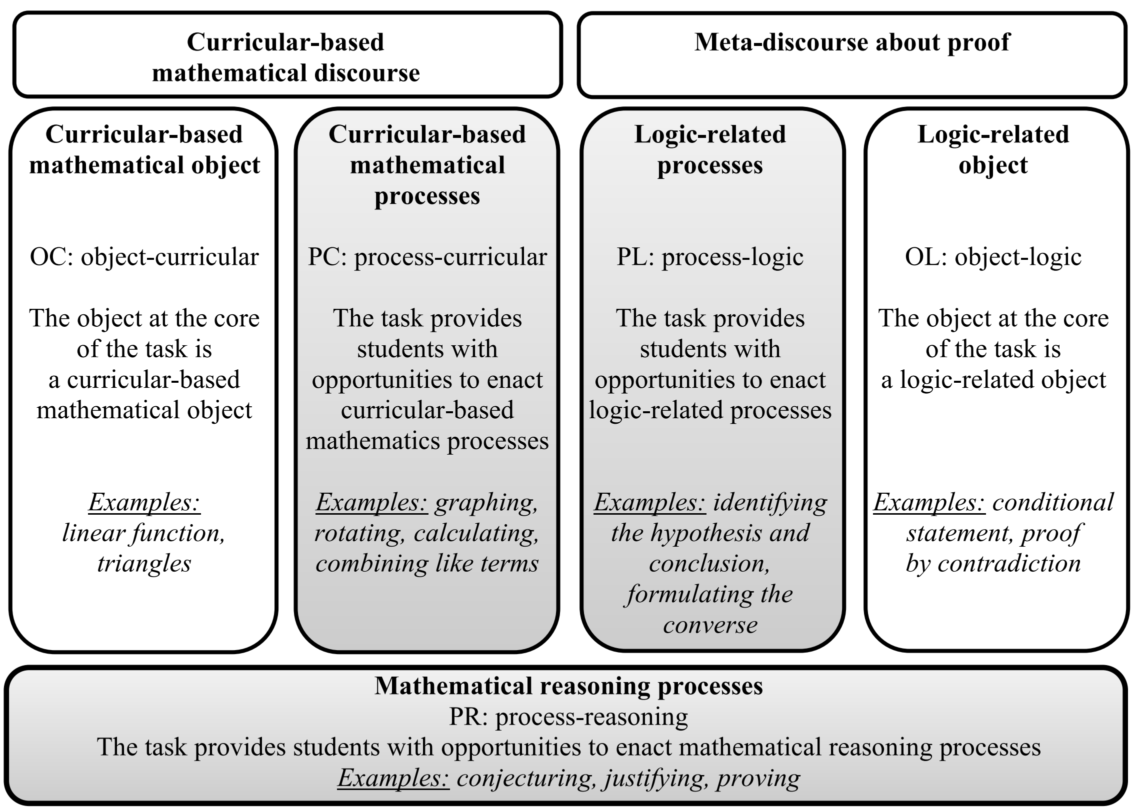

Figure 1: The OPR Task Analysis Framework

In what follows, we illustrate the application of the ORP Framework to identify types of ORP in tasks designed by prospective secondary teachers (PSTs) enrolled in a capstone course *Mathematical Reasoning and Proving for Secondary Teachers*. Our exploration was guided by the following research question: W*hat types of ORP can be identified in tasks designed by PSTs who learn how to teach mathematics via reasoning and proving?*

Application of the ORP Framework

Context: PSTs Learning to Teach Mathematics via Reasoning and Proving

This study is part of a larger research project which investigates beginning teachers' expertise to teach mathematics via reasoning and proving (Buchbinder & McCrone, in press). The first stage of this project focus on PSTs participating in a university-based capstone course: *Mathematical Reasoning and Proving for Secondary Teachers*. The course comprised four modules, which focused on: (1) direct proof and argument evaluation, (2) conditional statements, (3) roles of examples, and (4) indirect reasoning. Each module began with activities belonging to the meta-discourse about proof and contained activities engaging PSTs in integrating the proof themes with the regular curriculum. At the end of each module, each PST designed and taught in a local school a lesson that integrated a particular proof theme with the ongoing mathematical topic from the secondary school curriculum.

Data Corpus and Analysis

We analyzed 12 lesson plans designed by three PSTs who participated in the capstone course in 2021 Fall and consented to patriciate in the study. The analysis focused on mathematical tasks in these lesson plans. Since some tasks included one question while others had multiple questions, we chose the unit of analysis to be a single question – the smallest unit in which students were asked to come up with any type of answer. Overall, we analyzed 106 questions.

The analysis proceeded in several stages. First, we identified the object at the core of the question – namely, what is the question about? Questions that focused on curricular-based mathematical objects (e.g., isosceles triangles) were coded as OC (object-curricular), and questions that focused on logic-related objects (e.g., a counterexample) were coded as OL (object-logic). Second, we identified the different types of processes afforded by the question: curricular-based processes, e.g., graphing, formulating an equation, rotating (PC - process-curricular), logic-related processes, e.g., formulating the converse of a statement (PL - process-logic), and mathematical reasoning processes, e.g., justifying, conjecturing (PR - process-reasoning). For each question, we recorded its core object and the specific process.

We performed cluster analysis on the five variables: OC, OL, PC, PL, PR to identify types of opportunities for reasoning and proving. Cluster analysis is a statistical algorithm that groups a set of objects by identifying similar patterns, which are examined by the distance of the object from each other (Kaufman & Rousseeuw, 2009; Weingarden & Heyd-Metzuyanim, in press). Cluster analysis allowed us to identify similar patterns in the way questions were characterized by logic-related objects and processes, curricular-based mathematical objects and processes, and mathematical reasoning processes.

Types of ORP in Mathematical Tasks

The analysis revealed four clusters, which differ in the combinations of the five variables that characterize the questions designed by the PSTs. Table 1 describes the four clusters, the number of questions in each cluster and the frequencies of each variable in the cluster. The quality of this clustering according to Silhouette measure of cohesion and separation (Sarstedt & Mooi, 2014) was found to be good (between 0.5 to 1). In addition, a Chi-Square test between each of the five variables and the four clusters showed that there is a significant difference between the clusters (OC, OL, PL, PR: $\chi^2(3,106) = 106$, $p<0.001$. PC: $\chi^2(3,106) = 81.042$, $p<0.001$). The identified clusters correspond to four types of ORP that characterize the PSTs' questions (Table 1). In what follows, we describe these types of ORP, by depicting questions from each cluster.

Table 1: The four clusters describing the four types of ORPs

Variables	**Cluster 1:** Curricular-based mathematical discourse (OC-PC)	**Cluster 2:** Reasoning processes in the curricular-based mathematical discourse (OC-PC-PR)	**Cluster 3:** Meta-discourse about proof (OL-PL)	**Cluster 4:** Integrated curricular-based and logic-related discourse (OC-PC-PR-OL-PL)
	N = 37	N = 12	N = 36	N = 21
OC	**100%**	**100%**	0%	**100%**
PC	**100%**	**75%**	0%	**76.2%**
PR	0%	**100%**	0%	**100%**
OL	0%	0%	**100%**	**100%**
PL	0%	0%	**100%**	**100%**

Note. OC: Object-Curricular, PC: Process-Curricular, PR: Process-Reasoning, OL: Object-Logic, PL: Process-Logic

Cluster 1: Curricular-based Mathematical Discourse (OC-PC)

The first cluster includes questions belonging to a curricular-based mathematical discourse where both the object at the core of the question and the processes students can enact while engaging with the question are purely curricular-based.

During this activity, use the given quadrilateral and steps to reflect, rotate, or translate on the grid area.

1. Label the starting quadrilateral P
2. Rotate P'' 90 degrees clockwise about any corner, label your final shape P'''
3. Translate P', 2 inches in any direction, label the new shape P''
4. Reflect over line the x-axis, label the shape P'

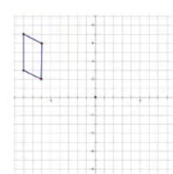

Figure 2: Questions that belong to curricular-based mathematical discourse

Figure 2 shows four questions from this cluster. The curricular-based mathematical object is geometrical shapes and the processes students are expected to perform are rotating, reflecting, and translating. These types of questions, as all questions in this cluster, provide only limited opportunities, if at all, for students to engage with reasoning and proving.

Cluster 2: Reasoning Processes in Curricular-based Mathematical Discourse (OC-PC-PR)

The second type of ORPs includes questions that belong to the curricular-based mathematical discourse but, in contrast to the questions in cluster 1, the questions in cluster 2 also involve mathematical reasoning processes (See Figure 3 for an example).

Create an equation that one can use to find the dimensions, area, number of smaller triangles for any given number triangle.

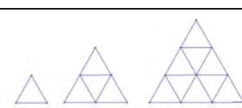

Figure 3: A question involving reasoning processes in a curricular-based mathematical discourse

Figure 3 shows the last question in a task which had students explore the growth of a triangular pattern. The four preceding questions were: (1) what would the next triangle look like? (2) What would its dimensions be? (3) How many triangles would be in the larger triangle? and (4) how many sticks would the next triangle be made up of? These questions belong to the curricular-based mathematical discourse (cluster 1) since the processes involved are drawing and counting sides and triangles, which are performed on the growing series of figures (mathematical objects). The last question of this task (Figure 3) involved curricular-based processes – creating an equation that describes the growing series of figures. However, this question also involved mathematical reasoning processes of identifying a pattern, generalizing, and conjecturing. Although the first four questions of this task provide limited ORP, they can be seen as scaffolding toward the last question (Figure 3), and specifically for the reasoning processes of identifying a pattern and generalizing.

Cluster 3: Meta-Discourse about Proof (OL-PL)

In contrast to the first two types of ORP that include questions that belong to the curricular-based mathematical discourse, the third type of ORP includes questions that belong to the meta-discourse about proof. Both the object at the core of the question and the potential processes provided are logic-related. Figure 4 presents two questions from this cluster.

Using the given conditional statements, circle the given and underline the conclusion. At the end, write the form of these statements in terms of P and Q (These statements are in the form If P, then Q):

- Tim knows that if he misses the practice before the game, then he will not be able to be a starting player in the game.
- If a shape has 4 right angles, then it is a square.

Figure 4: Questions characterized by OPR in the meta-discourse about proof

The logic-related object of these questions is a conditional statement, where the logic-related processes embedded in these questions are identifying the hypothesis and conclusion in the conditional statement and writing a conditional statement in the form of "if-then." Such questions focus on the nature and the logical aspects of proof. Note that although the second question relates to squares and angels, in contrast to the first question that does not refer to mathematical objects at all, both questions focus on conditional statements and their structure rather than the content of the statements.

Cluster 4: Integrated Curricular-based and Logic-related discourse (OC-PC-PR-OL-PL)

The fourth type of ORP includes questions characterized both by opportunities for enacting reasoning processes in the curricular-based mathematical discourse (similar to cluster 2) and by logic-related objects and processes (as cluster 3).

Now, let's make a conditional statement about this [an acute triangles that students were asked to construct in the former section] and equilateral triangles. (You can look back at your previous drawing for reference). Discuss with your partner what claim could be made that relates an equilateral triangle to an acute triangle.

Figure 5: A question characterized by curricular-based reasoning and logic-related ORP

As such, these types of questions provide rich opportunities for students to engage with reasoning and proving. See Figure 5 for an example. This question belongs to the meta-discourse about proof since it deals with a logic-related object – conditional statement ("let's make a conditional statement") and a logic-related process: writing a conditional statement. In addition, this question involves curricular-based mathematical objects – equilateral and acute triangles, and curricular-based processes, such as drawing triangles and recognizing the properties of different triangles. By integrating the two types of discourses, this question, like the other questions in cluster 4, provides students opportunities both to derive narratives about curricular-based mathematical objects, that of isosceles and equilateral triangles, while using mathematical reasoning processes such as conjecturing, and to deepen their deductive thinking about logic-related objects of conditional statements.

Discussion and Contributions of this Study

In this theoretical paper we offer a novel framework – *Opportunities for Reasoning-and-Proving (ORP) Task Analysis Framework*, for examining, characterizing, and classifying mathematical tasks according to the ORP provided by them. Cluster analysis performed on 106 questions revealed four different clusters corresponding to different types of ORP.

The first type represents *limited* OPR, as it corresponds to types of tasks focused solely on mathematical objects and includes curricular-based processes, as illustrated in Figure 2. These tasks belong to the curricular-based mathematical discourse without any specific demands on students to enact reasoning processes, such as conjecturing, justifying, or proving.

In contrast, *curricular-based reasoning* ORP corresponds to tasks that involve the enactment of reasoning processes on curricular-based mathematical objects (see example in Figure 3). Tasks characterized by this type of ORP are underrepresented in mathematical textbooks (Davis, 2012; Stylianides, 2009; Thompson et al., 2012), even in high-school geometry (Otten et al., 2014). However, curricular-based reasoning ORP are essential for supporting students' mathematical sense-making (Ellis et al., 2012) and for teaching mathematics via reasoning and proving (Buchbinder & McCrone, in press). Thus, teachers have an important role in designing tasks with curricular-based reasoning ORP, and teacher educators have an important role in preparing PSTs to design such tasks for students (Arbaugh et al., 2018; NCTM, 2014).

The third type of ORP – *logic related* ORP – appears in tasks characterized by logic-related objects (e.g., conditional statement) and can engage students with logic-related processes, such as identifying the hypothesis and conclusion, determining what needs to be done for proving or refuting a statement (see example in Figure 4). These types of tasks rarely occur outside high-school geometry chapter on proof (Otten et al., 2014), but they are essential for student engagement with reasoning and proving due to their focus on the nature of proof, the logical structure of theorems and how they are written and used (Cirillo & May, 2020).

The fourth type of ORP– *fully integrated* ORP – involves opportunities to enact reasoning processes on the curricular-based mathematical object with participating in the meta-discourse about proof. This type of task engages students with deductive reasoning and logical inferences, which are fundamental for learning mathematics (Harel & Sowder, 2007) while operating with mathematical objects (Figure 5). The fully integrated ORP can be contrasted with the 3rd cluster questions with logic related ORP where the mathematical objects often serve as a mere background for logic-related processes, such as identifying the structure of statements (see Figure 4 for an example). Tasks with fully integrated ORP require students to apply the logic-related processes on the mathematical objects. The questions in this cluster sensibly integrated both objects – the curricular and logic, so that students must operate on both, applying two types of processes: curricular-based and logic-related.

The four types of ORP described above came out of analyzing a specific corpus of data based on 12 lesson plans of three PSTs participating in a university-based course. Despite this methodological limitation of our study and the need to further validate its outcomes, our study offers several theoretical and practical contributions.

First, the *ORP Framework* combines two fundamental perspectives underlying learning and teaching mathematics via reasoning and proving (Buchbinder & McCrone, in press). One perspective focuses on reasoning and proving as a set of processes, such as identifying a pattern, conjecturing, and proving involved in deriving narratives about mathematical objects (Ellis et al., 2012; Jeannotte & Kieran, 2017; Stylianides, 2008). The second perspective focuses on the structure of theorems and the logical aspect of proof (Cirillo & May, 2020). The establishment of the *ORP Framework* strengthens previous studies that pursue the importance of engaging students with reasoning and proving and provides a unique tool for examining various discourses – curriculum-based and meta-discourse about proof – within a unified framework.

The second contribution of our study is identifying the four types of ORPs. While theoretical considerations suggest two types of objects at the core of the task and three types of processes (Figure 1), only some combinations of the five variables showed up empirically. Moreover, only two clusters, curricular-based mathematical discourse and meta-discourse about proof (clusters 1 and 3), contain tasks that fall under a single object-process characterization. Clusters 2 and 4 comprise tasks with multiple characterizations (Table 1).

Collectively, the *ORP Framework* and the OPR identified in this study contribute to further conceptualizing and operationalizing the notion of learning and teaching mathematics via reasoning and proof. While Buchbinder and McCrone (in press) suggested principles for *teaching* mathematics via reasoning and proving, we maintain that *learning* mathematics via reasoning and proving can be conceptualized discursively (Sfard, 2008) as students participating in the meta-discourse about proof and in a curricular-based mathematical discourse while enacting mathematical reasoning processes. This operationalization can also be used in the context of preparing PSTs to teach mathematics via reasoning and proving. PSTs need to develop expertise both in the logical aspect of proof (i.e. different types of proofs, valid and invalid modes of reasoning, the roles of examples in proving, logical relations), and in the pedagogical aspect of integrating reasoning and proof in curricular-based materials (Buchbinder & McCrone, 2020a). The *ORP Framework* can be used by teacher educators as a pedagogical learning tool for teachers, both to design tasks with various types of ORP and to discuss the potential of mathematical tasks in engaging students with reasoning and proving. The framework can enable teacher educators and PSTs to communicate about these OPR by operating with definite characteristics such as objects and processes. This may contribute to more explicit, and unambiguous communication among teachers and teacher educators about mathematical and pedagogical ideas (Weingarden, 2021).

In addition, the *ORP Framework* can be applied to various research settings which examine tasks and the ORP provided by them. These may include tasks designed by PSTs, beginning teachers, in-service teachers who participate in a professional development program, or tasks that appear in textbooks and other resources. In a related, ongoing study, we use the *ORP Framework* to examine how beginning teachers who participated in the capstone course integrate reasoning and proving in the tasks they design in their classroom. By promoting teacher competencies in designing tasks that embed rich ORP, teacher educators can contribute to the goal defined by NCTM (2014) as creating “systemic excellence” and providing “mathematics education that supports the learning of *all* students at the highest possible level” (NCTM, 2014, p. 2).

A number of factors contribute to vaccine hesitancy including citizens' determination of the risks and benefits of vaccination. In this study, we use interviews and surveys to understand how United States and South Korean citizens quantify the risks of COVID-19 infection and vaccination. Many citizens used benchmark values such as 0%, 50%, 100% to estimate their risks of COVID-19 infection and COVID-19 vaccination. Although neither infection nor vaccination has a 50% risk of severe outcome, the citizens' thinking is consistent with the outcome approach described by Konold (1989, 1991). In his work, a 50% risk often implied uncertainty about if an outcome would happen in a single trial. It is important to support citizens' understanding of risk because in our sample the citizens who thought COVID-19 vaccination was riskier than COVID-19 infection were often unvaccinated.

Keywords: Probability, Vaccine Hesitancy, Outcome Approach, Cognition

Introduction

The development of the COVID-19 vaccine has been a critical strategy to battle the pandemic. To mitigate the economic and personal impacts of COVID-19, sufficient population vaccination is critical. However, even vaccine availability does not directly lead to a higher vaccination rate because of pervasive COVID-19 vaccine hesitancy across the world (Troiano & Nardi, 2021). The WHO identified vaccine hesitancy as one of the top 10 global health threats in 2019 (World Health Organization, 2019). Many people have concerns over the safety and efficacy of COVID-19 vaccines (Callaghan et al., 2020).

COVID-19 vaccines are widely recommended because the risks of side effects are smaller compared to the reduction in personal and collective risk from COVID-19 infection (World Health Organization, 2020). However, many citizens are unwilling to take a new vaccination solely because authorities recommend it, and they want to understand the risks and benefits for themselves first (Machingaidze & Wiysonge, 2021). Weighing the risks and benefits of vaccination involves comparing percentages less than one, analysis of data from clinical trials, computing expected values, mathematical modeling of measuring quantities such as infection fatality rates, and more (Tenforde, 2021). Given that much of the mathematics and statistics involved in forming recommendations for vaccination is beyond that commonly taught in secondary or tertiary education (Kollosche & Meyerhöfer, 2021), it is important to understand how citizens are making sense of vaccination and infection risks. Prior studies argue the necessity of evidence-based vaccine education campaigns (Chou & Budenz, 2020; Dror et al., 2020; Loomba et al., 2021), and building a successful education campaign is contingent on understanding citizens' thinking about vaccination risks and benefits. We look for harmony between vaccine hesitancy research to understand the dissonant perspectives on COVID-19 vaccines.

We use constructs from mathematics education research on probabilistic thinking to model how citizens quantify the risk of COVID-19 infection and COVID-19 vaccination. Thus, we investigate the questions:

1. How do citizens estimate their risk of the COVID-19 infection and vaccination?
2. How do citizens' estimates of the relative risk of COVID-19 infection and vaccination correlate to their vaccination status?

Many citizens estimated risks using reasoning that is consistent with the outcome approach, so we focus on our answer to question one using that construct (Konold, 1989, 1991).

COVID-19 Vaccine Hesitancy

Vaccine hesitancy refers to delay in acceptance or refusal of vaccination despite the availability of vaccination services (MacDonald, 2015). Vaccine hesitancy is not a new issue globally and many researchers are interested in understanding "the reasons why a considerable number of people do not receive recommended vaccinations" for the purpose of designing interventions to increase vaccine acceptance (Betsch et. al, 2018, p. 1). A common cause of general vaccine hesitancy is a lack of confidence in the safety and efficacy of vaccines and the systems that deliver them (Betsch et. al, 2018). Other important factors identified in the literature include "complacency (not perceiving diseases as high risk), constraints (structural and psychological barriers), calculation (engagement in extensive information searching), and aspects pertaining to collective responsibility (willingness to protect others)" (Betsch et. al, 2018, p. 1).

COVID-19 specific vaccine hesitancy has also arisen because of the vaccine's novelty (Callaghan et al., 2020; Machingaidze & Wiysonge, 2021; Schwarzinger et al., 2021; Ward et al., 2020) even though recent studies show COVID-19 vaccines have similar safety and efficacy with other previously approved vaccines (Polack et al., 2020). Many think the vaccine development and production have occurred too quickly (Troiano & Nardi, 2021).

Incorrect or misleading information about COVID-19 vaccines also lowers citizens' intent to be vaccinated (Loomba et al., 2021). Information such as, "Vaccine trial participants have died after taking a candidate COVID-19 vaccine" (p.337), contributes to people's fears, doubts, or cynicism over new COVID-19 vaccines. Even among medical staff, there is vaccine skepticism due to fears of the safety and rapid development of vaccines (Dror et al., 2020).
Modeling thinking related to vaccination is complex because it involves social, emotional, scientific, statistical, and mathematical thinking. Despite our acknowledgment that approaching the problem from a mathematics education lens will miss other important factors contributing to vaccine hesitancy, we want to do our part to understand this global issue. Mathematics educators are positioned to model citizens' understandings of the risk of COVID-19 infection (which is related to complacency), and their understandings of the risks and benefits of vaccination (which is related to confidence in safety and efficacy).

Theoretical Perspectives on Probabilistic Thinking

The probability of an event occurring can be understood in multiple ways. Konold (1991) describes both formal theories and beliefs of probability that are held by experts such as classical, frequentist, and subjectivist, and informal theories which are the ways that people actually think about and make sense of probabilities. Our focus is on an informal theory: the outcome approach (Konold, 1989, 1991).

Konold (1989, 1991) introduced the outcome approach construct as an informal model of probability for binary decisions. People using the outcome approach interpret probability as predicting the outcome of the next trial and often evaluate their prediction as being correct or incorrect after one trial. In interpreting probabilities with an outcome approach, Konold (1989, 1991) found that students often use benchmark values of 0%, 50%, and 100% to represent “No, it will not occur”, “I don’t know if it will occur”, and “Yes, it will occur”, respectively. These three benchmark percentages help someone decide what will happen given a probability to interpret. When Konold (1989, 1991) asked students to explain a weather prediction of 70% chance of rain tomorrow, the students using the outcome approach interpreted this to mean that it will rain tomorrow since 70% is close to their 100% benchmark. A 30% chance of an event occurring could be interpreted similarly to 0% meaning its likelihood of occurrence is low (Konold, 1989). When using an outcome approach people interpret 50% as an indicator that “anything could happen” instead of that it on average happens 5 times out of 10 trials. This is because 50% is the mid-point of the decision continuum and implicates equally possible results of yes or no. In general, people using an outcome approach often ignore frequency information and instead focus on other features such as causality and physical features when interpreting probability (Konold, 1991).

Methods

We use Zoom interviews and an online survey to understand how U.S. and South Korean citizens quantify their risk of COVID-19 infection and vaccination. We do not analyze the interviews in depth in this study and instead explain how they served as inspiration for the online survey. We conducted task-based clinical interviews with 11 U.S. and 7 SK citizens between Oct 26th, 2020 and May 19th, 2021. Each interview lasted approximately one hour and included one researcher and one citizen. Interviews were recorded using Zoom and we paid participants 50 dollars per hour. We intentionally recruited a diverse group of citizens with respect to race, education level, political beliefs, geographic location, and views toward COVID-19 and vaccination. During the interviews, we asked citizens to estimate risks associated with COVID-19 infection for themselves and well-known public figures, asked for their opinions about COVID-19 vaccination, and asked them to interpret the Relative Risk Tool (Joshua et al., 2022). We noticed that interview participants (even those with an advanced mathematics background) gave surprisingly high estimates of the risk of COVID-19 infection. This is consistent with other surveys of US citizens’ assessment of COVID-19 hospitalization risk. Rothwell and Witters (2021) reported that 41% of Democrats and 22% of Republicans estimated the risk of hospitalization for an unvaccinated person as 50% or higher. Further, interview participants were more worried about side effects of vaccination than many of their everyday activities that had greater risk such as driving. We noticed that the way many interview participants responded was consistent with the outcome approach described by Konold (1989, 1991), and decided to survey a random sample of U.S. citizens to investigate this idea.

We conducted a survey with a random sample of 151 U.S. adults between Jan 31st, 2022 and Feb 8th, 2022 using CloudResearch Prime Panel formerly known as TurkPrime (CloudResearch, 2022). CloudResearch supports collecting random human subjects data in multiple fields, including social and behavioral sciences (Chandler et al., 2019; Litman et al., 2017). Using CloudResearch allowed us to obtain a diverse and random sample. All participants were informed of the goals of the study and consented to be involved in research before completing the survey.

Survey questions included:1) Have you had a COVID-19 vaccine?; 2) If you were infected with COVID-19, what do you think your percent risk of dying from COVID-19 would be? (Enter number between 0 and 100 without % sign.) Why?; 3) If you receive a COVID-19 vaccine in the future, what do you think your percent risks of a serious adverse reaction would be? An example of a serious adverse reaction is an allergic reaction requiring treatment in a hospital. Do not include your risk of common side effects such as fatigue. Why?; and 4) In your opinion, is COVID-19 infection or a COVID-19 vaccination more risky for you? We included other questions not reported in this paper such as demographic information, items from prior risk literacy studies (Lipkus et al., 2001), and their reasons for choosing or delaying vaccination.

Results

Our goal is to understand citizens' decisions regarding vaccines by using the outcome approach, so we focus on citizens' use of benchmark values (0%, 50%, 100%) when estimating their risks of COVID-19 infection and vaccination. We then discuss the relationships between citizens' estimates of risk and vaccination status.

COVID-19 Death Risk Estimates and Risk of COVID-19 Vaccination Estimates

COVID-19 death risk estimates in interviews. We first present the interviews because they inspired the online survey. Minji, a 32-year-old South Korean who holds an undergraduate degree in mathematics education, was interviewed on May 19th, 2021. She said that she wanted to receive either Pfizer or Moderna vaccines instead of AstraZeneca vaccine. Other Korean citizens also had negative perceptions of AstraZeneca's COVID-19 vaccines due to its side effects, especially of blood clotting (Seo, 2021). In May 2021, COVID-19 vaccine refusal rate in South Korea had reached 33% among citizens who were eligible for COVID-19 vaccination (Lee et al., 2021). When Minji was asked about her estimate of her COVID-19 death risk, she said "honestly, it is really hard for me to predict it, the death risk." The interviewer encouraged her to give a rough estimate and she said:

> Minji: Rough estimate of the death risk… it's 50% though. I think it's about 50%? Because I've never had the virus before, I cannot say for sure whether I would die or not from COVID-19. I don't have any numerical information that allows me to think about how sick I will be.

The excerpt shows that Minji did not know whether she would die from COVID-19 or not, so she estimated her risk of dying from COVID-19 was roughly 50% which is consistent with the outcome approach because she used 50% to indicate uncertainty. We hypothesize Minji did not want to give a value above or below 50% because that would indicate a prediction of what would happen that she did not feel comfortable making.

Ian, a 27-year-old U.S. citizen who holds a PhD in chemistry, was interviewed on October 26th, 2020. He estimated that his risk of death due to COVID-19 infection was less than 1% for a variety of reasons. For example, he said "I have a balanced micronutrient and macronutrient intake and I also exercise regularly with both resistance training and cardiovascular training." We asked him to estimate Donald Trump's risk of dying from COVID-19 on the day he was diagnosed. Ian said "50 percent. Yeah, based off his risk factors". Ian did not seem to be attending to frequencies of infections and deaths in his estimate of 50% for Trump. We knew Ian was capable of estimating how many citizens would die if large numbers of people similar to Trump were infected. Many others picked values close to 0% to estimate risk for a young, healthy person and values greater than or equal to 50% to estimate the risk of an older person. The outcome approach construct is a plausible explanation for why citizens might pick widely spaced risk estimates for young and old. They are trying to convey the outcome for a young person will likely be good and the outcome for an old person will likely be bad.

Across many other interviews, citizens gave surprisingly high estimates for the risk of COVID-19 infection and also expressed substantial concern about extremely rare side effects of vaccination. Many responses made more sense when we interpreted the numbers as predictions of the single next outcome as opposed to citizens' thinking about frequencies.

COVID-19 infection death risk estimates in the online survey. The mean of the survey participants' ages is 45.13 and its standard deviation is 14.93. In our sample, there were 52 citizens who had not received a COVID-19 vaccine, 14 citizens who were partially vaccinated for COVID-19 (one dose of Pfizer or Moderna), 30 citizens who were fully vaccinated for COVID-19 (two-dose of Pfizer of Moderna, or single dose of J&J vaccine) without a booster shot, and 55 citizens who were fully vaccinated for COVID-19 with a booster shot.

We first present the results from citizens' estimates of percent risks of dying from COVID-19 infection and discuss the difference between citizens who received no vaccine and citizens who received at least one vaccine (Figure 1). There are 52 citizens who received no vaccine and 99 citizens who received at least one vaccine.

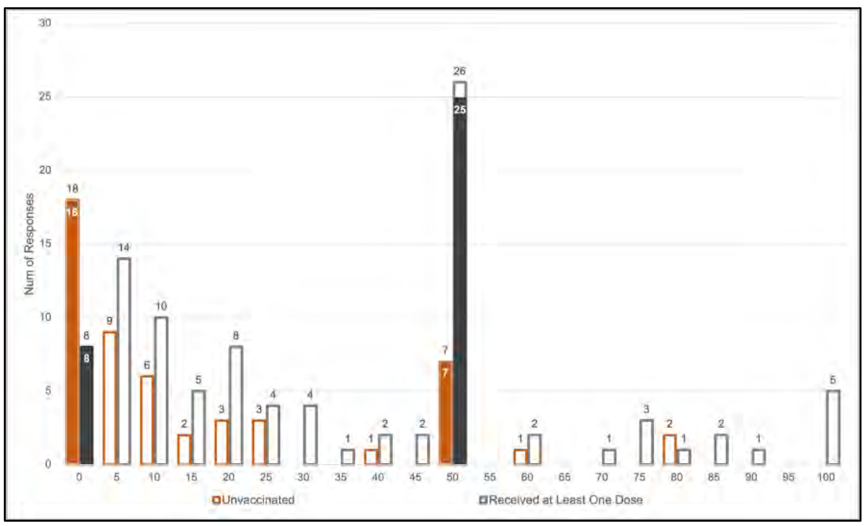

Figure 1. Citizens' estimates of COVID-19 death risk by vaccination status.

In Figure 1, citizens' estimated values of 0 are graphed above the number 0, estimated values that are greater than 0 and less than or equal to 5 are graphed above the number 5, estimated values that are greater than 5 and less than or equal to 10 are graphed above the number 10, etc. The red and blue outline bars above 50% represent the number of citizens that estimated their risk as greater than 45% and less than or equal to 50%. The red and blue solid bars represent the number of citizens who estimated their risk at exactly 50%. Among unvaccinated citizens, these counts were the same, but for the citizens receiving at least one vaccine, the counts differ (one citizen estimated their risk at 49% and so 25 out of 26 citizens estimated their risk at exactly 50%). Both citizens who received no vaccine and citizens who received at least one vaccine overestimated their risks of dying from COVID-19 infection. Figure 1 shows that about 38% (58 of 151) citizens estimated their death risk from COVID-19 at exactly the benchmark values of 0% and 50%.

Approximately 35% of citizens (18 of 52) who received no vaccine used 0% as a benchmark value. Many, but not all of the explanations associated with 0%, conveyed that the person was sure that he or she would not die from COVID-19 and associated the number 0% with something that is not likely to happen. Examples include, “I am healthy and take vitamins”, “I can fight it off”, and “COVID-19 is nothing but a common cold”. Some citizens wrote “I never had symptoms” and “I personally know no one that died from it”.

About 25% of citizens (25 of 99) who received at least one dose of the vaccine, estimated their risk of death as 50%. Many but not all of the explanations associated with 50% conveyed that the person was uncertain about what would happen and associated the number 50% with uncertainty. Examples include, “Because I think it’s something you can never know”, “Do not know until I get it”, and “I don’t know either way.” Another wrote, “I have a really good immune system but I have heart failure so it’s a gamble.” Some citizens did not mention uncertainty in their responses and instead wrote about personal risk factors. For example, “I am a smoker and a little overweight” or “because I’m 76 yrs old.” It is possible that citizens who wrote about their personal risk factors are reasoning using the outcome approach, but the evidence is inconclusive.

The citizens who had not received a COVID-19 vaccine (mean 16.73%) gave lower estimates of COVID-19 death risk compared to citizens with at least one vaccine (mean 33.78%). Citizens who received no vaccine tended to use 0% as a benchmark value whereas citizens who received at least one dose of the vaccine tended to use 50% as a benchmark value when estimating their risk of COVID-19 infection death.

Many citizens who estimated their risks between 0% and 50% also appeared to be using the outcome approach instead of focusing on frequencies of outcomes. For example, 12 out of 41 citizens who estimated their risk of death between 10% and 25% said they were “somewhat” or “moderately concerned” about COVID-19 infection. If they are considering 10% as meaning that the next time they are infected they will not die, this makes sense. Based on interviews, we do not think that the citizens who said they were slightly concerned about a 10% risk of death are focused on frequencies. In interviews, once citizens computed 1% of 50 million (as an example) they started to think of 1% risk of death as substantial.

Risks of COVID-19 vaccination estimates in the online survey. We report the results from citizens’ estimates of percent risks of severe adverse reactions to COVID-19 vaccination and discuss the difference between vaccinated and unvaccinated citizens’ estimates. Again, we identify two clusters in 0% (43 of 151) and 50% (27 of 151) that could be explained by the citizens’ use of the outcome approach.

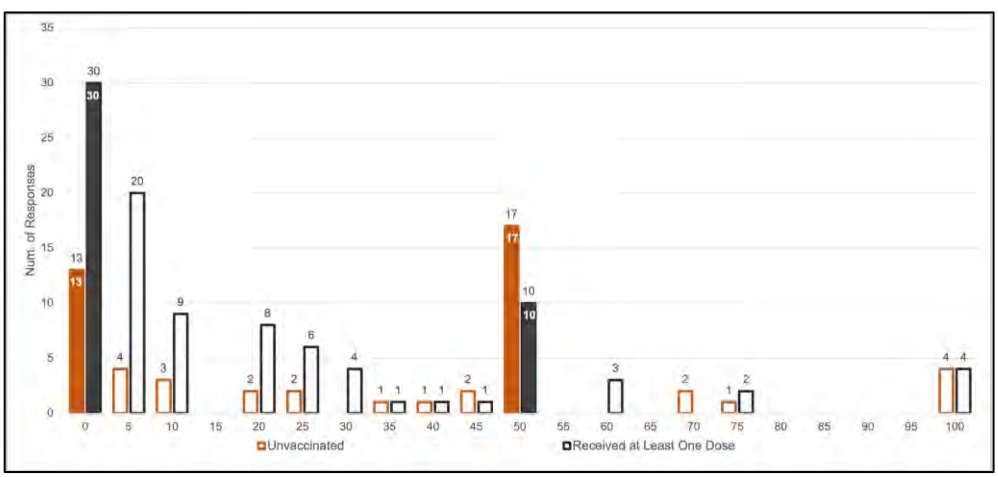

Figure 2. Citizens' estimates of COVID-19 vaccination risk by vaccination status

A number of people who estimated 0% risk had already been vaccinated without an allergic reaction or had no history of allergies. Their estimate of 0% could be explained with the outcome approach because their prediction of the outcome of a single next trial is that they would not have a reaction. The estimates of 0% are also consistent with more normative ways of thinking about probability. The general risk of severe allergic reaction is around four in 1.8 million (CDC, 2021), and the risk is likely even lower for people who have already been vaccinated with no reactions. The citizens' estimates are close to the actual risk. There is a wide variety of ways of thinking that could result in those values including normative probabilistic thinking. Even vaccinated citizens tended to dramatically overestimate the risks of vaccination. We found in interviews that people who had been vaccinated were often still frightened of vaccination because they thought there was substantial potential for long-term side-effects.

The majority of citizens who estimated a risk of 50% of severe side effects indicated uncertainty in their explanations of their risk. For example, they wrote "because I'm not sure what's in this vaccine", "It effects everyone different and you don't know until you have a reaction", and "Do not know until it happens." One citizen estimated at a 50% risk for all questions in the survey including a question about getting in a serious car accident over the course of one year. He explained, "because like I said always a 50/50 chance." The citizens with at least one vaccine typed lower numbers compared to unvaccinated citizens. Unvaccinated citizens often used 50% (17 of 52) as a benchmark value and citizens with at least one vaccine often used 0% (30 of 99).

Relationship between Estimates of Risk and Vaccination Status

Thinking about estimates of risk using the outcome approach is a viable strategy for many areas of life. For example, if someone interprets a 50% chance of rain as meaning that the weatherman does not really have information about whether or not it will rain, they might make a reasonable decision to bring an umbrella. In our interviews, we found that citizens who overestimated their risk of COVID-19 infection were not necessarily constrained by their estimates. Many who overestimated their risks were not stopping their lives due to fear of COVID-19 and were still socializing but just taking precautions such as wearing masks. We are concerned that using the outcome approach is not adequate to weigh the relative risk of COVID-19 infection and COVID-19 vaccination. It is more important to think about the relative risk of infection and vaccination than to focus on the uncertainty of any medical outcome. In fact, medical professionals compare risks and benefits to decide whether or not to approve a vaccination. If citizens estimate the risk of both infection and vaccination at 50% because they are uncertain of the outcome of either event, it does not help them make a productive decision about the benefits of vaccination. In fact, we found that citizens who are unsure about the relative risk of infection and vaccination are less likely to be vaccinated (See Table 1).

Table 1. The relative risk of infection and vaccination by vaccine status

	No vaccine	Partially vaccinated	Fully vaccinated	Fully vaccinated with a booster shot	Total
Equally risky[1]	19	4	12	6	41
Vaccine risky[2]	30	2	2	3	37
Infection risky[3]	3	8	16	46	73
Total	52	14	30	55	151

[1]COVID-19 infection is equally risky as a COVID-19 vaccination for me.

[2]COVID-19 infection is less risky than a COVID-19 vaccination for me.
[3]COVID-19 infection is more risky than a COVID-19 vaccination for me.

Table 1 shows that about 46% (19 of 41) people who think COVID-19 infection is equally risky as a COVID-19 vaccination for them did not receive a vaccine. Table 1 also demonstrates that people who think COVID-19 infection is less risky than a COVID-19 vaccination for them tended not to receive a vaccine (30 of 37). If a person thinks COVID-19 infection is riskier than a COVID-19 vaccination for them, the person tended to be either boosted or fully vaccinated (62 of 73). The relationship between a citizens' response about risk and vaccination status is statistically significant $\chi^2(6,151) = 78.9$, $p < .001$.

We also noticed that many vaccinated citizens without a booster (partially and fully vaccinated) are often unsure about whether or not infection or vaccination is riskier. We were somewhat surprised by the number of citizens who received a vaccine despite thinking vaccination might be as risky as COVID-19 infection. We acknowledge again that there are a number of factors such as social or emotional thinking influencing people's decisions to be vaccinated beyond their assessments of risks. We think that our part is to use a mathematics education lens to model citizens' thinking about COVID-19 infection and vaccination risks.

Discussion

The results demonstrated that using Konold's outcome approach can provide plausible explanations for citizens' thinking about their estimates of COVID-19 risks. Many citizens used benchmark values "0%" to represent "I will not die from COVID-19" and "50%" to represent "I don't know if I will die from COVID-19 or not". Citizens who have at least one COVID-19 vaccine showed a tendency to use "50%" as their estimate of COVID-19 death risk and "0%" as their estimate of COVID-19 vaccination risk. Citizens without a COVID-19 vaccine tended to use "0%" as their estimate of COVID-19 death risk and "50%" as their estimate of COVID-19 vaccination risk. As in Konold's (1991) data, citizens appeared to move up or down from benchmark values to indicate varying degrees of certainty. For example, many citizens who were somewhat concerned about COVID-19 infection listed a death risk of 10%. We think that mathematics educators could help students develop formal interpretations of probability such as understanding percent risks based on the relative frequency of outcomes.

Variations in citizens' estimates of risk explain a fair amount of variation in vaccination status. Of course, many other factors are also involved, but convincing citizens that vaccination is less risky than infection seems like a potentially important target for public health education. Many vaccinated citizens who do not yet have a booster are unsure about whether or not infection is riskier than vaccination and might be reassured by well-crafted messaging about relative risks. Kollosche and Meyerhöfer (2021) argue that mathematics related to COVID-19 is more complicated than what is commonly taught in school, and mathematics education could help a layperson understand health recommendations. Our results show that it is important to support citizens in understanding their risk of COVID-19 infection and vaccination. We think giving citizens opportunities to see their risks based on their ages would help them make informed decisions regarding COVID-19. We designed the Relative Risk Tool (https://www.covidtaser.com/relativerisk) to help citizens easily compare the relative risk of COVID-19 infection and COVID-19 vaccination without needing sophisticated mathematical or statistical knowledge (Joshua et al., 2022; Lipkus et al., 2001; Wong & Yang, 2021).

MATHEMATICIANS' UNDERSTANDING: AN ARGUMENT FOR THE VALUE OF PSEUDO-OBJECTS

Kyle Flanagan
Virginia Tech
flanaga5@vt.edu

Keywords: Advanced Mathematical Thinking, Mathematical Processes and Practices

In academia, mathematicians frequently engage in solving difficult mathematical problems. For these mathematicians, these problems often involve highly formal and abstract concepts. Still, professional mathematicians are successful at completing new mathematical research and "understanding" new abstract mathematical concepts that they encounter. This theoretical poster aims to present the beginnings of a theoretical framework addressing this phenomenon, which grates against commonly held beliefs in the mathematics education literature.

Various process-object theories have been developed to help explain mathematical understanding and thinking. Davis et al (1997) summarize these various theories of encapsulation and reification, which includes the building blocks of APOS theory. A commonplace of most of these theories is that an individual often (or must) progress from process-level to object-level understanding. Dubinsky and McDonald (2001) state about the four components of APOS theory, "each conception in the list must be constructed before the next step is possible" (p. 277). In the literature, having less than a process-object-level understanding is often considered unvaluable. Related to this, syntactic proof strategies, namely strategies involving symbol-pushing and unpacking definitions, are often seen as unproductive. Weber (2001) mentions these strategies "are not capable at solving complex problems" (p. 114).

Sfard (1992) defines a pseudostructural conception as an object that is not conceptualized as a process, which will be referred to as a pseudo-object following Zandieh (2000). Though a full process-object-level understanding is preferable, I argue that a pseudo-object-level understanding can be a productive place to operate, and hypothesize that, for a time, mathematicians likely function with that level of understanding when encountering new advanced concepts. It is also plausible that mathematicians may not have the time to always develop a process-object-level understanding for the new concepts they encounter, yet they still productively do mathematics with these concepts. To share a personal example, when first encountering inverse limits of modules in commutative algebra, I successfully used the inverse limit as a pseudo-object to learn subsequent material and write proofs (sometimes with syntactic proof strategies) but did not fully understand the underlying process other than the mathematical objects it consisted of. Only after revisiting the concept about a year later, did I begin to gain a process-level understanding too.

In support of this viewpoint, Weber and Alcock (2004) state that syntactic proof strategies are valuable and can be used to build intuition about a concept. Additionally, Weber (2019) provides evidence that set theorists can gain epistemic benefits from just knowing syntactic representations of concepts, rather than knowing the full derivation. This aligns closely with the belief that mathematicians may be content and successful with only having a pseudo-object-level understanding of certain concepts. If this hypothesis is accurate, then it would have significant implications for the teaching of advanced mathematics. If mathematicians often productively leverage a pseudo-object-level understanding, then teachers should not be quick to discount the value of the learning and progress that can take place in students with this level of understanding, when encountering new mathematics, especially at a more advanced mathematical level.

Keywords: Advanced Mathematical Thinking, Data Analysis and Statistics, Problem Solving

Introduction

When technology supports problem-solving activities, it promotes strategy implementation and heuristics extension (Santos-Trigo, 2014), it also can influence the development of certain aspects of the mathematical thinking, such as the way information is represented and the way the results are communicated by the students (Barrera-Mora & Reyes-Rodríguez, 2018).

The informal fitting of the line is considered to be an educational experience towards understanding the linear regression model (Bargagliotti et al., 2012 cited in (Casey, 2015)). This study examines the mathematical thinking developed by a group of students taking a Statistics course, in a problem-solving activity about linear regression and using the Rossman/Chance applet "Two Quantitative Variables" (Chance & Rossman, 2015).

Methods

A qualitative panel study was carried out in a group of 19 students from the Logistics and Transportation Engineering program at University of Guadalajara, all the students were 20 years old. After receiving instruction about the topic, the small-group problem-solving activity was worked over a hybrid session, due to COVID-19 restrictions. The data about the student's work was collected with Google Forms questionnaires and Google Meet recordings.

The context of the problem-solving activity was automated warehouses, the data provided had 11 entries and two variables: Number of vehicles and Time Spent in Congestion (in seconds). Using the data, the students were asked to propose "the best line" that better represents the relationship between variables using the movable line from the applet which also provides the line's algebraic representation.

Results

As students were exploring possible lines, questions about the intercept and the slope, in the context of the problem, arose among the teams. By answering these questions, the students were able to give meaning to the model's coefficients after placing different lines over the scatterplot. For the role of the intercept, they were able to communicate that it made no sense to have a time different than zero, if no vehicles were operating. This led some students to propose a model with no intercept. It was later shown in class that the intercept of the linear regression model for the data was not significant, and thus the best model had no intercept.

LINEAR OR NONLINEAR? RELATING COLLEGE ALGEBRA STUDENTS' COVARIATIONAL REASONING AND GRAPH SELECTION

Robert Knurek
University of Colorado Denver
robert.knurek@ucdenver.edu

Heather Lynn Johnson
University of Colorado Denver
heather.johnson@ucdenver.edu

Keywords: Assessment, Mathematical representations, Reasoning and proof

We investigate the following problem: How does students' covariational reasoning (Carlson et al., 2002; Thompson & Carlson, 2017) relate to their graph selection on a fully online assessment? In particular, we focus on students' distinction between linear and nonlinear graphs representing the same direction of change in variables. Figure 1 shows two such graphs.

Figure 1: Two graphs relating diameter and height for a fishbowl filling with water

When a student engages in covariational reasoning, they can conceive of relationships between attributes that they view to be capable of varying and possible to measure (Carlson et al., 2002; Thompson & Carlson, 2017). Per the framework from Thompson and Carlson (2017) an early level of covariational reasoning is the "gross coordination of values," which refers to a loose connection between the direction of change in attributes. For either graph in Figure 1, a student reasoning this way can conceive of the diameter increasing then decreasing while the height continues to increase (see Figure 1).

We situate this case study (Stake, 1994) in a larger interview-based validation study of a fully online covariation assessment (Johnson et al., 2021). The assessment contains six items; students view a video animation, then select one of four graphs that best represents a relationship between variables. We report on a case of an early undergraduate student, Maya, who spontaneously wondered how to select between graphs such as the ones shown in Figure 1.

On three items, Maya's covariational reasoning was at least at a level of gross coordination of values, as evidenced by her explanations. Appealing to the direction of change in attributes or a value of an attribute at a single instance, Maya narrowed down the graphs to two choices. Both represented the same direction of change in related attributes. She then selected a graph based on physical aspects of the situation (e.g., "the motion of the cone seems more linear than, than like a wave"). For Maya, either graph was satisfactory. The assessment forced her to make a choice.

Maya's case illustrates how students' covariational reasoning can intertwine with their interpretation of physical aspects of the situation. She demonstrates how students can engage in both figurative and operative thinking (Moore et al., 2019) when interpreting graphs, in ways that are compatible from a student perspective.

Chapter 8:

Number Concepts and Proportional Reasoning

SENTIDO NUMÉRICO ACERCA DE LOS NÚMEROS REALES: UN ESTUDIO INICIAL CON ALUMNOS DE 15-16 AÑOS

NUMBER SENSE ABOUT REAL NUMBERS: AN INITIAL STUDY WITH STUDENTS AGED 15-16

Virginia Garrido	Olimpia Figueras	Minerva Martínez
Cinvestav	Cinvestav	Cinvestav
virginia.garrido@cinvestav.mx	figuerao@cinvestav.mx	mmartinezo@cinvestav.mx

El sentido numérico ha sido estudiado desde diferentes perspectivas. Definirlo no ha sido una tarea sencilla y la mayoría de las definiciones que existen en la literatura versan sobre los números naturales, enteros y racionales. En esta comunicación se dan a conocer los avances de un estudio cuyo objetivo es caracterizar el sentido numérico acerca de los números reales. A partir de la revisión de la literatura se propusieron 15 habilidades, éstas se consideraron como indicadores del uso de un buen sentido numérico acerca de los números reales. Los indicadores fueron puestos a prueba al analizar las respuestas a preguntas de un cuestionario. Con el mismo test fue posible observar dificultades que enfrentan los estudiantes al usar tales números, y cómo en este estudio, el uso de la calculadora no fue determinante para valorar aspectos relacionados con el sentido numérico.

Palabras clave: High School Education, Number Concepts and Operations

En los Estándares Curriculares y de Evaluación para la Educación Matemática de los Estados Unidos (NCTM, 1989) se menciona que la expresión *sentido numérico* se refiere a la comprensión general que tiene una persona sobre los números, junto con la habilidad de usarla de forma flexible para hacer juicios matemáticos e implementar estrategias numéricas. Desarrollar un *buen sentido numérico* implica entender el sistema decimal, ser consciente de las múltiples relaciones que se dan entre los números (tanto gráficas, como simbólicas), reconocer su magnitud relativa, considerar el efecto relativo de las operaciones numéricas y disponer de puntos de referencia para las mediciones de objetos comunes y situaciones en el entorno.

Psicólogos e investigadores de educación matemática han propuesto definiciones de sentido numérico de acuerdo con el contexto y época en la que desarrollaron su investigación. Whitacre, Hening y Atabaş (2017) hicieron un estudio teórico en el que revisaron 124 artículos y argumentaron que las complicaciones o inconsistencias para definir el sentido numérico se originan porque se trata de un caso de polisemia, se usa la misma palabra para tres constructos: sentido numérico innato (*innate number sense*), sentido numérico temprano (*early number sense*) y sentido numérico maduro (*mature number sense*). Es decir, algunos investigadores reportan hallazgos sobre un constructo y otros sobre uno distinto usando el mismo término; esto genera una confusión acerca de lo que se va a entender por sentido numérico. Así que es necesario aclarar que en la investigación de la que forma parte este informe la expresión *sentido numérico* se considera como el constructo *sentido numérico maduro (mature number sense)* que se refiere a algo que no es innato y se puede desarrollar mediante la enseñanza en grados intermedios o posteriores a la educación básica.

Greeno, en 1991, afirmó que el sentido numérico es para la aritmética como el alfabeto para la escritura, por lo que promover su desarrollo en los primeros años escolares es indispensable. Sin embargo, Nguyen (2016) y Salinas (1985) pusieron de manifiesto que no sólo en la educación básica se requiere de una buena comprensión de los números, pues estos objetos matemáticos van cambiando y siendo más complejos a medida que se avanza en la educación posterior.

El desarrollo del sentido numérico ha sido estudiado en diferentes países, la mayoría de las investigaciones se han llevado a cabo con estudiantes de educación básica –de 5 a 14 años de edad– (ver, por ejemplo, Reys y Yang, 1998; Alajmi, 2009; Corso y Dorneles, 2017; Long y Melnikova, 2019). Los sistemas numéricos estudiados en este nivel educativo son los números naturales, enteros y racionales. Sin embargo, en el nivel medio superior –alumnos de 15 a 18 años de edad– además del dominio de esos sistemas numéricos, también se requiere emplear los números irracionales. En otras palabras, esos estudiantes necesitan usar los números reales, pero ¿han construido los conocimientos y desarrollado las habilidades necesarias para usar esos números con suficiente flexibilidad? Scalia (2000) y Castañeda (2011) dan un panorama sobre la respuesta a esta pregunta, pues documentaron dificultades que enfrentan alumnos de esas edades para comparar, ordenar y hacer operaciones con los números reales.

La investigación descrita en este documento forma parte de un estudio más amplio, en el cual se pretende desarrollar el sentido numérico de estudiantes del nivel medio superior acerca de los números reales y fortalecer aquel relacionado con los otros sistemas numéricos. Para ello es necesario analizar y reflexionar sobre semejanzas y diferencias que existen entre el sentido numérico definido por otros investigadores y el sentido numérico que se define en esta investigación. En este informe, se expone un primer acercamiento para responder la pregunta ¿Cómo caracterizar el sentido numérico acerca de los números reales? y el objetivo es determinar si dicha caracterización permite obtener evidencias de cómo usan el sentido numérico aquellos estudiantes que recién ingresaron al bachillerato.

Marco de referencia

Varios investigadores han propuesto definiciones que fueron modificadas por otros con la intención de esclarecer qué se debe entender por sentido numérico. Aun cuando tenían diferentes perspectivas, todos coinciden en la importancia de desarrollar un ‘buen sentido numérico’.

Greeno (1991) lo definió como una ‘expertez’ cognitiva, es decir, como el conocimiento que resulta de una actividad extensa a través de la cual las personas aprenden a interactuar exitosamente en diversos dominios conceptuales. Él describe al sentido numérico como un conocimiento situado dentro de un dominio conceptual y plantea metáforas con las cuáles es posible entender que el sentido numérico es diferente a los temas que regularmente se enseñan; pertenece a otra dimensión, si se imagina que las operaciones básicas están en un plano, el sentido numérico debería estar en una tercera dimensión; como un dron desde el cual se pueden ver y seleccionar las operaciones más convenientes para lograr un propósito.

A su vez Sowder (1992a) define el sentido numérico como una red conceptual bien organizada que le permite a uno relacionar las propiedades de los números y las operaciones, así como resolver problemas numéricos de formas flexibles y creativas. Para Marshall (1989), el sentido numérico es la riqueza de conexiones del conocimiento matemático.

Las tres definiciones anteriores en su momento tuvieron gran aceptación por parte de la comunidad científica, empero son muy generales. Un investigador puede imaginar la ‘expertez’, la red conceptual o la riqueza de conexiones; pero observar ese tipo de cosas en el aula no es tarea fácil, por ello las autoras de esta investigación decidieron buscar más definiciones o características que permitieran notar el sentido numérico que han desarrollado los estudiantes.

Como resultado de esa búsqueda se observó que el sentido numérico había sido definido de muchas formas (ver Reys y Barger, 1991; Reys, 1994; Löwenhielm, Marschall, Sayers y Andrews, 2017) pero invariablemente se identificaba la presencia de dos componentes: conocimientos y habilidades. Los conocimientos comprenden la información que se va a usar para desarrollar habilidades y ambos, en conjunto dan origen al sentido numérico.

Para caracterizar el sentido numérico acerca de los números reales, se analizó si alguna de las definiciones planteadas en estudios previos se adecuaba a las necesidades de la investigación global que lleva a cabo. La conclusión fue que lo más conveniente era formular otra definición que permitiera incluir actividades en las que se requirieran números reales, la propuesta es la siguiente:

> El sentido numérico es el conjunto de conocimientos y habilidades acerca de los números reales que usa una persona para hacer juicios matemáticos y desarrollar estrategias numéricas al resolver problemas.

Como la investigación es sobre el sentido numérico acerca de los números reales, los conocimientos son las propiedades de dicho sistema numérico y las habilidades son sobre su uso y las diferentes formas de representarlos. A continuación, se enlistan las habilidades que se han propuesto para la investigación que se lleva a cabo:

1. Habilidad para componer, descomponer y recomponer números
2. Habilidad para identificar cuál representación de un número es más conveniente que otra
3. Habilidad para comparar números
4. Habilidad para ordenar números
5. Habilidad para lidiar con el orden de magnitud de un número en situaciones concretas
6. Habilidad para usar puntos de referencia
7. Habilidad para vincular símbolos de operación y relación de manera significativa
8. Habilidad para reconocer los efectos de las operaciones en los números
9. Habilidad para hacer cálculos mentales mediante estrategias propias
10. Habilidad para hacer estimaciones
11. Habilidad para asociar los números con el contexto en el que aparecen
12. Habilidad para localizar números en la recta numérica
13. Habilidad para reconocer hechos dados
14. Habilidad para distinguir diferencias y semejanzas entre los sistemas numéricos
15. Habilidad para autorregularse

Las primeras diez habilidades tienen como base los comportamientos que demuestran la presencia del sentido numérico sugeridos por Sowder (1992b). Las siguientes cuatro habilidades fueron propuestas por las autoras de esta comunicación y están relacionadas con conocimientos específicos de los números reales, tales como la densidad, el proceso de racionalización y la potenciación que tienen características distintas a las de los otros sistemas numéricos. La última habilidad fue propuesta por Resnick (1989), se refiere a que una persona debe reconocer cuando en un procedimiento es mejor detenerse e iniciar otro camino para encontrar la solución de algo.

Las habilidades anteriores se pueden considerar como indicadores que permiten valorar el uso del sentido numérico por parte de los estudiantes. Para verificar si todas las habilidades propuestas son necesarias o si se requiere de alguna otra, se aplicó un test que se describe en la sección de método.

Método

Participantes. Fueron 56 estudiantes mexicanos, cuya edad oscila entre 15 y 16 años. En agosto de 2021 iniciaron su educación media superior en una institución pública ubicada en una zona rural.

Recolección de los datos. Los datos se obtuvieron a través de un cuestionario inicial. Para diseñar el test se tomaron en cuenta ítems sobre sentido numérico usados en otras investigaciones con adaptaciones y preguntas construidas exprofeso. Después de una validación con pares y un estudio piloto, el instrumento para la toma de datos quedó compuesto por 16 preguntas, de las cuales 8 son de elaboración propia. Además, se especificó cuáles habilidades y conocimientos que forman parte del sentido numérico están relacionadas con cada ítem. En la Tabla 1 se muestran dos ejemplos.

Tabla 1: Ejemplos de habilidades y conocimientos relacionadas con cada ítem

Ítem	Habilidad	Conocimiento	Intención
6. ¿Cómo se puede usar el resultado $156 - 100$ para calcular $156 - 99$? Adaptado de Hope (1989)	Habilidad para hacer cálculos mentales mediante estrategias propias.	Valor posicional de los números.	Observar la flexibilidad al hacer operaciones.
8. En la recta ubica los números -0.85, $-\frac{11}{8}, -\frac{9}{8}, -\sqrt{2}$	Habilidad para localizar números en la recta numérica.	Los números racionales tienen dos representaciones: una decimal y otra fraccionaria. Los números irracionales se pueden aproximar con números decimales.	Observar si las estrategias usadas para ubicar a los números positivos son congruentes al localizar números negativos

La aplicación del cuestionario inicial se llevó a cabo de forma presencial en octubre de 2021 en dos sesiones, en días diferentes pero consecutivos durante el horario de la asignatura Álgebra. Los estudiantes previamente fueron notificados de las fechas para este cuestionario y el material que necesitarían: papel, lápiz, colores y calculadora. Aunque el tiempo planeado para contestar cada parte del test era de 60 minutos no se dio esta información a los alumnos para reducir la presión o angustia. La mayoría lo entregó a los 50 minutos, en la última hoja del instrumento se anotó el tiempo de entrega de cada uno.

Los estudiantes estaban separados en dos grupos de 28 alumnos; a un grupo se le permitió el uso de calculadora y al otro no. Esta variante se propuso porque en investigaciones como las de Bobis (1991), Alajmi (2009) y Lyublinskay (2009) se plantea la posibilidad de usar recursos tecnológicos para desarrollar el sentido numérico. Se decidió iniciar la exploración con la calculadora por ser un recurso de fácil acceso.

Con previa autorización de los tutores de los alumnos, se grabó un video de la sesión del grupo que usó calculadora. Como no fue posible enfocar la cámara y grabar qué tecleaban o qué cálculos hacían los estudiantes con ella, al final se les pidió que en la mitad de una hoja blanca escribieran cómo usaron la calculadora y qué tipo de operaciones habían hecho con ella.

Análisis de los datos. El análisis de los datos se llevó a cabo en dos etapas, en la primera se hizo una distinción sobre cuáles fueron las preguntas en las que se tuvo mayor o menor éxito. En la Tabla 2 se muestra un ejemplo de este análisis.

Tabla 2: Análisis de la pregunta 1

Número de estudiantes	Con calculadora	17	Contestaron	17	Correctamente	9
					Incorrectamente	8
			No contestaron	0		
	Sin calculadora	39	Contestaron	37	Correctamente	0
					Incorrectamente	37
			No contestaron	2		

Dado que cada pregunta estaba relacionada con al menos una de las habilidades sobre el uso de los números reales y las diferentes formas de representarlos, en la segunda etapa se analizó la pertinencia de los indicadores propuestos. Durante este análisis, surgió la oportunidad de identificar algunas dificultades que tenían los estudiantes al emplear estos números. Por cuestiones de espacio, sólo se explican las observaciones hechas para los ítems 1 y 3.

Con respecto al ítem 1, que está relacionado con la *habilidad para componer, descomponer y recomponer números*. La pregunta fue si $\sqrt{40}$ era igual a $2\sqrt{10}$, esperando que los estudiantes se percataran que $\sqrt{40}$ se puede descomponer como $\sqrt{4(10)}$ además de tomar en cuenta que la raíz cuadrada de un producto es el producto de las raíces, es decir, $\sqrt{4(10)} = \sqrt{4}\sqrt{10} = 2\sqrt{10}$. En la Figura 1 se puede notar que algunos estudiantes por el hecho de ver números distintos aseguran que las expresiones numéricas son diferentes, no recurren a la descomposición del número. Entonces la *habilidad para componer, descomponer y recomponer números* es necesaria para desarrollar estrategias numéricas. Buscar comportamientos asociados a esta habilidad permitirá encontrar evidencias sobre el uso del sentido numérico por parte de los estudiantes. Por otro lado, el que no desarrollen esta habilidad provoca que tengan dificultades para escribir los números reales de diferentes formas.

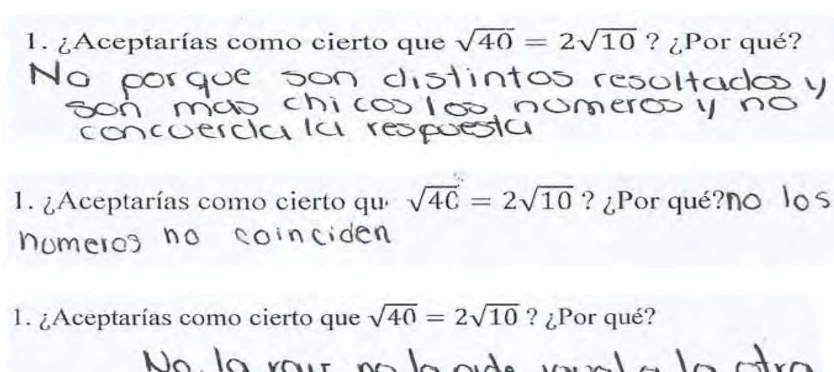

Figura 1. Respuestas al ítem 1, dadas por estudiantes sin uso de calculadora

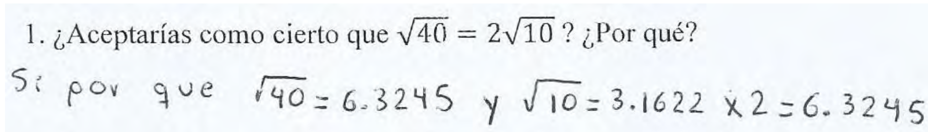
El grupo de estudiantes que usó calculadora hizo las operaciones correspondientes y un poco más de la mitad dio una respuesta correcta, aunque no hubo evidencia de que los estudiantes usaran la *habilidad para componer, descomponer y recomponer números*, ver Figura 2.



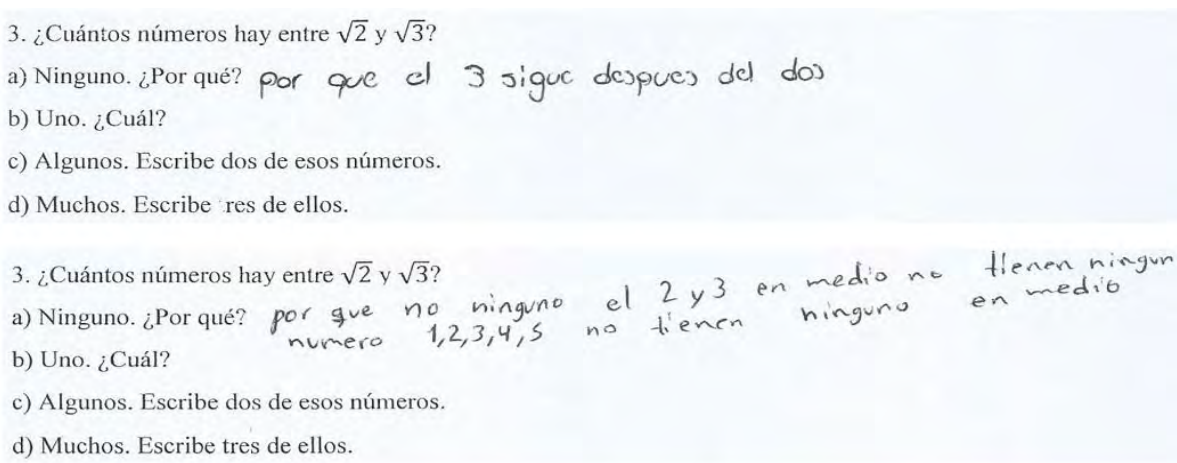
1. ¿Aceptarías como cierto que $\sqrt{40} = 2\sqrt{10}$? ¿Por qué?

Si por que $\sqrt{40} = 6.3245$ y $\sqrt{10} = 3.1622 \times 2 = 6.3245$

Figura 2. Respuesta al ítem 1, un estudiante con uso de calculadora

El ítem 3 (ver Figura 3) fue adaptado de Reys y Yang (1998), el propósito de la pregunta original era evaluar el conocimiento que tenían los estudiantes sobre la densidad de los números decimales. En este caso el ítem está relacionado con la *habilidad para distinguir diferencias y semejanzas entre los sistemas numéricos*. Es posible que en la educación básica los estudiantes no hayan tenido la necesidad de distinguir a qué sistema numérico pertenecían los números que estaban usando; sin embargo, en bachillerato hay asignaturas como cálculo diferencial, cálculo integral y probabilidad en las cuáles se requiere considerar las propiedades de los números que se están empleando (ver Secretaría de Educación Media Superior, 2022).

En la Figura 3 se puede ver como los estudiantes hacen referencia a una característica de los números naturales sin percatarse de que la pregunta involucra dos números irracionales. Los alumnos que podían utilizar la calculadora tampoco reflexionaron sobre las propiedades de los números que usaron porque aun cuando tenían la aproximación en decimales de los números $\sqrt{2}$ y $\sqrt{3}$ no lograron pensar en 3 números entre los extremos del intervalo, ver Figura 4.



3. ¿Cuántos números hay entre $\sqrt{2}$ y $\sqrt{3}$?

a) Ninguno. ¿Por qué? por que el 3 sigue despues del dos

b) Uno. ¿Cuál?

c) Algunos. Escribe dos de esos números.

d) Muchos. Escribe tres de ellos.

3. ¿Cuántos números hay entre $\sqrt{2}$ y $\sqrt{3}$?

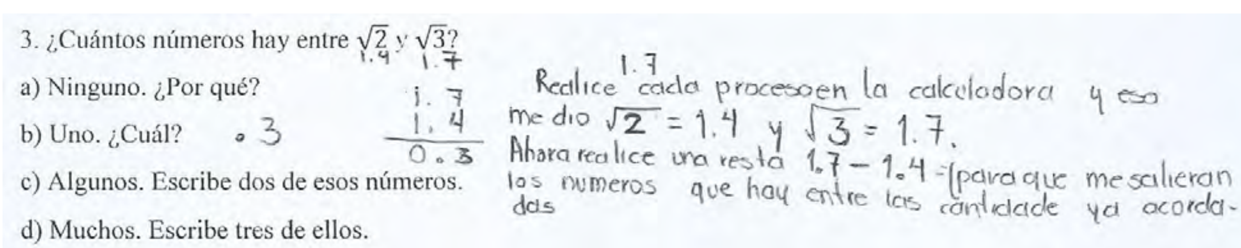
a) Ninguno. ¿Por qué? por que no ninguno numero 1,2,3,4,5 no tienen el 2 y 3 en medio no ninguno tienen ningun en medio

b) Uno. ¿Cuál?

c) Algunos. Escribe dos de esos números.

d) Muchos. Escribe tres de ellos.

Figura 3. Respuestas al ítem 3, dadas por estudiantes sin uso de calculadora



3. ¿Cuántos números hay entre $\sqrt{2}$ y $\sqrt{3}$?

a) Ninguno. ¿Por qué?

b) Uno. ¿Cuál? .3

c) Algunos. Escribe dos de esos números.

d) Muchos. Escribe tres de ellos.

1.4 1.7

1.7 − 1.4 = 0.3

Realice cada proceso en la calculadora y eso me dio $\sqrt{2} = 1.4$ y $\sqrt{3} = 1.7$. Ahora realice una resta 1.7 − 1.4 = (para que me salieran los numeros que hay entre las cantidade ya acorda-das

Figura 4. Respuesta al ítem 3, dada por un estudiante con uso de calculadora

El que para los estudiantes pasen desapercibidas las propiedades de los sistemas numéricos repercute en cómo hacen juicios matemáticos; por lo tanto, se puede asegurar que la *habilidad para distinguir diferencias y semejanzas entre los sistemas numéricos* es un indicador del uso de sentido numérico por parte de los estudiantes. El no haber desarrollado esta habilidad, puede estar relacionada con la dificultad que enfrentan los estudiantes al calcular la raíz cuadrada de un número o el que no se den cuenta que 0.3 no está entre los números 1.4 y 1.7 como lo asegura el estudiante con uso de calculadora, ver Figura 4.

Un análisis similar se hizo con las respuestas a cada ítem del cuestionario inicial, buscando evidencia sobre la pertinencia de los indicadores propuestos e identificando las dificultades que enfrentaban los estudiantes. En la sección de resultados se enuncian los hallazgos más importantes.

Resultados

Existen tres vertientes para los resultados: 1) sobre la pertinencia de los indicadores, 2) sobre el uso de la calculadora, y 3) con respecto a las dificultades que enfrentan los alumnos al ingresar al nivel medio superior.

Las habilidades que permiten analizar el desarrollo del sentido numérico propuestas por Sowder (1992b), que al parecer sólo se habían considerado para números naturales, enteros y racionales, también parecen servir como indicadores para evaluar el sentido numérico acerca de los números reales. Por ejemplo: *la habilidad para usar puntos de referencia* es necesaria para aproximar números reales, decidir qué valor es más grande $sen(60°) = \frac{\sqrt{3}}{2}$ o $\cos(45°) = \frac{\sqrt{2}}{2}$.

Por otro lado, los indicadores que se agregaron tienen pertinencia. La *habilidad para ubicar números en la recta* podría ser una herramienta para que los estudiantes comparen y ordenen números; la *habilidad para lidiar con el orden de magnitud de un número en situaciones concretas* ayudaría a que juzguen la razonabilidad de sus respuestas, es decir, reflexionen sobre la relación entre números y cantidades.

En el cuestionario inicial se planteó un ítem para validar la habilidad 15; sin embargo, la actuación asociada a dicha habilidad no es fácil de observar ya que está relacionada con funciones ejecutivas superiores. Por lo que será necesario analizar la pertinencia de esta habilidad o una mejor manera de valorarla. Un indicador que no estaba considerado, pero que parece ser necesario es la *habilidad para reconocer patrones*; en un ítem del cuestionario, para encontrar la solución, los estudiantes deberían notar que la suma de un número par de números nones es par, en otras palabras, reconocer un patrón. Aunque en el ítem la habilidad se observó para números naturales, ésta también podría ser un indicador del desarrollo del sentido numérico acerca de los números reales por parte de los estudiantes, pues les permitiría reconocer que si π es un número irracional, los números como $-2\pi, 3\pi, \frac{\pi}{4}$ también lo son.

Sobre el uso de calculadora, no hubo una diferencia significativa en las respuestas correctas e incorrectas dadas por los estudiantes (ver Tabla 2). Esto pudo haber sucedido porque previamente no se dio una instrucción sobre el funcionamiento o ventajas que ofrecía este artefacto, ya que en bachillerato sólo en temas específicos se permite el uso de la calculadora (Figueras, Valenzuela y Martínez, 2021). Por otro lado, se puede asegurar que el uso de la calculadora no sesga la información sobre el sentido numérico que han desarrollado los estudiantes porque habilidades *como descomponer, componer y recomponer números* o *distinguir diferencias y semejanzas entre los sistemas numéricos* deberían poderse observar con o sin calculadora. De hecho, si vemos el sentido numérico como una red conceptual con la que se entretejen conocimientos matemáticos como propuso Sowder (1992a), dentro de estos conocimientos pudiera estar el uso inteligente de la calculadora.

Con respecto a las dificultades que enfrentan los estudiantes al ingresar al bachillerato, al analizar sus respuestas se identificó que se les complica leer expresiones numéricas, escribir números de diferentes formas, compararlos, ordenarlos, usar puntos de referencia, hacer estimaciones y cálculos de forma flexible, así como identificar a qué sistema numérico pertenecen los números que están usando.

El que los estudiantes tengan las dificultades mencionadas en el párrafo anterior genera una disonancia crítica. Los profesores de educación media superior, inmersos en los tiempos y contenidos marcados en los planes y programas de estudio, asumen que los alumnos conocen y pueden usar los números reales sin complicaciones así que continúan con las actividades correspondientes a los temas del curso; mientras que algunos estudiantes no logran entender por qué una expresión numérica es igual a otra o siguen pensando que entre dos números decimales no hay otros números. Esto pone en desventaja a muchos jóvenes, que de acuerdo con Nguyen (2016) al no desarrollar un buen sentido numérico su desempeño en matemáticas se ve disminuido.

Una de las autoras es profesora en la institución educativa en la que se lleva a cabo la investigación y durante varios años ha observado como esta disonancia crítica abre una brecha entre los estudiantes que han desarrollado un buen sentido numérico y los que no. Fortalecer el sentido numérico de los estudiantes contribuye a que todos tengan mejores oportunidades para concluir el bachillerato, incluso de seguir su preparación académica ya que en los exámenes de admisión a la universidad casi el 40% de los reactivos son de matemáticas.

A manera de conclusión, la caracterización del sentido numérico acerca de los números reales se hizo a través de un conjunto de habilidades y conocimientos para que fuera operativa y de esta manera poder valorar el sentido numérico que los estudiantes han desarrollado. Las dificultades identificadas alertan sobre focos de atención para diseñar actividades que coadyuven al desarrollo del sentido numérico, una segunda fase de la investigación que se está llevando a cabo.

NUMBER SENSE ABOUT REAL NUMBERS: AN INITIAL STUDY WITH STUDENTS AGED 15-16

Number sense has been studied from different perspectives. Defining it has not been an easy task and most of the definitions that exist in the literature deal with natural, integer and rational numbers. In this communication, the advances of a study whose objective is to characterize the number sense about real numbers are disclosed. From the review of the literature, 15 skills were proposed, these were considered as indicators of the use of a good number sense about real numbers. The indicators were put to the test by analyzing the responses to questions in a questionnaire. With the same test it was possible to observe difficulties that students face when using such numbers, and how in this study, the use of the calculator was not decisive to assess aspects related to number sense.

PROMOTING PROPORTIONAL REASONING WITH THE SUPPORT OF DIGITAL TECHNOLOGY

In this report, we present an advance of doctoral research. We explore teaching alternatives that promote proportional reasoning in Mexican students between 14 and 15 years old with the support of digital technology. We designed a sequence of activities that pretends to signify the concepts of ratio and proportion in their diverse representations and from the perspective of linear functions. For the design of the tasks, elements of the Realistic Mathematics Education framework and Cuevas-Pluvinage Didactics were used. The learning objectives and proposed activities were organized through a hypothetical learning trajectory. Subject to presenting the group results, we randomly selected a student to present the analysis of the results achieved. We found that the tasks promoted proportional reasoning.

Keywords: High School Education, Technology, Rational Numbers & Proportional Reasoning

Introduction

The concepts associated with proportional reasoning, such as fraction, ratio, and proportion, are essential in mathematics education at basic levels since they are pillars of higher mathematics because their application is transversal to other disciplines (Lamon, 2007). Given the importance of the problem, we agree with several studies (Lesh et al., 1988; Adjiage & Pluvinage, 2007) that the lack of success in the handling of ratios and proportions is caused by poor development of proportional skills, as well as an excessive arithmetization of the processes involved. As a consequence of the lack of sense in dealing with proportional situations in the classroom, a tendency of students to apply the proportional model in situations where it is not applicable has been observed, which has been called the illusion of linearity (De Book et al., 2002).

The problem facing the community is how to teach students to reason proportionally. The most frequent school approach to proportionality is from an arithmetic perspective, separating it from its links with functional relationships and their multiple representations. In our proposal, we rescue the results of research in this line and test a teaching design based on a functional approach through realistic contexts and supported by digital technology, with which we hope to obtain ideas that contribute to the design of activities that promote proportional reasoning.

Theoretical framework

The Realistic Mathematics Education (RME) teaching approach emphasizes that real situations are fundamental for learning mathematics since mathematics is part of a historical and cultural construction (Freudenthal, 2002). In this current, students are active participants in developing their learning and constructing models that mathematize reality from an everyday context (Gravemeijer, 2004). In RME, two types of mathematization are identified: horizontal mathematization, where students move from the real to the symbolic of responding to problems in their context; and vertical mathematization, where students make conceptual connections and create strategies to solve problems within the mathematical system, which may or may not refer to the initial context. That is, they detach from the context towards the path of abstraction and generalization (Van den Heuvel-Panhuizen & Drijvers, 2020).

As for proportional reasoning, we start from the definition of Lesh et al. (1988):

> Proportional reasoning is a form of mathematical reasoning that involves a sense of co-variation and of multiple comparisons, and the ability to mentally store and process several pieces of information. Proportional reasoning is very much concerned with inference and prediction and involves both qualitative and quantitative methods of thought. (p. 93)

According to this rationale, we assume as valid the proportional reasoning model proposed by Modestou & Gagatsis (2010) and recognize the need for research invoked by the studies on the illusion of linearity by De Bock et al. (2002). In our study, we identify proportional skills as those faculties considered necessary for a person to possess sound proportional reasoning. Lobato et al. (2010) and Weiland et al. (2021) indicate that these skills should include: 1) Attending to and coordinating two quantities that vary dependently, 2) Recognizing and using the structures of proportional situations (unit ratio, constant of proportionality, linearity), 3) Identifying the invariant in a proportion, 4) Understanding proportionality from multiple representations, 5) Distinguishing linear from nonlinear situations. We consider these five skills as key to our study, and they are the ones we invoke with the term proportional skills.

To encompass the theoretical framework and structure of the intervention, we rely on the Design-Based Research (DBR) approach proposed by Bakker (2018). Since DBR design and innovation in the classroom are vital aspects, digital technology is proposed to allow students to interact with multiple representations, facilitate the simulation of realistic situations, and test their results in Virtual Interactive Didactic Scenarios (VIDS).

To organize the design of the tasks that guide students in the mathematization process, we rely on the Hypothetical Learning Trajectory (HLT) (Simon, 1995). For the design of the activities that integrate each task, we rely on the Cuevas-Pluvinage didactic framework, which provides didactic engineering that rescues several didactic principles of the active school and Piaget and adapts them to mathematics education (Cuevas & Pluvinage, 2003).

We agree with Sierpinska (2004) that "reporting tasks is necessary to probe the effectiveness of the teaching approach" (p. 13). According to the author, the problematization, justification, and discussion of the tasks begin with the a priori analysis of the design. However, the problematization is even more substantial and fruitful in the a posteriori analysis, that is, after the experimentation in the classroom. In this order of ideas, in this report, we show the problematization both in the design phase and the retrospective analysis phase since it provides guidelines for redesigning our tasks.

One of the most complex tasks for a teacher is implementing constructivist didactic principles in a traditional classroom with the usual elements. For example, introducing a mathematical concept through the problematization of an everyday situation in a conventional classroom is almost impossible. A possible solution is to have a virtual scenario that simulates a real phenomenon, in which students can interact with various contexts dynamically, and, in addition, its use allows the construction of mathematical knowledge (Moyer et al., 2016). In this way, students are endowed with the opportunity for action, where each student can learn at their own pace. Digital technology provides the student and the teacher with a portable laboratory using various devices, such as cell phones, tablets, or computers.

The above considerations lead us to the research question: How to design a didactic sequence, in realistic contexts mediated by technology, that helps students to develop their proportional reasoning and allows them to progress in the mathematical levels of RME?

Methodology

Based on our methodological framework, the DBR approach consists of the following phases: preparation and design, teaching experiment, and retrospective analysis.

Preparation and design phase

The following were designed and developed in this phase: 1) A pretest to collect students' prior knowledge. 2) A HLT who leads the teaching process and sets the learning objectives. 3) Three sequences of didactic activities with their respective VIDS: "Naranjada", "Zoom Totoro" and "Autos". 4) A survey to inquire about the students' perspectives on their experience using the VIDS and the Guided Learning and Exploration Sheets (GLES) activities. The pretest and final survey were hosted on Google forms to answer at home to save classroom time.

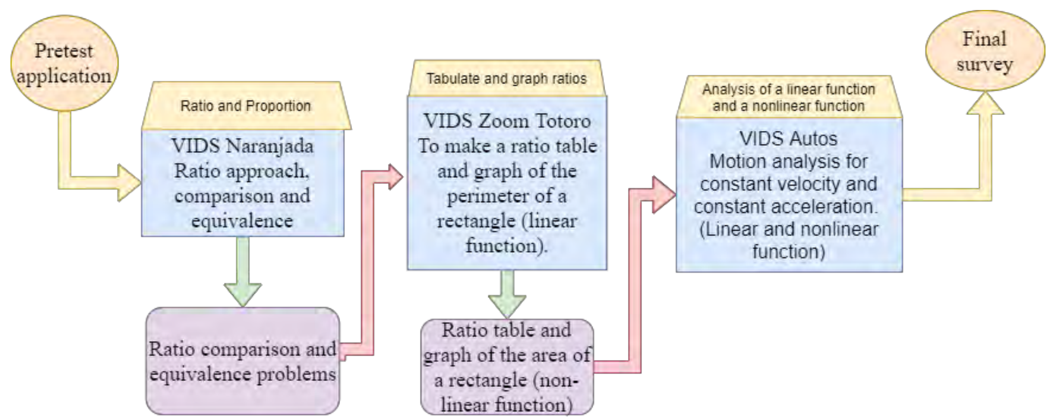

Figure 1: Design of the didactic pathway guiding the instructional sequence

Task 1. The task's context is to compare proposals for mixing orange juice and water (see Figures 2a and 2b). The objective is for students to learn: to pose, compare and determine equivalence between ratios, as well as to generate tables of equivalent ratios and identify the constant of proportionality. Finally, an extra activity is performed to apply the knowledge learned in a different context. The activities are: 1) Expressing a ratio in different notations, e.g., three glasses of juice for every five glasses of water: 3 to 5, 3:5 and 3/5. 2) Coordinate the covariation between two variables; given a ratio of A glasses of orange to every B glasses of water, the taste is more intense orange if A increases or B decreases. 3) Comparison of two ratios, given two random orangeade proposals with orange to water ratios A:B and C:D, determine which will have an intense orange flavor.

Task 2. The task consists of performing a "zoom" effect to reduce or increase an image of Totoro figures according to a similarity ratio entered in an input box (see Figure 2c). The objective is for students to perform similarity activities using the constant of proportionality. Also, it is intended to address the problem of the illusion of linearity by tabulating and graphing the ratio-perimeter (linear) and ratio-area (quadratic) relationships to lead students to compare both models.

Task 3. The task's context is to visualize a car moving at a constant speed above the allowed limit and a patrol car initiating a chase with constant acceleration as the car passes (see Figure 2d). The objective is for students to interact with the VIDS as they describe, analyze, and compare the characteristics of the two motions, i.e., uniform rectilinear motion (URM) and uniformly accelerated rectilinear motion (UARM). Students must identify the models present (linear and quadratic) and compare them as they transit between their representations.

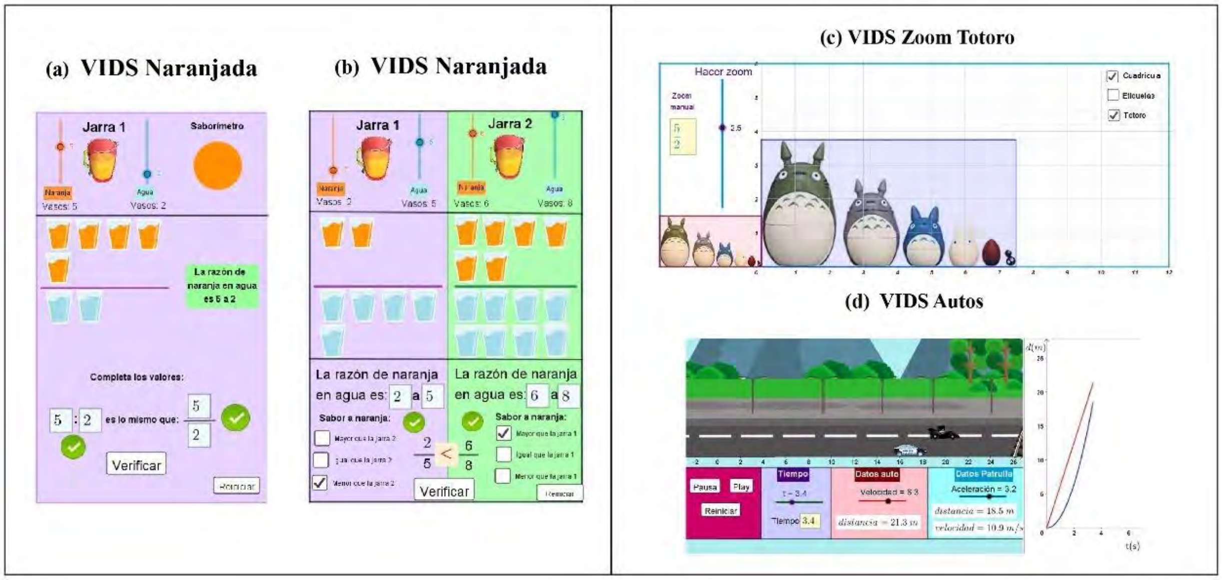

Figure 2. VIDS used in the teaching sequence

Teaching experiment phase

The study was performed through a face-to-face intervention in two groups in a secondary school in Mexico. Thirty-five students (14-15 years old) participated in the study in the winter of 2021. The instruction was divided into three 90-minute sessions in a computer room at the school. Each student had a personal computer that had VIDS preloaded, and each student had their respective GLES. The first author conducted the intervention, supported by the group's teacher and a research assistant. During the sessions, collaborative learning was promoted, and the answers were discussed as a group.

Results and retrospective analysis

According to Freudenthal (2002), the context and didactic design should allow students to move from horizontal mathematization to vertical mathematization. Gravemeijer (2004) identifies four levels towards vertical mathematization: N1) Situational level. Reality is interpreted and organized through informal and context-dependent mathematical reasoning (horizontal mathematization). N2) Referential level. Schemes and models that make sense within the initial context are created, and vertical mathematization begins with the emergence of "models of...". N3) General level. Concepts are related, strategies separated from the context are generated, reasoning occurs in the mathematical world, and "models for..." emerge. N4) Formal level. Concepts are understood by employing their mathematical symbolism, support from a real context is no longer needed, and reflection has moved to the mathematical world.

Subject to presenting the whole group's results, we randomly selected one student, whom we will call Lucy. Based on this student's findings, we will present a detailed analysis of the results of the tasks and the evaluation of the levels of vertical mathematization proposed in the RME.

Results of Task 1. "Naranjada"

Lucy uses her previous knowledge to perform the activities, i.e., the activities lead her to a horizontal mathematization, correctly assimilating the three notations for ratio. In addition, she found that in a random proposal of orange and water mixture, the intensity of flavor depends on a covariation process. At this stage, Lucy is at the situational level because she moves within the numerical world only to interpret the context and make a judgment. The horizontal mathematization is coming and going from the context to the mathematical world.

One finding occurred when the virtual scenario showed Lucy the following pair of orange to water ratios: 2:7 and 3:8 (see Figure 4a). Lucy mentally performed a 1-to-1 bijection between the glasses of orange and the glasses of water. Once the bijection was done, when the same number of glasses of water remained unassociated in both scenarios, Lucy intuitively responded that the two have the same taste, i.e., the same ratio. This erroneous way of comparing ratios, analogous to the erroneous additive principle, she extended to all situations, and it worked for her when the remaining glasses of water were different. However, when the remaining glasses of water were the same, the virtual scenario pointed out the error, which was incomprehensible to Lucy. At the close of the session, through group discussion, methods for comparing ratios were specified, and it was found that most students adopted the reasoning described. Some students were even surprised that the method failed. Since this exact situation was present in most students, we will call it a "proportionality illusion".

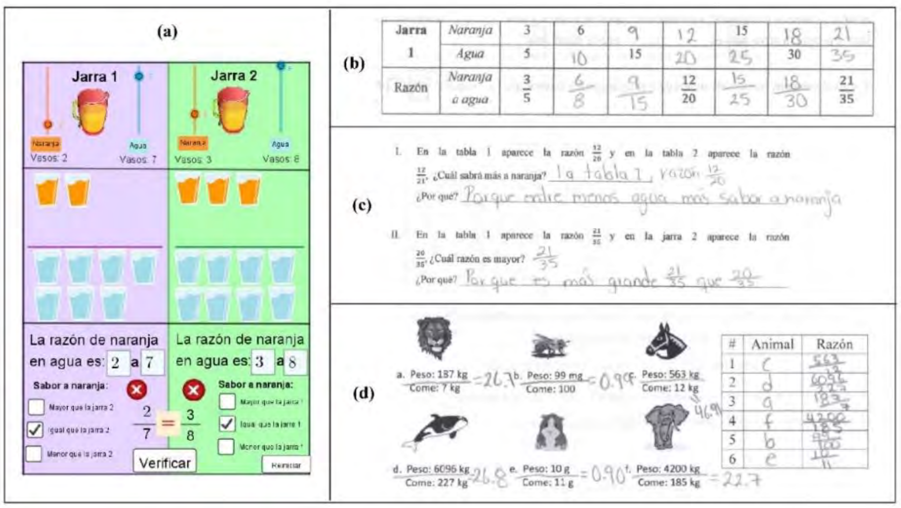

Figure 3. Evidence of the activities corresponding to Task 1.

The activity of completing tables of equivalent ratios is subject to the context (orange-water mixtures in the same proportion), but the multiplicative pattern that Lucy uses to fill the table is given in the mathematical domain; it is also observed that at the beginning, the additive reasoning persists (see Figure 3b). One way to compare equivalent ratios in the tables is to consider pairs of ratios that have equal numerators or denominators, and Lucy uses that fact (see Figure 3c) to make numerical judgments and gives a covariation argument based on the denominator of the ratios, so a referential level is evident.

Lucy uses the unit ratio method in application exercises in a context other than mixtures. Figure 3d shows a ratio ordering exercise (adapted from Lamon, 2020), which consists of ordering a set of animals about their weight. Lucy applies the unit ratio method to solve these problems. It is inferred that she has acquired a "model for" and progress from the referential level to the general level is glimpsed.

In this task, Lucy shows skills in posing ratios in different notations, comparing ratios, applying the multiplicative principle to obtain equivalent ratios, and using the unit ratio method to solve practical problems. At this level, students already possess proportional reasoning skills.

However, the data show that Lucy had a rootedness in additive reasoning in her knowledge structure, which she managed to modify and even consolidate the unit ratio method.

Results of task 2. "Zoom Totoro"

In the initial stage, processes of observation, measurement, and multiplicative principle are involved. The activity of calculating the dimensions of the image for different ratios is anchored to the context (situational level); however, following the pattern marks the way to the referential level since Lucy notices that to obtain the measurements of the replicated image, the measurements of the original image are multiplied by the similarity ratio (see table in Figure 4a).

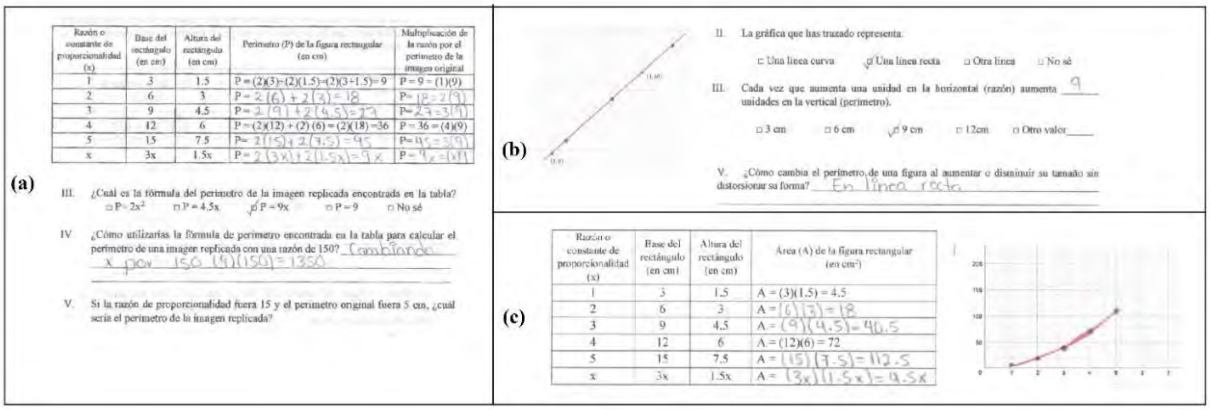

Figure 4. Evidence of the activities corresponding to Task 2.

In the table for calculating the perimeter of magnified images according to a similarity ratio, Lucy relies on the dimensions table. She departs from the context because the initial concept is related, in the first instance with the perimeter and the second with the area. Lucy calculates the perimeters for the proposed ratios by following the initial example in the table until she arrives at the linear expression P=9x and applies the "model of" found (see Figure 4a). To plot the ratio-perimeter relationship, Lucy transits between the tabular-graphical representations and manages to see the linear variation (see Figure 4b). As for the ratio-area relationship, she completes the table and makes the graph, describing it as curved (see Figure 4c). However, she does not conclude in the "model of" sought (a quadratic relationship) and does not get to the contrast between perimeter and area.

In performing this task, Lucy showed the ability to move between tabular, graphical and algebraic representations of proportionality; identifying the value of the constant of proportionality in the case of perimeter, and also obtaining a model that describes the particular case. However, Lucy is not able to arrive at a general model.

Results of task 3. "Autos"

Initially, the activities in this VIDS, are of instrumentation and contextualization. Lucy identifies the characteristics of movements, both at a constant speed and constant acceleration. Her previous and informal ideas about such concepts were modified after interacting with the VIDS and observing the change in the variables, their relationship, and numerical observations.

As shown in Figure 5c, Lucy transitions correctly between tabular and graphical representations and identifies linear and nonlinear features in both the graph and tables. In this task, Lucy sees relationships between variables that go beyond the initial context by identifying a "model of", using it, and concluding that the variation is proportional (in the car) and quadratic (in the patrol car); also, she distinguishes linear and nonlinear behaviors in the representations. However, Lucy failed to propose a model for constant acceleration.

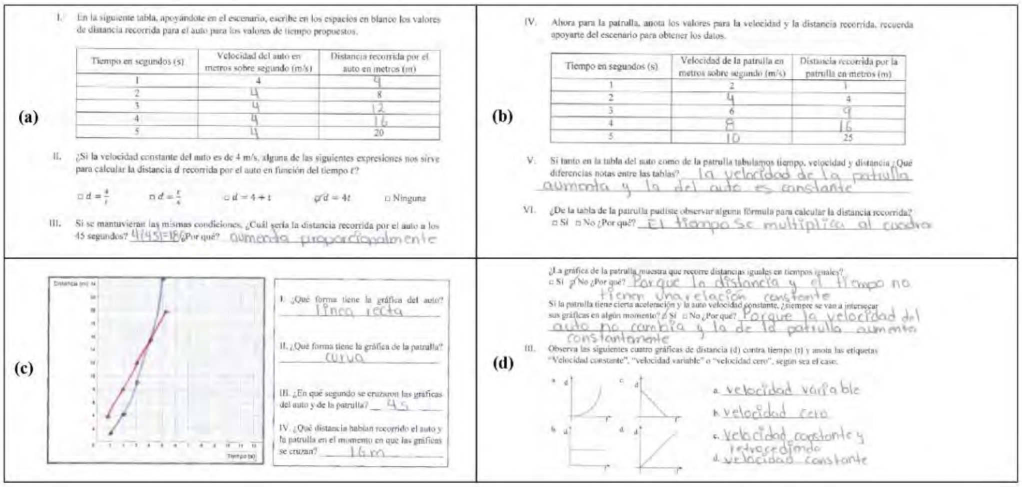

Figure 5. Evidence from Task 3 activities.

By visualizing and comparing the graphs of the movements for various parameters of speed and acceleration, Lucy interprets growth and variation, arguing: "if equal distances are traveled in equal times, distance and time have a constant relationship", and that the growth of acceleration will always exceed that of speed because "the speed of the car does not change and that of the patrol car is constantly increasing" (see Figure 5d). In Lucy's reasoning, we observe a conceptual enrichment that transcends the context, and although they are not numerical or algebraic manipulations, they are of a general nature. They are general reasonings that apply to any URM and UARM context. In the words of Freudental (2002), "The relationship between constant ratio and linearity is a feat of vertical mathematization" (p.43).

In performing this task, Lucy shows the ability to distinguish a linear situation from a nonlinear situation and identify the distinctive features of each in different representations. Thus, she shows clear progress in her proportional reasoning.

Discussion and conclusion

In Task 1, Lucy had difficulties comparing two ratios whose difference between numerator and denominator was the same, 2/7 and 3/8; that idea changed with the task. We infer that there are difficulties in students' understanding that emerge with this activity. According to Sierpinska (2004), "tasks should be able to reveal students' most hidden misconceptions" (p. 14). In Task 2, the objective is to confront the illusion of linearity regarding the confusion students present when assuming that area and volume have a linear relationship with the similarity ratio. However, the activities do not prove to be sufficient and should be redesigned. It is necessary to add geometric figures so that students distinguish the linear relationship of the perimeter with the quadratic relationship of the area and the cubic relationship of volume in a more playful geometric way. In Task 3, the detailed analysis of Lucy's responses sets the tone for more in-depth activities that bring out the "models for" and generalization.

The detailed analysis of Lucy's answers in each task shows us the learning she acquires to work with ratios, move between proportional representations and contrast them with non-linear phenomena in different contexts. The above gives us elements to answer our research question and gives us sufficient guidelines for redesigning the activities organized by the HLT. On the other hand, it provides us with enough evidence to discern which of the tasks should be deepened in order to achieve that students show better progress in the levels of vertical mathematization. That is to say, the diversity of contexts favors horizontal mathematization. Considering the times in the curriculum, the designers of didactic sequences must discern what is most convenient in each situation since reducing the number of contexts could increase the opportunity to achieve greater depth in the mathematization process. In this sense, we consider that there is also a need for fully mathematized activities without reference to any context that deals with the formal level.

In this development research, we try to find teaching ways to address the concepts involved in proportional reasoning through approaches to linear functions and their representations (symbolic, tabular, and graphical). In this sense, the first axis of the proposal is to prioritize the concept of ratio as a precursor to accessing equivalence, comparison, and ratio tables, which leads inexorably towards linear functions; the second axis is that the student faces diverse contexts to explore proportional situations in their different representations and the third axis consists of considering the phenomenon of the illusion of linearity. It is intended that students experience realistic situations, both linear and nonlinear, and question linearity (or the absence of it) each time they face a problem, reacting in a reasoned manner according to the characteristics of the situation.

Concerning the influence of technology in the study, it is clear that its use makes it possible to simulate and replicate everyday situations that can be problematized and provide pragmatic and epistemic advantages. For example, the use of VIDS makes it possible to present random data to the student, interact with contexts dynamically, show mathematical objects in different representations and validate results. As described in the analysis, the students' experience with VIDS made it possible to observe misconceptions that would go unnoticed, probably in traditional forms of teaching. On the other hand, interacting with the VIDS provoked an interest that went beyond the mathematical context posed, involving them with problems derived from the tasks.

The results are not conclusive; however, they encourage us to continue this work. It is necessary to mention that we had an external variable to consider since the students were returning to face-to-face classes after a long pandemic period.

En este artículo presentamos un avance de investigación doctoral en donde exploramos formas alternativas de enseñanza que promuevan el razonamiento proporcional en estudiantes mexicanos entre 14 y 15 años, con apoyo de la tecnología digital. Diseñamos una secuencia de actividades que pretende significar los conceptos de razón y proporción, en sus diversas representaciones y desde la perspectiva de las funciones lineales. Para el diseño de tareas se emplearon elementos del marco de la Educación Matemática Realista y de la Didáctica de Cuevas-Pluvinage. Los objetivos de aprendizaje y las actividades propuestas fueron organizadas mediante una trayectoria hipotética de aprendizaje. A reserva de presentar los resultados del grupo, seleccionamos aleatoriamente a una estudiante para presentar el análisis de los resultados obtenidos. Encontramos que las tareas promovieron un razonamiento proporcional.

Palabras clave: Educación secundaria, tecnología, números racionales y razonamiento proporcional

Introducción

Los conceptos asociados al razonamiento proporcional, tales como fracción, razón y proporción son clave en la educación matemática en los niveles básicos, ya que son pilares de las matemáticas superiores y su aplicación es transversal a otras disciplinas (Lamon, 2007). Dada la importancia de la problemática, coincidimos con diversos trabajos (Lesh et al., 1988; Adjiage y Pluvinage, 2007), en que la falta de éxito en el manejo de las razones y proporciones es causada por un pobre desarrollo de las habilidades proporcionales, así como una excesiva aritmetización de los procesos involucrados. Como consecuencia a la carencia de sentido al abordar situaciones proporcionales en el aula, se ha observado una tendencia de los estudiantes a aplicar el modelo proporcional en situaciones donde no es aplicable, lo que se ha denominado ilusión de la linealidad (De Book et al., 2002).

El problema al que se enfrenta la comunidad es cómo enseñar a los estudiantes a razonar proporcionalmente. El acercamiento escolar más frecuente hacia la proporcionalidad se da desde una perspectiva aritmética, separándola de sus vínculos con las relaciones funcionales y sus múltiples representaciones. En nuestra propuesta rescatamos los resultados de investigación en esta línea y ponemos a prueba un diseño de enseñanza basado en un acercamiento funcional mediante contextos realistas y apoyado en la tecnología digital; con lo cual, se espera obtener ideas que aporten al diseño de actividades que promuevan el razonamiento proporcional

Marco teórico

El enfoque de enseñanza de la Educación Matemática Realista (EMR) destaca que las situaciones realistas son fundamentales para el aprendizaje de las matemáticas, ya que las matemáticas son parte de una construcción histórica y cultural (Freudenthal, 2002). En esta corriente, los estudiantes son participantes activos en el desarrollo de su propio aprendizaje y en la construcción de modelos que matematizan la realidad a partir de un contexto cotidiano (Gravemeijer, 2004). En la EMR se identifican dos tipos de matematización: la matematización horizontal, donde los estudiantes transitan de lo real a lo simbólico para dar respuesta a problemas del propio contexto; y la matematización vertical, donde los estudiantes realizan conexiones conceptuales y crean estrategias para resolver problemas dentro del sistema matemático, que pueden o no referirse al contexto inicial. Es decir, se separan del contexto hacia el camino de la abstracción y la generalización (Van den Heuvel-Panhuizen y Drijvers, 2020).

En cuanto al razonamiento proporcional, partimos de la definición de Lesh et al. (1988):

> El razonamiento proporcional es la habilidad que permite trabajar con situaciones que impliquen variación, cambio, sentido de covariación y comparación múltiple, además de la capacidad de procesar y almacenar mentalmente varias piezas de información; también está ligado a la inferencia y a la predicción e involucra tanto métodos cualitativos como cuantitativos. (p. 93)

Acorde a este fundamento, asumimos como válido el modelo de razonamiento proporcional propuesto por Modestou y Gagatsis (2010) y reconocemos la necesidad de investigación a la que invocan los estudios sobre la ilusión de la linealidad de De Bock et al. (2002). En nuestro estudio identificamos a las habilidades proporcionales como aquellas facultades que son consideradas necesarias para que una persona posea un razonamiento proporcional sólido. Lobato et al. (2010) y Weiland et al. (2021) indican que esas habilidades deben incluir: 1) Atender y coordinar dos cantidades que varían de forma dependiente, 2) Reconocer y utilizar las estructuras de las situaciones proporcionales (razón unitaria, constante de proporcionalidad, linealidad), 3) Identificar el invariante en una proporción, 4) Comprender la proporcionalidad desde múltiples representaciones, 5) Distinguir las situaciones lineales de las no lineales. Consideramos a estas cinco habilidades como clave para nuestro estudio y son las que invocamos con el término habilidades proporcionales.

Para englobar el marco teórico y estructurar la intervención nos apoyamos del enfoque de Investigación Basada en Diseño (IBD) propuesto por Bakker (2018). Dado que en la IBD el diseño y la innovación en el aula son aspectos clave, se propone el uso de tecnología digital como medio que permita a los estudiantes interactuar con múltiples representaciones, facilitar la simulación de situaciones realistas y comprobar sus propios resultados en Entornos Didácticos Virtuales Interactivos (EDVI).

Para organizar el diseño de las tareas que guían a los estudiantes en el proceso de matematización, nos basamos en la Trayectoria Hipotética de Aprendizaje (THA) (Simon, 1995). Para el diseño de las actividades que integra cada tarea nos apoyamos del marco didáctico Cuevas-Pluvinage, que aporta una ingeniería didáctica que rescata principios didácticos de la escuela activa y Piaget adaptados a la educación matemática (Cuevas y Pluvinage, 2003).

Coincidimos con Sierpinska (2004) en que “reportar las tareas es necesario para probar la eficacia del enfoque de enseñanza” (p. 13). Según la autora, la problematización, justificación y discusión de las tareas inicia con el análisis a priori del diseño, sin embargo, la problematización es aún más sustancial y fructífera en el análisis a posteriori; es decir, después de la experimentación en el aula. En este orden de ideas, en este informe mostramos la problematización tanto en la fase de diseño como en la fase de análisis retrospectivo, ya que da pautas para el rediseño de nuestras tareas.

Una de las labores más complejas para un docente es tratar de implementar principios de una didáctica de corte constructivista en un aula tradicional con los elementos usuales. Por ejemplo, introducir un concepto matemático mediante la problematización de una situación cotidiana, en un aula tradicional, resulta casi imposible. Una posible solución es contar con un escenario virtual que simule un fenómeno real, en el que los estudiantes puedan interactuar con diversos contextos de forma dinámica y, además, su uso permita la construcción de conocimiento matemático (Moyer et al., 2016). De este modo, se dota a los estudiantes de la oportunidad de acción, en donde cada estudiante puede aprender a su propio ritmo. La tecnología digital brinda al estudiante y al profesor de una especie de laboratorio portátil, al utilizar diversos dispositivos, como móviles, tabletas, etc.

Las consideraciones anteriores nos conducen a la pregunta de investigación: ¿Cómo diseñar una secuencia didáctica, en contextos realistas mediados por la tecnología, que ayude a los estudiantes a desarrollar su razonamiento proporcional y les permita progresar en los niveles de matematización de la EMR?

Metodología

Con base en nuestro marco metodológico, el enfoque de IBD utilizado consta de las siguientes fases: preparación y diseño, experimento de enseñanza y análisis retrospectivo.

Fase de preparación y diseño

En esta fase se diseñaron y desarrollaron: 1) Un pretest para recabar conocimientos previos de los estudiantes. 2) Una THA que guía el proceso de enseñanza y marca los objetivos de aprendizaje. 3) Tres secuencias de actividades didácticas con sus respectivos EDVI "Naranjada", "Zoom Totoro" y "Autos". 4) Una encuesta para indagar acerca de la perspectiva de los estudiantes en su experiencia con el uso de los EDVI y las actividades de las hojas de exploración y aprendizaje guiado (HEAG). El pretest y la encuesta final se alojaron en formularios de Google para responder en casa con el fin de ahorrar tiempo de aula.

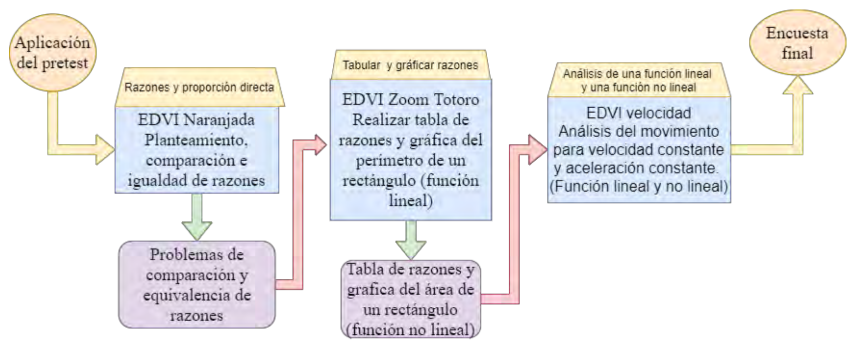

Figura 1: Diseño de la ruta didáctica que guía la secuencia de instrucción

Tarea 1. El contexto de la tarea consiste en comparar propuestas de mezcla de zumo de naranja y agua (ver figura 2a y 2b). El objetivo es que los estudiantes aprendan: a plantear, comparar y determinar equivalencia, entre razones; así como generar tablas de razones equivalentes e identificar la constante de proporcionalidad. Finalmente se realiza una actividad extra para aplicar el conocimiento aprendido en un contexto diferente. Las actividades que se realizan son: expresar una razón en notaciones diferentes, por ejemplo, 3 vasos de jugo por cada 5 de agua: 3 a 5, 3:5 y 3/5). 2) Coordinar la covariación entre dos variables, dada una razón de A vasos de naranja por cada B de agua, el sabor es más intenso a naranja si A aumenta o si B disminuye. 3) Comparación de dos razones. Dadas dos propuestas aleatorias de naranjada con razones de naranja en agua A:B y C:D, determinar cuál tendrá un mayor sabor a naranja.

Tarea 2. La tarea consiste en realizar un efecto "zoom" para reducir o aumentar una imagen de figuras Totoro acorde con una razón de semejanza que se introduce en una casilla de entrada (ver figura 2c). El objetivo es que los estudiantes realicen actividades de semejanza utilizando la constante de proporcionalidad. También, se pretende afrontar el problema de la ilusión de la linealidad al, tabular y graficar, las relaciones razón-perímetro (lineal) y razón-área (cuadrática), con el fin de conducir a los estudiantes hacia la comparación de ambos modelos.

Tarea 3. El contexto de la tarea consiste en visualizar un auto que se mueve a una velocidad constante superior al límite permitido y una patrulla que inicia una persecución con aceleración constante en el momento que el auto pasa a su lado (ver figura 2d). El objetivo es que los estudiantes interactúen con el EDVI mientras describen, analizan y comparan las características y las representaciones de los dos movimientos, es decir, el movimiento rectilíneo uniforme (MRU) y el movimiento rectilíneo uniformemente acelerado (MRUA). De este modo, los estudiantes deben identificar los modelos presentes (lineal y cuadrático) para comparar ambos comportamientos y transitar en sus representaciones.

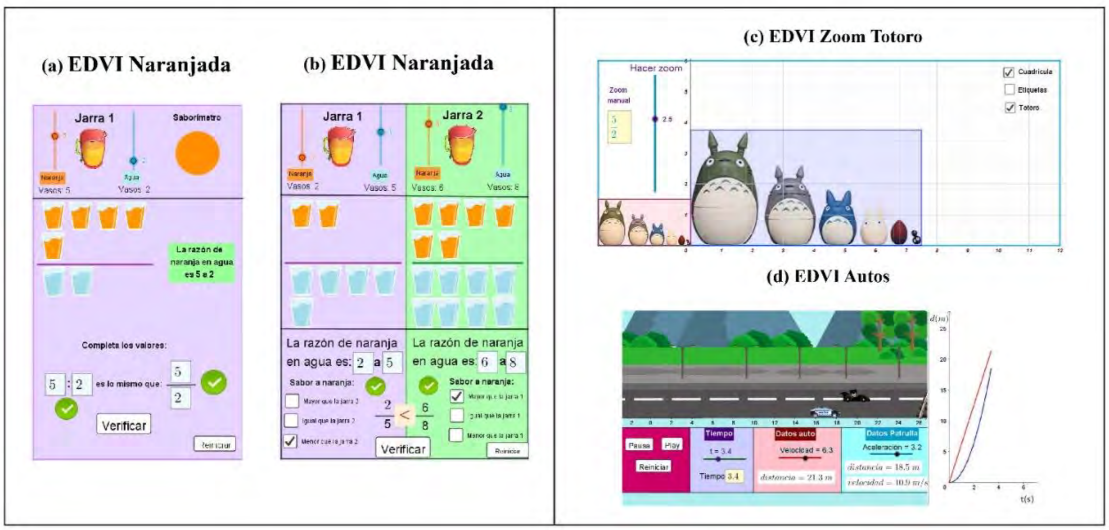

Figura 2. EDVI´s utilizados en la secuencia de enseñanza

Fase de experimento de enseñanza

El estudio se realizó mediante una intervención presencial en dos grupos de una Escuela Secundaria en México. Participaron en el estudio 35 estudiantes (14-15 años) en el invierno de 2021. La instrucción se dividió en tres sesiones de 90 minutos en un salón de cómputo de la escuela. Cada estudiante contaba con una computadora personal que tenía precargados los EDVI, también cada estudiante contaba con sus respectivas HEAG. La intervención estuvo a cargo del primer autor, apoyado por el profesor del grupo y un asistente de investigación. En las sesiones se promovió un aprendizaje colaborativo y se discutieron las respuestas en grupo.

Resultados y análisis retrospectivo

De acuerdo con Freudenthal (2002), el contexto y el diseño didáctico deben permitir a los estudiantes transitar de la matematización horizontal hacia la matematización vertical. Gravemeijer (2004) identifica cuatro niveles hacia la matematización vertical: N1) Nivel situacional. Se interpreta y organiza la realidad mediante razonamientos matemáticos informales y dependientes del contexto (matematización horizontal). N2) Nivel referencial. Se crean esquemas y modelos que tienen sentido dentro del contexto inicial, inicia la matematización vertical al surgir “modelos de...”. N3) Nivel general. Se relacionan los conceptos, se generan estrategias que se separan del contexto, el razonamiento se da en el mundo matemático y surgen “modelos para...”. N4) Nivel formal. Se comprenden los conceptos mediante su simbolismo matemático, ya no se necesita apoyo de algún contexto real, la reflexión ha transitado al mundo matemático y se puede prescindir de los modelos.

A reserva de presentar los resultados del grupo, seleccionamos aleatoriamente a una estudiante, que llamaremos Lucy, para presentar un análisis detallado de los resultados de las tareas y su evaluación mediante los niveles de matematización vertical propuestos en la EMR.

Resultados de la Tarea 1. “Naranjada”

Para realizar las actividades de la naranjada, Lucy utiliza sus conocimientos previos, es decir, las actividades la conducen a una matematización horizontal, asimilando correctamente las tres notaciones para razón. Además, encontró que a una propuesta aleatoria de naranjada la intensidad de sabor depende de un proceso de covariación. En esta fase Lucy se encuentra en el nivel situacional, porque se mueve dentro del mundo numérico solo para interpretar el contexto y emitir un juicio, la matematización horizontal es un ir y venir del contexto al mundo matemático.

Un hallazgo se dio cuando el EDVI mostró a Lucy el siguiente par de razones de naranja a agua: 2:7 y 3:8 (ver figura 4a), Lucy Realizó mentalmente una biyección 1 a 1 entre los vasos de naranja y los vasos de agua. Una vez hecha la biyección, cuando en ambos escenarios quedó el mismo número de vasos de agua sin asociar, Lucy respondió, intuitivamente, que las dos tienen el mismo sabor, es decir, la misma proporción. Esta forma errónea de comparar razones, análoga al erróneo principio aditivo, la extendió a todas las situaciones, y le funcionó cuando los vasos restantes de agua fueron distintos. No obstante, cuando los vasos restantes de agua fueron iguales el EDVI señaló un error, incomprensible para Lucy. Al cierre de la sesión, mediante discusión grupal, se precisaron métodos para comparar razones y se comprobó que la mayoría de los estudiantes adoptaba el razonamiento descrito, e incluso algunos estudiantes se mostraron sorprendidos de que el método fallara. Como esta misma situación se presentó en la mayoría de los estudiantes la llamaremos “ilusión de la proporcionalidad”.

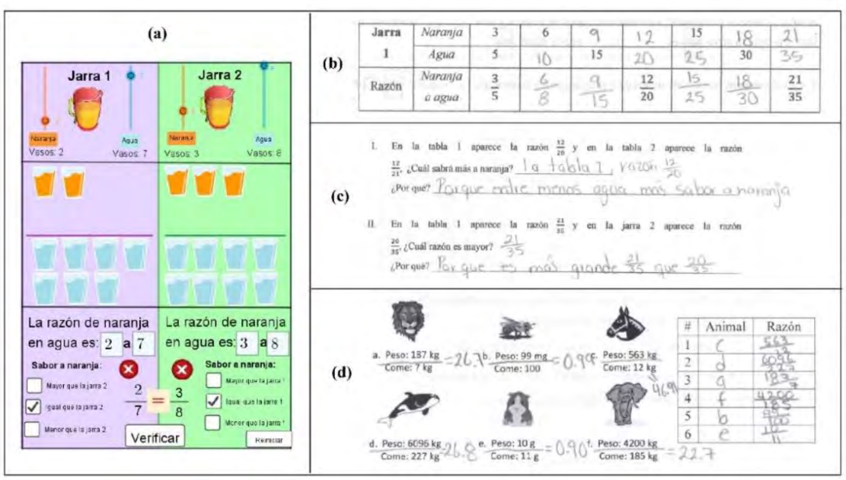

Figura 3. Evidencia de las actividades correspondientes a la Tarea 1

La actividad de completar tablas de razones equivalentes está sujeto al contexto (mezclas naranja-agua en la misma proporción), pero el patrón multiplicativo que Lucy usa para llenar la tabla se da en el ámbito matemático, también se observa que al inicio persiste el razonamiento aditivo (Ver figura 3b). Una manera de comparar las razones equivalentes de las tablas es considerar pares de razones que tengan numeradores o denominadores iguales, Lucy se vale de ese hecho (ver figura 3c) para hacer juicios numéricos y da un argumento de covariación basado en el denominador de las razones, por lo que es claro un nivel referencial.

En los ejercicios de aplicación, posteriores a la actividad con el EDVI, Lucy utiliza eficientemente el método de la razón unitaria. En la figura 3d se muestra un ejercicio de ordenamiento de razones (adaptado de Lamon, 2020), que consiste en ordenar a un conjunto de animales en relación con su peso. Lucy aplica el método de la razón unitaria para resolver problemas en contextos diferentes, se infiere que ha adquirido un “modelo para” y se vislumbra un progreso del nivel referencial al nivel general.

En esta tarea, Lucy muestra habilidades para plantear razones en distintas notaciones, comparar razones, aplicar el principio multiplicativo para obtener razones equivalentes y utilizar el método de la razón unitaria para resolver problemas prácticos. En este nivel, los estudiantes ya poseen habilidades de razonamiento proporcional. Sin embargo, los datos muestran que Lucy tenía, en su estructura de conocimientos un arraigo en el razonamiento aditivo; el cual se logró modificar, e incluso se consolidó el método de la razón unitaria.

Resultados de la tarea 2. “Zoom Totoro”

En la etapa inicial se involucran procesos de observación, medida y principio multiplicativo. La actividad de calcular las dimensiones de la imagen para distintas razones está anclado al contexto (nivel situacional), sin embargo, al seguir el patrón se marca el camino al nivel referencial, ya que Lucy nota que para obtener las medidas de la imagen replicada se multiplican las medidas de la imagen original por la razón de semejanza (ver tabla en la figura 4a).

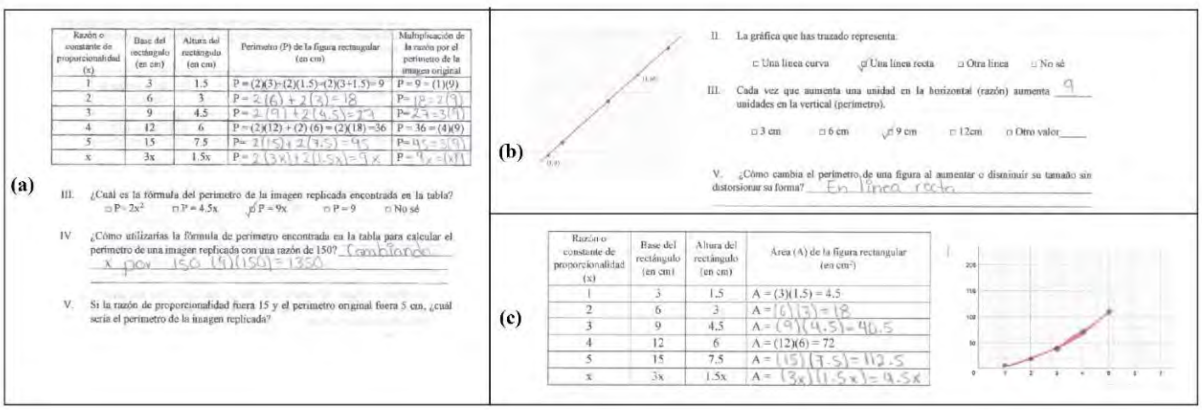

Figura 4. Evidencia de las actividades correspondientes a la Tarea 2

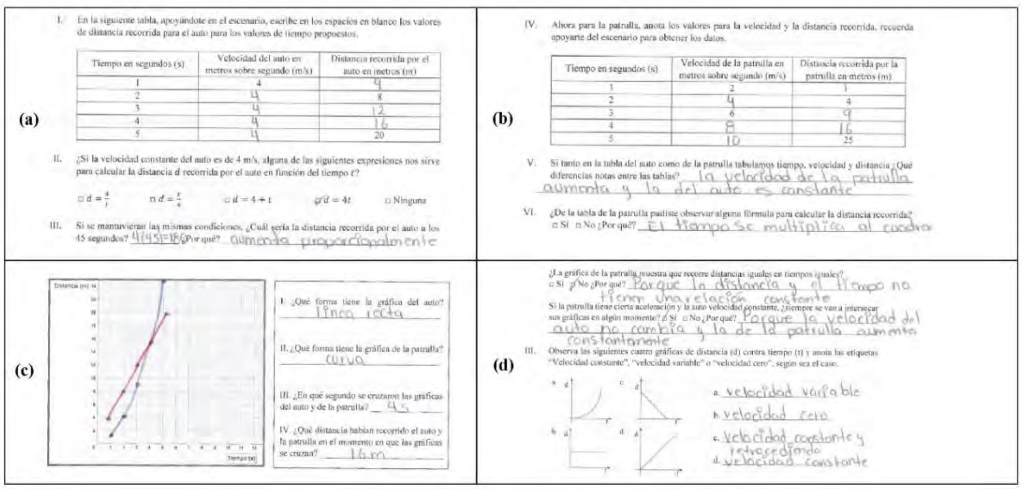
En la tabla para calcular el perímetro de imágenes aumentadas según una razón de semejanza, Lucy se basa en la tabla de dimensiones y se aleja del contexto debido a que el concepto inicial se relaciona, en primera instancia con el perímetro, y en segunda con el área. Lucy calcula los perímetros para las razones propuestas siguiendo el ejemplo inicial de la tabla hasta llegar a la expresión lineal P=9x y aplica el “modelo de” encontrado (ver figura 4a). Para graficar la relación razón-perímetro, Lucy transita entre las representaciones tabular-gráfica y logra ver la variación lineal (ver figura 4b). En cuanto a la relación razón-área, completa la tabla y realiza la gráfica, describiendo que es curva (ver figura 4c). Sin embargo, no concluye en el “modelo de” buscado (relación cuadrática) y no se llega a contrastar entre perímetro y área.

Al realizar esta tarea, Lucy mostró la habilidad para transitar entre las representaciones tabular, gráfica y algebraica de la proporcionalidad; identificando el valor de la constante de proporcionalidad en el caso del perímetro, y además obteniendo un modelo que describe el caso particular. Sin embargo, no se logra avanzar hacia el nivel general.

Resultados de la tarea 3. "Autos"

De inicio, las actividades en este EDVI, son de instrumentación y contextualización. Lucy identifica las características de los movimientos, tanto a velocidad constante como a aceleración constante. Sus ideas previas e informales sobre tales conceptos se modificaron después de interactuar con el EDVI y observar el cambio en las variables, su relación y al realizar observaciones numéricas.

Como se puede observar en la figura 5c, Lucy transita correctamente entre las representaciones tabulares y gráficas, y también identifica características lineales y no lineales, tanto en la gráfica como en las tablas. En esta tarea Lucy ve relaciones entre las variables que van más allá del contexto inicial, al identificar un "modelo de", utilizarlo y concluir que la variación es proporcional (en el auto) y cuadrático (en la patrulla); también, distingue los comportamientos lineales y no lineales en las representaciones. Sin embargo, Lucy no logró proponer un modelo para la aceleración constante.



(a)

I. En la siguiente tabla, apoyándote en el escenario, escribe en los espacios en blanco los valores de distancia recorrida para el auto para los valores de tiempo propuestos.

Tiempo en segundos (s)	Velocidad del auto en metros sobre segundo (m/s)	Distancia recorrida por el auto en metros (m)
1	4	4
2	4	8
3	4	12
4	4	16
5	4	20

II. ¿Si la velocidad constante del auto es de 4 m/s, alguna de las siguientes expresiones nos sirve para calcular la distancia d recorrida por el auto en función del tiempo t?

□ $d = \frac{4}{t}$ □ $d = \frac{t}{4}$ □ $d = 4 + t$ ☑ $d = 4t$ □ Ninguna

III. Si se mantuvieran las mismas condiciones, ¿Cuál sería la distancia recorrida por el auto a los 45 segundos? 4(45)=180 ¿Por qué? aumenta proporcionalmente

(b)

IV. Ahora para la patrulla, anota los valores para la velocidad y la distancia recorrida, recuerda apoyarte del escenario para obtener los datos.

Tiempo en segundos (s)	Velocidad de la patrulla en metros sobre segundo (m/s)	Distancia recorrida por la patrulla en metros (m)
1	2	1
2	4	4
3	6	9
4	8	16
5	10	25

V. Si tanto en la tabla del auto como de la patrulla tabulamos tiempo, velocidad y distancia ¿Qué diferencias notas entre las tablas? la velocidad de la patrulla aumenta y la del auto es constante

VI. ¿De la tabla de la patrulla pudiste observar alguna fórmula para calcular la distancia recorrida? □ Sí □ No ¿Por qué? El tiempo se multiplica al cuadro

(c)

I. ¿Qué forma tiene la gráfica del auto? línea recta

II. ¿Qué forma tiene la gráfica de la patrulla? curva

III. ¿En qué segundo se cruzaron las gráficas del auto y de la patrulla? 4 s

IV. ¿Qué distancia habían recorrido el auto y la patrulla en el momento en que las gráficas se cruzan? 16 m

(d)

¿La gráfica de la patrulla muestra que recorre distancias iguales en tiempos iguales? □ Sí ☑ No ¿Por qué? Porque la distancia y el tiempo no tienen una relación constante

Si la patrulla tiene cierta aceleración y la auto velocidad constante, ¿siempre se van a intersecar sus gráficas en algún momento? ☑ Sí □ No ¿Por qué? Porque la velocidad del auto no cambia y la de la patrulla aumenta constantemente

III. Observa las siguientes cuatro gráficas de distancia (d) contra tiempo (t) y anota las etiquetas "Velocidad constante", "velocidad variable" o "velocidad cero", según sea el caso.

a. velocidad variable
b. velocidad cero
c. velocidad constante y retrocediendo
d. velocidad constante

Figura 5. Evidencia de las actividades correspondientes a la Tarea 3

Al visualizar y comparar las gráficas de los movimientos para diversos parámetros de velocidad y aceleración, Lucy interpreta el crecimiento y la variación, al argumentar: "si se recorren distancias iguales en tiempos iguales, distancia y tiempo tienen una relación constante", y que el crecimiento de la aceleración siempre superará al de la velocidad porque "la velocidad del auto no cambia y la de la patrulla aumenta constantemente" (ver figura 5d). En los razonamientos de Lucy se observa un enriquecimiento conceptual que trasciende al contexto y, aunque no son manipulaciones numéricas o algebraicas, son de carácter general. Es decir, son razonamientos generales que aplican para cualquier contexto de MRU y MRUA. En palabras de Freudental (2002), "La relación entre la razón constante y la linealidad es una hazaña de matematización vertical" (p.43).

Al realizar esta tarea, Lucy muestra la habilidad de distinguir una situación lineal de una situación no lineal, e identificando los rasgos distintivos de cada una en distintas representaciones. Con lo cual, muestra claros progresos en su razonamiento proporcional.

Discusión y conclusión

En la Tarea 1 Lucy tuvo dificultades para comparar dos razones cuya diferencia entre numerador y denominador era la misma, 2/7 y 3/8, esa idea cambió con la tarea, inferimos que hay dificultades en la comprensión de los estudiantes que emergen con esta actividad, de acuerdo con Sierpinska (2004), "las tareas deben ser capaces de revelar las concepciones erróneas más ocultas de los estudiantes" (p. 14). En la Tarea 2 el objetivo es confrontar la ilusión de la linealidad, respecto a la confusión que presentan los estudiantes al suponer que el área y el volumen guardan una relación lineal con la razón de semejanza. Sin embargo, las actividades no dan muestra de ser suficientes por lo que deben rediseñarse. Es necesario añadir figuras geométricas, para que los estudiantes distingan la relación lineal del perímetro con la cuadrática del área y la cúbica del volumen, de una manera geométrica más activa. En la Tarea 3, el análisis detallado sobre las respuestas de Lucy nos marca la pauta para profundizar en las actividades que hagan surgir los "modelos para" y se logre la generalización.

El análisis detallado de las respuestas de Lucy en cada tarea da muestras del aprendizaje que adquiere para trabajar con razones, transitar en representaciones proporcionales y contrastarlas con fenómenos no lineales en diferentes contextos. Lo anterior nos da elementos para responder nuestra pregunta de investigación y nos da pautas suficientes para el rediseño de las actividades que organiza la THA en cada una de las tareas propuestas. También, nos aporta evidencia suficiente para discernir en cuál de las tareas, y de qué forma, se debe profundizar para lograr que los estudiantes muestren mejores progresos en los niveles de matematización vertical. Es decir, la diversidad de contextos favorece la matematización horizontal (nivel situacional), en consecuencia, considerando los tiempos en el currículo, los diseñadores de secuencias didácticas debemos discernir qué es lo más conveniente en cada situación, ya que al reducir el número de contextos podría aumentar la oportunidad de lograr mayor profundidad en el proceso de matematización. En este sentido, consideramos que también son necesarias actividades totalmente matematizadas sin referencia a ningún contexto que den cuenta del nivel formal.

En esta investigación en desarrollo, tratamos de encontrar vías de enseñanza para abordar los conceptos involucrados en el razonamiento proporcional. Primero con acercamientos hacia la razón y la proporción con las funciones lineales y sus representaciones (simbólica, tabular y gráfica). En este sentido, un primer eje de la propuesta es priorizar el concepto de razón como precursor para acceder a la equivalencia, la comparación y las tablas de razones, lo cual conduce inexorablemente hacia las funciones lineales; un segundo eje es que el estudiante se enfrente a diversos contextos para explorar situaciones proporcionales en sus distintas representaciones y el tercer eje consiste en considerar el fenómeno de la ilusión de la linealidad. Se intenta que los estudiantes experimenten situaciones realistas tanto lineales como no lineales y cuestionen la linealidad (o la ausencia de ella) cada vez que se enfrenten a un problema, reaccionando de manera razonada de acuerdo con las características de la situación.

En cuanto a la influencia de la tecnología en el estudio, es claro que su uso permite simular y replicar situaciones cotidianas susceptibles de problematizarse, además de brindar ventajas pragmáticas y epistémicas. Por ejemplo, el uso de EDVI posibilita: presentar al estudiante datos aleatorios, interactuar con los contextos de forma dinámica, mostrar los objetos matemáticos en distintas representaciones y validar los resultados. Como se ha descrito en el análisis, la experiencia de los estudiantes con los EDVI permitió observar concepciones erróneas que, probablemente en formas de enseñanza tradicionales, pasarían inadvertidas. Por otro lado, interactuar con los EDVI provocó en los estudiantes un interés que iba más allá del contexto matemático planteado, involucrándose con problemas que se derivaban de las tareas.

Students exhibiting mature number sense make sense of numbers and operations, use reasoning to notice patterns, and flexibly select the most effective and efficient problem-solving strategies (McIntosh et al., 1997; Reys et al., 1999; Yang, 2005). Despite being highlighted in national standards and policy documents (CCSS, 2010; NCTM, 2000, 2014), students' mature number sense and its nomological network are not yet well specified. For example, how does students' mature number sense relate to their knowledge of fractions and their grade-level mathematics achievement? We analyzed 129 middle school students' scores on measures of mature number sense, fraction and decimal computation, and grade-level mathematics achievement. We found mature number sense to be measurably distinct from their fraction and decimal knowledge and uniquely associated with students' grade-level mathematics achievement.

Keywords: Number Concepts and Operations; Cognition; Assessment; Rational Numbers

Over the last three decades, "number sense" has emerged as a central goal of mathematics education. While high quality mathematics teachers were certainly already teaching in ways that helped students make sense of number and operations before then, "number sense" was not yet a commonly used term in mathematics education. In the late 1980's, government commissioned reports (e.g., National Research Council, 1989) and national curriculum frameworks (e.g., National Council of Teachers of Mathematics (NCTM), 1989) highlighted "number sense" as a core objective of K-12 mathematics education. Students showing strong mature number sense exhibit the disposition to *make sense of numerical situations* and use a rich conceptual understanding of number and operations to flexibly solve problems.

Despite being a central objective in mathematics education, there is little evidence in the literature on how students' mature number sense relates to other important psychological constructs in mathematics education. For example, how do students' levels of mature number sense relate to their grade-level mathematics achievement or their understanding of fractions? Without an understanding of the nomological network, it is harder for researchers to explain how students construct mature number sense, leaving educators without rigorous evidence on how best to address it within their own classrooms. In this study, we aimed to begin to address this gap in the literature by examining how middle school students' mature number sense relates to other theoretically related constructs, testing the hypothesis that mature number sense is both distinct from fraction and decimal computation and grade-level mathematics achievement and uniquely associated with students' grade-level mathematics achievement.

Background and Theoretical Framework

Number sense is a difficult construct to define (e.g., Berch, 2005). How the construct is operationalized and assessed looks very different across the disciplines of cognitive and developmental psychology, mathematics education, and special education (summarized in Whitacre et al., 2020). In this project, our construct of interest is what Whitacre et al. (2020) have termed *mature number sense*, which we define in line with McIntosh et al. (1992) as "a person's general understanding of number and operations along with the ability and inclination to use this understanding in flexible ways." This focus is distinct from research on approximate number sense (e.g., Dehaene, 2001) or early number sense (e.g., Jordan et al., 2009).

Perhaps to help facilitate operationalizing it in empirical research, mature number sense has often been subdivided into components (McIntosh et al., 1997; NCTM, 1989; Reys et al., 1999; Yang & Lin, 2015). Building from this prior work and in consultation with expert mathematics teachers, teacher educators, and mathematics education researchers, we specified a four-component framework of mature number sense (Kirkland et al., *under review*) as follows:

1. Understanding the effect of operations on numbers: Students demonstrating strong mature number sense recognize how the four core operations affect whole numbers as well as fractions and decimals. They understand that patterns observed with operations with whole numbers may not hold true for fractions and decimals between 0 and 1. Students use this understanding to efficiently estimate computational results and ensure the results make sense given the relationship between operations and rational numbers.
2. Using multiple representations of a number: Students demonstrating strong mature number sense are able to translate among multiple representations of rational numbers efficiently and flexibly to solve problems. Students recognize that fractions are numbers, for example, rather than separately perceiving the numerator and denominator. Students are able to use this understanding to translate between representations to make sense of numerical situations.
3. Understanding mathematical equivalence: Students demonstrating strong mature number sense understand the equal sign as a relational symbol, reflecting that the two sides of an equation are equal and interchangeable. Rather than approaching equations with an "operational" approach, students understanding equivalence recognize patterns across the equal sign and use this relational thinking to flexibly solve problems (c.f. Jacobs et al., 2007).
4. Understanding basic number concepts and number magnitude: Students demonstrating strong mature number sense have a rich conceptual understanding of fractions, decimals, and whole numbers. Students use their understanding of place value and rational number magnitude to efficiently estimate results using concepts such as unit fractions.

We hypothesized, similar to Yang (2019), that mature number sense would be an overarching hierarchical latent construct, with the four components each theoretically related to mature number sense. That is, a student's understanding of the effect of operations on a number reflects their mature number sense as well as a more specific understanding of how operations affect computational results. In our initial development of a brief assessment of mature number sense (Kirkland et al., *under review*), the structure of the response data reflected this hypothesized framework. A bifactor model with each component as a specific factor best fit the response data over other theoretically related models. We now aimed to use this brief assessment to further knowledge about mature number sense's nomological network, including other important psychological constructs in mathematics education.

Rationale for Current Study

Mature number sense has been measured and studied internationally over the last twenty-five years (summarized in Whitacre et al., 2020), most frequently in a single time point. Most of these studies comment on the "low" levels of students' mature number sense observed. However, few studies have analyzed its potential overlap with other related psychological constructs in mathematics education. Understanding how mature number sense fits together with constructs such as fraction computation and school mathematics achievement is important for establishing the construct validity of measures of mature number sense (Cronbach & Meehl, 1955). Throughout the literature, mature number sense is often contrasted with standardized school mathematics achievement and the algorithmic, overly procedural mathematics instruction common in schools (Whitacre et al., 2020). On the other hand, it is reasonable to hypothesize that students with strong mature number sense are flexible problem solvers with a deep understanding of number and operation and, thus, that they might do well on more "traditional" school assessments. Yang et al. (2008) is the only study we are aware of that examined this association. They found 5^{th} grade Taiwanese students' number sense were positively associated with school achievement, but there was no detail on how math achievement was measured (e.g., school grades, standardized tests, etc.). In addition, given Taiwanese students' strong performance on international standardized mathematics tests (ranked 5^{th} in world in PISA 2018) and its centralized education system (Lin et al., 2021), Taiwan may be a unique context to compare students' mature number sense and school math achievement.

To begin to address this gap in the literature, we aimed to study how US middle school students' mature number sense related to their grade-level mathematics achievement, controlling for a variety of other potentially related factors, including fraction knowledge and addition fluency. Our research questions were as follows: 1) Is the mature number sense of middle school students measurably distinct from their fraction and decimal computation skills as well as their grade-level mathematics achievement? and 2) Is mature number sense uniquely associated with students' standardized grade-level mathematics achievement, even after controlling for their fraction and decimal computation?

Methods

Participants

One hundred twenty-nine middle school (6^{th}-8^{th} grade) students from schools surrounding a university in the midwestern United States participated (45% identified as female; 67% identified as White, 13% Multiracial, 8% Black, and 4% Hispanic). Sessions took place after school hours in a local middle school *(N = 36)* or university building *(N = 93)*. Students were participants in timepoint 1 of a larger (still ongoing) longitudinal study. They completed eight measures over the course of two 45-minute sessions, scheduled about a week apart (median of 7 days between sessions). For this analysis, we focused on the four measures described below, but note that the results reported hold up to robustness checks that include the additional measures.

Measures and Procedure

Brief Assessment of Mature Number Sense (Kirkland et al., *under review*). This is an electronic, 24 item multiple-choice test of students' mature number sense, aligned with our theoretical framework detailed above. Items differ from a traditional curriculum and are designed to specially assess students' number sense. Each item has a time limit of 60 seconds and students are not allowed to use paper and pencil to discourage the use of traditional algorithms. Student's total sum score is used in the analyses. Figure 1 includes an example item for each of the four components in our mature number sense framework. In the validation analysis (Kirkland et al., *under review*), student scores on the brief assessment were reliable over time (r = 0.83) and had evidence from expert reviews, factor analyses, student think-alouds, and item response theory analyses to support our validity argument.

Massachusetts Comprehensive Assessment System (MCAS) Grade-Level Mathematics Test (2019). Students completed the released 2019 MCAS paper test appropriate for their grade level. This is a freely available standardized test designed to assess student proficiency with grade-level mathematics standards. Student scores are converted to percent correct because the maximum possible correct differs by grade level. Students had no time limit to complete each section of the test and could use scratch paper but not calculators.

Rational Numbers Measure (Powell, 2014). This is a 35-item paper and pencil test of students' computational skills with fractions, decimals, and percent. Students are asked to perform the four operations with both fractions and decimals, find common denominators of fractions, generate equivalent fractions, and connect representations of fractions, decimals, and percent (e.g., "Convert 2.08 to a percentage"). Students had 20 minutes to work. They could use scratch paper but not calculators. Students received 1 point for each correct response.

Addition Fluency Task (Geary et al., 1996). This measure includes all combinations of randomly presented single digit addition facts with the numbers 1-9. Students were tasked with solving as many correctly as they could in 1 minute. The order of the facts was predetermined randomly and then kept standard for all participants. Students received 1 point for each correct response.

Understanding the Effect of Operations on Numbers	**Number Concepts and Magnitude**
What is the best estimate for 26 * ¾ ? O Less than 26 O Equal to 26 O Greater than 26 O Can't know	Which fraction represents the largest amount? O 5/6 O 5/7 O 5/8 O 5/9

What is true about the number 2/5 (two-fifths)? O It is greater than ½ (one half). O It is the same as 2.5. O It is equivalent to 0.4 O It is less than 1/6 (one sixth).	47 + 16 + ___ = 16 + 8 + 47 O 8 O 63 O 71 O 4716

Figure 1: Sample Items Assessing Mature Number Sense Organized by Component

Data Analyses

To address the research question on whether mature number sense is measurably distinct from students' general mathematics achievement, we first calculated the zero-order correlations between the constructs. We predicted mature number sense to be most closely related to students' grade-level math achievement on the MCAS and scores on the Rational Numbers Measure. We expected mature number sense to be least closely related to addition fluency. We then ran a series of partial correlation analyses. We analyzed the correlation between mature number sense and both other constructs after controlling for students' addition fluency scores. We then analyzed the associations between students' grade-level math achievement, fraction and decimal computation, and mature number sense, controlling for each in turn. In each case, we predict the relationship between mature number sense and the other construct to remain significant, even after controlling for a strongly related third variable.

For additional evidence that mature number sense and fraction and decimal computation are distinct, we then conducted a series of factor analyses (Shaffer et al., 2016). We used a common method where we tested a constrained model with 2 latent factors set with a covariance equal to 1 and an unconstrainted model where the 2 latent factors are allowed to freely covary with each other. If the unconstrained model provides a better fit through a RMSEA test that is significant, then the two measures of interest can be said to be distinct. We tested these two models using a chi-squared, $\chi 2$, difference test. Due to each grade's different test for the MCAS, we are unable to perform this same analysis on grade-level mathematics achievement.

To address research question 2, we ran a partial correlation test on the relationship between grade-level mathematics achievement and fraction and decimal computation, controlling for mature number sense. We then ran a linear regression model, regressing mature number sense and other predictors measured in the study on students' grade-level mathematics achievement.

Findings

We first begin with the overall student performance on the measures in the study. Students solved on average 14.3 (*60%)* items correctly on our brief assessment of mature number sense (*SD* = 5.65). Overall, students performed slightly better on the brief assessment than in the original validation study (*M* = *56%* correct). Across the three grade levels, students solved on average 50% of the items correctly on the MCAS. Out of a maximum possible of 35 correct, students answered on average 9.74 items correct on the Rational Numbers measure. While this number may appear very low as a percentage correct (*28%*), this measure was designed by Powell to include many problems to help differentiate students' fraction and decimal computation up to the college level. Finally, on average, students answered correctly 19.48 (*SD* = 6.72) single-digit addition problems on the addition fluency task.

To begin to address research question 1, the zero-order correlations between the measured constructs are summarized in Table 1. As predicted, students' mature number sense scores correlated very highly with their fraction and decimal computation skills (*r* = 0.80) and grade-level mathematics achievement (*r* = 0.76), and this was significantly higher than the correlation with addition fluency (*r* = 0.49).

Table 1: Correlation Between Measures in Study

Construct	*M*	*SD*	1	2	3	4
1. Mature Number Sense	14.34	5.65	-			
2. MCAS – Grade-Level Achievement	50.00%	24%	0.76	-		
3. Fraction and Decimal Computation	9.74	7.21	0.80	0.66	-	
4. Addition Fluency	19.48	6.72	0.49	0.36	0.53	-

Controlling for students' addition fluency scores, students' mature number sense still correlated highly with their grade-level mathematics achievement (r =0.72, $t(126)$ = 11.52, p < .001) and their fraction and decimal computation (r =0.73, $t(126)$ = 11.90, p < .001). We then further examined the associations between each pair of these three mathematics-specific constructs. Controlling for students' fraction and decimal computation, their mature number sense scores still were significantly positively related with their grade-level achievement (r =0.52, $t(126)$ = 6.77, p < .001). The same was true when controlling for grade-level achievement and examining mature number sense's relationship with fraction and decimal computation (r =0.61, $t(126)$ = 8.59, p < .001). We would predict that if mature number sense and grade-level mathematics achievement are redundant constructs, this relationship would no longer be significant. Together, this all provides initial evidence that mature number sense is distinct from their grade-level mathematics achievement.

As discussed above, we then ran a series of confirmatory factor analyses for evidence on if mature number sense and fraction and decimal computation are distinct (Shaffer et al., 2016). These analyses provided evidence that the Rational Numbers Measure and the Brief Assessment of Mature Number Sense measure distinct constructs, χ^2 difference = 56.65, p < 0.001; *CIF* difference = 0.02 compared to benchmark of 0.002. This suggests the constructs, as measured in this study, are highly related, but not redundant.

To further examine the unique importance of mature number sense, we first tested the partial correlation between fraction and decimal computation and grade-level achievement. Interestingly, when controlling for students' mature number sense, there is no longer a significant correlation between the two other constructs (r =0.13, $t(126)$ = 1.51, p =0.13). We then ran a linear regression on students' grade-level mathematics achievement (Model $R^2 = 0.59$). Results from the model are summarized in Table 2. Students' mature number sense was significantly positively related ($B_{NS} = 0.03, p$ < .001) to students' grade-level mathematics achievement. However, students' fraction and decimal computation ($B_{RN} = 0.005, p$ =0.11) and addition fluency ($B_{Add} = -0.002, p$ =0.54) were not significantly related to achievement. To compare the relative importance of each regressor, we examined the semipartial correlation of each predictor in the model (Darlington & Hayes, 2016; Hayes & Rockwood, 2017). The semipartial correlation coefficient for mature number sense was significant (sr = 0.39, $t(126)$ = 4.74, p < .001). However, the semipartial correlation for fraction and decimal knowledge (sr = 0.09, $t(126)$ = 0.98, p = 0.33) was not significant. We can interpret the ratio of the two semipartial correlations (0.39/0.09 = 4.33) as a measure of the relative importance of each in explaining students' grade-level achievement. As another way to quantify mature number sense's importance, we ran an additional linear regression model with mature number sense removed from the model. The model R^2 dropped from 0.59 to 0.43 (adjusted R^2 from 0.58 to 0.42).

Table 2: Summary of Regression Model Predicting Grade-Level Mathematics Achievement

Variable	*B*	*SE*	*t*	*p*
(Intercept)	0.08	0.051	1.645	0.103
Mature Number Sense	0.03	0.004	6.78	<0.001
Fraction and Decimal Computation	0.005	0.003	1.61	0.11

Discussion and Implications

From the evidence presented here, students' mature number sense is distinct from their general grade-level mathematics achievement and fraction and decimal computation skills. It is not the same to say, for example, that a student has "strong number sense" and is "good with fraction operations." We also found students' mature number sense to be predictive of their mathematics achievement, above and beyond their computation skills with fractions and decimals. Mature number sense explained a significant portion of that association, suggesting that mature number sense is uniquely associated with students' math achievement.

It is perhaps surprising that mature number sense was a stronger predictor of grade level mathematics achievement than students' fraction and decimal computation, given the significance fraction knowledge in particular has been shown to play in students' mathematics achievement (e.g., Barbieri et al., 2021; Booth et al., 2014; Booth & Newton, 2012; Siegler et al., 2013). Fractions are often seen as a "gatekeeper" to success in algebra or later mathematics courses (e.g., Powell et al., 2019; Siegler & Pyke, 2013). However, we see in this study that middle school students' mature number sense was a more important factor than their knowledge of fractions and decimals. Perhaps students' ability to make sense of numbers and operations and use that knowledge flexibly to solve problems is a better indicator of future mathematics achievement than fraction or decimal computation skills. Further research is needed to understand the nomological network more fully, especially in a longitudinal setting where the potential mediating role of mature number sense can be accurately tested.

In reviewing the item level data from the brief assessment of mature number sense, students performed better overall on whole number items than those involving fractions and decimals. For example, 79% of students solved this whole number distributive property item (4 x 36 = 4 x (___ + 6)) correctly. However, only 36% of students correctly identified that the answer to $12 \div \frac{1}{5}$ would be greater than 12 whereas 50% of students said it would be less than 12. Across this and other items, students struggled estimating the effect of operations on fractions and decimals less than one, displaying a continued bias toward "rules" learned with whole number operations, such as multiplication always makes the answer bigger, division makes the answer smaller, and each number has a unique predecessor and successor (Fazio et al., 2016; Siegler, 2016). Greater attention is required to address these misconceptions that are often learned as "rules" in early elementary classrooms (Karp et al., 2015). Encouragingly, a greater number of students displayed accurate understanding of fraction and decimal magnitude. For example, 72% of students correctly identified $\frac{5}{6}$ as the largest among the following fractions: $\frac{5}{6}, \frac{5}{7}, \frac{5}{8}, \frac{5}{9}$. Such "common numerator" problems have been shown to be significantly more difficult for students than the much more frequently seen "common denominator" comparisons (Fazio et al., 2016).

Overall, we have initial evidence here to start to build a nomological network for mature number sense and its associated psychological constructs in mathematics education. This is an important step forward to future research more fully examining how mature number sense might lay a foundation for future mathematics achievement or whether improving mature number sense might be a more important target for instruction than, say, computational skills with fractions. This is, however, only one initial study with a sample of students that may not be wholly representative of middle school students more broadly. In addition, we only have evidence from a single time-point rather than longitudinal data to test if mature number sense precedes and predicts grade level mathematics achievement. By continuing to characterize mature number sense's nomological network, researchers can more fully explain how students develop understanding of important psychological constructs in mathematics education and provide rigorous evidence to educators on how to help ensure all students have the disposition to *make sense of numerical situations*.

THE PRIME NUMBER THEOREM AS A MAPPING BETWEEN TWO MATHEMATICAL WORLDS

Anderson Norton

Kyle Flanagan
Virginia Tech
flanaga5@vt.edu

This paper frames children's mathematics as mathematics. Specifically, it draws upon our knowledge of children's mathematics and applies it to understanding the prime number theorem. Elementary school arithmetic emphasizes two principal operations: addition and multiplication. Through their units coordination activity, children construct two mathematical worlds: an additive world and a multiplicative world. Understanding how children might map between their additive and multiplicative worlds provides insights into the prime number theorem. It also helps us appreciate the power of children's mathematics, constructed through the coordination of their own mental actions.

Keywords: Cognition; Elementary School Education; Learning Theory; Number Concepts and Operations

Prime numbers fascinate mathematicians of all ages. When we learn to count, we learn that we can build numbers additively, without end, by continuing an iteration of 1s (e.g., 6 as 1+1+1+1+1+1). With prime numbers, we can build those same numbers multiplicatively, as a product of primes (e.g., 6 as 2×3). Confrey and Smith (1995) have described these constructions as two different worlds: an additive world and a multiplicative world. The prime number theorem relates those two worlds in a surprisingly simple way. It states that the number of primes less than or equal to any natural number, n, is approximately n/ln(n). In this way, the theorem relates the additive building blocks of number (n 1s) to its multiplicative building blocks (the π(n) prime numbers less than or equal to n). It states π(n)≈n/ln(n).

Aside from its simplicity, the prime number theorem is surprising in that it describes the relative distribution of primes without discerning a pattern of primes. Attempts to generate primes algorithmically have never failed to fail (e.g., the first five Fermat numbers are prime but, as far as we know, none of the others are). In fact, our national security depends on such failures (though quantum computing might change the game). Moreover, simple conjectures about primes, such as whether every even number can be written as the sum of two primes (e.g., 24=11+13; Goldbach's conjecture), remain unproved.

The prime number theorem is also surprising because, in spite of the simplicity of the theorem itself, its proofs are notoriously complex. Attempts to understand the distribution of primes and prove the prime number theorem led to the invention of the Riemann zeta function—a function defined through an infinite sum of complex-valued terms. Indeed most proofs of the prime number theorem rely on that function. The apparent disconnect between the simplicity of the theorem and its proofs led mathematicians like Atle Selberg (1949) and Paul Erdös (1949) to generate "elementary proofs." Clever as they may be, these proofs are at least as convoluted as the complex ones, but we cannot blame them for trying. After all, prime numbers are natural numbers, and their definition relies on a sieving process that remains contained within the natural numbers. So, why should investigations of prime numbers appeal to complex numbers? One clue appears in the theorem itself, in the form of the natural logarithm.

Confrey and Smith (1995) framed logarithms as mappings between multiplicative and additive worlds. Logarithmic functions convert the formal operation of multiplication into one of addition, thus potentially transforming multiplicative building blocks into additive ones. Indeed, that's precisely what the prime number theorem implies. Formally, this implication appears in the claim (equivalent to the prime number theorem) that the second Chebyshev function—the psi function—approaches n asymptotically. We return to this function later.

Although this paper ostensibly concerns the prime number theorem, it is fundamentally about the nature of mathematics itself: an epistemology of mathematics that we can learn through interactions with children. In tracing the roots of mathematics to a coordination of actions, we can find in children's actions the primary source of all mathematics. We can learn mathematics from children, not only as a source of content knowledge for improving our instruction (Ball, Thames, & Phelps, 2008), but also as a trace of the historical development of formal mathematics. In the case of the prime number theorem, research on children's numerical development teaches us how mathematicians construct additive and multiplicative worlds and how they might navigate between those two worlds. This perspective stands in contrast to Platonist views that have become crystallized in formal mathematics (Lakatos, 1976). As such, this theoretical paper addresses three questions raised in this year's conference theme:

1. How does your work improve learning conditions for each and every mathematics learner?
2. How does your work challenge a settled mathematics learning status quo?
3. Whose voice does your work center in the mathematics learning process? What can be learned from reflecting on this question?

The purpose of this paper is to review research on the additive and multiplicative worlds that children construct and to theorize how our understanding of children's mathematics elucidates our understanding of mathematics as a whole. Along the way, the paper also theorizes why addition and multiplication appear as the two principal operations in formal arithmetic. The paper frames children's arithmetic as the construction, transformation, and coordination of units. In doing so, it privileges students' units coordinating activity as the psychological basis for formal arithmetic, complex analysis, and the prime number theorem. In addition to the framing offered by Confrey and Smith's (1995) mapping between worlds, the paper draws heavily from Ulrich's (2015, 2016) framing of additive and multiplicative units coordination, as well as Boulet's (1998) characterizations of multiplicative reasoning as a transformation of units.

Preserving Units in the Additive World

Researchers who build models of students' mathematics privilege students' mathematics over school mathematics. They explicitly recognize students' ways of operating as the focus of mathematics education: "If, as teachers, we want to foster understanding, we will have a better chance of success once we have more reliable models of students' conceptual structures, because it is precisely those structures upon which we hope to have some effect." (von Glasersfeld & Steffe, 1991, p. 102). Specifically, Steffe and colleagues began a research program to build models of the ways that students construct and transform units to solve arithmetic problems. These ways of operating become the basis for counting and arithmetic. Ulrich (2015, 2016) has exquisitely synthesized this knowledge gained from children in a pair of articles published in *For the Learning of Mathematics*.

According to Euclid, "a *unit* is that by virtue of which each of the things that exist is called one" (*Elements*, Book VII). This definition fits well enough but overlooks the human activity that goes into constructing units of 1. Children begin to construct units through their counting activity. At first, they count by pointing to figurative items (e.g., chips), building a one-to-one correspondence between their number words and their acts of pointing. A number word, say "five," might then stand in place of that activity (Steffe, 1992).

Arithmetic units emerge from the child's reflection on such activity, when they can take any of the counting acts as an identical unit of 1 (Steffe, 1992). The child can then iterate that unit of 1 to produce collections of 1's, such as a 5. This 5 might then become a composite unit, composed of five 1s, as well as a unit in itself (one 5). Reasoning additively amounts to partitioning composite units into other units—ultimately units of 1—and continuing an iteration of those units. This activity produces nested sequences of numbers (e.g., the explicitly nested number sequence; Steffe, 1992), wherein 5 contains 4, 4 contains 3, and so on.

Since Plato, Western philosophers have marveled at the absolute truth of mathematical equalities, such as 2+2=4. However, if we appreciate the human activity of constructing mathematical objects, like 2 and 4, the mystery fades away. If 2 is two iterations of 1, the addition of another 2 continues the iteration of identical units of 1, so that we have 1+1+1+1, also known as 4. One, two, and four do not have an existence apart from such activity, and that same activity establishes their various relationships. In the case of addition, we continue the iteration of a common unit.

Addition preserves units. If a and b are natural numbers, defined by the iteration of a unit of 1, then a+b is defined through the iteration of that same unit of 1. However, if a and b are fractions, we have to find a common unit for measuring each of them. Usually we refer to a common denominator, but implicitly this refers to a unit fraction that we could iterate to produce both a and b (Steffe, 2003). Moreover, the result, a+b, is expressed as an iteration of this same unit fraction; again, units are preserved.

Now consider the case of repeated addition, say determining the value of 4×5 through the addition 5+5+5+5. In this case, we have four composite units of 5, and we can think about the product as four iterations of an identical unit of 5. Alternatively, we can think about each 5 as five 1s, so that 4×5 becomes (1+1+1+1+1)+(1+1+1+1+1)+(1+1+1+1+1)+(1+1+1+1+1)=20. Either way, units (5s and 1s) are preserved. Ostensibly, we have completed a multiplication task via addition: four 5s is twenty 1s. However, multiplicative reasoning does not operate like additive reasoning. It does not preserve units; it transforms them. As we will see, additive and multiplicative reasoning are distinct, though related through units coordinating activity (Ulrich, 2015, 2016).

Transforming Units in the Multiplicative World

In another article published in *For the Learning of Mathematics*, Boulet (1998) set out to "formulate a uniform concept of multiplication that is not simply another arithmetical operation in disguise" (i.e. repeated addition; p. 12). Her approach stands in contrast to that of Vergnaud (1983) who required three subtypes to address multiplication across the domains of natural numbers, integers, and fractions. Following Davydov (1992), Boulet (1998) promoted multiplicative reasoning as a transformation of units. Boulet extended this perspective to include the multiplication of negative numbers, fractions, and irrational numbers. Consider the example illustrated in Figure 1.

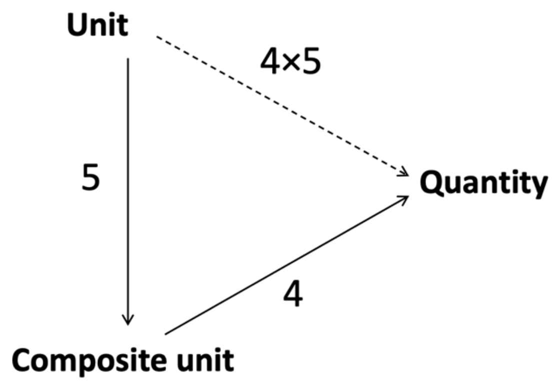

Figure 1: Multiplication as a Transformation of Units

When assimilated as a multiplicative task, 4×5 does not represent the repeated addition of 5s but, rather, a transformation from units of 5 to units of 1 (or vice versa). The product 4 times 5 generates a quantity that measures four units of 5, but we want to know its measure in units of 1, so we project five units of 1 into each unit of 5, transforming each unit of 5 into five units of 1. In terms of units coordination, we have distributed five units of 1 into each of the four composite units of 5 (Steffe, 1992). We could compute the result by counting by 5s (as in repeated addition), but the transformation itself produces the product. Rather than working within a single number sequence, we have transformed numbers across two number sequences: one measured in units of 1 and the other measured in units of 5, with a 5-to-1 transformation between those units.

Boulet's (1998) framing of multiplication places special emphasis on the distinction between roles of multiplicand and multiplier. The multiplicand is the composite unit; it is related to the unit of 1 through a unit transformation (i.e., a distribution of units). The multiplier describes the number of iterations of that unit. With repeated addition, we would take the composite unit (the multiplicand, say 5) and iterate it (say four times). With multiplicative reasoning, we take the four units of 5 and transform them into 20 units of 1, all at once, even if we have to determine their numerosity through skip counting. The focus of activity is on the multiplicand instead of the multiplier.

From this perspective, the fundamental theorem of arithmetic states that we can uniquely produce every natural number in either of two ways: through the iteration of units (a multiplier applied to a multiplicand), or through a transformation of units (transforming the multiplicand). The atoms of addition are units of 1; the atoms for multiplication are primes. Prime factorization of a number, then, represents a sequence of transformations of units, from units of 1, to units of n, where $n=p_1^{R1}p_2^{R2}\ldots p_k^{Rk}$. This idea is generalized in linear algebra, wherein vectors represent units, scalars represent iterations of a unit, and matrices represent unit transformations, transforming vectors (including the basis for a vector space) into other vectors. Additionally, matrix multiplication allows for a recursive transformation of units M×M without reference to any particular scalar (multiplier) or any particular unit (vector). In this way, we can understand the product (-1)×(-1) as a transformation from units of 1 to units -1, and back (as if composing two reflections; Norton, 2022).

Mapping between Worlds

Buttressed by a four-year longitudinal study of upper elementary school students, Lamon (2007) produced the most comprehensive review of literature regarding advanced numerical reasoning. Lamon concluded her report with a list of outstanding questions, beginning with the following: “what are the links between additive and multiplicative structures?” Ulirch (2015, 2016) responded in terms of composite units and ways that students operate with those units: iterating composite units, disembedding units from a composite unit, distributing the units of one composite unit across the units of another composite unit. Essentially, both additive reasoning and multiplicative reasoning rely on the construction of composite units, so they have a common cognitive basis, but as we have seen, students operate on composite units differently in additive and multiplicative reasoning. Specifically, we have made a distinction between ways students preserve (composite) units when engaged in additive reasoning, and ways they transform units when engaged in multiplicative reasoning.

Lamon’s (2007) review included Confrey’s (1994) concept of a split, through which students might transform a unit of 1 into a unit of n. Steffe (2002) proposed a similar concept, describing ways students could partition a whole into five equal parts and, reversibly, reconstruct the whole by iterating any one of those parts five times. For both Confrey and Steffe, splitting describes a multiplicative way of operating. However, in anticipating a mapping between additive and multiplicative worlds, Confrey (with Smith, 1995) included the possibility of recursive splits.

Confrey and Smith (1995) used “basic splits” to refer to splits by prime numbers (e.g., a one-to-seven split). They used basic splits recursively to consider how students might map between additive and multiplicative worlds. In the additive world, we begin at 0 and iterate by units of 1 to produce other natural numbers. In the multiplicative world, we being at 1 and perform basic splits to produce those same numbers. To map between the worlds, we rely on logarithms and exponential functions.

We can define exponential and logarithmic functions as mappings between additive and multiplicative structures. Formally, we say they are isomorphisms between the group of integers under the operation of addition, and the group of positive real numbers, under multiplication (e.g., $\log_2(1/4\times8)=-2+3$). Pedagogically, they relate children’s counting activity to their splitting activity. Following Confrey and Smith (1995), we can use the activity of paper folding to exemplify. In the example of $\log_2(1/4\times8)$ we might say that, starting from a folded sheet of paper, if we fold it in half twice more (-2; or 1/4) and then unfold it three times (+3, or ×8), we end up with a sheet that has twice the area we started with (+1, or 1/4×8).

Proofs of the Prime Number Theorem

Two and a half millennia after Plato, Platonist views of mathematics still dominate the field (Lakatos, 1976). When we make and prove conjectures about prime numbers, we tend to think about those numbers as pre-existing, lying in wait for their discovery; this despite the fact that Eratosthenes demonstrated, through his sieve, that prime numbers are the result of a process of filtering out multiples of units, beginning with multiples of 2. Indeed, the clearest existing explanation of the prime number theorem follows quickly from the fact that, to find primes up to n, we need only apply the sieving process up to the square root of n (Marshall & Smith, 2017). However, this proof is not generally accepted as rigorous because it relies on what professional mathematicians consider to be probabilistic arguments about the density of prime numbers. Neither will professional mathematicians trust empirical arguments, and rightly so, but again, such arguments suggest that the prime number theorem is not about prime numbers at all. Specifically, in computer simulations where a random sieve is applied to the natural numbers (randomly eliminating half of the numbers, taking the smallest remaining number, k, and randomly removing 1/k of the remaining numbers, and so on) the distribution of these “random primes” behaves the same way (Brown, 1978, citing a study by Hawkins, 1958). There are approximately n/ln(n) of them less than or equal to n, as n gets large.

To prove the prime number theorem, mathematicians are more comfortable moving into the complex plane, which comes complete with a geometry of numbers and all kinds of computational power, including infinite sums, complex roots, and calculus. The first proofs of the prime number theorem relied on the Riemann zeta function. Interestingly, and in line with more intuitive arguments introduced here, the infinite sum that defines the zeta function can also be expressed as an infinite product of terms involving distinct primes. However, the complexity of existing proofs has left mathematicians wondering whether a simpler proof could be found. After all, and to echo a question first raised by David Hilbert (Kreisel, 1984), why should the proof of a theorem about natural numbers rely on complex analysis?

Driven by such questions, Selberg (1949) and Erdös (1949) developed proofs that relied only on arithmetic functions. Paul Erdös was a Hungarian mathematician and a prolific mathematical collaborator. The subject of *The Man Who Loved Only Numbers* (Hoffman, 1998), Erdös believed in a Book of perfect proofs held by the supreme fascist (i.e., God), who withholds from us knowledge of the Platonic realm. No doubt, the convoluted proofs that he and Selberg developed—though clever—are not in the book. Without the computational power of complex analysis, they relied on several specialized functions, such as the Chebyshev functions, which were designed to investigate prime numbers. For example, Chebyshev's psi function ($\psi(n)$) takes a natural number, n, and produces the sum of natural logarithms of new prime factors introduced by numbers less than or equal to n (e.g., $\psi(6)=0+\ln(2)+\ln(3)+\ln(2)+\ln(5)+0$). Note that the value for the fourth term in the sum is ln(2) because 4 introduces a second 2 in its prime factorization; and the value for the sixth term is zero because both prime factors of 6 (2 and 3) were introduced earlier in the sum.

Learning Mathematics from Children

Children have a lot to teach us, especially if we want to teach them. For teachers, learning from children is critical because, if the goal is to promote the development of students' mathematical structures, we must first understand how their mathematical structures operate. Hackenberg (2010) has framed the issue as one of "mathematical caring relations." Children feel cared for when we attempt to harmonize with their thinking. Beyond teaching and learning, the present focus is on an epistemology of mathematics and what children might teach us about mathematics itself.

Consider the prime number theorem in light of what we know about the additive and multiplicative worlds that children construct. In the additive world, children produce natural numbers, starting from 0, through an iteration of 1s. When 1s become iterable for the child, each number contains all the numbers that precede it, as a nested sequence (e.g., as five units of 1, 5 contains 4, which contains, 3, and so on). In the multiplicative world, children produce numbers, starting from 1, through a transformation of units. As the multiplicative analogue of a nested sequence, the least common multiple of a sequence of numbers contains all the numbers that precede it. For example, 60 is the least common multiple of 2, 3, 4, and 5, and contains each of those numbers within its prime factorization: $60=2^2\times3\times5$.

As Confrey and Smith (1995) suggested, we can understand logarithms and exponentials as mappings between those additive and multiplicative worlds. The prime number theorem pertains to such a mapping, so we should not be surprised at the appearance of a logarithm within it. Still, we might wonder why it is the natural logarithm, in particular, that appears. The natural number, e, is defined by a limit. Corresponding to this limit, e^x is defined as follows, and from this definition, we can derive a definition for its inverse function, ln(x):

- $e^x = \lim_{n\to\infty}\left(1+\frac{x}{n}\right)^n$
- $ln(x) = \lim_{n\to\infty} n(\sqrt[n]{x} - 1)$

Thinking about units and unit transformations, we can read a lot into this definition of the natural logarithm. We have a multiplier, n, applied to the difference of two units: the nth root of x, and 1. In an additive world, we would produce n through n iterations of the unit of 1. In a multiplicative world, we would produce x through a sequence of n unit transformations, each with the n^{th} root of x as its ratio.

Now consider what happens when x is the least common multiple of the first k natural numbers. The prime factorization of x would be the union of the prime factors of 1, 2, 3, …, k (including multiples of the same prime factor), and ln(x) would be the sum of the logarithms of those prime factors. Because the logarithm function maps multiplicative worlds to additive worlds, we should expect this sum to be k: the multiplicative world containing the numbers 1 through k would get mapped to the additive world containing the numbers 1 through k. In fact, that is exactly what the natural logarithm function does as k gets large, and that fact is equivalent to the prime number theorem.

The least common multiple of the first k numbers is the product of the union of prime factors up to k. So, the natural logarithm of this least common multiple is the sum of the natural logarithms of those prime factors. This sum is Chebyshev's psi function, as Table 1 illustrates.

Table 1: The Prime Number Theorem

Iterations of 1	k	Product of Primes	New Unit Transformations	New Terms in Sum	Value of Sum
+1	1	p^0	×1	0	0
+1	2	p_1	$\times p_1$	$+\log(p_1)$	0.693
+1	3	p_2	$\times p_2$	$+\log(p_2)$	1.792
+1	4	p_1^2	$\times p_1$	$+\log(p_1)$	2.485
+1	5	p_3	$\times p_3$	$+\log(p_3)$	4.094
+1	6	p_1p_2	×1	+0	4.094
+1	7	p_4	$\times p_4$	$+\log(p_4)$	6.040
+1	8	p_1^3	$\times p_1$	$+\log(p_1)$	6.733
+1	9	p_2^2	$\times p_2$	$+\log(p_2)$	7.832
+1	10	p_1p_3	×1	+0	7.832
+1	11	p_5	$\times p_5$	$+\log(p_5)$	10.300
			$(p_1^{R1})\ldots(p_{\pi(k)}^{R\pi(k)})$	$\psi(k) \rightarrow \log(k)\pi(k)$	$\rightarrow k$

The left two columns in Table 1 show the production of natural numbers, k, through the iteration of a unit of 1, beginning from 0. The third column shows the production of each of those natural numbers through a transformation of units (a product of primes), beginning from 1. The fourth column shows new prime numbers introduced in the prime factorization of each natural number (×1 indicates no new primes). The fifth column shows the natural logarithms of new prime factors, which are the terms in the sum that define Chebyshev's psi function. The rightmost column shows this sum, up to each k. Note that because the iteration of 1s begins at 0 and the sequence of unit transformations begin at 1, the value in this right column would better approximate k if we added 1 to it.

The bottom line is that each number, from 1 to k, can be expressed as the product of primes contained within the least common multiple of those numbers. This is expressed in the bottom row of the third column as $(p_1^{R1})(p_2^{R2})\ldots(p_{\pi(k)}^{R\pi(k)})$, where Ri is the highest power to which each prime p_i can be raised without exceeding n. Note that there are π(k) factors, p_i^{Ri}, and as k gets large, each of the factors approximates k. So, the entire product is approximately k raised to the π(k). Correspondingly, ψ(k) is approximately π(k)×ln(k). As suggested by the definition of natural logarithm given above (as a mapping from nested products to nested sums), and as shown in the right column, ψ(k) is also approximately k, which implies the prime number theorem. Moreover, this definition of natural logarithm, along with the prime number theorem, suggests an alternate definition of e. As proved below, we can define e as the n^{th} root of the least common multiple of the first n natural numbers, as n gets large:

- $\Psi(k) = \ln(\mathrm{lcm}(1,2,\ldots,k)) = \lim_{n\to\infty} n(\sqrt[n]{\mathrm{lcm}(1,2,\ldots,k)} - 1)$
- In units of k, $\lim_{n\to\infty} nk(\sqrt[nk]{\mathrm{lcm}(1,2,\ldots,k)} - 1) = \lim_{n\to\infty} nk(\sqrt[n]{\mathrm{lcm}(1,2,\ldots,k)^{1/k}} - 1)$
- So, $\frac{\Psi(k)}{k} = \lim_{n\to\infty} n(\sqrt[n]{\mathrm{lcm}(1,2,\ldots,k)^{1/k}} - 1) = \ln\sqrt[k]{\mathrm{lcm}(1,2,\ldots,k)}$
- Because $\frac{\Psi(k)}{k} \to 1$, $\sqrt[k]{\mathrm{lcm}(1,2,\ldots,k)} \to e$, so $e = \lim_{n\to\infty} \sqrt[n]{\mathrm{lcm}(1,2,\ldots,n)}$.

Summary

To summarize the heuristic argument about the prime number theorem, if we knew that the natural logarithm mapped the nested product of the first n natural numbers (their least common multiple) to their nested sum (n), the prime number theorem would follow. The ideas of nested number sequences and logarithms as maps between multiplicative worlds were informed by research on children's mathematics (e.g., Steffe, 1992; Ulrich, 2015a, 2015b). Related constructs, such as units and unit transformations, provide additional insights into why we might call the natural logarithm natural.

Aside from arguments about the prime number theorem, this paper makes an argument about the epistemology of mathematics, particularly regarding questions related to the conference theme. The first question asks about improving learning conditions for all children. In response, we frame children's mathematics as genuine mathematics. This mathematics is important to teachers as they support children's continued development as mathematicians. This idea is in line with calls for teachers to develop pedagogical content knowledge (e.g., Ball, Thames, & Phelps, 2008), as well as Hackenberg's (2010) descriptions of mathematical caring relations as "harmonizing with students' schemes" (p. 242). Additionally, we argue that children's mathematics is mathematics that can inform research in mathematics, even at advanced levels.

In framing children's mathematics as mathematics, we answer the second question (regarding the status quo) by challenging Platonist perspectives that still the dominate the field. For instance, there is a tendency to think about prime numbers as pre-existing as if the prime number theorem pertains to discovering some kind of pattern in the fabric of the universe. However, our heuristic argument buttresses prior arguments (e.g., investigations of random primes; Hawkins, 1958) that suggest that the theorem pertains to processes of producing prime factors (e.g., sieving) and has little to do with a pre-determined subset of the natural numbers. In response to the third question, we privilege the voices of children, from whom we have much more to learn.

DIFFERENT WAYS OF LEARNING NUMBER DENSITY: A HYPOTHETICAL TRAJECTORY WITH HIGH SCHOOL STUDENTS

DIFERENTES FORMAS DE APRENDER LA DENSIDAD NUMÉRICA: UNA TRAYECTORIA HIPOTÉTICA CON ESTUDIANTES DE BACHILLERATO

We present a study where we designed a Hypothetical Learning Trajectory (HLT) for promoting the learning of the property of numerical density in high-school students. The tasks of the HLT used various school mathematics topics that can provide opportunities for thinking about that property and were framed in several contexts and semiotic representation registers. We present the sequence of the HLT, as well as some results of its implementation with four high-school students. We analyze the participants' data in terms of their thinking regarding discreteness and density. We observed that at the end of the HLT tasks, the participants recognized more easily an infinite quantity of intermediate rational or real numbers in an interval, although they didn't fully comprehend that only natural numbers have successors.

Keywords: Learning trajectories and progressions, mathematical representations, number concepts and operations, rational numbers

Introduction and Research Questions

In many countries, it is common for high school students to learn about representations of numbers on the number line, classes of intervals, as well as the continuity of real numbers, but not about the property of density (Vamvakoussi & Vosniadou, 2010; McMullen & Van Hoof, 2020). The density property of a number set is defined as that given any two numbers in that set, there is a number between them. If a number set satisfies this property, it implies that, in that set: 1) No number can have an (immediate) successor; 2) Any interval contains an infinity of numbers. Likewise, a completely dense set is not discrete, understanding discrete, as stated by Vamvakoussi and Vosniadou (2010), in terms of order relations.

Some students arrive at the university level education, with poor conceptions about this property. Among the difficulties that are observed are the misconceptions that: 1) In any number set, beyond the sets of natural or integers, a successor exists for any number; and 2) there is a finite quantity of numbers in an interval of the rational numbers. For example, the second misconception was observed with preservice teachers in Israel by Tirosh et al., (1999). Also, Merenluoto and Lehtinen (2004) observed that 10% of students studying Mathematics at a university in Finland believed that there was a finite number of rational numbers in an interval. Likewise, discrete thinking stemming from thinking related to natural numbers is problematic: Vamvakoussi and Vosniadou (2010), in a study in Greece, found that the idea of the discrete was dominant in their observed students and that the symbolic representation of the extremes of the interval had an effect in their judgments regarding, not only the number of intermediate numbers in an interval, but also what kinds of numbers are in it (i.e., some of these students considered that there can only be decimals in an interval whose endpoints are decimal numbers, but there cannot be fractions).

Based on the above and on the difficulties that students have to learn and understand the property of number density, in the research presented here, we developed a Hypothetical

Learning Trajectory (HLT), as part of a design-based research (Cobb and Gravemeijer, 2008), with the aim of promoting the learning of this property in high school students. In the HLT, we use different contexts, situations and representations, inspired by McMullen and Van Hoof (2020), who indicate that there are moments in school mathematics that can provide, with additional instruction, opportunities to reason about number density.

This report is an extension of the research study carried out by Suárez-Rodríguez and Sacristán (2021), where we addressed the following research questions :

a) How can we design a sequence of tasks with a specified HLT, to promote the learning of the density property in the set of real numbers?

b) How do high school students understand the property of density in real numbers using semiotic representations produced during our proposed tasks?

Theoretical and Methodological Frameworks

Thinking about the discrete and the dense

As Vamvakoussi and Vosniadou (2004, 2010) indicate, the properties of natural numbers tend to be transferred to other number sets and this affects students' conceptions of the property of density. These authors (Vamvakoussi and Vosniadou, 2004) defined certain categories of thinking about the discrete, the dense and its relationship with the number of numbers in an interval, to identify ways of reasoning in students (Table 1 shows a reinterpretation by us of these categories).

Natural numbers, unlike real numbers, have the property of discreteness as established in the Peano axioms where it is stated that between a natural number and the following one, there is no other number (Ni and Zhou, 2005). Furthermore, all natural numbers have a successor (Ni and Zhou, 2005) – since it is a well-ordered set.

Thus, from the study of natural numbers, a thinking linked to the discrete is formed. Vamvakoussi and Vosniadou (2004) used the term *naive*, coined by Carey (1987) to define two of their categories of thinking that refer to "naive ideas"(see Table 1): The category *naive thinking about the discrete* refers to a "naive idea" that rational numbers are consecutive. Likewise, naive *thinking about the dense* is when it is considered that there is an infinity of numbers in an interval, but it is not possible to justify why the existence of this infinity. Contrasting these naive thinking are the categories of forward thinking: The category of *discrete forward thinking* is when it is believed that there are a finite number of numbers in an interval; while in the category *sophisticated thinking about the dense*, the formal definition of density is understood.

Table 1: Categories of thinking about the discrete and the dense

Naive discreteness [Naive thinking about the discrete]	The thinking is that there is no number between two *consecutive false* rational numbers. Vamvakoussi and Vosniadou (2004) coined this expression to refer to the idea that a successor of a rational number exists.
Advanced discreteness [Advanced thinking about the discrete]	The thinking is that there is a finite quantity of numbers between two consecutive false rational numbers.
Discreteness–density [Mixed thinking between discrete and dense]	In some cases, the thinking is that between two rational numbers there is an infinity of numbers; and in other cases, that there is a finite number.

Naive density [Naive thinking about density]	There is an understanding that there is an infinity of numbers in an interval, but this situation is not justified by using the density property. The symbolic representation of the extremes of an interval influences this way of thinking; it is believed there can only be an infinite number of decimal numbers between decimals and an infinity of fractions between fractions, but not an infinity of fractions between decimals or otherwise.
Sophisticated density [Advanced thinking about density]	There is a sophisticated understanding of the density property; that is, it is understood that there is an infinite number of numbers between two rational numbers, regardless of their symbolic representation and this is justified through the use of the density property.

Description of a Hypothetical Learning Trajectory (HLT)

Simon and Tzur (2004) define a HLT as a series or sequence of teaching activities that comprise conjectures or hypotheses about how the student can learn certain mathematical concepts. Thus, a HLT is a prediction of a learning path that includes didactic interventions through the sequence of activities (Simon, 1995). Thus, in a THA it is essential to develop and propose hypotheses on how to support the student in the construction of new knowledge (Simon, 1995). In fact, Simon (1995) establishes three components in the design of a HLT: 1) The *learning goal* that defines the direction of the HLT so that the student builds new knowledge; 2) the *learning activities* that follow a sequence; and 3) *the hypothetical learning process*, where a prediction is made of how the students' thinking and understanding will evolve, and that defines how to support their learning process. During the activities, the researcher (or teacher) observes how the student is learning in the scenarios proposed in the HLT to determine if the design is adequate and changes need to be made (Simon, 1995).

Semiotic registers of representation

One way that we consider important to support the learning of the property of density is the use of several registers of representation. Mathematics deals with different registers of representation –be it geometric, algebraic (symbolic expressions), arithmetic, even colloquial language (linguistic expressions)– and each of these registers constitutes a different semiotic form (Duval, 1995/2004); that is, it communicates meaning differently. Semiotic representations are fundamental for the development of mathematical activity itself, which depends on a writing system (decimal, fractional, binary, etc.) (Duval, 1995/2004). This is also particularly relevant because when working with real numbers (as is our case), it is necessary to take into account that the real number has different representations (Apostol, 1976/2006).

Methodology

Design and development of the HLT activities

As we already mentioned, in our research we developed a HLT according to the guidelines of design-based research (Cobb and Gravemeijer, 2008), a methodological approach in which a researcher carries out a detailed analysis of how to test and improve the conjectures that are outlined. Cobb and Gravemeijer (2008) recommend the design and elaboration of more than one cycle of activities in order to refine or modify the conjectures raised during the first cycle. In our research, two cycles of activities were planned; in this report, we present some results from the first cycle, from data by four students from Colombia, between 15 and 17 years of age: Angie, Paola and Néstor (pseudonyms), who were high-school students; and Violeta (pseudonym), who was in her last year of middle-school. These students solved some tasks proposed by the HLT in person, while other tasks were carried out online, due to the COVID-19 pandemic.

The preparation and implementation of the first cycle of the HLT activities consisted of three phases. The first phase was the application of a questionnaire as a pre-test; in the second, the activities of the HLT were carried out; and in the last phase, the questionnaire was applied again as a post-test. We describe below the phases of the HLT, then we present some results of the first two phases and give an example of what happened in the last phase.

First and third phase. *Pre-test and post-test*. The same questionnaire (to be answered in approximately 30 min) was used for the pre- and post-tests, in order to determine the possible evolution of the students' thinking. The questionnaire consists of four questions related to the number of intermediate numbers in an interval –those questions were based on those by Suárez-Rodríguez and Figueras (2020), as well as others by Vamvakoussi and Vosniadou (2004). The aim of the questionnaire was to find out how much the participants knew about the property of number density; the answers were classified according to the categories proposed by Vamvakoussi and Vosniadou (2004) (see Table 1). The questions included in the test are: *How many numbers are there between 0 and 1? Can you find decimal numbers and/or fractions between 0.49 and 1/2? How many numbers are there between 0.899 and 0.90?* In the fourth question, the following situation was presented:

> Pedro wants to draw a line where he can place decimal numbers. He starts with the number 0.1. Then he places 0.2. At that point, Laura interrupts him and says that the number, "next" to 0.1, is 0.11. Who is right, Pedro or Laura? Or neither? Or both?

Second phase. *Implementation of the HLT activities*. The HLT was designed to be carried out in four activity sessions, each with a corresponding learning hypothesis (see Table 2; similar to the one that appears in Suárez-Rodríguez and Sacristán, 2021, p. 1223). The hypotheses were defined taking into account various topics of school mathematics that we supposed can guide the student to a learning and understanding of the property of density. It is not necessary for the student to follow the sequence of the sessions, although a first approach to density is through decimal numbers, and the sequence ends with irrational numbers. Each session lasted about 1h30'.

Table 2: HLT sessions with their corresponding hypotheses

Levels	*Hypotheses*
Level 1. Initial approaches to number density.	From two situations: one related to everyday life and the other related to a hypothetical scenario, it is thought that the student can have his first approaches to the property of density.
Level 2. Approach to number density through the similarity of triangles.	It is considered that by using triangle similarity students can learn about the density property of rational numbers.
Level 3. Approach to number density through arithmetic progressions and geometric progressions.	It is possible that by finding arithmetic and geometric halves in an interval, students can understand the density property of rational numbers in the set of real numbers.
Level 4. Approach to numerical density through the property of continuity.	Using the continuity property, students are believed to understand the density property of irrational numbers in the set of real numbers.

Through this HLT students are expected to achieve a metaconceptual awareness, realizing that their suppositions and beliefs are not unquestionable and that they constrain the way in which new knowledge is acquired (Vosniadou, 1994). At the end of the HLT activities, students are expected to be able to distinguish between a discrete set and a dense set.

Results

The categories of Vamvakoussi and Vosniadou (2004) (Table 1) were used for the analysis of the responses to the questionnaire, as well as for the data from the HLT activities.

Pre-test results (phase 1)

Figure 1 shows Angie's response to the question about the quantity of numbers between 0.899 and 0.90: *"[t]here is only one, because it is in the middle of the two and because it leads to the next number".* A *naive thinking about the discrete* in Angie, that comes from her knowledge that the natural numbers are discrete, is inferred when she says that "there is only one" and that, for her, a decimal number has a successor ("it leads to the next number").

solo ay uno, porque esta en la mitad de los dos y porque da paso al siguiente numero *There is only one, because it is in the middle of the two and because it leads to the next number*

Figure 1: Example of naive thinking about the discrete (Angie – pre-test)

In Figure 2, we observe that the answers of Violeta, Angie and Néstor to the question of whether there is a number that follows 0.1, all coincide in that 0.2 is the number that follows 0.1. In Paola's answer: "*Yes, there is a number that follows 0.1[:] 0.11, 0.111, 0.111...,*" we observe that although, in her colloquial language, she affirms the existence of a successor, and names several: "0.11, 0.111, 0.111[1]…", for her, the fact of adding the number 1 each time in the decimal part of the number, indicates that there are more "successors" for 0.1. We consider that these four students exhibited in this question, *a naive thinking about the discrete* since, apparently, they believe that, for decimals, there exists a successor (or several in Paola's case).

4. b. Is there a number that follows 0.1? If your answer is yes, write the number that you think follows 0.1. But if your answer is not affirmative, explain why.	
Angie's response 0.1 Le sigue 0.2 *0.1 follows 0.2*	Violeta's response Si existe es el 0.2 y asi sucesivamente con lo demas *Yes, it exists; it is 0.2 and so on with the others*
Néstor's response Rta. Para mi creo que es 0.2 *For me I think it's 0.2*	Paola's response Si, existe un número que le sigue a 0,1. 0,11, 0,111, 0,111... *Yes, there is a number that follows 0.1, 0.11, 0.111, 0.111…*

Figure 2: Other examples of naive thinking about the discrete (Pre-test)

Results of the HLT activities (phase 2)

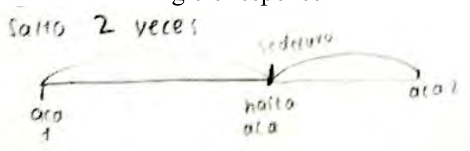
We present some results from the four students' data during the development of the HLT.

Session 1. In the first session, the students solved two learning activities that were meant as a first approach to density. The second of those activities involved the following:

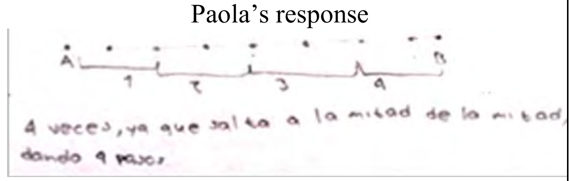
> Imagine that you see that a frog starts to jump from point A and tries to reach point B in the following way: 1st step: The frog jumps half the distance [from A to B]. 2nd step: It then jumps half the distance that remains. 3rd step: Again, it jumps half of what remains. And so on.
> 1. After imagining the situation, now describe it, or explain it...
> 2. How many times will the frog jump between points A and B? Explain your answer.

In solving this activity, we consider that Angie, Violeta and Paola (see Figure 3) are approaching *advanced thinking about the discrete*, when they indicate that the frog has jumped a finite number of times and use as a representation a segment of points in a graphic log. On the other hand, Néstor says *"The Frog is going to jump successively until it reaches point B; […] it will reach its destination, jumping each [time] halves"*; one might think that he conceives of a potential infinity of jumps (also in the previous activity he had said that there were "infinite numbers" between two decimal places); we could say that he shows a *naive thinking about the dense*.

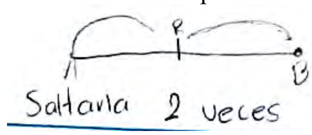
<table>
<tr><td>Angie's response



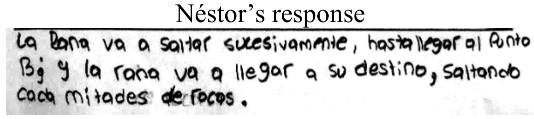
It jumped twice</td><td>Paola's response



4 times, since it jumps half of a half, taking 4 steps</td></tr>
<tr><td>Violeta's response



It would jump 2 times</td><td>Néstor's response



The frog will jump successively, until reaching point B; and the frog will reach its destination, jumping over each [time] halves [between the] rocks.</td></tr>
</table>

Figure 3: Responses of the four students in the activity "Frog Jumps" (Session 1)

Session 2. The activity of this session is based on tasks done by Tovar (2011). The hypothesis is that the density property of fractions and decimals can be learned by working with constructions of similar triangles using the number line, both in GeoGebra (geometric register) and with paper and pencil (arithmetic or algebraic register). Students are asked to locate the points A = 0 and B = 1 on the line and construct a triangle ABD. Then they are asked to create another similar triangle AXC, with C as midpoint of $\overline{AD}$ (Figure 4). They then have to find the numerical value corresponding to X. Figure 5a shows that Angie found X = 0.5 by applying proportions. They then repeat the process for a third similar triangle AGF, with F as midpoint of $\overline{AC}$ (Figure 4), and find the numerical value corresponding to G. Figure 5b shows that Angie found G = 0.25 applying again proportions. So, Angie found the numbers 0.25 and 0.5 between 0 and 1, using semiotic representations in an algebraic register, writing fractions and decimals.

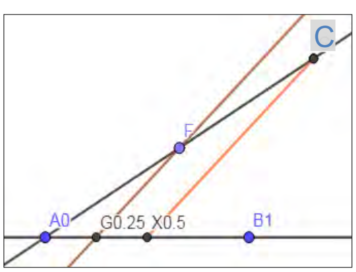


Figure 4: Angie's graph in GeoGebra, locating points between A=0 and B=1 using similar triangles (Session 2)

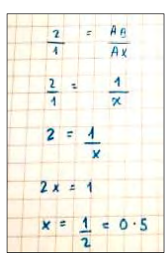
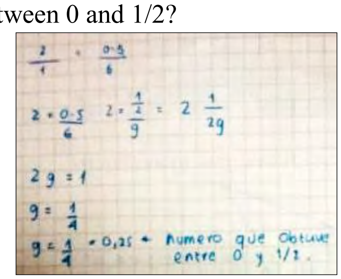
a. Using triangle similarity find the intersection point (x)



b. Do the same procedure for the interval between 0 and 1/2. What number did you get between 0 and 1/2?



0,25← the number I got between 0 and 1

Figure 5: Answers from Angie (Session 2) for:
a. finding the value of point x between 0 and 1
b. finding the number between 0 and 1/2

Subsequently, the students have to find another point between 0 and 1, such as 3/4 (0.75), and they are asked: *What happens if you continue to carry out the same procedure between 3/4 and 1? And so on, successively? How many rational numbers would be obtained?* Figure 6 shows the responses of the four students to these questions. Angie and Néstor seem to show *advanced discrete thinking* because they refer to a finite number of numbers (they say that there are "several" rational numbers between 3/4 and 1, and that more can be obtained). On the other hand, Violeta's response *("the number of numbers continues to increase; many rational numbers will be obtained")* could perhaps indicate a potential infinity, which would correspond to a *naive thinking about the dense*. As for Paola, she says: *"We would continue to obtain half between 3/4 and 1 and so on"*, which may indicate that she considers a potential infinity of rational numbers, which would correspond to a *sophisticated thinking about the dense*, since she justifies it with the process of removing halves successively.

Angie	Se podrán ver más de un numero racional ya que si de 0 a 1 hay varios, de $\frac{3}{4}$ a 1 tendrían más *You can see more than one rational number because, if there are several from 0 to 1, from 3/4 to 1 there would be more.*
Néstor	Rta: Pueden obtener varios números racionales, pero no se puede pasar de 1. *You can get multiple rational numbers, but you can't go past 1.*
Violeta	Siguen aumentando la cantidad de numeros Se obtendrian muchos numeros racionales. *Numbers keep increasing. Many rational numbers would be obtained*
Paola	Se seguiría obteniendo la mitad entre $\frac{3}{4}$ y 1 y así sucesivamente Infinitos *You would still get half between 3/4 and 1 and so on. Infinite.*

Figure 6: Responses of the four students in the activity on proportions (S2)

Session 3. In this session, three activities related to arithmetic progressions and geometric progressions were carried out so that students could see another way of finding numbers in an interval (in order to learn about the density of rationals in the real number set). Initially, students had to find five arithmetic means between 4 and 22 using the nth term of a sequence: $u = a + (n - 1)d$, where a is the first term, n the number of terms, and d the difference between one term and another. They were then asked what the new arithmetic means would be if the difference, d, were halved (see Figure 7, Violeta).

If d were halved, that is, $d=1.5$, or $d=3/2$, what would be the new arithmetic means between 4 and 22?

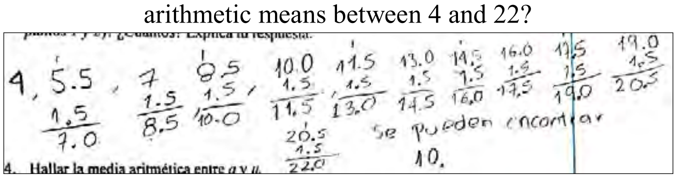


Figure 7: Violeta's Response (Session 3)

Can you find more numbers between 4 and 22 (other than the numbers found in the previous questions)? How many? Explain your answer

Rta: La Respuesta es, son infinitos.

The answer is, they are infinite.

Figure 8: Néstor's response (S3)

Figure 7 shows how Violeta finds the new arithmetic means –5.5, 7, 8.5, 10, 11.5, 13, 14.5, 16, 17.5, 19, 20.5–, and answers the question of whether more numbers can be found between 4 and 22 (different from the numbers found in the previous questions of the activity), how many and why. She replies that *"10 can be found"* (although it was 11 that she found), that is, a finite quantity of numbers between 4 and 22, so she shows *advanced discrete thinking*. Violeta uses decimal writing as a representation and adds to an arithmetic register. Néstor (Figure 8) exhibits a *naive thinking about the dense*, when he affirms that an infinity of numbers can be found.

Session 4. In this session, another activity based on exercises proposed by Tovar (2011) was used. The hypothesis is that students can learn about the density of the irrational numbers in the real numbers, through the continuity of the line in relation to the non-correspondence between rational numbers and the points on the line. They were asked to trace a square of side 1, in the cartesian plane, with a vertex on the origin, and rotate its diagonal so that it would lie on the line of the x-axis (see segment $\overline{DF}$ in Figure 9 –Angie's example). Students noted that the “right endpoint” of the diagonal did not coincide with any rational number on the line when they zoomed in several times with GeoGebra. They wrote then various intervals that would enclose that point: Figure 10a shows two intervals given by Néstor that contain the point. Paola (Figure 10b) gave four increasingly smaller intervals. With this, the students could note that between two real numbers, an irrational number can be found (here, $\sqrt{2}$). No further analysis was done here.

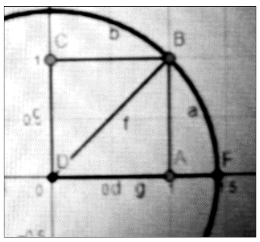

Figure 9: Angie's graph in GeoGebra (S4)

a. Néstor´s response **b.** Paola’s response

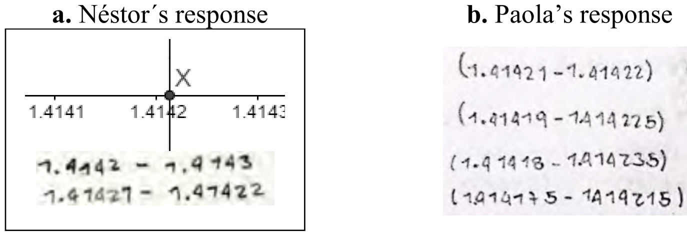

Figure 10: Intervals written by Néstor and Paola that enclose the value of the point corresponding to the length of the square’s diagonal (S4)

Post-test results (phase 3)

In their responses to the post-test, the students showed evidence of having changed their thinking in their answers to the questions related to the quantity of numbers in an interval, with respect to those given in the pre-test (phase 1). For example, for the question *Can you find decimal numbers or fractions between 0.49 and 1/2? How many numbers?* Néstor changed from *naive thinking about discreteness* in the pre-test (when he said: *“1/2 = 0.5 follows 0.49; there are no [numbers]”*) to *naive thinking about dense* (when, in the post-test, he said: *“there are infinite numbers”*).

Concluding remarks

The activities proposed in the HLT aimed for students to learn about the property of number density when solving tasks in various contexts and semiotic registers. Topics such as constructions of similar triangles using the number line, arithmetic and geometric progressions, the property of continuity, make it easy to find different ways to locate numbers in an interval. Likewise, the students had the opportunity to use several semiotic registers of representation, such as the algebraic and the geometric, using fractional and decimal writing, as well as colloquial language to express their ideas during the implementation of the HLT. In some situations, the students were able to understand that there was an infinity of numbers in an interval in the reals. In others, however, they could not overcome the belief that any number has a successor (or perhaps they understand “successor” to refer to any number that is greater). Therefore, we suggest to develop activities focused on overcoming this difficulty.

DIFERENTES FORMAS DE APRENDER LA DENSIDAD NUMÉRICA: UNA TRAYECTORIA HIPOTÉTICA CON ESTUDIANTES DE BACHILLERATO

DIFFERENT WAYS OF LEARNING NUMBER DENSITY: A HYPOTHETICAL TRAJECTORY WITH HIGH SCHOOL STUDENTS

Mayra Suárez-Rodríguez

Se presenta un estudio donde se diseñó una Trayectoria Hipotética de Aprendizaje (THA) para promover el aprendizaje de la propiedad de densidad numérica en estudiantes de bachillerato. Las actividades de la THA se inspiraron en varios temas de la matemática escolar que se pueden aprovechar para hablar de esta propiedad y se enmarcan en diversos contextos y registros semióticos. Mostramos la secuencia de la THA y algunos resultados de una implementación de esta con cuatro estudiantes de bachillerato. Se analiza el pensamiento de los participantes en términos de sus pensamientos sobre lo discreto y lo denso. Se observa que al final de la THA se acercan a reconocer una infinidad de números racionales o reales intermedios en un intervalo, aunque no logran comprender del todo que solamente los números naturales tienen sucesores.

Palabras clave: Trayectorias de aprendizaje y progresiones, representaciones matemáticas, conceptos y operaciones numéricas, números racionales

Introducción y Preguntas de Investigación

En muchos países es común que estudiantes de bachillerato aprendan sobre representaciones de números en la recta numérica, clases de intervalos, así como la continuidad de los reales, pero no la propiedad de densidad (Vamvakoussi y Vosniadou, 2010; McMullen y Van Hoof, 2020). La propiedad de densidad de un conjunto numérico es que dados cualesquiera dos números de ese conjunto, existe un número entre ellos. Si un conjunto numérico cumple dicha propiedad eso implica que, en ese conjunto: 1) ningún número puede tener un sucesor (inmediato); 2) cualquier intervalo contiene una infinidad de números. Asimismo, un conjunto completamente denso no es discreto, entendiendo discreto, en palabras de Vamvakoussi y Vosniadou (2010), en términos de relaciones de orden.

Algunos estudiantes llegan al nivel de educación superior (universidad), con concepciones deficientes sobre esta propiedad. Entre las dificultades que se observan están las creencias érroneas de que: 1) la existencia de un sucesor en cualquier conjunto de números, más allá de los conjuntos de los naturales o enteros; y 2) hay una cantidad finita de números en un intervalo de números racionales. Por ejemplo, la segunda creencia fue observada con profesores en formación en Israel por Tirosh et al., (1999). Por su parte, Merenluoto y Lehtinen (2004) observaron que 10% de los estudiantes que estudiaban la carrera de Matemáticas en una universidad en Finlandia creía que había una cantidad finita de números racionales en un intervalo. Asimismo, el pensamiento discreto proveniente del pensamiento relacionado con los números naturales es problemático: Vamvakoussi y Vosniadou (2010), en un estudio en Grecia encontraron que la idea de lo discreto era dominante en los estudiantes observados y la representación simbólica de los extremos del intervalo afectaba para decidir no solamente la cantidad de números intermedios en un intervalo, sino también qué tipo de números se encuentran en él (i.e., algunos de esos estudiantes consideraban que solo puede haber decimales en un intervalo cuyos extremos son números decimales, pero no puede haber fracciones).

Con base en lo expuesto anteriormente y las dificultades que tienen los estudiantes para aprender y comprender la propiedad de densidad numérica, en la investigación que aquí presentamos, elaboramos una Trayectoria Hipotética de Aprendizaje (THA), como parte de una investigación basada en diseño (Cobb y Gravemeijer, 2008), con el objetivo de promover el aprendizaje de esa propiedad en estudiantes de bachillerato. Para la THA tomamos diferentes contextos, situaciones y representaciones, inspiradas en McMullen y Van Hoof (2020) quienes indican que hay momentos de la matemática escolar que, con instrucción adicional, pueden proporcionar oportunidades para razonar sobre la densidad numérica.

El presente informe es una extensión del estudio de investigación hecho por Suárez-Rodríguez y Sacristán (2021) donde se plantearon dos preguntas de investigación:

1. ¿Cómo diseñar una secuencia de actividades con una THA para para promover el aprendizaje de la propiedad de densidad en el conjunto de los números reales?
2. ¿Cómo estudiantes de bachillerato comprenden la propiedad de densidad en los números reales usando representaciones semióticas generadas durante la secuencia propuesta?

Marcos Teórico y Metodológico

Pensamiento sobre lo discreto y lo denso

Como señalan Vamvakoussi y Vosniadou (2004, 2010), las propiedades de los números naturales se tienden a transferir a otros conjuntos numéricos y esto afecta las concepciones de los alumnos en relación con la propiedad de densidad. Estas autoras (Vamvakoussi y Vosniadou, 2004) definieron ciertas categorías de pensamiento sobre lo discreto, lo denso y su relación con la cantidad de números en un intervalo, para identificar formas de razonar en los alumnos (la Tabla 1 muestra una reinterpretación de esas categorías explicadas por nosotras).

Los números naturales, a diferencia de los números reales, tienen la propiedad de lo discreto como se establece en los axiomas de Peano cuando se define que entre un número natural y el que sigue no existe otro número (Ni y Zhou, 2005). Más aún, todos los números naturales tienen sucesor (Ni y Zhou, 2005) –es un conjunto bien ordenado.

Así, a partir del estudio de los números naturales, se va formando un pensamiento vinculado con lo discreto. Vamvakoussi y Vosniadou (2004) usaron el término *ingenuo,* acuñado por Carey (1987) al referirse a "ideas ingenuas", para definir dos de sus categorías de pensamiento (ver Tabla 1): La categoría *pensamiento ingenuo sobre lo discreto* se refiere a una "idea ingenua" de que los números racionales son consecutivos. Asimismo, *el pensamiento ingenuo sobre lo denso* es cuando se considera que sí existe una infinidad de números en un intervalo, pero no se logra justificar por qué la existencia de esta infinidad. En contraposición a esos pensamientos ingenuos, están las categorías de pensamiento avanzado: La categoría *pensamiento avanzado sobre lo discreto* es cuando se cree que hay una cantidad finita de números en un intervalo; mientras que en la categoría *pensamiento sofísticado sobre lo denso*, se comprende la definición formal de la densidad.

Tabla 1: Categorías de pensamiento sobre lo discreto y lo denso

Pensamiento ingenuo sobre lo discreto	Se considera que no hay otro número entre dos números racionales *consecutivos falsos* (expresión acuñada por Vamvakoussi y Vosniadou, 2004, para decir que existe un sucesor en los números racionales.)
Pensamiento avanzado sobre lo discreto	Se cree que hay un número finito de números intermedios entre dos números racionales consecutivos falsos.
Pensamiento entre lo discreto y lo denso	En algunas situaciones se piensa que entre dos números racionales hay una cantidad infinita de números, y en otros, que hay una cantidad finita.

Pensamiento ingenuo sobre lo denso	Se contempla que hay una infinidad de números en un intervalo, pero no se justifica la situación usando la propiedad de densidad. La representación simbólica de los extremos de un intervalo influye en la forma de pensar; se cree que solo puede haber una infinidad de decimales entre decimales, pero no fracciones; de igual modo sucede con fracciones entre fracciones.
Pensamiento sofísticado sobre lo denso	Hay una comprensión bastante sofisticada de la propiedad de densidad, es decir, se pone de manifiesto que se entiende que entre dos números racionales hay una infinidad de números, independientemente de su representación simbólica, y se justifica con la propiedad de la densidad.

Descripción de una Trayectoria Hipotética de Aprendizaje (THA)

Simon y Tzur (2004) definen una THA como una serie o secuencia de actividades de enseñanza que comprenden unas conjeturas o hipótesis de cómo el estudiante puede aprender ciertos conceptos matemáticos. Así, una THA es una predicción de una ruta de aprendizaje que incluye intervenciones didácticas por medio de la secuencia de actividades (Simon, 1995). Así, en una THA es fundamental la elaboración y planteamiento de hipótesis de cómo apoyar al estudiante en la construcción de conocimientos nuevos (Simon, 1995). De hecho, Simon (1995) establece tres elementos fundamentales para el diseño de una THA: 1) *los objetivos*, entendidos como los propósitos que se quiere lograr para que el estudiante construya nuevos conocimientos, 2) *la ruta de aprendizaje*, que se conforma de actividades instruccionales siguiendo una secuencia, y 3) *planteamiento de hipótesis*, en el que el investigador elabora conjeturas para apoyar el proceso de aprendizaje del estudiante. Durante las actividades, el investigador (o profesor) observa cómo va aprendiendo el estudiante en los escenarios propuestos en la THA para determinar si el diseño es el adecuado y cambios a realizar (Simon, 1995).

Registros semióticos de representación

Una manera que consideramos importante para apoyar el aprendizaje de la propiedad de densidad es el uso de varios registros de representación. La matemática trata con diferentes registros de representación –ya sea el geométrico, el algebraico (expresiones simbólicas), el aritmético, incluso el lenguaje coloquial (expresiones lingüísticas) – y cada uno de estos registros constituye una forma semiótica diferente (Duval, 1995/2004); es decir, comunica el significado de manera diferente. Las representaciones semióticas son fundamentales para el desarrollo de la actividad matemática misma que dependen de un sistema de escritura (decimal, fraccionaria, binaria, etc.) (Duval, 1995/2004). Esto además es particularmente relevante porque cuando se trabaja con números reales (como es nuestro caso), es necesario tener en cuenta que el número real tiene diversas representaciones (Apostol, 1976/2006).

Metodología

Diseño y elaboración de las actividades de la THA

Como ya mencionamos, en nuestra investigación trazamos una THA de acuerdo con los lineamientos de una investigación basada en diseño (Cobb y Gravemeijer, 2008), un enfoque metodológico en el que un investigador realiza un análisis minucioso de cómo probar y mejorar las conjeturas que se bosquejan. Cobb y Gravemeijer (2008) recomiendan el diseño y elaboración de más de un ciclo de actividades con el fin de refinar o modificar las conjeturas planteadas durante primer ciclo. Para esta investigación se contemplaron dos ciclos de actividades, y en el presente informe documentaremos algunos resultados del primer ciclo por cuatro estudiantes de Colombia, de entre 15 y 17 años de edad: Angie, Paola y Néstor (pseudónimos), quienes cursaban en su momento la educación media (bachillerato); y Violeta (pseudónimo), quien cursaba el último año de educación básica (secundaria). Estos estudiantes resolvieron algunas tareas propuestas de la THA de manera presencial, mientras que otras fueron desarrolladas de manera virtual, debido a la pandemia causada por el COVID-19.

La elaboración e implementación del primer ciclo de las actividades de la THA se conforma de tres fases. La primera fase corresponde a la aplicación de un cuestionario como pretest, la segunda corresponde a las actividades de la THA, y en la última se vuelve aplicar el cuestionario como postest. A continuación describimos las fases de la THA, luego presentamos resultados de las dos primeras fases y damos un ejemplo de lo ocurrido en la última fase.

Primera y tercera fase. *Pretest y postest.* Se utilizó el mismo cuestionario para el pre- y postest (con duración aproximada de 30 min), para observar la posible evolución del pensamiento de los alumnos. El cuestionario se conforma de cuatro ítems de preguntas vinculadas con la cantidad de números intermedios en un intervalo –preguntas inspiradas en las hechas por Suárez-Rodríguez y Figueras (2020), así como en otras planteadas por Vamvakoussi y Vosniadou (2004). La finalidad del cuestionario es conocer qué tanto saben los participantes respecto a la propiedad de densidad numérica, clasificando las respuestas de acuerdo a las categorías (ver Tabla 1) de Vamvakoussi y Vosniadou (2004). Las preguntas incluidas en el cuestionario son: *¿Cuántos números hay entre 0 y 1?*, *¿Puedes encontrar números decimales y/o fracciones entre 0.49 y 1/2?*, *¿Cuántos números hay entre 0.899 y 0.90?* En el cuarto ítem se presentó la siguiente situación:

> Pedro quiere dibujar una línea donde pueda ubicar números decimales. Inicia con el número 0.1. Después coloca el 0.2. En ese momento, Laura lo interrumpe y dice que el número que "sigue" de 0.1 es 0.11. ¿Quién tiene la razón, Pedro o Laura?, o ¿ninguno de los dos?, o ¿ambos?

Segunda fase. *La implementación de las actividades de la THA.* La THA se diseñó para llevarse a cabo en cuatro sesiones de actividades (ver Tabla 2; parecida a la que aparece en Suárez-Rodríguez y Sacristán, 2021, p. 1223), cada una con una hipótesis de aprendizaje correspondiente. Las hipótesis se definieron teniendo en cuenta varios temas de la matemática escolar que supusimos pueden guiar al estudiante a un aprendizaje y comprensión de la propiedad de densidad. No es necesario que el estudiante siga la secuencia de las sesiones, aunque se hace un primer acercamiento a la densidad con la de los números decimales, y se finaliza con los números irracionales. Cada sesión tuvo una duración de alrededor de 1h30'.

Tabla 2: Sesiones de la THA con sus hipótesis correspondientes

Sesión	*Hipótesis*
Sesión 1. Primeros acercamientos a la propiedad de densidad.	A partir de dos situaciones: una relacionada con la cotidianidad y otra vinculada con un escenario hipotético, se piensa que el estudiante puede tener sus primeros acercamientos a la propiedad de densidad.
Sesión 2. Acercamiento a la propiedad de densidad a través de la semejanza de triángulos.	Se contempla que usando semejanza de triángulos los estudiantes puedan aprender sobre la propiedad de densidad de los números racionales.
Sesión 3. Aproximación a la propiedad de densidad a partir de progresiones aritméticas y progresiones geométricas.	Es posible que hallando medios aritméticos y geométricos en un intervalo el estudiante comprenda la propiedad de densidad de los números racionales en el conjunto de los reales.
Sesión 4. Aproximación a la propiedad de densidad por medio de la propiedad de continuidad.	Se cree que usando la propiedad de continuidad los estudiantes comprenden la propiedad de densidad de los números irracionales en el conjunto de los reales.

Mediante esta THA se busca que los estudiantes logren una conciencia metaconceptual, al percatarse que sus concepciones no son incuestionables y que restringen la manera en que se adquiere un nuevo conocimiento (Vosniadou, 1994). Al final de las actividades de la THA se espera que el estudiante pueda distinguir entre un conjunto discreto y uno denso.

Resultados

Se usaron las categorías de Vamvakoussi y Vosniadou (2004) (Tabla 1) para el análisis de las respuestas del cuestionario, así como también de las respuestas en las actividades de la THA.

Resultados del pretest (primera fase)

La Figura 1 muestra la respuesta de Angie a la pregunta sobre la cantidad de números entre 0.899 y 0.90: *"solo [h]ay uno, porque está en la mitad de los dos y porque da paso al siguiente número".* Se deduce un *pensamiento ingenuo sobre lo discreto* en Angie derivado de sus conocimientos de los números naturales que son discretos, al decir "sólo hay uno" y que para ella un número decimal tiene sucesor ("da paso al siguiente número").

solo ay uno, porque esta en la mitad de los dos
y porque da paso al siguiente numero

Figura 1: Ejemplo de pensamiento ingenuo sobre lo discreto (Angie en pretest)

En la Figura 2 observamos que las respuestas de Violeta, Angie y Néstor a la pregunta de si existe un número que le sigue a 0.1, coinciden en que 0.2 es el número que le sigue a 0.1. En la respuesta de Paola: "*Sí existe un número que le sigue a 0.1[:] 0.11, 0.111, 0.111…,*" observamos que aunque, en su lenguaje coloquial, afirma la existencia de un sucesor, y nombra varios: "0.11, 0.111, 0.111[1]…", para ella, el hecho de añadir cada vez el número 1 en la parte decimal del número, le indica que existen más "sucesores" para 0.1. Consideramos que esos cuatro estudiantes exhibían allí un *pensamiento ingenuo sobre lo discreto* ya que, al parecer, creen en la existencia de un sucesor (o varios en el caso de Paola) en los decimales.

4. b. ¿Existe un número que le sigue a 0.1? Si tu respuesta es afirmativa, escribe el número que crees que sigue a 0.1. Pero si tu respuesta no es afirmativa explica por qué.

Respuesta de Angie

0.1 le sigue 0.2

Respuesta de Violeta

Si existe es el 0.2 y asi sucesivamente con los demas

Respuesta de Néstor

Rta. Para mi creo que es 0.2

Respuesta de Paola

Si, existe un número que le sigue a 0,1.
0,11, 0,111, 0,111...

Figura 2: Otros ejemplos de pensamiento ingenuo sobre lo discreto (Pretest)

Resultados de las actividades de la THA (segunda fase)

Se narran algunas actuaciones de los cuatro estudiantes durante el desarrollo de la THA.

Sesión 1. En la primera sesión los estudiantes resolvieron dos actividades de aprendizaje para tener un primer acercamiento a la densidad. En la segunda actividad se planteaba lo siguiente:

> Imagina que puedes observar a una rana que empieza a saltar desde el punto A y trata de llegar al punto B de la siguiente forma: 1er paso: La rana salta a la mitad. 2do paso: Luego salta a la mitad de lo que le quedó. 3er paso: Nuevamente, salta la mitad de lo que quedó, y así sucesivamente.
> 1. Después de que hayas imaginado la situación, ahora descríbela, o explícala…
> 2. ¿Cuántas veces saltará la rana entre los puntos A y B? Explica tu respuesta.

Al resolver esta actividad, consideramos que Angie, Violeta y Paola (ver Figura 3) se acercan a un *pensamiento avanzado sobre lo discreto*, cuando indican que la rana ha saltado una cantidad finita de veces, y usan como representación un segmento de puntos en un registro gráfico. Por otro lado, Néstor dice "*La Rana va a saltar sucesivamente hasta llega al punto B; […] va a llegar a su destino, saltando cada [vez] mitades*"; se podría pensar que concibe una infinidad potencial de saltos (también en la actividad previa había dicho que había "infinitos números" entre dos decimales); podría decirse que allí exhibe un *pensamiento ingenuo sobre lo denso*.

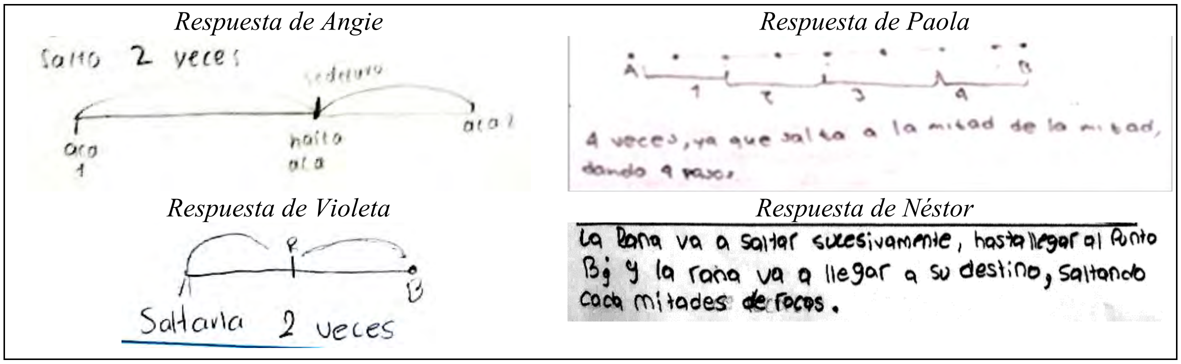

Figura 3: Respuestas de los cuatro estudiantes en la actividad "Saltos de Rana" (Sesión 1)

Sesión 2. La actividad de esta sesión se basa en tareas hechas por Tovar (2011). Se plantea la hipótesis de que se puede aprender sobre la propiedad de densidad de fracciones y decimales al trabajar con construcciones de triángulos semejantes sobre la recta numérica, tanto en GeoGebra (registro geométrico) como con lápiz y papel (registro aritmético o algebraico). Se pide ubicar los puntos A = 0 y B = 1 en la recta y construir un triángulo ABD. Luego se pide construir otro triángulo semejante AXC, con C punto medio de $\overline{AD}$ (Figura 4). Se pide hallar el valor numérico correspondiente a X. En la Figura 5a se observa que Angie halla X = 0.5 aplicando proporciones. Después se pide repetir el proceso para un tercer triángulo semejante AGF, con F punto medio de $\overline{AC}$ (Figura 4), y hallar el valor numérico correspondiente a G. En la Figura 5b se observa que Angie halla G = 0.25 aplicando nuevamente proporciones. Así Angie halla los números 0.25 y 0.5 entre 0 y 1, empleando representaciones semióticas en un registro algebraico como las escrituras fraccionaria y decimal.

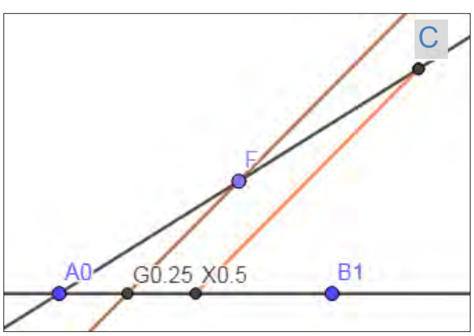

Figura 4: Gráfica de Angie en GeoGebra, localizando puntos entre A=0 y B=1 mediante semejanza de triángulos (Sesión 2)

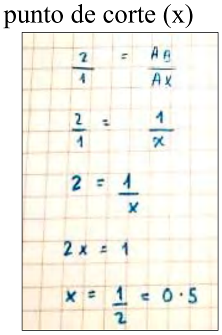
a. Usando semejanza de triángulos halla el punto de corte (x)



b. Realiza el mismo procedimiento para el intervalo entre 0 y 1/2. ¿Qué número obtuviste entre 0 y 1/2?

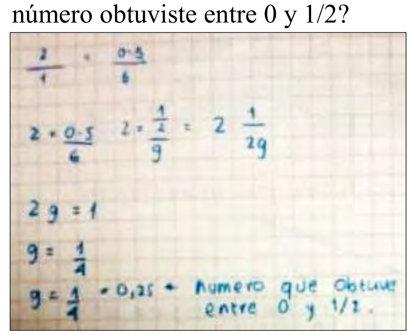


Figura 5: Respuestas de Angie (S2) para:
a. encontrar el valor del punto x entre 0 y 1
b. encontrar el número entre 0 y 1/2

Posteriormente, los estudiantes hallan otro punto entre 0 y 1 como es el 3/4 (0.75), y se les pregunta: *¿Qué sucede si continúas realizando el mismo procedimiento entre 3/4 y 1?,¿y así, en forma sucesiva?, ¿Cuántos números racionales se obtendrían?* La Figura 6 muestra las respuestas de los cuatro estudiantes a estas preguntas. Se puede pensar que Angie y Néstor exhiben un *pensamiento avanzado sobre lo discreto* porque hacen referencia a una cantidad de números finita (dicen que hay "varios" números racionales entre 3/4 y 1, y que se pueden obtener más). Por otro lado, la respuesta de Violeta ("*siguen aumentando la cantidad de números; se obtendrán muchos números racionales*") podría tal vez indicar un infinito potencial, lo que correspondería a un *pensamiento ingenuo sobre lo denso*. En cuanto a Paola, ella dice: "*Se seguiría obteniendo la mitad entre 3/4 y 1 y así sucesivamente*", lo que puede indicar que considera una infinidad potencial de números racionales, lo que correspondería a un *pensamiento sofisticado sobre lo denso,* ya que lo justifica con el proceso de sacar mitades en forma sucesiva.

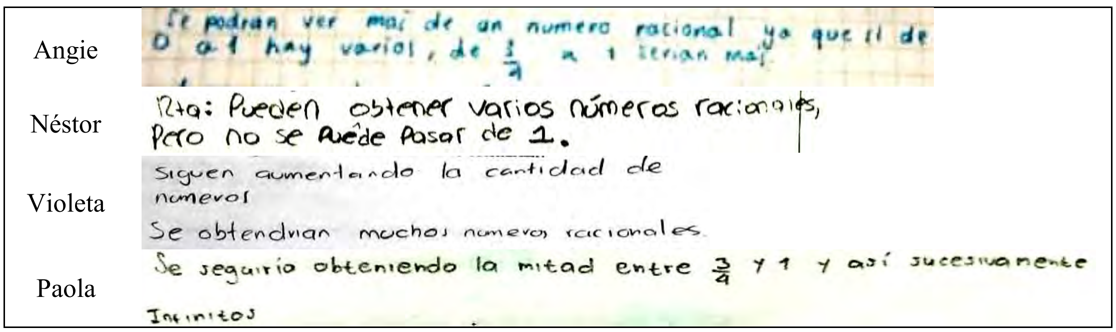

Figura 6: Respuestas de los cuatro estudiantes en la actividad sobre proporciones (S2)

Sesión 3. En esta sesión se llevaron a cabo tres actividades relacionadas con progresiones aritméticas y progresiones geométricas para que el estudiante pudiera ver otra forma de encontrar números en un intervalo (para aprender sobre la densidad de los racionales en los reales). Inicialmente, los estudiantes debían hallar cinco medios aritméticos entre 4 y 22 utilizando el término n-ésimo de una sucesión: $u = a + (n - 1)d$, donde a es el primer término, n el número de términos y d la diferencia entre un término y otro. Después se les preguntó cuáles serían los nuevos medios aritméticos si la diferencia, d, se redujera a la mitad (ver Figura 7, Violeta).

Si d se redujera a la mitad, es decir, d=1.5, o d=3/2, ¿cuáles serían los nuevos medios aritméticos entre 4 y 22?

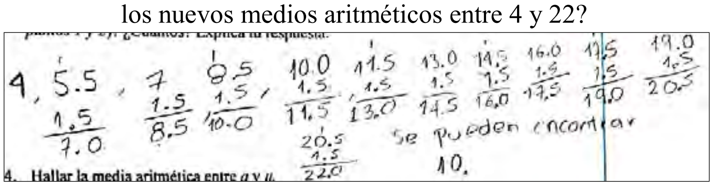

Figura 7: Respuesta de Violeta (Sesión 3)

¿Puedes hallar más números entre 4 y 22 (diferentes a los números hallados en las anteriores preguntas)? ¿Cuántos? Explica tu respuesta

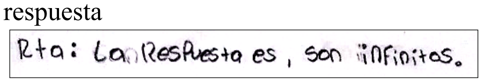

Figura 8: Respuesta de Néstor (S3)

La Figura 7 muestra cómo Violeta halla los nuevos medios aritméticos –5.5, 7, 8.5, 10, 11.5, 13, 14.5, 16, 17.5, 19, 20.5–, y responde a la pregunta de si se pueden hallar más números entre 4 y 22 (diferentes a los números hallados en las preguntas anteriores de la actividad), cuántos y por qué. Ella responde que *"se pueden encontrar 10"* (aunque fueron 11 los que halló), es decir, una cantidad finita de números entre 4 y 22, por lo que exhibe un *pensamiento avanzado sobre lo discreto*. Violeta usa la escritura decimal como representación y realiza adiciones en un registro aritmético. Néstor (ver Figura 8) exhibe un *pensamiento ingenuo sobre lo denso,* cuando afirma que se puede hallar una infinidad de números.

Sesión 4. En esta sesión se utilizó otra actividad basada en ejercicios propuestos por Tovar (2011). La hipótesis es que el estudiante puede aprender sobre la densidad de los irracionales en los reales, a partir de la continuidad de la recta con relación a la no correspondencia entre los números racionales y los puntos de la recta. Se pedía construir un cuadrado de lado 1, en el plano cartesiano, con un vértice en el origen, y rotar la diagonal del cuadrado para quedar sobre la recta del eje horizontal (ver el segmento $\overline{DF}$ en la Figura 9 – ejemplo de Angie). Los estudiantes observaron que el "extremo derecho" del segmento de la diagonal no coincidía con ningún número racional de la recta cuando realizaban varios zooms en GeoGebra. Luego ellos escribieron varios intervalos que encerraran a ese punto: la Figura 10a muestran dos intervalos dados por Néstor que contienen a ese punto. Paola (ver Figura 10b) dio cuatro intervalos cada vez más pequeños. Con esto los estudiantes observaron que entre dos números reales se puede hallar un número irracional (en este caso $\sqrt{2}$). Aquí no se hizo un análisis de los pensamientos.

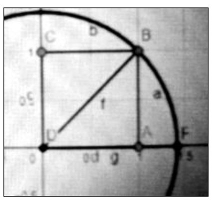

Figura 9: Gráfica de Angie en GeoGebra (S4)

a. Respuesta de Néstor

b. Respuesta de Paola

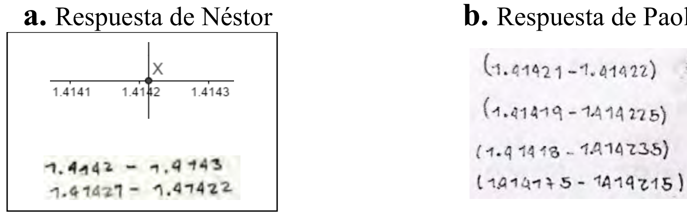

Figura 10: Intervalos escritos por Néstor y Paola que encierran al punto cuyo valor corresponde a la longitud de la diagonal del cuadrado (Sesión 4)

Resultados del postest (tercera fase)

En sus respuestas al postest, los estudiantes mostraron evidencia de haber cambiado sus formas de pensamiento en sus respuestas a las preguntas relacionadas con la cantidad de números en un intervalo con respecto a las dadas en el pretest (primera fase). Por ejemplo, para la pregunta *¿Puedes encontrar números decimales o fracciones entre 0.49 y 1/2? ¿cuántos números?* Néstor cambia de un *pensamiento ingenuo sobre lo discreto* en el pretest (donde él dice: "*1/2 = 0.5 sigue a 0.49. No hay* [*números*]") a un *pensamiento ingenuo sobre lo denso* (cuando en el postest cuando dice: "*hay infinitos números*").

Conclusiones

Las actividades propuestas en la THA tenían como objetivo que los estudiantes aprendieran sobre la propiedad de densidad numérica al resolver tareas en diversos contextos y registros semióticos. Temas como construcciones de triángulos semejantes sobre la recta numérica, progresiones aritméticas y geométricas, propiedad de continuidad, facilitan el encontrar diferentes formas de hallar números en un intervalo. Asimismo, los estudiantes tuvieron la oportunidad de usar varios registros semióticos de representación, como el algebraico y el geométrico, empleando las escrituras fraccionaria y decimal; incluso el lenguaje coloquial para expresar sus ideas durante la puesta en marcha de la THA. En algunas situaciones los estudiantes lograron comprender que existe una infinitud de números en un intervalo real. Sin embargo, en otras, no pudieron superar la creencia de que cualquier número tiene un sucesor (o tal vez entienden por "sucesor" a cualquier número mayor). Por ello, se sugiere la realización de actividades enfocadas a superar de esta dificultad.

Agradecimientos

CONCEPTUAL REORGANIZATION, FROM COUNT-UP-TO TO BREAK-APART-MAKE-TEN: A CASE OF A 6TH GRADER STRUGGLING IN MATHEMATICS

Through a constructivist teaching experiment, we studied how a 6th-grade student (Adam, pseudonym) struggling in mathematics may reorganize his available additive scheme (count-up-to) into a more advanced scheme involving the decomposition of composite units (break-apart-make-ten, or BAMT). First, we posed a task that led us to infer Adam was yet to construct the BAMT scheme at the anticipatory stage (solving a task without prompting). We thus turned to promote reorganization of his anticipatory, count-up-to scheme used to solve missing-addend tasks. Through reflection on the relationships between his goal, count-up-to actions, and effect of those actions, Adam independently brought forth what he called "easy number-pairs" (i.e., 10+X = X-teen). This seemed to afford his reorganization of count-up-to into the BAMT scheme. We discuss implications of this reorganization for theory building and practice.

Keywords: conceptual reorganization, concept of number, struggling student

We address the research question: How may a child, who constructed count-on for adding or count-up-to for solving a missing addend task (see Fuson, 1982, 1986) at the anticipatory stage (see below), advance to constructing the break-apart-make-ten (BAMT) strategy? The former two strategies indicate a concept of number that does not yet include disembedding units, whereas the latter does (Ulrich, 2015; see next section). Addressing this question is important in two ways. First, in additive reasoning, count-on (e.g., 8 + 5 = ?) and count-up-to (e.g., 8 + ? = 13) involve (a) recognition of the first addend as a unit of its own right and (b) *operating on 1s* of the second addend. In count-on, the child may use a sequential activity of concurrently uttering a number while putting up a finger for it (e.g., 8; 9-10-11-12-13). For count-up-to, the child may use a sequential activity of concurrently uttering numbers with fingers and stopping at the given total, then looking at their finger pattern to determine the answer. Critically, decomposing units by disembedding a part without "losing sight of a given total" is needed for subtraction to become the opposite of addition. For example, 13 is recognized as a unit made of two sub-units, 8 and 5, that could compose 13 or one unit be disembedded from 13 to figure out the other unit as the difference. Such a concept serves as a foundation for BAMT (e.g., 10 = 8 + 2 and 5 = 3 + 2, so "I can give 2 (from 5) to 8 to make a ten, then add the remaining 3 to 10).

Second, recent studies relating children's spontaneous additive strategies to multiplicative reasoning demonstrated that BAMT provides a stronger conceptual basis for the latter (Tzur et al., 2021; Zwanch & Wilkins, 2020). We further explain this linkage in the next section. Here, we only note that, to us, BAMT constitutes a direly needed 'conceptual key' to open the 'gate' for advancing any student, let alone those struggling in mathematics, to multiplicative reasoning. A study of how a child may construct BAMT as reorganization in their less advanced additive schemes can contribute to explaining, as well as promoting, this advance.

Conceptual Framework

Our study is informed by general and content specific notions of a constructivist theory. The former derive from Glasersfeld's (1995) scheme theory, which portrays the cognitive 'apparatus' a child uses in assimilation of mathematical problem situations (tasks). Drawing on the 3-part definition of a scheme (goal –> activity –> result/effect), Tzur & Simon (2004) postulated two stages in which a new scheme is being constructed. The first, *participatory* stage, is marked by the learner needing prompts to regenerate and use abstractions they have constructed. Without prompts, the learner brings forth and uses schemes available to them that are less advanced than the evolving (prompt-dependent) scheme. Available schemes are those at the *anticipatory* stage, which are marked by a learner's spontaneous use of those schemes to make sense of and solve given tasks (Tzur et al., 2021). To articulate how a learner reorganizes available schemes into more advanced ones we draw on Simon's (1995) notion of *hypothetical learning trajectory* (HLT). That is, we link goals specified for learners' construction with a hypothesized change process they may go through and with tasks that may foster that change process.

The content specific constructs revolve around Steffe and Cobb's (1988) core notion of *number as a composite unit*. They postulated a progression of schemes in children's numerical development. In the first, *Initial Number Sequence* (INS), a child anticipates a number to be the result of counting activities. The INS affords count-on because a child takes for granted both the first addend (e.g., uttering "8") and the second addend as shown in keeping track and anticipating where to stop the count (e.g., 9-10-11-12-13). However, a child reasoning with the INS is limited to operating on 1s and is yet to consider the nested nature of numbers – a scheme that evolves with the *Tacitly Nested Number Sequence* (TNS). Here, in activities that involve counting of 1s, a child can implicitly think of a given number (e.g., 8) as nested (embedded) within 9, or within 10, or within 13, etc. Whereas the TNS affords using count-up-to for solving missing addend tasks, a child reasoning with the TNS is yet to disembed composite units from a given number (e.g., 10) – a more advanced scheme known as the *Explicitly Nested Number Sequence* (ENS). Here, in situations that involve operating on 1s and composite units, a child can intentionally decompose given numbers into smaller numbers without losing sight of the given number. Thus, the ENS affords a child's use of BAMT, which requires intentionally decomposing the second addend in a way suitable for composing 10 with the first addend, then going back to the remaining part of the second addend (as explained in the previous section). Due to the new ability for composing/decomposing units at will, the child can also coordinate count-on and count-up-to with the use of "easy number pairs" in the second decade (i.e., $10 + 3 = 13$).

Methodology: A Constructivist Teaching Experiment

This study was part of a larger research and professional development project, focusing on teaching mathematics conceptually (grades K-8) and funded by a small school district in the USA southwest region (see Acknowledgment). We conducted a teaching experiment (Cobb & Steffe, 1983) with seven of the nine, struggling grade-6 students at the school who provided parent consent and a student assent. A teaching experiment is a qualitative methodology designed to build models of how learners construct (reorganize) schemes.

Participant and Context

Two main reasons led us to focus on Adam (pseudonym, age 11, grade 6, identified by teachers as struggling in mathematics), who worked with a partner (Gary). First, at the study start, Adam demonstrated spontaneous use of count-on and count-up-to (INS and TNS, respectively) considered a conceptual basis for constructing the BAMT strategy and thus advance to the ENS scheme. Second, despite our repeated efforts to promote BAMT during the first four episodes, using a task and manipulatives (see Double Decker Bus below) designed and successfully used in prior research, Adam was yet to construct BAMT. As our data show, BAMT was not yet available to Adam (or Gary) at the start of the episode reported in this study.

Accordingly, Adam can serve as a case for articulating an HLT from his anticipatory schemes to BAMT (and ENS). Consistent with literature on case studies (Creswell, 2013), we stress that the case is not Adam but rather the process of change we could infer from our work with him. That is, we designed our study to provide an explanatory account of the conceptual change process – not to demonstrate the extent to which it characterizes (many) other children's learning. We thus contend that the HLT explained here is likely to apply to other children who have an anticipatory count-up-strategy and spontaneously use "easy number pairs" as did Adam.

Data Collection

In a teaching experiment researchers serve as teachers of students whose schemes they intend to model. The lead researchers (denoted R1 and R2) conducted weekly teaching episodes with Adam and Gary, 20-40 minutes each, because they seemed conceptually near to one another. Due to the COVID-19 pandemic, we conducted the video recorded teaching episodes in a hybrid mode. R2 worked with the students on site. R1 participated virtually (Zoom) and created a back-up recording on that software. Our work required that we all wear masks, which limited the ability to observe the child's lip movements when operating silently. The presence of R2 allowed her to hear nearly everything the students whispered. To ascertain validity of our data, we thus constantly asked the students to first solve tasks as they wanted, then – using what we could observe – either repeat their work out loud or tell if a researcher's account of it is accurate.

In teaching Adam and Gary, we used a game called the *Double-Decker Bus* (DDB). The first author designed DDB to promote an advance to BAMT in children inferred to have an anticipatory stage of count-on or count-up-to. The students are introduced to the game with a picture of a double-decker bus and a rule made to constrain their operations on units so 10 becomes a special anchor. Each deck on the DDB has 10 seats; the rule is that all seats on the lower-deck must be filled before passengers can move to the upper-deck. In each round of the game, a task is posed using the following story line. The bus leaves main station empty, then a few passengers get on it at the first stop (e.g., 9) and at the second stop (e.g., 4). The child's goal is to figure out the total number of passengers on the DDB after the second stop.

To support the child's reasoning and reflection on their goal-directed activities, a two-row rekenrek, with 10 beads each (grouped by color as 5 + 5), is provided for them to use as they deem appropriate. In our example, a typical solution both Adam and Gary initially used was to move 5 + 4 beads on the lower-deck for 9 passengers, then count-on to add 1 more bead to that deck and up to the given four (hence, 3) to the upper deck. Then, they glean the answer from the manipulative as 10 + 3 = 13. The DDB can foster reflection on the decomposition of 10 into 9 + 1 as a step in the child's activity to find the total. For example, the researcher may ask students: "I asked you to add 4, so why are there only 3 on the upper-deck?" We note that numbers used in those tasks typically begin with 9 + x. Because 10 is the number after 9 (Baroody, 1995), a child is hypothesized to focus on decomposing just one unit of 1. Then, game variations proceed to 8 + x and to 7 + x. Children can reflect on their operation across different tasks (e.g., 9 + 3, 9 + 6, 9 + 4) to abstract the intended, invariant anticipation known as BAMT.

Data Analysis

To analyze our video records and field notes from each episode, we used three iterations. First, after each episode, we held an ongoing analysis (debrief) to discuss major events. These debriefs led to planning next episode tasks. Second, team members created and read transcripts of the episode on which we focus in this paper and the episode just prior to it, highlighting segments with critical events (Powell et al., 2003), such as changes in a student's strategy, or beneficial teaching moves. This iteration included hypotheses we raised about why Adam behaved in the ways he did. Third, we discussed (while re-observing) the highlighted segments to identify compelling evidence for our inferences and conceptual claims. We organized all segments in a story line (next section) that conveys the HLT from count-up-to into BAMT.

Results

We begin with data analysis indicating that, at the start of the episode in which Adam reorganized his concept of number, he was still using an anticipatory scheme involving count-up-to, that is, a concept of number characteristic of TNS students. Next, we shift to data analysis indicating his advance from that early numerical way of operating to the more sophisticated way of BAMT, characteristic of ENS students.

Adam's Anticipatory Count-Up-To Scheme (TNS)

During the first four episodes with Adam and Gary, they both appeared to use the count-on strategy spontaneously and independently. For example, when asked how many total candies they would have if adding 8 and 5, they both used their fingers to keep track of the second addend items (8; 9-10-11-12-13). During the episode prior to the one focused on in this paper, they also solved missing addend tasks using the count-up-to strategy (e.g., to solve how many more cubes are needed to create a tower of 12 if you already have 9 cubes, they both counted on their fingers: 9; 10-11-12 and then looked at the fingers they raised and respond, "3").

During those four episodes, we engaged Adam and Gary in solving Double Decker Bus (DDB) tasks. Using the manipulatives in activity, they showed some initial progress toward BAMT. For example, to add 9+4 they first moved one bead on the lower deck to complete the required number of 10 passengers. Then, they moved 3 more beads to complete the task and responded: "13" (pointing to 10+3 as the two "adjusted" addends). Furthermore, in reflection on their activity, they explained why the upper deck has only 3 passengers whereas the problem asked about 4 passengers added to 9 and responded: "Because you have to put 1 passenger here [lower deck] and 4 minus 1 is 3." In fact, at the fourth episode they also began solving tasks asking about 8 + 5 passengers (e.g., "we put 2 more on the bottom and 3 go here [upper deck]"). However, critically, when we presented a task at the start of each episode without any hints (e.g., How many in all are 9 cubes and 4 more cubes?), they reverted to spontaneously and independently using count-on to solve it.

After the 1.5-month winter break, we again presented a missing addend task for them to solve – not in the DDB context but rather in a context (towers and cubes) we never used with them before: "Pretend you made a tower of 9 cubes. Write 9 on your paper so you remember ... If I wanted to make the tower taller and have 16 cubes, how many more cubes would each of you need?" Excerpt 1 shows how Adam solved this task (R1 and R2 stand for the researchers).

Excerpt 1: Anticipatory count-up-to

R1: (After Gary explained his answer of 7) Adam, how did you get it?

Adam: I counted on my fingers; because 9; [then] 10 (puts up thumb on left hand), 11 (puts up index finger), 12 (puts up middle finger), 13 (puts up ring finger), 14 (puts up pinky), 15 (puts up thumb on right hand), 16 (puts up index finger; shows a full hand plus two more fingers). That's 7, so I know there's 7 [cubes needed].

Excerpt 1 indicates that, at the episode start, Adam has independently and spontaneously used the count-up-to strategy. As Tzur et al. (2021) explained, a spontaneous strategy for a task involving no hints serves as an indicator of a child's anticipatory scheme and, likely, the most advanced strategy (and concept) the child has available at the time. Because count-up-to involves operating on 1s while reasoning numerically about the missing addend, but not yet disembedding a composite unit, we attributed to them the TNS stage. We thus turned to further attempts of fostering their use of BAMT. Excerpt 2 presents a segment of those attempts. We emphasize that Adam's use of count-up-to was used as his answer-checking strategy, whereas his explanation of how he solved the task indicated a shift to BAMT.

Excerpt 2: Adam's shift to BAMT

R1: Now, you still have the tower of 9. [But] I said, you know what, 16 is too tall of a tower. I only want you to have 14. You already have 9, but you want to have 14, not 16. How many cubes would you need to ask for?

Adam: (First, immediately and with no indication of using his fingers, writes down "5" on the page. Then, seemingly to check his answer, he quietly uses count-up-to on his left-hand fingers, putting them up one at a time. After three times of checking his answer, he raises his hand to indicate, "I am done.")

R1: What is the answer?

Adam: Five (5).

R1: How did you get it?

A: I got it by taking away; because 9 + 1 is 10, then all you have to do is add 4 to it.

R1: This is really cool. I like it. (Turns to Gary) Did you understand what Adam said, or would you like him to repeat [his explanation]?

Gary: (To Adam) Could you repeat it?

Adam: I added 1 to 9, then I had 4 left; so, 14. [It is another] easy number-pair.

R1: Here's what I heard Adam say. I am at 9. I only need 1 more to make 10. Is that correct so far?

Adam: Yes.

R1: Now, if I take one to make 10, and I need 14, to get from 10 to 14, I need 4 more. Is that correct Adam?

Adam: Yes.

R1: Then, if I need to take 1 to make 10, and 4 more to make 14, the 1 and the 4, make 5. Adam, is that what you did?

Adam: (Nods head, "yes.")

R1: Adam, I then saw you also using your fingers like you did before. Did you do that to check?

Adam: (Nods head, "yes") Mm-hmm.

R1: So, first you did the 9+1 and 4 more, then you checked with your fingers?

Adam: (Nods head, "yes.")

R2: (A bit later) Adam, you said, "easy number-pair." Can you tell me what you mean by that?

Adam: Like 10+4, 10+3, 4+4, and different numbers like that.

R2: So, are you saying they're like easy numbers to add?

Adam: Yes.

R2: You're trying to create an easy number [to] add by making the 9 [into] a 10?

Adam: Yes.

R1: (A little later, asking about other easy number pairs) What if I wanted 19?

Adam: 10 + 9. Anything in the teens can be paired up with a 10.

R1: What about 13?

Adam: 10 + 3.

Excerpt 2 indicates the first time we witnessed Adam's use of BAMT independently, spontaneously, and not in the DDB context. Importantly, we neither taught Adam about "easy number pairs" nor have knowledge when and how he was taught to use it. Key here, however, is that for the first time he independently and spontaneously brought forth this idea in what, for him, seemed a novel situation. We explain his shift to BAMT as rooted in reflecting on his count-up-to strategy and its effect after solving the first task (9 + ? = 16).

Specifically, when solving and then explaining that first task, Adam repeatedly showed how he raised his thumb for 1 item added while uttering 10 as the number after 9. Upon completion of the count, he held up and looked at 7 fingers while uttering "16." We infer he noticed the effect of his count-up-to as a number in the teens, which brought forth his notion of easy number pairs. In turn, he likely also coordinated "6" in the easy number pair (10 + 6) as being 1 less than 7 given to him by the second addend (which he showed on his fingers). Our explanation resonates with how Adam explained to Gary why this (BAMT) strategy worked for finding how many more cubes were needed to make a tower of 14 cubes ("I added 1 to 9, then I had 4 left; so, 14. [Another] easy number-pair."). It was further corroborated by Adam's response ("Yes") to R2's question, "You're trying to create an easy number [to] add by making the 9 [into] a 10?" and to R1's follow-up question about 19: "10 + 9. Anything in the teens can be paired up with a 10."

We emphasize that Adam's work led us to explain his shift to BAMT differently than what would be a trajectory from count-on to BAMT. In such a typical shift, a child would have to first notice the need to decompose the second addend into two numbers, 1 and the number before the second addend (e.g., to add 9 + 7 they would decompose 7 into 6 + 1, then add 1 to 9 to make 10, and complete with adding 6). Adam's case presents a somewhat reversed order of the reflective process. That is, he did not begin by decomposing 7 into 6 + 1. Rather, he first reflected on his work to solve a missing addend task by noticing that a total in the teens (e.g., 16) could be thought of (decomposed) into 10 and another number in the easy pair (e.g., 6). In turn, this reflection seemed to lead to his consideration of that easy number pair addend as a constituent of the task's second addend (here, 7), which led to decomposing that given second addend (e.g., 7 = 6 + 1, and that 1 is used to "make 9 [into] a 10.") We contemplate that Adam's shift might be a more accessible one for students than the one requiring decomposing of the second addend because such a shift requires setting a sub-goal of disembedding 9 from 10 as a strategic first step (sub-goal) for a yet-to-be-foreseen decomposition of the second addend.

Following this realization of Adam's shift to BAMT, to further promote his and Gary's decomposition of 10 into composite units, we engaged them in creating a tower of 10 (each). Then, we asked one of them to "chop off" a few cubes and write an equation for their quantities. For example, we asked Adam to take the top 2 cubes and place them near the tower. To symbolize this situation involving his and Gary's cubes, he wrote: "10 = 8 + 2." Similarly, after Gary chopped off 3 from his tower of 10 cubes, Adam wrote the equation: "10 = 7 + 3." It is in those tasks that we realized the difference in the two students' reasoning. For Gary, writing an equation proved to be a tremendous challenge, mostly done after hearing Adam's explanation. For Adam, writing an equation symbolizing his decomposition activity seemed straightforward. We emphasize that his equations did not show an addition problem on the left and an answer on the right but rather what seemed to be an equivalence of the two quantities. At this point, we decided to turn back to tasks presented in the DDB context. The first task involved figuring out how many passengers need to get on the bus in the second bus-stop if there were already 9 passengers on it and no one went to the upper deck. Adam knew, and explained to Gary, why just 1 passenger would get on the bus at the second stop. We followed this task with one requiring to go beyond 10 passengers on the bus in all (Excerpt 3).

Excerpt 3: Adam's transfer of BAMT to the DDB context

R1: Let's go back to the start. First stop, 9 people get on the bus. Now, I want you to find the number of people who will get on at the second stop so in the end we will have 12 people on the bus in all. How many people should get on at the second stop, so we have 12 people?

Adam: (Immediately and with no hesitation uses the rekenrek to add 1 more bead to the lower level and 2 more to the upper level.)

R1: Adam, tell us how many you had to put in order to get to where you are.

Adam: Three (3), because there is one in the bottom deck. That makes 10, then 2 up here (points to the upper deck), makes 12.

R1: Why is it 3?

Adam: There's a rule saying the bottom deck has to be full before you go to the top one. So, 1 (shows moving again one bead on the lower level), 2 (moves a bead over on the top deck), 3 (moves another bead over on the top deck).

Excerpt 3 indicates that, in this new missing addend task, Adam transferred his evolving anticipation of the goal-directed activity in the towers and cubes context to a context (DDB) in which we never saw him using BAMT on his own. From his immediate actions we inferred that at this point he anticipated the activity sequence of first using an easy number-pair (12 = 10 + 2), leading to then concluding that 3 passengers would be added to 9 for that total to be accomplished because, for him, 1 would be necessary to compose 10 as the start of the easy number-pair. Based on this transfer, and on the fact that Adam spontaneously brought forth the easy number pair component of a BAMT strategy, we conjectured that he had constructed an anticipatory stage of an ENS concept of number, indicated by disembedding and decomposing two addends (i.e., 10 + x = x-teen and 10 = 9 + 1). We tested this conjecture with a no-hint task at the start of the following week's episode. It turned out we preemptively attributed the anticipatory stage to Adam. For example, he used count-on to solve the task: How many cookies are there in all if a baker placed 9 in one pan and 7 in another pan. We thus attributed to Adam an initial abstraction of BAMT at the participatory stage.

Discussion

In this study, we articulated an advance in a child's concept of number as a composite unit, from count-up-to (TNS) to the BAMT strategy (ENS). Being a case study of the phenomenon of such a conceptual advance, we contend that the reorganization articulated here is likely to pertain to other students at different ages, grade-bands, or mathematical aptitudes. In and of itself, this reorganization is key to the child's additive reasoning, that is, to decomposing and disembedding numbers as composite units when adding or subtracting whole numbers. For example, Adam's BAMT indicated he thought of 12 as a unit that could be decomposed in two related ways: (a) into 10+2 and (b) into 9+x, with x being composed of 1+(x-1). Such an understanding underlies thinking of "fact-families" (e.g., 9+3=12, 3+9-12, 12-3=9, and 12-9=3). Just as important, this conceptual advance opens the way to developing multiplicative reasoning with whole numbers, which are highly limited or impossible for INS or TNS students (Steffe & Cobb, 1988).

For research and theory, this study contributes a plausible HLT for advancing to BAMT. Importantly, the advance we studied did not begin with a child's use of the anticipatory count-on strategy (INS) and a corresponding attempt to promote decomposition of the second addend. In fact, our data indicated that this path, used with Adam and Gary during the first four episodes, failed to promote BAMT. Instead, capitalizing on what Adam taught us, our HLT builds on the child's count-up-to strategy (TNS) and focuses on disembedding and decomposing two addends that make up an "easy number-pair" in the second decade, or "x-teens" (e.g., 14 = 10 + 4). In cases of adding 9 + x (or 8 + x), the child would then bring forth a decomposition of 10 into 9 + 1 (or 8 + 2) and learn to use it strategically by subtracting the needed complement-to-10 (e.g., 1) from the given second addend (e.g., 4 – 1 = 3). In turn, the child would complete the process by adding that decomposed/disembedded unit to 10 (e.g., 3; so, 13).

For practice, our study can inform teachers' efforts to effectively foster what, arguably, is the most foundational concept in mathematics, namely, number as composite unit (Steffe & Cobb, 1988). The HLT we proposed would likely support children's construction of addition and subtraction of whole numbers as two sides of the same coin. Said differently, someone who can compose and decompose given units at will, could come to "see" that any whole number (e.g., 14) may be constituted as a part-part-whole relationships (14 = 10 + 4 = 9 + 5, etc.). Thus, this study supports a way of thinking about and carrying out teaching of BAMT to students, a concept that proved an asset in students' learning to reason multiplicatively (Tzur et al., 2021).

PROPORTIONAL REASONING: VISUALIZING A KNOWLEDGE RESOURCES FRAMEWORK

Keywords: Rational Numbers & Proportional Reasoning, Teacher Knowledge, Preservice Teacher Education

Proportional reasoning is a key concept in school mathematics. However, research on the teaching and learning of proportional reasoning is still lacking (Lamon, 2007). There has been wider recognition recently of the importance of proportional reasoning and new frameworks have emerged to help researchers make sense of how teachers draw upon their own knowledge of proportional reasoning when responding to classroom tasks about the subject. Among these is the Framework for Teachers' Robust Understanding of Proportional Reasoning for Teaching (Weiland, et al., 2020). This framework consists of 19 knowledge resources teachers could draw upon in responding to proportional reasoning tasks. Although, these resources are a contribution to the field of mathematics education, they are presented as a list, without structure, hierarchy, or relation, calling to question the relation between the knowledge resources.

In our recent use of this framework to code beginning teacher proportional reasoning responses (Glassmeyer et al., 2021), the research team documented patterns in coding which caused us to look beyond individual categories. We turned our attention to look for relationships that might exist, and if there was a hidden structure among these 19 knowledge resources that could emerge to help us make better sense of the framework. We began a process of grouping knowledge resources by topic and theme, noting that all the categories seemed to exist on a spectrum of proportional reasoning. Some knowledge resources put a primary focus on an individual ratio (e.g. creating the ratio, identifying the quantities within the ratio, abstracting a measure that the ratio described). Other knowledge resources put their focus on proportions that are created (e.g. equivalence, covariance, and preventing distortion). Between these tentpoles, other knowledge resources focused on the altering of a ratio into something equivalent, setting the stage for the creation of a proportion. Knowledge resources were placed along the spectrum in groupings with other related categories. A couple knowledge resources were broad in their description and covered a greater portion of the spectrum. The end result was an organized framework that delineates how the original knowledge resources (Weiland et al., 2020) coexist in relation to one another. To factcheck our framework, we sought the input of Weiland et al. (2020), who agreed that we maintained the original integrity of the knowledge resources.

This poster presents the visual organization resulting from the work done classifying and sorting the 19 knowledge resources of the Framework for Teachers' Robust Understanding of Proportional Reasoning for Teaching. We show how this visual organization, our revised framework, was used to help in the coding of proportional reasoning data. Additionally, we also show how the idea of the groupings along the spectrum allowed for new patterns to emerge when trying to make sense of coding results and how this may inform both researchers and teacher educators as they conceptualize how to support students with learning proportional reasoning. This poster would be helpful not just for those focused on proportional reasoning, but also for those looking to add new layers of understanding to existing frameworks in use.

Teacher leadership is essential to meet the needs of students, teachers, and schools in an effective way. To provide a better support system in high-need schools, the Rice University Robert Noyce Master Teaching Fellowship (RU-MTF) program further developed and supported 14 secondary mathematics teacher leaders. In this paper, we described two of the master teaching fellows' (MTF) reflections on and perceptions of teaching mathematics in high-need schools and teacher leadership throughout this program. To do so, we applied a deductive approach in thematic data analysis and relied on conceptual framework of teacher leadership and domains of teacher leader model standards. The emerged themes reflected the ways in which these two MTFs attempted to (a) promote student success, (b) address concerns around diversity and equity, and (c) facilitate uncertain challenges during COVID-19 pandemic.

Keywords: Instructional Leadership, Professional Development, Teacher Beliefs, Equity, Inclusion, and Diversity.

Teacher shortage and turnover have been a continuous concern in the United States particularly for mathematics teachers and in high-poverty and high-need schools (Carver-Thomas & Darling-Hammond, 2019). Effective teacher leadership can support developing and sustaining highly qualified teachers in the profession and positively affect student achievement (Darling-Hammond, 1998; Elmore, 2002; York-Barr & Duke, 2004). Thus, developing K-12 mathematics teacher leaders can support a system for teachers' persistence and retention (Green & Kent, 2016). Over a five-year period, Rice University Robert Noyce Master Teaching Fellowship (RU-MTF) program developed secondary mathematics teacher leaders with mathematical content and research-based pedagogical knowledge, leadership, and mathematics advocacy skills. As a part of exploring the effects of the RU-MTF program, in this paper, we describe two master teaching fellows' (MTF) perceptions of teaching mathematics in high-need schools and teacher leadership throughout this program.

Teacher Leadership

Over the past few decades, many constructs of teacher leadership have been discussed in which teachers play a central role in ways schools operate and in the core functions of teaching and learning (Danielson, 2007; York-Barr & Duke, 2004). Leadership by teachers is essential to serving the needs of students, schools, and the teaching profession (Teacher Leadership Exploratory Consortium [TLEC], 2011). Teacher leadership may be broadly defined as the active involvement of teachers in the improvement of school culture and instruction and ultimately student learning through their participation in school-wide decision-making, and promotion of their teaching and learning expertise (York-Barr & Duke, 2004). According to York-Barr and Duke (2004), the dimensions of teacher leaders' practices include coordination and management; district or school curriculum work; professional development of teacher peers; participation in school improvement efforts; parent and community involvement; professional contributions; and building partnerships with pre-service teacher education programs. Similar to these dimensions, the teacher leader model standards present seven domains: "fostering a collaborative culture to support educator development student learning;" "assessing and using research to improve practice and student learning;" "promoting professional learning for continuous improvement;" facilitating improvements in instruction and student learning;" "promoting the use of assessments and data for school and district improvement;" "improving outreach and collaboration with families and community;" and "advocating for student learning and the profession" (TLEC, 2011, p. 9).

To address the critical need for recruiting and supporting teachers to become teacher leaders in high-need schools as set forth by National Science Foundation's (2021) Robert Noyce Program and to build upon prior efforts for developing teacher leadership practices (e.g., York-Barr & Duke, 2004), RU-MTF aimed to engage MTFs in customized professional learning experiences that include university graduate-level mathematics coursework and Advancement Via Individual Determination (AVID) Path Training. In this paper, we focused on two MTFs and reported on their reflections and perceptions of teaching mathematics in high-need schools and teacher leadership within the RU-MTF program.

Methods

MTFs and Context

Fourteen secondary mathematics teachers (seven female and seven male) with exceptional academic merit reflecting the diversity of the student population and teachers (seven White, three Hispanic, two African American, and two Asian) from high-need schools in Houston Independence School District were selected as MTFs to participate in the five-year (2016-2021) RU-MTF program. In 2016, MTFs' teaching experience ranged from four to 40 years.

RU-MTF

In the first two years of the program, MTFs completed two one-week long summer courses in contemporary topics in secondary mathematics (e.g., equity, content, pedagogy, leadership skills in mathematics teaching) and two one-week long AVID Path Trainings to advance culturally relevant teaching practices for both educators and students. In addition, MTFs got involved in leadership activities (e.g., plan and co-teach with other mathematics teachers, work with colleagues to enhance students' self-efficacy, support and collaborate other MTFs, etc.) in their schools, school district, and at Rice University. Throughout each school year, MTFs also attended meetings to discuss the goals and expectations of their leadership work.

Data Sources and Analysis

In each year of the program, MTFs wrote their reflections for the Summer, Fall, and Spring semesters. In this paper, we focused on only two MTFs' reflections about teaching mathematics in high-need schools and teacher leadership. We chose Chad and Mark (pseudonyms) because as two high-school mathematics teachers with different years of teaching experience (17 and four respectively at the beginning of the RU-MTF program) and with different ethnic and educational backgrounds, these two teachers provided the most insightful reflections that are also representative of the whole group. We analyzed Chad's and Mark's written reflections (15 reflections in total per person and 2–5 pages each reflection) by applying a deductive approach in thematic data analysis (Saldana, 2013) and using York-Barr and Duke's (2004) conceptual framework of teacher leadership and domains of teacher leader model standards (TLEC, 2011).

Findings and Discussion

Before the RU-MTF program, Mark described "mentoring new teachers," serving as "content lead," and "shared decision-making committee" and Chad identified "unofficial mentor[ing] for several teachers" as part of their leadership, mentoring, and adult education. Across the five-year RU-MTF program, Chad's and Mark's reflections encompassed challenges and successes of teaching mathematics in high-need schools as well as ways of incorporating and sustaining leadership roles to: (a) promote student success, (b) address issues concerning diversity and equity; and (c) facilitate uncertainties during times like the COVID-19 pandemic. These emerged themes highlighted important components of York-Barr and Duke's (2004) conceptual framework such as "supportive culture," "supportive principal and colleagues," "resources," and "establish trusting and constructive relationship" (p. 289). Looking at these themes in-depth also illuminated domains of teacher leadership within teacher leader model standards (TLEC, 2011). To Mark, an effective mathematics instruction that prepares high-school students for college "involves gradually giving the student more autonomy." Chad's perspective is to prepare students to "become more capable of thinking abstractly…and model real-life phenomena."

Providing a Path to Student Success

"I'm frustrated with the inflexibility of our public school system… I'm concerned about kids that don't succeed in our very inflexible system."

Improving student success within the current school system, unsurprisingly, was one of the most common topics discussed in both Chad's and Mark's reflections, which involved the roles of school culture, administrations and colleagues, and testing.

School culture. Chad described his school culture as "a culture of teachers giving the students assignments, and the students complying with the assignments" and he wanted to introduce some of his teachings: "I simply cannot teach math as a set of rules to be followed, and for the students to believe those rules because I, the authority, told them so." Thus, Chad took the lead of the pre-calculus team to implement some of his visions. However, he continuously faced challenges because of the testing priority, school inflexibility, and unproductive collaboration.

> The reason that this isn't a HUGE problem is that [*my school*] has this high achievement culture where students are expected to memorize, memorize, memorize. So, they do. And they pass the tests. I'm really the only one that has a problem with it (well, me and the kids who don't memorize so well). My problem is that I feel we are missing the spirit of math.

Chad's challenge reflects the importance of establishing a school culture that advocates for collaboration, "shared leadership, differentiated roles for teachers, and mutual accountability for student learning" (TLEC, 2011, p. 28).

Administration and colleagues. Although Chad's department chair supported him to implement the changes in the pre-calculus course as a teacher leader, "[my] teammates basically withdrew from me, and became extremely critical of anything that I had to offer." As team members developed a climate of trust and critical reflection, their meetings became more collaborative and drew from backward lesson planning. Mark also encountered "a lot of skepticism and pushback from my appraiser" when incorporating technology into his teaching.

> There is a lot of pushback with this because there is an unrealistic expectation from administers to focus solely on specific objectives and not on the skills necessary to achieve those objectives…It's very frustrating to deal with this mentality and complete lack of understanding about the situation that we are dealing with at our campus.

In line with these examples are facilitating "skills to create trust among colleagues" and using "knowledge of existing and emerging technologies to guide colleagues in helping students skillfully and appropriately" from teacher leader model standards (TLEC, 2011, p. 16).

Testing. Mark alluded to "don't teach to those tests" in relation to student success:

> With administrators often only concerned with testing results or data, many teachers often panic and fall to pressure to push our kids on something that they can't easily fix. This creates a source of friction and to some degree distrust and resentment between those teachers and their students.

Although teaching for testing is not a path to student success, teachers and teacher leaders can work "individually and collaboratively to examine test and other performance data to understand each learner's progress" (TLEC, 2011, p. 53)—a crucial step in data-driven changes in school culture and "promoting the use of assessments and data for schools and district improvement" (TLEC, 2011, p. 18).

Diversity and Equity

As a white middle-class teacher in a predominately African American school, Chad discussed the "systemic racism and white supremacy" in the school culture.

> White teachers trying to "save" the minority students by getting them to buy into our culture instead of the culture of their family and their neighborhoods…I didn't realize at the time was that school culture wasn't just middle class, it was white middle class…I get very uncomfortable when I see us educators pushing particular values on students…I want to open people's minds and...teach students to think logically and rationally.

As Mark emphasized "that different cultures have conventions that are very different from American conventions," prompting instructional strategies that address diversity and equity issues (TLEC, 2011) is central to leadership standards.

The Good and Bad of the COVID-19 Pandemic

"Especially with everything that has been going on in this country, we have to set formulas and calculators aside sometimes, and reach their hearts if we want to reach their minds."

In the last two years of the program, MTFs shared lessons learned from transitioning to remote learning during the pandemic and leadership roles they took to facilitate this transition. Their leadership roles become even more critical as the uncertain condition called for "supportive culture," "resources," and "supportive principal and colleagues" (York-Barr & Duke, 2004, p. 289). Chad perceived both the good and bad of the pandemic:

> The main problem I have with online teaching and online meetings is just how tired they make me feel afterward… [during RU-MTF summer professional development], we had quite the international group. Not only were the facilitators from points scattered all over the globe, but the participants as well…It was interesting to hear people talk about the math education that they had on the other side of the world.

Mark shared how online teaching encouraged some of his students to participate more in classes but overall "a very low level of participation, and a large amount of inflation by teachers and administration." Acknowledging the limits, a virtual format contains, Mark's experiences with virtual professional development were overall positive, "I feel that many people felt more comfortable sharing in a virtual format, than in an in-person." These positive experiences with virtual professional development opportunities are important to consider even post-pandemic.

Mathematics specialists are prominent figures in calls to advance the teaching and learning of mathematics. While the calls for mathematics specialists have gone on for decades, research in this area of study is still emerging. Because of this, there is a need for the field of mathematics education to better understand the research that has been conducted to move the field forward. As such, we present preliminary findings of a literature synthesis investigating the ways in which mathematics specialists are studied within empirical research between the years 1981 and 2018. Our findings document the quality of the research, the research methods used, and the journal outlets research is disseminated around mathematics specialists, as well as discussion and implications based on our results.

Keywords: instructional leadership, research methods

In the United States, a call for mathematics specialists (MS) has been prominent over several decades, with a rise in this call and research related to mathematics specialists occurring since the late 2000s (Baker et al., 2022; Fennell, 2017). However, despite this increase in research, in general, MS are still under-investigated (e.g., Herbst et al., 2021; Hjalmarson & Baker, 2020), leading to policy decisions being made without ample evidence. MS are considered “an important lever” for advancing teacher learning (Marshall & Buenrostro, 2021, p. 8) by supporting teacher development and facilitating district efforts (Cobb et al., 2018; NCTM, 2020), we believe it is imperative for the field of mathematics education to better understand the research situated around MS to advance this work.

Mathematics Specialists

MS are instructional leaders who work to advance effective mathematics instruction and student learning through their work with teachers (McGatha & Rigelman, 2017). MS often take on many roles within a school or district and may have various responsibilities depending on the context of their work (Baker et al., 2022; Harbour et al., 2021; McGatha & Rigelman, 2017). MS may be charged with facilitating the implementation of school, district, or state initiatives, the integration of research-based practices and curriculum materials, and the use of assessment data (e.g., Campbell & Malkus, 2011; Fennell, 2017). MS may also model lessons and instructional strategies, as well as provide professional development (e.g., Chval et al., 2010; Fennell, 2017; Polly et al., 2013). While the roles and responsibilities of MS vary, the ways in which these supports are provided also varies. MS may work on school-level initiatives (e.g., Cobb et al., 2018) or work with small groups of teachers (e.g., Livers, 2019; Lesseig et al., 2016). MS may also work with individuals or pairs of teachers (e.g., Saclarides & Harbour, 2020).

Purpose

Because of the need to understand prior research to know what future research is needed, the purpose of our work is to synthesize existing research, through 1981-2018, to develop an understanding of the methodological considerations around MS. Our goal is to present preliminary findings to raise questions around methodological decisions and dissemination of existing research. We first extend prior synthesis work around MS (Baker et al., 2022; Hjalmarson et al., 2020) by evaluating the quality of each published article using an established criterion, an important step in a literature synthesis (Cooper et al., 2019). Following the application of the appraisal, or quality, criteria, we then sought to answer the following research questions: (a) what type of overarching methodology are researchers using when studying MS; and (b) how are researchers who study MS disseminating their empirical work (i.e., peer-reviewed articles)?

Methods

We draw upon earlier work (Baker et al., 2022), wherein we explored empirical research to examine the positioning of MS (see Baker et al., 2022 for a detailed process of inclusion and exclusion criteria). The researchers employed in vivo coding (Saldaña, 2021) across 130 research articles in a three-layer process. First, the population in which the MS engaged with was determined (e.g., in-service teachers, pre-service teachers). Next, building upon McGatha and Rigleman's (2017) positions for MS (coach, teacher leader, interventionist) were assigned. As codes were applied, new positioning of MS emerged, resulting in six distinct positionings, wherein three were previously defined (McGatha & Rigelman, 2017) and three newly emerged: (1) coach, (2) teacher, (3) interventionist, (4) university stakeholder, (5) other P-12 stakeholder, and (6) learner. Lastly, a layer of coding allowed for specificity of context (i.e., school or district levels), thus providing positionings such as MS as Coach: District-Level.

For the present study, we homed in on six unique positionings of MS whose primary audience was *in-service* to pilot our exploration (see Table 1, initial frequency). As our goals were to extend previous work and to develop an understanding of the methodological considerations around MS, we engaged in three types of analysis: (a) article quality evaluation, (b) methodological approaches, and (b) journal outlets. The methodology we used, results, and implications follows. Articles may have included more than one role.

Table 1: Mathematics Specialists Positioning

Positioning	Initial Frequency	Final Frequency
Inservice: MS as Math Coach: School-level	26	23
Inservice: MS as Math Coach: District-level	1	1
Inservice: MS as Instructional Coach: School-level	6	4
Inservice: MS as Teacher Leader	21	15
Inservice: MS as Learner	10	6

Article Quality Evaluation

To evaluate the quality of the studies meeting inclusion and exclusion criteria, we used the appraisal criteria of Risko et al. (2008). This evaluation tool has seven quality criteria and has been applied in previous research (e.g., Miller et al., 2015). Unlike criteria which only address one methodology (e.g., Thunder & Berry, 2016), Risko and colleagues' (2008) criteria enables the appraisal of articles from various methodologies. Paralleling the process established (Risko et al, 2008), articles that received a score of 7 (i.e., meet all criteria), were used in analyses.

We coded 65 articles which prominently featured MS. Three researchers coded 23 articles to establish reliability with the rubric, and then pairs of those researchers coded the remaining 42. In reaching consensus of 0 or 1 scores for each criteria indicator, we approached the subjective terms in the descriptions (e.g., the term *several*) with leniency. For instance, rather than articles needing all listed descriptors in the indicator, if the article had 50% of them, we scored the indicator as a 1. Of the 65 articles, 47 met all the criteria (i.e., 73%; see Table 1, final frequency). This inclusion rate is higher than the 35% inclusion rate reported in Risko et al. (2008). We also identified five tool development papers that we only include in the analysis of journal outlets. We did not score these 5 papers using the Risko et al. (2008) criteria because those articles were not structured in a way that fit the criteria's goals or purpose.

Methodology Approach Coding

To determine the overarching methodological approach used in each of the 47 articles that meet quality criteria (e.g., using Risko et al., 2008), a team of three researchers distributed the articles to where two researchers coded the methodology for each article and the third researcher was used, as needed, to reach 100% consensus. We coded articles in one of three ways: (a) Qualitative, (b) Quantitative, or (c) Mixed Methods. We then determined the frequency in which each of the overarching methodological approaches appeared.

Dissemination of Research: Journal Outlet

To determine how research around MS was disseminated, we collected where each article was published, determined the frequency count for each journal, followed by applying a code of "math" or "general" to each journal to determine the type of journals that were publishing research involving MS.

Results

Research Question 1: Methodologic Approaches

The 47 articles that met all the quality criteria (Risko et al., 2008) included 26 qualitative studies, 8 quantitative studies, and 13 mixed methods studies. We are still analyzing the methods in more detail (e.g., HLM, case study, social network analysis). Notably, there are a significant number of qualitative case studies (e.g., of specialists as individuals) within the 47 articles. Data gathered often includes interviews, observations of classroom or professional development, surveys, and other artifacts (e.g., lesson plans, student work). There are also assessments of teacher knowledge and beliefs. The quantitative work included studies linking mathematics coaching and student outcomes (e.g., Campbell & Malkus, 2011) and studies of the influence of math coaching (e.g., Sun et al., 2014). Mixed methods studies often included qualitative evidence coupled with interviews or surveys. For instance, Hopkins et al., 2017 was coded as mixed methods as it employed social network analysis along with analysis of interviews.

Research Question 2: Dissemination of Work

To describe dissemination efforts, we included the 47 research articles and 5 articles on tool development. The tool development studies were primarily about mathematics coaching or leadership, however, were not written in a way that aligned well with the Risko et al. (2008) appraisal criteria. However, to represent the landscape of outlets that are publishing work about MS, we included the five tool development articles in this portion of the analysis. We found there were 30 peer-reviewed journals represented in our data set of 52 articles. For brevity, we coded them as *mathematics journals* if the title indicated either a singular focus on mathematics or a dual focus of mathematics and science or *general journals* if they focused on other more general education topics (e.g., teacher education). Twenty-six articles were published in mathematics focused journals, and twenty-seven were published in general journals. The top five journals where MS research was disseminated were *The Journal of Mathematical Behavior* (n=7), *Journal of Mathematics Teacher Education* (n=6), *ZDM Mathematics Education* (n=4), and *The Elementary School Journal* (n=4). We note that six of the *JMB* articles appeared in a special issue.

Discussion

As we sought to develop an understanding of the quality of research, methodological considerations, and dissemination of work around MS, some interesting findings emerged that necessitate discussion and hopefully implications on future research involving MS.

First, using the appraisal criteria of Risko et al. (2008) to determine the quality of empirical research, we found most articles in our data set met criteria at a much higher rate reported by the authors. We find this a promising, indicating high-quality research is being conducted related to MS. Of importance for future research, most of the articles were eliminated due to methodological issues; specifically, around following three indicators: (a) "Ensures that methods are presented in sufficient detail and clarity to visualize procedures", (b), "Relies on measurements or observational methods that provide reliability, credibility, and trustworthiness", and (c) "Describes participants" (Risko et al., 2008, p. 256). Within the Risko et al. (2008) criteria, more information is provided for each indicator (shortened for brevity here). Many articles not meeting criteria were often scored lowest in participant description. This makes sense within the MS research as there are often blurred lines in their positioning and definition of who is a mathematics specialist (National Mathematics Advisory Panel, 2008). However, as previous work has now provided a framework of positionings (Baker et al., 2022), we hope that future research can employ this positioning and provide more details on the participants of studies.

Second, as we explored the methodological approaches used to study MS, we see the majority of published, empirical work employs qualitative methods. By no means are we suggesting that qualitative methodological approaches should not continue; however, we do believe it is important to note this uneven approach among qualitative and quantitative methodologies. Quantitative methodologies are important within research involving MS to determine causal links and provide evidence that is generalizable on a larger scale.

Third, we find the lack of a particular journal that represents a "home" for MS research both encouraging and problematic. It is encouraging to see there is MS research being published in mathematics education, teacher education, education leadership, and other domains. However, there is a need for studies about the preparation, practice, and impact of MS on teaching and learning. We also find the lack of focus in premiere mathematics education journals troubling. For example, the only article in this collection focused on MS published in the *Journal of Research in Mathematics Education* was a highly influential tool development study by Munter (2014). Outside of the special issue in *JMB*, other mathematics education journals only published 1-2 articles across this long period of time (i.e., 1981-2018).

Conclusion

While there has been growth in research about MS as leaders of teacher learning and professional development, there is clearly more work to be done. There are many lenses and bodies of existing research that can inform studies of MS, and there are clearly different educational arenas that are beginning to examine MS as part of the educational system. We encourage the field to continue these investigations and continue expanding the methods and theories that are used in these studies.

SUPPORTING DISCUSSION PRACTICE IN MATHEMATICS METHODS: APPLICATIONS OF WHOLE-CLASS SCAFFOLDING

Signe E. Kastberg	Alyson E. Lischka	Susan L Hillman

skastber@purdue.edu	Alyson.Lischka@mtsu.edu	shillman@svsu.edu

Discussion is a practice used in mathematics methods courses to support prospective teachers' pedagogical ideas. Underexamined but central to the development of instructional activities, including discussions of teaching, are mathematics teacher educators' (MTEs') tacit and explicit theories of learning and teaching. We report findings from a self-study of three MTEs' discussion practice in methods courses. Data sources include transcripts of MTEs' dialogic analysis of their discussion practice and evidentiary maps based on instructional artifacts. We argue that whole-class scaffolding serves as a tacit theory informing MTE discussion practice. We support this argument using evidence that our discussion practice was driven by prospective teachers' move toward independence and by layering instructional activities.

Keywords: Discussion, Preservice Teacher Education, Teacher Educators

Learning theories (Casey et al., 2018) and professional experiences (Leikin, 2020) have been shown to inform mathematics teacher educator (MTE) practices. Furthermore, professional practices shape the "learning potential" (Grossman et al., 2009, p. 2090) of instructional activities. These findings link theories and experiences of MTEs to learning opportunities provided to prospective mathematics teachers (PTs). Calls for the study of MTE work (Grossman et al., 2009; Lee & Mewborn, 2009) have resulted in descriptions of MTE practices (e.g., van Es et al., 2014), instructional activities (e.g., Tyminski et al., 2021), and MTE knowledge (e.g., Beswick & Goos, 2018) with a few studies exploring MTEs' professional growth (Krainer et al., 2021). In this paper we address MTEs' professional growth of discussion practice, providing an example of how the learning potential of discussions of teaching are developed. Beyond providing descriptions of discussion practice as useful models for MTEs, unpacking theories that inform such practice links MTEs' learning to teach about teaching to PTs' opportunities to learn mathematics teaching.

In this paper we use self-study methodology to identify tacit theory that informs the discussion practice of three white MTEs' teaching mathematics methods at different institutions to elementary and secondary PTs. The three MTEs' are relational (Kitchen, 2005) constructive teachers (Steffe & D'Ambrosio, 1995) of mathematics teaching who utilize relationships with PTs and evidence of their pedagogical concepts to inform instructional decisions. Relational teacher educators view relationships as central to creating opportunities to learn about teaching. Constructivist teachers view learning as an intersubjective activity that includes learner discussions in a collaborative community (Kastberg, 2014; Steffe & D'Ambrosio, 1995). Taken together relational constructivist MTEs view whole class discussions of teaching as opportunities to theorize about teaching and problems from experience.

As relational constructivist MTEs, we use whole class discussions to support PTs' teaching practices. Self-study of our discussion practice resulted in new approaches to posing discussion questions (Kastberg et al., 2019) and creating phenomenological conditions (Lischka et al., 2020) supportive of discussions of teaching. Yet we continued to struggle to facilitate discussions with

PTs, instead often creating recitations during which PTs' shared ideas without addressing the ideas of others. To expand the domain of potential action (Brown & Coles, 2020) available in planning and facilitating discussions of teaching in mathematics methods courses we were guided by the question: *What tacit theories inform mathematics teacher educators' discussion practice in mathematics methods courses?*

Background and Literature

Loughran (2014) defines pedagogy as "two complementary aspects of knowledge and practice: teaching about teaching and learning about teaching" (p. 275) kept in relation. Loughran's definition situates pedagogy as a theory that maintains a relationship between teaching about teaching and learning about teaching. Such theories in mathematics teacher education have been used to design and implement instructional activities for PTs (Kastberg et al., 2018). Making theories that inform MTEs' practice explicit (Mewborn & Stanulis, 2000) is essential to expanding possibilities for instructional choices and engaging in discussions of those choices beyond simply modeling practices (Teuscher, et al., 2016). In this paper we focus on tacit theories that inform MTEs' whole class discussions of teaching.

Discussion is defined as human interaction to address "a question of common concern" (Dillon, 1994, p. 8) through an exchange of ideas (Alexander, 2019) and an examination of differing viewpoints (Kim & Wilkinson, 2019). Discussion differs from recitation in that recitation involves sharing ideas without engaging others in those ideas while discussion involves a sharing of ideas in which others take up those ideas and add to or counter them (Dillon, 1994). We define discussion as a talk strategy MTEs use to support development of PTs' pedagogical concepts (Simon, 2008). MTEs' use of discussion practice is informed by their "knowledge, theories, and understandings" (Pinnegar & Hamilton, 2009, p. 16) to develop "knowledge from practice" (Pinnegar & Hamilton, 2009, p. 17) as a way of "knowing to" (p. 18) engage PTs in a given practice.

Existing reports of MTEs' facilitation of discussions have identified practices associated online discussions (McDuffy & Slavit, 2002), ambitious teaching (Kazemi et al., 2016) and teaching videos (van Es et al, 2014). MTEs' facilitation of pedagogical discussions (Lischka et al., 2020; Kastberg et al., 2021) is also informed by phenomenological factors (Dillon, 1994) such as a sense of community and relevant common experiences. MTEs' discussion practices, including posing discussion questions, and supporting interpretation of the question, impacts the form (i.e., IRE, recitation, discussion) and content of the PTs' talk (Kastberg et al., 2021). Evidence teachers use to support claims made during discussions of teaching informs MTEs' discussion practice, yet findings are mixed. Steele (2005) identified teachers' use of experience to support claims in discussions of mathematics teaching while Dick et al. (2018) suggested teachers did not provide evidentiary support for claims made during discussions of their mathematics teaching. Such research illustrates that teachers' address of discussion prompts focused on teaching are conditional and respectful of the authority of experience (Munby & Russell, 1994), thus raising questions about how MTEs' can initiate and sustain discussions of teaching that move beyond sharing ideas to taking up and countering the ideas of others.

One theory that may support MTE's discussion practice draws from linking whole-class scaffolding and dialogic teaching (Bakker et al., 2015) including discussion. Smit et al. (2013) asserts that whole-class scaffolding involves interpreting and responding to learners' understandings and needs while fostering independence (Visnovska & Cobb, 2015). Whole-class scaffolding is "layered, distributed and cumulative" (Smit et al., 2013, p. 829) and takes place before, during, and after whole-class interactions. Bakker et al. (2015) illustrates ways whole-class scaffolding can inform dialogic teaching including discussions. Keys to whole-class scaffolding include understanding that instructional activities produce layers of opportunities for developing concepts while supporting movement toward engaging in activities independently. These two key components of whole-class scaffolding align with the existing reports of MTE work that illustrate the importance of PTs' movement toward independent teaching (Grossman et al., 2009) and the need to use pedagogies of practice in concert (Ghousseini & Herbst, 2016).

Methodology and Methods

Self-study methodology is a form of empirical practitioner research focused on improving practice in context. As practitioner research (Borko et al., 2007), self-study methodology supports inquiry into pedagogy of practice. Self-study is self-initiated, improvement-aimed, interactive, uses qualitative methods, and defines validity as based in trustworthiness (LaBoskey, 2007). Our study of tacit theories that inform discussion practices was initiated to inquire into how we planned for and enacted discussions of teaching in mathematics methods with a focus on improving our discussion practices. Beginning in 2015, our collaboration has included weekly meetings to discuss the development of instructional activities and practices. As a collaborative self-study group of MTEs from three different US institutions, we are critical friends (Schuck & Russell, 2005) who undertake scholarly inquiry (Lee & Mewborn, 2009) of our practices.

Our institutional missions range from teaching-focused to research-intensive and our program foci span elementary to secondary teacher certification. Signe's discussion study was guided by the question: How do children learn mathematics? Alyson's discussion study was guided by the question: What is the role of mathematics teachers related to social justice and equity? Susan's discussion study was guided by the question: How does cognitive demand of tasks and knowledge of children's mathematical thinking inform planning instruction? Studying our practice, we identify "living contradictions" (Whitehead, 1989, 41) between our intended and working models of practice.

Critical friendships serve as dialogic communities where dialogue serves as a process of coming to know. Pinnegar and Hamilton (2009) align the scientific method, action research cycle and dialogue as processes of coming to know in different methodologies. In self-study methodology dialogue involves expressing ideas in conversations to be "accepted and elaborated or rejected, rephrased, questioned, or ignored" (p. 87). Participants in the dialogue "may provide evidence, examples, representations, metaphors, or analogies in support of or opposition to the idea or as a way to synthesize and integrate the idea with others" (p. 87). Such dialogues in mathematics teacher education produce "theorizing" about MTE practice that "extends the range of possible behaviors, by dwelling in the details of the experience of teaching and considering the details on a more general level" (Brown & Coles, 2020 p. 99). Assessing the trustworthiness or quality of qualitative research (Grant & Lincoln, 2021) involves planning for and committing to making transparent authenticities that emerge in the study. In the case of self-study, ontological authenticity is central as researchers gather evidence of knowledge of self that illustrates what is learned through dialogic analysis and other analytical methods.

Within the methodology of self-study we used three qualitative analytic methods: analytical dialogues (Guilfoyle et al., 2007), evidentiary maps, and descriptive coding (Saldana, 2016). (1) We engaged in 8 analytic dialogues of our discussion practice in fall 2020 (Covid-19 hyflex teaching). Conversations focused on "coming to know" how we used discussion in our teaching that served as the basis for "action" (Guilfoyle et al., 2007, p. 1111) in our ongoing discussion practice. At the conclusion of this period we had formed a collection of categories that informed our discussion practices. (2) In spring 2021 we used course artifacts (recordings of whole class discussions, class summaries, assignments, and PT work samples) to create evidentiary maps (see Table 1 for an excerpt) of the "structure of events" (Jordan & Henderson, 1995, p. 57) in our fall 2020 discussion practice. Each map was analyzed using categories from the dialogic analysis. Confirming or contradicting evidence from the dialogic analysis was identified. (3) Descriptive coding (Saldana, 2016) of transcripts from analytical dialogues was used to triangulate results from analytic dialogues and evidentiary maps by linking the findings from the analytic dialogues to evidence in the transcripts of our dialogues. Analysis revealed evidence of commonalities across three MTEs' discussion practices. Movement in these analytical methods proceeded from dialogue to course artifacts and back to dialogue. These three analytic methods created an evidentiary basis for findings common across three MTEs' discussion practice and related contexts.

Findings

This section describes two components of whole-class scaffolding (Smit et al., 2013) that influenced our discussion practice: (1) the move toward independence in mathematics methods courses, and (2) layering learning activities driven by the move toward independence. Data from the three authors' practices were used to derive the findings. This paper uses examples from Susan's pedagogy of discussion practice drawn from transcripts of dialogic conversations and evidentiary maps to illustrate our findings for the research question: What tacit theories inform MTEs' discussion practice in mathematics methods courses? The findings are structured to first present an integrated view of Susan's practice in the form of a vignette. Based on the vignette and with example from our critical friend conversations we highlight each component of scaffolding, beginning with layering of instructional activities and turning to the move toward independence.

Susan's Vignette

One learning goal in Susan's elementary mathematics methods course was to understand cognitive demand of tasks to support PTs' lesson planning. She reasoned that distinguishing between demands of tasks, such as those focused on producing answers and those focused on sense-making, would support PTs' design of problem-based lessons. Susan planned for a discussion on cognitive demand of mathematics tasks for the third class.

The day before Susan's first class, Alyson identified the importance of anticipating in planning for discussions of teaching, just as we would for teaching mathematics.

> Alyson: So you are seeing these different perspectives that might come out from the PTs. Would it help if you thought through those different perspectives, and have some ideas of what you might want to draw out or probe a little more deeply? . . . It's like anticipating different directions that the discussion might go and being ok with different outcomes based on what they're bringing to the table. (Conversation 08-31-2020)

As a result, Susan considered how her first day activities, including eliciting PTs' memories of mathematics tasks, might inform the planned whole class discussion of cognitive demand (Table 1, Class 3). How might PTs associate tasks with children's mathematical thinking? Susan anticipated experiences PTs might share, and purposely planned instructional activities for the first two classes (Table 1) and the autobiography assignment to elicit PTs' ideas about tasks and mathematical thinking. As planned, PTs' shared experiences and perspectives on types of thinking involved in learning mathematics. Some were expected, such as timed facts tests associated with memorization. Others were unexpected necessitating modifications to support connections between PTs' experiences with mathematics tasks and mathematics learning.

Table 1: Excerpts from Evidentiary Map

Date	Event	Description
Sep 1	Class 1 Online	Think-Pair-Share: What are your memories of learning mathematics? First assignment: mathematics autobiography due two days later.
Sep 3	Class 2 In-Person	Small group activity: Examine K-5 mathematics curriculum standards. List verbs; classify levels and types of thinking.
Sep 15	Class 3 Online	From memories: identify thinking involved in learning mathematics. Introduce the Cognitive Demand framework (Smith et al., 1998). Small groups: examine tasks using the framework; whole class: share a claim about a task and *discuss level of cognitive demand*.
Sep 17	Class 4 In-Person	Reviewed verbs from Class 2 and mathematics tasks from Class 3. Small groups: What helps determine if a task involves lower- or higher- cognitive demand? Individual reflection prompt.
Sep 22	Class 5 Online	Revisit tasks from Class 3: Describe cognitive demand. Follow-up: choose a task and make a video explaining the cognitive demand.
Sep 23 – Nov 24	Individual Conferences	Consultations with PTs on lesson plans with attention to cognitive demand of tasks.

During Class 3 Susan initiated a discussion on cognitive demand of tasks by asking groups of PTs to make claims about a small collection of tasks. She knew this was risky given the limited time for the development of phenomenological characteristics (Dillon, 1994) needed for productive discussions. PTs shared claims about the cognitive demand of different tasks, but little evidence was offered. No PT challenged another PT's claim, a move that might have sparked a discussion. Instead, the PTs took turns sharing. Susan described the class activity as a recitation and turned to redesigning instructional activities for Class 4.

Our conversations focused on benefits and limitations of introducing PTs to professional language such as "cognitive demand." Alyson described the importance of introducing professional vocabulary, like cognitive demand, to support PTs' descriptions of teaching.

> Alyson: I still think that we share some of the best practices in different ways. As part of building that common experience and building opportunities for [PTs] to have language like the cognitive demand idea puts words to descriptions that they can then think about . . . I guess I feel like we are spending a lot of time developing that language.
>
> Susan: This whole thing about language and cognitive demand, . . . I don't think they [PTs] have thought about it [cognitive demand] even though I know they are introduced to levels of thinking [in previous classes] but when they come to math methods it's [cognitive demand of tasks] not connected to that [prior experience with levels of thinking]. I'm trying to connect to language other classes have been using. (Conversation, 09-21-20)

Susan describes her effort to connect language from other courses to cognitive demand.

Susan re-designed her instructional activity for Class 4 in response to PTs' association of mathematical tasks and cognitive demand. Susan had hoped to create a discussion of cognitive demand during Class 3 that would connect cognitive demand of tasks and student thinking. Instead PTs' shared tasks with rationales that exhibited limited understanding of the elements of cognitive demand. Susan adapted her next instructional activity to provide PTs with opportunities to explicitly describe task characteristics in relation to specific elements of cognitive demand.

Susan's initial lessons were designed to gather evidence of PTs' experiences and views of teaching and learning mathematics. Subsequent instructional activities were designed to support PTs to connect their experiences, cognitive demand of tasks, and types of thinking the tasks might elicit from children. Although Susan planned a discussion of cognitive demand of mathematics tasks for Class 3, the PTs had not yet developed connections between their experiences, demand of tasks, and opportunities for children's mathematical thinking. The PTs' responses allowed Susan to make sense of their ideas about cognitive demand. Susan used the PTs' ideas to re-design subsequent instructional activities to focus on connecting cognitive demand and task characteristics (Table 1). Susan did not intend the Class 3 discussion of cognitive demand to result in associating a level of cognitive demand for each task, but to relate levels of cognitive demand to task features and opportunities for children's mathematical thinking. Susan viewed these connections as essential in PTs' lesson planning later in the semester.

Moving Toward Independence

Our conversations about how to provide learning opportunities to support discussion focused on the importance of modeling PTs' ideas and designing instructional activities that would prepare PTs for planned discussions. We focused on developing meanings for key terms in the discussion questions and the significance of such questions in learning to teach. We reasoned from our experiences teaching mathematics, that we could use models of PTs' ideas about teaching (cognitive demand, learning, and social justice) to design instructional activities. Further, using PTs' ideas, we could facilitate the development of connections among ideas about teaching mathematics. This idea is illustrated as Signe describes her movement to using PTs' vocabulary, "way of talking," in instructional activities and discussions.

> Signe: When I finally did use the PTs' way of talking, they had something to say, and they knew they were going to be attended to when they were talking about it, because it was a significant idea. And, it matters when you're trying to do your planning for discussion. (Conversation 11-10-2020)

As we supported PTs to link their "way of talking" to key terms in mathematics teaching, such as cognitive demand in Susan's case, we noticed our assumptions about discussions and PTs' move toward independence. Signe described the need to move on to teaching other concepts, but our awareness that PTs would need to apply learned concepts in their teaching remained.

> Signe: For a while, it [conceptual understanding] was kind of a mystery, like they kind of used some of the words that I used ... but then the rubber meets the road and you get to the final discussion. . . . only that's not the final word, because I have their lesson plans, I have their concept summary . . . So there's not an end, because they're going to do more stuff with that idea, but I'm not going to focus on it anymore. I felt like I got to where I needed to get to, to be able to help them with facilitation of their lessons. (Conversation 11-10-2020)

Our conversations continued to focus on how layers of instructional activity related to planned discussion questions and supporting PTs' planning and teaching of mathematics lessons.

Layering to Support Discussions

Central in our conversations was how we could provide multiple opportunities for PTs to connect their knowledge and experience to key ideas during discussions of teaching. Susan's constructivist pedagogy informed her design and re-design of layers of instructional activity to support PTs' ideas about cognitive demand. Susan provided opportunities for PTs to create ideas about cognitive demand of mathematics tasks and opportunities for learners of mathematics from PTs' experiences. As she created models of PTs' ideas about cognitive demand, Susan designed layers of activity for PTs' to use their ideas in examining mathematics tasks.

Susan, Signe, and Alyson began the semester with dates for discussions on the syllabus. As these dates came, all three MTEs identified the need to build understanding of the concepts so that PTs could meaningfully engage in discussions of the concepts. Our conversations revealed how initial target dates for discussions were shifted back repeatedly to accommodate layering. Signe described trying to find the parameters for the discussion and understandings needed.

> Signe: The first stage of a discussion is to understand everyone's experience and futz around with the parameters of the discussion. Maybe I can't have 'where does knowledge for mathematics teaching come from' until they go into the field. But I can 'have how do students learn math' before that because they've been working on it.
>
> Alyson: moving that to the end, you'll have more shared experience to have that conversation, by the end of the semester. (Conversation 09-07-2020)

PTs needed time to build their ideas about key concepts through experiences with layers of instructional activities provided. We realized that often we planned whole class discussions too early before the PTs had developed ideas about teaching. Our premature rush to discuss as in Susan's Class 3 effort to connect experiences, task characteristics, cognitive demand, and children's mathematical thinking, positioned PTs as experts with knowledge of pedagogical concepts and ways to describe that knowledge. As Susan's evidentiary map illustrates, layers of instructional activities are created as MTEs' gather evidence of PTs sense making and re-design subsequent activities. These layers provide opportunities for PTs, but also suggest that MTEs' discussion practice is informed by the interpretation of PTs' pedagogical concepts.

Discussion

Findings confirm that components of whole-class scaffolding (Bakker et al., 2015; Smit et al., 2013), including movement toward independence and layering of instructional activities, informed our discussion practice. The significance of this finding lies in the potential of MTE theories (Casey et al., 2018), professional experiences (Leiken, 2020), and practices (Grossman et al., 2009) to shape the "learning potential" (p. 2090) of instructional activities. Explicit knowing of theories that inform discussion practice expands the possibility space (Brown & Coles, 2020) for MTE's decisions in planning and facilitating discussions of teaching. Findings from self-study of teaching provide evidence beyond descriptions of practice that serve as models of scholarly practice (Lee & Mewborn, 2009) to identify and describe factors that influence MTE's professional growth (Krainer et al., 2021).

Existing research exploring teacher discussions of practice provides evidence of the challenges MTEs' face in facilitating discussions. Of significance is whether (Dick et al, 2018) and how (Steele, 2005) teachers support claims about teaching during whole class discussions. This illustrates a central challenge in facilitating discussions where talk moves beyond sharing ideas to the consideration of those ideas by others who add to or counter them. Susan's effort to initiate a discussion of cognitive demand illustrates how two interrelated components of whole-class scaffolding informed her discussion practices. First, efforts to engage the class in discussions of cognitive demand were informed by the need for PTs to plan and teach lessons at the end of the term. In the practical work of methods teaching, dates for field experience and practicum are fixed in the schedule. PTs must be able to function independently when those dates arrive. This practical consideration in methods teaching informs decisions about when PTs must use ideas about teaching relevant to planning mathematics lessons. Susan knew that she needed to prepare the PTs to plan lessons (Table 1, Individual Conferences). Second and related to this practical press toward independence, is the layering of instructional activities as informed by evidence of PTs' pedagogical concepts. Susan knew almost immediately during the discussion of tasks and cognitive demand in Class 3 that a discussion would not be possible. PTs did as she asked and shared tasks and levels of cognitive demand, but there was no adding on or countering of PTs' claims. The evidence of PTs' sense making informed a redesign of instructional activities for Class 4 (Table 1) to provide additional opportunities for the development of connections between tasks, cognitive demand, and opportunities for children's mathematics thinking. Susan's discussion practice illustrates the interconnected nature of components of MTE discussion practice informed by whole-class scaffolding. Movement toward independence drives the development of instructional activities, yet evidence of PTs' thinking encourages MTEs to redesign instructional activities creating layers that provide opportunities for PTs to develop new versions of pedagogical concepts like cognitive demand of mathematics tasks.

Findings from our self-study support the claim that characteristics of whole-class scaffolding, including move toward independence and layering of instructional activities, were embedded in our planning for and facilitation of discussions. We do not claim that we use these components in particular ways or at particular times in our discussion practice. In addition, we do not make claims about coordination of whole-class scaffolding and other theories (e.g., Kitchen, 2005; Steffe & D'Ambrosio, 1995) used explicitly in planning for and implementing discussions of teaching. Instead, we claim that in the development of discussion practice, we attended to the practical work of teaching about teaching by providing opportunities for PTs' to learn about teaching. Additional work is needed to address how MTEs' use theories in concert in planning for and facilitating whole class discussions. For example, how do Susan's explicit theories of relational teacher education (Kitchen, 2005) and constructivist teaching (Kastberg, 2014; Steffe & D'Ambrosio, 1995) support and inform her development of instructional activities that would support PTs' concept of cognitive demand? Questions like this assume that theories are used in concert, but perhaps some theories or components of theories are used for planning, while others are used to facilitate PTs' discussions of teaching.

The two components of whole-class scaffolding, move toward independence and layering instructional activities, illustrate one tacit theory which informed our discussion practice. We claim these components contribute to the integrative concept of whole-class scaffolding (Bakker et al., 2015) that helps us maintain the complementarity between teaching and learning (Loughran, 2014) while informing our discussion practice. Structured this way, MTEs' discussion practice is informed by components of whole-class scaffolding (Bakker et al., 2015). Although we do not claim that all MTEs build discussions on a theory of whole-class scaffolding, we do claim that unpacking explicit and tacit theories that inform MTEs' discussion practice will contribute new knowledge of MTE growth of professional practice called for by Krainer et al. (2021). Findings from such studies have the potential to support MTEs beyond providing models of instructional activities described in studies of professional practice (Tyminski et al., 2021) to understanding the diversity of knowledge and experience that drives the decisions involved in professional practices. Such findings address in part how MTEs' tacit theories play a key role in the "learning potential" (Grossman et al., 2009, p. 2089) of instructional activities used in professional practice, while providing evidence of the "integration between knowledge and practice" (Krainer et al., 2021, p. S11).

PROFESSIONAL LEARNING AT SCALE: DESIGNING A BOUNDARY OBJECT

Education policies and innovations that aim to improve instructional quality often fail to produce any meaningful or sustained changes to teaching when implemented at scale because of the significant learning demands they place on the individuals, groups, and organizations that comprise an educational system. In this paper, we describe an implementation resource developed to promote professional learning and cross role discussions about new state mathematics standards and report on the ways educators at different levels of the state system used them. Results demonstrate how implementation resources designed to be a boundary object for educators at multiple levels of an educational system have the potential to support learning and create systemic conditions conducive of change.

Keywords: Policy, Systemic Change, Standards, Professional Development

In the US, education legislation, innovations, or policies aimed at improving instruction and student learning at scale have seldom led to even modest lasting improvements to teaching (Coburn et al., 2016). Critical scholars, policy researchers, and implementation scientists have offered various explanations for why large-scale educational reform remains elusive, one of the main ones being that it requires significant individual and organizational learning (Fullan & Pomfret, 1977). Initiatives are often implemented quickly, ignoring the time, structures, and resources needed to support the significant shifts required of teachers and teacher leaders. When working with smaller scale initiatives, teachers, curriculum leaders and/or mathematics teacher educators can come together and engage in professional learning experiences over time and in context. In contrast, when working with sweeping changes at scale we need to consider what structures and resources can support professional learning across all roles in ways that are aligned with what we know about effective professional learning experiences (PD).

In the context of this study, our focus was on the state-wide implementation of new high school mathematics standards. The State Board of Education adopted the standards in June with implementation expected in August. In response, our partnership of state and district leaders, mathematics education researchers, and classroom teachers quickly went to work designing structures and resources for state-wide, cross-role, professional learning experiences to support all stakeholders during the implementation. One of the key messages that accompanied the roll-out of the new standards was that they were based on research on teaching and learning. Through formal and informal feedback, stakeholders expressed that they wanted to know more about the research in which the standards were grounded. To address this need, a new set of resources were created and included in a multi-pronged professional learning structure—a collection of 20 two-page Research-Practice Briefs (R-P Briefs). These R-P Briefs were widely accessed and referenced by our stakeholders which left us wondering how the purposeful design of the R-P

Briefs contributed to their widespread use and in what ways the design features supported our stakeholders as they implemented the new standards.

Background

Much research has been done concerning the core features of effective professional learning experiences for teachers (e.g., Wei et al., 2009). Whether in person or online, effective PD provides opportunities that are responsive to the needs of participants, of sufficient duration, content focused, include active learning, driven by teachers' work with students, while also being focused around communities of practice and connected to solving a problem of practice (e.g., Desminone, 2009; Mantranga & Silverman, 2020; Wei et al., 2009). Implicit in these descriptions is that effective PD needs to be guided by research on teaching and learning (Loucks-Horsey et al., 2009). For example, PD focused on supporting students' developing number sense might be grounded in research on cognitively guided instruction (e.g., Carpenter et al., 2015) and learning trajectories (e.g., Clements & Sarama, 2009). While PD focused on supporting teachers' facilitation of whole class mathematical discussions might be grounded in the research on noticing mathematically significant pedagogical opportunities (Leatham et al., 2015; Stockero & VanZoest, 2013). Further, participants benefit from opportunities to interact with research through discussion, productive debate, and social interactions because research and its use are a social process (e.g., Nutley et al., 2007; Tseng, 2012). However, engaging with research in these ways is challenging as there are many barriers that make such engagement difficult to bring to fruition, especially in the context of addressing fast paced initiatives. Such barriers include addressing structural issues of access, time, and designing for engagement.

One of the most basic barriers to interacting around research is access (e.g., Hemsley-Brown & Sharp, 2003; Shkedi,1998). Since much research is hidden behind paywalls and protected by copyright laws, addressing a state-wide interaction around research is complicated by the reality that many stakeholders cannot access it (Shkedi, 1998). Even if it was accessible, there is the reality of the time it would take to read and make sense of primary resources (e.g., Behrstock et al., 2009; Hemsley-Brown & Sharp, 2003). It is widely acknowledged that the current structure of teachers' work day does not provide sufficient time for the everyday work of teaching, let alone time for professional learning. To address these concerns, researchers have created open-access research briefs as a way to disseminate research (Anderson et al., 2019); the idea being to present research in a format that is widely accessible, synthesized around a narrow topic, and easy to read in a short amount of time. The potential of this format to address accessibility led us to wonder how we might leverage it as a resource to support professional learning. To do so would not only require that we align its contents with the features of effective PD, but also that we consider how its design might encourage and support interactions around it.

Context & Theoretical Perspectives

This study took place in the context of a statewide research-practice partnership (Penuel et al., 2015) that focused on a shared problem of practice − improving the implementation process for new high school mathematics standards. Our first goal was to co-design and study a statewide professional learning initiative to support implementation efforts. Our co-design efforts follow from a theoretical perspective of communities of practice (Lave & Wenger, 1991; Wenger, 1998). Because practice is a defining characteristic of a community, communities are formed by collaboratively engaging with common resources toward a common goal. Though boundaries of practice distinguish communities across the social landscape, they are also a source of new learning. Boundary encounters allow for members of distinct communities to jointly negotiate meaning around boundary objects—artifacts that carry meaning in multiple communities and support the coordination of practices across them (Star & Griesemer, 1989; Wenger, 1998).

Many resources were co-developed in support of the partnership initiative and were intended to act as boundary objects. These included (but were not limited to) online PD modules, instructional frameworks, and the collection of R-P Briefs. Our hope was that each of the resources would become a boundary object, in that they would support knowledge exchange across the many different communities in our partnership (e.g., teachers, math leaders). The design principles for the R-P Briefs were initially informed by the literature on effective PD and refined over time through feedback from the statewide co-design network via surveys and focus group interviews. Ultimately, 20 R-P Briefs were developed, one for each unit of instruction across three different high school mathematics courses. Each R-P Brief was exactly 2 pages long and included: explanation of vertical alignment of the mathematics in the unit (both within the course and across courses), description of why the mathematics concepts included are important, at least one example task, research on students' mathematical thinking and learning related to the big mathematical ideas in the unit, research on effective pedagogy specific to the unit, explicit attention to connections to the Standards for Mathematical Practice (SMPs), and discussion questions to consider with colleagues.

The R-P Briefs were disseminated within online PD modules, on the partnership's website, and in many state, regional, and local meetings (e.g., sessions at state affiliate NCTM conferences). The number of downloads for each R-P Brief at the time of this study from just the online PD modules, are shown in Table 1. The download data, coupled with the other ways we were aware they were being accessed, indicated that the briefs were widely used, which prompted us to wonder if our intentional design played out like we expected—to support teacher and teacher leader learning about the standards themselves and the research that informed them, as well as their implementation of the standards.

Table 1: Number of Canvas Downloads as of July 2018

Math 1 Briefs (n=6)	Number of Downloads	Math 2 Briefs (n=6)	Number of Downloads	Math 3 Briefs (n=8)	Number of Downloads
1.1	416	2.1	593	3.1	693
1.2	455	2.2	105	3.2	152
1.3	111	2.3	302	3.3	212
1.4	82	2.4	84	3.4	72
1.5	262	2.5	30	3.5	218
1.6	68	2.6	9	3.6	45
				3.7	84
				3.8	78
Total	1394		1123		1554

Methods

This study used survey methods to build an understanding of how the R-P Briefs supported teacher learning about the implementation of new mathematics standards. To that end we aimed to address the following research questions: What aspects of the R-P Briefs do math teachers and math leaders say are helpful?; How do math teachers and math leaders say they use the R-P Briefs?; and What actions do math teachers and math leaders that use the R-P Briefs say they take as a result of reading them?

The partnership developed and administered a survey in Spring 2018 to inform its ongoing efforts to support standards implementation. Respondents were assigned to sets of questions specifically addressing the partnership's implementation resources and supports developed for their grade band. In this report, we focus on the set of questions addressing the R-P Briefs which was assigned to those identifying they worked in the high school grade bands.

The survey was distributed through the state agency's listservs to approximately 20,000 mathematics teachers, school administrators, and district mathematics leaders. A total of 1,768 educators from 96% of the state school districts accessed and completed at least 80% of the survey. Here, we report on responses from the 346 educators from 85 of 115 school districts who had an opportunity to respond to the set of questions focused on the R-P Briefs. The questions in this block asked participants if they were aware of the R-P Briefs. The numbers were about evenly split with 184 people (53%) said they were aware and 162 (47%) said they were not aware. The remaining analysis is based on the 184 people who were aware of the R-P Briefs. This includes responses to three survey items. The first two asked about how participants used the R-P Briefs and which aspects of them they found helpful. These were both "select all that apply" items. The third was an open response item that asked, "What are some of the actions you have taken (if any) after engaging in the research-practice briefs?"

The responses to the first two questions were analyzed by determining frequencies and percentages for each response option and then disaggregated by role group (e.g., teacher, math leader–i.e., school-based coaches, district curriculum leaders, school administrators). To analyze the responses to the open-ended, all members of the research team first read all of the responses to become familiar with their contents, making memos of common themes that emerged. This process and the ensuing team discussion led to the generation of five codes that captured the range of participants' actions with the R-P Briefs. Using our set of codes (e.g., planning, learning/reflection, shared with others, lead PD, guide curriculum decisions), each team member individually coded the participants' responses. Any coding disagreements were reconciled through group discussion. In the following sections we report the results of our analysis with respect to each of the research questions.

Findings

Useful Features of the R-P Briefs

The survey question that asked about the usefulness of particular features of the R-P Briefs was multiple response in format with answer choices aligned with the 7 design principles for the R-P Briefs described above. The design features that were selected as useful by more than half of the respondents were vertical alignment and tasks (51% and 53% respectively), with the description of why the topic is important being the least useful (9%). Disaggregating the data, revealed teachers and math leaders find some features similarly helpful, but respond quite differently to others. For example, while 48% of math leaders indicated that the discussion questions to consider with colleagues were useful, only 13% of the teachers selected this feature. While not as dichotomous, there are similar results for the research features and the SMPs. Such results suggest that usefulness of features may be aligned with how they are connected to one's daily work responsibilities as teachers and math leaders, while both are responsible for the implementation of the standards, they each have different roles in the implementation process.

Table 2: I find the following aspects of the R-P briefs useful [Select all that apply]

	All Participants (n=184)	Teachers (n=138)	Math Leaders (n=46)
Vertical alignment (grade/course distinctions)	51%	47%	63%
Description of why a topic is important	9%	9%	7%

Tasks/Examples	53%	52%	57%
Discussion questions to consider with colleagues	22%	13%	48%
Research on students' mathematical thinking and learning	29%	22%	52%
Research on effective mathematics pedagogy	27%	17%	57%
Explicit attention to the Standards of Mathematical Practice	27%	23%	37%
Other	2%	2%	0%

How the R-P Briefs are Being Used

The survey question that asked about how the R-P Briefs are being used was multiple response in format with answer choices that were aligned with not only the design elements of the R-P Briefs, but also the intention of sharing related research on teaching and learning in a usable way (See Table 3). High response rates on learning more about the mathematics of courses taught (54%), supporting instructional decisions (43%), and gaining more resources for instruction (57%) speak to the immediate needs of teachers in their daily work, but also indicate a valuing of what research says about teaching and learning by the teacher respondents. Math leaders also found the R-P Briefs useful for instructional decision making and resources (43% and 59%, respectively). This shows that as a boundary object, the two communities found common purpose for the R-P Briefs in addressing the overlapping aspects of the work of the two communities—supporting and implementing mathematics instruction.

Table 3: I use the R-P Briefs to … [Select all that apply]

	All Participants (n=184)	Teachers (n=138)	Math Leaders (n=46)
Learn about content for the math courses I teach	49%	54%	35%
Learn about pedagogy for the math courses I teach	36%	36%	35%
Learn about vertical alignment from previous math courses	42%	46%	30%
Participate in discussions with colleagues in informal settings	19%	15%	30%
Participate in discussions with colleagues in formal settings	32%	25%	52%
Support my instructional decisions	43%	43%	43%
Share information with my principal, colleagues, or district level personnel	16%	8%	41%
Get instructional resources	58%	57%	59%
I am familiar with the [blinded] briefs, but I do not find them useful	4%	5%	0%
Item left Blank	21%	21%	20%

Stark differences in the ways these two communities (i.e., teachers and math leaders) say they use the R-P Briefs appear in the collaboration-related response choices and vertical alignment. While some teachers used the R-P Briefs in formal or informal discussions with colleagues, a larger proportion of math leaders responded with the use of the R-P Briefs in this way. In particular over half of the math leaders responded that they use the R-P Briefs in formal settings. Further, only 8% of teachers indicated that they shared the tool with colleagues, compared with 41% of math leaders who reported that they had shared the R-P Briefs. Another distinction in how the tool was used by the different communities appeared when considering the learning about mathematics content choice alongside the vertical alignment choice. These response options speak to the usefulness of the R-P Briefs for teachers in situating these new courses within the K-12 continuum, an aspect also valued by math leaders but to a lesser extent.

Actions Taken as a Result of Engaging with the R-P Briefs

Of the 184 people that responded to the R-P Briefs question block, 107 of them (76 classroom teachers, 31 math leaders) responded to the open-ended item asking them to describe some of the actions they have taken (if any) after engaging with the R-P briefs. The results suggest that actions tended to be related to classroom level lesson planning, personal learning or reflection, sharing the R-P Briefs with others, using them when leading professional development, and using them to guide school or district-level curriculum decisions (see Table 4). In essence, this question ended up providing an opportunity for people to provide further detail regarding how they are using the R-P Briefs.

Table 4: Percent of Participants that Noted an Action by Theme

	Planning	Learning and/or Reflection	Shared with Others	Lead PD	Guide Curriculum Decisions
Teachers	70%	37%	20%	3%	4%
Math Leaders	1%	23%	52%	26%	13%
Total	52%	33%	29%	~1%	~1%

The most common actions described by teachers were different from those described by math leaders. Teachers overwhelmingly noted that they used what they gleaned from the R-P Briefs to inform their lesson planning and/or to reflect on their own learning. In contrast, math leaders most commonly noted they physically shared the R-P Briefs with others and/or used them when leading professional development. In the sections that follow we provide further description of the actions described in each of these categories.

Classroom level lesson planning. As we saw earlier, many respondents noted they used the R-P Briefs to support their instructional decisions and to get instructional resources. Consistent with that finding, almost three-quarters of the teachers that responded to this item described the ways they adjusted their classroom level lesson plans based on what they learned from the R-P Briefs. For example, T47 noted “I adjusted my lessons based on the research”, and T49 wrote “I have implemented some of the tasks suggested”. One of the most common planning actions was related to adjusting instructional emphasis based on the vertical alignment feature. For example, T22 wrote “Used for adjusting my instruction to better meet the curriculum without going too far”, T33 wrote, “Tweaked emphasis on units, placing less emphasis on some topics and increasing others.”, and T74 wrote, “Honing in on the exact type problems my students will have to pass. In the past it has been too broad and this helps streamline materials.” In fact, with the exception of the “discuss with your colleagues” feature, all of the R-P Brief features emerged as being used to inform classroom level planning in some way.

Personal learning or reflection. From the previous question, we know that teachers and math leaders used the R-P Briefs to learn about content, pedagogy, and vertical alignment. The open-ended responses that were focused on personal learning or reflection add to this picture because they highlighted participants’ attention to research on student thinking or pedagogy. For example, T16 notes using the R-P Briefs toward “Trying to better understand how students’ think”, and T43 noted “I have used these to gain a deeper understanding of what my students need to engage them in the mathematics outside of everyday calculations.” The most referenced aspect of the R-P Briefs was the vertical alignment of content. This seemed to support teachers and math leaders in understanding how the standards are situated both within and across courses. For example, T11 noted:

> For me, the briefs give me a better understanding of the depth of understanding the course is expected to achieve. In the past, I always went way too deep and students and parents would come back and say the student learned nothing in the next course or two that the learner took because too much had been covered. Knowing when to stop was a major challenge in the past. I can now see more clearly and confidently that concepts will be covered in due course and I did not have to feel responsible for getting the learners through too much material.

These responses indicate that not only did the teachers and math leaders go to the R-P Briefs with the intention to learn and reflect, but also that they found the features related to vertical alignment and research on teaching/learning to be the most impactful when they took this action.

Sharing the R-P Briefs with others. Across all roles, participants acted by sharing and discussing the R-P Briefs with others. There are examples of sharing and discussing the R-P Briefs with peers, administrators, and even parents. In some instances, it is unclear if sharing simply means giving the R-P Brief to someone else with no additional interaction (e.g., "Shared briefs with preservice teachers", T48). In other instances, it is clear that the sharing included interacting with each other around the R-P Brief in a meaningful way. For example, T46 responded, "I have had numerous planning meetings with the math 2/3 teacher at our small school to ensure we are using similar research based practices for teaching." and TL87 wrote, "Sharing information from the briefs with administrators and teachers. Encouraging use in Math PLCs." These responses give us a sense of how the R-P Briefs might land in the hands of people that might not have otherwise seen them and they illustrate how various communities (e.g., departments, professional learning teams, friendly colleagues) might be interacting around them.

Leading professional development. While we know the R-P Briefs are being shared and discussed, there is also evidence that math leaders are using them in their professional development work. This includes both formal professional development sessions and one-on-one coaching. For example, TL96 noted, "I have used them in PD with my district to try to get buy-in for using tasks on a regular basis." While TL103 explained, "I use them in facilitating discussion with the teachers I coach." These actions suggest that the briefs enabled connections between communities and were helpful in making meaning across boundaries.

Guide school or district level curriculum decisions. Among the many ways that participants said they acted on the R-P Briefs were actions to guide both school level and district level curriculum decisions. For example, TL85 noted,

> The briefs were used in each Math 1 and Math 2 Professional Learning session to discuss the vertical alignment of the mathematics and to understand the focus of the content for the unit for the course. The briefs are a part of the Math 1 Unit Framework that is currently being developed in our district.

Similarly, TL92 responded "Curriculum decisions - pacing, order of content, etc. for district-level documents." These actions are different from classroom level planning noted above in that such decisions affect teachers and students across a system.

Discussion & Conclusion

This study was motivated by a need for designed structures and resources that supported professional learning related to the implementation of large-scale educational innovations. In our case, this was the implementation of new state math standards. Given that our theory of learning is grounded in communities of practice (Wenger, 1998), any resources we designed were intended to be boundary objects–spanning the boundaries of the multiple communities of stakeholders in the system. Our findings suggest that the R-P Briefs not only supported professional learning as intended, but also acted as a boundary object in ways beyond those for which it was originally designed.

Our design principles were informed by the research on effective PD. Findings suggest that all but one of these features was seen as useful to at least 20% of the respondents, the only exception being the explanation of the usefulness of the mathematical concept. This exception is likely explained by the fact that the participants already know why the content is useful (they are math folks). Thinking about the R-P Briefs as both a resource to support learning and as a boundary object, the findings shed interesting light. First, there is evidence that the R-P Briefs physically crossed community boundaries. They were shared and/or discussed in communities of teachers, communities of math leaders, communities of teachers and math leaders together in a school, and even communities of teachers, parents, and students in a single class.

Second, Star & Greisemer (1989) describe boundary objects as, “objects which are both plastic enough to adapt to local needs and constraints of the several parties employing them, yet robust enough to maintain a common identity across sites” (p. 393). Looking at the two communities of focus, teachers and math leaders, the findings indicate that some of the R-P Brief features were found equally useful within each community, suggesting that these features mean something to both. Yet there were other features that seemed more useful to one community than the other. This coupled with the finding that different communities are using the resources in different ways, suggest that an important design feature of the R-P Briefs was including content that was recognizable and meaningful to both communities yet presented in a way that it was malleable enough to be used by the different communities in different ways. Ultimately, we designed the R-P Briefs to be boundary objects, and the findings indicate that they in fact are.

For others considering how such a resource might support work in a different context, our findings suggest that in addition to designing based on what is known about effective PD, design should attend to the needs of the communities you hope to span. Specifically, design principles should include some features that are recognizable and important to multiple communities to support the development of a common language and an avenue for important boundary encounters, while also including features directly connected to the work of the individual communities. At the same time, we caution you to be careful about what is and is not included in the design and content. Findings here suggest that when a resource travels across boundaries in a large system, it develops power and could be used in ways that were not originally intended.

To date, over 10,000 R-P Briefs have been downloaded, and we know from the results here that people are accessing them in other ways as well. We have come to see the R-P Briefs as one example of a group of designs that our partnership developed to support systemic coherence in the implementation of new innovations. Like the briefs, other implementation resources were also grounded in research on teacher and student learning, instruction, and implementation. Collectively they provide access to safe professional learning opportunities and represent the expertise of a diverse set of educators within the system. Our hope is that findings from studies like this one can support others in designing implementation resources as boundary objects that support professional learning in the context of implementing educational innovations at scale.

DISSONANCE, HARMONY, AND CULTURAL CONFLICT IN INTERDISCIPLINARY CO-TEACHING

Aubrey Neihaus
Wichita State University
aubrey.neihaus@wichita.edu

Scott Kaschner
Butler University
skaschne@butler.edu

In this brief research report, we share our preliminary findings from a collaborative analytic autoethnography investigating our co-teaching across the disciplines of mathematics and mathematics education. We used identity to investigate sources of conflict and found that even successful interdisciplinary collaborations can give rise to conflict. This conflict may be attributable to contestation of identities stemming from disciplinary cultural differences.

Keywords: Teacher Educators; Professional Development; Autoethnography; Collaboration

The growing desire for interdisciplinary collaboration and the promise of its benefits are often blunted by fear of working beyond one's own familiar disciplinary community or even of conflict. What role does identity play in conflict that arises in interdisciplinary collaboration? Through this autoethnographic study, we illustrate how story as identity makes visible: 1) the causes of conflict in interdisciplinary collaboration, 2) the relation of conflict to identity, and 3) how understanding these aspects can make conflict resolution possible. These understandings provide interdisciplinary collaborators with both a language and means for minimizing conflict and resolving it as it arises. This study is a brief report on the emergent findings of a larger, on-going analytic autoethnography.

The need for collaboration between mathematicians and mathematics educators, particularly regarding the education of prospective mathematics teachers, has been well-documented (CBMS 2001, 2012; Graham & Fennell, 2001). This type of collaboration has taken many forms, including collaborative teaching partnerships between mathematicians and mathematics educators (Bleiler, 2015; Grassl & Mingus, 2007; Thompson et al., 2012). Co-teaching arrangements are often complicated by differences between the two fields in conventions, beliefs, language, and both research and instructional methods (Fried, 2014; Sultan & Artzt, 2005). While difficulty in overcoming these differences can result in either conflict or a passive collaboration, in which labor is distributed more than shared (Friend & Cook, 1993), there are examples of long-standing, successful teaching collaborations between mathematicians and mathematics educators (Bass & Ball, 2014; Goos & Bennison, 2018; Heaton & Lewis, 2011).

Arbaugh, McGraw, and Patterson (2019) note that the differences between mathematicians' and mathematics educators' disciplines can most accurately be understood as cultural differences. They suggest that co-teaching in which "members of different cultures and communities come together to design and implement experiences for teachers that are more impactful" are more successful than in which the groups designed and implemented them separately (p. 160). They also contend that a necessary condition for successful collaboration is that "the members of a collaborative mathematics teacher education team have an *ethnorelative* cultural sensitivity" (p. 163, italics in original). Differences in disciplinary culture can also produce conflict, and part of successful collaboration is working through that conflict by way of mutual cultural understanding.

We sought to better understand how conflict can arise in collaborations between a mathematician and mathematics educator (even long-standing, successful ones) and how identity as members in the respective disciplinary cultures contributes to this conflict.

Theoretical Frames

Autoethnography, our methodology for this study, is often employed to create meaningful research that is grounded in personal experience and has been used to speak to issues of identity (Ellis et al., 2011). It provides teacher educators "a means to understand themselves and enhance their practice" (Chapman et al., 2020) and has been used in education research as an insightful way to connect the personal to the cultural (Dyson, 2007). Guyotte and Sochacka (2016) found collaborative autoethnography to be particularly useful in investigating their own interdisciplinary collaborative teaching. This method of research can create empathy across different groups and thus, is pertinent to investigating interdisciplinary collaboration.

While there exist critiques of autoethnography as atheoretical or "navel-gazing" (Marshall & Rossman, 2016), it is notable that there is a range of approaches and analytic autoethnography is one that is rooted in traditional symbolic interactionism (Anderson, 2006a). Analytic autoethnography is ethnography in which the researcher: 1) is a full member of the research setting, 2) makes this membership visible in publication, and 3) uses an analytic framework focused on improving theoretical understandings of the broader phenomenon under study.

Sfard and Prusak (2005) define identity as a set of stories that are socially constructed (i.e., these stories can be told by others about the subject or by the subject themselves). Since identity is storied, it is not fixed but is continuously told and re-told through interactions with others and the self. Further, some of the "most significant stories are often those that imply one's memberships in, or exclusions from, various communities" (p. 17). When combined with analytic collaborative autoethnography, identity as story creates a powerful framework through which to investigate conflict in successful interdisciplinary collaboration, allowing us to consider both identity and cultural aspects of the conflict.

Methods

Participants and Context

We are positioned as both researchers and participants in this study. As a math education researcher, Aubrey's primary area of expertise is teaching mathematics; as a research mathematician, Scott's primary area of expertise is mathematics. Each has worked in their respective fields for over a decade. However, our expertise does overlap, as Aubrey's secondary area of expertise is mathematics and Scott's secondary area of expertise is teaching mathematics. As a person with expertise in teaching mathematics, Aubrey identifies as a supportive co-teacher; similarly, Scott identities as a good teacher of mathematics.

We have collaborated many times over the last eight years, from grant writing to research to professional development for both teachers and higher education faculty. We have served as references and letter writers for one another for professional advancement. We also reach out to each other for advice on working with and in one another's respective disciplines. We both view our various collaborations as successful and appreciate the professional insights of one another.

In the summer of 2018, we co-taught a two-week, 80-hour intensive mathematics content professional development program for practicing K-8 teachers. The program called for the course to be co-taught by a mathematician and mathematics educator and set the sequence of topics and tasks. This was the fourth consecutive summer that we co-taught this course but the first time at that location.

Data Collection and Analyses

During the professional development, we recorded audio of daily debriefing conversations. From nine separate sessions, there was a total of nearly four and a half hours of audio. Data analysis was conducted in four stages. First, we summarized the content of the recordings. Then using these summaries, we identified areas where conflict was a topic of discussion. Next, we reduced the data to one instance of conflict that was particularly compelling and clear. We then transcribed this section by hand and collaboratively hand coded it for themes (Guest et al., 2011; Saldaña, 2016). Last, we analyzed the data for identity (Sfard & Prusak, 2005), understood as a set of stories, and threats to identity.

We were intentional about two aspects of our data analyses: timing and co-construction. We allowed time to lapse between the data collection and the analysis of these data. This allowed us space to create distinction between ourselves as participants and ourselves as researchers. A year passed between recording the data and the summary analysis; another between the summary analysis and the data reduction to moments of conflict.

Co-construction was also an important aspect of our analyses, as it ensured that we created meaning from the data dialogically (Anderson, 2006b), and were in essence using member checking to ensure validity (Creswell, 2014).

Findings

The findings fall into two areas: evidence of the success of our collaboration and how identity contributed to conflict. First, the collaboration was largely successful and harmonious, and conflict was rare. This was seen in both early analysis (summaries) and in the identity analysis. The summaries showed that the content of the debriefs included multiple topics indicating the success of the collaboration (e.g., joint classroom management; victories and challenges; distribution of work; strategies for supporting learners). While our investigation here undertakes one of the conflicts experienced within our collaboration, it is worth noting that in general, conflict was only one of many topics and could not be said to characterize the debrief data overall. Further, in the later identity analysis of the conflict under investigation, there are multiple instances of endorsing one another's stories and of working through contested stories to find a story both could endorse.

Second, we found that in the specific instance of conflict under investigation here, the conflict arose when one of our stories threatened the other's identity. Further, the conflict arose when a particular interaction gave rise to multiple stories that were then contested. The resolution came from understanding 1) that identity was threatened by an interaction, 2) this caused the story to be contested, and 3) why it is important in the respective disciplinary culture. We use the following vignette to illustrate this phenomenon.

Treating for Mathematical Status and Hand Raising Protocols

In general, both of us recognize that within a teacher professional development course on mathematics content, there will be status differentials among the teachers, and that as the instructors, it is our responsibility to treat for status.[1] In the past, we have agreed to establish a hand-raising protocol early in the course to ensure that participation is more equitably distributed and that all the teachers have sufficient time to process and formulate responses when questions are posed to the group.

On the first day of the course when Scott taught, he did not initiate this hand raising protocol. He had an alternate plan for treating for status—to allow the over-participators to attempt to answer the posed question, but to focus on a lower status teacher when they notice the intended aspect(s) of the task at hand, thereby assigning competence to the lower status teacher.

Aubrey noticed that Scott had not initiated the hand-raising protocol. She knew that when he teaches undergraduate mathematics courses, he doesn't rely as heavily on this type of tool,

[1] See Cohen & Lotan, 2014.

preferring to instead develop a learning community with freely exchanged academic ideas and that he treats for status in alternate ways over the semester. Aubrey contemplated signaling to him to suggest initiating the hand-raising protocol, but instead decided to bring it up later, assuming that he had just forgotten and was using his usual techniques. When she did bring it up, she asked Scott if he had forgotten about the hand raising protocol. Scott interpreted this question as a judgment on his teaching and responded by asking whether Aubrey trusted him to make pedagogical decisions. Later, they were able to talk through this experience and understand one another's perspective and how their meanings were intended and misunderstood.

Contested Narratives and Threats to Identity

While the vignette above is brief, it provides an opportunity to consider how the stories from the interaction—and their contestation—explain the source of the conflict. In the vignette, there is an endorsed story shared by both Aubrey and Scott—that treating for status differentials in a mathematics class is important. This shared and endorsed story identified both Aubrey and Scott as "good mathematics teachers" in the sense that their teaching is informed by research on equitable mathematics teaching.

When Scott made an in-the-moment decision to treat for status in a different way, Aubrey assumed that he had forgotten the usual strategy and asked if he forgot. This event is where their individual stories (and the associated identities) diverge. Aubrey characterized that move as a reminder, thereby identifying herself as a supportive collaborator. Scott characterized that move as questioning his pedagogical acumen and thereby calling his identity as a "good mathematics teacher" into question. Scott's response, questioning whether Aubrey trusted him to make instructional choices, further clarifies that he is contesting the story that identified him as "not a good mathematics teacher." His response not only contests the story that he is not a good mathematics teacher, it also contests Aubrey's story that she is a supportive co-teacher. The resolution of the conflict comes only when these perspectives and cultural misunderstanding are made clear to one another.

Discussion and Conclusions

On the surface, this vignette displays a disagreement about how to best address status differentials in a mathematics professional development course. We found that an underlying source of tension is the way in which our identities are contested by one another, whether intentionally or not. Aubrey called Scott's identity as a "good teacher of mathematics" into question when she attempted to remind him of their usual pedagogical choice. Scott called Aubrey's identity as a "supportive co-teacher" into question when he questioned whether she trusted his choices. However, the conflict arose (and escalated) because of how these stories about pedagogical choices and trust signal something deeper about how we each identify the other in relation to our own primary expertise. This significance is compounded by the fact that in each case, one's primary expertise is the other's secondary expertise.

Owning to complementary expertise and disciplinary cultural differences, there is still opportunity for conflict. Despite the many years of collaboration across multiple aspects of our professional lives, and mutual respect for one another, we still find that conflicts arise. It seems unlikely that in our collaborations, we will be able to eliminate conflict completely, given that we are each firmly established in our respective disciplinary cultures. However, by identifying and managing the underlying causes–identity and disciplinary cultural differences–we are able to see what gives rise to conflicts, resolve them, and learn from them.

Mathematics education researchers (MERs) engage in interdisciplinary collaborations that contribute to the mathematics education discipline. MERs' learned forms of work and discourse, i.e., practices, are particular to their mathematics education discipline and might not align with practices needed to conduct interdisciplinary work. We interviewed four MERs who were leaders of interdisciplinary groups to learn about practices they reported using while collaborating with their groups. Using qualitative content analysis, we describe five practices commonly reported by the four MERs. We argue that these five practices are central ways of knowing and doing for MERs when working in interdisciplinary groups. Our study contributes to the mathematics education discipline by unpacking practices MERs use to engage in interdisciplinary groups that are influenced by interpersonal relationships.

Keywords: Mathematics education, interdisciplinary collaborations, practices, disciplines.

Mathematics Education Discipline and Work

Disciplines are defined by Williams et al. (2016) as a "phenomenon" involving "specialization" of work and discourse (p. 4). Disciplines are constantly evolving while increasing their specialization and differentiation. For instance, mathematics education as a discipline has evolved from being informed by the disciplines of psychology and mathematics (Kilpatrick, 2014; Stinson & Walshaw, 2017) to embracing disciplines such as neuroscience (e.g., Norton et al., 2019), science education (e.g., de Freitas & Palmer, 2016), and anthropology (González et al., 2001; Gutiérrez, 2013). Disciplinary practitioners are introduced to disciplinary ways of knowing and doing in their training programs. Mathematics Education Researchers (MERs) develop their professional identity by learning research practices within the discipline of mathematics education. In their career, practitioners gain status in their discipline by engaging in disciplinary forms of discourse. MERs further interact with practitioners from other disciplines and collaborate in interdisciplinary groups.

MERs have engaged in interdisciplinary work to address complex problems. For instance, Civil joined González from anthropology to explore funds of knowledge (González et al., 2001). Norton joined colleagues from computer science to develop software systems (Jones et al., 2015) and neuroscience to explore students' anxiety (Norton et al., 2019). Davis joined colleagues from various disciplines to explore spatial reasoning (Bruce et al., 2017). We can learn about MERs' interdisciplinary collaborations from publications, but because the collaborations are not the focus of the publications, descriptions about the process of interdisciplinary work are thin. Schön (1992) stated that practitioners of a discipline do their work by using more than "research-based technique" (p. 54). Conducting work involves aspects such as interpersonal relationships where people act and work towards solving important problems and finding common ground (Fletcher, 1998). Interpersonal relationships involve social exchanges that welcome and lift people involved academically and emotionally. We argue that working in interdisciplinary groups is more than contributing discipline specific expertise, it involves the negotiation of disciplinarity through interpersonal relationships. This includes paying attention to ways of being, interacting and doing within the groups. It also includes identifying disciplinary-based practices that are essential, can be modified or compromised, or do not align with the interdisciplinary work.

Because members of interdisciplinary groups have been trained in their respective disciplinary ways of knowing, communication and representation differences might emerge when coming together. Bruce et al. (2017) reported that members of an interdisciplinary group need to study "discipline-specific vocabularies and methodologies" and articulate problems so that all members can "identify and situate themselves" (p. 158). Goos and Bennison (2018) described the value of disciplinary knowledge to interdisciplinary team members. In addition, team members felt threatened when their disciplinary knowledge and ways of operating were not recognized professionally when "working outside their discipline" (p. 267).

Disciplinary ways of knowing and doing work are called practices (Hyland, 2004; Williams et al., 2016). In this paper, practices and practice categories are italicized to help the reader recognize when words or phrases are being used to describe practices. Building from existing research (e.g., Cobb & Yackel, 1996; MacIntyre, 1984; Schön, 1983, Wenger, 1998), Suazo-Flores et al. (2021a, para. 4) defined practices as "established ways of *being*, *operating*, and *interacting* with others." Suazo-Flores et al. (2021a, para. 9) found that in interdisciplinary groups, MERs engage in practices such as *working towards research interests*, *cultivating trust and open-mindedness*, and *understanding of institutional support*. Building from this work, we interviewed MERs who worked in interdisciplinary groups. Our initial analysis resulted in a revision of the categories of our definition of practices, where:

> *Being* […] refers to MERs describing their view of themselves and others in the interdisciplinary group including specific roles taken on by group members. *Operating* […] means members' ways of doing in the interdisciplinary group and acknowledging institutional policies and actions in order to complete the work. *Interacting* is […] developing communication standards, negotiating the meaning of ideas that allows the group to collaborate, and explaining work to people outside of the group. (Suazo-Flores et al., 2021b, p. 827, italics added)

With this revised definition, we conducted further research to address the question: What practices did MERs commonly report using in interdisciplinary research groups?

Methods and Analysis

This research is part of a larger project focused on describing MERs' lived experiences of working in interdisciplinary groups (Suazo-Flores, et al., 2021b; Suazo-Flores, et al., 2021c). Four MERs from three different projects who identified themselves as members of interdisciplinary research groups volunteered to participate in this research: Amelia, Ian and Alexis, and Iris (pseudonyms). Amelia was a faculty member as well as a primary developer and leader of her interdisciplinary project. Her project involved improving curriculum and pedagogy for university pre-service mathematics education programs. Ian and Alexis collaborated on a project to create engineering tasks that would allow students to learn new mathematics content. Ian was a graduate student and Alexis was a faculty member and Ian's advisor. Iris was a faculty member and leader of a project between mathematicians and mathematics teacher educators. The project developed curricular modules to help students learn mathematics content. We conducted three semi-structured interviews (Kvale, 1996) with the four MERs (Ian and Alexis were interviewed together) focused on practices that developed and were used in the interdisciplinary groups. MERs shared the story of the interdisciplinary group, ways of doing in the group, and reflections as a member of the group. For example, we asked MERs to describe situations when working in the group was an asset or a constraint.

To create codes and definitions for the categories of practices and to identify examples, we used grounded theory (Charmaz, 2005) to code Amelia's transcript (Suazo-Flores, et al., 2021b). Each practice was categorized as *being*, *operating*, or *interacting* and assigned a short descriptive phrase. Three phases of analysis resulted in a codebook with definitions of the practice categories, descriptions, and examples of different practices. For example, the following excerpt was coded as the practice *acknowledging a personal view of self* within the *being* category.

> Amelia: For me, it's been a wonderful growing experience. So, I don't feel like I've lost anything because I still have my life in my discipline, and I have a much enriched and expanded life as well by having these experiences that I didn't realize I was going to get.

Amelia referred to her *personal view of self* as an MER noting, "I still have my life in my discipline." She also recognized that her work in the interdisciplinary group had "enriched and expanded" her life. We identified this as a way of *being* because it provided evidence of her evolving identity as an MER through her work with people from other disciplines.

We then used the codebook to code all three interviews. Evidence of practices reported by the four participants in the form of interview transcripts constitutes our data. A deductive approach using the codebook allowed for analysis of the transcript data consistent with qualitative content analysis, such that the coding and analysis included two steps: "the first is a qualitative-interpretative step following a hermeneutical logic in assigning categories to text passages; the second is a quantitative analysis of frequencies of those assignments" (Mayring, 2015, p. 366).

For reliability, each transcript was coded by a member of the research team using the codebook and then checked by a second member of the research team. When coding differences between researchers were found, the coded practices were discussed by the entire research team to share reasoning and clarify codes. Once agreement was reached regarding the use of a code or its definition, the codebook was updated. Once this qualitative-interpretive step was completed, the codebook was updated and the coded items in each of the transcripts were reviewed for alignment with the updated codebook (c.f., Mayring, 2015).

Following the final coding of the three transcripts, frequency tables were created to identify how often each practice occurred in the data. Table 1 is the frequency table for the five practices described in this paper. The frequencies of the coded practices were disaggregated by project and show the amount of evidence from each of the projects used to make a claim. For example, there were 22 instances where the *being* practice *acknowledging a personal view of others' roles* was coded across three interview transcripts. Disaggregation showed that 6 of these codes were from Amelia's transcript, 9 of these codes were from Ian and Alexis' transcript, and 7 of these codes were from Iris's transcript. The frequency tables allowed for the identification of practices that were common between all of the participants. This research presents the five practices that were reported in each of the three transcripts at least three times.

Table 1: Frequency Table for Common Practices

Category	Practice	Amelia	Ian and Alexis	Iris	Total
Being	Acknowledging a personal view of self	4	6	20	30
Being	Acknowledging a personal view of others	6	9	7	22
Interacting	Developing ideas between partners	6	7	3	16
Operating	Working towards common goals	9	5	5	19
Operating	Using ways of working together	4	3	4	10

Findings

Our analysis identified five practices MERs commonly reported using in their interdisciplinary groups: *acknowledging a personal view of self*, *acknowledging a personal view of others*, *developing ideas between partners*, *working towards common goals*, and *using ways of working together*. The first two practices are in the *being* category, the third practice is in the *interacting* category, and the last two practices are in the *operating* category. Below, we describe each practice and use examples from the data to illustrate the category.

Being: Acknowledging a Personal View of Self

Acknowledging a personal view of self was coded as a type of *being* practice. This practice involved MERs using individual identity, including their dispositions, interests, sense of efficacy, and roles to engage with others in the group's work. Our participants showed evidence of recognizing their roles and dispositions in their interdisciplinary groups. For example, Ian indicated, he "was the central person" who at the beginning of the project "was trying to meet the needs of so many people," which we interpreted as him acknowledging his role in the group and others' expertise. In Iris' research group, she described how she was "not a mathematician," but brought her vast teacher education background to the project, "I have lots of experience in working with teachers."

Being: Acknowledging a Personal View of Others

Acknowledging a personal view of others was classified as a *being* practice because participants described how they perceived others as part of the interdisciplinary group. The code *acknowledging a personal view of others* was used when participants described other group members as members of a discipline, as taking on special roles in the group, or as influential members due to the added diversity of knowledge/experience. For instance, Iris described a member of her interdisciplinary group as having a "very strong mathematics background" with experience in the "high tech industry" and "a high school teacher." Iris acknowledged the member's expertise and experiences and appreciated that both were committed to "narrowing the gap between school mathematics and contemporary mathematics," which was the main goal of the interdisciplinary project. As a member of Ian's interdisciplinary group, Alexis described how she recognized roles and expertise in her colleagues. Alexis stated, "the primary role that the team members play was to bring their expertise to the table," and she noted that "Ian really was the lead in designing the material or coming up with the context and coming up with the activities."

Interacting: Developing Ideas Between Partners

Developing ideas between partners was coded as an *interacting* practice because MERs reported how group members negotiated the meaning of ideas, representations, or frameworks. When MERs described developing understandings and common definitions that allowed members of the group to collaborate and communicate to external audiences, we coded those instances as *developing ideas between partners*. For example, Iris indicated that she and a group member who was a mathematician had "arguments on the buildup, on the things that [the mathematician] thought would be very accessible." Iris and the mathematician had discussions regarding unpacking the mathematics content and making it accessible to students. She explained that such discussions allowed them to develop new ways to represent mathematics to external audiences. "I don't think I would be able to do it on my own, and I don't think he [the mathematician] would be able to do it on his own." In another example, Amelia indicated how it was important for the interdisciplinary group members to develop ways of communicating. Amelia described that given the different disciplinary expertise, people in the group needed "to be good listeners and very respectful and making it possible for questions to be asked and to be able to respond to those questions in a way that's serious and takes things seriously."

Operating: Working towards Common Goals

Working towards common goals was classified as an *operating* practice because the use of common goals was a factor in "ways of doing" for the groups. This practice was described by the participants when they shared purposes or common goals used by the group to focus the work being done. There were also times when MERs described working with the interdisciplinary group to develop common goals. Such instances were classified as an *interacting* practice like *developing ideas between partners* (see above) because developing goals involved exchanging ideas to build shared understandings. *Working towards common goals* was coded when (1) the group goals were described by a participant, (2) it was clear that the goals were established, and (3) it was clear that the goals were used to focus the work being done. For instance, Amelia's articulation of the initial purpose of her interdisciplinary group is that "it was a funded project" and that "the central purpose kept [them] together. So those two goals were always there." Ian described how the group's purpose was to create a curriculum for the "learning of new mathematics and new engineering at the same time."

Operating: Using Ways of Working Together

Similar to *working towards common goals*, *using ways of working together* is classified as an *operating* practice because it represents "ways of doing" for a group. *Using ways of working together* is how an interdisciplinary group worked as a team or a process that the group used to get work done. Iris described her work as "a true teamwork." She encouraged the mathematician to "set up a storyboard, so to speak," to tell the story around the targeted mathematics concept. Later, they worked together to add the "know-how" pieces. This is how the new story around the targeted mathematics concept began "with a question instead of starting with declarations." In Amelia's research group, she described how different group members already had different systems in place. The group shared these other systems, which created a menu of items, "and then we each picked something from that menu that we decided to try this approach next year, and then we swapped and learned from each other." The group developed a way of working together to learn from each other by picking different approaches from the menu.

Discussion

We have described five practices MERs commonly reported using in their interdisciplinary groups. Two practices are in the *being* category, one in the *interacting* category, and two in the *operating* category, respectively: *acknowledging a personal view of self*, *acknowledging a personal view of others*, *developing ideas between partners*, *working towards common goals*, and *using ways of working together*.

The practices identified in this research provide evidence that conducting interdisciplinary work is more than contributing disciplinary expertise, as asserted by Schön (1992). MERs used the *being*, *interacting,* and *operating* practices to navigate interpersonal relationships and conduct interdisciplinary work. The *being* types of practices reflect how MERs saw themselves in relation to others and how they perceived others in their groups. The practices of *acknowledging a personal view of self* and *others* allowed MERs to acknowledge disciplinary expertise and navigate work with others by finding common ground and contributing to the interdisciplinary group work. The *interacting* practice, *developing ideas between partners*, identifies the development and use of discourse norms within interdisciplinary groups to understand, listen to each other's perspectives, and build common understandings. The *operating* practices of *working towards common goals* and *using ways of working together* describe "ways of doing" in interdisciplinary groups. Members of interdisciplinary groups worked towards goals that met their interests and the interdisciplinary project; they also developed work systems that built from each other's expertise and backgrounds.

Because the members of interdisciplinary research projects come from different disciplines, that have different practices (Williams et al., 2016), MERs need to use *interacting* practices, which allow the group to negotiate and develop a common language among themselves and for external audiences. MERs in our study had discussions of meanings within the groups to conduct the interdisciplinary work and communicate the product of the collaboration to external audiences. For instance, Ian described how he acknowledged different peoples' expertise and then realized that his role and other team members' roles allowed the project to be more successful. Iris described the integral role of diversity in her team, highlighting the need to discuss ideas with colleagues from different disciplinary backgrounds to construct new knowledge. Amelia's description of team members' approach to interactions as "good listeners and very respectful" aligns with descriptions of dispositions of team members provided by Bruce et al. (2017). We also noted that the common language the members of the interdisciplinary group developed was unique to the members of the group and the project's final product. For instance, Iris reflected that it took many discussions for the group to narrow down ways of representing the product of their work to others. Iris' interaction with her colleagues and the consideration of how external audiences would use the project was instrumental in developing a way of communicating the work. Iris recognized that this important goal could not have been realized without each team member's contributions and expertise.

Once the group members have used *interacting* practices to cultivate a common language and framework, *operating* practices develop. We identified two operating practices: *working towards common goals* and *using ways of working together*. For instance, Iris and her group used the story system to start with the pure mathematics content to add know-how prompts that would allow the audience to have entry points to engage. Amelia and her group built from each of their experiences in teacher education to learn from each other instead of using mandating systems.

Our study exemplifies Williams et al.'s (2016) definition of disciplines for mathematics education. Mathematics education as a discipline has evolving forms of discourse and work. As

MERs are being asked to join interdisciplinary groups to expand the boundaries of mathematics education research (Cai et al., 2020), we advocate for professional development spaces where MERs reflect on ways of *being*, *interacting*, and *operating* in such groups. MERs need to learn how to productively work outside of their discipline and, with that, expand their expertise. MERs need to consider their role in the project and their personal goals in relationship to the project's goals and the group members from other disciplines. MERs also need to create spaces where members of interdisciplinary groups can openly discuss ideas. In such discussions, MERs need to acknowledge their colleagues' expertise and recognize that as a group in dialogue, new ideas will emerge that inform the final product of the interdisciplinary work.

The results of this research are influenced by the fact that each of our participants were leaders of their interdisciplinary groups. MERs as members of interdisciplinary groups led by others may contain practices not captured here. Similarly, more studies are needed to explore how power relationships influence work in interdisciplinary groups that include a MER. The study reported here did not capture the breadth of experiences that members of the research team have experienced as MERs on interdisciplinary projects, suggesting that additional work is needed. Similarly, studies on how MERs' race and ethnicity backgrounds influence their interpersonal relationships and practices in interdisciplinary groups are also needed.

DEVELOPMENT OF TEACHER LEADERS IN HIGH-NEED URBAN SCHOOLS

Adem Ekmekci	Mahtob Aqazade	Anne Papakonstantinou

Keywords: Equity, Inclusion, and Diversity; Instructional Leadership; Mathematical Knowledge for Teaching; Professional Development.

The Rice University Robert Noyce Master Teaching Fellowship (RU-MTF) was a five-year program designed to develop 14 exemplary secondary mathematics teachers into mathematics teacher leaders who are deeply grounded in sound mathematics content, pedagogical content knowledge (Hill et al., 2008), teacher leadership (York-Barr & Duke, 2004), adult education, and culturally relevant teaching (Ladson-Billings, 1994). RU-MTF's goals were to create an innovative, multi-faceted research-informed model for identifying, developing, and supporting mathematics leaders that can be replicated for different grade bands and in urban, suburban, and rural school districts.

In this paper, we report on lessons learned from implementing RU-MTF, particularly during COVID-19, and RU-MTF's impact on master teaching fellows' (MTF) leadership skills, mathematical knowledge for teaching (MKT), and diversity dispositions. Leadership skills (Mills et al., 2014) and diversity dispositions (i.e., Schulte et al., 2008) are measured through self-reported 5-point Likert-scale items. MKT is measured through learning mathematics for teaching assessment (Hill et al., 2008). We further highlight MTFs' focus group conversations and open-ended responses to, for example, their perceptions of effective mathematics instruction, effects of RU-MTF on beliefs about equity, and complications caused by the pandemic.

The COVID-19 pandemic created complications for teachers including "exacerbated learning gaps," "weakened community connections," "obstructed feedback cycles for colleagues," and "worsened social interactions." MTFs' perceptions of remote education during COVID-19 revealed the importance of developing equipped and energized teacher leaders who are devoted to improving mathematics instruction by supporting K-12 teachers, students, and parents. During this time of uncertainty, MTFs realized, even more than ever, the value of "community connections" and "leadership engagement." The quantitative data indicated that MTFs' leadership skills, MKT, and beliefs about diversity in education significantly improved from the onset to the end of RU-MTF. MTFs highlighted "student engagement," "hands-on learning," "learning by discovery," and "communication in flexible and variety of ways" as important parts of effective mathematics instruction. However, their concerns disrupting such approaches in effective teaching of mathematics included "tests being perceived as the most important element" and the "deficit understanding of effective math instruction." As MTFs' perspective of leadership roles "changed from individual to collaborative style" and their beliefs about equity in mathematics "evolved in to having a wider scope," we can argue that RU-MTF served as an effective model for developing teacher leaders.

Results include implications for both research and practice fields regarding teacher leader development (including whys and hows) and effective characteristics of a teacher leader development program.

Keywords: Instructional Leadership; Teacher Beliefs

Mathematics and science teacher turnover is a great and consistent problem in the U.S., particularly in high-need, high-minority, and urban schools (Cross, 2017). Most teachers leave the profession because of dissatisfaction, lack of support, lack of autonomy, and lack of collaboration opportunities (Carver-Thomas & Darling-Hammond, 2019). Thus, it is essential to understand the motivational, school-environmental, and social networking factors in relation to teacher retention. For instance, teachers' self-efficacy beliefs are important in fostering constructivist learning, student motivation, and higher academic performance, which impact job satisfaction and retention or attrition in the profession (Yost, 2006). Further, opportunities to develop leadership skills and engage in a collaborative school-work environment to improve school culture and instruction can support and sustain high-qualified teachers (Dauksas & White, 2010). Some features of teachers' social networks (e.g., density) support their persistence and are correlated with their self-efficacy (Polizzi et al., 2021). Lastly, positive diversity dispositions are associated with persisting in teaching in high-need schools (Williams et al., 2016).

In this paper, we explored the extent to which teachers' self-efficacy for teaching, leadership skills, diversity dispositions, school-work environment, and social network are related to their retention. From the Greater Houston area, about 250 teachers (27% male and 73% female; 30% elementary and 70% secondary teachers; 65% White and 35% from minoritized backgrounds) with, on average, 14 years of teaching experience (SD = 8.70) completed a survey responding to questions related to teaching, self-efficacy (Klassen et al., 2009), teacher leadership skills (Watt et al., 2010), person-organization fit (Pogodzinski et al., 2013), principal autonomy support (Baard et al., 2004), diversity dispositions (Schulte et al., 2009), and social network (e.g., size; Polizzi et al., 2021). Among these teachers, 14 were identified as shifters (who shifted to a leadership position) and 18 as leavers (who left or retired from K-12 teaching/education).

We conducted multinomial logistics regression analyses with retention as a three-level nominal outcome (Mayer et al., 2017). Findings indicated that secondary teachers were more likely to shift to a non-teaching position compared to stayers. The higher level of teacher leadership skills and lower degrees of person-organization fit were associated with shifting to a leadership position. Lastly, a higher level of teaching self-efficacy was observed in leavers compared to stayers. Reasons for shifting included teaching burnout, better pay, and having greater impact. Reasons for leaving included the pandemic, retirement, family, stress, and burnout. There are implications for practitioners, researchers, and administrators for supporting teachers to persist in teaching or shifting to a leadership position where they can have a greater impact for educational outcomes.

DEVELOPING ELEMENTARY SCHOOL PRINCIPALS' NOTICING TOWARDS A SHARED VISION OF HIGH-QUALITY MATHEMATICS INSTRUCTION

Keywords: Instructional Leadership, Instructional Vision, Professional Development.

When trying to achieve instructional improvement, principal leadership plays a significant role in changing teachers' instructional practices (Supovitz et al., 2010). This study is part of a larger project, a research-practice partnership (RPP) with a school district that aims to develop school principals' instructional leadership practices so they can support their teachers in creating more socially just mathematics classrooms for their predominantly Latinx population.

We report on work conducted by our RPP team (district leaders, six school principals, and three researchers) towards one of the collaboratively defined goals for the 2021-2022 school year: building a shared vision of high-quality math instruction. We designed a learning experience inspired by Math Labs (Kazemi et al., 2018), consisting of five monthly visits to a fourth-grade math class to engage in observation and debriefing with the teacher on instructional practices and classroom interactions. In this context, our research examined in detail principals' learning process as they are involved in practice-based professional development. We attended to the following questions: How does the principals' noticing of student mathematical thinking evolve over the visits?; How is the noticing of each principal related to their instructional vision of high-quality mathematics instruction?

A vision of high-quality mathematics instruction involves the discourse that principals use to describe ideal classroom practices that are not necessarily mastered yet (Munter, 2014)--a first step for them to then support their teachers' learning effectively. High-quality mathematics teaching practices have been widely researched in mathematics education. We draw on observation tools that systematize them in specific dimensions that encompass rich and meaningful mathematics, ambitious practices (Boston, 2012), and culturally responsive teaching (Aguirre et al., 2013). We also draw on the construct of teacher noticing (Sherin et al., 2011) and hypothesize that developing the skills of attending to specific aspects of mathematics instruction, reasoning about them using frames of reference that characterize high-quality practices, and discussing the teacher's instructional decisions, will support principals in developing a shared vision of high-quality mathematics instruction. In this way, we seek to contribute to the limited existing research on principals' noticing and on how noticing relates to the development of a vision for high-quality math instruction. We collected data from four sources: audio transcripts of the sessions, a noticing task at the end of each session, field notes, and a final individual interview. Using dimensions from existing research (Aguirre et al., 2013; Boston, 2012; Munter, 2014), we developed a coding system to analyze and triangulate data, allowing emerging codes during the coding process.

Initial findings suggest that principals' noticing became more sophisticated, evolving from attention to general aspects of the lesson toward noticing specific elements of students' mathematical thinking and the instructional moves that led to and supported them. The data obtained in the final interview about the participants' vision will be analyzed alongside responses to the noticing task to examine relationships between the two constructs.

Keywords: Instructional Vision, Instructional Leadership

Principals influence student achievement through setting school-wide goals, engaging in instructionally focused conversations with teachers, and providing opportunities for professional development and collaboration (Grissom et al., 2021; Supovitz & Sirinides, 2010). A well-developed vision of high-quality instruction will inform each of these activities. Further, in the context of district-wide instructional improvement, a shared vision will support coherence across professional development initiatives (Cobb et al., 2020). In this study, we explored how a shared instructional vision can be developed among district and school leaders in a research practice partnership (RPP) focused on improving elementary school students' mathematics learning, and in particular, the achievement of Latinx students within a district.

Through a collaborative process, RPP members (six principals, three district leaders, a mathematics coordinator and three university researchers) identified developing a shared vision as a key goal of improvement efforts. In service of this goal, RPP members participated in four Math Labs in a 4th grade classroom. The design of each Math Lab emphasized school leader learning in practice and was inspired by previous Math Labs designed by Kazemi et al. (2018). The Math Labs provided a context for district and school leaders to co-enact instructionally focused conversations with the teacher. In this study, we asked: how do Math Labs support the development of a shared vision of high-quality and equitable mathematics instruction?

Munter (2014) describes vision as an image of what is possible in a classroom space, though may not currently be enacted. He characterizes individual trajectories of a vision of high-quality mathematics instruction across four dimensions: mathematical tasks, the role of the teacher, classroom discourse, and student engagement. We extend this work in two ways. First, we explicitly integrate equitable practices as described by Aguirre et al., (2013) within a vision of high-quality instruction. Further, drawing from Goodwin's (1994) description of professional vision, we situate school and district leaders' vision of high-quality instruction within the shared discursive practices used to see and understand a classroom space. While elements of high-quality instruction can be observed during the Math Labs, how district and school leaders ultimately see those practices is informed by their roles within the context and larger society.

Transcripts of discussions and participant interviews and field notes from Math Labs and design sessions were coded by the team of researchers. Artifacts generated from the Math Labs were included in the data analysis. We explored the process by which a shared vision begins to take shape. Initial findings suggest that a shared experience, immersed in a classroom setting, provides a rich opportunity to make sense of aspects of high-quality and equitable instruction and to develop a shared discourse around teacher professional identity. Yet, we identified moments when what is seen is mediated by participant roles, suggesting how professional vision reflects and influences the image of high-quality instruction. Our study expands current literature on contexts that contribute to development of shared vision of high-quality mathematics instruction for school leaders.

Graduate student peer-mentoring programs benefit participants by providing unique academic, social, psychological, and career development opportunities (Lorenzatti et al., 2019). However, the positive effects of research-oriented peer-mentoring programs are much better understood than teaching-oriented ones. In our poster, we consider mentees and mentors' perceptions of effective mentoring in a teaching-oriented peer mentorship program.

Previous research provides possible frameworks regarding mentee-mentor interactions. Rose (2003) designed the Ideal Mentor Scale for doctoral students to consider the qualities they value most in a faculty mentor: *integrity, guidance*, and *relationship*. With regard to school-based youth mentoring, Brodeur et al. (2015) identified the dimensions of *structure, engagement, autonomy,* and *competency support* that governed mentee and mentor impressions of mentor behaviors. However, no existing theoretical or empirical framework could be identified to address the unique nuance of peer GTA teaching mentoring relationships.

As part of a multi-component program, *Promoting Success in Undergraduate Mathematics Through Graduate Teaching Assistant Training* (PSUM-GTT; Harrell-Williams et al., 2020), GTAs participated in a peer teaching mentoring program. This study focuses on two research questions: What are mentees and mentors' conceptualizations of "effective" peer teaching mentors? How do mentors' views of themselves compare to their conceptualizations?

Survey data was collected from mentees and mentors, with Likert-type and open-ended items relating to each groups' conceptualization of an effective mentor. For example, we asked mentors where they saw a mentor on a continuum of an authority figure (scored as "1") to a collaborator (scored as "5") and compared this to how they saw themselves as mentors using the same scale. According to a contingency table analysis, 10 of 15 mentors rated themselves as more collaborative (more "4"s or "5"s) than they imagine a mentor in general should be (more "2"s and "3"s). According to a psycholinguistic analysis in Linguistic Inquiry and Word Count (LIWC) 2022 (Boyd et al., 2022), 11 of the 15 mentors felt more confident, according to the LIWC clout score, when reporting about the nature of an ideal mentor than when they wrote about their own role as a mentor. Taken together, this suggests that our peer mentors didn't see themselves as being as much of an "authority" as they would like to in their new roles. Further results concerning mentees and mentors' conceptualizations and their alignment in conceptualizations will be presented in our poster.

Keywords: Instructional Vision, Systemic Change

This project aims to test the conjecture that developing a shared vision of high quality mathematics instruction (HQMI) is foundational to the successful implementation of STEM education innovations. Since 2016, our research practice partnership (RPP) of state, district, and school-based leaders, mathematics teachers, and researchers have engaged in design-based implementation research (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013) to iteratively co-design instructional resources that promote a shared, state-wide vision of HQMI. We aim to build upon this work by investigating the visions of HQMI held by educators at different levels of a state educational system, the extent to which those visions are shared, and how the visions mediate and are mediated by the co-design and uptake of implementation resources.

HQMI aims for teachers to be intentional in supporting students, for example, by problematizing ideas (Munter, 2014), supporting students in developing mathematical authority (Lampert, 1990), and scaffolding classroom discussions in ways that formalize learning goals for students (Smith & Stein, 2011). Established and emerging research suggests that sharing a vision of HQMI can support successful implementation of new programs or policies (Gamoran, 2003), relates to improved instructional quality (Munter & Correnti, 2017), and can lead to improvements in students' academic outcomes (Chance & Segura, 2009). In addition, research points to the ways in which educators' visions are shaped by participating in different social contexts (Munter & Wilhelm, 2021) and informed by different or conflicting messages from both inside and outside schools (Ticknor & Schwartz, 2017). Teacher collaboration, PD, and productive collaborations across educator roles are rarely effective unless they are tied to a shared vision of instruction (Peterson et al., 1996).

Using a mixed methods design we are studying our design process with a goal of understanding the ways in which vision of HQMI and implementation resources interact across a state educational system and the extent to which a shared vision of HQMI leads to coherence. Our poster presentation will describe the project as a whole, share the initial iteration of our framework design, and report our initial findings.

Keywords: Equity, Inclusion, and Diversity; Instructional Leadership; Instructional Vision

School administrators play an important role in influencing instruction (Nelson and Sassi, 2000) and building organizational capacity for equity (Galloway and Ishamaru, 2020). Previous research has focused separately on administrator content knowledge (Steele et al., 2015) and perceptions of equity (Nadelson et al., 2020). However, limited research details how administrators think about equity *within* the context of math instruction. Meanwhile, studies of teachers have shown a connection between their *visions* and their instructional practice (Munter & Correnti, 2017). Therefore, administrators' visions of equitable instruction may also affect math teaching and learning. This study examines this relationship, asking: *How do district administrators characterize their visions of equitable math instruction?*

Methods

This study is situated within a multi-year design-based implementation research initiative: the CASPIR Math Project. Leaders from two districts (Elm, n = 6; Maple, n = 5) were interviewed using the visions of high-quality mathematics instruction instrument (Munter, 2014) with the added question: *What would you look for to determine whether instruction is equitable?* The National Council of Teachers of Mathematics (NCTM) equity position statement (2014) provided an instruction-centered framework for coding, which included the following topics: access, students, curriculum, teachers, differentiation, progress monitoring, accommodations, and remediation/additional challenge. Authors looked for patterns within and across districts.

Initial Findings and Implications

No two individuals expressed the same vision. However, three categories emerged revealing patterns in how administrators spoke about equitable instruction: methods to achieve equitable math instruction, perception of students, and challenges to implementation. Administrators from Maple tended to mention grouping as the main form of differentiation, referring to students in three leveled groups. In contrast, Elm administrators mentioned more specific and varied forms of differentiation focusing on lesson planning and task modification, whilst maintaining high cognitive demand. They also tended to discuss students through a more individualized lens. On the other hand, challenges to equitable instruction in both districts were discussed and included teachers' ability and mindset, curriculum, and family support. These findings, while preliminary, have implications for researchers and practitioners. Alignment in visions cannot be assumed among administrators. Thus, conversations about what equitable mathematics instruction is, who should be working towards it, how it should be achieved, and for what reasons may be required to move towards a more common understanding.

La pregunta es: ¿Cómo razonan los estudiantes de ingeniería que han llevado un curso tradicional de cálculo ante problemas simples de flujo de líquido en los que el proceso de solución involucra el teorema fundamental del cálculo? Un cuestionario de tres preguntas se administró a 18 estudiantes de ingeniería de una universidad de la ciudad de México que habían llevado un curso ordinario de Cálculo. Desde una perspectiva de Teoría Fundamentada se codificaron sus respuestas y se generaron tres categorías generales que hemos denominado razonamientos procedimental, transicional o conceptual. Los resultados, al igual que estudios previos, muestran que la mayoría de los estudiantes utilizan un razonamiento procedimental, no obstante, el análisis permite proponer rasgos que indican la transición hacia un razonamiento conceptual. Además, se propone un marco para analizar el razonamiento de los estudiantes.

Palabras clave: Teorema Fundamental del Cálculo, Razonamiento procedimental, transicional y conceptual.

Thompson (1994, p. 142) se refiere al Teorema Fundamental del Cálculo (TFC) como “uno de los sellos intelectuales en el desarrollo del cálculo” y, por tanto, es uno de los objetivos importantes de aprendizaje de un curso anual de cálculo. El TFC conecta los dos grandes temas clásicos del cálculo: derivación e integración. En la enseñanza inicial y tradicional del cálculo cada uno de estos temas tiene un desarrollo propio y se motivan con modelos intuitivos (Fischbein, 1977) que no tienen que ver uno con el otro: por un lado, la pendiente de una línea tangente a la función que se deriva, por otro, el área bajo la curva de la función que se integra. No obstante, el curso anual de cálculo de una escuela de ingeniería suele incluir el TFC, ¿cómo lo procesan los estudiantes? En la investigación en educación matemática se han identificado las dificultades para entender el TFC y se han propuesto alternativas para superarlas, por ejemplo, el apoyo de modelos geométrico-visuales (Kirsch, 1976, 2014) o el modelo de la integral como acumulación asociada al modelo de derivada como razón de cambio (Thompson, 1994). Teniendo en perspectiva este modelo, nosotros nos preguntamos ¿Cómo razonan los estudiantes de ingeniería que han llevado un curso tradicional de cálculo ante problemas simples de flujo de líquido en los que el proceso de solución involucra del TFC? Responder a esta pregunta daría información sobre las tendencias de razonamiento hacia el TFC de los estudiantes actuales de ingeniería, al menos de la escuela en la que se hizo la investigación, y permitiría diseñar los cambios graduales del enfoque en los cursos de cálculo tradicionales sobre la base de dicha información y las nuevas propuestas que la investigación sugiere.

Marco conceptual

Se entiende por razonamiento a los procesos para obtener y verificar proposiciones (conclusiones) sobre la base de la evidencia o de conocimientos establecidos (teoremas) o suposiciones. El razonamiento puede tomar muchas formas que van desde argumentaciones informales hasta demostraciones deductivas (Mahir, 2009). Cuando los estudiantes responden a la pregunta ¿Por qué…?, ellos muestran aspectos importantes de su razonamiento. Las respuestas de los estudiantes las clasificamos en los siguientes tres niveles de acuerdo con el razonamiento que reflejan.

Razonamiento procedimental. Consiste en aplicar algoritmos o procedimientos típicos para responder a la pregunta sin utilizar los teoremas pertinentes para simplificar o evitar operaciones y llegar a la solución.

Razonamiento transicional. Ocurre cuando se identifican teoremas que permiten encontrar relaciones pertinentes para responder a la pregunta, pero tienen dificultades para su instrumentación.

Razonamiento conceptual. Consiste en utilizar una red de relaciones. Se identifican los teoremas pertinentes y se encuentran las relaciones con los datos del problema, los procedimientos y el uso de la notación simbólica.

Sfard (1991) desarrolló la idea de que la naturaleza de las entidades matemáticas es dual: se presentan como procesos y como objetos. Estas formas suelen captarse por los estudiantes en ese orden, primero como procesos y luego como objetos, aunque en ciertos casos pueden captarse a la inversa. Sfard señala que en la literatura se han formulado varias dicotomías que buscan dar cuenta de la naturaleza dual del conocimiento/pensamiento/comprensión matemática, por ejemplo, abstractas y algorítmicas (Halmos, 1985), declarativas y procedimentales (Anderson, 1976), proceso y producto (Kaput, 1979; Davis, 1975). En esta misma clase de dicotomías está la clásica distinción de Skemp (1976) de entendimiento procedimental y relacional.

En nuestro caso, en lugar de que el objeto de estudio sean las entidades matemáticas, el pensamiento o la comprensión hemos preferido elegir el razonamiento; este tiene la ventaja de que su calidad se puede evaluar en las respuestas de los estudiantes en las que intentan justificar un resultado. Por otro lado, a la dualidad procedimental-conceptual agregamos la categoría intermedia de razonamiento transicional que da cuenta de que el paso de uno a otro tiene rasgos que combina un cierto grado de desarrollo del primero y rasgos incipientes del segundo.

Antecedentes

Dos estados del arte recientes sobre aprendizaje y enseñanza del cálculo incluyen un panorama de la investigación en los temas de integral y TFC, estos son Bressoud (2016) y Larsen et al. (2018). En estas reseñas encontramos referencias que se relacionan con ideas de la presente investigación. Por ejemplo, Mahir (2009) y Rasslan y Tall (2002) sostienen que la mayoría de los estudiantes que han completado un curso del cálculo tienen una visión procedimental de la integración y son incapaces de interpretarla en otros contextos. Por otro lado, los estudios que tienden a enfatizar aspectos conceptuales de integración proponen introducir la integral con sumas de Riemann (Sealey, 2014) o desde el modelo de acumulación (Thompson, 1994); esto ayudaría a superar el enfoque puramente procedimental. Thompson y Silverman (2008) afirmaron que la noción de acumulación es sencilla en el sentido de que la mayoría de las personas entienden la idea de "acumular una cantidad a medida que obtenemos más" (p. 43). Un problema de estos acercamientos alternativos cuyo objetivo es destacar el aspecto conceptual de la integral es que no ponen énfasis en las relaciones de la integral con los procedimientos de integración y el manejo de la notación simbólica.

Varios autores han enfatizado en que el conocimiento conceptual puede visualizarse como una red de relaciones interconectadas (Skemp, 1978, Miller y Hudson, 2007; Rittle-Johnson y Schneider, 2015). Las conexiones de la integral, por ejemplo, abarcan la definición, la notación y los teoremas, además, por supuesto, su relación con las sumas de Riemann y los modelos de áreas y de acumulación. Es por esto que, en este trabajo, se exploran y caracterizan las relaciones que los estudiantes logran ver y utilizar exitosamente o no.

Método

El presente estudio explora el razonamiento que reflejan las respuestas de los estudiantes a los problemas del instrumento. Este se creó de manera que se relacionaran con el TFC y se planteara una situación de flujos. Las respuestas de los estudiantes se codificaron y se organizaron en los tipos de razonamiento presentados en el marco conceptual. Este análisis estuvo inspirado en los procedimientos de la teoría fundamentada (Birks y Mills, 2015).

Participantes

Dieciocho estudiantes de ingeniería (entre 18 y 21 años) de una universidad privada ubicada en la ciudad de México resolvieron individualmente los problemas diseñados para el presente estudio. Ellos habían finalizado su primer curso de cálculo antes de la aplicación del instrumento.

Instrumento

Consistió en tres problemas elaborados por los autores, dos ubicados en el contexto de flujos de agua y otro abstracto. La idea de los problemas es que pudieran resolverse con el TFC en un contexto en el que la derivada se interpreta como razón de cambio y la integral como acumulación. Otro rasgo de los problemas es que se pueden resolver mediante procedimientos algorítmicos, pero interpretando el TFC. Los problemas del instrumento se muestran en la figura 1.

1. Por un grifo sale agua a una razón variable $q(t) = \frac{1}{10}\sqrt{t+4} - \frac{2}{10}$ (dada en litros/segundo) que es colectada en un contenedor. $V(x)$ representa el agua que se ha colectado desde que se abre el grifo ($t = 0$) hasta el tiempo $t = x$
   1.1. ¿Cuál es la razón de cambio del volumen $V(x)$ respecto al tiempo, en los tiempos $t = 5\ s,\ t = 21\ s$ y $t = 32\ s$?
   1.2. Obtenga una expresión para: $V(x)$
   1.3. $V_a(x)$ representa el volumen que se ha almacenado desde $t = a$ hasta $t = x$ $(x > a)$. Obtenga una expression para: $V_a(x)$
   1.4. Obtenga $\frac{dV_a(x)}{dx}$
2. Se tiene un depósito de forma cilíndrica cuyo radio de la base es r y altura H; el depósito contiene agua hasta una altura h. $V(x)$ representa el volumen de agua contenido en tal depósito cuando h toma el valor x.
   2.1 Exprese $V(h)$ como una integral
   2.2 Obtenga $\frac{dV(x)}{dx}$
3. Si $F(x) = \int_a^x f(t)\,dt$, obtenga $F'(x)$, justifique su respuesta

Figura 1: Problemas del instrumento

Con relación al problema 1 anterior, consideramos que el razonamiento procedimental se presenta cuando se llevan a cabo las operaciones que indican las expresiones: $q'(t)$ y $\int q(t)dt.$ En cambio, el razonamiento conceptual se expresa cuando se plantea la expresión $V(x) = \int_0^x q(t)dt,$ y se obtienen las consecuencias del TFC sin necesariamente realizar muchas operaciones; es decir, se debe saber que si $q(x)$ es una función continua entonces V(x) es derivable y V'(x) = q(x). Como el flujo es continuo no se requieren otras versiones más generales del TFC.

Procedimiento

El profesor titular del grupo colaboró con los autores para aplicar el instrumento en su grupo; los estudiantes que accedieron a resolver los problemas lo hicieron voluntariamente a invitación expresa de su profesor. En una sesión de 45 minutos los estudiantes resolvieron sólo con lápiz y papel los problemas. Se les pidió que explicaran lo mejor posible y por escrito sus soluciones.

Procedimiento de análisis

Se codificaron las respuestas de los estudiantes mediante las comparaciones de unas con otras para determinar patrones de razonamiento que, mediante un proceso de abstracción, subsumimos en las categorías que se presentan en el marco conceptual. Cabe mencionar que tales categorías fueron emergentes del análisis y que no se tenían presentes antes de llevarlo a cabo.

Resultados

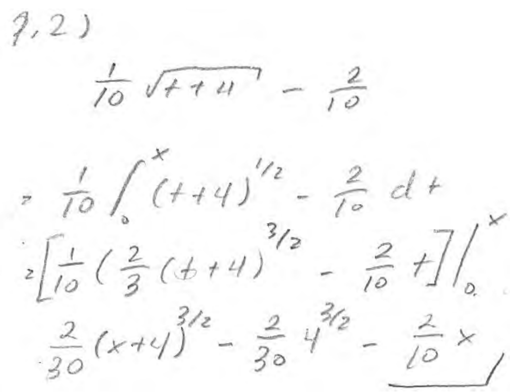
Las respuestas escritas que los estudiantes dieron a los problemas se analizaron, se codificaron y se agruparon en los tres tipos de razonamiento definidos en el marco. La tabla 1 muestra las frecuencias de respuestas a las preguntas 1.1, 1.2, 1.3, 1.4, 2.2 y 3 que cayeron en cada categoría. Después de la tabla se mostrarán ejemplos de soluciones de cada tipo de razonamiento.

Tabla 1: Frecuencia de respuestas por tipo de razonamiento

	Problemas						
Tipo de respuesta	1.1	1.2	1.3	1.4	2.2	3	Total
1. Procedimental	11	15	14	10	13	0	63
2. Transicional	5	0	3	1	0	8	17
3. Conceptual	1	0	0	1	0	7	9
4. Sin respuesta	1	3	1	6	5	3	19

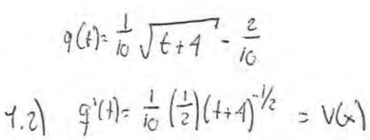
Como se puede observar en la tabla 1, el razonamiento procedimental es el que predominó en las soluciones que propusieron los estudiantes en el problema 1 y en el 2.2. La solución que se esperaba en el problema 1.2 era la expresión: $V(x) = \int_0^x q(t)dt$, sustituyendo $q(t)$ por la expresión que la define. No obstante, la totalidad de los estudiantes que respondieron no se conforman con lo anterior y entienden que deben llevar a cabo todos los cálculos. Por ejemplo, en la figura 2 se exhibe la solución de un estudiante al problema 1.2; al final de su solución el estudiante omite un exponente.

Dentro de las respuestas que reflejan un razonamiento procedimental, se observa la tendencia a creer que las respuestas a los problemas implican necesariamente llevar a cabo un procedimiento, sin imaginar que se les pide sólo indicar una relación pertinente. Por ejemplo, en el problema 1.4, que pedía sólo que se identificara que $\frac{dV(x)}{dx} = q(x)$, la mitad de los estudiantes respondieron derivando q(x), probablemente porque era la única función explícita que podían derivar. En la figura 3 se ilustra la respuesta de un estudiante.



$$" \frac{1}{10}\sqrt{t+4} - \frac{2}{10}$$
$$= \frac{1}{10}\int_0^x (t+4)^{\frac{1}{2}} - \frac{2}{10}dt$$
$$= \frac{1}{10}\left(\frac{2}{3}(t+4)^{\frac{3}{2}} - \frac{2}{10}t\right)\Big|_0^x$$
$$\frac{2}{30}(x+4)^{\frac{3}{2}} - \frac{2}{30}4^{\frac{3}{2}} - \frac{2}{10}x$$

Figura 2: Razonamiento procedimental. Respuesta al problema 1.2

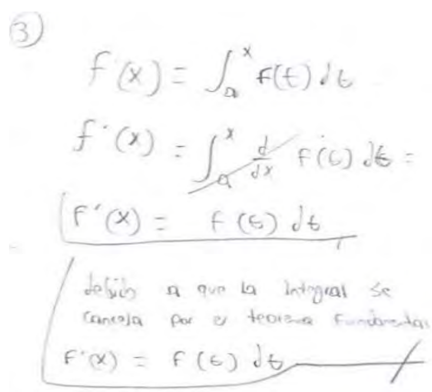


“$q(t) = \frac{1}{10}\sqrt{t+4} - \frac{2}{10}$

1.2) $q'^{(t)} = \frac{1}{10}\left(\frac{1}{2}\right)(t+4)^{-1/2} = V(x)$”

Figura 3: Razonamiento procedimental. Respuesta a la pregunta 1.4

Un razonamiento transicional lo detectamos con mucho menos frecuencia, del total de las 108 respuestas, clasificamos en transicional cerca del 16%. El estudiante 3, propone la respuesta de la figura 4. Este estudiante tiene una noción del TFC, no obstante, en varios aspectos importantes falla.



“$\mathrm{F}(x) = \int_a^x f(t)dt$

$$\mathrm{F}'(x) = \int_a^x \frac{d}{dx} f(t)\, dt$$

$$\mathrm{F}'(x) = f(t)dt$$

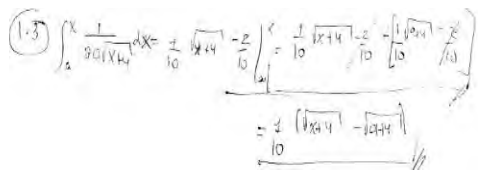
Debido a que la integral se cancela por el TFC:

$\mathrm{F}'(x) = f(t)dt$”

Figura 4: Razonamiento transicional. Respuesta de un estudiante al problema 3

Los estudiantes que manifiestan un razonamiento transicional en sus respuestas tratan de relacionar los problemas con el TFC, pero varios de ellos tienen una concepción imprecisa del él. Por ejemplo, algunos creen que la relación del TFC es la siguiente: $f(x) = \int_a^x \frac{d}{dx} f(x)dx$, la cual, de hecho, es falsa. Conviene observar en la respuesta al problema 3, cómo el estudiante en el segundo paso pretende haber obtenido esta expresión. Tampoco supo manejar la notación, manteniendo la variable muda t y el signo del diferencial dt.

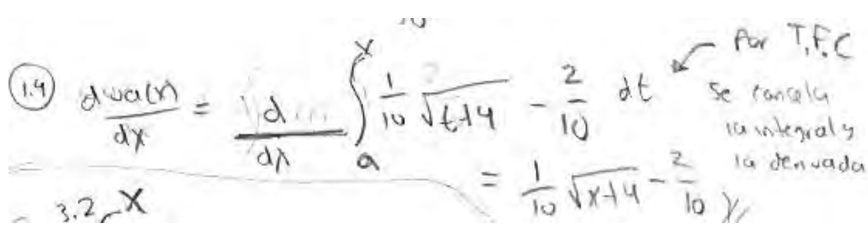
En la figura 5, vemos una respuesta al problema 1.3, que también clasificamos como transicional porque aparentemente se utiliza el TFC. En efecto, se puede notar que trató de reproducir la ecuación: $\int_a^x \frac{d}{dt} q(t)dt = q(x) - q(a)$. No obstante, en lugar de considerar que la integral indefinida del integrando es una constante cualquiera, utilizó 2/10; aunque este error intermedio al final no afecta. El problema es que no consideró que el flujo q(x) ya es una derivada y que la derivada de este flujo no es pertinente al problema.



$$\text{“}\int_a^x \frac{1}{20\sqrt{x+4}} dx = \frac{1}{10}\sqrt{x+4} - \frac{2}{10}\Big|_a^x = \frac{1}{10}\sqrt{x+4} - \frac{2}{10} - \left[\frac{1}{10}\sqrt{a+4} - \frac{2}{10}\right]$$
$$= \frac{1}{10}\left(\sqrt{x+4} - \sqrt{a+4}\right)\text{”}$$

Figura 5: Razonamiento transicional. Respuesta de un estudiante al problema 1.3

Finalmente, con relación al razonamiento conceptual, sólo 8% del total de las respuestas reflejaron este tipo de razonamiento. Un ejemplo es la respuesta del problema 1.4 de la figura 6, en la simpleza de dicha respuesta se esconden varias decisiones que el estudiante debió realizar, a saber, ha aplicado el modelo de acumulación al definir el volumen en términos de la integral de la función de flujo. Luego, sin apresurarse a calcular esta integral, deriva ambas partes de la ecuación integral que define el volumen, observando que al derivar una integral definida puede aplicar el TFC, menciona que se cancela las operaciones de derivada e integral, pero tiene el cuidado de sustituir la variable muda t, por la variable x (que representa el tiempo). Estas decisiones implican el conocimiento y coordinación de varias relaciones, por lo tanto, no se puede creer que es un procedimiento rutinario, sino que reflejan un nivel de razonamiento conceptual.



$$\text{“}\frac{dV_a(x)}{dx} = \frac{d}{dx}\int_a^x \frac{1}{10}\sqrt{t+4} - \frac{2}{10} dt \ = \frac{1}{10}\sqrt{x+4} - \frac{2}{10}$$

Por el TFC se cancela la integral y la derivada”

Figura 6: Razonamiento conceptual. Respuesta a la pregunta 1.4

Conviene aclarar que los 7 estudiantes cuyas respuestas se clasificaron como conceptuales en el problema 3 (abstracto), no necesariamente aplicaron el mismo tipo de razonamiento en los problemas en contexto, sino que en algunos casos sus respuestas fueron transicionales y en otros incluso procedimentales, por ejemplo, en las respuestas al problema 1.2.

Discusión y conclusiones

Es conocido que los estudiantes de ingeniería, en contraste con estudiantes de matemáticas, tienden a interesarse por los conocimientos que ellos creen que son prácticos, y evitan involucrarse con aquellos que consideran teóricos. El razonamiento procedimental se asocia más al conocimiento práctico, mientras que se piensa que el razonamiento conceptual es más afín al conocimiento teórico. Con esta tendencia, enfocan su conocimiento de los teoremas más en sus posibilidades de aplicación para fortalecer las herramientas prácticas, que en su función explicativa; por ejemplo, para ellos, suele no ser muy relevante la prueba de un teorema. No es sorprendente entonces verificar que la mayoría de los estudiantes del presente estudio reflejen en sus respuestas un razonamiento procedimental.

Un rasgo importante de las dos primeras situaciones/problema es que las funciones se presentaron en el contexto de flujos de agua; este contexto remite al modelo intuitivo de la integral como acumulación. En este sentido, cabe señalar, que en la mayoría de los casos los estudiantes no tuvieron dificultades para representar a la función volumen como una integral definida. Una vez identificado esto, la mayoría echaron mano de los procedimientos de derivación e integración para responder las preguntas. Sólo algunos estudiantes lograron percibir que el TFC podría ser utilizado para evitar procedimientos laboriosos y, de estos, sólo dos lograron tener control suficiente de la notación simbólica involucrada.

De manera más general, lo anterior nos lleva a reflexionar de que los teoremas permiten hacer más eficaces a los procedimientos, como lo ilustra claramente el TFC, pues sin él resulta muy laborioso el cálculo de integrales. Entonces el desarrollo de un razonamiento procedimental no es ajeno a un razonamiento conceptual. La interpretación y uso de los teoremas y el control de la simbología que implican requiere del dominio de muchas relaciones. En las respuestas que se clasificaron en transicional se puede ver que, aunque los estudiantes entienden que pueden aplicar el TFC, aparte de que requieren interpretar de manera adecuada éste, deben relacionarlo con los datos de la situación/problemas y con la notación simbólica correspondiente. Como conclusión, proponemos un marco para analizar el desarrollo del razonamiento conceptual en tareas de Cálculo de los estudiantes. Este consiste en las relaciones entre los siguientes cinco términos: 1) Situación/problema, 2) Modelo intuitivo, 3) Procedimientos, 4) Teoremas, 5) Notación simbólica.

En este modelo, el razonamiento procedimental es sólo uno de los términos de las relaciones que contiene el razonamiento conceptual, pues este requiere de la incorporación de otras relaciones. Los modelos intuitivos como el área bajo la curva, o las situaciones de acumulación para la integral, también representa un término de las múltiples relaciones que se requieren dominar. Pero lo anterior debe ser consistente con los teoremas que, aunque los estudiantes de ingeniería no los tengan que demostrar, los tienen que interpretar y usar para sus fines. Finalmente, el proceso del dominio de las anteriores relaciones debe ir en paralelo con el desarrollo del lenguaje matemáticos, que se refleja en el control de la notación simbólica. Este modelo puede servir para orientar la enseñanza del cálculo para desarrollar el razonamiento conceptual de los estudiantes de ingeniería sin que crean que es un enfoque muy teórico en detrimento de sus expectativas por un conocimiento práctico.

COMPRENSIÓN DEPENDENCIA LINEAL: UNA PERSPECTIVA DE LAS ESTRUCTURAS Y MECANISMOS MENTALES CON ESTUDIANTES UNIVERSITARIOS

UNDERSTANDING LINEAR DEPENDENCE: A PERSPECTIVE OF MENTAL STRUCTURES AND MECHANISMS WITH UNIVERSITY STUDENTS

Silvia Juliana Ballesteros Gualdrón
Universidad Nacional del Rosario
julianaballesterosg@hotmail.com

Solange Roa Fuentes
Universidad Industrial de Santander
roafuentes@gmail.com

Este artículo tiene como objetivo presentar el diseño de una descomposición genética del concepto de dependencia lineal a partir del análisis de los libros de textos, de investigaciones anteriores relacionadas con el concepto y de los resultados de una intervención con estudiantes de álgebra lineal de una universidad pública en Colombia. En donde se busca tener un modelo cognitivo que sea el resultado de la primera fase de la metodología propuesta por APOE.

Palabras clave: Educación superior, Álgebra y Pensamiento Algebraico.

Objetivos del estudio

El concepto de dependencia lineal se considera como un objeto abstracto en la asignatura de álgebra lineal. Saldanha (1995) menciona que comprender el concepto de dependencia lineal a partir de diferentes enfoques es difícil para el estudiante y por eso no solo se necesita de actividades que motiven su aprendizaje sino también que promuevan acciones mentales que pueden potenciar su construcción.

Trigueros y Possani (2013) por ejemplo, mencionan que es un concepto nuevo que se ve en un primer curso de álgebra lineal, con el cual los estudiantes no se han encontrado en años anteriores; además indican que, a pesar de ello, el concepto de dependencia lineal es un concepto básico para entender temas más avanzados del álgebra lineal (Trigueros y Possani, 2013). Otros investigadores como Stewart y Thomas (2010) dan cuenta de las dificultades que tienen los estudiantes al trabajar con el concepto de dependencia lineal. Los resultados muestran que un énfasis en los procesos matriciales no ayuda al estudiante a entender el concepto, es decir, se necesita además reflexionar sobre ellos.

Con base en lo anterior, las siguientes preguntas planteadas guían esta investigación:

¿Qué estructuras y mecanismos mentales desarrollan estudiantes de álgebra lineal cuando abordan el concepto de dependencia lineal desde su representación numérica, geométrica, y algebraica?

¿Qué mecanismos mentales evidencian estudiantes de álgebra lineal I de una universidad pública de Colombia cuando estructuran el concepto de dependencia lineal desde de sus interpretaciones concretas y abstractas?

Así, el objetivo general de esta investigación es:

Diseñar una descomposición genética validada del concepto de dependencia lineal que parta de la aplicación de Acciones sobre objetos concretos para la construcción de Objetos abstractos.

Marco teórico

La construcción de un concepto matemático, según la teoría APOE, consiste en la construcción de estructuras mentales necesarias para comprender ese concepto. Cada estructura mental se construye a través de un mecanismo mental o también llamado *abstracción reflexiva*, según Piaget.

En la tabla 1, se muestra cómo están clasificadas las estructuras y los mecanismos mentales.

Tabla 1: Estructuras y mecanismos mentales (Síntesis de Arnon, et al., 2014)

Estructuras mentales	Mecanismos mentales
Acción	Interiorización
Proceso	Reversión
Objeto	Encapsulación
Esquema	Coordinación
	Inversión
	Des-encapsulación
	Generalización

A continuación, se describen las cuatro estructuras mentales y como están relacionadas con los mecanismos, descritos anteriormente.

Acción: Se define como la transformación que se aplica a un Objeto, sin reflexionar sobre él. Dubinsky (1997) considera que la Acción que es realizada por un sujeto es externa a él. En este sentido, se puede considerar como una Acción, por ejemplo: una operación o un algoritmo matemático que se realiza de manera mecánica sin omitir pasos.

Proceso: Es una comprensión de las acciones aplicadas a un objeto. En términos de Asiala et al., (1996) cuando se repite una Acción, y el individuo reflexiona sobre ella, puede ser interiorizada como un Proceso. En este sentido, se puede considerar que un estudiante ha construido un Proceso, cuando omite pasos al realizar un algoritmo o no necesita del algoritmo para inferir sobre el resultado de una operación, como consecuencia de una reflexión de sus procedimientos. Un Proceso puede ser revertido para construir otro Proceso.

También dos Procesos pueden ser coordinados respectivamente y este resultado encapsulado para formar un nuevo Objeto. Cuando un Proceso ha sido encapsulado en un Objeto, puede volver a des-encapsularse cuando sea necesario.

Objeto: Se define como una estructura estática que fue transformada (encapsulada) de una estructura dinámica (Proceso) sobre la que el estudiante puede aplicar nuevas Acciones.

Esquema: Se define como una colección de Acciones, Procesos y Objetos y otros Esquemas que utiliza un individuo para resolver determinado problema.

En la figura 1 se sintetiza lo mencionado anteriormente, donde a partir de un Objeto (por ejemplo, dos vectores en $\mathbb{R}^2$) sobre el cual se le aplican Acciones (hallar el determinante) que se pueden entender como transformaciones sobre el objeto, en las cuales no se reflexiona, es decir, como aplicar un algoritmo sin interpretar el resultado (en el caso del determinante) se puede, por medio de interiorizaciones acerca dichas Acciones, llegar a una estructura mental Proceso (en donde el estudiante relaciona que si el determinante es cero es porque los vectores son linealmente dependientes), el cual se puede ver como un objeto dinámico que está en constante evolución, ya que se pueden generar nuevos Procesos por el mecanismo de *coordinación* y por medio del mecanismo de *encapsulación* puede ser transformado a una estructura mental Objeto, en donde ya se vuelve un objeto estático, el cual se puede utilizar para construir un nuevo concepto, como el concepto de base o transformación lineal.

El mecanismo de *desencapsulación* se utiliza cuando se necesita volver del Objeto al Proceso del cual dio origen.

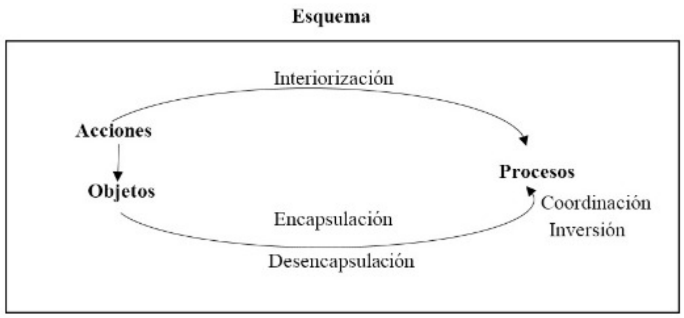

Figura 1: Estructuras y mecanismos mentales para la construcción del conocimiento matemático (Arnon et. al., 2014, p. 18)

Métodos de investigación

Contexto y participantes:

Este estudio fue realizado con un grupo de 28 estudiantes de álgebra lineal de primer semestre, de la carrera de Ingeniería Electrónica, en una universidad pública de Colombia.

Se realizaron 4 sesiones de clase donde se abordaron 17 problemas. Además se diseñó y realizó una entrevista didáctica, según Oktaç (2019) "didactic interviews give detailed information about the learning process" (p. 3), para lograr un análisis más fino de las estructuras y/o mecnaismos mentales, que los estudiantes lograron evidenciar en su razonamiento. Cuando se realiza la entrevista con el estudiante se pueden dar pistas o hacer preguntas a partir de las respuestas, para motivar razonamientos que el estudiante no ha realizado de manera previa.

Análisis Teórico:

A continuación, se presenta el modelo cognitivo propuesto para describir las estructuras y mecanismos mentales que a nuestro criterio, un estudiante necesita para construir el concepto de dependencia lineal a partir de la aplicación de Acciones sobre Objetos concretos que pueden dar paso a la construcción de Objetos abstractos.

Descomposición genética del concepto de dependencia lineal

Para iniciar un estudiante puede determinar las características de un conjunto de vectores representado geométricamente, esto es, pude encontrar cuándo son colineales o coplanares. Para esta investigación esto obedece a los Objetos concretos de los cuales partimos para construir el concepto de dependencia lineal. Entonces a partir de una gráfica como la que aparece a continuación (ver figura 2), el estudiante debe aplicar Acciones específicas que le permitan garantizar que los vectores colineales o coplanar.

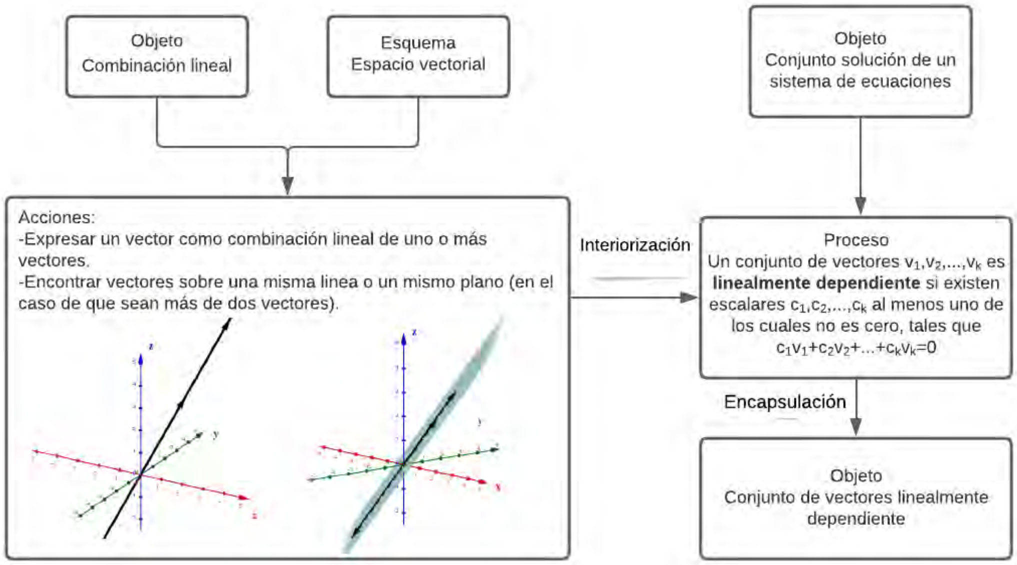

Figura 1: Estructuras y mecanismos en la construcción del concepto de dependencia lineal: Descomposición genética inicial

Las interpretaciones geométricas deben estar acompañadas de un análisis numérico que permita argumentar que los vectores son colineales más allá de la persepción visual del indivudo que observa la gráfica. Esto es una evidencia de que las Acciones que se aplican inicialmente sobre un Objeto concreto se están interiorizando en un Proceso abstracto.

Esto está determinado por la búsqueda del escalar, que permiten dado un vector u y a partir del producto por un escalar $\propto u$, detetminar qué valor de $\propto$ alarga, encoge o rota el vector u. Ahora la pregunta es:

¿Qué relación puede definirse entre los vectores u y $\propto u$?

A partir de una exploración sobre dichos vectores los estudiantes pueden empezar a construir el concepto de dependencia lineal, el vector $\propto u$ depende de u. Por tanto los vectores u y $\propto u$ son linealmente dependientes. Así la aplicaciones de Acciones para determinar si dos o más vectores son linealmente dependientes están asociadas a determinar cuándo uno de ellos es múltiplo escalar de otro o combinación lineal de otros vectores del conjunto.

Mediante la reflexión de las Acciones descritas anteriormente, el estudiante puede interiorizar dichas Acciones para describir de manera general el comportamiento de los vectores; es decir qué relación existen entre las interpretaciones algebraicas, geométricas y numéricas de los vectores, que dan cuenta de las características que tiene un conjunto de vectores linealmente dependiente.

Concepción Proceso: Para tener una concepción Proceso del concepto de dependencia lineal, un estudiante necesita una concepción Proceso de combinación lineal, para poder ver un vector en términos de uno o más vectores. También debe tener una concepción Objeto de conjunto solución de una ecuación, para considerar el conjunto de todas las posibles soluciones de un sistema de ecuaciones lineales. Mediante el mecanismo de coordinación el estudiante puede determinar todas las soluciones de las combinaciones lineales que dan el vector cero. En este caso el estudiante puede identificar que si la solución no es única entonces el conjunto es linealmente dependiente.

Concepción Objeto: Un estudiante evidencia una concepción Objeto, cuando ha encapsulado el Proceso de dependencia lineal, es decir, cuando realiza Acciones sobre el Objeto de un conjunto de vectores linealmente dependiente. También un estudiante da evidencia de una concepción Objeto, cuando puede desencapsular el Objeto para volver al Proceso del cual dio origen.

Resultados

A continuación, se presenta el análisis de un Caso de Estudio que llamamos Camilo. Camilo es un estudiante de ingeniería electrónica, que hace parte de un curso de álgebra lineal de estudiantes de ingeniería de primer año. Se propone a Camilo como caso de estudio ya que durante el desarrollo de las actividades (talleres y entrevista) realizadas en diferentes sesiones de clase, da evidencias de haber construido el concepto de dependencia lineal. A continuación, se presenta con detalle los razonamientos realizados por Camilo, analizados a la luz de la descomposición genética.

Aplicación de Acciones sobre Objetos concretos: El análisis de los procedimientos realizados por Camilo, evidencia la aplicación de Acciones sobre vectores como Objetos concretos, que representa de manera geométrica o que transforma en su mente a través de “movimientos” que relaciona con un vector y sus múltiplos escalares. Esto como se señala más adelante, no está determinado por la representación de los vectores en el enunciado del problema, sino que emerge como una manera de acceder a formas más abstractas relacionadas con el concepto de dependencia lineal.

Los procedimientos evidenciados por Camilo muestran que constantemente usa interpretaciones que abstrae de representaciones geométricas y/o numéricas, relacionadas con la colinealidad de los vectores y la relación múltiplo escalar, respectivamente. Por ejemplo, durante el taller se pide a Camilo trabajar con un conjunto de vectores definidos sobre un plano representado en GeoGebra (Tabla 2).

Tabla 2: Pregunta 5 taller 1

Pregunta 5 - Taller 1	Representación de los vectores dado en un archivo en GeoGebra
Los vectores $u = (1, -1, 1), v = (2, 0, 2)$ y $w = (-1, 3, -1)$ están sobre un mismo plano. ¿Existen $\alpha, \beta \in \mathbb{R}$ tales que $w = \alpha u + \beta v$?	Si ya que w puede ser conbinacion lineal de ~~ø~~ u, v ? Esto por que estan en el mismo plano y u y v son LI entre ello	

A partir de la interpretación que Camilo estructura de la representación gráfica responde: “Si, ya que w puede ser combinación lineal de u, v. Esto por que están en el mismo plano y u y v son L.I. entre ellos” [esto es, u y v son Linealmente Independientes]. Es importante resaltar que a partir de la representación gráfica de los vectores Camilo puede determinar que los vectores u y v son linealmente independientes, ya que no están sobre una misma recta. De la actividad generada en el desarrollo del taller, se deduce que el razonamiento de Camilo está considerando que los vectores u y v generan cualquier vector sobre el plano y por lo tanto generan a w. Esto muestra que Camilo está interiorizando las Acciones que aplica sobre Objetos concretos en un Proceso abstracto que relaciona con la combinación lineal como una estructura dinámica. Para el problema presentado en la Tabla 2, Camilo no necesita determinar $\propto$ y β de manera específica para aceptar que existen.

Interiorización de Acciones en un Proceso: Durante el trabajo de Camilo en el Taller 2 sigue dando evidencias de que ha logrado una concepción Proceso de la dependencia lineal. Frente al problema que aparece en la Tabla 3, Camilo determina a partir de su interpretación geométrica, que, si tiene 3 vectores en $\mathbb{R}^2$, necesariamente son linealmente dependientes. Camilo escribe: “El conjunto de vectores $\{u, v, w\}$ son linealmente dependientes ya que puedo formar alguno con combinaciones lineales de los otros”.

Tabla 3: Pregunta 1 taller 2.

Pregunta 1 - Taller 2	Representación de los vectores dado en un archivo en GeoGebra
¿Los vectores u, v y w son linealmente dependientes o independientes?	El conjunto de vectores {U, w, V} Son lineal mente dependientes ya que puedo formar alguno con combinaciones lineales de los otros	

Como se señaló en la descomposición genética de la sección anterior, el concepto de combinación lineal juega un rol fundamental en la construcción de la dependencia lineal. Los argumentos de Camilo a partir de la colinealidad (Acción sobre Objetos concretos) son reestructurados por medio de la combinación lineal. Esta estructura le permite reflexionar sobre dichas relación entre los vectores, sin pensar en sus coordenadas o en escalares específicos que determinan la combinación lineal.

Conclusiones

La presentación de las conclusiones las realizamos en tres secciones; i) Reflexiones sobre los resultados encontrados; ii) recomendaciones didácticas.

Reflexiones sobre los resultados encontrados

Consideramos que un primer curso de álgebra lineal debe tener una parte geométrica, ya que interpretar un concepto del álgebra abstracta de manera geométrica y algebraica ayuda al estudiante a comprender el concepto en cuestión, ya que le da herramientas para argumentar sus ideas, que posteriormente podrá generalizar.

A pesar de que en la mayoría de los libros de texto que se trabajan en algebra lineal se define la independencia lineal a partir de la dependencia lineal, creemos al igual que Mares (2016) que el tener la definición de dependencia lineal, no implica tener la definición de independencia lineal, por eso se deben definir por separado, para que un estudiante puede comprender las características que diferencia un concepto del otro.

Recomendaciones didácticas

El rediseño de la descomposición genética propuesta en esta investigación es una herramienta para profesores de álgebra lineal, ya que sirve de guía para la enseñanza del concepto de dependencia lineal, teniendo en cuenta los pre saberes que necesitan los estudiantes para construir el concepto. También en la forma como se desarrolla el concepto, ya que en la descomposición genética proponemos dos enfoques: algebraicos y geométricos. En este sentido, se vuelve indispensable realizar actividades que fomenten distintos tipos de Acciones y Procesos de forma tanto algebraica como geométrica.

UNDERSTANDING LINEAR DEPENDENCE: A PERSPECTIVE OF MENTAL STRUCTURES AND MECHANISMS WITH UNIVERSITY STUDENTS

This article aims to present the design of a genetic decomposition of the concept of linear dependence based on the analysis of textbooks, previous research related to the concept and the results of an intervention with students of linear algebra from the public university in Colombia. It is sought to have a cognitive model that is the result of the first phase of the methodology proposed by APOE.

STUDENTS' INTUITIVE MEANINGS FOR INFINITE SERIES CONVERGENCE AND CORRESPONDING IMPLICATIONS

Derek Eckman

Arizona State University
khroh@asu.edu

This paper describes our work to determine the naturalistic images that first-time second-semester university calculus students possess for series convergence. We found that the students we interviewed most frequently determined whether a series converged by imagining a process of appending summands into a running total and examining whether this running total appeared to approach an asymptotic value. We provide examples and three corresponding implications of this "asymptotic running total" that informed students' actions while determining series convergence or the value of convergence. Our paper adds to the research literature by confirming students' meanings for limits reported for other topics (e.g., limit of sequence, function, Taylor series) apply to infinite series and proposing relationships between previously reported meanings for series convergence.

Keywords: Calculus, Cognition, Undergraduate Education, Advanced Mathematical Thinking

Introduction and Literature Review

Infinite series convergence is a central mathematical topic applied across many branches of mathematics and other disciplines such as physics and engineering (Azevedo, 2021). The topic of infinite series also incorporates many other pivotal topics in advanced mathematics, such as sequence, limit, and infinity (Martin, 2013). Research related to infinite series has focused on the state of curricula and instruction (e.g., González-Martín et al., 2011; Lindaman & Gay, 2012); effective interventions to promote productive student thinking about limit or convergence (Martin et al., 2011; Roh, 2008, 2010b, 2010a; Swinyard & Larsen, 2012); and how students conceive of series convergence, the sequence of partial sums or the symbolic forms of representation students utilize to express series (Barahmand, 2021; Eckman & Roh, accepted; Kidron, 2002; Kidron & Vinner, 1983; Martin, 2013; Martínez-Planell et al., 2012; Strand et al., 2012; Strand & Larsen, 2013).

Most of the reports about students' meanings for infinite series describe students who have previously received (or are currently receiving) instruction on this topic. The purpose of this study is to examine how first-time university second-semester calculus students consider the concept of series convergence before receiving formal instruction on sequences and series. Documenting students' naturalistic images for infinite series before they receive formal instruction can (1) assist instructors in better anticipating students' initial perceptions of series convergence and (2) help researchers better describe students' acquisition of rigorous and productive meanings for convergence. We summarize the goals of this study with the following research questions: (1) *What meanings for series convergence do first-time university calculus students conceive before receiving formal instruction on infinite series?* (2) *How do the implications of these students' meanings for convergence inform their actions for determining whether a series converges and the value to which a convergent series converges?*

Theoretical Perspective

In this study, we attempt to describe individual students' meanings for series convergence and their utilization of these meanings to reason about various series. We adopt a radical constructivist (Glasersfeld, 1995; Thompson et al., 2014) approach for the term *meaning*. Thompson et al. (2014) described a *meaning* as the space of implications resulting from assimilating a situation. We consider assimilation, in this case, to refer to an individual's ability to consider her situation as analogous to previous experience (Glasersfeld, 1995) such that her subsequent actions are selected from the implications elicited by the meaning in her mind.

The concept of *meaning* can effectively describe student thinking and actions for reasoning about series convergence. Suppose that a student, while examining the series $1+\frac{1}{2}+\frac{1}{4}+\cdots+\frac{1}{2^{n-1}}+\cdots$, conceives a dynamic image of adding consecutive summands and decides to track the value of the "moving sum" generated through this process. We call this "moving sum" a *running total*. An implication of the student's evoked *meaning* for the series might involve a belief that if the *running total* approaches a particular value, then the series converges. An alternative implication of the *meaning* might include the notion that if the *running total* does not approach an asymptotic value, the series does not converge. The student's subsequent actions to determine whether the *running total* approaches an asymptotic value are grounded in the implication evoked as part of the student's *meaning* for series convergence. In the results section, we propose an overarching meaning for series that the students in this study appeared to possess and the implications that informed the students' actions to determine convergence.

Research Methodology

In this report, we detail the meanings and implications that students exhibited for series convergence during a set of individual 90-minute clinical interviews (Clement, 2000) that simultaneously functioned as a selection and pre-test interview for a constructivist teaching experiment (Steffe & Thompson, 2000). The purpose of the teaching experiment was to offer calculus students specific tasks designed for developing productive meanings for series convergence while documenting the evolution of their corresponding symbolization for series convergence. The virtual clinical interviews were conducted during the Fall 2021 semester, prior to formal coursework on sequences and series, at a large public university in the United States. Our analysis and results focus on two students, Monica and Sylvia (pseudonyms), who were first-time second-semester calculus enrollees at the university level.

We presented the students with six infinite series in expanded form (see Table 1). We chose not to present infinite series using summation notation to mitigate students' potential difficulties interpreting this notation (Strand et al., 2012; Strand & Larsen, 2013). Series 1-4 reflect various behaviors of sequences of partial sums (i.e., monotone convergent, monotone divergent, oscillating convergent, oscillating divergent). Series 5-6 reflect series types that have been reported as problematic for students, such as the decimal expansion of an irrational number (Kidron, 2002; Kidron & Vinner, 1983) and variations of Grandi's series (Bagni, 2005; Martínez-Planell et al., 2012).

For each series, we asked the student two questions adopted from the sequences and series unit in Larson and Edwards (2015): (1) *Does the series converge?* and (2) *If the series converges, what value does the series converge to?* After the student responded to the two questions for each series, we presented each question in a generalized form to determine what students believed about convergence and the value of convergence for any series.

After compiling and transcribing the interviews, we identified and analyzed individual moments of the interviews in the spirit of grounded theory (Strauss & Corbin, 1998). We considered a new moment to begin when a student either (1) encountered a new series, (2) changed their thinking about whether a series converged, or (3) proposed a particular value to which they believed the series converged. For each moment, we recorded whether a student believed the series converged, the convergent value (if applicable), the meaning that students appeared to exhibit for series convergence, and how the students' actions to determine series convergence might be viewed as implications of their meaning. We found that the two students reported in this study appeared to have a similar meaning for series convergence and that three distinct implications of this meaning emerged as the students interacted with various series.

Table 1: The six series presented to students during the interviews

Series	Rule	Expanded Form	Series type	Sequence of Partial Sums	Value of Convergence
1	$\sum_{n=0}^{\infty}\frac{3}{\sqrt{n}}$	$\frac{3}{\sqrt{1}}+\frac{3}{\sqrt{2}}+\frac{3}{\sqrt{3}}+\cdots$	p-series $(0<p<1)$	Monotone increasing divergent	
2	$\sum_{n=1}^{\infty}\frac{2(-1)^{n-1}}{n^5}$	$\frac{2}{1^5}-\frac{2}{2^5}+\frac{2}{3^5}-\cdots$	Alternating p-series $(p>1)$	Oscillating convergent	≈ 1.94
3	$\sum_{n=1}^{\infty}\sum_{i=1}^{99}\left[10^{-2n-1}-10^{-2(n+1)-1}i\right]$ $=\sum_{k=0}^{\infty}\frac{495}{10000}\left(\frac{1}{100}\right)^k$	$\frac{99}{10^3}+\frac{98}{10^3}+\cdots+\frac{1}{10^3}+$ $\frac{99}{10^5}+\cdots+\frac{1}{10^5}+$ $\frac{99}{10^7}+\cdots+\frac{1}{10^7}+\cdots$	Geometric	Monotone increasing convergent	$\frac{1}{20}$
4	$\sum_{n=0}^{\infty}\frac{(200-2n)(-1)^n}{n+1}$	$\frac{200}{1}-\frac{198}{2}+\frac{196}{3}-\cdots$	Alternating series	Oscillating divergent	
5	$\sum_{i=0}^{\infty}a_i$ (where a_i corresponds to the i^{th} decimal place of π and $a_0=3$.)	$3+.1+.04+\cdots$	Decimal expansion of irrational number	Monotone increasing convergent	π
6	$\sum_{n=0}^{\infty}(.07)\cdot(-1)^n$	$.07-.07+.07-\cdots$	Alternating series (Grandi's)	Oscillating divergent	

Results

The results comprise two sections. The first section explains the students' meaning of series convergence as analogous to a running total approaching an asymptotic value. The second section describes three distinct implications of this meaning that informed the students' actions to determine the convergence and convergence value of various types of series. We reflect on potential relationships between the implications in the discussion section.

Students' Meaning for Convergence as a Running Total Approaching an Asymptotic Value

Monica provided normative final responses for each series' convergence except series 3 and 4, while Sylvia provided normative responses for series 2, 5, and 6 (see Table 2; "Y" and "N" stand for "Yes" and "No"). However, in instances where both students believed that the series converged (i.e., series 2, series 4, series 5), the students proposed differing convergence values.

Both students exhibited similar meanings for series convergence, which appeared to involve imagining a dynamic *running total* approaching an asymptotic value as additional summands are calculated into the running total. We call this meaning an *asymptotic running total* meaning. Monica's response to the final interview question regarding general series convergence provides an image of her *asymptotic running total* meaning. Note that in each of the following transcripts, the ellipses (…) refer to omitted text.

Monica: OK. So for the first question [*How can I tell whether a series converges?]*. The first thing I thought of was, kind of like with the limits thing, where are we approaching with every new, like, next iteration of this series? Are we approaching a value or infinity?... [In] the one where we were adding and subtracting and then adding and subtracting [series 4], but the numbers were decreasing, you still saw like a general trend towards, a number, which in that case was zero. So that's what I would say when I'm thinking about, how can I tell whether [the] series converges… Like I'm interested in, what it's approaching [i.e., the running total] and how adding on each next piece of the series is getting it closer to that value.

Int: OK.

Monica: So then the last one [series 6] where it [i.e., subsequent summand] was like essentially undoing what the previous one had done. That was why I said it [series 6] wasn't converging. Because there was not like one overall direction it was going.

Int: OK. Now, when you say one direction "it" was going. Just to clarify, what do you mean by the "it" that's going somewhere?

Monica: The series as a whole, or like the sum of the series as a whole [i.e., running total]. So like, if I were to take…like one plus two plus three plus four. And on this like, huge number line and I just go up all the way to like a very large number, and that number that was getting big, closer and closer to infinity. And then I went to the 200th part of that series. I can be like, Yeah, that's still getting close to infinity, and I could go to the 1000th part and it would be like, yeah, it still goes to infinity.

In Monica's initial comment she states that a convergent series will exhibit a "general trend" or "overall direction" towards a particular value. When the interviewer asked Monica to clarify the "it" moving towards the asymptotic value, Monica stated that she envisioned instantiations of the *running total* after summing various numbers of summands (i.e., 200 or 1000 summands). However, there is no indication that Monica coordinated these instantiations of the *running total* with an index to form the sequence of partial sums. For this reason, we use the terminology *summand* and *running total* in place of normative terminology (e.g., *term, partial sum, sequence of partial sums*) to make clear that we do not consider either student to have constructed explicit sequences through their reasoning about series convergence.

Implications of Asymptotic Running Total Meaning for Determining Series Convergence

In this section, we report three distinctive implications of the students' *asymptotic running total* meaning which contextualize students' actions while determining series convergence. The three implications we describe are *decreasing summands convergence*, *monotone running total divergence*, and *running total recreation through grouping*.

Implication 1: Decreasing summands convergence. One implication of an *asymptotic running total* meaning is that a student might believe that if each consecutive summand in an infinite series is smaller than the previous summand, the running total will eventually trend toward one specific value, suggesting that the series will converge. We call this implication *decreasing summands convergence*. In conventional mathematics, the notion of decreasing summands is a necessary but insufficient property of a convergent series (the most famous example of this principle is the harmonic series, $\sum_{n=1}^{\infty} \frac{1}{n}$).

Both students' actions in various moments related to series 1 appeared to align with the *decreasing summands convergence* implication of the *asymptotic running total* meaning. We constructed series 1 to reflect a divergent p-series with a monotone increasing sequence of partial sums (see Table 1). We provide an example from Sylvia's reasoning about series 1 as evidence of the *decreasing summands convergence* implication.

Sylvia: OK, now I'm thinking that the series doesn't converge and like it [i.e., running total] keeps adding up and getting bigger and approaches like infinity or something like that.
Int: OK.
Sylvia: Wait…
Int: OK… can you say a little bit more about any of the stuff that you're thinking?
Sylvia: Um…if you picture like a perfect square root like three over the square root of nine is three over three, and that's one [$\frac{3}{\sqrt{9}} = \frac{3}{3} = 1$]. But then if you had like three over the square root of 81, that's one-third [$\frac{3}{\sqrt{81}} = \frac{1}{3}$]. So…each item in a series that you're adding on [*brings up hand and mimics placing summands of series sequentially*] is getting smaller. Yes, it is getting smaller. So it's going to… converge to something, but it's not going to be four. [*brief pause*] Yes, that's my view.

In Sylvia's initial conception of the convergence of series 1, she argued that series 1 does not converge because the *running total* will perpetually increase. She later determined that each subsequent summand is smaller than the previous summands, which lead to her declaration that the series converges to an unknown value. In this moment, Sylvia's asymptotic running total meaning implies that decreasing summands suggest convergence. However, we note that the *decreasing summands convergence* implication was insufficient for Sylvia to make a substantive claim regarding the value to which series 1 might converge.

Implication 2: Monotone running total divergence. Another implication of an *asymptotic running total* meaning is that a student might believe that since the *running total* perpetually increases (or decreases) in a monotone series, the *running total* will eventually surpass every potential upper bound (i.e., asymptotic value) that might indicate convergence. We call this implication *monotone running total divergence*.

Both students' actions in various moments related to series 3 aligned with the *monotone running total divergence* implication (Monica's actions related to series 1 also aligned with this meaning during certain moments). The authors constructed series 3, a convergent geometric series, by expanding each summand of the original geometric series into a finite arithmetic series that summed to the summand in the geometric series. Consequently, the expanded form of series 3 resembled a double summation (see Table 1). We provide an instance of Monica's reasoning about series 3 as an instance of the *monotone running total divergence* implication.

Monica: Um. [*pause*] So. In this case… we're adding very, very, very small fractions [i.e., summands], but they're always going to be positive numbers and then we're adding all of them together. This one [series 3]…the rate of growth would be significantly slower.

Int: OK.

Monica: But it would still, if you just did this forever [*makes a gesture to the right indicating extending series indefinitely*]…it [i.e., the running total] would just continue to increase.

Int: OK. So if I'm just summarizing what you've said, you're saying that this third series does not converge. And the reason why is once again, similar to the first series, all of the fractions [i.e., summands] are positive, they're all being added together. And so therefore, our value [i.e., running total] will never stop growing. And so as we continue on indefinitely, we'll approach infinity.

Monica: Right.

In Monica's comments, she noted that all of the summands in series 3 are positive and that although the rate at which the running total will grow is slow, the running total will never stop increasing. The interviewer then rephrased Monica's comment to determine whether Monica imagined that a monotone running total implies non-convergence, which Monica confirmed. In Sylvia's case, she recognized that although the summands for series 1 and series 3 both decrease in value, she claimed that series 1 converged and series 3 did not. Sylvia acknowledged the apparent contradiction in her reasoning but was unable to reconcile the issue.

Implication 3: Running total recreation through grouping. A final implication of an *asymptotic running total* meaning is that a student might believe that if she groups the terms in an alternating series to construct a uni-directional *running total*, the series will converge. We call this implication *running total recreation through grouping*.

Both students' actions related to various moments related to series 4 appeared to align with the *running total recreation through grouping* implication (Sylvia's actions related to series 2 were nearly identical to her actions for series 4). We constructed series 4 to reflect an alternating divergent series with a linearly decreasing numerator and linearly increasing denominator (see Table 1). Monica tenuously claimed that series 4 converged to zero and Sylvia confidently claimed the series converged to 200 (the value of the initial summand).

We provide Monica's rationale for claiming that series 4 converges to zero in the transcript below.

Monica: I think that if I were to say that it [series 4] does converge, then I would also say that it converges to zero.

Int: OK. Can you say a little bit more about that?

Monica: …So in this case, instead of seeing like each individual adding on a fraction is one thing [*places hands close together with small space between*], I'm kind of grouping them together, where we are subtracting and adding and that, I'm grouping that together in my head.

Int: OK, could you could you like, mark on the screen what it is that you're grouping together just so that I'm sure that I know?

Monica: Yes. So I would put these together [*draws a bracket above second and third summand*] and then I would put these together [*draws a bracket above the fourth and fifth summand*]… and I take the number 200 and I, do these two things do it [*cursor indicates second and third summands*], I'm going to have a number here [*moves cursor between third summand and minus sign separating third and fourth summand*] that's less than

200, but still very close to it. So basically, what I've decided is if you were to sum these two values [*moves cursor back to indicate second and third summands*], you would have a very small number and you subtract those… So that, that's what makes me think that this [i.e., the running total] is getting smaller and smaller and smaller and smaller.

In her response, Monica envisioned a *running total* that started at 200 (the value of the first summand) and noticed that by grouping each pair of consecutive summands after the first summand, she could construct a new series that had a distinctive pattern of $200 + (\text{small negative value}) + (\text{small negative value}) + \cdots$. Based upon her reconstruction of series 4 by grouping, Monica perceived a running total that approached an asymptotic value of zero.

In the transcript below, we provide Sylvia's rationale for claiming that series 4 converged to 200, which involved a different grouping action than Monica.

Sylvia: So I'm going to say that this one [series 4] converges. And I think I'm going to follow the same logic that I did with [series 2,] that it kind of…drops some and increases a little bit less than it dropped [*draws concave-up curve starting from (0, 200) that stops before reaching* $y = 200$], if that makes sense. And then it, like each wave gets smaller [*draws more waves with decreasing amplitudes that progressively move closer and closer to horizontal line at y = 200*]. And I would say my guess is that it converges to 200.
[omitted dialogue]
Int: So, can you explain a little bit more to me about how you're…seeing that come about [convergence to 200]?
Sylvia: So I guess like, if we start at 200, we subtract 99, we'll get 101, and then you add one ninety-six over three [$\frac{196}{3}$], and that number is smaller than 99. Yes. And so you're going to go back up and essentially cancel out some of the, the subtraction that you did. But not like all the way, like you're not going to get back up to 200.
Int: OK.
Sylvia: And then you're going to go down a little bit more, but not as great as just went up. And then, like, follow that pattern.
Int: So there. So it's like you're imagining that every time we jump up, we're jumping up farther than we drop down. And so over time, we're slowly moving back up towards 200.
Sylvia: Yes.

In her response, Sylvia's stated that the *running total* begins at 200, drops to 101, and then begins to move back toward 200 in progressively smaller "waves." Sylvia constructed her "waves" by recognizing that the sum of the third and fourth summand would be a positive value, and every subsequent pair of summands would yield positive—albeit decreasing—values. Sylvia then reconstructed series 4 as $101 + (\text{small positive value}) + (\text{small positive value}) + \cdots$ and envisioned that the *running total* would eventually approach the asymptotic value of 200, the initial summand of the series.

Discussion and Conclusion

Our findings provide unique and relevant contributions to the mathematics education literature. For instance, our description of the *asymptotic running total* meaning provides valuable insight into how students might initially perceive series convergence in university calculus courses. The three implications we described both emerge from and deepen the explanatory power of the *asymptotic running total* meaning. The first implication, *decreasing summands convergence*, emerges from an *asymptotic running total* meaning when a student imagines that if the summands in a series tend toward zero, the *running total* will eventually stabilize around a particular value. The second implication, *monotone running total divergence*, emerges when a student envisions that a never-ending string of non-zero summands imply that the *running total* will perpetually increase and eventually surpass all potential asymptotic values. The third implication, *running total recreation through grouping*, emerges when a student considers that she can regroup the terms in an alternating series to create a uni-directional *running total.* For the students in our study, recreating the series resulted in not only a uni-directional *running total,* but a plausible (in the students' minds) candidate for the asymptotic value to which the recreated *running total* might converge. In this manner, the three implications provide a connection between students' actions while considering the convergence of individual series and their overarching image of convergence as a *running total* approaching an asymptote.

Our findings both complement and extend work done by previous researchers. For example, the *asymptotic running total meaning* indicates that students consider series convergence as a dynamic process of approaching an asymptote, which has been previously reported about students' meanings for the limit of sequences (e.g., Roh, 2008) and functions (e.g., Swinyard & Larsen, 2012). Our findings also provide analogous results and additional insight into Martin's (2013) report on students' thinking for Taylor series convergence. For instance, Martin's (2013) *dynamic partial sum* image in the Taylor series case is analogous to the *asymptotic running total* meaning for the infinite series case. However, our report extends the findings of Martin (2013) by reporting new implications of the *asymptotic running total* meaning (e.g., *running total recreation through grouping*) and providing a meaning-implication relationship between images that were previously reported distinctly (i.e., *dynamic partial sum* and *termwise*).

Our data did not provide sufficient evidence to make rigorous claims about relationships between the three implications described in the results section. Still, we make two anecdotal comments about potential relationships. First, both students' actions tended to align with the *decreasing summands convergence* implication after constructing and reasoning about closed-form rules for the general summand in a series. In contrast, the *monotone running total divergence* implication often emerged during moments when the students could not construct a closed-form rule for the general summand or reasoned about the *running total* without referencing a closed-form rule for summand values. Second, the *monotone running total divergence* implication did not emerge during moments after students regrouped an alternating series. Rather, the students' responses indicated that although the regrouped series' running total would perpetually increase or decrease, the inherent oscillation of the original running total was sufficient to render the *monotone running total divergence* implication irrelevant.

We anticipate that our ongoing analysis of the teaching experiment data from which this report emerged will provide insight into effective instructional interventions to foster productive student meanings for series convergence. In particular, we hope to discern how to leverage students' naturalistic images of a series as a *running total* to construct a productive meaning for the sequence of partial sums, which Martínez-Planell et al. (2012) stated is pivotal to comprehending the formal definition of a series as the limit of its sequence of partial sums. We also hope to investigate possible relationships between the three implications we have described and uncover additional meanings and implications that first-time second-semester calculus students possess for series convergence.

TOWARDS THE CONSTITUTION OF THE MENTAL OBJECT SYSTEM OF LINEAR EQUATIONS IN PRE-UNIVERSITY STUDENTS

Xochitl Josefina García López

xgarcial@cinvestav.mx

Hugo Rogelio Mejía Velasco
CINVESTAV-IPN
hmejia@cinvestav.mx

The constitution of a mental object in a student implies their competence to perform an adequate reading and execute processes in the different contexts in which it is possible to find that related concept. As part of the constitution of the mental object system of linear equations, we consider that pre-university students must be competent in the use of a resolution method that allows recognizing a system of equations as a mathematical object and identifying the nature of its solution set. In addition, we consider necessary the competence to identify the elements of systems of linear equations in different mathematical sign systems.

Keywords: Cognition, Mathematical representations, Modeling, Problem solving.

The mastery of systems of linear equations (SLE) is fundamental in the learning of some disciplines in higher education (Oktaç & Trigueros, 2010). There is evidence that many university students are not competent in solving SLEs and working with their different forms of representation, as well as in understanding concepts such as the equivalence of SLEs and the existence of SLEs with no solution or with infinite solutions (DeVries & Arnon, 2004; Manzanero, 2007; Mares, 2016; Oktaç, 2018; Parraguez & Bozt, 2012). In learning linear algebra, university students have to understand a large number of concepts that do not seem to be related to previous mathematical knowledge (Mares, 2016). Students face problems with respect to learning SLE-related concepts and processes from the basic level (Filloy, Rojano & Solares, 2010) that are replicated at later levels. We consider the study of systems of linear equations at the pre-university level as an opportunity to detect and overcome students' difficulties in understanding and solving SLEs.

Purposes of the study

The objective of the study is to propose, analyze and interpret teaching activities focused on promoting the sense production of pre-university students around the concept of SLE and to strengthen the related mental object. Our hypothesis is that the systematic use of systems of equivalent equations mediated by the Gaussian elimination method favors the understanding of systems of equations as a mathematical object and allows determining and interpreting the nature of their solution. Through an intertextual analysis we seek to identify elements that allow students to acquire competence in modeling, solving and interpreting SLE solutions.

Theoretical framework

For the analysis of the development of competence in students we consider the concept of intertextuality. The concept of intertextuality is developed in contrast to the idea that the reading process is the extraction of a unique meaning deposited in a text by its author; it is considered that, in the search for meaning, a reader is immersed in a network of relationships between an infinite number of texts that are part of their previous experiences, which generates a unique and personal meaning of the text (Allen, 2011).

Rojano, Filloy and Puig (2014) point out that learning algebra is done by reading texts that are related to other texts and that, when reading, students are immersed in a network of intertextual relationships derived from their pool of linguistic and mathematical experiences. Once the student brings their intertextual network into play read or produce meaning, they generate a new text that will become part of their intertextuality. The tendencies, allusions or references in the students' productions allow us to observe in what ways their intertextuality facilitates or hinders the reading and production of texts. The use of the notion of intertextuality in this report is focused on the analysis and description of the development of student competencies in SLEs learning.

According to Puig (1997), when a person can correctly interpret the use of a mathematical object according to its context, they do not need its encyclopedic meaning, but their own personal semantic field, which is the result of the meanings they have managed to construct through the senses production. Hence the importance of ensuring that the students' semantic field is so rich that it allows them to adequately interpret mathematical objects in all possible situations. The objective is to build a personal intertextuality in mathematics composed of the concepts and mental objects related to that concept that allow the student to perform adequate readings and execute processes competently.

Methods

The experiment was carried out with three pre-university students whose real names have been protected. The data analyzed were obtained from the recordings of interviews with didactic intervention carried out on a videoconferencing platform. The analysis included the students' productions in worksheets and in a digital whiteboard application. The interviews were intended to promote discussion, reflection and the use of mathematical discourse. In some of the sessions, the dynamic geometry software (DGS) GeoGebra was used for the analysis of SLE representations in the plane and space of coordinate axes and in the tabular representation. This report presents the results of eight activities that made up the experimental phase. This is intended to exemplify some changes in the students' intertextuality in relation to SLEs. The activities began with the linear equation with one and more variables, analytical work for statement problems, and representations of SLEs. It concludes with the resolution of statement problems by applying the Gauss's method to the algebraic models proposed by the students.

Data Analysis and Findings

Given that one of the difficulties detected in high school students is the assumption that for each variable in a SLE there is a solution, we proposed in the third activity the numerical analysis of a problem statement divided into two conditions with two unknown quantities. Condition 1: There are two trucks. Truck A with a capacity of two tons and truck B with a capacity of four tons. You want to know how many trips each truck made given that 20 tons of material were transported to a construction site and that no truck traveled with less than its capacity, how many and which solutions are there? Condition 2: If it is known that for each trip of truck A the company charges 2 thousand pesos and for each trip of truck B 3 thousand pesos and the payment for the trips was 18 thousand pesos, what would the solution be?

From this activity we identify sense production with respect to the fact that the solution of an SLE can be a set of values and that at least two conditions are required to find two unknown quantities (Figure 1).

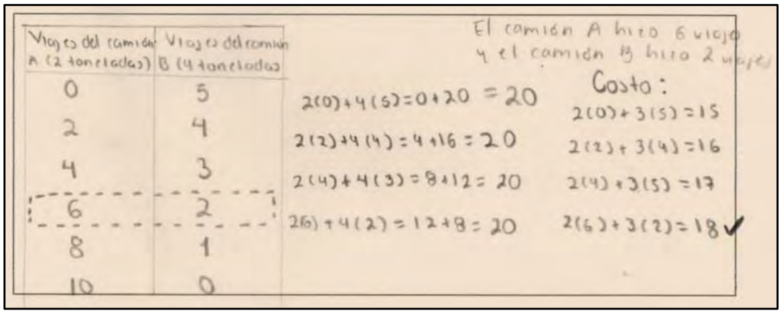

Figure 1: Vanessa´s numerical analysis of the statement problem

Before the didactic intervention, we identified that the concept of equivalent equation was not part of the students' intertextuality. During the development of the activity, there was evidence of the sense production with respect to the recognition of some of the transformations to obtain equivalent SLE. We observed evidence of competence in the use of the Gauss' method once the students incorporated the concept of equivalent scaled SLE into their intertextuality. A part of the activity for the use of Gaussian method was developed with the support of the DGS. The work that the students carried out was the identification of the operations per line necessary to find an equivalent scaled SLE and the analysis of the results obtained (Figure 2).

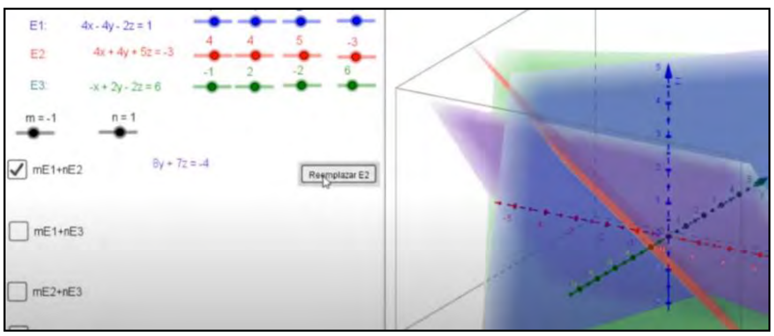

Figure 2: Solving a SEL using GeoGebra by Ana

The use of the DGS made it possible to complement the algebraic transformations and the results obtained with the visualization of the representation of SLEs and their transformations in graphical form and to produce meaning with respect to SLEs with no solution, with one and with infinite solutions. For example, by observing the SLE (Figure 3) the student identifies that it has infinite solutions.

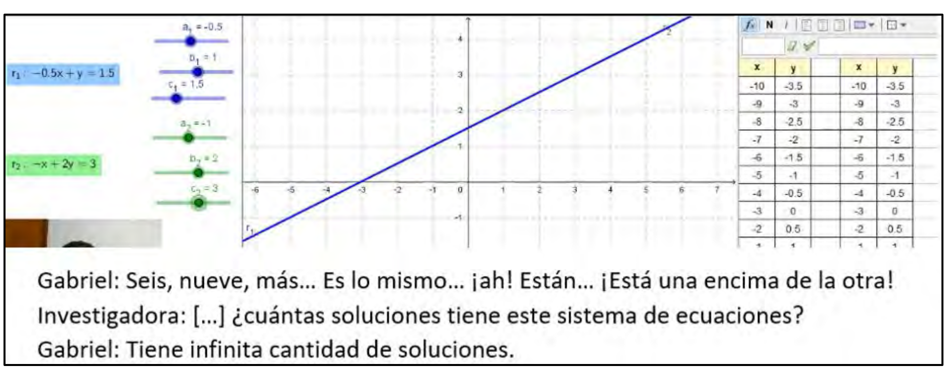

Figure 3. Representations of a SEL in interaction with Gabriel

With respect to solving word problems, students were competent in identifying unknown quantities and relating them to literals for their algebraic treatment. They also expressed the solution or results in terms of the problem. One of the major difficulties for the students was modeling the problem conditions in equations. However, through the use of concrete values, students were able to make sense of the relationships between known and unknown quantities, either to reflect and propose an equation or to revise their inferences (Figure 4).

> [Para plantear la condición de que la suma de respuestas correctas e incorrectas en un examen es 100]
> *Investigadora: Tú me dices que* $x-y=100$*, pero qué pasa si* x *vale 30, por ejemplo, entonces sería* $30-70=100$*. Y eso no es correcto, ¿cierto?*
> *Gabriel: Ok, entonces sería... 30 menos 70 no es... ¡Ah no! Es* $x+y=100$.

Figure 4: Interaction with Gabriel doing scans with specific values

Once the activities were carried out, the construction that the students achieved of the SLE mental object was influenced by the students' own intertextuality as related to first-degree equations with one unknown and the transformations necessary to solve them, as well as by the way the teaching situations were approached.

Discussion

There are significant differences in the students' personal intertextuality, which determines the senses production and competencies, not only before, but also during and after the development of the activities. However, we identified some coincidences in the constitution of mental objects. The students were able to incorporate elements to their intertextuality that allowed them to competently read systems of up to three equations with three unknowns without solution, with one or with infinite solutions in the plane, in the corresponding tables of numerical values and in algebraic form.

Some difficulties were encountered with systems of equations with three unknowns. The analysis in its different representations by means of the DGS was important for their understanding. The incorporation in the students' intertextuality of the equivalent SLE mathematical object and the recognition of the transformations to obtain them was evidenced, as well as the advantage of having a stepwise SLE to find their solution. Students showed competence in identifying unknown quantities and relating them to literals for their algebraic treatment. Finally, they showed difficulties in modeling problem conditions in equations that they overcame by using concrete values.

Access to free, high-quality, institutionally provided tutoring services can be critical to the success of university students. When the pandemic forced university tutoring operations to close or move online, many chose to move operations online. The Fall 2021 semester saw the return of in-person tutoring at many institutions; however, online options remained in place to serve students who may not be able to participate in-person. This created more equitable access to a critical student support. We collected data on which format students chose at two research-focused institutions. At one institution, visits were split at 47% online and 53% in-person. In contrast, visits at the other institution were split at 5% online, and 95% in-person. We will discuss the courses with the highest usage in each format and explore why students may be choosing one format over the other.

Keywords: Undergraduate education; Instructional Activities and Practices; Online and Distance Education; Equity, Inclusion, and Diversity

Tutoring services supply essential support for students, helping them to succeed in college mathematics classes. Although professional tutoring is available outside of the university, such services are not financially accessible to all students. University-based tutoring centers offer services to students at no additional cost. Access to high-quality online tutoring services can be critical to the success of students, especially those who are first-generation, are from low-socioeconomic backgrounds, or are facing other challenges to making in-person meetings. In this paper, we discuss students' usage of in-person and online tutoring options at two large research-focused institutions. Further, we will examine how this data may inform future tutoring structures.

Background

Institution-based mathematics tutoring services play a necessary role in preserving equitable access to resources among students. Student use of tutoring resources has been correlated with an increase in final course grades (Byerley et al., 2018; Rickard & Mills, 2018; Xu et al., 2001) and with improvements in persistence, retention, and degree completion (Astin, 1993; Pascarella & Terenzini, 1991, 2005; Rheinheimer et al., 2010; Rheinheimer & Mann, 2000; Rouche & Snow, 1977). First-generation college graduates have reported needing to work harder than their peers to attain the same level of achievement, and minoritized students have reported that lacking a sense of belonging presented a significant challenge to persistence in college (Richardson &

Skinner, 1992). Mathematics tutoring centers act as an academic scaffold for struggling students, allowing instruction to be tailored to the needs of the individual students (Anghileri, 2006) while also helping students develop their mathematical identities through social interaction (Bjorkman & Nickerson, 2019). Access to quality tutoring services is likely to play a significant role in student achievement in the coming years, as it is projected that secondary school students' performance in reading and mathematics will suffer as a result of interrupted instruction due to school closures (e.g., related to the pandemic or weather events), particularly in less affluent areas (Chetty et al., 2020; Kuhfeld et al., 2020).

Existing research points to the importance of tutor training both for in-person and online tutoring (Fitzmaurice et al., 2016; Johns & Mills, 2021; Simão et al., 2008; Turrentine & MacDonald, 2006). Lepper and Woolverton (2002), in a comparison of the practices of expert tutors, identified characteristics of and techniques used by those tutors during tutoring sessions. The behaviors identified in these expert tutors include cognitive, metacognitive, and affective pedagogical strategies and considerations which focus not only on the academic content under consideration but also emphasize the importance of study skills and student mindsets. Research on students' success in school (Blackwell et al., 2007; Boaler, 2013; Cohen & Sherman, 2014; Dweck, 2007; Good et al., 2003; Moser et al., 2011) has shown that non-cognitive or motivational factors including students' mindsets and beliefs about themselves as learners, their feelings about school, and their ability to self-regulate "can matter even more than cognitive factors for students' academic performance" (Dweck et al., 2014, p. 2). Students who work with a tutor tend to use prior knowledge, monitor their progress, utilize effective learning strategies, and seek help more often than those who do not – practices which lead to improved performance on assessments and development of mental models (Azevedo et al., 2008). The role played by tutors is much more than simple presentation of content; effective tutors also provide emotional support and help students learn how to self-regulate and develop productive mindsets about themselves as learners. Tutoring practices, like those discussed above, are known to be effective in the traditional, face-to-face tutoring environment, but in light of the COVID-19 pandemic, many tutoring centers moved operations online and will likely continue to provide their services either entirely or partially in an online environment to meet the needs of their students.

Theoretical Framing

We view tutoring from the perspective of Weisbord's Six-Box Model of how organizations function (Weisbord, 1976). The six boxes are: 1) Purpose, 2) Structure, 3) Relationships, 4) Rewards, 5) Leadership, and 6) Helpful Mechanisms. For this report, we focus on the dimensions of *purpose*, what "business" we are in, and *structure*, how we divide up the work. The purpose of our university tutoring centers is to provide students access to free, high-quality tutoring, and our structure consists of dividing the work between in-person and online offerings. Each of these dimensions is influenced by the environment (i.e., forces from the outside that cannot be controlled) in which it exists.

Weisbord suggested collecting data through observations, surveys, interviews, and readings (of written records) to assist in determining discrepancies between what people say and what people do as well as how the organization exists and how it ought to exist.

An organization should have *helpful mechanisms* that monitor, identify and revise any of the other boxes in Weisbord's model, as needed, to make the organization more effective. In this study, we report on the deliberate use of institutional data to study the university students' usage of and satisfaction with their mathematics tutoring centers in a pandemic era. We will consider if using this data is a helpful mechanism to identify how university tutoring centers might optimally fulfill their purposes considering structural changes implemented to benefit students. In terms of Weisbord's model, our research question is: How might student attendance at in-person and online tutoring sessions be used as a helpful mechanism to support the purposes and structures of tutoring centers? We then speculate on other mechanisms that would be helpful in determining the optimal structures that might help two different universities achieve their organizational purposes.

Context and Data Collection

The data presented here is part of a larger project examining the online tutoring experience. As part of this larger study, training materials for online tutors are being developed and tested with the goal of providing an online tutoring experience that is more comparable to in-person tutoring. Here, we are examining how students' choices of tutoring experience (in-person or online) may inform an institution of how well their structures are fulfilling their purposes with respect to tutoring offerings. Data for this paper include the number of visits to in-person and online tutoring sessions and a student experience satisfaction survey sent to those who attended online sessions.

We tracked the number of student visits to tutoring services provided by the mathematics departments at two large, research-focused universities, U1 and U2, during the Fall 2021 semester. Student visits to the mathematics tutoring centers were tracked via EAB's Navigate and TutorTrac, respectively, for U1 and U2. For in-person visits, students' university ID cards were swiped when they entered and exited to capture information about the mathematics course in which they were enrolled, and the time spent in the tutoring center. Online visits captured this data through a manual entering of the student's ID number by the tutor on duty. At the conclusion of the semester, data were downloaded, summarized, and analyzed.

It should be noted that students who attend in-person tutoring are not necessarily working with a tutor for the entirety of their visit. It is common for students to sit in the tutoring center working on problems independently and only work with a tutor as questions arise. In contrast, in the online environment, students are more likely to be working with a tutor for the duration of their tutoring center visits. Hence, while time spent in the tutoring center (in-person and online) is tracked, we only consider the number of visits in our analysis here. Tracking time spent in the tutoring center is valuable for determining operating hours and physical space considerations.

All online tutors were provided with a Samsung Galaxy Tab S6 Lite tablet to use for their tutoring sessions. Students who used the online tutoring services at U1 and U2 received a 3-question satisfaction survey. Students were asked: 1) Please rate the overall quality of your tutoring session (on a scale of 1 to 5), 2) Please indicate whether the technology allowed for effective interactions with your tutor (on a scale of 1 to 5), and 3) Is there anything else we should know to help serve you better in the future?

The satisfaction survey was sent only to users of the online tutoring services. In-person tutoring has a proven track-record of helping students succeed, and large numbers of students at U1 and U2 used these services pre-pandemic. The purpose of the current study was to determine how the online tutoring environment differed from the in-person, with a focus on how technology facilitates tutor-student interactions.

U1 Context

U1 is a research-focused institution in the mid-Atlantic region of the U.S. with a total enrollment of about 21,000 undergraduate students. It is approximately 50% residential, with mostly freshmen living on campus. U1 has two campuses, Campus A and Campus B, about 2 miles apart. The mathematics tutoring center is located on Campus A in the same building as the mathematics department and offers drop-in in-person tutoring. Although most math courses are offered on Campus A, only about 9% attend their mathematics class in the same building as the mathematics tutoring center and 25% of students enrolled in a math class attend their class on Campus B.

Most tutors were undergraduate students. All tutors (in-person and online) participated in tutor training with sessions occurring both synchronously and asynchronously online. This training consisted of an initial one-on-one meeting with the tutor coordinator to discuss tutoring basics, regular written self-reflections on the tutor's own practice, and the analysis of recorded mock tutoring sessions. Online tutors were encouraged to enroll in a separate one-credit hour course so that those who were working in the online environment received additional training on how to tutor online and how to effectively use technology to facilitate interactions between students and tutors.

At U1, in-person and online tutoring was offered throughout the semester. In-person tutoring was offered all semester, Monday – Friday from 10am-3pm for a total of 375 hours (63% of available tutoring hours). Online tutoring was offered all semester Sunday – Thursday from 6pm-9pm for 225 total hours (38% of available tutoring hours). Online tutoring sessions were conducted via Zoom. All students, regardless of whether they were enrolled in in-person or online classes, could attend either in-person or online tutoring.

U2 Context

U2 is a research-focused institution in the southwest region of the U.S. with a total enrollment of about 23,000 undergraduates. It is 29% residential, with most freshmen residing on campus. U2's mathematics tutoring center offers drop-in tutoring. U2's in-person tutoring center is located on the main floor of the building where about 75% of its math classes are offered and where all mathematics instructors' offices are located.

The tutors are a mix of faculty, graduate students, and undergraduate students. The graduate and undergraduate tutors undergo training. All tutors attend 6 hours of general training on tutoring prior to their first semester, of which 1 hour is dedicated to online tutoring. Graduate students take 30 hours of content training throughout their first year to qualify to tutor for the different courses served by U2's center. The graduate student tutors have an opportunity at the beginning of the year to reduce the number of hours of training if they pass one or more of the content exams. Undergraduate tutors earn raises for each additional content training they attend and exam they pass. U2's online tutors were selected from experienced undergraduate tutors who were also working, or had worked before, as in-person tutors. Online tutors receive additional training on how to tutor online, including how to use digital devices to display written or digital renderings of graphs, equations, tables, and writing for students to see.

Like U1, U2 offered both in-person and online tutoring options throughout the semester. At U2, in-person tutoring was offered on weekdays (Monday-Thursday, 10am-5pm and Fridays, 10am-2pm) for 479 hours (67% of available tutoring hours) during the semester while online tutoring was offered on weekday evenings (Monday-Thursday, 5pm-9pm) and Sunday afternoons (3pm-7pm) for 232 hours (33% of available tutoring hours). Online tutoring sessions were conducted via Zoom. All students, regardless of whether they were enrolled in in-person or online classes, could attend either in-person or online tutoring.

It should be noted that during the first year of the pandemic, when tutoring was only offered online, both U1 and U2 saw a significant decrease in the number of students seeking university provided tutoring services. Johns and Mills (2021) reported a similar phenomenon at 25 other universities.

Findings

We report on student enrollment and tutoring usage for the courses in two tracks: STEM intending and non-STEM intending. Within these tracks, we examine the data for the course of: College Algebra (STEM vs. non-STEM), Precalculus/Trigonometry, Calculus I, Calculus II, Calculus III, and Applied Calculus. While the general student populations at the two campuses are very similar, they make different choices regarding how they attend tutoring.

In-person Versus Online Usage

Table 1 displays the number of students enrolled in each course and the number of tutoring visits by course and modality. Note that the number of students enrolled in the courses under consideration at U1 (3,986) is almost twice as many as the number of students enrolled in those same courses at U2 (2,171). We observe that even though U2 has fewer students enrolled in these courses, the number of tutoring visits is significantly higher than those of U1. This equates to about 0.5 visits per student at U1, and 2.3 visits per student at U2. Further, we observe that the number of in-person tutoring visits at U1 (1,084) is approximately one-fourth that at U2 (4,679). For online tutoring visits, U1 had about two-and-a-half times as many visits (969) as U2 (372). Hence, we see that U2's students more frequently availed themselves of tutoring services and students heavily favored the in-person tutoring experience. In contrast, U1's students did not use tutoring services as often but used online and in-person tutoring services almost equally.

Table 1: Population and Tutoring Attendance for Algebra, Precalculus/Trigonometry and Calculus Courses

Track	Course	U1				U2			
		Course Population		Tutoring Visits		Course Population		Tutoring Visits	
		in-person	online	in-person	online	in-person	online	in-person	online
		n=3535	n=451	n=1084	n=969	n=1950	n=221	n=4679	n=372
STEM	Coll Algebra	466	14	44	118	344	31	551	43
	Precalc/Trig	159	75	136	24	421	23	1020	61
	Calculus I	731	118	187	282	542	57	2028	143
	Calculus II	240	50	120	89	194	63	678	87
	Calculus III	368	39	29	36	449	47	402	38
Non-STEM (Applied)	Coll Algebra	589	35	471	264	*	*	*	*
	Calculus	982	120	42	44	*	*	*	*

*Since U2 had no regular online offerings for non-STEM classes; such data were not considered.

Table 2 shows the percentages of students enrolled in each course modality and the percentage of tutoring visits utilized by those students. The majority of U1's students (88.7%) were taking math courses in person, and the majority (62.5% of possible hours) of U1's tutoring was offered in-person, while U1's in-person tutoring accounted for about half (52.8%) of its tutoring attendance.

The majority of U2's students (89.8%) were taking College Algebra, Precalculus/Trigonometry, and Calculus courses in person, and the majority (67.4% of possible hours) of U2's tutoring was offered in-person, while U2's in-person tutoring accounted for 92.6% of its normal tutoring attendance.

Table 2: Percentage of Tutoring Visits by Population for Algebra, Precalculus/Trigonometry and Calculus Courses

Track	Course	U1	U2

		Course Population		Tutoring Visits		Course Population		Tutoring Visits	
		in-person	online	in-person	online	in-person	online	in-person	online
		n=3535	n=451	n=1084	n=969	n=1950	n=221	n=4679	n=372
STEM	Coll Algebra	13.2	3.1	4.1	12.2	17.6	14.0	11.8	11.6

	Calculus	27.8	26.6	3.8	4.5	*	*	*	*

U2 also offered special tutoring opportunities either one or two evenings before coordinated exams (for both STEM and non-STEM mathematics classes). For each exam, there were two types of review opportunities: an online evening facilitator-centered review session that was followed by an in-person “After Dark” tutoring session. Over the course of the Fall 2021 semester, the online review sessions were offered for 20 hours, and the After Dark in-person tutoring was offered for 30 hours. The attendance at these review opportunities (which is in addition to the numbers for regular tutoring provided in Table 1) was 1,058 for the online reviews and 1,507 for the in-person tutoring. The majority of U2’s review opportunities (60% of possible hours) was offered in-person and accounted for 58.8% of the student visits to special tutoring opportunities. U2’s online reviews accounted for 41.2% of its attendance at review opportunities and accounted for 40% of the possible hours to special tutoring opportunities.

Satisfaction Survey

We received 130 responses to the satisfaction survey, over 90% of which were from U1. The results of the survey suggest that students were generally pleased with their online tutoring experiences. Overall, 79% (24% and 55%, respectively) of survey responses rated the tutoring session as “very effective” or “extremely effective.” 86% (24% and 62%, respectively) of survey responses indicated that their tutor’s available technology “very effectively” or “extremely effectively” facilitated their interactions in the online tutoring environment.

In line with the numerical results of the survey, when students provided comments, they were often positive, though students also left negative feedback. Among the positive comments, students complimented their tutors: “[My tutor] was incredibly helpful”; “My tutor was FANTASTIC and incredibly helpful.” Others mentioned specific teaching strategies employed by their tutors: “She asked me to re-explain the problem to her, which helped me really understand the concept.” Within the negative comments, students cited errors made by their tutor: “Tutor didn’t do the problem right, misled me for my homework.” and a desire for longer sessions and more one-on-one tutoring (as opposed to small groups), as well as factors beyond the tutors’ control (“Internet connection was terrible.”, “…a way to have multiple people sharing screens in zoom”). Students also sometimes requested that the tutoring center hire additional tutors for specific courses.

Discussion

As Weisbord (1976) noted, helpful mechanisms should exist to monitor, identify, and inform revision of the other boxes in the Six-Box model. The attendance and survey data we collected serves as a helpful mechanism, providing feedback on the purposes and structures of the tutoring centers at U1 and U2. These data allowed us to monitor and identify what format students chose when seeking tutoring. We acknowledge that during some of these visits, particularly in-person centers, students may spend minimal time interacting with tutors and are using the space to study and work independently, knowing help is near. The data from U1 highlights that their students use the two tutoring structures (in-person and online) almost equally. In contrast, the data from U2 shows that their students are much more likely to attend in-person tutoring. Furthermore, the survey data collected suggests that students who utilized the university's online mathematics tutoring services largely found their experiences beneficial. For those students who did not find their experiences as fulfilling, the reasons they cited were mostly beyond the tutors' control.

Students at the different sites used the in-person and online environments in very different proportions. The locations of U1's and U2's mathematics tutor centers may help explain students' choices of tutoring modality. Though U1 has a larger number of residential students than U2, it witnessed a significantly higher rate of online tutoring attendance than U2. We hypothesize that this disparity may be due to U1 being split across two campuses. The tutoring center at U1 is located on Campus A, but many students live and take classes on Campus B, which sits approximately 2 miles away, making it difficult to visit the tutoring center in person for some students. For these students, online tutoring provides an option to receive help between classes on Campus B or during other times when reaching Campus A may be challenging or inconvenient. Even though the number of U2 residential students is lower than U1's, the number of students who live close to campus, either as part of the Greek system or in off campus apartments, is quite large. So, almost all undergraduate students walk or drive to campus then stay on campus for their classes.

Data from the satisfaction survey serves as a helpful mechanism by identifying components of the tutoring structures that students appreciated as well as others they would like to see changed. Some of the feedback provided by students about online tutoring is reminiscent of feedback often received about in-person tutoring; sometimes tutors are fantastic, and sometimes tutors make mistakes. Focusing on novel feedback, we were able to distinguish between aspects of the online tutoring experience that are within the control of tutors and tutoring centers and those that are beyond our control. For example, students' access to quality internet is beyond the control of tutors and tutoring centers. However, tutoring centers can place an emphasis on ensuring that tutors are provided with appropriate equipment (e.g., pen-enabled tablets) and ensuring that there are sufficient numbers of tutors for courses with particularly high demand for tutoring. In our future work, we will investigate the specific ways in which the use of appropriate equipment fosters online tutoring interactions.

The purpose of the tutoring centers at U1 and U2 is to provide access to free, high-quality tutoring. Our data suggest that students do find value in attending, as both institutions have many repeat users of their tutoring services, and those who completed the satisfaction survey largely rated their experiences positively. For students at U1, it appears that both the in-person and online tutoring options are equally valuable, as they use these services more or less equally. As mentioned above, this could be due to the difficulty in traveling between campuses at U1. We also believe U1 and U2 are offering a better online experience than 6 - 12 months ago. Although our initial implementation of online tutoring saw significantly diminished usage, we have seen higher traffic in recent months. In our future research, we will continue the use of the satisfaction survey.

In sum, we found that students valued the online option equally with the in-person option at U1, while students at U2 clearly favored the in-person option for regular tutoring but attended the in-person and online evening review sessions prior to exams in the same proportions the hours were offered. This data allows each institution to examine the modalities of their tutoring services and adjust to better suit their student populations.

Acknowledgments

WHICH SHOULD COME FIRST: ISOMORPHISM OR HOMOMORPHISM?

Alison Mirin
University of Arizona
amirin@math.arizona.edu

Rachel Rupnow
Northern Illinois University
rrupnow@niu.edu

Isomorphism and homomorphism are central concepts in abstract algebra, but their interrelatedness provokes questions about which should be taught first. This study investigates instructors' pedagogical preferences and rationales for their ordering of the concepts and compares them to textbooks that they use. We found that for a third of participants, there was a lack of alignment between preferences and textbooks. Additionally, the metaphors used in support of a homomorphism-first approach centered on the idea of formal definition, while those used in support of an isomorphism-first approach focused on sameness.

Keywords: Undergraduate Education, Advanced Mathematical Thinking, Curriculum.

Isomorphism and homomorphism are central concepts in abstract algebra. There are multiple ways to view isomorphism and homomorphism as being related, two of which are opposite sides of the same coin. On one side, an isomorphism can be viewed as a specific type of homomorphism (bijective). On the other side, we have the notion that homomorphism can be viewed as a generalization or abstraction of isomorphism. While the four most commonly-used (Melhuish, 2015) introductory abstract algebra textbooks in the United States (Fraleigh, 2003; Gallian, 2009; Gilbert & Gilbert, 2008; Hungerford, 2012) all introduce isomorphism first (Mirin & Rupnow, in press), there are some other, more advanced, texts that introduce homomorphism first (e.g., Dummit & Foote, 2004; Lang, 2002). Our work addresses the following questions: (1) To what extent do the participants and their chosen textbooks have aligned ordering? (2) What conceptual metaphors about isomorphism and homomorphism did the participants use to describe, justify, or explain their ordering?

Background and Literature

There is a variety of mathematics education work on isomorphism and homomorphism (Dubinsky et al., 1994; Hausberger, 2017; Larsen, 2013; Leron et al., 1995; Melhuish, 2018; Melhuish et al., 2020; Rupnow, 2021). Although not focused specifically on the ordering of isomorphism and homomorphism, some work provides insight into instructors' ordering preferences. For example, in their work on instructors' goals when assigning homework, Rupnow et al. (2021) found that some instructors would prefer to teach homomorphism first, despite being given a textbook introducing isomorphism first. In contrast, other instructors do choose to teach isomorphism first, both in following Larsen's Teaching Abstract Algebra for Understanding materials (Larsen, 2013) and in making their own decisions (Rupnow, 2021).

Gilbert and Gilbert (2008) point to a tension between generalization (isomorphism first) and specification (homomorphism first) by stating, "Isomorphism is a special case of homomorphism, while homomorphism is a generalization of isomorphism. Isomorphisms were placed first in this book with the thought that 'same structure' is the simpler idea" (p.137). It seems that, while Gilbert and Gilbert acknowledge a dilemma between generalization and specification, they eventually decide that isomorphism is an easier concept to introduce than homomorphism. This can be viewed as starting with what is conceptually simpler, even if the definition of homomorphism is more concise and with fewer conditions. We investigate the order in which instructors introduce these concepts and their rationales. Note that the notion of generalization starting with a simpler or more accessible concept is not unique to isomorphism versus homomorphism. For example, Tall (1991) explains that mathematically one must learn the notion of limit before learning the derivative. However, he points out that this instructional sequencing might result in students seeing limits as unmotivated, and that purely "logical" sequencing can be "blinkered and limiting" (p.18).

We use the notion of *conceptual metaphors* (Lakoff & Nuñez, 1997) as a framework, in which a metaphor is viewed as a relationship between a source domain and a target domain. While these domains can inform each other, the source domain is generally intended to provide insight into the target domain. For example, "An isomorphism is a special homomorphism" can be viewed as a metaphor in which *isomorphism* is the target domain, and *homomorphism* is a source domain that provides insight into the nature of isomorphism.

Methods

Participants were selected from a subset of mathematicians who were research-active in an algebra-related field and provided clear responses to a survey about sameness. Nine (labeled here as A, B, C, D, E, F, G, H, and J) who had taught abstract algebra at least once, participated in an interview. The interview questions centered on how the participants describe and characterize isomorphism and homomorphism in a variety of contexts. Here, we concern ourselves only with the data pertinent to our research questions about ordering and rationales for ordering. For eight of the nine participants, this amounts to examining their responses to the question, "do you teach isomorphism or homomorphism first, and what is your rationale?". One participant, E, addressed the question in response to an earlier question and was not explicitly asked about ordering.

We collaboratively coded to consensus using thematic analysis (Braun & Clarke, 2006). Specifically, for each participant, we catalogued and analyzed (1) the ordering preference of isomorphism and homomorphism, (2) how they used metaphors in their rationale for the ordering preference, and (3) any rationale given for an ordering that was not their stated preference. In doing so, we utilized the metaphors delineated in Rupnow and Randazzo (this volume) to see which metaphors surrounding isomorphism and homomorphism the participants used as warrants or explanations for each ordering. While Rupnow and Randazzo (this volume) note seven metaphor clusters, all metaphors in this paper relate to four clusters: sameness, sameness/mapping, sameness/formal definition, and formal definition.

Results

Six of the nine participants stated that they teach homomorphism first, and three stated that they teach isomorphism first. While the course textbooks were known for only six of the participants (B refused to state their textbook but had one in mind; C did not have a particular textbook in mind and talked about adjusting to whatever text they were given; E "hardly ever crack[s] open the textbook"), we nonetheless examine the alignment between the participants' instructional sequencing and that of their adopted textbooks. Three participants (A, F, and G) use textbooks in which isomorphism is introduced first yet teach homomorphism first. The other three participants are consistent: two use a text in which homomorphism is introduced first (Dummit & Foote, 2004) and do indeed teach homomorphism first, while one uses a text (Hungerford, 2012) in which isomorphism is introduced first and does indeed introduce isomorphism first. To summarize, of the six participants whose textbooks are known, half teach isomorphism and homomorphism in an order that aligns with their textbook, while the other half teach homomorphism first despite having textbooks that introduce isomorphism first. The ordering preferences and alignment with textbooks are summarized below (Table 1).

(Participants generally stated an author for their text; here we cite the most recent edition by the author(s).)

Table 1: Textbook Ordering and Instructional Ordering

	Isomorphism first in text	Homomorphism first in text	Unknown text
Homomorphism first teaching	A (Judson, 2019), F (Armstrong, 1997), G (Fraleigh, 2003)	D and H (both Dummit & Foote, 2004)	B
Isomorphism first teaching	J (Hungerford, 2012)		C, E

The reason for teaching homomorphism first was consistent across participants; all justified this ordering in a way that employed the metaphors capturing the notion that an isomorphism is a special type of homomorphism. This came in two distinct (targets and sources flipped) but related metaphors from the formal definition cluster: *special homomorphism* and *isomorphism without bijectivity*. For example, one participant (D) mentioned "convenience" of communication as a reason for introducing homomorphism first: "it's convenient if students already know the definition of homomorphism and are comfortable with this before defining isomorphism…I would like to be able to give the definition of isomorphism in a nice, condensed manner". Participant A, although not mentioning convenience explicitly, hinted at the idea: "we inherit the theory from homomorphism (when studying isomorphism)". Participant E even suggested that homomorphism might be "easier…from a logical point of view" due to not having to "worry" about bijectivity. Yet another participant (F) described homomorphism as "simpler". Despite these variations, we understand these notions of "simplicity", "convenience" and "easiness" as instances of the same core metaphor, stated by all participants who endorsed the homomorphism-first approach and by some who rationalized why homomorphism might be taught first (despite preferring isomorphism first): isomorphism is a *special homomorphism.*

The notion of isomorphism as an instance of homomorphism was *not* explicitly used in support of an isomorphism-first approach. Instead, participants primarily justified that approach with metaphors from sameness-based clusters. They contrasted the sameness of isomorphism with the more complicated nature of homomorphism. For example, J used sameness metaphors for both isomorphism and homomorphism to explain that isomorphism should be taught first because isomorphism sameness is more intuitive than homomorphism sameness:

> Are these objects actually the same? So that, I think, motivates the isomorphism question and the definition of isomorphism. But I feel like homomorphism needs to come a little later because homomorphism really is not talking about exact copies, it's talking about, there's kind of lots of different ways the homomorphism can manifest as I said, with collapsing or exact copies. And so there, it's a little bit fuzzier of a notion and of comparing two objects.

While there was consistency in the use of sameness-based metaphors for justifying isomorphism-first, the particular choices of metaphors varied. The most commonly used metaphor was *generic sameness* (a sameness-cluster metaphor); this was used by C and J (quoted above) to justify why they used an isomorphism-first approach, and it was additionally used by homomorphism-first participants (A, B, H) to characterize an isomorphism-first approach. Other sameness-related metaphors used to explain an isomorphism-first approach included *matching* (a sameness/mapping-cluster metaphor, used by J), *renaming/relabeling* (a sameness/mapping-cluster metaphor, used by E and C), *classification* (a sameness-cluster metaphor, used by G), *logical equivalence* (a sameness-cluster metaphor, used by G), and *structure preservation* (a sameness/formal definition-cluster metaphor, used by C). For example, C explained: "I think it's easier to think about sort of we're preserving all the structure, and isomorphism is in a sense just a relabeling, if you're in the context of group theory. Just relabeling the elements but it ends up being the same group or something".

In summary, while there was only the formal definition cluster of metaphors used to justify a homomorphism-first approach (*special homomorphism* and *isomorphism without bijectivity*), there were varied metaphors from all three sameness clusters (sameness, sameness/mapping, sameness/formal definition) justifying an isomorphism-first approach.

Discussion

Prior metaphor-focused work with isomorphism and homomorphism has separately focused on ways people think or on textbooks (Melhuish et al., 2020; Mirin & Rupnow, in press; Rupnow, 2021). Our research expands this work by using metaphors to interpret the instructional decision making of research-active algebraists. One possible direction for future research is to examine mathematics *education* researchers' views on this topic to determine whether their views align with isomorphism first (like textbooks) or homomorphism first (like some of the mathematicians) and see if there are, in fact, differences between these populations' views.

With respect to ordering, while there was some alignment between mathematicians' textbooks and descriptions of instruction, our work demonstrates that this alignment should not be assumed. These particular participants were research-active faculty with experience in algebra beyond their coursework; potentially the text could be more impactful on those who are not research-active in these areas. Nevertheless, this study raises questions about the extent to which upper-level undergraduate textbooks should be viewed as the "intended curriculum" (Fan, 2013; Zhu & Fan, 2006) as opposed to a secondary resource for reexamining material from another perspective. Furthermore, while some research has begun examining how students use dynamic textbooks in upper-level courses (Mesa & Mali, 2020), how faculty want upper-level undergraduate students to engage with textbooks remains understudied.

With respect to rationales, we saw dominant metaphor clusters for each ordering. Those who preferred to teach homomorphism first referred to the logic-based relationship between isomorphism and homomorphism encoded in their formal definitions (*special homomorphism* and *isomorphism without bijectivity* metaphors) for justification. In contrast, those who preferred to teach isomorphism first drew on sameness-based metaphors such as *generic sameness*, *matching*, *renaming/relabeling*, *classification*, *logical equivalence*, and *structure-preservation,* which together relate to all three sameness-based clusters. Thus, despite differences of opinion on which ordering is best, the participants displayed consistency in the rationale for each choice. While we acknowledge that choosing participants from respondents to a survey about sameness might lead to expectations that they would talk about sameness to justify their thinking, we note that not all participants spoke about sameness, and none used it to justify homomorphism-first. Future research should examine the extent to which these findings generalize.

WHAT FACTORS CONTRIBUTE TO STUDENT SUCCESS IN PRECALCULUS FLIPPED CLASSROOMS

Florence F Obielodan

jiwonson@buffalo.edu

Flipped instruction has been flaunted as a pedagogical strategy that supports improved learning and retentive abilities of students. Nevertheless, one of the twin challenges reported in the literature, students' failing to complete preparatory work, impedes the efficacy of the model. Thus, learners' motivation and attitude to work are essential for the successful implementation of the constructivist learning-centric approach. Yet very few studies have examined the connections between students' motivation and achievement goals in flipped instruction. To address the current gap, this study investigated the relationship between students' motivation beliefs, flipped method, and achievement in precalculus using pre- and post-course surveys collected from 32 undergraduates. Both motivation beliefs and flipped instruction influenced academic achievement positively in the course and were moderated by students' efforts.

Keywords: Flipped instruction, precalculus, motivation beliefs,

The literature on undergraduate education in science, technology, engineering, and mathematics (STEM) indicated that mathematics, especially, calculus prevents many students from pursuing a career in STEM (Almeida, Queiruga-Dios, & Cáceres, 2021; Bressoud, 2015; Rasmussen et al., 2019; Sande & Reiser, 2018). Prior research faulted inadequate preparation at high school (Bressoud, Camp, & Teague, 2017; Sadler & Sonnert, 2016) and subpar teaching methods (Gilboy, Heinerichs, & Pazzaglia, 2015; Rasmussen et al., 2019). Thus, educators continue to explore active learner-centered strategies to provide individualized instructions for each student (Blumberg, 2008; Weimer, 2012). The flipped instruction method embodies this description.

The current study investigated the contributions of the flipped strategy on students' perceived motivation to learn precalculus, an extensive and rather demanding course with a high failure rate but required for success in calculus (Bressoud, 2021). Many of the students enrolled in the college precalculus have taken the course in high school, but often struggle to comprehend the course content and become unmotivated to pursue success (Bressoud et al., 2017; Sadler & Sonnert, 2016). Comparative studies have been conducted on the efficacy of flipped instruction in secondary and postsecondary courses by comparing students' performances in courses taught using flipped instruction with the same taught using the lecture method (Love, Hodge, Grandgenett, & Swift, 2014; Pattanaphanchai, 2019). However, research on the flipped strategy remained underexplored; particularly, the role of motivation on achievement goals in a flipped instruction setting. We aimed to contribute to the literature by examining the relationship between the components of motivation beliefs. We also examined how preference for flipped instruction affected students' cognitive processes and learning achievement in the course. The following research questions are used in this study:

1. What are the relationships between the components of students' motivation beliefs including expectancy beliefs, perceived value, the cost of and preference for learning precalculus in a flipped instruction?
2. To what extent do effort, motivation beliefs and preference for the flipped instructional method contribute to students' overall academic success in a flipped college precalculus course?

Research on Flipped Instruction

Flipped instruction is a constructivist learning-centric approach (Araujo, Otten, & Birisci, 2017; Gilboy et al., 2015) that provides learners the opportunities to construct knowledge of content independently and through collaborative efforts for effective learning, increased engagement, improved academic performance, and better retention (Araujo et al., 2017; Clark, 2015; Graziano & Hall, 2017; Love et al., 2014). The model involves moving all or part of content delivery outside of the classroom by having students watch video lectures and/or read assigned texts at home, while class time is used for discussions and problem-solving to promote conceptual understanding (Nielsen, Bean, & Larsen, 2018). The didactic approach promotes effective learning through the construction and reconstruction of content knowledge (Gilboy et al., 2015; Love et al., 2015). This is to say students have two attempts at learning concepts: first, independently before class, and again during class under the tutelage of the teachers and through collaborative learning with peers. However, motivation is crucial for academic success in a flipped instruction setting (Huang & Hong, 2016; Zainuddin, 2018), where the onus of learning is more student-centered. Yet, limited studies explored the direct connection between students' motivation (Zainuddin, 2018), including their ability beliefs, expectancy for success, interest and perceived value of learning, and the effort needed to succeed (Barron & Hulleman, 2015) in a flipped instruction.

Despite the enumerated benefits, a commonly reported limitation in the literature is inadequate pre-class preparations, especially failing to watch lecture videos (Araujo et al., 2017). Others are resistance to change due to increased student and teacher workload, time constraint (Araujo et al., 2017), difficulty of learning tasks (Clark, 2015; Graziano & Hall, 2017), and inability for students to receive immediate feedback during out-of-class activities (Chen, Wang, Kinhuk, & Chen, 2014). Empirical data revealed that curriculum, task difficulty, and test anxiety, correlate with students' effort and perceived beliefs of their ability to successfully complete a task (Almeida et al., 2021; Barron & Hulleman, 2015; Wigfield, 1994). Although the flipped instruction method is supportive of multiple higher-order-thinking learning strategies (Akçayır & Akçayır, 2018), the same could lead to an increased psychological state of the student and impede their academic success rather than improve it (Barron & Hulleman, 2015; Flake, Barron, Hulleman, McCoach, & Welsh, 2015). Consequently, learning achievement is dependent on the extent to which students can relate novel situations to prior learning (Dawson, Meadows, & Haffie, 2010), motivation, and the effort committed to learning content.

Several studies revealed that students have positive attitudes toward the flipped instruction approach (Clark, 2015; Graziano & Hall, 2017; Pattanaphanchai, 2019). Nonetheless, their positive perceptions about the model did not necessarily translate into learning gains. This is an indication that other factors may be influencing the achievement of desired outcomes. Thus, this study examined the role of student's motivation beliefs and commitment to learning achievement regardless of challenges experienced. While several studies have used qualitative research approaches to explore the efficacy of flipped instruction, the current study utilized quantitative method to investigate the relationship between components of undergraduates' motivation beliefs and efforts to learn content in a flipped college precalculus course.

Theoretical Framework: Expectancy-Value-Cost Theory

Achievement theorists postulated that individual's actions and inactions, including their decisions and determinations to succeed, are driven by subjective beliefs about their abilities, expectancies for success, interest, and perceived value of the desired outcome, and preferences (Wigfield & Eccles, 2000). The Expectancy-Value-Cost (EVC) theory of motivation (Barron & Hulleman, 2015) is an extension of the Expectancy-Value (EV) theory, which has been reviewed extensively by theorists in the achievement traditions (Barron & Hulleman, 2015; Getty et al., 2017). However, the cost component of the EVC model is a relatively novel field of study (Barron & Hulleman, 2015; Getty et al., 2017). The component exists because of the limitation of the EV theory at explaining why an individual with excellent expectancy and a strong perception of the utility of certain tasks, would fall short of achievement. It was inferred that other factors like the difficulty of the task, discouragement, embarrassment, related and unrelated efforts required for success were not accounted for by the EV theory (Barron & Hulleman, 2015; Flake, Barron, Hulleman, McCoach, & Welsh, 2015).

Cost, deemed as the forgotten component of the EV theory (Flake et al., 2015), was originally introduced as a subcomponent of the value component (Wigfield, 1994; Wigfield & Eccles, 2000) and was hypothesized to moderate the effect of the value component on an individual's motivation beliefs and achievement goals (Barron &Hulleman, 2015; Flake et al., 2015; Wigfield & Eccles, 2000). Cost, a barrier-related construct, is multi-dimensional and focuses on what an individual must sacrifice to achieve success (Wigfield, 1994). The construct elucidates negative appraisal of time and effort related to the task, outside of task effort, loss of valued alternatives, and emotional cost of success (Flake et al., 2015). Thus, the cost component is a negative predictor of success and mitigates the effect of both expectancy and value.

Eccles and colleagues (1983) (cited in Wigfield & Eccles, 2000) postulate the expectancy component as a two-dimension construct comprised of ability beliefs and expectancies for success (Wigfield, 1994; Wigfield & Eccles, 2000). Ability beliefs pertain to what the student perceives he or she can do now, while expectancy beliefs are apropos for the future. In this study, we focus on students' perception of their present ability to succeed at learning precalculus in a flipped classroom. Because passing the course and retention in college are utmost for first-year students who already viewed the remedial course as a setback (Kane et al., 2020).

The value component focuses on students' beliefs about the importance and interest of the task and provides answers to the questions: "Do I want to do this task?" and "Why am I doing this task?" (Barron &Hulleman, 2015). The component is described as having four subcomponents including intrinsic value, (student enjoys watching lecture videos because it is fun and interesting), utility value (actively learning precalculus because it is required for desired major), attainment value (passing the course allow students to move to Calculus I and be on track for timely graduation) and cost a negative predictor of the overall value of tasks. The same has now become the third component of the EVC theory (Barron & Hulleman, 2015; Getty et al., 2017). In this study, the EVC theory as defined by Barron and Hulleman (2015) was used to explain and interpret the data collected about the effect of students' expectancies, perceived values, and cost implications, as well as preference for the flipped instructional approach on their academic success.

Methods

The current study used observational methodology to examine students' expectancy beliefs, perceived values, and the cost of learning the content in a flipped college precalculus course. The cross-sectional study utilized data from self-reported surveys.

Participants and Data Collection

Data was collected in a flipped college Precalculus course in a four-year college in the Midwestern region of the United States during the fall 2019 semester using motivation scale. Thirty-two students (7 females and 25 males) representing 71% of the students taught that semester using the flipped method participated in the study. The participants self-registered for the course, although they are unaware of the teacher's planned teaching method. Most of the participants (82%) took Precalculus in High School and 49% reported taking Calculus. All participants indicated interest in pursuing a major in STEM-related disciplines.

Research Instrument

Students responded to two online surveys (pre-course and post-course) during the first and last week of the semester, respectively. The main component of the surveys consisted of eight motivation-related items adapted from Expectancy-Value-Cost Scale (EVC-S) (Getty et al., 2017; Kosovich, Hulleman, Barron, & Getty, 2015), and four researchers-created items to measure students' perceived liking for flipped instruction. The 12 ordinal items were theorized to measure motivation beliefs and likability for the flipped instructional strategy.

EVC-S, which was developed, field-tested, and validated is novel and had reliable psychometric properties (Getty et al., 2017; Kosovich et al., 2015). For example, a rapid version of the scale consisted of three subscales with three items measuring *Expectancy* ($\alpha = \omega = 0.82$), three measuring *Value* ($\alpha = \omega = 0.84$, and four items to measure the *cost* ($\alpha = \omega = 0.83$) subscale (Getty et al., 2017). To keep our instrument short, we dropped two of the original items, one from expectancy, and reworded a statement to combine two items from the cost subscale into one while still preserving the intended meaning of both constructs. The adapted research instrument was validated to ensure its consistency with the original EVC-scale and to determine the reliability and validity of the additional items. The following constructs were addressed.

Expectancy. This subscale focused on self-confidence, that is, the importance of believing in one's ability to succeed on a task (Barron & Hulleman, 2015; Kosovich et al., 2015; Wigfield & Eccles, 2000). Expectancy included two items (*I am sure, I can learn the material for Precalculus;* and *I am confident that I can do well in Precalculus this semester*) with a reliability coefficient of $\alpha = 0.89$.

Value. The value subscale addressed the reasons why the students would want to engage in certain actions or achieve academic success. The value subscale contained three items focused on understanding students' perceptions of the importance and personal interest for learning Precalculus, (e.g., "*Precalculus is an interesting course*," "*Precalculus is useful to me*," etc.). The value subscale had a reliability of 0.77.

Cost. The cost subscale addressed "what is invested, required, or forgone engaging in a task" (Flake et al., 2017; p.235). The construct was hypothesized to influence motivation through effort and time related and unrelated to the task, the loss of valued alternative, and negative effect (Barron & Hulleman, 2015; Flake et al., 2017; Getty et al., 2017). There were three cost items including, *I have to sacrifice too many things to do well in Precalculus, etc.* with a reliability of $\alpha = 0.88$.

Preference for Flipped Method Subscale. The remaining four were researcher-created items to measure students' preference for the flipped method. This was based on a study by

Sahin, Cavlazoglu, & Zeytuncu (2015) with calculus students. The authors investigated students' views and experience in flipped courses, and the impacts on their academic achievement, when compared with non-flipped classes. Sahin and colleagues found that students preferred watching class videos to reading their textbook and preferred courses with lecture videos. On this premise, we developed the following four questions to verify the validity of their claims. Q9-*I am sure I will learn more in a flipped instruction*; Q10-*I prefer a course with video lessons to a course without video lessons*; Q11-*I like the flexibility of choosing how I learn the course content in this course*; and Q12- *the syllabus helped me understand the goals and expectations of this course*. The last question was later dropped due to low factor loading. The subscale had a reliability of 0.92.

All responses were rated on a 5-point scale where 1 = strongly agree and 5 = strongly disagree. We recoded positively worded statements. Overall, there were 57 (pre-course = 29 and post-course = 28) usable survey data from both surveys before multiple imputations.

Data Analysis

Based on the EVC theoretical perspective as well as a review of relevant studies, the study utilized structural equation modeling (SEM) (Schumacker & Lomax, 2016) to examine the relationship between components of students' motivation and to determine predictive abilities of effort, flipped instruction method, and motivation beliefs on academic success in Precalculus.

A two-steps full-SEM (Anderson & Gerbing, 1988) in Lisrel 11 software (Jöreskog & Sörbom, 2021) is used to analyze the predictive abilities of motivation beliefs and preference for flipped instruction on academic success in a college Precalculus course. The statistical technique which combines both measurement and path analyses was selected because of its ability to explain the causal relationships between and among the latent and observed variables (Schumacker & Lomax, 2016). The measurement part was used to verify the existence of the study's latent variables (*expectancy, value, cost, preference, effort, and success*) and to determine whether the latent variables can be explained by the observed variables (using responses from the self-reported questionnaires). The structural model postulates the relationships between the variables, including the strength and direction of the causal relationships as follows. *Effort* was measured by the number of time students logged in to watch lecture videos (*Watch-Video*) is theorized to explained academic success (Dweck & Yeager, 2019; Flake et al., 2017). We hypothesized that the observed variables would measure *expectancy, value, cost*, and *preference* for the flipped method. Then *expectancy, value,* and *cost* were conjectured to measure motivation beliefs (Getty et al., 2017), and preference measured the use of the flipped method (Sahin et al., 2015). Both second-order factors would then have positive effects on *academic success* (measured by *grades*) and moderated by *effort* as shown in figure 1, the hypothetical model.

Considering our sample size, we generated values in LISREL for the first order latent variables and used them in higher-order analysis, thereby reducing the number of estimated parameters.

Several fit indices were used to assess the adequacy of the proposed model based on recommendations of Schumacker and Lomax (2016). The model was evaluated using the following indices: (a) Comparative Fit Index (CFI), (b) Goodness of Fit Index (GFI), (c) Normed Fit Index (NFI), (d) the Root Mean Square of Approximation (RMSEA), and (e) Chi-square test ($\chi 2$). The recommended cut-off that indicates a good fit for CFI, GFI, and NFI is 0.90 or higher. A non-significant chi-square is desired indicating a close fit and RMSEA values less 0.08 represents a good fit (Hu & Bentler, 1999; Schumacker & Lomax, 2016).

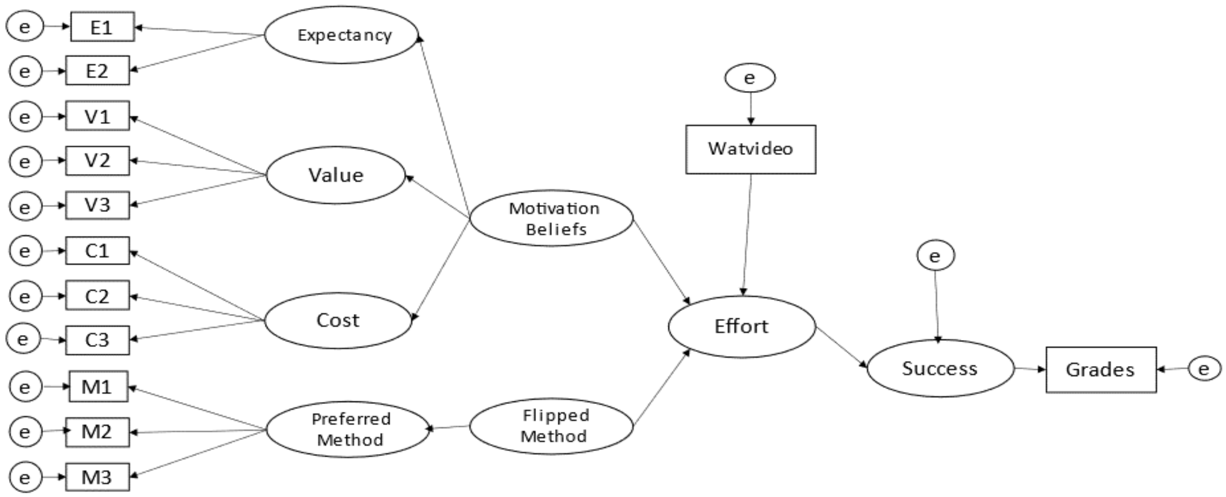

Figure 1: Research **Model**

Results

This study examined whether college students who report high expectancies and values for success would also report a higher preference for the flipped method. Using confirmatory factor analysis (CFA), we also tested whether there is a direct effect of students' motivation beliefs and flipped instruction on success moderated by students' efforts (measured by the number of logins to watch prerecorded lecture videos). Table 1 presents the direct, indirect, and total effects between motivation beliefs, preference for the flipped instructional method and students' overall academic success in a flipped college precalculus course. Figure 2 specifically shows direct effect of students' motivation beliefs (expectancy, subjective values, and cost beliefs) and flipped instruction (high preference for the method) on success (grades) moderated by students' efforts (measured by the number of logins to watch prerecorded lecture videos).

Table 1: Direct, indirect, and total effects of variables on Academic Success

Variable	Direct effect	Indirect effect	Total effect
Motivation Beliefs	0.126	-0.022	0.105
Method	**0.085**	-0.059	0.026
Effort	**-0.220**		-0.220

First, it was revealed that students who reported high *expectancy* for success also reported high *value* and are favorably disposed to learning in a flipped instruction (see Table 1). However, *effort* had a negative influence on success in the course, thereby moderating the effect of motivation and method on achievement as theorized.

Next, to determine the strengths and directions of each factor in relation to learning achievement, we further analyzed how well the hypothesized model fit our data. Figure 2 shows that the collected data supported a four-factors solution, which validates and extends the EVC theory to include preference for specific cause, in this case, flipped method.

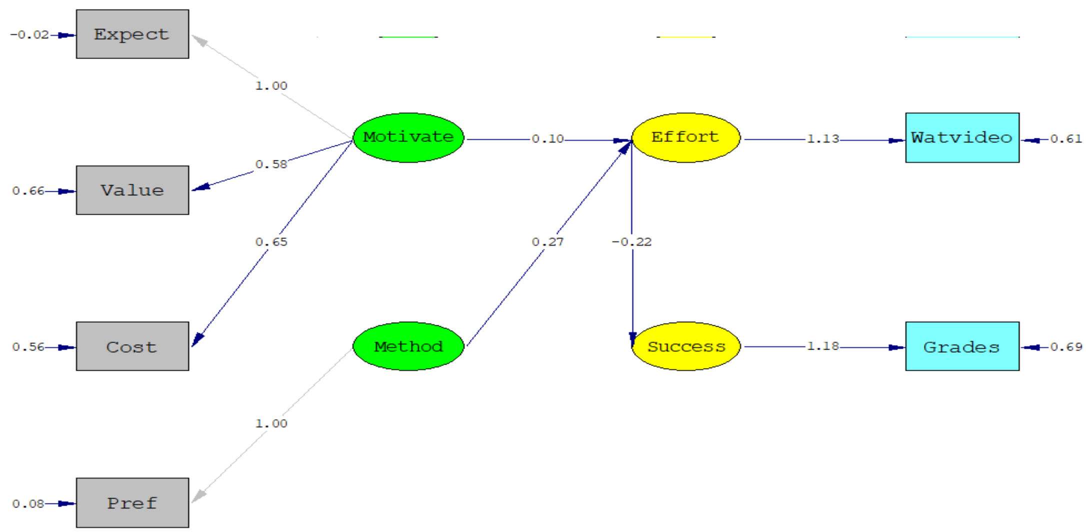

Figure 2: Analytical Model

The correlations between the factors ranges from moderate to strong positive relationship except the connection between *Grades* and *Watch-Videos* (r = -0.017, p >0.05). There is a direct effect of students' motivation beliefs (expectancy, subjective values, and cost beliefs) and flipped instruction (high preference for the method) on success (grades) moderated by students' efforts (measured by the number of logins to watch prerecorded lecture videos). As shown in Figure 2, the measurement model fits the data well showing that all indicator variables each explained only one latent variable as hypothesized. All the fit indices except RMSEA were within acceptable ranges ($\chi^2(3) = 5.29, p > 0.05$, RMSEA = 0.11, NFI = 0.94, and CFI =0.97, GFI = 0.97). Both motivation beliefs and flipped method contributed positively to success, although the significance of the paths could not be determined. The fit indices remained unchanged with the addition of the structural paths. The findings show that a combination of preferred method and motivation would lead to academic success by jointly explaining about 11% of the variations in success and 33% of students' effort. Conversely, students' commitment to learning (*Effort*) contributed negatively to success. Possible explanations may include poor learning retentions, or students may be watching the lecture just to check boxes and could become overconfident since the content is somewhat familiar. The significant error variances of *Watvideo* and *Grades* are indications that the latent variables were influenced by other confounding variables than the hypothesized indicators.

Discussion and Conclusion

We found that students who reported high *expectancy* for success also reported high *value* and are favorably disposed to learning in a flipped instruction. This finding can be supported by prior research studies (e.g., Kosovich et al., 2015; Getty et al., 2017). Yet, different from Barron and Hulleman (2015), we found positive, and significant relationships between cost and both expectancy and value. Furthermore, students' preference toward flipped method was an excellent indicator for the effective implementation of flipped instruction. We noted that a direct relationship existed between motivation and success and between flipped method and success. This may not be surprising, because motivation plays a significant role in human's achievement of desirable goals (Dweck & Yeager, 2019). Several studies found flipped instruction useful for promoting deep learning (Akçayır & Akçayır, 2018; Araujo et al., 2017; Graziano & Hall, 2017;

Huang & Hong, 2016; Zainuddin, 2018); but none considered the effect of personal preference for the model. This study shows that a combination of preferred method and motivation jointly explained about 11% of the variations in success and 33% of students' effort. Conversely, students' commitment to learn (*Effort*) contributed negatively to success needing further research.

Considering students' motivation and preference when selecting teaching methods could improve learning and achievement, the findings of this study provide teachers with tools to educate, inspire, and involve students in how they learn (e.g., freedom to choose based on personal preference). This study also addresses research gaps on motivation and effectiveness of flipped instruction. A few limitations should be noted, such as the small sample size, lack of diversity of instructors, subjects, and learner groups. More research and replications are needed to substantiate the study's findings.

BELIEFS OF TEACHING ASSISTANTS IN AN INTRODUCTORY PROOF COURSE

T. Royce Olarte	Micah Swartz	Sarah A. Roberts
University of California Santa Barbara	Texas State University	University of California Santa Barbara
tolarte@ucsb.edu	mas762@txstate.edu	sroberts@education.ucsb.edu

This study examined the beliefs that teaching assistants (TAs) of an introductory proof course had about their students, about how their students learned, about their teaching, and about mathematics. We sought to examine TAs' beliefs and better understand their approaches to teaching and instruction. Five mathematics TAs participated in the study and we qualitatively analyzed their responses to semi-structured interviews. We found that TAs understood that their students learned in various ways and they believed they should be able to support students' multiple ways of engaging with proofs. They also understood that introductory proof courses necessitate higher levels of cognitive demand and that many students struggle in these courses. Our preliminary findings can inform future efforts that more critically examine the beliefs of mathematics teaching assistants.

Keywords: Beliefs, Values, Teaching Assistants, Higher Education, Proof Courses

Introduction

Mathematics teachers' beliefs about their students, how their students learn, the mathematics content they are teaching, and their roles in engaging students in learning experiences are fundamental to shaping their instructional practices (e.g., Pajares, 1992; Wilkins, 2008; Goldin et al., 2009). However, there is still limited work that examines the beliefs of the individuals involved in undergraduate mathematics education - particularly, those of mathematics graduate students who serve as teaching assistants (TAs). What graduate students believe about students, learning, and the teaching of mathematics not only impacts their current roles as TAs, but are foundational to many continuing on to be mathematics faculty. In this exploratory study, we examined the beliefs of teaching assistants of an introductory proof course called Math A. Introductory proof courses mark a critical junction in the mathematical trajectories of many students. Proof-construction poses significant challenges for many students (Weber, 2001), because the problem-solving experiences and sensemaking demands associated with proof-construction are unlike those of courses such as calculus and linear algebra. Thus, TAs play important roles in supporting student learning and understanding as they transition to upper division mathematics courses that heavily rely on proof-construction competencies. It is important that we better understand what mathematics TAs believe about students, learning, and teaching at this important junction as it can inform how higher education institutions and mathematics departments can better support graduate students' pedagogies. The research question that guided this study was: How did mathematics teaching assistants reflect on their beliefs about students, learning, teaching, and mathematics in an introductory proof course?

Literature Review and Framing

Research on teachers' beliefs has evolved over the past decades. From behaviorism to cognitive science, research has investigated teachers' behaviors and the ways in which teachers think, perceive, and analyze their practices (Calderhead, 1996). While their subject matter knowledge, specialized content knowledge and pedagogical content knowledge are important aspects of teaching (Ball et al., 2008), what teachers believe about mathematics, teaching, and learning may have a greater influence on their instructional practices (Bryan, 2012). Research has illuminated that the knowledge teachers view as important and appropriate is impacted and molded by their beliefs (Pajares, 1992). Additionally, prior scholars have suggested that exploring beliefs can be a tool to understand how teachers make choices (Ernest, 1989) and how they filter new knowledge (Fives & Buehl, 2010). We take up beliefs to be the conceptions, convictions, and values that can shape and impact how one teaches and learns (Thompson, 1984; Thompson, 1992).

In this study, we adapted the work of Speer (2001) that connected teaching assistants' beliefs to their teaching practices in reform-oriented calculus courses. Speer (2001) described teaching assistants' *belief profiles* to encompass what the teaching assistants believed about their students (e.g., "Students should be independent."), what they believed about teaching (e.g., "Teachers should be guides who ask students questions."), what they believed about learning (e.g., "Learning is making something your own."), and what they believed about mathematics (e.g., "Calculus entails learning to think and acquiring skills but does not showcase the beauty of mathematics."). We situate this framework in the context of introductory proof courses to better understand what TAs believe about students and their pedagogical practices at this important mathematical junction.

Method

This study was conducted within a larger project at a Minority-Serving Institution in California about transfer students' experiences in a set of mathematics courses designed to develop proof-construction competencies and support their transition to a four-year university. Purposeful sampling (Creswell, 2013) was used to select five graduate students who were teaching assistants for an introductory proof course, Math A, that was part of this set of courses. The participants were 2nd- and 3rd- year doctoral students in the mathematics department and all had prior experiences as teaching assistants. We use the pseudonyms Federico, Nestor, Wyatt, Kaitlyn, and Lisa to refer to the five TAs interviewed for this research project. We qualitatively analyzed their responses to semi-structured interviews (Rubin & Rubin, 2011). We used the following a priori codes (Miles et al., 2020) derived from the work of Speer (2001) to categorize their beliefs: (1) beliefs about students, (2) beliefs about how students learn, (3) beliefs about how they should teach and engage students in mathematics, and (4) beliefs about mathematics. This last code encompassed their beliefs about mathematics in general and their beliefs related to introductory-proof-courses. The research team wrote memos and discussed important themes in the TAs reflections.

Findings

We present preliminary findings that highlight the four dimensions of the TAs' belief profiles. Broadly, TAs believed that students learn in various ways and that collaborative work in safe learning environments supports student learning. We observed a range of TAs' beliefs from positioning students as competent and capable to having some deficit perspectives about their engagement. They also expressed certain beliefs unique to the context of and circumstances around introductory-proof courses (e.g., it is a course mainly for mathematics majors, it is the gatekeeper to upper division courses, etc.).

TAs' Beliefs About Students

The TAs revealed a multitude of beliefs about their students broadly centering around students' capabilities and their backgrounds. For example, Wyatt noticed the diversity of students in Math A, noting: "I can tell you from my experience with teaching Math A, they're [students of color] equally capable, equally hard working." Wyatt held the belief that all students are equally capable of succeeding in Math A. This view of students contrasted Nestor's view that "if you have someone from a different culture, you know, like especially Chinese students, if you pair them up with American students, maybe it's going to be hard for them to engage." Nestor believed that students from different cultures may struggle to engage and work collaboratively with students in the dominant population, which reflects a deficit perspective of the minority students. We acknowledge that TAs may not be regularly engaging in critical reflections of their beliefs about students, but it is important to explore these beliefs, identify deficit perspectives, and then work to reframe these beliefs.

TAs' Beliefs About How Students Learn

TAs' beliefs about how students learn were related to their beliefs about pedagogical practices and departmental logistics. Firstly, TAs' expressed the belief that students are unique learners and that they engage in mathematics differently. Regarding the content students are presented with, Lisa mentioned, "student[s] won't get a deep understanding unless there's like this, you know, do the easy examples, try to do a hard interesting example." This illustrates Lisa's belief about the importance of giving students problems with varying levels of cognitive demand. She also described the value of contextualizing problems so that students can better engage with the material they are learning. Additionally, Wyatt expressed his belief about student learning when he said, "I think that the undergraduate students are better served when the class sizes are smaller." He explained that students work best in small class sizes as well as collaborative work environments. Wyatt highlighted his belief that group work was crucial in helping students learn and understand the material. We observed numerous instances of TAs indicating that students learn best in community and in safe environments, as well as the belief that students benefit from contextualized, cognitively demanding tasks.

TAs' Beliefs About Teaching

Broadly, the participants believed that their pedagogical practices should be responsive to the various ways their students learned. Wyatt mentioned, "As a TA, you have to put students first…You have to accommodate multiple ways of thinking." Here, we not only observe a student-centered approach to pedagogy but also an attention to the idea that there is not one set way to learn mathematics. We also found that TAs believed that qualities such as flexibility, personability, and approachability should guide their interactions with students. Creating a comfortable learning environment was especially important for the participants and many described efforts to create this comfortable learning environment during their sections. Kaitlyn said, "You don't want anybody to feel like they, you know, can't ask something or stupid questions or whatever. You want them to feel comfortable." Furthermore, Kaitlyn and Nestor identified that using judgmental and derogatory language to respond to students' questions is one way that can disrupt a safe and comfortable learning environment. Overall, participants' beliefs about teaching centered on attending to students' different ways of learning mathematics and ensuring that students feel comfortable and safe to take intellectual risks.

TAs' Beliefs About Mathematics

The TAs believed that the content of introductory proof courses necessitate higher levels of cognitive demand that may be unfamiliar to students and that these courses not only delineate lower division and upper division courses, but also distinguish mathematics majors from non-mathematics majors. Kaitlyn said, "There's also an intensity that comes with Math A that maybe make students feel a little bit more, I don't know, fearful about doing perfect in the class or whatever." She illustrated the frequently held belief amongst the participants that Math A is extremely challenging and intimidating for students. Federico explicitly understood introductory proof courses to be junctions that mark mathematics majors continuing to upper division courses and he mentioned enjoying opportunities to interact and engage with these students because he can provide them with advice relevant to their academic trajectories. Lastly, regarding overall beliefs about mathematics, the participants understood mathematics to be a creative discipline. Wyatt said, “If you want people to enjoy, you gotta have them recognize it's extremely creative and there are many, many ways to get to the destination.” Wyatt contended the commonly held notion of mathematics as a rigid and overly procedural discipline and instead, upholds a belief that mathematics is creative and more open-ended.

Discussion and Conclusion

Consistent with the literature (e.g., Pajares, 1992), we found connections between TAs’ beliefs about students, how students learn, and their understanding of pedagogy. TAs understood that students learn in distinct ways and that they should be responsive to these differences. Furthermore, they believed that fostering a safe learning community affords intellectual risk taking. They recognized that introductory proof courses mark a distinction in the cognitive demands of the content as well as in the demographics of students in subsequent courses. It is imperative to highlight that some TAs held deficit views of students and these may have subconsciously shaped their instructional practices. With teacher beliefs informing pedagogical practices (e.g., Ernest, 1989; Speer, 2001), we argue that TAs of introductory proof courses need to be more reflective of their beliefs as they support students at this significant mathematical junction. Limitations of this study include the limited number of participants and a more general conception of beliefs. Future research should more closely examine TAs’ beliefs through a critical lens - focusing on dimensions of their beliefs that intersect with important critical, transformative frameworks (e.g., critical race theories, antiracist education, queer theories, gender theories, etc.). Our findings shed light on the diversity of TAs’ beliefs and their approaches to pedagogy, and this can inform institutions about more equity-centered and social justice-oriented professional development opportunities for graduate students.

GRADUATE TEACHING ASSISTANTS’ ENGAGEMENT OF STUDENTS’ ERRORS

Jungeun Park
University of Delaware
jungeun@udel.edu

Graduate Teaching Assistants (TAs) play an important role in undergraduate students’ learning of mathematics, especially Calculus, and spend significant time evaluating students’ work. This study examined TAs’ engagement of students’ errors by following the process of their identifying students’ errors, planning to address them, and implementing the plans in teaching. Our results showed that (a) TAs only identified a small portion of errors that students made, (b) errors TAs identified often did not include the ones made most frequently by their students, (c) many errors that TAs identify were procedural in nature and addressed with plans to provide the “correct” procedure, (d) the levels of specific details of students’ errors dropped from identifying, to planning, to teaching, and (e) even with drops, in many cases, the levels of details of students’ errors involved in TAs’ identifying was the same as the levels of their planning and teaching.

Keywords: Calculus, Undergraduate Education, Professional Development

Graduate Teaching Assistants (TAs) play crucial roles in teaching and learning of entry-level undergraduate mathematics including Calculus (American Association for the Advancement of Science (AAAS), 2019). In many U.S. universities, TAs directly impact students’ learning of Calculus (Ellis, 2014) through their class, office hours, and tutoring centers. However, our knowledge about TAs and their teaching is still limited (AAAS, 2019). Given that TAs usually spent a large amount of time grading students’ written work, we investigated if and how they engage with students’ errors in various phases of teaching. We followed the process of TAs’ identifying of students’ errors, planning how to address them, and implementing the plans in class to address the following research questions: (a) *To what extent do TAs identify students’ errors while grading students’ work on problems?* (b) *To what extent are the specifics of students’ errors used in TAs’ plans to address them and their teaching of the problems in class?*

In this study we analyzed the levels of specific details of students’ errors that TAs engaged with in their identifying, planning, and teaching. Our analysis shows the types of errors that TAs identified from students’ work, and how they used them in planning and classroom teaching.

Theoretical Background

Using students’ errors in teaching has been studied mainly at K-12 levels, but also at the college level. Those studies examined the attributes and the quality of teachers’ response to errors (Bray, 2011; Santagana & Bray, 2016); various ways of engaging with students’ errors (e.g., Ingram et al., 2015; Tulis, 2013); impact of error-handling PD on teachers’ view of using students’ errors (Brodie, 2014); teachers’ in-the-moment error handling (e.g., Ingram et al., 2015; Schleppenbach et al., 2007). In this study, we view students’ errors as sources of difficulty students experience in their learning of mathematics, that are systematic and persistent, (Brodie, 2014) which may not be quickly corrected (Ingram et al., 2015). Addressing errors in teaching is important because errors can offer students opportunities to view questions from different angles, allow teachers to reflect on their students’ thinking, and emphasize mathematical aspects related to the errors (Santagana & Bray, 2016; Van de Pol et al., 2011). This study represents beginning efforts to understand TAs’ engagement with student error throughout several phases of teaching by exposing TAs to students’ difficulties about the content *before* they teach students. Several studies suggested, in general, three steps that teachers go through while dealing with students' errors: perceiving errors (identifying), looking for reasons for errors (interpreting), and planning instructional approaches to help students "overcome the misconception" regarding errors (planning) (Heinrichs & Kaiser, 2008, p. 84). Those studies emphasized the use of specifics of students' errors and making instructional plans to address students' errors (Biza, et al., 2018; Heinrichs & Kaiser, 2008). Building on these studies, we analyzed TAs' engagement with errors regarding the levels of specificity in identifying, planning, and classroom teaching. Given that TAs often have little teaching-related background, we did not include "interpreting" as part of our design, but we added their classroom teaching to observe how they implemented their plans.

Research Design

Participants

Our study was conducted in a single-variable calculus course at a large public university in the U.S. The course is offered as coordinated lectures taught by faculty instructors for 100-150 students with discussion sections taught by TAs for 25-30 students. In the discussion sections, TAs mainly solve problems from the textbooks and review the concepts that were covered in lectures. All five TAs who taught the discussion sections voluntarily participated in this study. All TAs had one semester of experience teaching discussion sections before participating in the study, but two of them taught the course before as an instructor of record before they joined the mathematics PhD program at the institution. Prior to our study, they received general instructions about their teaching responsibility, did a 5-minute teaching demo, and received feedback from faculty, but had not received any training on how to use students' work or errors in teaching.

Problem Development and Analysis of Students' Responses

The author with extensive research experience in teaching and learning of Calculus, who has been working on PD for TAs at their institution by incorporating what they learned from the national effort to improve PD for TAs (e.g., MAA, 2022), conducted the study in collaboration with other mathematicians and graduate students. We developed 8 calculus problems from online resources (CLEAR Calculus, 2021; The Better File Cabinet, n.d.) and widely-used textbooks (Bressoud et al., 2013). We collected students' responses on the problems from the TAs' classes. We identified the errors in student responses and grouped them into error types (i.e., codes) regarding mathematical components such as functions, limit, and derivative. For each problem, we used a table to record the number of codes we identified from each TA's classroom and the number of corresponding errors for each of the codes. We also grouped the codes regarding their nature: (a) How to compute or graph (How to), (b) Meaning of mathematical objects or their relationships (Meaning or Relationship), and (c) Missing mathematical components or properties (Missing Component). For each problem, we used a table to record the number of codes from each TAs' classroom that belonged to each nature and the number of corresponding errors.

Data Collection on TAs' Identifying, Planning, and Teaching

For each problem, we ask TAs to grade their students' responses, and record students' difficulties that they identified and plans to address them in a Google Docs shared with the researchers. Although there might in principle be differences between what TAs considered as students' difficulties and what the researchers considered as error types, most difficulties that the TAs identified easily matched with the codes we developed. We also video-recorded TAs' teaching of the problems.

Analysis of TAs' identifying, Planning, Teaching

We first identified codes matched with students' difficulties that TAs submitted. For each problem we recorded the number of those codes and the number of errors corresponding to each of the codes. We then computed the percentages of those numbers in comparison to the number of codes and the number of errors that we identified from the TA's student responses. We did the same computation of the percentages in terms of the three natures of error types described above.

We then analyzed the level at which TAs used students' error types (codes) in their identifying according to the specific details of the error type that were involved as following:

- Robust: Identifying error types with specific mathematical aspects they are regarding.
- Limited: Stating general categories of error types regarding derivative components or their nature without to student work or mentioning they saw students' work in class.
- No-Data: TA does not fill out Google Docs or no mention of students' error in class

For planning, we used the following levels:

- Robust: Incorporating students' work in their plan suggesting extra representations/ problems, or alternative approaches, and revisit mathematical aspects of the errors.
- Limited: Planning to address limited aspects of student errors with extra examples/ representations or by providing correct statements/answers that student work violated.
- No-data: TA does not fill out Google Docs

For teaching, we used the same levels that we used with planning with additional subcategories for the limited level such as pointing out the part of students' solution that was incorrect, or explaining what students should or should not do in terms of solving the problem.

Results

TAs' Identifying Students' Errors

We made several important observations from the types of errors TAs identified. First, the average percentage of error types that each TA identified relative to what we, the researchers, identified ranged from 10~33%, and the average percentage of corresponding errors relative to what we identified ranged from 7~25%. A closer look at TAs' identifying shows that the error types that they identified are limited in terms of frequencies and the natures. Regarding the frequency, the error types that they identified are often made by only 1 or 2 students in their class where there were other error types made by 3 or more students (frequent error types) that they did not identify. The average percentage of each TA identifying frequent error types ranged from 8%~44% across the 8 problems. This means that 56%~92% of the frequent error types were not identified by TAs, thus not addressed in class. Moreover, among 39 TA-problem combinations (5 TAs and 8 problems except one due to missing data), only in 14 combinations, did TAs identify the most frequent error type that their students made. Among the other 25 combinations where TAs missed such error types, in 18 combinations the most frequent error types were found in 5 or more students' work, and in 14 combinations, they were found in 7 or more students' work. Regarding the natures of error types, we found that many error types that TAs identified were procedural in nature. Compared to what we identified, we found that they identified How-to error types and the corresponding errors (about 60% in both) much more frequently then Meaning-or-Relationship (about 30% in both) or Missing-Component (about 10% in both) types.

Levels TAs' Identifying, Planning, and Teaching

As a total of 58 error types that the TAs identified, 37 were at the robust level and 21 were at the limited level. When we look at the combination of identifying levels with the natures of error types, the prevalence of How-to error types become more obvious. Among 39 How-to error types that they identified, 27 (about 70%) were at the robust level, but less than half Meaning-and-Relationship error types (7 among 15) were at the robust level.

Among 56 TAs' submitted plans, 24 were at the robust level and 32 were at the limited level. The most common robust planning categories were providing extra examples/representations that address mathematical aspects of error types, and most common limited plans were providing correct answers/statements students' solutions violated. We also found that most of identifying-playing pairs have the same levels. 22 identifying-planning pairs were both at the robust level, and 18 identifying-planning pairs were both at the limited level. However, we observed a noticeable drop in the details of students' errors used from identifying to planning. There were 14 robust-identifying and limited-planning pairs. Most of those cases involved How-to error types and TAs' plan to address them with the correct procedures or mathematical statements.

Among 58 error types that TAs identified, 41 were used in their teaching. Among 41, 23 were used at the robust level, and 18 were used at the limited level. We observed that a large number of TAs' identifying-and-planning pairs were at the same level. Similarly, a large number of their identifying and teaching pairs was at the same level. However, we also noticed that there were 16 error types that TAs identified and planned to address, but did not address in their classroom teaching. Most of those error types were procedural (How-to) in nature, which the TAs planned to address by providing the correct procedures. In such cases, TAs teaching was similar to a solution that one may find in a solution manure without any evidence that they used students' errors.

Discussion and Conclusions

Our results indicate important considerations for professional development (PD) for TAs. First, we observed that the TAs' identifying of students' errors could improve; the error types they identified were a relatively small portion of what the researchers identified from their students work, and in most problems, they missed the error types that were made by most students in their class. There may be various reasons for this, such as what TAs consider important in teaching mathematics or previous student work that they encountered. However, TAs' focusing on not-frequent error types means TAs are potentially spending time on content that is not helping many students in their class, and suggests that PD could address why focusing on certain errors and possible students' ideas behind them is important in class. Also, a large portion of errors that they identified were procedural in nature. This may be associated with the belief that their primary role is to "work problems so students know how to do them" as some calculus instructors or TAs indicated in Ellis (2014a, p. 94), or with what they believe a goal of teaching calculus to be (e.g., teaching students patterns of how to solve problems) as some U.S. TAs indicated in Kim (2014). However, given that students also made a significant number of errors of other natures, such as "mathematical meanings and relationships", future PD should provide opportunities for TAs to attend to and engage with these types of errors as well.

Second, we observed that the levels of details of student errors involved in identifying, planning, and teaching in general were same although there were a significant number of drops in level. These observations suggest that their ability to identify students' errors needs more attention than their ability to plan and implement the plans to address errors that they identified, but there is room for improvement in all the aspects. Explicitly asking TAs to identify prominent errors from student work may help them to focus on those errors. PD could help them understand errors from students' point of view and engage with errors of various natures throughout several phase of teaching to reduce drops in levels. These suggestions are aligned with other suggestions that PD for TAs should emphasize. The nationally held MAA (2022) workshop for improving PD for TAs included intensive discussions and practices on understanding and interpreting student work including systematic errors. Our aim is to help TAs engage with student errors to provide responsive teaching to students' mathematical needs in their learning.

USE OF SIGNIFIERS IN MATHEMATICAL DISCOURSE IN KOREAN AND ENGLISH

Jungeun Park
University of Delaware
jungeun@udel.edu

Douglas Rizzolo
University of Delaware
drizzolo@udel.edu

We consider how the existence of different signifiers for mathematical objects in different languages manifests in discourse about those objects. Based on the observation that there is a common signifier "derivative" in English used for both the derivative at a point and the derivative function and two phonetically and semantically different signifiers for those objects in Korean, we explore the differences between one Korean teacher's discourse and one American teacher's discourse about the derivative. Our analysis uncovered differences in metarules regarding the use of signifiers, as well as differences in possible connections to colloquial discourse. Additionally, we found that, after both objects are defined, the American teacher's discourse shifts in a way that precludes the simultaneous use of the common signifier for both objects whereas, in the Korean teacher's discourse, there was no similar shift.

Keywords: commognition, derivative, calculus, mathematical object, realization tree

Recently, the impact of the language in which mathematics is practiced on mathematical discourse has been emphasized. Examining students' or teachers' uses of mathematical words is an important part in this literature (e.g., Kim et al., 2012; Han & Ginsburg, 2001). Our study examines uses of terms in mathematical discourse in different languages in an effort to understand the language-dependent nature of the discourse. We focused on the discourse about the derivative in Korean and American English (English, here after), which provides a useful context for the study. The derivative is a crucial concept in Calculus and needed for multiple disciplines. Commonly, within introductory calculus, derivatives can be separated into the derivative at a point and the derivative function. By "the derivative function" we mean a function obtained by differentiating another function. Studies have addressed challenges students face distinguishing or relating these objects (Font & Contreras, 2008; Font et al., 2007; Park, 2013).

We take a commognitive perspective (Sfard, 2008) to examine discourse on the derivative at a point, the derivative function, and the narratives connecting these objects. In the commognitive approach to mathematics education, "learning mathematics is the process in which students extends their discursive repertoire by individualizing the historically established discourse called mathematics" (Sfard, 2018, p. 222). Individualizing a discourse essentially means developing one's ability to communicate with others and oneself according to the rules of the discourse. In each language, we will refer to the historically established discourse called mathematics as the canonic discourse. As Kim et al. (2012) noted, from the commognitive perspective, one should not expect mathematical discourse in different languages to be homeomorphic. Thus, one should expect differences in the canonic discourses in different languages. From this perspective, differences in canonic discourses are differences in what students are trying to individualize.

The motivation for our study is the observation that in English, the word "derivative" is included in "the derivative at a point" and "the derivative function" and the word "derivative" alone is often used for these objects, while in Korean the phonetically and semantically different terms "mi-bun-gye-su" and "do-ham-su" are used respectively for the corresponding objects and there is no common term like "derivative" that can be used for either object. Thus, this difference between English and Korean is a difference in the canonic discourses of the two languages.

While the non-homeomorphic nature of mathematical discourse in different languages has been investigated from the student perspective, to our knowledge, our study is the first to focus on differences caused by differences within the canonic discourses. In contrast to previous studies that focus on aspects of students' discourse that one would expect students to outgrow as they attain proficiency (e.g., Favilli et al., 2013; Han & Ginsburg, 2001; Kim et al., 2012; Miller & Stigler, 1987; Paik & Mix, 2003), we consider a different aspect of language-dependency in which one language has a common term for two different but related objects and the other does not, which results in a difference in the mathematics that students in each language are trying to learn. This is an important difference to investigate because several researchers have suggested that one term/notation being used for multiple objects creates challenges for teaching and learning about those objects in different mathematical discourses (e.g., inverse in algebra or discrete mathematics, Thompson & Rubenstein, 2000; tangent line in geometry and analysis, Biza & Zachariades, 2010). Especially, multiple uses of one term in the same discourse are hard to communicate with students (e.g., limit as a number and limit as a process in (Güçler, 2013)).

To investigate the differences in the canonic discourses, we examined one Korean mathematics teacher's classroom discourse and one American teacher's classroom discourse considering those teachers as participants in the canonic discourse in Korean and English, respectively, and addressed the following research question: *What are the differences between canonic discourse in English and Korean that can be observed based on an American mathematics teacher's discourse involving a common word "derivative" and a Korean mathematics teacher's discourse involving two words "mi-bun-gye-su" and "do-ham-su"?*

Based on the comparison between two teachers' discursive characteristics, we learned about the differences between canonic discourse in each language regarding metarules about word use, in relationships between canonic discourse and colloquial discourse, and in ways mathematical objects were connected. We adopted a case study approach because it allows researchers to "closely examine the data in a specific context" (Zainal, 2007, p. 1) and many recent mathematics education studies that examine teachers' discursive characteristics through in-depth analysis adopted a case study approach (e.g., González, 2015; Kontorovich, 2021). A limitation of our approach is that it may not find all of the differences between the canonic discourses or identify which differences would be most commonly observed in a large sample of classrooms. However, in-depth engagement with one teacher's discourse involving the specific terminologies of interest in each language, which a case study allows, was needed for researchers to explore mathematical discourse in each language "in action" and compare potential differences. To make our inference about differences in the canonic discourses in each language valid we followed case study design guidelines from Check and Schutt (2017), Rubin and Rubin (1995 & 2005), and Zainal (2007). We carefully chose teachers whose discourse would allow us to learn about differences in canonic discourse in each language and collected data that would enlighten us about the connections between mathematical objects made within the canonic discourse and its connection with colloquial discourse in each language. We then produced a chain of evidence about the differences in the canonic discourses in each language based on our analysis of the data from holistic point of view by examining their discourse following commognitive research guidelines from e.g., Kontorovich (2021), Nachlieli & Tabach (2012) and Sfard (2008 & 2012).

Theoretical Background

Prior Work on Differences in Mathematical Discourses in Different Languages

The commognitive framework has been used in several settings to examine the dependence of mathematical discourse on language. This conceptual and discourse-analysis framework combines cognition and communication. It asserts that thinking is communicating with oneself and views mathematics as a type of discourse. Commognition makes the language-dependent nature of mathematics almost self-evident because languages are the medium for communicating (Kim et al., 2012), which makes it a natural framework for studying such dependence.

Language studies using the commognitive framework have focused on the discourse of students. For example, Kim et al. (2012) used this framework to study differences between students' discourses about infinity in Korean and English based on phonetic and semantic disconnections between "Korean formal mathematical discourse in infinity and its informal, colloquial predecessor" and "the cohesiveness of the infinity discourse" in colloquial and formal discourse in English (p. 95). Ní Ríordáin (2013) adopts the commognitive framework, discussing how, theoretically, the syntactical structures of Irish "lend itself to easier interpretation of mathematical meaning in comparison to English" (pp. 1581-1582), which was supported empirically by the later study (Ní Ríordáin & Flanagan, 2020).

Outside of the commognitive literature, if one views the ability to correctly solve problems as a proxy for fluency in a discourse, there is a long history of investigating phenomena similar to what Ní Ríordáin and Flanagan (2020) investigated. For example, some of these studies considered the feature of Asian language terms stating mathematical concepts clearly, such as part-whole relations in fraction words, which is not a feature in other languages (e.g., English) as an explanation for Asian-language speaking students' higher performance regarding those concepts (Han & Ginsburg, 2001; Miller & Stigler, 1987; Miura, 1987; Miura et al., 1999).

Most of these studies focus on, or give insight into, phenomena within student discourse that students are intended to outgrow as they become proficient participants in the canonic discourse. In contrast, our study considers differences within the canonic discourses, which therefore will become present and persist after students become fluent in the canonic discourse.

Canonic and Teacher Discourse

From the commognitive perspective, a discourse is a "special type of communication made distinct by its repertoire of admissible actions and the way these actions are paired with re-actions" (Sfard, 2008, p. 297). Canonic discourse can be difficult to identify in general because it is historically established by practice. Thus, we grounded our identification of canonic discourse in content that has broad, objectively observable acceptance. In particular, we decided to use widely accepted curricula as the basis for identifying the canonic discourse in Korea and the United States. In Korea calculus is part of the national high school mathematics curriculum set by the Korean government (Ministry of Education, 2020), which also reviews and approves high school textbooks. In the United States there is no similar nationally controlled curriculum for calculus. Rather, there is the Advanced Placement Calculus AB curriculum set by the College Board (2020), which is a private company. Although privately set, Advanced Placement (AP) Calculus courses are taught in many high schools (public and private) and high school students may receive college credit at many colleges (including highly ranked ones like Harvard University) by scoring well on the standardized AP Calculus AB Exam at the end of each year. From this, we conclude that the AP Calculus curriculum is broadly accepted in the United States. We consider certified teachers who teach these curricula to be among the participants in the canonic discourse of their country and selected our participants from among this group.

Within the commognitive framework, teaching can be defined as "the communicational activity the motive of which is to bring the learners' discourse closer to a canonic discourse" (Tabach & Nachlieli, 2016, p.303). This view is consistent with other discursive approaches. For example, as reviewed in Schutte (2018), Pimm (1987) sees learning mathematics as similar to learning a foreign language, which is both written and spoken language which has to be used extensively within the mathematics classroom, and views the teacher as similar to a “native speaker” in a new language (p. 26). Therefore, the mathematical discourse of qualified teachers teaching courses that follow broadly accepted curricula is likely to provide examples of canonic discourse, with the understanding that teachers may occasionally include non-canonic discourse through making mistakes or adopting idiosyncratic discourse in the process of trying to bring students’ discourse closer to the canonic discourse. In practice, this essentially means that, with the exception of occasional mistakes or adoptions of idiosyncratic discourse, we treat the mathematical statements endorsed as correct by qualified teachers as though they would be endorsed as correct by other qualified teachers and others who have mastered the content of the broadly accepted curriculum. We remark that the discourse of different participants in the canonic discourse may vary dramatically, see e.g. Moschkovich (2007) about the differences between academic and school discourse, but the hallmark of discourse being canonic is that it would be endorsed as correct by other participants in the canonic discourse.

Methods

This study uses teachers’ discourse in each language to learn about canonic calculus discourse in English and Korean. As noted in the introduction, we adopted a case study approach to conduct an in-depth analysis. This section details the research design with our rationale to produce valid conclusions through our selection of participants, data collection, and analysis.

Participants

To ensure the validity of our choice of teachers in terms of addressing our research question, our recruiting of teachers was guided by strategies for purposive sampling in which participants are selected for a purpose (Rubin & Rubin, 1995, as cited in Check & Schutt, 2017), such as “knowledgeable about…the situation…being studied,” and “willing to talk” with “a range of” view points” (p. 20). In selecting the American teacher, we discussed our study with faculty at a midsized U.S. university, who work at a center that organizes professional development (PD) for mathematics teachers. Of the teachers they recommended, William was recommended as the best “potential” participant given that William has taught Calculus multiple times, been engaged in PD for mathematics education, and participated in the design of the state-wide mathematics tests. William was also “willing to talk” about the subject of our study and to open their classroom being observed. We operationalized “the range of points of view” as using various communicational means in their teaching, especially including a range of representations and terminology in the mathematical context of our study. William described how they usually teach the topic of the study with the intention of using mathematical terms and concepts rigorously, as well as utilizing a variety of real-life contexts and mathematical representations (e.g. graphical and symbolic), which fit our operationalization of the third point. In selecting the Korean teacher, we considered Korean mathematics teachers from mathematics education master’s programs at highly regarded universities in Korea and also considered Korean high school teachers who attended calculus related talks at the International Congress on Mathematical Education that happened in South Korea. Kim was an experienced high school mathematics teacher, who passed a highly competitive national test to become a secondary public school teacher, taught Calculus over several years, and was also a master’s student in mathematics education. Kim also engaged in PD and taught in a mathematics program for gifted students.

Aligned with our conception of canonic discourse, the class we observed William teaching was an AP Calculus AB course in a public high school in the U.S. The Korean class we observed was a public high school course in Korea that followed the national curriculum.

Students in both classes were native speakers of the language of instruction. In general, the teachers organized their class with explanations of key words, solving examples on the board, students' individual work on problems, and then whole class discussions about the problems the they had solved. The teachers' discourse observed in their explanations and their interaction with students helped us understand how the key words of our interest were used in each language.

Data Collection

Class observations occurred at the beginning of the derivative unit before the class concentrated on computing the derivative. This part of their class was chosen to collect the relevant data for the teacher's discourse where we could potentially observe two uses of the "derivative" in English, where "mi-bun-gye-su" and "do-ham-su" were defined and connected to each other in Korean, and where other related words and real-life phenomena were discussed.

The first author video-recorded seven 50-minute lessons from Kim's class and six 90-minute lessons from William's class from the back of the classroom. There is a difference in length of the video-recorded lessons. Kim's discourse stayed related to the mathematical objects of the lesson whereas William's class included various non-mathematical discourses (e.g., information about AP exams) and reviewing of topics irrelevant to this study (e.g., computing limits), for which we did not find direct connections to our study. We included all derivative-related talk, and approximately, 400 minutes of relevant discourse were recorded in William's class.

Once the recording was completed, the first author (who is fluent in English and Korean), one Korean-speaking research assistant, and one English-speaking research assistant transcribed the videos focusing on what is said as well as what is done (non-verbal communication) following the guidelines from Sfard (2008) for transcribing the recorded data. Once the data was transcribed, the first author translated the Korean transcripts into English. A sample from the translations was checked by another mathematics education researcher who is fluent in English and Korean. Both authors reviewed the transcripts to check the match between the video data and the transcripts and added screen shots from the videos to complement "what is done".

Analysis

Our analysis of the teachers' discourse was guided by the principles of commognitive research (Kontorovich, 2021; Nachlieli& Tabach, 2012; Sfard, 2008 & 2012). In our analysis, we treated the totality of each teacher's discourse, collected over multiple days, as our unit of analysis. However, we separated lessons into several episodes to see how words were used in different contexts. Episodes were defined by each teacher's different teaching activities. Specifically, each episode was determined by completing a mathematical task, defining a new mathematical term, providing a story involving a real-life object prior to defining a mathematical term, making connections between a newly defined term and previously defined terms, or making connections between a newly defined term and a real-life object. Episodes were defined this way because changes in teaching activities correspond to changes in the context of discourse and, therefore, to potential changes in usage of words whose meaning is context-dependent (Biza & Zachariades, 2010; Thompson & Rubenstein, 2000), like "derivative" in English. Following this definition, we identified 57 episodes in Kim's class and 54 episodes in William's class.

With our interest in linguistic differences related to the signifiers "derivative" in English and "mi-bun-gye-su" and "do-ham-su" in Korean, we needed to identify the mathematical objects that these signifiers signified in each teachers' discourse. It was done based on the formalization of the derivative as a mathematical object in the commognitive framework as in (Park, 2016). After this, we examined the coded data focusing on how the derivative at a point and the derivative function were connected. Once the objects in each teacher's individualized discourse were identified, we coded each episode according to the objects and primary signifiers used to determined which objects appeared in each episode regarding how those language-specific terms were used. For example, for William's episodes, we distinguished (a) episodes in which "derivative" is used as (or as part of) a signifier for those two objects (showing the common use of the "derivative" for the two objects) from (b) episodes in which both objects signified by "derivative" appeared but in which "derivative" was only used as (or as part of) a signifier for at most one of these objects (not showing the common use of the "derivative"). Each author individually coded each of William's uses of "derivative" as described above. The coding originally matched, except for 2 episodes which were discussed until agreement was reached. The English translation of the Korean data was reviewed by another Korean and English speaking commognitive researcher, and the English-translated Korean data and English data were analyzed through discussions among the authors, one of whom is a native English speaker.

Results

Our analysis leads to three main results. First, the canonic discourse in English (AMD) contains metarules for distinguishing whether the signifier "derivative" is being used for the derivative at a point or the derivative function that has no analogue in the canonic discourse in Korean (KMD). On four occasions William provided the following rule for distinguishing the two uses of derivative: If context shows the object signified by "derivative" is a number, "derivative" is signifying the derivative at a point, and if context shows the object signified by "derivative" is a function, "derivative" is signifying the derivative function. He said, for example

> This idea of, well the derivative can be thought of as a number, which represents the slope of the tangent line at a point. But, notice that I can talk about slope of the function at every point along this curve…the slope is always changing. Now, what we get then, is a function that represents the slope of the tangent line at any point on here, as a function of x…That's called the derivative too. From the context, you understand what I'm talking about…just remember now we're talking about numbers and we're talking about functions, and we have to keep them straight. Then we get into the other half of Calc 1 and talk about integrals. There will be the same thing. There will be some integrals that are numbers, some integrals that are functions. We use the same words because the concepts are related (Day 2, 6 minutes)

One would expect that participants in AMD have some way for distinguishing between the two uses of "derivative". Thus, the existence of such metarules is not surprising, but their existence shows that the differences between AMD and KMD extend beyond simply having a different signifier structure. We concluded that this rule is part of the canonic discourse, in addition to William being a participant in the canonic discourse, because it combines two statements from the canonic discourse (that the derivative at a point is a number and that the derivative function is a function) with the generally applicable rule that one can try to use context to infer the meaning of a word that potentially has multiple meanings. We thus believe that this metarule would be endorsed by the other participants in the canonic discourse. This metarule of AMD has no counterpart in KMD because there is no signifier in KMD whose use must be distinguished.

Second, when teaching in English, one can use the fact that "derivative" is a signifier of two objects in AMD to make connections to the colloquial discourse in English for which there are no analogous connections between KMD and colloquial discourse in Korean. For example, William used "speed" in colloquial stories about reading changing numbers on a speedometer to motivate the construction of the derivative function as follows,

> As I start out on my trip, how fast am I going?...Pretty fast!…As I travel along, what is happening to the slope or my instantaneous velocity sort of thing, instantaneous rate of change? It is going down right?… I have a whole succession of changing speeds or changing rate of changes…Let's say…I have a flea, following this line and the flea has a rate of change meter on. It's the speedometer! So, he's traveling along the line, this number is changing all the time. Now, I- (Slamming hands against the board) squash the flea at one point. That number is frozen…That number I'm gonna use as the slope, and that line (drawing the tangent line at the point)…that's what we call the tangent line…that keeps visible that slope or that instantaneous rate of change at that point (Day 1, 37 minutes)

In colloquial discourse (in both Korean and English), "speed" behaves like "derivative" in AMD in the sense that it can be used as a number or as an (informal) function of time. Thus, in an English-speaking class, a teacher could explicitly recall this dual use of speed and then explain that "derivative" works in the same way students are familiar with "speed" working and, from context, one can determine if it is being used as a number or a changing quantity.

Our third result is that William's use of "derivative" shifted after he introduced the derivative function. Specifically, in episodes that only involve the derivative at a point, "derivative" was the dominant signifier used by William for this object. However, in episodes that involved both the derivative at a point and the derivative function, William dominantly used "derivative" as a signifier for the derivative function (56 out of 70 uses) and "slope of the tangent line" as a signifier for the derivative at a point. We did not observe any such shift in Kim's discourse. Rather, Kim routinely used the term "mi-bun-gye-su" to refer to the result of evaluating the "do-ham-su" at a point. Unlike our first two results, which are results about AMD and KMD, this shift depends on William's didactic choices, in particular the choice to primarily use "slope of the tangent line" to signify the result of evaluating the derivative function, and other teachers' discourse may not include such a shift. For example, one could use "derivative" assuming what it is used for would be obvious to students or always use "the derivative at a point" and "the derivative function" to avoid confusion. However, we decided that it is interesting to report because, assuming that people naturally tend to try to communicate clearly, we conjecture that not using one term for different objects in the same context is common in AMD. Similarly, we conjecture that such shifts are uncommon in KMD.

Discussion and Conclusion

In our results, we showed that the differences between the canonic mathematical discourse in English (AMD) and the canonic mathematical discourse in Korean (KMD) extend beyond the fact that AMD has a signifier "derivative" that can be used for two objects while KMD does not have common signifier for both objects. Specifically, we argued that AMD also has metarules for using context to determine which object "derivative" is signifying based on whether the object is a number or a function. Although not every instructor in AMD will necessarily include this metarule in their classroom discourse, we argued that this metarule is part of the canonic discourse, i.e. would be endorsed as correct by other qualified teachers and participants in the canonic discourse, because it combines a statement from the canonic discourse about the difference between the derivative at a point and the derivative function with the general rule that context can be used to determine the meaning of words that have multiple uses. Indeed, it has been found in other contexts that preservice mathematics teachers use context to explain the uses of other mathematical symbols that have multiple meanings (Zazkis & Kontorovich, 2016). Our result further confirms the hypothesis that Kim et al. (2012) put forward that mathematical discourse in different languages is not necessarily homeomorphic. They supported this claim by observing differences in student discourse about infinity, but we have shown differences in both the signifier structure and metarules of the canonic discourses themselves. In addition to adding to our theoretical understanding of the relationships between canonic discourses in different languages, we believe that this has some practical instructional consequences. For example, there are many students from Korea and Japan (signifiers for derivatives in Japanese and Korean are homeomorphic) who go to the U.S. for graduate school and teach calculus. These students may not be expected to know elements of AMD that do not exist in the canonic discourses of their native languages and may not be able to teach these elements to their students.

In addition to providing the metarule for distinguishing the uses of "derivative", William's first quote in Results includes a noteworthy discussion of integrals. The metarule that William provided for the use of "derivative" can be used as an analogy to explain the metarules around the use the signifier "integral" later in the course. In KMD, the terminology around integrals is similar to AMD, there is a signifier for "definite integrals" and signifier for "indefinite integrals" and a signifier like "integral" that can be used for either. However, it cannot be explained by analogy with the use of signifiers around derivatives. This further supports the conclusion of Kim et al. (2012) that "teachers need to be cognizant of those language-specific features of the discourse that may support learning and of those that may hinder successful participation" (p. 106). Because this result pertains only to the existence of certain language-specific features, whose existence we have just demonstrated, it is not limited by our case study methodology.

The discursive shift we observed in William's class, but not in Kim's leads to a theoretical hypothesis about students' learning. From commognitive theory, within higher-mathematics, which features extreme objectification and rigor that is often unfamiliar to students, new students' learning "begins with an exposure to" instructors' discursive practices (Sfard, 2014, p. 202). Then, students start "collaborating across communicational conflict" due to the differences between this new discourse and their old discourse "by observing, and then imitating, the expert's moves while also trying to figure out the reasons", which might be the only way students "come to grips with the objects" at the abstract level (Sfard, 2014, p. 202). A consequence of this is that as students start learning higher-mathematics, their discourse will include imitations of experts' discursive moves and, just as importantly, will not include moves from the canonical discourse that they have not observed (e.g, from their instructor, textbook or other resources). This leads to the hypothesis that students in courses featuring discursive shifts as in William's will initially connect evaluating the "derivative function" with obtaining "the slope of the tangent line" rather than "the derivative at a point", while students in courses like Kim's that do not feature such a shift will initially connect evaluating the "do-ham-su" with obtaining the "mi-bun-gye-su". It would be interesting to investigate whether discursive shifts as in William's class are common and to investigate the effects such shifts have on student learning.

This would be particularly interesting because the literature has shown that the connection between the derivative at a point and the derivative function can be challenging for students (Font & Contreras, 2008; Park, 2013) and implicit shifts in instructor discourse have been tied to student difficulties (Güçler, 2013). Although derivatives have been intensely studied in the literature, we have not seen shifts like the one we discuss documented before. Note, however, that the instructors in (Park, 2015) also dominantly connected "derivative function" to "slope of the of the tangent line" and this leads us to conjecture that this shift may be widespread, but not documented because previous analyses were not looking for such large-scale discursive patterns.

PERSONAL INFERENCES AS WARRANTS OF UNDERGRADUATE STUDENTS' ARGUMENTS IN CALCULUS CONTEXTS

The purpose of this paper is to highlight issues related to students' personal inferences that arise when students verbally explain their justification for calculus statements. We conducted clinical interviews with three undergraduate students who had taken first-semester calculus but had not yet been exposed to formal proof writing activities through undergraduate mathematics courses. We analyzed these students' verbal justification of four statements, each of which described a different relationship between two quantified variables in calculus contexts. In this paper, we document students' personal inferences that were evoked in their justifications and discuss how they are similar to or different from the logical inferences that have been accepted and practiced by the mathematics community for mathematical arguments.

Keywords: Calculus, reasoning and arguments, inferences, Toulmin's model of argumentation.

Reasoning and arguments are foundational aspects of mathematics. NCTM (2000) and Common Core State Standards (2010) have emphasized teaching students in all age groups to develop, evaluate, and use various types of reasoning and methods of mathematical arguments. On the other hand, research in undergraduate mathematics education has reported that students frequently make their arguments on empirical bases (Shipman & Shipman, 2013). Students often believed that examining a few cases would be sufficient as a justification in mathematics (Harel & Sowder, 1998) or stated that both example-based proofs and formal deductive proofs are equally valid (Martin & Harel, 1989). In addition, when reading an argument, students often accept it by ignoring, or without attending to, inferences inherent in the argument (Alcock & Weber, 2005). Dawkins and Zazkis (2021) reported that some students with no experience in mathematical proof construction did not envision proof as an unbroken chain of implications leading from the first line to the last line of an argument. Stylianides et al.'s (2004) study also documented that even undergraduate students who studied mathematics did not accept or use the equivalence between a conditional statement and its contrapositive. A similar phenomenon was also reported in Dawkins et al.'s (2021) study in which students did not conceive of an inference from the contrapositive equivalence in reading an argument and believed that a proof of the contrapositive of a conditional statement would not prove the original conditional statement. Instead, these students accepted an argument directly proving the converse of a conditional statement as a proof of the original conditional statement.

Likewise, we see some gap between students' personal inferences, as utilized in their proof-writing or validating others' arguments, and logical inferences, as accepted and practiced by the mathematics community. In this paper, we examine if such a gap still exists when students verbally express their arguments. Focusing on three undergraduate students who had not yet taken proof-oriented mathematics courses at university levels, we address the following research question: *What are the types of personal inferences that students naturally use, and how do they use their personal inferences as warrants to support their claims in calculus contexts*?

Theoretical Perspective

By *personal inference,* we mean an act or process that an individual draws to make a claim from things that are known to him or her. We consider students' personal inferences through the lens of radical constructivism (Glasersfeld, 1995). From this perspective, we assume that students' inferences consist of sets of action schemes which are built and refined through their experience. Students' inferences are personal, in this view, as their unique experiences have shaped the ways they support arguments. Even if students have not yet experienced reading or constructing formal mathematical proofs, they would have made inferences for their arguments through their experience. These personal inferences may or may not align with what the mathematics community considers conventional valid logical inference rules such as modus ponens, modus tollens, or various syllogisms. Additionally, from this perspective, we as researchers are limited to what we can access about students' personal inferences. At best, we can only hope to model students' personal inferences. Further, we acknowledge that the tasks used in this study may have evoked only some of the ways in which students may use personal inference to support their claims when making arguments. In other words, we do not intend to document all of a student's personal inferences. Rather, in this paper, we highlight the students' personal inferences that were *evoked* by the context and task.

We also adopt Toulmin's (2003) model of argumentation to further refine our consideration of students' personal inferences. Toulmin's (2003) model, shown in Figure 1, includes data, a claim, and warrants. In his model of argumentation, an individual perceives data, and formulates a claim, which is a conclusion made based on data. The warrant refers to the justification that the individual uses to explain how the data support the claim. In this paper, we focus on students' personal inferences as warrant types. These personal inferences (warrants) are embedded in their arguments as they justify their own data-based claims.

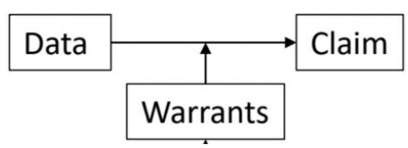

Figure 1: Toulmin's model of argumentation (2003)

Research Methodology

The data for this paper are from a more extensive study (e.g., David et al., 2019, 2020; Sellers et al., 2021). In that study, we conducted individual clinical interviews (Clement, 2000) with nine students at a large public university in the USA. This paper focuses on three students, Marie, Zack, and Hannah (pseudonyms), who had completed a first-semester calculus course but had not yet taken any proof-oriented mathematics courses. Each author of this paper served as an interviewer, witness, or researcher analyzing these students' personal inferences from their verbal justification of statements in a calculus context.

The main tasks implemented during the clinical interviews and relevant to this paper are about four statements as follows:

S1: Suppose f is a continuous function on the closed interval $[a, b]$, where $f(a) \neq f(b)$. Then for all real numbers c in (a, b), there exists a real number N between $f(a)$ and $f(b)$ such that $f(c) = N$.

S2: Suppose f is a continuous function on the closed interval $[a, b]$, where $f(a) \neq f(b)$. Then for all real numbers N between $f(a)$ and $f(b)$, there exists a real number c in (a, b) such that $f(c) = N$.

S3: Suppose f is a continuous function on the closed interval $[a, b]$, where $f(a) \neq f(b)$. Then there exists a real number N between $f(a)$ and $f(b)$ such that for all real numbers c in (a, b), $f(c) = N$.

S4: Suppose f is a continuous function on the closed interval $[a, b]$, where $f(a) \neq f(b)$. Then there exists a real number c in (a, b) such that for all real numbers N between $f(a)$ and $f(b)$, $f(c) = N$.

These four statements are similar in that they are all conditional statements with the same premise, and their conclusions describe a relationship between two quantified variables, *c* and *N*. On the other hand, each of their conclusions represents different relationships between the two quantified variables. The S2 (a version of the Intermediate Value Theorem, ITV) is the only true statement among the four statements.

Without informing the students that S2 is the IVT statement, the interviewer first showed one statement at a time. Each student was then asked to interpret each statement in their own words, evaluate whether it is true or false, and explain how they could tell. Grid paper was also provided for those who wanted to sketch their example functions during the interviews. Once a student completed his/her evaluation of the four statements, the interviewer showed all four statements together and asked to compare and review their evaluations of these statements altogether.

Based on the students' utterances, gestures, and diagrams that they produced to explain their reasoning, we modeled students' arguments regarding how they would tell whether the given statements are true or false. In particular, we used Toulmin's (2003) framework to identify what students perceive (data) from the statement, their evaluation of the truth-value of the statement (claim), and how they support their claims from their data (warrants). Two types of warrants emerged from our process of analyzing students' responses to the interviewer's question about how they could determine the truth-value of the statement. One type of warrants that we found was related to students' meaning or construal of calculus concepts or their properties. Their reference to a working definition for functions and continuous functions is an example that we classified as this type of meaning-based warrants. On the other hand, the other warrants were not content-specific and were rather general rules or principles that students could apply to any content area in moving from data to claim in their arguments. In this paper, we focus on the second type of warrants, i.e., students' personal inferences that these students used as warrant types in their arguments.

Results

While some of the students changed their evaluation of the statements, all three students determined S1-S4 as true statements in their final evaluation. Thus, we identified the *claims* in these students' arguments as identical to "the statement is true" across all four statements. On the other hand, there were differences in what constituted data of each student argument as they perceived different things from the given statements. There were also differences in their personal inferences as ways in which they justified their claims about the statements' truth. In the following subsections, we present these differences in the students' *data* and detail personal inferences that the students utilized as warrants in their arguments.

Marie's Use of Biconditional Elimination and Generalization from a Particular

To support her claim that S1 is true, Marie drew a graph of a function f (see Fig. 2). She then explained that her function f is continuous on $[a, b]$ because of no holes or jumps on the graph of f. She also explained $f(a) \neq f(b)$ because $f(a) < 0$ and $f(b) > 0$. She then picked a value of c between a and b $(a < b)$ on the x-axis and then confirmed that its corresponding function value $f(c)$ is between $f(a)$ and $f(b)$ and thus N is between $f(a)$ and $f(b)$, which seemed sufficient for her to conclude S1 is true. Referring to the same graph, Marie described her reasoning about the other three statements, S2-S4, in a similar way. For instance, explaining her reasoning about S2, she said, "So N is gonna be in between here [$f(a)$] and here [$f(b)$]. And then c is gonna be in between a and b. (long pause) Okay, so N is in between $f(b)$ and $f(a)$, and because it's continuous, c is gonna be in between a and b." Here, we found what she perceived from the given statements was her graph of a continuous function f where $f(a) \neq f(b)$. Thus, we identified her graph as *data* in her arguments.

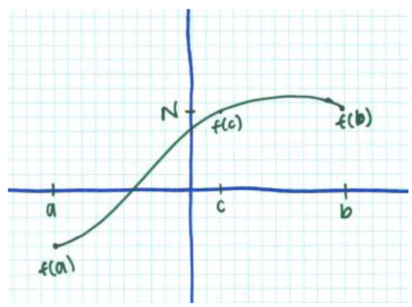

Figure 2: Marie's graph

Marie mainly used two inferences to support her claims. Her first personal inference is what is called *biconditional elimination*, $[(p \leftrightarrow p') \wedge p'] \rightarrow p$, in the conventional logic. Her use of this inference appeared when she replaced or substituted the premise and conclusion of the given statement to her own interpretation of them, respectively. In the case of S2, Marie interpreted the premise of the statement as a description of a function with no holes or jumps on its graph, and the conclusion as a description of the input of the function to be between a and b and the output of the function to be between $f(a)$ and $f(b)$. At the moment when she substituted the conclusion to these two conditions about where the input and outputs are contained, Marie neglected the quantifier words 'there exists' and 'for all.' Consequently, her interpretation of the conclusion of all four statements S1-S4 became the same. Although Marie used normatively biconditional elimination as her personal inference, her reasoning entailed invalid arguments as her evoked meaning from the given statements was not equivalent to the conclusions.

There was another inference Marie used across her arguments during the interview, which is what we refer to as a *generalization from a particular*[1], $P(x_o) \rightarrow (\forall x, P(x))$. Her function f (Fig. 2) was merely an example that satisfied her evoked meaning of the given statements. However, she drew a claim that the statements are true from this particular example. Generalization from a particular is not a valid inference in conventional mathematical logic.

1 We detailed in Sellers et al. (2021) that generalization from a particular may be connected to students' quantifications.

Zack's Use of Conjunction Elimination, Existential Instantiation, & Hypothetical Syllogism

During Zack's interpretation of S1, the interviewer recommended that he draw a graph of a function. In response, Zack drew a graph of a linear function with a positive slope (see Fig. 3) because the graph "is just simple so I can imagine myself." However, Zack described that "f will be anything, any type of a graph." In fact, he did not make his arguments based on this particular graph. His way of using a graph for illustration purposes was thus distinct from Marie's use of a graph for generalization from a particular.

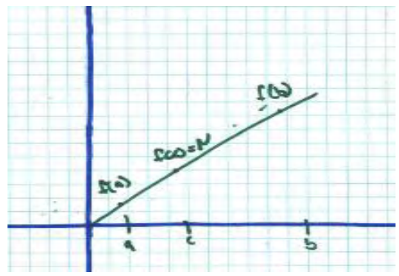

Figure 3: Zack's graph

Zack repeatedly pointed out a functional relationship between inputs and their corresponding outputs. Specifically, he started with *a*, *b*, and *c* as inputs and then described $f(a), f(b), f(c)$ as the corresponding outputs of a function, respectively. Zack's action-related explanation indicates that he mainly focused on the functional relationship between *c* and *N*. We thus identify his construal of such a functional relationship as *data* of his arguments. See the transcript below for his focus on the functional relationship.

> Zack on S1: When I put $f(a)$, we get that here (marks $f(a)$ on the graph) [...] $f(b)$ somewhere here (marks $f(b)$ on the graph). And then, [...] I would show it [*c*] over here (between *a* and *b* on the *x*-axis). I would hope it [$f(c)$] would be on the same line in between the interval from a to b ($f(a)$ and $f(b)$ in his graph, Fig. 3). That [$f(c)$] is a real number and exists right here (between $f(a)$ and $f(b)$). Now it [$f(c)$] will be like N.

We noticed that Zack leveraged the functional relationship that he was envisioning (i.e., *data*) to claim that the truth value for S1 and S2 are the same. Zack attended to the quantifier words such as "for all" and "there exists" and the order differences between quantified variables c and N in each statement. However, his attendance to such syntactic differences between the given statements was insufficient to evoke a different construal from each statement. For instance, he explained that "this one [S2] is almost a converse statement of the previous [S1]. I think the previous [S1] was asking if N existed, and this one [S2] is asking if c existed. So, I will say this statement 2 is true." His wording here also supports our model of data in his arguments that he perceived the functional relationship between *c* and *N*.

Zack used several inferences to warrant his arguments to his claims that all four statements are true, and they were often compatible with normative inferences. First, he examined only the functional relationship but excluded the other conditions from the premise of the statements, such as f being continuous and $f(a) \neq f(b)$[2]. We consider he subconsciously used what is called *conjunction elimination* ($p \wedge q \rightarrow p$) in conventional logic. His use of this inference

2 David et al. (2019) documented Zack's ways of thinking about the outputs of a function as spatial locations in grid paper, which explains why he excluded the condition $f(a) \neq f(b)$ from his interpretation of the premise because to him it is always the case for all functions.

differed from Marie's use of biconditional elimination: Marie replaced or substituted a condition to another as she treated them as equivalent, whereas Zack excluded some conditions from the given statement.

We also noted from Zack's explanation on S1 that he did not treat *N* as another label for an output $f(c)$, or use *N* to refer to the output value $f(c)$, until he checked that $f(c)$ is between $f(a)$ and $f(b)$. He said, "That [$f(c)$] is a real number and exists right here (between $f(a)$ and $f(b)$). Now it [$f(c)$] will be like N." Zack's wording here indicates that he labeled the output value $f(c)$ as N as a way to justify the existence of *N*. Once Zack showed the existence of *N* from his work on S1, he used both $f(c)$ and N to refer to the output value for the specific input value *c* in explaining S2-S4. We consider his labeling of *N* here as evidence of his use of what is called *existential instantiation* in conventional logic, i.e., $(x_0 \in X \ \wedge P(x_0)) \Longrightarrow (\exists x \in X(P(x))$. This inference is one of the conventional logical rules that are predominantly used in mathematics as a warrant while proving an existentially quantified statement. However, such an inference will unlikely be students' personal inference if they do not attend to the existential quantifier, as shown in Marie's case. Thus, it is noteworthy that Zack exhibited existential instantiation as his personal inference in his arguments.

Finally, we found that Zack used a chain of inferences when he used his evaluation of S1 to determine the other three statements S2-S4 to be true: He first compared the conclusion of S1 with the conclusion of S2 and insisted that if the conclusion of S1 is true, then the conclusion of S2 is true. Using his earlier justification regarding the conclusion of S1 to be true, he contended that the conclusion of S2 is also true. We consider it as an example of his use of a *logical syllogism* $([(p \to q) \wedge (q \to r)] \to (p \to r))$ in a normative way. On the other hand, he did not provide any further warrant to support his first inference between the conclusions of S1 and S2. He just said "there is no logical reasoning behind" in his action of choosing *N* first and then choosing *c* when thinking about the conclusion of S2, and he could do the other way "choosing *c* first and then choosing *N*" as he was thinking about the conclusion of S1. To him, the conclusions of all four statements represent the same functional relationship in which c is an input and $f(c)$, or N, is its corresponding output. Consequently, while Zack used conventional inferences normatively in his arguments, his arguments were often invalid because he construed only the functional relationship from all four statements.

Hannah's Use of Universal Generalization, Modus Ponens, & Modus Inverse

When the interviewer asked Hannah to evaluate S1, she drew a graph of a function as an example of a continuous function (Fig. 4, left). Hannah also drew two more graphs for discontinuous functions, which contained either a hole or a jump (Fig. 4, right). She used both graph types to explain her reasoning behind her evaluation. Although she drew these specific example graphs for continuous or discontinuous functions, she said that "[it] doesn't matter what it [the graph of a function] looks like." It is thus likely that what Hannah perceived from the given statements are generic functions satisfying or failing to satisfy the premise. We thus her generic examples as *data* in her arguments.

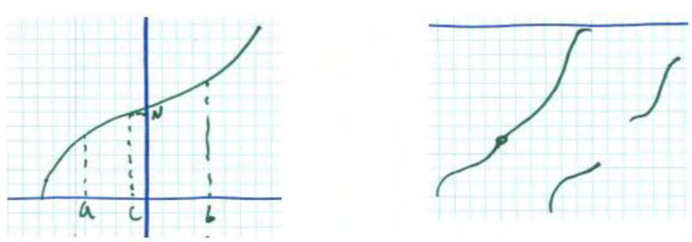

Figure 4: Hannah's graph

Hannah on S1: Because there is [are] no breaks, […] if you have this graph and there is a hole in it (Fig. 4, right), then that won't be continuous. So that would be an example of where this [the premise of S1] would be false. But since it's continuous, there is [are] no breaks [un]like this, or there is [are] no jumps [un]like that. (Fig. 4, left) So […] there has to be a $f(c)$ that equals to N, which is like, when you input any value of x between a and b, for example, c (marks c on Fig. 4, left), there has to be a y for it, a number that N equals, this roughly would be an *N* (marks *N* on Fig.4, left).

Hannah used several inferential warrants in normative ways to support her claims from her data. First of all, her use of continuous functions and discontinuous functions as any particular example indicates that she used what is called *universal generalization*, i.e., (for any fixed $x_0 \in X$, $P(x_0)) \rightarrow (\forall\, x \in X(P(x))$. We also found that Hannah used another inference that we call *modus ponens*, $(p \rightarrow q) \wedge p) \rightarrow q$, normatively in her argument for S1: She assumed the premise of S1. For her, a continuous function is equivalent to (or at least implies) that there is no break or hole in its graph. And, for her, no breaks or holes on the graph means for each input *c* between *a* and *b*, the output $f(c)$ is between $f(a)$ and $f(b)$.

Hannah attended to the syntactic differences between S1 and S2 and construed distinct meanings from each statement. Furthermore, she conceived that S1 and S2 would potentially represent different each-to-some relationships, i.e., S1 represents the each-c-to-some-N relationship, whereas S2 represents the each-N-to-some-c relationship. Her construal of different relationships from different statements characterizes her arguments distinct from Marie and Zack. However, she expressed her confusion about S3. In particular, she was not sure if the conclusion of S3 would describe a one-to-every relationship or an each-to-some relationship. Although she finally interpreted the conclusion of S3 as a description of an each-to-some relationship between *c* and *N*, she was uncertain about her interpretation of the conclusion of S3.

Hannah on S3: It sounded different [from S2]. But if you think it through, it's not saying that there is only one *N*. (reading the conclusion of S2) Okay, I am confused. Is it saying there is only one *N* or there exists a number, just any number? That's what is confusing me.

As she experienced some difficulty with S3, she focused on the sameness rather than differences between the statements, saying, "All four [statements] are equivalent because like they are just saying that there exists an input where there is a real output in this interval. So, they [S1-S4] are all saying the same thing." Here, Hannah demonstrated that some parts of the statements were distinct. However, she used her meaning of function and the input-output relationship to conclude that all four statements held the same meaning. Hannah resolved her confusion by substituting the conclusion of S3 to a conjunction of two conditions about the existence of the input and output values.

Once Hannah treated all four statements as equivalent, she also provided another way of justifying her claims about these statements, namely treating each of the given statements S1-S4 as equivalent to its inverse. She believed that she could say a statement is true by showing a statement which is what we call the inverse of a conditional statement. She thought that if a function *f* is not continuous, then the conclusion of the given statement must be false. Therefore, if *f* is continuous, then the conclusion of the statement is true.

Hannah: If you take a part of the statement, I guess, into two parts, it's saying it has to be a continuous function at first. Because this is discontinuous, in order to prove this statement true, you have to show that in a situation where it's not a continuous function, the second part [the conclusion] is not true. If you take a situation where like it doesn't meet like the basic requirements [the premise], the second part [the conclusion] can't be true for this statement to be true.

We characterize her use of such a personal inference as what we refer to in this paper as *modus inverse*, $[(p \rightarrow q) \wedge \neg p] \rightarrow \neg q$. Her use of modus inverse seemed rooted in her conception of the equivalence between a conditional statement and its inverse, i.e., $(p \rightarrow q) \Leftrightarrow (\neg p \rightarrow \neg q)$. On the other hand, the modus inverse was not aligned with normative logical inferences as there are cases in that a conditional statement is not equivalent to its inverse. Thus, her use of this inference made her assertion invalid in this case.

Conclusion & Discussion

Our findings suggest that these calculus students do have intuitive personal inferences that are quite sophisticated and often in line with mathematical/logical convention. All three students spontaneously used various inferences rules normatively. Marie and Hannah's use of biconditional elimination, Zack's use of conjunctive elimination, existential instantiation, and hypothetical syllogism, and Hannah's use of universal generalization and modus ponens were examples of personal inferences that these students used normatively. It was noteworthy that these students utilized these logical inference rules normatively to support their claims even though they had not received any formal instruction for conventional logic or proof writing in mathematics.

While these students used several logical inferences normatively, their arguments often led to inaccurate conclusions. Partially, these students' invalid personal inferences (e.g., Marie's use of generalization from a particular and Hannah's use of modus inverse) explain how inaccurate conclusions were derived in their arguments. However, in some other cases, these students' use of content-specific warrants affected their argument to be invalid even if their personal inferences were valid. Marie's meanings for quantified variables influenced the invalidity in her arguments. Zack's location thinking (i.e., thinking of output values of a function as the spatial locations of points on the graph of a function) was also closely related to his invalid argument. We hope to investigate further how to leverage students to use their personal inferences with content-specific warrants for valid arguments in mathematics.

MATHEMATICIANS' LANGUAGE FOR ISOMORPHISM AND HOMOMORPHISM

Rachel Rupnow
Northern Illinois University
rrupnow@niu.edu

Brooke Randazzo
Northern Illinois University
bk-randazzo@niu.edu

Isomorphism and homomorphism appear throughout abstract algebra, yet how algebraists characterize these concepts, especially homomorphism, remains understudied. Based on interviews with nine research-active mathematicians, we highlight new sameness-based conceptual metaphors and three new clusters of metaphors: sameness/formal definition, changing perspectives, and generalizations beyond algebra. Implications include a way to articulate a conceptual purpose for homomorphism beyond its relationship to isomorphism: namely, as a tool for changing perspectives when problem-solving.

Keywords: Advanced Mathematical Thinking, Communication, Undergraduate Education.

Isomorphism and homomorphism are widely recognized as central to introductory abstract algebra coursework—not only do research-based curricula expressly focus on their development (Larsen, 2013) but they also serve crucial roles in fundamental theorems of algebra (e.g., the First Isomorphism Theorem (Gallian, 2009), also referred to as the Fundamental Homomorphism Theorem (Fraleigh, 2003)). Furthermore, isomorphism can be viewed as a type of sameness that expands on students' prior experiences with equality and congruence (Rupnow & Johnson, 2021) and serves an important classification role for objects like groups and rings (Randazzo & Rupnow, 2021). Nevertheless, limited research has focused explicitly on how mathematicians understand homomorphism's utility in abstract algebra.

To address this gap, we examine nine research-active mathematicians' language for isomorphism and homomorphism. In so doing, we expand on Rupnow (2021)'s characterization of instructors' language, especially with respect to homomorphism. Furthermore, we provide insight into conceptual purposes for homomorphism beyond relating it to isomorphism.

Literature Review and Theoretical Perspective

Researchers have long been interested in understanding students' views of isomorphism and enhancing students' problem-solving around isomorphism. Early research examined how students approached determining whether groups were isomorphic (Dubinsky et al., 1994; Leron et al., 1995) or approached proving theorems related to isomorphism (Weber & Alcock, 2004; Weber, 2002). More recent work has created a local instructional theory for isomorphism (Larsen, 2013), built on students' approaches to proofs using isomorphism (Melhuish, 2018), and delved into the function-nature of isomorphism (Melhuish et al., 2020).

Researchers have also begun examining students' views of homomorphism. Though many early studies examined conceptions of homomorphism in service of examining students' understanding of isomorphism (e.g., Larsen et al., 2013; Weber, 2001), more recent work has examined conceptions of homomorphism independently. Hausberger (2017) highlighted homomorphism's description as a "structure-preserving function" in textbooks, as well as what students took away from tasks intended to help students abstract the notion of ring homomorphism from their experiences with groups. Like with isomorphism, recent attention has often focused on how students coordinate the homomorphism concept and their function knowledge (Melhuish et al., 2020) as well as metaphors students use for homomorphism (Melhuish & Fagan, 2018; Rupnow, 2017).

In contrast to the many student-focused studies, limited research has been conducted on mathematicians' views of isomorphism or homomorphism. Weber and Alcock (2004) examined mathematicians' understandings in the context of proof while Ioannou and Nardi (2010) studied mathematicians' use of images in the classroom. Recent work has focused more on instructors' conceptual metaphors (described below) for isomorphism and homomorphism. Rupnow (2021) interviewed and observed instruction of two abstract algebra instructors, neither of whom did research in abstract algebra, and found four clusters of isomorphism and homomorphism metaphors: sameness, sameness/mapping, mapping, and the formal definition. Rupnow and Sassman (2021) built upon this by examining survey results from 197 mathematicians and observed examples of metaphors from each of these four clusters. To extend this work, we interviewed nine mathematicians with research specialties related to abstract algebra or category theory to see whether a larger population and a more research-oriented group of mathematicians invoked other types of conceptual metaphors for isomorphism or, especially, homomorphism.

Conceptual metaphors are a theoretical lens aimed at revealing individuals' structure of thought based on their choices of language (e.g., Lakoff & Johnson 1980; Lakoff & Núñez, 1997). Specifically, cross-domain conceptual mappings are used to connect one's cognitive structure for a target concept (e.g., isomorphism, homomorphism) to one's more developed thoughts in source domains (e.g., sameness, structure-preservation). For instance, "A homomorphism is a method for gaining information" is a conceptual metaphor that gives information about a target domain (homomorphism) by relating it to a more developed source domain with which people have had other experiences (a method for gaining information). We acknowledge that this theoretical perspective imposes the researchers' view on the mathematicians' statements; that is, we do not claim that the mathematicians intended to speak metaphorically in their responses (Steen, 2001). Nevertheless, we believe this lens does permit insight into how understandings can be clustered and the types of reasoning that can be employed when thinking about or using isomorphism and homomorphism.

Conceptual metaphors have influenced examinations of students' understandings of bases in linear algebra (Adiredja & Zandieh, 2020) as well as been used as a framework for examining college students' beliefs about mathematics (Olsen et al., 2020). More closely tied to this study, conceptual metaphors have been used to examine understandings of functions in high school and linear algebra (Zandieh et al., 2016) and in abstract algebra (Melhuish et al., 2020; Rupnow, 2017), as well as mathematicians' views of isomorphism and homomorphism (Rupnow, 2021; Rupnow & Sassman, 2021). Here we aim to extend the framework proposed in Rupnow (2021) to incorporate new clusters of metaphors based on new ideas raised by the mathematicians in this study. We thereby answer two research questions: What conceptual metaphors do research mathematicians employ to characterize (1) isomorphism and (2) homomorphism?

Methods

Data were collected from Zoom interviews conducted with nine mathematicians, given gender-neutral pseudonyms in this paper. These mathematicians had previously completed a survey about sameness in mathematics and were selected from those who had provided clear responses to the survey and had characterized themselves as research-active in abstract algebra, category theory, or a field interacting with abstract algebra. All participants had taught abstract algebra and/or category theory at least once (one once, three 2-5 times, four 6-10 times, and one 11+ times). The interviews focused on how participants characterized isomorphism and homomorphism for research, teaching, and laypeople (e.g., "How, if at all, does isomorphism play a role in your research?", "How would you describe a homomorphism to a layperson?").

Two researchers coded the interviews separately using the conceptual metaphors for isomorphism and homomorphism in Rupnow (2021) as codes (e.g., operation-preserving, journey) and then met to discuss coding and reach consensus. Each talk-turn was coded with all metaphors that appeared within that talk-turn. Although each phrase could only be associated with one metaphor, a talk-turn could contain multiple sentences and multiple metaphors. When new metaphors arose that were not clearly aligned with existing codes, these were added to the codebook, and interviews were iteratively reexamined in light of the new codes. This process aligns with codebook thematic analysis (Braun et al., 2019) in which an a priori codebook provides structure to the analysis, but space is made for emergent themes to be incorporated.

Results

We found that the original four metaphor clusters in Rupnow (2021) (sameness, sameness/mapping, mapping, and formal definition) were represented in this data as well, with some new codes being added to the sameness and mapping clusters. Additionally, three new clusters (sameness/formal definition, changing perspectives, and generalizations) were added to the framework to accommodate the new language used by participants in this study.

Sameness

This cluster contains codes referring to isomorphism or homomorphism as encoding information about the sameness of objects. This includes codes originally from Rupnow (2021), such as *generic sameness*, where participants described isomorphic objects as objects that are (essentially) the same, and *same properties*, where participants described isomorphic objects as those that have the same properties or invariants (e.g., cardinality). Several new codes were also included in this cluster and are discussed below.

Two participants were given the code *indistinguishable* when they described isomorphic objects as exact copies or not distinct from one another. For example, Avery said:

> I'm trying to teach [students] that isomorphism is measuring sameness so that they actually start to think of isomorphic objects as no longer being distinct… I might try to get them to stop distinguishing between isomorphic objects, and therefore, we can talk about *the* dihedral group of order 8 as opposed to different models of that group.

While Avery appears to be encouraging students to avoid viewing different manifestations of the dihedral group of order 8 as different, this identity-focused interpretation was not necessary to be coded as *indistinguishable*. Note that participants here were still thinking of isomorphic objects as being "the same," but used more specific language than those coded with *generic sameness*.

The code *embedding* was used when participants described homomorphisms as an embedding or a mapping into part of a larger object. This code also included sameness of homomorphic images in terms of the structure of one object appearing in another object or a copy of one object "sitting inside" another object. For instance, Indy remarked:

> [S]o I say, an isomorphism is an exact copy. These things are exactly the same. But a homomorphism,…maybe we don't have this bijection anymore. But somehow some of this structure is appearing in this other object. And the ways that that could happen—one of the ways is maybe—I have an exact copy sitting inside this larger object.

This quote was also given the code *indistinguishable* due to the comment about an isomorphism being an exact copy, which highlights the similarity between these two ideas: *indistinguishable* refers to isomorphisms as producing exact copies, whereas *embedding* refers to homomorphisms producing copies inside a larger object.

The code *logical equivalence* was given to participants who described an isomorphism or homomorphism as a transfer of knowledge in which truth values or facts about objects are preserved. When discussing different ways of writing isomorphic groups, Blair remarked:

> And so it's okay if we pick different ways of writing down what ultimately results in the same structure…At the end of the day, they're going to have the same structure because they're isomorphic in the logical sense as well. Any statement of group theory that is true about one of those structures will be true if and only if it's true in the other structure.

Others talked about isomorphism in terms of classification problems and were given the code *classification*. For instance, Hayden said:

> So I think the example of the classification of finite simple groups in the 20th century is just one of the tools of 20th century algebra. But that statement properly understood suggests that we've written sometimes in infinite families…what all the finite simple groups are up to isomorphism, not what they all are but up to isomorphism…

Notice they specify these classification problems are not listing all possible objects, just those "up to isomorphism", which relates to Avery's focus on "*the* dihedral group of order 8" above—these participants seem to view isomorphism as the "sameness" that matters in abstract algebra.

Sameness/Mapping

This cluster contains codes about isomorphism or homomorphism that showcase sameness via mappings, which are all included in Rupnow (2021). In particular, five participants spoke of isomorphism as a *renaming/relabeling*, or described isomorphic objects as the same, except for their names. Others were coded with *matching* when they talked about matching or pairing up elements between isomorphic objects in some way. The code *equivalence classes* was given to homomorphism-focused responses that explicitly mentioned equivalence classes or cosets. This code also included responses talking about homomorphisms in terms of an "orderly collapsing where things line up," or the process of "stacking [elements] into the same bins" (Indy). These latter types of responses make it clear why this code was included in this category, as they emphasize the sameness of a grouping of elements under a homomorphism. Note here that the idea of "lining things up" is what is implying the existence of *equivalence classes*; the word "collapsing" is coded with *structure loss* in the changing perspectives cluster below.

Mapping

This category includes responses that talk about isomorphisms and homomorphisms as functions or maps between mathematical objects, focusing on the map or process of mapping rather than the objects. The code *generic mapping* was given to participants who described isomorphism or homomorphism generally in terms of a function, morphism, arrow, map, or correspondence, whereas the code *journey* was given to participants who were explicit about the directionality of the map or used some sort of movement metaphor (e.g., elements being "sent to" one another). Both of these codes are included in Rupnow (2021).

The new code *invertibility* was given to four participants who highlighted the necessity of an isomorphism being reversible or comprised of maps that compose to the identity. Greer provides a clear example of the former:

> I mean, all the things I really think about when I think about the way isomorphisms would occur in the non-mathematical world maybe, really are sort of reversible processes. So now I was just thinking about cyphers and codes,…and that's a really concrete example of the way

> an isomorphism would work. It's even within the English language, but it's turning all messages in English to other messages in English in a completely reversible process.

Notice Greer's explanation of isomorphism for a non-mathematician focuses on the reversibility of isomorphism. Finley provides an example of the identity-focused version of invertibility:

> An isomorphism between groups is a homomorphism from G to H together with a homomorphism from H to G so that the composites are identities. But then, you could also say an isomorphism is a bijective homomorphism because that's a theorem that in the category of groups, the categorical isomorphisms coincide with the bijective homomorphisms. So I usually will present those two different ways.

Observe Finley distinguishes between bijective homomorphisms and homomorphisms with inverses that are also homomorphisms—although the definitions coincide in abstract algebra, they do not when generalizing to other contexts (e.g., continuous bijections need not have continuous inverses in topology).

The new code *transformation* was given to two participants who talked about isomorphism or homomorphism as a process that morphs or transforms one object into another (similar to Zandieh et al., 2016). For instance, Greer said:

> I use the word mechanism like an isomorphism really is a process to me. It's a process of turning one object into another in some sense. It's not turning the objects into each other, it's reframing your thinking from…one object to another object, I would say. Objects themselves are distinct. Completely distinct to me, and they're identified by isomorphisms.

Notice that Greer characterizes isomorphic objects as being distinct, in contrast to the examples given the *indistinguishable* code above.

Formal Definition

These are codes given to responses that utilized the formal definition to reason about isomorphism or homomorphism. All of these codes are included in Rupnow (2021). The code *literal formal definition* includes instances of describing an isomorphism as a bijection, often with special properties, or describing isomorphic objects as simply objects that have an isomorphism between them. While this code included responses using the literal string of symbols in the homomorphism property in Rupnow (2021), these types of responses did not exist in this study, likely because the mathematicians were not asked to engage in problem-solving.

Several participants also defined isomorphism based on homomorphism, and vice versa. The code *special homomorphism* was given to responses describing isomorphism in terms of homomorphism, either formally (e.g., "an isomorphism is a bijective homomorphism", Finley) or informally (e.g., "I think of isomorphism as homomorphism plus extra things", Greer). Similarly, the code *isomorphism without bijectivity* was used for responses that focused on describing homomorphism by relating to isomorphism (e.g., "[Homomorphism is] 'Sort of an isomorphism' is what comes to my mind. So we still want to preserve the structure, but maybe we don't insist on one-to-oneness anymore or one-to-one correspondence", Cameron).

Sameness/Formal Definition

Codes here include crucial parts of the formal definition (i.e., structure/operation preservation), but stated in an informal way. These two codes were originally included in the formal definition category in Rupnow (2021) because they were generally used as unexplained stand-ins for the homomorphism property/homomorphism by those participants. However, we now view them as a separate cluster because participants here seemed to use them to explain what they meant by sameness (e.g., "preserving the algebraic structure, same algebraic structure", Dallas). Cameron illustrates both *structure-preserving* and *operation-preserving*:

> And so when I cite preservation of structure, I mean that all these [mathematical sub-]fields have a notion of isomorphism in there. And you're usually referring to a bijection which preserves the structure of whatever it is you're looking at. So in topology, it's like a bijection that preserves continuity in both directions. And in abstract algebra, it's a bijection that preserves your multiplication, addition operations, whatever. In graph theory, it's a bijection that preserves adjacency.

We note here that the ideas of operation-preservation and structure-preservation are very similar, and Cameron seems to be using them interchangeably in the context of abstract algebra, though the notion of structure-preservation could carry over to other mathematical sub-fields as well.

Changing Perspectives

The metaphors in this category are all new codes involving responses that emphasize how homomorphisms force a change of perspective (*quotient group construction, structure loss*), or that explicitly mention using isomorphisms or homomorphisms to change perspective for the purpose of aiding mathematical research *(information gain*).

Two participants were given the code *quotient group construction* when they mentioned that homomorphisms arise from quotient groups or vice versa. Blair talked about viewing these two concepts interchangeably, even though students may see them as distinct initially.

> And a quotient object is exactly how you make rigorous this notion of collapsing down and the most important result… is that homomorphisms are the same things as quotients… a really important idea for students is that a group homomorphism between two groups is *the same thing* as a certain type of equivalence relation, a certain type of quotient group as well.

This quote mentions the idea of "collapsing" in relation to homomorphism, so was given the code *structure loss* as well, which involved responses talking about homomorphisms in terms of collapsing or similar ideas such as simplifying, losing, or ignoring structure. For example, Emerson describes homomorphism in the following way: "[T]aking a homomorphism is preserving some structure but losing something along the way. Hopefully, something that you are trying to ignore or that you don't care as much about as the stuff you're trying to preserve." The similar concept of getting only partial or limited information from a homomorphism was also included here. Greer observed:

> I think describing a homomorphism to a layperson… I want to say that it's about maybe collapsing and simplifying structure in mathematics, but I think it's actually a pretty foreign idea to the real world, this idea that you can take something you care about and record only partial information, and still learn something about whatever you're studying, but maybe not.

Thus, while only partial information is retained from a homomorphism, Greer believes that homomorphisms are still helpful in learning something about the relevant objects.

Four participants used metaphors related to *information gain.* This code captures the idea that homomorphisms are used to gain understanding about one or both of the objects involved. For example, Blair gave the following reason for using homomorphisms in their research but was relatively vague on the details about what sort of information is gained from this.

> And a great example of that would be like group actions. A group acts on a metric space. And even if you—a group action is a homomorphism from a group into the isometry group

> of this metric space. And even if you didn't understand that much about the metric—or you knew some things about the metric space, you knew some things about the groups, the information can go both ways. You can use things you learn about the metric space to learn things about the group, and you can use algebra that you can actually compute in the group to learn things about the metric space. So, you can gain knowledge in both directions.

Others, like Hayden, referred to this information gain as part of their mathematical tool set:

> It's our basic tool in moving around between algebraic objects [we] want to sort of exhibit. Often when you're trying to find out something about some object, you will apply some homomorphism to it to understand it, maybe in a simpler context. That's part of the grammar of doing research in algebra.

Isomorphisms were similarly mentioned as useful for shifting perspectives to gain information (e.g., "isomorphisms are used in my research, I would say, to build bridges between two different ways of thinking," Greer).

Generalizations

Here we include generalizations and analogues of isomorphism and homomorphism across different branches of mathematics. Five participants noted that isomorphisms are an example of an *equivalence relation*. Blair uses this idea to talk about isomorphisms broadly in any category.

> So *everything* I do when I talk about two things being equal or the same, there's always some explicit or implicit notion of an equivalence relation. It's up to something. And every equivalence relation gives rise to some notion of isomorphism in the right category.

Blair seems to be speaking about isomorphism in the category theoretical sense here, which includes the algebraic notion.

In a similar vein, all nine participants brought up *other branch analogues* to isomorphism in abstract algebra. Some of these were in response to being asked whether they view isomorphism in a specific context or more broadly. For example, Dallas made connections to analogous concepts in topology: "But the concept of isomorphism… extends kind of beyond just algebra.… So I think of concepts like homeomorphism, diffeomorphism, or homotopy equivalence even as being analogous to isomorphism." Finley also talked about isomorphism existing outside of algebra: "I think most mathematicians will think of [isomorphism] as a general thing across mathematics. But for me, the reason… is because it's a thing in category theory, and then you can apply it in any category." Again, we see the idea of category theory being a way to talk about these concepts in a more general way.

Some *other branch analogues* were also discussed in response to the final interview questions, which specifically asked about these analogues: "Some people answering the survey saw connections between isomorphism/homomorphism and equivalent fractions or congruence/similarity in geometry. Do you agree that there is some level of similarity between these contexts? Do you think it would be helpful to highlight these similarities with students?" Indy compared equivalent fractions to the relabeling conception of isomorphism: "I think equivalent fractions is kind of an interesting notion in the sense that they're the same number, but they're written differently. So it is kind of this idea of, we have different names for the same object." However, they didn't feel like similar triangles were a strong enough analogy to use for homomorphism: "The similar triangles… that one I don't like as much because… you're only zooming in and out. You're not even kind of like folding it… I feel like the similar triangles would give an impression of too much rigidity." This comment brings up the importance of being careful how analogues are used in the classroom, in order to avoid encouraging too narrow or loose conceptions about isomorphism or homomorphism.

Discussion

Isomorphism and homomorphism have a variety of conceptual facets to them. As previously observed, they can be interpreted formally through their definitions, through the lens of sameness, as mappings, and as sameness-focused mappings (Rupnow, 2021). One way we add to prior work is by noting new ways that sameness (e.g., *indistinguishable*) and mapping (e.g., *invertible*, *transformation*) metaphors can manifest. While these metaphors were only used by a few mathematicians, we note that they reveal opposite views of how much sameness is conveyed by isomorphism. For *indistinguishable*, objects linked by the isomorphism are not worth viewing as different—in all important ways they are the same. In contrast, *transformation* emphasizes differences still exist, even for isomorphic objects. Although these perspectives are in tension, they provide complimentary views depending on what is important for a specific context.

Furthermore, even the four original clusters do not fully capture ways in which isomorphism and homomorphism are understood. Here we see formal definitions conveying a type of sameness (formal definition/sameness cluster) through operation-preservation and structure-preservation. Though these metaphors can be used as stand-ins for the homomorphism property, the preservation aspect also highlights the sameness of elements' interactions with each other. We also see ways in which isomorphism and homomorphism are part of a broader system of interconnected ideas, permitting connections to similar concepts in other parts of mathematics (generalizations cluster). These connections can be viewed thematically (*equivalence relations*) or as specific other instantiations (*other branch analogues* like homeomorphism). Finally, the changing perspectives cluster highlights a route for viewing problems in new ways when problem solving. Specifically, these mathematicians working in or near algebra/category theory provide homomorphism a purpose of its own rather than viewing homomorphism as important only for its relationship to isomorphism or for having a tenuous connection to sameness.

Furthermore, the changing perspectives cluster highlights potential routes for future research. For instance, considering these homomorphism purposes did not arise in the prior study and were only noted by four mathematicians here, how prevalent are these notions? Similarly, would math instructors who teach but do not research algebra benefit from explicit conversations and professional development on this topic to make their teaching more relevant? Alternatively, do students find the changing perspectives cluster relevant if they are not interested in pursuing higher level math courses? Further explorations of such connections between instructors' understandings and teaching as well as teaching and students' understandings seem justified.

Finally, this examination of experts' language highlights desirable conceptions for students. Prior work has carefully examined students' use of properties and approaches to determining whether groups are isomorphic (e.g., Dubinsky et al., 1994; Leron et al., 1995) as well as focused on the function nature of isomorphism and homomorphism (e.g., Melhuish et al., 2020). Here we highlight a framework that permits and structures simultaneous examination of both while connecting to analogous topics in other mathematical subfields. Future research could examine the benefits of using particular clusters of metaphors, contexts in which different clusters are optimal, and ways to foster explicit connections among these metaphor clusters in the classroom.

RELATIONSHIPS BETWEEN DIMENSIONS OF AUTHENTICITY DURING AN INQUIRY-ORIENTED ABSTRACT ALGEBRA ACTIVITY

One of the goals of advanced undergraduate mathematics courses is to engage students in activity that is authentic to the mathematics discipline. However, engaging students in such activity often involves managing tensions between authenticity-to-students and authenticity-to-the-discipline. In this paper, we use the Authentic Mathematical Proof Activity (AMPA) Framework to further explore potential relationships and tensions between different dimensions of authenticity. We analyzed classroom data from an inquiry-oriented abstract algebra course where instruction focused on unpacking the fundamental homomorphism theorem. Our results focus on the complexity dimension of authenticity and how this dimension relates to other dimensions of authenticity within instruction. We identify ways that instructor decisions shape authenticity even within the context of a carefully developed task.

Keywords: Undergraduate Education, Reasoning and Proof, Instructional Activities and Practices

Many mathematics educators value engaging students in “authentic” mathematical activity. The use of the term authentic often reflects ties to the work of the discipline where the goal is to engage students in activity reflective of research mathematicians (e.g., Watson, 2008). However, what constitutes authentic activity and the degree to which such activity should be the goal of school mathematics is an unsettled topic (Weber & Dawkins, 2020). Further, engendering students in authentic activity is often subject to intrinsic tensions between authenticity to students and authenticity to the discipline (e.g., Melhuish et al., 2021; Ball, 1993; Lampert, 1992; Herbst, 2002). A well-documented tension is that between authenticity-to-the-discipline (as in Weiss et al. 2009) in terms of accuracy of content and alignment with student contributions that often diverge from the norms of the discipline (e.g., Chazan & Ball, 1999). Herbst (2002) has further illustrated dilemmas in proof courses where there is a double bind on the teacher to progress a class in normative ways related to proof argumentation while also staying authentic to the contributions and activity of students in class. As noted in Dawkins et al.’s (2019) analysis of an inquiry-based instructor, this tension remains salient at the advanced undergraduate level.

In Melhuish and colleague’s (2021) recent work, they have suggested a need to better operationalize authenticity for the context of proof-based courses. Drawing on diverse design-based research projects, they built on Weiss et al.’s (2009) initial decomposition of authenticity to suggest both student/discipline dimensions and practice/content dimensions of authenticity that are at play in the advanced proof-based settings. In this paper, we build directly on this work by adapting this framework (developed in the settings of task-based interviews) to the classroom setting to better explore how different dimensions of authenticity may align or diverge in order to better understand instruction in such classes. For the scope of this paper, we forefront elements of practice, that is the nature of activities, as they have been less explored than their parallels in relation to content.

Our study is situated in the context of abstract algebra, a course taken by mathematics majors and pre-service secondary teachers. The advanced undergraduate setting is often a place where students are apprenticed into the work of research mathematicians with a focus on formal proving. It is well-documented that students often struggle to grasp the abstract concepts that are central to the course (e.g., Dubinsky et al., 1994; Melhuish et. al, 2019). As a result, there has been a growing body of research on how to improve the teaching of abstract algebra and a continued development of inquiry-oriented abstract algebra curriculum (e.g., Larsen et al., 2013) with a focus on engaging students in authentic activity. We are building on such work by elaborating on the tensions and relationships amongst competing authenticity goals observable in instruction.

Theoretical Framework

Drawing from activity theory (Engeström, 2000), we frame both students and instructors as operating within activity systems. These activity systems relate goal-driven actions to how members of a community work together toward shared goals. The assumption underlying our work is that advanced mathematics courses provide students with an opportunity to engage in activities that align with the activities of research mathematicians. Advanced mathematics courses may provide students an opportunity to use tools (e.g., examples, warranting, deformalizing) to meet objectives that can be deconstructed into motives (e.g., explore, test, construct) in reference to an object (proof, statement, concept). Evidence of participatory learning can be seen through expansions in activity within an activity system. For example, students may introduce tools, thus adding more variety and increasing their role in the division of labor.

We draw from the Authentic Mathematical Proof Activity (AMPA) framework (Melhuish et al., 2021) which was developed to capture components of student activity that reflect the work of research mathematicians. The framework includes ten tools: analyzing/refining, formalizing, deformalizing, warranting, analogizing/transferring, examples, diagrams, logic, structure/frameworks, and existent objects. These tools are used alongside three motives: constructing, exploring, and testing, in reference to three objects: proofs, statements, and concepts. Authenticity is operationalized across six dimensions to account for different, sometimes competing, notions of authenticity. Notably, the three dimensions: variety, complexity, and accuracy reflect the discipline and stem from analysis of mathematician activity while agency, authority, and alignment reflect features of authenticity to student activity and contributions. See Table 1 below for the dimensions of the Authentic Mathematical Proof Activity (AMPA) framework along with our elaboration of four levels within each dimension.

Table 1: Dimensions of Authenticity

Dimension of Authenticity	Levels
Variety: Degree of variation within tools used: formal, informal, generative, translating	Low: Only one type of tool at play Low-Mid: Two of the four types of tools at play Mid-High: Three of the four types of tools at play High: Informal, formal, translating, and generating tools at play
Complexity: Degree in which tools are used in isolation or in conjunction	Low: Single tool Low-Mid: A variety of tools are used in isolation Mid-High: Many tools used in conjunction

(and shifts from outcomes to tools)	High: Objects shift to tools
Accuracy: Degree in which the tools used would be accurate within the mathematical community	Low: Inaccurate Low-Mid: Mixed - correct tools but incorrect outcome Mid-High: Similar but imprecise High: Tools and outcomes are accurate
Alignment: Degree in which tools aligned with student contributions (whose tools are endorsed)	Low: Teacher Contributions Low-Mid: Mostly Teacher/ Some Student Contributions Mid-High: Mostly Student Contributions/ Some Teacher or Refined Student Contribution High: Tools and Outcomes are Student Contributions
Agency: Degree in which students generate tools	Low: Teacher generates/uses Tools Low-Mid: Teachers generate tools and students Use Tools Mid-High: Students Generate Tools (prompted) High: Students Generate Tools (unprompted)
Authority: Degree in which students determine how tools/ outcomes connect (validity of tools/ outcomes at play)	Low: Instructor links & explains Low-Mid: Instructor links & students explain Mid-High: Students link & explain (sometimes) High: Students link & explain (mostly)

Background: Fundamental Homomorphism Theorem and Quotient Groups

The focal task in our study involves students exploring the proof of the Fundamental Homomorphism Theorem (FHT). Both the FHT and quotient groups are key topics in an abstract algebra curriculum, but they are also two of the most difficult topics for students to understand (Melhuish et al., 2021). The FHT (see figure 1 below) involves both a homomorphism and an isomorphism to show that the quotient group is isomorphic to the image of the homomorphism.

Literature suggests that students may struggle to coordinate the homomorphism and isomorphism in the FHT (Nardi, 2000). Nardi (2000) elaborated that mathematical abstraction is particularly challenging in such proof settings. For students to productively engage with this theorem and proof, they need to coordinate a number of abstract mathematical objects including functions and quotient groups. Yet, Hazzan (1999) suggests that students often try to create less abstract environments for themselves by relying on things like the coset algorithm which in turn hides the structure of quotient groups. With the inherent challenges of abstract functions (e.g., Melhuish et al., 2021, year) and quotient groups (e.g., Dubinsky et al., 1994), we anticipate substantial opportunities to study authenticity dimensions where student contributions may often be in tension with disciplinary norms.

Theorem 1 (The First Isomorphism Theorem or the Fundamental Homomorphism Theorem).
If $\phi : G \to H$ is a group homomorphism, then

$$\frac{G}{\ker\phi} \cong \phi(G).$$

Proof. First, we note that the kernel, $K = \ker\phi$ is normal in G.

Define $\beta : \frac{G}{K} \to \phi(G)$ by $\beta(gK) = \phi(g)$. We first show that β is a well-defined map. If $g_1K = g_2K$, then for some $k \in K, g_1k = g_2$; consequently,

$$\beta(g_1K) = \phi(g_1) = \phi(g_1)\phi(k) = \phi(g_1k) = \phi(g_2) = \beta(g_2K).$$

Thus, β does not depend on the choice of coset representatives, and the map $\beta : G/K \to \phi(G)$ is well-defined.

We must also show that β is a homomorphism:

$$\begin{aligned}\beta(g_1Kg_2K) &= \beta(g_1g_2K)\\ &= \phi(g_1g_2)\\ &= \phi(g_1)\phi(g_2)\\ &= \beta(g_1K)\beta(g_2K).\end{aligned}$$

Clearly, β is onto $\phi(G)$. To show that β is one-to-one, suppose that $\beta(g_1K) = \beta(g_2K)$. Then $\phi(g_1) = \phi(g_2)$. This implies that $\phi(g_1^{-1}g_2) = e$, or $g_1^{-1}g_2$ is in the kernel of ϕ; hence, $g_1^{-1}g_2K = K$; that is, $g_1K = g_2K$. □

Figure 1: Statement and Proof of the FHT

Methods

The data for this report was collected at a large public university in the United States as a part of a design-based research project focused on orchestrating discussion around proof. More specifically, the data comes from an activity in which students were tasked with engaging with the Fundamental Homomorphism Theorem. This activity spanned one and a half class periods. On the first day, students worked in small groups on two tasks. For the first task, each group was given a different homomorphism between groups and asked to draw a function diagram where the homomorphism, kernel, cosets, and isomorphism were all labeled. This task concluded with a whole class discussion.

The second task involved unpacking the proof of the FHT. Students were first tasked with partitioning the proof into sections based on the property being proved (well-defined, homomorphism property, one-to-one, and onto). Since there were four groups, each group was assigned a section and given a set of questions about their section of the proof to facilitate a small group discussion. After each small group spent some time discussing their section of the proof, a representative from each group went to the front of their class to present their answers to each question and discuss their overall understanding of their section of the proof. The presentations occurred during the following class period.

This activity was video recorded, audio recorded, and transcribed. Using the video data from the two class sessions, we segmented the class into segments based on activity. A new segment was created when shifts in conversation such as a new topic of conversation or more major changes such as whole class to small group discussion occurred. The coding was done in two stages by two of the authors. The first stage was a trial coding of two segments, the second stage consisted of coding the rest of the segments. Using the AMPA framework, 21 segments with an average length of 6 minutes and 40 seconds were coded along six dimensions and received a code of low, low-mid, mid-high, or high. Any discrepancies between the two coders were resolved through discussion.

After we coded our data, we looked for patterns and trends throughout the coded data to find relationships and conflicts. We identified any segments that conflicted with the general trends of the data set. We discuss the findings of our analysis below.

Results

For this report, we forefront the dimension of complexity in order to better understand the relationships between complexity and other dimensions of authenticity that emerged from our analysis. Complexity captures the degree to which a set of tools are used interrelatedly to make progress towards an outcome. We use quotes and descriptions of the video data to provide context for each relationship. Note that all students have been assigned a pseudonym in these segments.

Before discussing the relationship between complexity and the other dimensions of authenticity, we present a figure (Figure 2) that summarizes the authority dimension levels across our segments. The grey boxes correspond to small group segments (focusing on the small group reported later in the results) while the white boxes are whole class segments. We note that we transition between lessons at the 80-minute mark. We can observe that authenticity dimensions are infrequently all at the high-level, with both discipline (variety, complexity, accuracy) and student (agency, authority, alignment) varying in different segments.

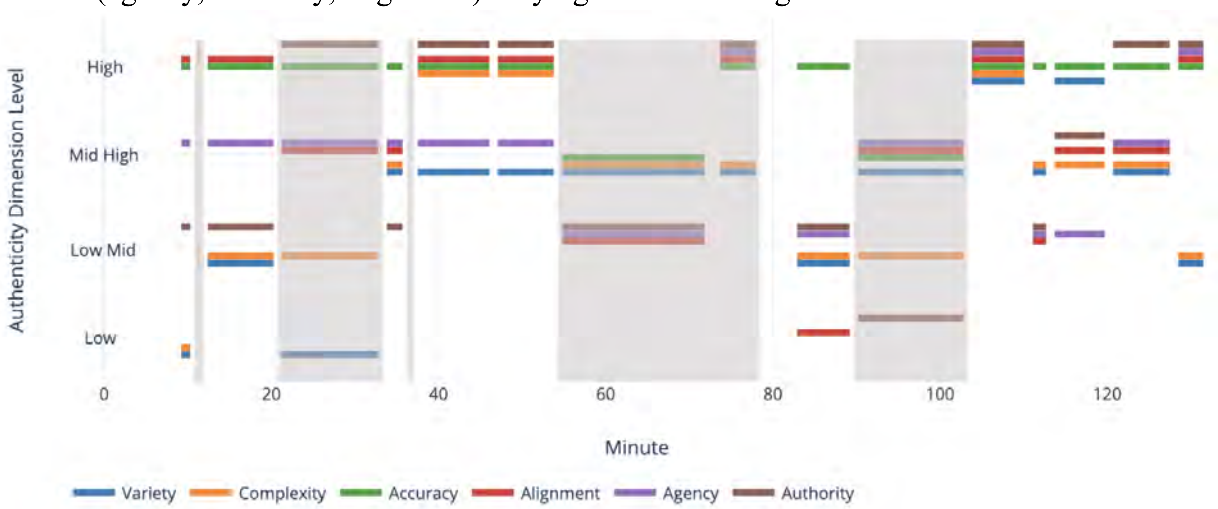

Figure 2: Coding Over Time By Whole Class And Small Group 1

Variety, a Necessary, but Not Sufficient Condition for Complexity

From a simplistic view, complexity and variety are interrelated. In order for multiple tools to be used in conjunction (high complexity), there must first be multiple tools available to use (high variety). For example, consider the following quote from the end of a segment where a student, Joe, is explaining a portion of the proof to his classmates:

> And then the last thing, which I hate. Oh, I hate this line so much is, what does it mean that beta does not depend on the choice of coset representatives, which is a really horrible way of saying that something's "well-defined". So, basically to translate what this means... I didn't know what it meant when I first saw it. A coset representative is like, if you think about our group over here, 1 and 4 would both be like coset representatives that are equal, right? Because they map to the same thing when paired with a kernel. And in our actual proof here, g_1 and g_2 are our coset representatives. And what we're trying to show in this proof is that it doesn't matter what you call them. Doesn't matter which one's being used, as long as they are equal, you will get the same result,

Joe generated several different types of tools in this segment. First, he is deformalizing when he translates the formal language in the proof to more informal language. Then, he is warranting by referring to an example, and formalizing by relating the example back to the formal proof. The variety of tools that were generated by Joe, as well as the tools being used in tandem, resulted in the segment having high levels of both variety and complexity. Across the lesson, students often generated tools with the intention of using them in conjunction with other tools. Similarly, with few tools at play (low variety), there are fewer opportunities for complex usage (low complexity.) Overall, levels of variety and complexity corresponded (both higher or both lower) in 20 of the 21 total segments.

A Deviation for the Trend of Variety and Complexity Co-Occurrence - and a Tension with Authority.

While most of the instances included variety and complexity playing out in tandem, one segment provided counter evidence to this trend. A small group of students was tasked with making sense of the onto portion of the FHT proof. Throughout this segment, students generated many different tools. For example, they referenced an example of a homomorphism between two groups, as well as deformalized the formal definition of onto by stating “everything in the codomain gets hit”. Despite generating a variety of tools, the students did not end up using any of the tools in tandem. This led to them having trouble making progress toward unpacking and understanding their portion of the proof. The instructor intervened and stated, “So, actually you have everything... So, let’s make sense of this”, and attempted to prompt students to begin using some of the tools they generated in tandem. This deviation from the trend we noticed provides evidence that students being able to successfully generate tools does not guarantee that they will use them together. The intervention by the instructor increased the level of complexity for the segment (tools began being used in tandem) but decreased authority (the instructor was primarily the one linking tools to outcomes – that is, evaluating that they had the right tools). Without the instructor’s intervention, the students appeared at an impasse in their activity. By decreasing authority (a student-related dimension), the instructor promoted increased complexity (a discipline-related dimension). Thus, this case suggests a tension between these dimensions, since linking between tools and outcomes often requires using a variety of tools in tandem.

Decreasing Agency to Increase Variety and Complexity

The final relationship we observed was that levels of agency related to levels of both variety and complexity. There were several instances where the students were not generating very many tools. If the instructor was not present, then this would necessarily lead to both low variety and complexity, because there would not be very many tools at play. However, it was often the case that if the instructor noticed that students were not generating many tools, they would step in to introduce a new tool, and sometimes even use the tool in tandem with another tool. This move by the instructor resulted in increasing both variety and complexity for the segment but decreasing agency –as the tools were no longer being generated strictly by the students. Consider the following exchange where one of the members of the group from the previous section (Nick) is presenting their explanation of the onto portion of the proof. The student started by writing out what was known: φ is onto. Then the student proceeded to attempt to explain why this necessarily meant that β was onto.

> Nick: So, now it's time for us to address β. And we were given the definition for β, what it is. And I think if I remember it correctly, it has something to do with the kernel. Do you guys remember what the definition for β is? How is β defined?
>
> Joe: Beta of G times the kernel equals □(□)?
>
> Nick: Yeah. So, it's elements in G operated with the kernel, right?
>
> Joe: Which are quotient group elements.
>
> Nick: Yeah. So, would it be too much of a jump to say that □(□)is equal to □(□) operated with K?
>
> Joe: You are allowed to do that
>
> Nick: And why am I allowed to do that? I'm actually asking you.
>
> Joe: That's the definition of beta
>
> Nick: Okay
>
> Kevin: Because why is it □(□). Right so, it is an element in the big □(□), which we just said was equal to beta of little gK or in this case, little x big K. So, you've just replaced Y with that.

Nick then notes that his classmates' contributions helped him "understand a little better" but still does not think he has the "best grasp on it." After this comment, the instructor states they have a "general insight on what is going on with the onto," but introduces a diagram (a new tool), to think through the argument. The introduction of a diagram of a homomorphism from $\mathbb{Z}_9$ to $\mathbb{Z}_6$ increased variety, since a new type of tool (informal) was being discussed. Additionally, the instructor used the tool in reference to existent objects (homomorphism, image) to warrant why the section of the proof was true. Thus, not only was variety increased, but complexity was increased as well. However, since the new tool being used was generated by the instructor, agency was decreased. This example shows that when a limited number of tools are at play and are being used in isolation, the instructor will often step in and introduce a new tool, as well as use that new tool in tandem with other tools. This results in increasing variety and complexity but decreasing agency.

Discussion

The AMPA framework was designed to document how students engage in authentic mathematical activity in a proof-based setting. Through our work, we have expanded the use of this framework to the classroom setting. We note that the course that we examined was an inquiry-oriented class which, in many ways, was naturally designed to foster an environment where students are engaging in many of these activities. Social norms within inquiry classes often include the expectation that the students are engaging actively in a disciplinary activity. Such a setting provides a robust opportunity to explore tensions in authenticity dimensions;

however, we caution that we cannot generalize these dimension relationships to a more traditional classroom.

Due to the inquiry nature of the classroom, the presence of the instructor varies from segment-to-segment. This influenced the levels of the dimensions of authenticity because when the instructor was not present in a small group, the dimensions of alignment, agency, and authority (presuming activity was occurring) all defaulted to high. The reason for this was because the instructor did not have an opportunity to prompt the students to introduce additional tools or give input on the validity of outcomes. In this paper, we shared three segments where the instructor was present throughout to better explore relationships between dimensions of authenticity.

If we turn back to the literature on authenticity, we can see evidence of the underlying tension between authenticity-to-students and authenticity-to-the-discipline found in the K-12 literature (e.g., Chazan & Ball, 1999; Lampert, 1992). The overarching goal for this abstract algebra lesson involved students engaging in authentic activities related to comprehending a theorem and a proof. In order to do this, the students needed to use a variety of tools in complex ways to make sense of a rather abstract theorem and proof. Variety was a necessity for complexity, and when variety was low, the instructor sometimes limited agency in order to introduce new tools. Further, variety did not assure complexity, and we observed the instructor lowering authority to assist students in connecting their tools to outcomes.

We also anticipate that the instructor's values and beliefs affected the authenticity profile of this class. For example, in the last exchange, the instructor introduced a diagram (which increased variety but decreased agency). We can reasonably conjecture this was for the purpose of supporting students' understanding of the onto portion of the proof. In other words, at this moment, the instructor appeared to value the students' engaging with a diagram more than ensuring that all of the tools at play were generated by the students. Further, this explanation means the increase in a disciplinary dimension was not necessarily motivated by authenticity intentions, but a consequence of other pedagogical intentions – attending to students' understanding.

Inquiry-based classes provide an opportunity for authority (i.e., the source(s) of legitimacy within a classroom) to be shared among the members of the classroom rather than simply concentrated within the instructor or textbook (Amit & Fried, 2005; Gerson & Bateman, 2010). Inquiry-based classes focused on mathematical proof provide a context to investigate the nature of students' decision-making during the proving process (Bleiler-Baxter et al., 2021; Langer-Osuna, 2016). While mathematics educators espouse the importance of "allow[ing] students ample opportunities to be the bearers of granted authority" (Gerson & Bateman, 2010, p. 206) in mathematics classrooms, we know less about students' tendencies when granted such authority. In this study we seek to gain further insight into student decision making during collaborative group proving. We ask the following research question (Bleiler-Baxter et al., under review): To what aspects of proof do students in an undergraduate inquiry-based introduction to proof course attend when granted authority to co-construct mathematical proofs within small groups?

This study was conducted in an inquiry-based introduction to proof course in the Spring 2020 semester. Students were placed in small groups of approximately three students and were asked to co-construct group proofs for various claims over the course of the semester. During these small-group sessions, students received minimal feedback/guidance from the instructor and had to make decisions about the best ways to spend their time to develop a final proof product they would then present to the whole class. We collected nine video episodes of small-group collaborative proving before we halted data collection due to the instructional transitions caused by the COVID-19 pandemic. We adapted Stylianides' (2007) framework to define three aspects of proof to which students may attend when making decisions in their small-groups: set of accepted statements (S), modes of argumentation (A), and modes of argument representation (R). We coded the episodes by talk-turn using the S, A, R framework, and then met as a team to come to a consensus on our coding.

This poster will present findings from our research question and how we operationalized Stylianides' (2007) framework to serve as an analytic coding framework. We believe this operationalization presents a powerful tool for future research in proof that will allow researchers to dissect how students discuss and make decisions about aspects of the proving process. Further, we will use the poster as a venue to discuss some of the theoretical implications of this coding scheme. For example, there were times when single talk-turns were coded with multiple aspects of the Stylianides framework. These instances of double-coded talk-turns, such a talk-turn coded with both an "S" code and an "A" code, often indicated times when students expressed their arguments (A) with more precision due to their reliance on accepted statements (S). We believe that a poster session will serve as a valuable setting for us to engage in conversation with other mathematics education researchers who may have ideas for directions of future related work and implications for both research and practice in proof-based mathematics courses.

Chapter 11:

Pre-Service Teacher Education

EXPLORING THE RELATIONSHIP BETWEEN PRESERVICE TEACHERS MATHEMATICAL NOTICINGS AND THEIR 360 VIDEO VIEWING

Christine K. Austin — Kent State University — causti17@kent.edu

Jennifer Heisler — Kent State University — Jheisle4@kent.edu

Karl W. Kosko — Kent State University — kkosko1@kent.edu

This study discusses the difference in a preservice teachers' (PSTs) mathematical noticings and the relationship between where they attend in a 360 video. Using a convergent mixed methods approach, our evidence provides support that PSTs who are more explicit in their written noticing of mathematical references are more focused in their viewing of a 360 video on a group of students or area of the classroom than those who look around more often.

Keywords: Teacher Noticing; Technology; Preservice Teacher Education.

Overview & Purpose

Teacher noticing is a critical skill amongst mathematics teachers (Jacobs, 2010; Sherin, 2005). Additionally, attending to students mathematical reasoning and thinking is vital to effective teaching (AMTE, 2017). This attention to a students' mathematical reasoning and the ability to interpret a students' thinking is a subset of professional teacher noticing (Jacobs, 2010; Sherin, 2005). The use of video in preservice teachers (PSTs) methods courses has been shown to support teachers' growth in professional noticing (van Es et al., 2017; Roche & Rolland, 2020). Recently, mathematics educators have begun to use and study 360 videos in teacher noticing, which record an omnidirectional view of the classroom. Evidence suggests that 360 video facilitates a PSTs' development of professional noticing (Kosko et al., 2021b; Roche & Rolland, 2020). PSTs who look around the recorded classroom more often in a 360 video attend to more generic student actions in their written noticing (Gold & Windscheid, 2020; Huang et al., 2021b). However, many of these studies have focused on attending to aspects of classroom behavior, and not to more content-specific facets. The purpose of this study is to examine the relationship between PSTs' mathematical noticing and how they view 360 videos.

Background Literature & Theoretical Perspectives

Professional noticing has been studied extensively in the context of mathematics education (Jacobs, 2010; Sherin, 2005). Professional noticing involves the three interrelated actions of attending to, interpreting of, and deciding how to respond to pedagogical events (Jacobs, 2010; Sherin & Russ 2014). Novice teachers tend to initially attend to students' generic actions (i.e., participation) and behavior, or focus on the teacher's instructional activities. By contrast, more experienced teachers attend more to students' mathematical thinking (Huang & Li, 2012; Kosko et al., 2021b). Mathematics teacher noticing can be facilitated and is the aim of many teacher education programs. However, this noticing should be structured, with an early focus of teacher educators to develop professional noticing skills (Jacobs, 2010; Star & Strickland, 2008).

In characterizing PSTs' noticing practices, and expanding upon prior conceptualizations (i.e., Jacobs et al., 2010), van Es et al., (2017) described a trajectory of noticing from generic to specific descriptions of students' mathematics. The noticing of mathematical thinking relies on specific strategies identified within students' mathematical development (Jacobs et al., 2010). In other words, the mathematics content is conveyed more precisely and defined with a higher degree of noticing. This is consistent with other findings that suggest that PSTs who are attending to other classroom happenings such as ‘student investigation’ or ‘group work’ did not describe specific mathematical content even when prompted to do so (Kosko et al. 2022).

The emerging scholarship on teachers’ noticing through 360 video suggests a relationship between teachers’ linguistic descriptions and their actual viewing behavior (Kosko et al., 2022; Weston & Amador, 2021). Much of the analysis on this phenomenon has been limited to screen recordings of PSTs’ field of view (Gold & Windscheid, 2020; Huang et al., 2021b; Kosko et al., 2021b) or interviews with PSTs re-viewing 360 videos of their own teaching (Balzeretti et al., 2019; Buchbinder et al., 2021; Weston & Amador, 2021). We conjectured that PSTs’ perceptions of where they focused attention may be an additional lens in understanding their experiences within a 360 video of a classroom. With this focus, we sought to answer:

How do PSTs’ variance in perceived focus in viewing a 360 video associate with the specificity of their professional noticing of students’ mathematics?

Method

Sample and Procedure

The sample included 47 undergraduate students who were enrolled in an educational technology course in a Midwestern University. Students enrolled in this course were required to fulfill a credit, which could be completed by participating in this study. Much of the sample identified as white (n = 43), female (n = 41), and early childhood education majors (n = 28).

PSTs were asked to record their viewing of the 360 video. The video was a 5 minute, 50 second excerpt of a fourth-grade lesson on reviewing equivalent fractions. In the video, students were provided fraction strips and tasked with finding equivalent fractions for 5/6 and then 3/8. After viewing the video initially, participants reported where they focused their attention most by marking up to 10 red Xs on a provided classroom map (see Figure 1). They then were asked to “describe any and all pivotal moments you noticed during the lesson (i.e., any moment you believe is important for teaching and/or learning of mathematics).” Next, PSTs recorded their viewing sessions and rewatched the fourth-grade lesson. After viewing, PSTs again self-reported where they focused their attention most before being asked to focus on “ONE pivotal moment” in the 360 video and describe why it was important for the teaching and/or learning of mathematics. For the purposes of this initial analysis of data, we focused on analysis of PSTs second viewing of the 360 video.

Analysis and Results

We utilized a convergent mixed methods design to examine a relationship between where PSTs reported to have attended in the 360 video on a classroom map (i.e. self-reported heat map) and their written mathematical noticing. Convergent mixed methods design involves independently analyzing both qualitative and quantitative data before merging them to better understand a given phenomenon (Creswell & Plano Clark, 2011). For this analysis, we focused on PSTs’ written attending and qualitatively analyzed writing using an adaptation of van Es et al.’s (2017) rubric for mathematics specificity. Concurrently, the self-reported heatmaps categorized along designated regions (see Figure 1). This categorical data was then used to calculate an unalikeability statistic—a non-parametric statistic of variance in nominal data. Qualitative codings were quantitized into an ordinal variable and unalikeability statistics were compared using an independent sample Kruskal-Wallis test. This allowed for examination of how variance reported aligned with the specificity of their mathematical noticing.

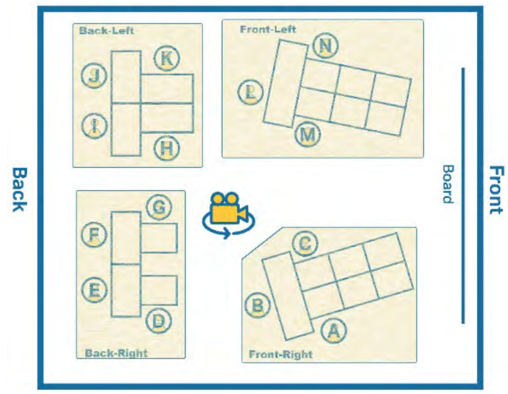

Figure 1: Classroom map for the 360 video with regions highlighted.

Qualitative analysis of PSTs' noticing. We used a coding framework for PSTs' attending to students' mathematics that was developed by van Es et al. (2017). For specificity to mathematics content, van Es et al. (2017) included three hierarchical levels: little or no attention to the mathematics in the lesson; noting the specific task or problem; and attending to / inferring from the task to the broader learning goal in the mathematics lesson. Our own adaptation included: 1) No reference to the mathematics in the lesson (i.e., equivalent fractions); 2) Generic or vague reference to the mathematics in the lesson; and 3) Reference to mathematics of the lesson. Excerpts of three participants are illustrated in Table 1 to help illustrate the difference in codes. The second and third author independently analyzed participants' written noticing using van Es et al.'s (2017) adapted framework. Findings indicated substantial agreement (K=0.714) before the authors reconciled analysis of writing. Across the sample, 14.9% of participants had no reference to the mathematics, 42.6% included generic references, and 42.6% included mathematical references in their written noticing.

Table 1: Example Excerpts of Attending to Mathematics by Classification of Focus.

No Reference	Generic Reference	Mathematical Reference
All the students are interacting and doing the activity. This allows the students to see multiple answers. It also allows them to see multiple ways of doing the question. Because the teacher is asking the students questions and asking for their answers it makes the learning experience better.	The students figured out that they could not represent the fractions because they were not on the fraction papers.	One pivotal point I noticed was when the teacher gave them a fraction in which they couldn't use their fraction strips. I think it allowed them to strengthen their multiplication skills as well as broaden their ideas of how to find similar fractions.

Quantitative analysis and results. Qualitative findings for PSTs' attending to mathematics were quantitized into ordinal data (0=No Reference; 1=Generic Reference; 2=Mathematical Reference) for use in quantitative analysis. Additionally, PSTs self-reported heat map data was coded as an unalikeability statistic (U_2). In this study, a U_2 statistic of 0 would indicate that the PST is not looking around the room and is only attending to one specific region (e.g. the front-left), whereas a 1 would indicate that a PST was looking across all regions of the room for an equal amount of time.

We used an independent sample Kruskal-Wallis test to compare U_2 statistics between PSTs who provided no reference, a generic reference, or a mathematical reference in their written noticing. The median U_2 statistic indicated a much higher degree of unalikeability (U_2 = 0.7456) for the no mathematical reference group than the generic ($U_2 = 0.6803$) or mathematical reference groups (U_2 = 0.6779). These differences were found to be statistically different ($H(2)$ = 6.291, p = 0.43). A Dunn post-hoc test indicated a statistically significant difference in the U_2 statistics between the mathematical reference group and the no mathematical reference group (p = 0.013), as well as between the general reference group and no mathematical reference group (p = 0.039). This difference may be due to the no mathematical reference group having a larger U_2 statistic, which indicates that they perceived focusing on a larger spread of the classroom than the other groups. These findings suggest that participants who perceive they focus on more of the classroom have less specificity in their professional noticing of students' mathematics.

Discussion

The reports of this study are preliminary but contribute to emerging research that the use of 360 video aides in the facilitation of professional noticing (Buchbinder et al., 2021; Walshe et al., 2021; Weston & Amador, 2021). The findings in this study support and extend observations in prior literature that PSTs have less specific noticings when they look around the 360 video frequently (Ferdig et al., 2020; Kosko et al., 2021b, Kosko et al., 2022). The results from our analysis indicates that PSTs with higher U_2 statistics tended to make no mathematical references in their written noticing. Results also suggest the possibility of a trend regarding specificity and focus, but additional data and future research are needed. These results align the work of Kosko et al. (2021b), which noted that PSTs tend to be more conceptual in their writing of mathematical reasoning when they focus on a set of students in the classroom for longer periods of time. Thus, a high variability of PST viewing may lead to PSTs attempting to focus on too many things and miss more specific pivotal moments within a classroom, such as student actions, mathematical discussions, and/or student reasoning. While the differences were not statistically significant between the mathematical reference and general reference groups, average U_2 statistics in these groups do suggest a trend.

Although analysis is ongoing, this study provides several important implications. First, mathematics teacher educators seeking to integrate 360 video may wish to scaffold PSTs' use to encourage more focus on limited number of students. Advocated by Weston and Amador (2021), this focusing may include tasking PSTs with focusing on key locations for a set period of time before looking elsewhere, and providing specific prompts associated with their viewing. A second key implication is the potential for using self-reported focusing as a possible alternative to manual analysis of PSTs' screen recordings (Zolfaghari et al., 2020). Finally, the current paper provides further evidence towards the notion of attending as a subset of perception (van Es & Sherin, 2021). Those teachers better able to be selective in what they perceive demonstrate more sophistication in how they describe what occurred in the classroom. It is possible that PSTs with lower U_2 statistics tend to be better at disregarding selected features of pedagogy than their peers with higher U_2 statistics. However, future research is needed to better understand this interplay and how it may best be used to inform mathematics teacher education for professional noticing.

borowsr@wwu.edu

To prepare preservice teachers (PTs) to create equitable, culturally responsive mathematics classrooms, mathematics teacher educators must support them in making connections between theory and practice. Critical examination of culture, its role in the mathematics classroom, and PTs own culture and experiences can be an entry point for this important work. In this study, preservice elementary teachers at various points in their teacher preparation programs engaged in activities that supported their understanding of culturally responsive and relevant mathematics. Using a Culturally Relevant Cognitively Demanding (CRCD) rubric (Matthews et al., 2013) to evaluate tasks and reflect upon the various issues that the tasks illuminate can be transformative experiences for PTs as they develop their identities as equitable mathematics teachers. This multiple case study examines how PTs' understanding of cultural relevance and responsiveness evolved over both content and methods courses.

Keywords: culturally responsive pedagogy; preservice teachers; teacher preparation

Equity and cultural responsiveness as a key component to teacher preparation programs has gained significant traction in recent years. There is broad support for considering both culture and equity in mathematics teaching (Gay, 2018; Ladson-Billings, 1995), and teacher preparation programs are being tasked to support preservice teachers' understanding and practice of equity, diversity, and inclusion (NCTM 2000; 2014). In this brief, we present on three teacher educators' experiences implementing a curriculum for culturally responsive teaching in elementary teacher preparation courses. Our goal of the intervention is twofold. First, we initiate critical dissonance for our PTs by asking a primarily dominant group to consider a part of their identity, one hidden by overarching systems (Leonardo, 2009). In bringing forth this dissonance, we seek to push our PTs to strive for more socially just contexts for learning and teaching mathematics by provoking a critical examination of the role of culture in math classrooms through analysis of mathematics task(s) using a culturally relevant, cognitively demanding framework (Matthews et al., 2013; Matthews et al, 2022).

Culturally Responsive Pedagogy

Culturally responsive teaching is defined as "using the cultural knowledge, prior experiences, frames of reference, and performance styles of ethnically diverse students to make learning encounters more relevant to and effective for them" (Gay, 2018, p. 36). While culturally *relevant* teaching can be considered within the broader umbrella of culturally responsive teaching, its definition and purpose are different. Culturally relevant pedagogy is a "theoretical model that not only addresses student achievement but also helps students to accept and affirm their cultural identity while developing critical perspectives that challenge inequities that schools (and other institutions) perpetuate" (Ladson-Billings, 1995, p. 469). By defining both culturally *responsive* pedagogy and culturally *relevant* pedagogy, we acknowledge the differences between the two theories. We also note the role of Ladson-Billings' (1994,1995) scholarship on the fields' understanding of culturally *responsive* pedagogy and teaching for justice. So, while we position this manuscript within the theory of culturally *responsive* pedagogy, we draw on the work of scholarship in culturally *relevant* pedagogy.

Scholars have shown what it looks like to implement culturally relevant pedagogy successfully in practice through several case studies (Ladson-Billings, 1994; Matthews, 2009). However, attending to and incorporating students' cultures and lived experiences into a math classroom is difficult. For example, Sleeter (2012) discusses the potential pitfalls of mis-enacted culturally responsive teaching and tasks. Compounding this, prospective teachers have been shown to be dismissive or resistant to incorporating issues of culture and equity in their teaching (Ahlquist, 2001). However, fostering PTs' examination and reflection of their beliefs has been shown to decrease this resistance and expand how PTs might more equitably approach the teaching of mathematics (de Freitas, 2008). To provoke such critical examination and reflection, we employ the culturally relevant, cognitively demanding framework (Matthews et al., 2013).

CRCD Framework

In their framework, Matthews and colleagues' (2013) draw on research on cognitive demand (Stein et al., 2000) and culturally relevant pedagogy (Ladson-Billings, 1995) to build and evaluate mathematics tasks that make connections to students' culture and that maximize students' opportunity to learn mathematics. In Stein and colleagues' (2001) framework for cognitive demand they offer criteria for analyzing mathematics tasks by the depth of thinking that they elicit. Tasks that are more procedural without connections to broader aspects of mathematics are *low* in complexity, while tasks that draw mathematical connections and/or target conceptual understandings are *high* in complexity. Table 1 shows how Matthews and colleagues (2013) synthesize cognitive demand with culturally *relevant* pedagogy and draw upon the complexity component of cognitive demand in their analysis of task structure.

Table 1. Culturally Relevant, Cognitively Demanding Rubric

	Degree in Task Structure		
Description	**High**	**Medium**	**Low**
Mathematics task explicitly requires students to inquire (at times problematically) about themselves, their communities, and the world about them.			
May draw from connections to other subjects and issues.			
Mathematics task draws from students' community and cultural knowledge.			
Task may explicitly seek to add to this knowledge through mathematical activity.			
Task is mathematically rich and cognitively demanding, embedded in cultural activity			
Task asks students to engage discontinuity and divide between school and their own lives - home and school			
Task is real-world focused, requiring students to make sense of the world through mathematics.			
The explicit goal of the task is to critique society - that is, make empowered decisions about themselves, their communities, and the world.			

How does a curricular unit that asks PTs to analyze mathematics tasks with the Culturally Relevant Cognitively Demanding rubric shape their beliefs about culture in a math classroom?

Methods

In this multiple case study, we draw on empirical data collected from two elementary teacher preparation programs at two universities in the United States during the Spring semester of 2022. The two universities are predominantly white, and the prospective teacher programs are predominantly female. The case study examines how a culturally responsive curriculum influences preservice teachers' beliefs about culture and its place in the mathematics classroom (Yin, 2009). Qualitative methods were employed for the inquiry. Data from the curriculum implementation was collected across three early mathematics content courses and one mathematics methods and field experience course. In addition to implementation artifacts, pre- and post-surveys were given to learn more about PTs thoughts about their own culture, and more broadly, the role of culture in the mathematics classroom. Finally, as a reflexive tool, the three teacher educators journaled through the design and implementation of the curriculum. For us, this journaling presented a means at potentially avoiding misrepresentation and misinterpretation of participants (Milner, 2007), particularly when confronting systems of domination (Leonard, 2009).

Toward a Culturally Responsive Curriculum

To develop a collective understanding of culturally *responsive* teaching, preservice teachers first read and discussed an excerpt from *Advancing a Framework for Culturally Relevant, Cognitively Demanding Mathematics Tasks* (Matthews et al., 2013). The whole class analyzed and discussed the first task, *So You Think You Can Draw* with the CRCD rubric (Figure 1). Then, as small groups, the preservice teachers analyzed and discussed task 5, *Curfew Currency*, and Task 7, *Reduce, Reuse, Recycle.* Finally, the whole class analyzed and discussed a task from a prior lesson, such as the *Locker Problem* (Kimani et al., 2016). Discussions emphasized justifications for the rubric rates. At this point, we reasoned the preservice teachers had a general understanding of how to use the rubric to rate mathematics tasks with the rubric.

From here, the task was introduced to the preservice teachers. We chose a task that aligned with fifth to sixth grade standards and a task that was similar to application and style to the included tasks (Matthews et al., 2013). *Justice for Janitors* was chosen from *ReThinking Mathematics* (Gustein & Peterson, 2006). The task draws from a children's book, *¡Si, Se Puede! / Yes, we can!* (Cohn, 2002), whose context is the 2000 janitor strike in Los Angeles. For homework, the preservice teachers listened to an audio recording of the book and solved the task. During the next course meeting time, we discussed the task, analyzed the task with the CRCD rubric, and discussed our analysis.

Data Collection

To analyze the effects of the curriculum, we collected artifacts including preservice teachers' solutions and analysis of the task *Justice for Janitors*. We also conducted an open-ended pre- and post- survey which asked participants to reflect on their culture, their experiences with culture in a mathematics classroom, and the importance of culture in the teaching and learning of mathematics through the following prompts:

- What is culture? How do you define it? What do you think it is? How would you describe your culture?
- What role does students' culture play in a math classroom?

- What responsibility do math teachers have to consider and incorporate students' cultures into their teaching?
- Have you heard of culturally responsive pedagogy? What does that term mean to you? What experience do you have with it?
- What does a culturally relevant math task look like? Can you give an example from your math experiences?

In total, we collected 122 participant responses. For this brief proposal, we draw from Randy, a preservice teacher in a mathematics methods course. She is white, in her early twenties, and she is currently placed in a kindergarten classroom.

Analysis and Preliminary Results

Our analysis will orient on PTs' awareness of their own culture and the role of culture in the mathematics classroom. Given that our data collection is currently in progress, we report on pre-survey responses. PTs, in general, could articulate a definition of culture but struggled to name their own culture. For example:

> I think culture is everything that makes an individual who they are. It is their background, their experiences, their relationships, status, beliefs, all of the above. All these things affect the lens in which you view the world. I would describe my culture as my thoughts, beliefs, and attitudes in which I navigate this world. I personally have a very positive disposition and believe that people are put on this world to do good and make differences in people's lives for the better. This belief affects every decision I make in my life and is the lens in which I view the world.

Randy's description of her disposition and perspective of others speaks to the difficulty PTs have in describing their culture and beliefs. Leonardo (2009) speaks to the role of education of the dominant group and the power of normativity in perpetuating systems of domination. While Randy struggles to name her culture, she anticipates how culture shapes a math classroom:

> I definitely know that there are ways to implement culturally relevant math in your classroom, but I haven't thought much about specific tasks. I am thinking it could look something like allowing your students to connect with the content in a meaningful way. This can be done by having students collect data on their family, then represent that data using a graph and then sharing it with your family. Or it could look like looking at the current state of the world to inform a math lesson. It might be on statistics of an endangered species and comparing the percentage in which their population is dropping? This could open up conversation on why these species are endangered and how we can play a part in it. I am not entirely sure if this is what culturally relevant math looks like, but just some ideas.

Randy's responses, as one case, speaks to the need of our curricular intervention for PTs' development of their cultural understandings. Upon completion of our data collection, we will offer a comparison of responses of PTs across content and methods courses, particularly the ways PTs in different phases of their certification engage with the ideas of culturally responsive pedagogy and how these ideas shape their beliefs.

DISSONANCE CREATED THROUGH OPEN MATHEMATICAL TASKS: PRESERVICE TEACHERS' BELIEFS ILLUMINATED

Amy Brass

ead202@psu.edu

It is well-documented that elementary preservice teachers (PSTs) enter teacher education programs with beliefs about mathematics education largely formed from their own schooling experiences. These beliefs are often narrow and strongly influence how PSTs will eventually teach mathematics to their elementary students. In an effort to create dissonance regarding these beliefs, we presented PSTs with four tasks of varying levels of openness as part of their elementary math methods course. After participating in discussions surrounding these tasks, PSTs completed an open-ended questionnaire that asked them about the experience. Preliminary findings suggest the open tasks challenged PSTs' beliefs about mathematics as a subject, mathematics learning, and mathematics teaching.

Keywords: Affect, Emotion, Beliefs, and Attitude; Preservice Teacher Education

Preservice teachers' (PSTs) beliefs about the teaching and learning of mathematics are formed through their own experiences as students of mathematics (e.g., Lampert, 2002; Thompson, 1992). As PSTs' previous schooling experiences often contradict with goals of the mathematics education community, Ball (1990) called for mathematics methods courses to be a place of dissonance to interrupt the "smooth continuity from student to teacher" (p. 11). The work we report here emphasizes the breaking of such continuity and the creation of dissonance related to PSTs' experiences with mathematical tasks. We aimed to unsettle their notions of mathematical tasks through the use of tasks involving varying levels of openness (e.g., Leikin, 2018; Silver, 1995). In our analysis of PSTs' reactions to these tasks, we focused on their beliefs about mathematics education. We addressed this research question: What do elementary PSTs' perceptions of tasks of varying levels of openness illuminate regarding their beliefs about mathematics education?

Theoretical and Conceptual Framings

Through synthesizing past research, Op't Eynde et al. (2002) developed a framework of students' mathematical beliefs and defined mathematics-related beliefs as "implicitly or explicitly held subjective conceptions students hold to be true about mathematics education, about themselves as mathematicians, and about the mathematics class context" (p. 27). Their resulting framework was comprised of a person's beliefs about mathematics education, a person's beliefs about the self, and a person's beliefs about the social context (p. 28). Here, we focus specifically on PSTs' beliefs about mathematics education, which Op't Eynde et al. viewed as the compilation of three different subsets of beliefs: (1) a person's beliefs about mathematics as a subject, (2) a person's beliefs about mathematics learning and problem solving, and (3) a person's beliefs about mathematic teaching (p. 28).

We used tasks of varying levels of openness as a platform to explore PSTs' beliefs about mathematics education. Leikin (2018) outlined three different types of openness to mathematical tasks. *Open-start tasks* allow for multiple ways to start the task and multiple strategies to solve the task. *Open-end tasks* have multiple valid answers to them. The third type of task, *open-start and open-end combined tasks*, are ones in which multiple strategies and different, valid answers are possible. Due to the various levels of openness within Leikin's classification structure, we created categorizations for the tasks we used with PSTs: (1) *open-start, closed-end* tasks allowed for different entry points and strategies but culminated in one, single answer; (2) *open-start, limited-end* tasks provided for different entry points and strategies but focused the multiple valid answers relevant to a limited number of contexts; and (3) *open-start, open-end* tasks allowed for multiple entry points, strategies, and valid answers.

Methods

This study is part of a larger exploratory study conducted for the purpose of describing PSTs' engagement in open-ended mathematical tasks. We report here on a single case – one section of an elementary math methods course – and focus specifically on what PSTs' perceptions of their own engagement in mathematical tasks of varying levels of openness illuminated about their beliefs about mathematics education.

Participants and Context

This study was conducted at a large Mid-Atlantic university. In the section of the elementary math methods course we describe here, there were 23 participants. The majority of the participants were White females; there was only one male participant.

During their math methods course, PSTs engaged in four tasks that were designed to have varying levels of openness. PSTs also participated in a discussion of each task led by their instructor. These tasks included a "Which One Doesn't Belong?" (WODB) task (Danielson, 2016), a word problem (WP) of high cognitive demand (Hallman-Thrasher & Spangler, 2020), a "How Many?" (HM) task (Danielson, 2018), and a "Notice and Wonder" (N&W) task (Fetter, 2021; Ray-Riek, 2013). Descriptions of the specific tasks are provided in Table 1.

Table 1: Task Descriptions

Task	Type	Description
Task 1: WODB	open-start, limited-end	PSTs were presented with four addition expressions, three of which had three single-digit addends and one of which had four single-digit addends. PSTs could assert any of the four options did not belong as long as they provided justification.
Task 2: WP	open start, closed-end	Given a total number of cupcakes and boxes with specific capacities for two separate flavors, PSTs were asked to find how many boxes could be made of each flavor.
Task 3: HM	open-start, open-end	PSTs were presented with an image of a large box of sidewalk chalk. The top of the box was removed and the chalk was arranged in columns according to color. Several pieces of chalk were also visible outside of the box. PSTs could choose what and how to count.
Task 4: N&W	open-start, open-end	PSTs were presented with a pictorial representation of the composition of ingredients of nine espresso-based coffee drinks. PSTs were asked to share what they noticed and wondered about the image.

Data Collection

We visited the section of elementary math methods on four separate occasions. Before each visit, we met with the instructor to choose a task that aligned with the planned content. We also collaborated with the instructor to anticipate possible PST responses and to generate potential discussion prompts. For each implementation of the task, the instructor introduced the task, gave

PSTs time to work on the task individually, then facilitated a whole-class discussion of PSTs' thinking surrounding the task. We video-recorded each task session and also took field notes as we observed. Following each discussion, PSTs completed a nine-item, open-ended questionnaire that asked them about their experience and engagement with the task. Based on PSTs' responses on the questionnaire after the first two implementations, we adapted some of the questions for the latter two implementations.

Data Analysis

In exploring our research question as to PSTs' beliefs about mathematics education, we focused our analysis on specific items from the questionnaire. Both versions of the questionnaire included a question that asked PSTs to describe their emotions and a question that asked "When you think about math, is this a task you expect? Why or why not?" PSTs' responses to these questions were included in analysis for all four task sessions. Other questions included in analysis were a question that asked about how PSTs felt about their identity as a learner of mathematics during the task and discussion (first two task implementations) and a question that asked how PSTs' experience of the task and discussion compared to their typical experiences with mathematics (third and fourth task implementations).

When jointly coding the PSTs' responses, we used a combination of inductive and deductive coding (Miles et al., 2014). We used inductive coding when examining each PSTs' responses to the above-mentioned questions for whether or not each task matched the PSTs' expectations for mathematical tasks and when analyzing PSTs' responses for the beliefs they communicated about mathematics education. In doing so, we looked for common phrases and themes within PSTs' responses. We also took note of responses that differed from these themes. We used deductive coding when we categorized our inductive codes using Op't Eynde et al.'s (2002) subsets of beliefs about mathematics education: beliefs about mathematics as a subject, beliefs about mathematics learning, and beliefs about mathematics teaching in general.

Results

For our preliminary results, we looked for predominant themes that emerged in each of these subsets of beliefs about mathematics education. These findings are briefly described below.

Beliefs About Mathematics as a Subject

When we coded PSTs' responses in the subset of beliefs about mathematics as a subject, the most commonly apparent belief involved mathematics as a content area or a set of topics. Of the 84 questionnaires completed across four tasks, 37% of responses (n=31) expressed a belief about mathematics that involved specific content. These responses most commonly involved a belief that mathematics involved numbers and operations (20 of 31 responses, or 65%). For example, when completing Task 3 (HM), one PST stated that in math, they expect "to either add, subtract, multiply, or divide something and in this case we did" (Biscuit; all names are pseudonyms). When completing Task 4 (N&W), another PST shared they were "very taken aback by the lack of numbers" (Krystal). When PSTs were coded as having expressed a belief about mathematics, that belief most often involved a content area or a set of topics.

Beliefs About Mathematics Learning

The most predominant theme in PSTs' beliefs about mathematics learning involved whether they expected one or multiple answers and/or one or multiple possible strategies. Of the 84 submitted questionnaires, 40% (n=34) provided evidence of belief in this area. Of the 34 responses involving number of answers and/or strategies, 56% (n=19) mentioned expecting a task to have one correct answer. After engaging with Task 1 (WODB), one PST explained they tend to think of math as "coming up with one particular answer… while there are many ways to solve… the answer remains the same” (Katherine). Including Katherine, 44% (n=14) of 34 PSTs mentioned the belief that math can involve multiple strategies. Maria noted of Task 3 (HM), “This problem had many ways of solving it and to me that is what I usually expect from a math task.” However, 44% (n=14) of 34 PSTs expressed a belief that math usually involves one set strategy or approach. For example, when solving Task 2 (WP), Becca shared that in her past experience as a math student, “we always were told to solve [problems] one specific way.” Importantly, across all questionnaires, no PSTs stated that they expected a task to have multiple possible answers.

Additionally, although discussions were held for all tasks so that PSTs could share their strategies and solutions, these discussions seemed out of place for PSTs in the tasks allowing for multiple valid answers. This was not the case for the for open-start, closed-end task (Task 2, WP), in which discussion seemed to be expected. For the other tasks, however, the PSTs made comments like these: “Traditionally, I think about math as less of a conversation” (Emma, Task 1, WODB), “The discussion was a bit different because I haven't really had to fully express my thought process in the past” (Oliver, Task 3, HM), and “…this task is not really similar because a lot of math problems are not open-ended and discussion based” (Biscuit, Task 4, N&W).

Beliefs about Mathematics Teaching

We also saw PSTs’ experiences as influencing their beliefs about mathematics teaching as they reacted to tasks of varying levels of openness. Although PSTs commented on the similarity or differences between the tasks and their experiences as mathematics learners, when they took a teacher’s perspective, prior experience in the math methods course influenced their beliefs. This was specifically the case with Task 1, a WODB task that was facilitated after PSTs were introduced to another WODB task earlier in the semester. When asked if this was a type of task they expect when they think about math, approximately 23% (n=5) indicated that previous experience with a WODB task in the mathematics methods course influenced their thinking. As examples, one PST responded, “Before taking this course, I would not [have] felt that this was as much math as it actually is. I had never seen this done before and I find it to be super beneficial” (Pam), and another PST commented, “Prior to this course, I would say no, as it is not something I ever experienced before. Today yes, simply because we have done it in class before” (Calleigh). Interestingly, although PSTs had also engaged in another HM task earlier in the semester, none of them mentioned that experience influencing their views on whether they expect that type of task when thinking about mathematics.

Discussion

The dissonance created by implementing mathematical tasks with varying levels of openness with PSTs illuminated their beliefs about mathematics as a subject, mathematics learning, and mathematics teaching. Preliminary findings suggest that PSTs view mathematics as a set of topics, and not as “an activity grounded in human practices, a science of patterns with problem solving at the heart of it” (Op’t Eynde et al., p. 29). Additionally, several PSTs expected a mathematics task to have one valid answer (e.g., Schoenfeld, 1992). None of the PSTs expected a task with multiple solutions, and many expressed surprise at encountering tasks that allowed for multiple answers. PSTs’ previous experiences also influenced their beliefs (e.g., Ball, 1990) for when mathematics could include discussion (e.g., open-start, closed-end tasks) and about what types of tasks they expect when they think about mathematics. In closing, we offer this question: Because moments of dissonance lead to moments of growth and learning, how do we leverage breaks in experience (Ball), such as the use of open-start, open-end tasks, with PSTs in ways that help them see the potentials, rather than the differences, of such experiences?

In this paper, we report on two years of collaboration with inservice teachers to rethink field work in elementary mathematics education. We engaged teachers who had completed the K5 Mathematics endorsement to serve as university supervisors. Their unique position as practicing teachers and agents of the university provided insight into program improvement. The teacher mentors shared equity tools and rubrics with the preservice teachers. Inservice teachers, preservice teachers, and the researchers interrogated their practice with these tools and provided insight into each other's practices. At times there was harmony in our thinking and at other times productive dissonance between researchers, inservice teachers, and preservice teachers.

Keywords: Equity, Inclusion, and Diversity, Classroom Discourse, Preservice Teacher Education, Teacher Educators

In this paper, we investigate the collaboration between university researchers and inservice teachers to support preservice teachers (PSTs) in building equitable mathematics learning communities and attending to marginalized students or groups. We employed three tools to support our own and the PSTs' practice. In this practice, we had a trifold foci: supporting robust mathematics identities; the use of high-leverage practices to build discourse; and equitable participation in the community.

Perspectives

To shift practices in schools, teachers at all levels need practice with innovative teaching strategies or they are likely to revert to the patterns of schooling they experienced (Beyer & Zeichner, 2018; Britzman, 1991). PSTs typically begin their teaching career as part of a triad—the PST, the field supervisor from the university, and the cooperating teacher in the school. There is a critical need to explore the nature of effective supervision further, especially in light of high-stakes assessments (Donovan & Cannon, 2018). Cooperating teachers are embedded in schools but are often removed from the theory and methods taught at universities. Zeichner (2010) describes the disconnect between universities and schools as one of the "central problems" in teacher education (p. 480) and recommends the construction of hybrid spaces where university and field-based education can come together. Other studies have explored and found success in bridging the theory to practice gap by recruiting program alumni as cooperating teachers (Ragland, 2017). In this project, we have recruited inservice teachers with mathematics expertise to bridge the space between university and field by serving as field supervisors and induction mentors for PSTs.

We recruited graduates of our mathematics endorsement program (ECs) to support preservice teachers in their final internship. The focus of this support is on the use of high-leverage practices, mathematics identities, and equitable participation. We incorporated three tools to serve as pedagogical guides: the EQUIP (Equity Quantified in Participation) app (Reinholz & Shah, 2018); the Levels of Classroom Discourse (LCD) rubric (Hufferd-Ackles et al., 2004); and a culturally relevant task rubric (CRT). Boston et al. (2015) posited that tools allow teachers to focus in on aspects of instruction to "provide a concrete structure for the development of new practices by specifying criteria and identifying standards for the implementation of the intended practice" (p. 154).

Together with the inservice teachers, who had used the tools in their coursework, we considered the drawbacks and potential of each tool and how they might best be incorporated into field work. Drawing from the work of Herbel-Eisenmann and Shah (2019), our goal was to use EQUIP to help teachers and ourselves to develop critical consciousness toward a change in practice.

Elementary supervisors must possess strong mathematics content knowledge and pedagogy to support PSTs fully. By supporting PSTs in the field with ECs, we work to close the theory to practice gap for elementary mathematics teachers. At our university, 1 of the 33 existing university supervisors had a mathematics content specialty. By recruiting ECs to serve as university supervisors, student teachers had access to mentors in the field who have both a command of research-based practices and theories and were attuned to the realities of the classroom since they were currently teaching. We found that this was especially important during the 2020-2021 school year as teachers navigated various models and combinations of online and face-to-face instruction for the first time.

The questions that guided this project were:

- How do we collaborate with teachers in moving from an intention to be equitable to critical consideration of how equitable our practice is?
- What are the benefits and drawbacks of using the EQUIP, LCD, and CRT tools with inservice and preservice teachers to increase high leverage practices?
- How might the coordination of the three tools in a recursive cycle across university and schools promote the creation and maintenance of an equitable mathematics learning community?

Methods

Georgia is one of 19 states in the United States that has developed a route for endorsement of elementary mathematics specialists. This study was drawn out of a nine-semester elementary endorsement program comprised of three courses focused on equitable mathematics teaching. Each eight-week course was designed to embed content and pedagogy. The courses were designed to be fully online and asynchronous, but we offered synchronous sessions weekly, which the majority of the teachers attended. Through this exploratory qualitative inquiry, we report on three cohorts of in-service teachers (2019-2020, 2020-2021, 2021-2022) and their engagement with two cohorts of PSTs (2020-21, 2021-22).

Teaching and teacher education are complex social and political acts; therefore, we employ exploratory case study methodology (Yin, 2009) to account for context, agency, and temporality (Byrne & Callinghan, 2014). We conducted cross case analysis across the three EC cohorts and between EC and PST cohorts. Since we are building on two previously researched tools, to analyze the data we are using provisional coding (Saldaña, 2016). This means that the codes are predetermined for anticipated categories. For this study, the codes include the areas of the LCD rubric and the discourse and demographics in the EQUIP app. We also use invivo coding to "prioritize and honor the participant's voice" (Saldaña, 2016, p. 106) which is often not the case with teachers.

Results

From the data we collected with three cohorts of inservice teachers and two cohorts of preservice teachers, there is an overwhelmingly positive reaction to the use of the two tools within their practice. All the teachers expressed positive shifts in their practice and the usefulness of the tools to improve their instruction and build more equitable mathematics learning communities. We share their reflections below as they related to the areas of the LCD rubric and the EQUIP app.

In the area of *teacher role and questions*, as the teachers began using the EQUIP app and LCD rubric, several teachers first noticed the lack of time they gave their students to speak. One teacher called herself the "main talker" and another described herself as "dominating the conversation." As the teachers reflected later in their practice after using the tools several times, they were able to shift and to "take a step back and allow my students to carry through the mathematical discourse and only prompt and probe when necessary to achieve deeper thinking." One teacher reflected on this shift by stating that "allowing [students] to respectfully talk about their strategies and their answers can help them respect classmates in the long run." Another teacher reflected on this shift and identified her own understanding that "when students work together and complete mathematical tasks, they talk to each other more and rely less on me and more on each other for guidance and advice."

Though many of the teachers in our programs were in school settings that encouraged or mandated, gradual release (I do, we do, you do) instructional paradigms, the use of the LCD rubric helped them to identify and attune to key practices that would shift the mathematical authority in the classroom for teacher centered to student centered.

In the area of *Student Responsibility*, after the implementation of both the tools, several teachers identified that their students were capable of more than they had originally thought. In their reflections, the teachers demonstrated that they had begun to see their students as mathematical leaders. One teacher stated, "I have learned that if I believe my students are capable of doing what others might label as too hard for them, then they will gain the confidence in themselves and be able to complete most tasks presented to them with little to no assistance from myself." This shift is significant and difficult when teachers are being asked by their districts to show their students how to do everything, every day before they allow students to do any mathematics. Another teacher commented, "I was afraid to try higher level activities with my students." The work with the LCD rubric, as a guiding document, allowed these teachers to envision another type of mathematics classroom, a community in which students are leaders.

In the area of *Explaining Mathematical Thinking,* we posit that along with the data from EQUIP, the LCD rubric prompted teachers to listen more carefully to their students. One teacher stated, "I have been more cognizant of looking for those areas in which the students shine and finding ways to use those to help themselves and others gain a better understanding of problem solving or completing tasks."

Moving from gradual release to classrooms focused on pedagogies centering mathematical discourse changed the way that some teachers thought about the purpose of talk in their classrooms. We posit that the LCD tool provided an authoritative pedagogical model that allowed inservice teachers to push back against the mandates of their districts.

Several teachers noted that EQUIP opened their eyes to different ways of thinking about how to be equitable in their classrooms. One teacher noted, "I had never seen anything wrong with who I call on, what I ask, and how I have students respond but this had a totally different spin on it." Another teacher wrote, "Equity wasn't something that was covered in my undergraduate classes, and the importance of equity in the curriculum has never crossed my mind. …My students come from all different backgrounds and homes, so assuming that they all know what I am talking about at all times is a grave mistake."

Drawing on their experiences with the tools, ECs were able to guide PSTs to meaningfully implement the tools in their own practice. Looking across the responses of ECs and PSTs to the tools, we found that both groups became more aware of marginalized groups and individuals. However, the PSTs had fewer resources and ideas as to how to draw in the marginalized populations. Guidance from ECs was crucial in navigating both their critical consciousness and the practical moves they could make in their classrooms to respond to issues of status and marginalization.

Discussion

We found that while teachers quickly admitted that they were the main talker in the room and openly discussed their intent to provide more and different opportunities for student talk, there was less attention in the first two cohorts to directly addressing race when considering marginalized individuals and groups. Teachers discussed gender, location of students in the room, and strength in mathematics as demographic dimensions. While we do assert that the use of these two tools in concert led the teachers to foster more equitable mathematics learning communities and to increase their use of high-leverage practices, we are interested in how the teachers' consideration of their practice could be more critical.

The EQUIP app allowed flexibility for teachers to create their own discourse and demographic dimensions. We see this as a positive as the context of classrooms and schools varies widely. However, this flexibility left an opening for teachers to avoid race as a consideration in their classroom dynamics. It is too easy to be complicit in supporting or ignoring colorblindness in teacher education (Gordon, 2005).

Though EQUIP allows teachers to see patterns of participation, the ways the app is set up and the degree to which a teacher digs into the data can influence the impact of the app. When they introduced EQUIP in 2018, Rhienhalz and Shah, asked, "What are the affordances and limitations of a quantitative approach to measuring aspects of equity and inequity in classroom discourse?" (p. 141). We share this question, and we also share the acknowledgment that classrooms are incredibly complex spaces and that these and other tools should be used in concert to guide and encourage deeper reflection. However, we found, unsurprisingly, that the use of EQUIP alone cannot undo marginalization in classrooms.

In our most recent iteration of the endorsement course sequence, we have incorporated identity work with teachers, direct conversations about White Supremacist tenants in mathematics classrooms, and more guidance in setting up and reflecting on the data from the EQUIP app. We have drawn more attention to the structures and systems in the United States and in schools that disproportionately disadvantage Black and African-American students.

En este artículo se presentan los resultados de una investigación que atiende la desconexión entre la matemática escolar y la realidad, en particular se reconoce que esa desconexión ha obligado a privilegiar la representación gráfica de asíntota como recta, negando otro tipo de comportamientos asintóticos. Se construyó un diseño escolar que favoreció a modificar el tratamiento de la asíntota con 5 profesores de matemáticas en formación inicial. Se implementó en un ambiente virtual mediante zoom. El marco teórico fue la teoría socioepistemológica de la matemática educativa. Fue un estudio de caso instrumental. Como resultado se amplió el universo de asíntota en la comunidad de estudio y se conformó un marco de referencia para enseñar la asíntota.

Palabras clave: Cálculo, Conocimiento matemático para la enseñanza, Precálculo, Modelado.

Introducción

Una preocupación que hay en la matemática educativa, y en particular del profesor, es ¿cómo conectar esa matemática que se enseña con la realidad? Además, el docente es cuestionado por los estudiantes en cuanto a la "utilidad de la matemática" en contextos de la vida real. Bajo esta visión de incorporar y conectar el conocimiento que se aprende en el aula con la realidad, existen perspectivas teóricas en matemática educativa que se han preocupado por valorar las matemáticas no escolares. Por ejemplo, Rosa y Orey (2015) advierten la necesidad de valorar y promover en el currículo de matemáticas el conocimiento local desarrollado por los miembros de la comunidad que interactúan en un determinado entorno escolar. Ante esta preocupación, Codero et al. (2015) señalan que en lugar de enfocar la atención en lo que saben los estudiantes es preciso mirar cómo usan el conocimiento.

El objetivo de esta investigación fue conocer, según el modelo de socialización contemporánea de Gómez (2015), los procesos de construcción y organización del conocimiento que pasaron los profesores de matemáticas en formación al enfrentarse a situaciones específicas de la realidad en un diseño escolar y que permitieron ampliar el universo de asíntota. La aplicación del diseño se llevó a cabo mediante la plataforma de zoom. La pregunta de investigación fue ¿Cómo se dan los procesos de socialización de lo asintótico en una comunidad de profesores de matemáticas en formación al enfrentarse a un diseño de situación escolar?

Marco teórico

La teoría socioepistemológica de la matemática educativa considera la importancia de incorporar otros saberes que han estado ausentes en la escuela y favorecerían a una matemática útil para el que aprende. Cordero et al. (2015) reconocen como problemática de la enseñanza y aprendizaje de la matemática al discurso matemático escolar (dME). Este ha invisibilizado significados del cotidiano y por tanto hay una desconexión entre la realidad y la matemática escolar. Este fenómeno se reconoce como opacidad. Lo anterior, requiere trabajar en la socialización contemporánea del conocimiento matemático, de tal forma que la realidad sea un marco de referencia para enseñar matemáticas y lo que se aprende en la escuela sea útil para la vida (Gómez, 2015; Pérez-Oxte, 2021).

Gómez (2015), propone tres procesos que dan cuenta de la socialización del conocimiento matemático: proceso funcional, historial e institucional. El proceso funcional se expresa en el conocimiento útil para la comunidad: los usos. Según Cordero (2008) y Cordero, Mena y Montalto (2010) el uso del conocimiento matemático se caracteriza con referencia a dos elementos dialécticos: el funcionamiento (Fu), es decir ¿qué hace? y la forma (Fo); ¿cómo se hace? Además, Cordero y Flores (2007) afirman que las tareas pueden ser actividades, acciones y ejecuciones. El proceso historial requiere establecer relaciones entre usos de una situación específica a otra, a esto se le llama resignificar el conocimiento. Finalmente, el proceso institucional muestra la organización de las relaciones entre los usos sintetizados en categorías de conocimiento, es decir, argumentaciones basadas en lo vivencial del que aprende.

Un ejemplo de categoría es el comportamiento tendencial de funciones (CTF) (Cordero, 1998; Cordero y Solís, 2001; Buendía y Cordero, 2005). Según Cordero (1998), el CTF es un "argumento que establece relaciones entre funciones y está compuesto por una colección coordinada de conceptos y situaciones del Cálculo donde se discuten aspectos globales de variación" (p. 56). Un estudiante dará cuenta de la emergencia de la categoría CTF cuando establezca relaciones entre funciones acerca de su comportamiento en el infinito, recurriendo a procedimientos como la variación de parámetros a partir de modelos gráficos y analíticos.

El modelo de socialización es considerado como una perspectiva que provee de elementos teóricos-metodológicos para la construcción del diseño y análisis de datos.

Metodología

La investigación fue de tipo cualitativa y un estudio de casos instrumental (Skate, 2005). Se sometió a prueba que la socialización de lo asintótico propicia un entorno de relaciones recíprocas entre la asíntota y sus usos, permitiendo al docente ampliar su universo de asíntota.

La aplicación del diseño escolar en el ambiente virtual zoom, debido a las condiciones provocadas por el Covid19. La población de estudio fue conformada por 5 estudiantes del profesorado de matemáticas de la Universidad Pedagógica Nacional Francisco Morazán, en Honduras. Posterior a la aplicación del diseño se realizó una entrevista con el fin de profundizar sobre sus respuestas.

Momentos de la ruta metodológica

Momento 1. Reconocimiento de la categoría CTF. Se retomó los resultados de estudios previos (Mendoza, 2020; Soto y Vilches, 2018) sobre el CTF para estudiar la epistemología que emerge en otras comunidades como las de ingeniería y la biología. Se confrontó con lo habitual de la enseñanza de la asíntota.

Momento 2. Conformación de la epistemología. Se consideró tres situaciones específicas de tres dominios distintos, a saber: el control de temperatura de un foco (ingeniería biónica), la capacidad de soporte poblacional (biología) y la dinámica de una epidemia (epidemiología). A partir de esto se reinterpretó esta epistemología de usos para el diseño de tareas en cada situación.

Momento 3. Construcción del diseño escolar. Se construyó cada una de las situaciones y tareas con base en la epistemología de usos. Se ejecutó un pilotaje que permitió mejorarlo, validarlo y construir un guion para la entrevista no dirigida. Como resultado se estructuró en tres fases coherentes con la perspectiva de socialización: 1) evidenciar elementos de opacidad, 2) poner en juego las situaciones específicas para dar cuenta del proceso funcional e historial y 3) develar la emergencia de la categoría comportamiento tendencial de funciones, para ampliar el universo de asíntota a partir de nuevos argumentos gráficos.

Momento 4. Puesta en escena del diseño escolar. Se desarrolló a través de la plataforma Zoom, con una duración de 4 horas. Se utilizó WhatsApp como medio para que los estudiantes enviaran el desarrollo de las tareas. Posteriormente se entrevistó individualmente a cada participante, para ahondar en sus respuestas, procedimientos y argumentaciones.

Momento 5. Análisis de datos. El análisis se desarrolló en tres secciones que corresponden a las fases del diseño y la perspectiva de socialización. Por lo cual, en la sección I se analizan elementos de opacidad en la comunidad, en la sección II se analiza el proceso funcional e historial y en la sección III, se analiza el proceso institucional. Según Pérez-Oxté (2021) rendir cuentas de algún proceso significa identificar expresiones asociadas a cada proceso. De esta manera se identificó relaciones en las expresiones matemáticas de la comunidad que pudieran darse entre lo matemático y la situación específica (tabla 1).

Tabla 1: Cuestionamientos para caracterizar procesos de socialización.

Procesos	Cuestionamientos
Funcional	¿cómo usan la asíntota? ¿qué significan en cada situación? ¿cuáles son los funcionamientos de su conocimiento matemático?
Historial	¿qué debates surgen entre los usos de la asíntota en cada dominio? ¿cuáles son los procedimientos? ¿cuáles son las formas de uso en que se manifiesta su conocimiento?
Institucional	¿Cómo emerge la categoría comportamiento tendencial? ¿Qué instrumentos se presentaron en las situaciones? ¿Cuál es la relación que hay entre la asíntota y la categoría de comportamiento tendencial?

Nota: adaptado de Pérez-Oxté (2021)

En las transcripciones se utilizó P1, …, P5 para mostrar las respuestas de las participantes.

Resultados y discusión

Sección 1 del análisis

En la fase 1 del diseño se preguntó a los participantes ¿qué es la asíntota? Las respuestas mostraron que la recta tiene un papel hegemónico en las argumentaciones gráficas de la comunidad para definir la asíntota. P2 indicó que la asíntota "es una recta a la que se aproxima continuamente la gráfica de una función.", mientras P3 respondió que "Es una línea recta que prolongada de forma indefinida se acerca progresivamente a una curva sin llegar nunca a encontrarla." Los tipos de asíntota que se manifiestan son la asíntota vertical, horizontal y oblicua, evidenciando que no existen argumentos sobre comportamientos asintóticos curvos. Ante la pregunta ¿cómo enseñaría la asíntota? se evidencia la falta de marcos de referencia para enseñar la asíntota. El sentido de "aplicar del concepto" está presente a través de ejemplos gráficos, pero no hay referencias de la realidad que favorezcan al uso de la asíntota.

Sección 2 del análisis

En la fase 2 del diseño se presentan tres situaciones específicas que rescatan la epistemología de lo cotidiano en los dominios: ingeniería biónica, biología y epidemiología. Las situaciones específicas son:

- Se1: el control de temperatura de un foco,
- Se2: la capacidad de soporte poblacional y
- Se3: la dinámica de una epidemia.

Se buscó la alternancia de dominios que generan nuevos usos de la asíntota, los que están dados por establecer una relación mutua entre alcanzar y mantener una temperatura deseada, mantener la fluctuación de una población alrededor de la capacidad de soporte y determinar una tasa de recuperación favorable en una epidemia.

En la Se1 se pidió que describieran el comportamiento de la función de temperatura de un foco $T(t)$ al transcurrir el tiempo, sabiendo que debe alcanzar y mantenerse lo más cercano a la temperatura de referencia $Tr(t)$ (Figura 1).

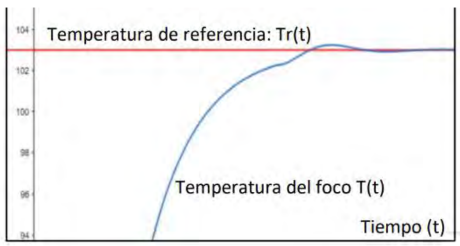

Figura 1: Temperatura $T(t)$ de un foco y temperatura de referencia $Tr(t)$.

Se sabe que un control on-off restablece la temperatura del foco $T(t)$ comparándola con la temperatura de referencia $Tr(t)$, determinando un error $\mathcal{E}(t)$ que controla el encendido y el apagado del foco y con esto su temperatura.

Se pidió escribir una expresión que relacione $T(t)$, $Tr(t)$ y $\mathcal{E}(t)$. Los participantes compararon $T(t)$ y $Tr(t)$ a través de la resta para determinar el error $\mathcal{E}(t)$. Modelando un patrón de construcción que conllevó procedimientos de variación de parámetros y organizar comportamientos asintóticos. Esto dotó de significados a la asíntota como la reproducción de la temperatura deseada considerando que se debe alcanzar y mantener. Además, se preguntó ¿Cuál debe ser el comportamiento de $\mathcal{E}(t)$ para mantener $T(t)$ lo más cercana a $Tr(t)$? Para lo que establecieron condiciones necesarias. Por ejemplo, profesora P1 describió que la condición para reproducir la temperatura deseada es que $\mathcal{E}(t)$ debe tener una tendencia hacia cero cuando el tiempo tiende al infinito (figura 2).

Respuesta	Transcripción de respuesta
	El comportamiento de E(t) para mantener a T(t) lo más cercano a Tr(t) debe ser cada vez menor *hasta llegar a cero.*

Figura 2: Comportamiento de E(t) en la se1.

El patrón de construcción que significó a la asíntota en la $Se1$ se resignifica en la $Se2$, donde se busca reproducir la tendencia de una dinámica de población hacia una capacidad de soporte poblacional. Aquí, la resta también es la forma de comparación que lleva a modelar el patrón $P(t) = C(t) + S(t)$. Donde $P(t)$ representa la dinámica de población, $C(t)$ la capacidad de soporte poblacional y $S(t)$ la sobresaturación.

En ambas situaciones, los profesores recurrieron a la forma de la tendencia para destacar el comportamiento global de las funciones T(t) y P(t) a partir de comparar su tendencia con Tr(t) y C(t) respectivamente. Por ejemplo P1, habla de la estabilidad entre las funciones y afirmando que P(t) tiende a la capacidad de soporte C(t). El proceso funcional describe los usos en cada situación específica y el proceso historial la resignificación entre ellos (figura 3).

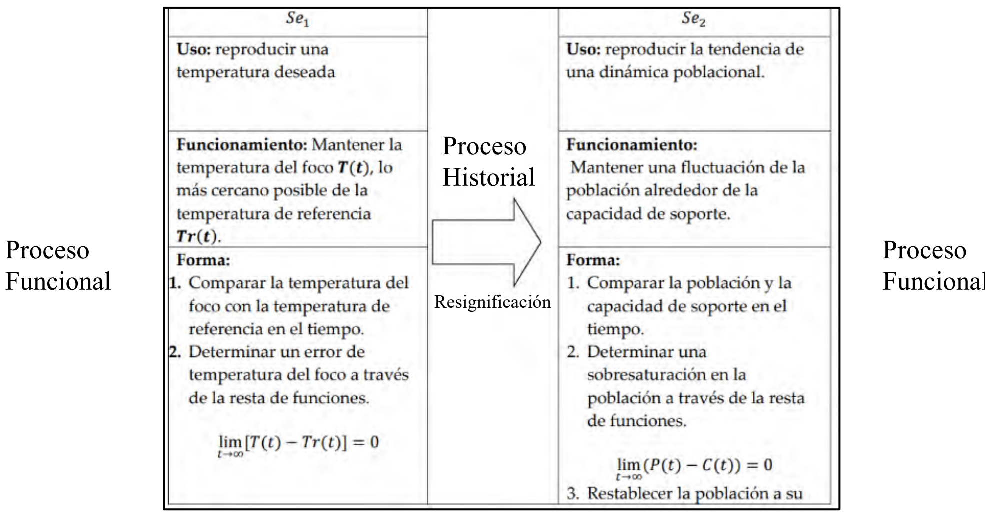

Figura 3: Resignificación de usos de la asíntota entre la Se1 y Se2.

Los profesores concluyeron que existen comportamientos asintóticos en las gráficas de temperatura y dinámica poblacional con lo que surge un primer criterio de asintoticidad: Sean $f(x)$, $g(x)$ y $h(x)$ funciones reales, donde $f(x) = g(x) + h(x)$, tal que $h(x) \to 0$ cuando $x \to \infty$. *Si* $\lim_{x\to\infty}(f(x) - g(x)) = 0$ entonces $g(x)$ es asíntota de $f(x)$. De esta manera, dada una asíntota g(x), lograron construir funciones asintóticas $f(x)$ al sumarle una función $h(x)$ tal que $h(x) \to 0$ cuando $x \to \infty$. Al variar $h(x)$ organizan infinitos comportamientos asintóticos no solo lineales sino curvos, la situación misma propicia esta ampliación.

En la Se3, dada la función $f(t) = e^{-t} + \frac{1}{t+1}$ para la tasa de infección. Se pide que elijan entre las funciones $k_1(t) = e^{-t}$ o $k_2(t) = \frac{1}{t+1}$, la tasa de recuperación que representa un mejor escenario de la epidemia. Se solicita que usen el criterio $\lim_{t\to\infty}(f(t) - k(t))$. Los participantes se dan cuenta que este criterio no es suficiente para determinar la mejor tasa de recuperación. Sin embargo, surge la expresión "aunque $k_2(t)$ decrece menos" lo que sugiere un significado para la asíntota como la rapidez de la tendencia. Es aquí donde se les presenta una noción de la epidemiología: el número básico de reproducción (R°), que permitió ampliar la situación ofreciendo tres posibilidades para decidir cuál tasa de recuperación es la mejor opción. R° representa el número de personas que un infectado puede contagiar y se obtiene a través del cociente: $R°$ = tasa de infección/tasa de recuperación. Esto llevó a una forma de comparación por cociente donde surgió un segundo criterio de asintoticidad: Sean $f(x)$, $g(x)$ y $h(x)$ funciones de x, si $\lim\limits_{x\to\infty} \left(\frac{f(x)}{g(x)}\right) = 1$ entonces $g(x)$ es asíntota de $f(x)$.

La resignificación que se mostró en las situaciones antes expuestas resultó de un debate de usos que se resumen en: reproducir comportamientos con tendencia.

Sección 3 del análisis

El proceso institucional sintetiza ese debate en una categoría de conocimiento: el comportamiento tendencial de funciones. Las tareas que provocan la construcción de lo asintótico están estrechamente relacionadas con mantener la forma y rapidez de la tendencia de una función a otra. Esto se llevó a cabo mediante la comparación del comportamiento de funciones "en el infinito" y la determinación de sus tendencias a través de la resta y/o el cociente. Lo anterior es una argumentación que modifica la enseñanza habitual de la asíntota, ampliando sus significados con base en lo cotidiano de otros dominios del conocimiento.

Se_1	Se_2	Se_3	Lo asintótico
Uso: reproducir una temperatura deseada	**Uso:** reproducir la tendencia de una dinámica poblacional.	**Uso:** reproducir una tendencia favorable en la tasa de recuperación de un virus.	**Uso:** reproducir comportamientos con tendencia
Funcionamiento: Mantener la temperatura del foco $\boldsymbol{T(t)}$, lo más cercano posible de la temperatura de referencia $\boldsymbol{Tr(t)}$.	**Funcionamiento:** Mantener una fluctuación de la población alrededor de la capacidad de soporte.	**Funcionamiento:** Distingue la tasa de recuperación que tiende con mayor rapidez a la tasa de infección.	**Funcionamiento:** Mantener la *forma* y/o rapidez de la tendencia de una función.
Forma: 1. Comparar la temperatura del foco con la temperatura de referencia en el tiempo 2. Determinar un error de temperatura del foco a través de la resta de funciones. $\lim\limits_{t\to\infty}[T(t) - Tr(t)] = 0$ 3. Restablecer la temperatura de un foco	**Forma:** 1. Comparar la población y la capacidad de soporte en el tiempo. 2. Determinar una sobresaturación en la población a través de la resta de funciones. $\lim\limits_{t\to\infty}(P(t) - C(t)) = 0$ 3. Restablecer la población a su capacidad de soporte	**Forma:** 1. Comparar las posibles tasas de recuperación con la tasa de infección a través del cociente. 2. Determinar la tasa que tiende más rápido a la tasa de infección. $\lim\limits_{t\to\infty}\left(\frac{f(t)}{k(t)}\right) = 1$	**Forma:** 1. Comparar el comportamiento de dos funciones cuando la variable independiente tiende al infinito. 2. Determinar sus tendencias a través de la resta y/o el cociente. $\lim\limits_{x\to\infty}[f(x) - g(x)] = 0$ $\lim\limits_{x\to\infty}\left(\frac{f(x)}{g(x)}\right) = 1$

Proceso Institucional

Argumento: ***comportamiento tendencial***

Ampliación del universo de asíntota

Figura 4: Proceso institucional y la ampliación del universo de asíntota

Conclusiones

Ante la pregunta ¿Cómo se dan los procesos de socialización de lo asintótico en una comunidad de profesores de matemáticas en formación al enfrentarse a un diseño de situación escolar? Se concluye que el proceso funcional describió los usos de la asíntota en cada situación específica, es decir, mostró el conocimiento que le fue útil a la comunidad:

1. Reproducir una temperatura deseada
2. Reproducir la tendencia de una dinámica poblacional
3. Reproducir una tendencia favorable entre la tasa de recuperación y tasa de infección de un virus.

El proceso historial dio cuenta del debate entre estos usos y se resumen en una función orgánica más general: reproducir comportamientos con tendencia. Donde el funcionamiento está dado por mantener la forma y/o rapidez de la tendencia de una función hacia otra; y las formas serán:

- Comparar el comportamiento de dos funciones cuando la variable independiente tiende al infinito.
- Determinar sus tendencias a través de la resta y/o el cociente.

Finalmente, el proceso institucional dilucidó la emergencia del comportamiento tendencial, lo cual dotó de significados a la asíntota a partir de patrones de comportamientos gráficos y analíticos, donde la resta y el cociente son los criterios que permiten construir funciones $\boldsymbol{f}(\boldsymbol{x})$ asintóticas a una función $\boldsymbol{g}(\boldsymbol{x})$ dada. La función asíntota se reconoce como una instrucción que organiza comportamientos con tendencia.

Se observó que los profesores establecieron relaciones entre las funciones acerca de su comportamiento global, donde los procedimientos como variar parámetros les permite construir funciones asintóticas a una función dada.

Lo anterior, amplió el universo de asíntota en los profesores de matemáticas en formación inicial que participaron en el estudio y se conformó un marco de referencia que modifica en tratamiento habitual de este objeto matemático.

This article presents the results of a research that addresses the disconnection between school mathematics and reality, in particular, it is recognized that this disconnection has forced to privilege the graphic representation of asymptote as a straight line, denying other types of asymptotic behaviors. A school design that favored to modify the treatment of the asymptote was built with 5 mathematics teachers in initial training. It was implemented in a virtual environment using Zoom. The theoretical framework was the socioepistemological theory of educational mathematics. It was an instrumental case study. As a result, the universe of asymptotics in the study community was expanded and a framework for teaching asymptotics was formed.

Keywords: Calculus, Mathematical knowledge for teaching, Precalculus, Modeling.

Introduction

A concern in educational mathematics, and in particular for the teacher, is how to connect the mathematics being taught with reality. In addition, the teacher is questioned by students as to the "usefulness of mathematics" in real life contexts. Under this vision of incorporating and connecting the knowledge learned in the classroom with reality, there are theoretical perspectives in educational mathematics that have been concerned with valuing non-school mathematics. For example, Rosa and Orey (2015) warn of the need to value and promote in the mathematics curriculum the local knowledge developed by community members who interact in a given school environment. Given this concern, Codero et al. (2015) point out that instead of focusing attention on what students know, it is necessary to look at how they use knowledge.

The objective of this research was to know, according to the contemporary socialization model of Gómez (2015), the processes of construction and organization of knowledge that mathematics teachers in training went through when faced with specific situations of reality in a school design and that allowed the asymptote universe to be expanded. The application of the design was carried out using the zoom platform. The research question was How do the processes of socialization of the asymptotic occur in a community of mathematics teachers in training when confronted with a school situation design?

Theoretical framework

The socio-epistemological theory of educational mathematics considers the importance of incorporating other knowledge that has been absent in school and would favor a useful mathematics for the learner. Cordero et al. (2015) recognize as a problem in the teaching and learning of mathematics the school mathematical discourse (SMD). This has made everyday meanings invisible and therefore there is a disconnection between reality and school mathematics. This phenomenon is recognized as opacity. This requires working on the contemporary socialization of mathematical knowledge, so that reality is a frame of reference for teaching mathematics and what is learned in school is useful for life (Gómez, 2015; Pérez-Oxte, 2021).

Gómez (2015), proposes three processes that account for the socialization of mathematical knowledge: functional, historical and institutional process. The functional process is expressed in the knowledge useful to the community: the uses. According to Cordero (2008) and Cordero, Mena and Montalto (2010) the use of mathematical knowledge is characterized with reference to two dialectical elements: the functioning (Fu), i.e. what does it do? and the form (Fo); how is it done? Furthermore, Cordero and Flores (2007) state that tasks can be activities, actions and executions. The historical process requires establishing relationships between uses from one specific situation to another; this is called resignifying knowledge. Finally, the institutional process shows the organization of relationships between uses synthesized in knowledge categories, i.e., arguments based on the learner's experience.

An example of category is the tendential behavior of functions (TBF) (Cordero, 1998; Cordero and Solís, 2001; Buendía and Cordero, 2005). According to Cordero (1998), the TBF is an "argument that establishes relationships between functions and is composed of a coordinated collection of concepts and situations of the Calculus where global aspects of variation are discussed" (p. 56). A student will account for the emergence of the TBF category when establishing relations between functions about their behavior at infinity, resorting to procedures such as the variation of parameters from graphical and analytical models.

The socialization model is considered as a perspective that provides theoretical-methodological elements for the construction of data design and analysis.

Methodology

The research was qualitative and an instrumental case study (Skate, 2005). It was tested that the socialization of the asymptotic propitiates an environment of reciprocal relations between the asymptote and its uses, allowing the teacher to expand his universe of asymptote.

The application of the school design was through Zoom, due to the conditions caused by Covid19. The study population consisted of 5 students of the mathematics faculty of the Francisco Morazán National Pedagogical University, in Honduras. After the application of the design, an interview was carried out in order to deepen their answers.

Moments of the methodological route

Moment 1. Recognition of the TBF category. The results of previous studies (Mendoza, 2020; Soto and Vilches, 2018) on the TBF were taken up to study the epistemology that emerges in other communities such as engineering and biology. It was confronted with the usual of asymptote teaching.

Moment 2. Conformation of epistemology. Three specific situations from three different domains were considered, namely: temperature control of a focus (bionic engineering), population support capacity (biology) and the dynamics of an epidemic (epidemiology). From this, this epistemology of uses was reinterpreted for the design of tasks in each situation.

Moment 3. Construction of the school design. Each of the situations and tasks was constructed based on the epistemology of uses. A pilot test was carried out to improve it, validate it and construct a script for the non-directed interview. As a result, it was structured in three phases coherent with the socialization perspective: 1) to evidence elements of opacity, 2) to put into play the specific situations to account for the functional and historical process and 3) to unveil the emergence of the tendency behavior category of functions, to expand the universe of asymptotes based on new graphic arguments.

Moment 4. Staging of the school design. It was developed through the Zoom platform, with a duration of 4 hours. WhatsApp was used as a means for students to send the development of the tasks. Subsequently, each participant was interviewed individually, to delve into their answers, procedures and arguments.

Moment 5. Data analysis. The analysis was developed in three sections that correspond to the phases of the design and the socialization perspective. Thus, section I analyzes elements of opacity in the community, section II analyzes the functional process and history, and section III analyzes the institutional process. According to Pérez-Oxté (2021), to account for a process means to identify expressions associated with each process. In this way, relationships were identified in the mathematical expressions of the community that could occur between the mathematical and the specific situation (Table 1).

Table 1: Questions to characterize socialization processes.

Process	Questions
Functional	How do they use the asymptote? what do they mean in each situation? what are the functioning of their mathematical knowledge?
Historical	What debates arise between the uses of the asymptote in each domain? what are the procedures? what are the forms of use in which its knowledge is forms of use in which its knowledge is manifested?
Institutional	How does the category of trend behavior emerge? What instruments were present in the situations? What is the relationship between the asymptote and the category of trend behavior?

Note: Adapted from Pérez-Oxté (2021).

In the transcripts, P1, ..., P5 were used to show the participants' responses.

Results and discussion

Section 1 of the analysis

In phase 1 of the design, participants were asked what is asymptote? The responses showed that the straight line has a hegemonic role in the community's graphical arguments for defining the asymptote. P2 indicated that the asymptote "is a straight line to which the graph of a function continuously approaches.", while P3 responded that "It is a straight line that prolonged indefinitely progressively approaches a curve without ever meeting it." The types of asymptote manifested are vertical, horizontal and oblique asymptote, evidencing that there are no arguments about curved asymptotic behaviors. In response to the question "How would you teach the asymptote?", the lack of reference frameworks for teaching the asymptote is evident. The sense of "applying the concept" is present through graphic examples, but there are no references to reality that favor the use of the asymptote.

Section 2 of the analysis

In phase 2 of the design, three specific situations are presented that rescue the epistemology of everyday life in the domains: bionic engineering, biology and epidemiology. The specific situations are:

- Se1: the temperature control of a light bulb,
- Se2: the population support capacity, and.
- Se3: the dynamics of an epidemic.

The alternation of domains that generate new uses of the asymptote was sought, those given by establishing a mutual relationship between reaching and maintaining a desired temperature, maintaining the fluctuation of a population around the carrying capacity and determining a favorable recovery rate in an epidemic.

In Se1 they were asked to describe the behavior of the temperature function of a focus $T(t)$ as time elapses, knowing that it should reach and maintain as close as possible to the reference temperature $Tr(t)$ (Figure 1).

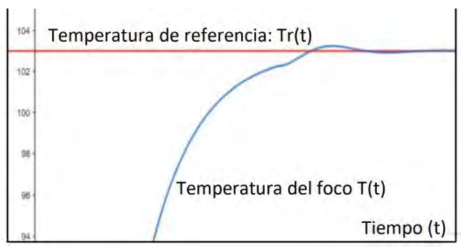

Figure 1: Temperature $T(t)$ of a focus and reference temperature $Tr(t)$.

It is known that an on-off control resets the light bulb temperature $T(t)$ by comparing it with the reference temperature $Tr(t)$, determining an error $\mathcal{E}(t)$ that controls the on-off switching of the light bulb and with this its temperature.

They were asked to write an expression relating $T(t)$, $Tr(t)$ and $\mathcal{E}(t)$. Participants compared $T(t)$ and $Tr(t)$ through subtraction to determine the error $\mathcal{E}(t)$. Modeling a construction pattern that entailed parameter variation procedures and organizing asymptotic behaviors. This endowed meanings to the asymptote as the reproduction of the desired temperature considering that it should be reached and maintained. Furthermore, it was asked what should be the behavior of $\mathcal{E}(t)$ to maintain $T(t)$ as close to $Tr(t)$ as possible? For which they established necessary conditions. For example, teacher P1 described that the condition to reproduce the desired temperature is that $\mathcal{E}(t)$ must have a trend toward zero when time tends to infinity (Figure 2).

Respuesta	Transcripción de respuesta
	El comportamiento de E(t) para mantener a T(t) lo más cercano a Tr(t) debe ser cada vez menor *hasta llegar a cero.*

Figure 2: Behavior of E(t) in se1.

The construction pattern that signified the asymptote in $Se1$ is re-signified in $Se2$, where we seek to reproduce the trend of a population dynamic towards a population carrying capacity. Here, subtraction is also the form of comparison that leads to model the pattern $P(t) = C(t) + S(t)$. Where $P(t)$ represents population dynamics, $C(t)$ represents population carrying capacity, and $S(t)$ represents oversaturation.

In both situations, the teachers resorted to the trend form to highlight the overall behavior of the functions T(t) and P(t) from comparing their trend with Tr(t) and C(t) respectively. For example P1, talks about the stability between the functions and stating that P(t) tends to the bearing capacity C(t). The functional process describes the uses in each specific situation and the historical process the resignification between them (Figure 3).

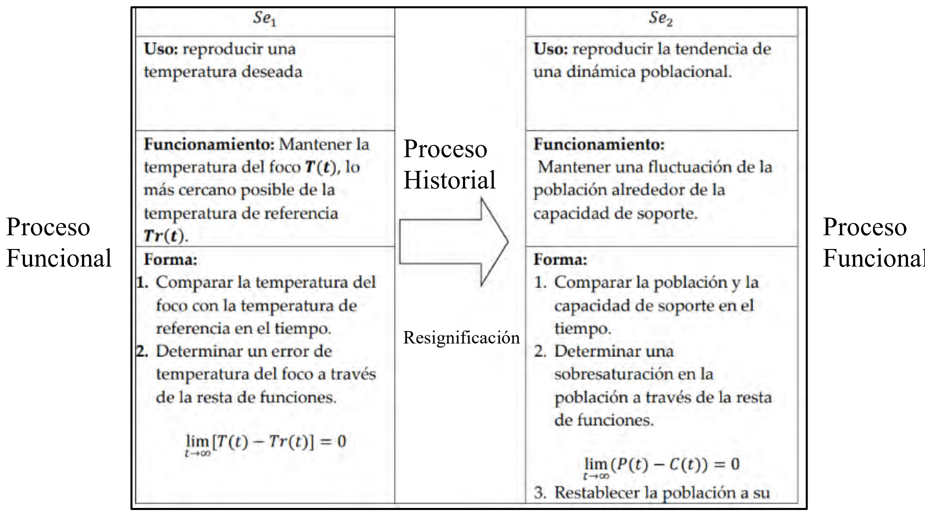

Figure 3: Resignification of uses of the asymptote between Se1 and Se2.

The professors concluded that there are asymptotic behaviors in the temperature and population dynamics plots with which a first criterion of asymptoticity emerges: Let $f(x)$, $g(x)$ and $h(x)$ be real functions, where $f(x) = g(x) + h(x)$, such that $h(x) \to 0$ when $x \to \infty$. If $\lim_{x\to\infty}(f(x) - g(x)) = 0$ then $g(x)$ is asymptote of $f(x)$. Thus, given an asymptote g(x), they succeeded in constructing asymptotic functions $f(x)$ by adding to it a function $h(x)$ such that $h(x) \to 0$ when $x \to \infty$. By varying $h(x)$ organize infinite asymptotic behaviors not only linear but curved, the situation itself is conducive to this extension.

In Se3, given the function $f(t) = e^{-t} + \frac{1}{t+1}$ for the infection rate. They are asked to choose between the functions $k_1(t) = e^{-t}$ or $k_2(t) = \frac{1}{t+1}$, the recovery rate that represents a best-case scenario of the epidemic. They are asked to use the criterion $\lim_{t\to\infty}(f(t) - k(t))$. The participants realize that this criterion is not sufficient to determine the best recovery rate. However, the expression "although $k2$ (t) decreases less" emerges which suggests a meaning for the asymptote as the rapidity of the trend. It is here that they are introduced to a notion from epidemiology: the basic reproduction number (R°), which allowed them to broaden the situation by offering three possibilities for deciding which recovery rate is the best option. R° represents the number of people an infected person can infect and is obtained through the quotient: $R°$ = infection rate/recovery rate. This led to a form of comparison by quotient where a second criterion of asymptoticity emerged: Let $f(x)$, $g(x)$ and $h(x)$ be functions of x, if $\lim_{x\to\infty}\left(\frac{f(x)}{g(x)}\right) = 1$ then $g(x)$ is asymptote of $f(x)$.

The resignification shown in the above situations resulted from a discussion of uses that can be summarized as: reproduce behaviors with tendency.

Section 3 of the analysis

The institutional process synthesizes this debate into a category of knowledge: tendential behavior of functions. The tasks that trigger the construction of the asymptotic are closely related to maintaining the shape and speed of the trend from one function to another. This was done by comparing the behavior of functions "at infinity" and determining their trends through subtraction and/or quotient. The above is an argument that modifies the usual teaching of the asymptote, expanding its meanings based on the everyday of other domains of knowledge.

Figure 4: Institutional process and the extension of the asymptote universe.

Conclusions

In response to the question How do the processes of socialization of the asymptotic occur in a community of mathematics teachers in training when facing a school situation design? It is concluded that the functional process described the uses of the asymptote in each specific situation, that is, it showed the knowledge that was useful to the community:

1. Reproduce a desired temperature
2. Reproduce the trend of a population dynamic
3. Reproduce a favorable trend between the recovery rate and infection rate of a virus.

The historical process accounted for the debate between these uses and is summarized in a more general organic function: to reproduce behaviors with trend. Where the function is given by maintaining the shape and/or speed of the trend from one function to another; and the shapes will be:

- Compare the behavior of two functions when the independent variable tends to infinity.
- Determine their tendencies through subtraction and/or quotient.

Finally, the institutional process elucidated the emergence of the trend behavior, which endowed the asymptote with meanings from graphical and analytical behavior patterns, where the subtraction and the quotient are the criteria that allow constructing functions $\boldsymbol{f}(\boldsymbol{x})$ asymptotic to a given function $\boldsymbol{g}(\boldsymbol{x})$. The asymptotic function is recognized as an instruction that organizes behaviors with trend.

It was observed that teachers established relationships between functions about their global behavior, where procedures such as varying parameters allow them to construct asymptotic functions to a given function.

This expanded the universe of asymptote in the mathematics teachers in initial training who participated in the study, and a frame of reference was formed that modifies the usual treatment of this mathematical object.

SUPPORTING THE DEVELOPMENT OF POSITIVE MATHEMATICS TEACHING IDENTITIES IN PRESERVICE TEACHER EDUCATION

Lara Condon
University of Pennsylvania
condonl@upenn.edu

Janine T. Remillard
University of Pennsylvania
janiner@upenn.edu

Research suggests that preservice teachers enter teacher education with predominantly negative dispositions towards mathematics. We present a case study of an approach to supporting the development of positive mathematics teaching identities among students in a middle-level math methods course. Our findings suggest that engaging in narrative reflection in tandem with collaborative problem solving in a mathematical discourse community over time helped students to transform their relationships with mathematics and forge positive mathematics identities. Providing opportunities for students to share and work through their vulnerabilities was critical to this process. Our findings illustrate a promising approach for teacher educators to support the development of positive mathematics teaching identities in preservice teacher education.

Keywords: Preservice teacher education, problem solving, affect, emotion, beliefs, and attitudes

Introduction

Preparing preservice teachers (PSTs) to teach mathematics involves attending to the development of complex knowledge, skills, and reasoning practices. It also involves supporting the identity work that novice teachers must do to position themselves as mathematics teachers (Ntow & Adler, 2019; Lutovac & Kaasila, 2014). This identity work is made especially challenging by common approaches to mathematics instruction that permeate U.S. K-12 schools. Confronted by years of memorizing facts and procedures, in settings that emphasize being first and fastest, the majority of young people entering teaching view mathematics as a body of disconnected, procedural skills that need to be memorized, leading many to conclude that they are simply "not a math person" (Relich, 1996; Machalow et al., 2020).

This paper presents findings from a small study of an effort to support the mathematical identity work of a group of middle-level PSTs through mathematics problem solving and reflections. Building on the work of Machalow and colleagues (2020), we see PSTs' identities as teachers of mathematics as grounded in their experiences as learners of mathematics and intertwined with their orientations toward the subject (Gresalfi & Cobb, 2011; Ntow & Alder, 2019). Our research was guided by the following questions:

1. What connections between mathematics learning experiences and orientations toward the subject are surfaced through PSTs mathematics identity work?
2. How does engaging in collaborative problem solving influence PSTs' relationships with and orientations towards mathematics?

The participants in this study were students in a one-year teacher preparation program, seeking middle-level (ML) certification (grades 4-8). The context of the study was a semester-long mathematics methods course for all ML candidates, the majority of whom were specializing in subjects other than mathematics. The authors were both instructors of the course.

Conceptual Framework

The conceptual framework guiding our study builds on work by Machalow et a. (2020), which conceptualizes mathematics identity for teaching as being shaped by teachers' interpretations of their experiences and their related mathematics orientations. We understand *mathematics identity* as a learner's interpretations of themself in relation to mathematics (Darragh, 2016; Graven & Heyd-Metzuyanim, 2019). Learners develop and continuously reshape their mathematics identities through experiences learning mathematics, in which multiple social factors are implicated. When learners engage with mathematics, they are also influenced by relationships with teachers and classmates, their social identities, such as race, gender, and class, and institutional systems that often make mathematics dehumanizing (Sfard & Prusak, 2005; Gutierrez, 2002). PSTs' mathematics identities are central to their development as teachers. Teachers with negative mathematics identities are more likely to focus on rote procedures and exhibit low expectations for their students (Brady & Bowd, 2005; Relich, 1996).

Teachers' orientations toward mathematics are core to their mathematics identities. Machalow and colleagues (2020) define *mathematics orientations* as one's beliefs about the nature of mathematics knowledge. They employ Skemp's (1976) two contrasting approaches to understanding mathematics to distinguish between a view of mathematics as *instrumental,* comprised of procedural knowledge, and *relational,* characterized by understanding why rules work and the relationships between them. Often, PSTs enter teacher education having learned mathematics in highly instrumental ways and have come to think of mathematics as a series of rules and procedures. Studies suggest that when students are exposed to relationally oriented approaches to mathematics, they have more of an opportunity to develop positive relationships with mathematics as a subject (McCulloch et al., 2013; Brady & Bowd, 2005).

Literature Review

Increasingly, learning is understood as a process of identity formation or becoming a certain type of person in a particular context (Lave & Wenger, 1991). Learning to teach mathematics involves developing an identity as a mathematics teacher (Hodges & Hodge, 2017; Ntow & Adler, 2019), in which mathematics identity plays a central role. Many preservice elementary teachers, however, have had problematic relationships with mathematics and are likely to experience feelings of math anxiety or lack confidence in their own ability to effectively teach mathematics based on negative formational experiences as mathematics learners (*eg.,* Brady & Bowd, 2005, Machalow et al., 2020, McGlynn-Stewart, 2010). Research on efforts to shift PSTs' relationships to mathematics offer two distinct approaches: exploring mathematics in order to "break" from one's past experiences with the subject (Ball, 1990) and engaging them in identity work to influence their mathematics teaching identities (Ntow & Adler, 2019).

Engaging PSTs in doing mathematics in ways that emphasize relational understanding (Skemp, 1976) and are likely to differ substantially from their experience as K-12 students is a well-established approach used by teacher educators (e.g., Ball, 1990). Various studies demonstrate how such opportunities to re-learn primary mathematics in methods classes can support positive shifts in mathematics orientations and identities (Harkness et al., 2007; McGlynn-Stewart, 2010). Harkness and colleagues (2017), for example, found that by working constructively in groups to make sense of mathematics increased PSTs' self-concept and self-efficacy, as well as their understanding the role that the teacher played in facilitating this productive struggle. Researchers have also found, however, that success of these approaches is dependent upon several key components of instructional design, including emphasis on relational understanding of mathematics concepts using concrete representations, positive support from teachers and peers, and collaborative work in communities of practice (Harkness et al., 2017; Kaasila et al., 2008; Machalow, et al., 2020).

Research that examines efforts in teacher education to positively influence PSTs' mathematics identities has emerged as promising in the last decade. One widely discussed strategy is to provide PSTs with opportunities to explore their own identities through narrative accounts. In these studies, researchers (who are often teacher educators) invite students to recount their own formative mathematics learning experiences as narrative texts, hypothesizing that this type of narrative work promotes reflection and understanding of one's own mathematics learning experiences (Kaasila et al., 2008; LoPresto & Drake, 2004; McCulloch, 2013). Further, asking PSTs to reflect on how their experiences have shaped their relationship with mathematics allows them to consider how common classroom practices influence how they come to think of themselves in relation to mathematics (e.g., Machalow et al., 2020; Remillard, 1993). Zazkis (2015) further argues that personifying the object of the narrative (mathematics) can emphasize the potency of the relationship learners have with the subject. The impact of identity on teachers' future orientations towards teaching underscores the importance of identity work in preservice teacher education. When teachers are able to reframe their past learning experiences through identity work, there is an increased likelihood that they will feel a sense of agency over their future mathematics teaching (Lutovac & Kaasila, 2014) and a greater capacity to foster positive math identities to future students (Machalow et al., 2020).

Our mathematics methods course combined these two approaches to surfacing and nurturing PSTs' relationships to mathematics: we engaged them in re-learning mathematics from a relational perspective and asked them to write narratives about their relationship with a *personified* version of mathematics. These narratives provided a window into PSTs' developing orientations toward mathematics and their mathematics identities. Our research used the narratives and other artifacts and observations to examine the connections between PSTs' experiences and their orientations toward and relationships with mathematics.

Methods

The eight participants in the study comprised the 2021-22 cohort of ML teacher candidates in a one-year, K-12 program, situated in a private (PWI) university in a large east-coast city. The program aims to prepare teachers to work in poverty-impacted, urban schools. The ML certification covered all subjects for grades 4-6 and content specialization for grades 7-8. Only one of the 8 participants was seeking a specialization in mathematics; the others were specializing in ELA (n=3), social studies (n=3), and science (n=1) and enrolled in content-specific courses for grades 7-12. All were enrolled in the ML mathematics methods course, taught by the authors. The fact that the majority of students in the course would be certified to teach grades 4-6 mathematics but identified as teachers of other subjects presented an instructional challenge and a research opportunity. Our aim was to explore the potential of the approach described above for nurturing non-mathematics PSTs' identities as teachers of mathematics. Three of the participants identified as white females, one as a white male, two as black females, one as a white trans-masculine non-binary, and one as an Asian male. Both authors identify as white females.

During the semester-long mathematics methods course, students were presented with a weekly Problem of the Week, an open-strategy problem involving mathematics content appropriate for grades 5-8. In the example (Figure 1), *Squares to Stairs*, students are prompted to justify their thinking as they explain the progression of the figure, followed by subsequent questions about increasingly complex case numbers and numbers of squares.

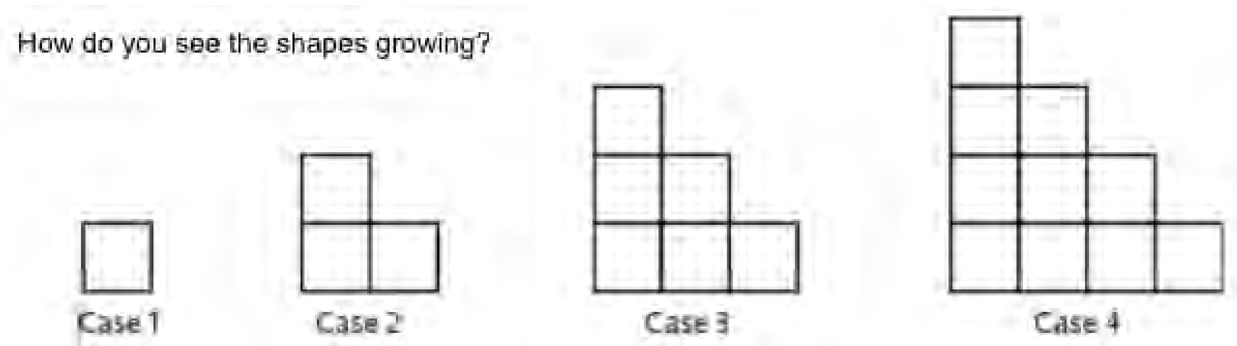

Figure 1. Squares to Stairs

Students worked on the problem outside of class and submitted a "rough draft" solution (Jansen, 2020) on an electronic document that all students had access to. The first 30 minutes of each class were devoted to paired and whole-class work on the problem, facilitated by the instructors.

The data for this study consist of two narratives written by participants, one prior to the beginning of the semester and one upon completion of the course, as well as the teacher educator/researchers' observations of students' work and interactions during in-class problem-solving sessions. The first narrative, called a "Dear Math Letter," was inspired by Bertolone-Smith and MacDonald (2020) and followed Zazkis's (2015) approach of personification. During the summer term, they were prompted to "Write a letter to Math as if Math was a person that you know." For the second narrative, students reflected on their work on the Problems of the Week in relation to the experiences and sentiments described in their initial letter.

We used inductive coding to analyze the narratives, highlighting emergent themes in the students' reflections. Themes in both narratives included salient mathematics learning experiences, shifts in views of mathematics and self-perceptions, and other influential factors such as teachers, classmates, or family members. We also applied a priori codes to indicate instrumental or relational mathematics orientations (Machalow et al., 2020). For the second narrative, we also noted specific problems mentioned by students as influential in their learning and the date during the semester when the problem was assigned. We then compared the two narratives for each participant to identify shifts and discussed themes across the trajectory of the cohort as a whole. Additionally, we used analysis of student work and observations from class sessions to supplement our understanding of the themes.

Results

Similar to previous research, we find that these PSTs entered preparation having had troubled relationships with mathematics, instrumental orientations toward the subject, and negative perceptions of themselves mathematically. PSTs described these relationships in connection to mathematics learning experiences that prioritized memorization, academic achievement, and external evaluation. These findings confirm prior accounts of the power of experiences in shaping PSTs' mathematics teaching identities (Gresalfi & Cobb, 2011; Machalow et al., 2020; Sfard & Prusak, 2005). Despite these negative entry points, students expressed a desire to improve their relationships with math for the sake of their future students.

Over the course of the semester and through participation in collaborative problem-solving sessions, we observed two parallel and related changes. As PSTs engaged with new types of mathematics learning experiences, they began to shift orientations towards mathematics and also began to form new mathematics identities, showing increased confidence and comfort with mathematics as a subject. We hypothesize that these shifts were supported by both the nature of the mathematical problem-solving tasks and the role of a supportive mathematics discourse community within the class.

The sections that follow are structured to illustrate the trajectory of PSTs' developing mathematics teaching identities as they relate to past and current mathematics experiences. We begin by describing the findings from PSTs' "Dear Math Letters", indicating the patterns in the mathematics identities and orientations surfaced through their narrative descriptions. We then outline the changes that occurred throughout the course of the semester as described in their end-of-semester reflections and corroborated by researcher observations. These changes occurred within three discernable phases: *initial apprehensions*, as PSTs began the semester deeply influenced by their prior negative associations with mathematics; *aha moments*, which occurred several weeks into the semester, as PSTs began to experience new realizations about mathematics in their problem-solving work; and, finally, *transformed relationships with mathematics*, where PSTs were adopting new strategies and approaches to problem solving and becoming more confident in their ability as learners and teachers of mathematics. We conclude by discussing how collaboration in a mathematics discourse community served as a key mediator for the transformations described by PSTs at the end of the semester.

"Dear Math, You Are Such a Heartbreaker."

The act of personifying math in their initial *Dear Math* letters brought forth the emotional nature of students' relationships with mathematics. Students revealed predominantly negative mathematics identities, which were deeply intertwined with their social identities. The letters were moving for us as instructors to read; students shared heart wrenching accounts of tears, frustration, anxiety, pressure, and feelings of inadequacy defining their past experiences with mathematics. For example, Faith began her letter telling math: "you have always frustrated me, and I won't deny that I've cried over you more than once…the academic pressure on me felt so crippling."

These accounts of negative experiences often pointed to an instrumental understanding of mathematics, in which memorization of rote procedures and a need to get the answer "right" figured significantly. Students wrote about their experiences with "drills", "missing points", the demoralization of "never getting an A" or the devastation of "getting an F." All eight students mentioned testing as contributing to a sense of inadequacy or uncertainty in relationship to mathematics. In these and other similar comments, students described math as an individual endeavor where one fails or succeeds on their own.

Along with the individualized pressure to succeed, PSTs' descriptions of mathematics learning experiences demonstrated how institutionalized presentations of math can be seen to be highly dehumanizing, perpetuating notions that mathematics ability is linked to a person's value in society. This type of comparison often occurred in relation to other dimensions of students' social identities. In many cases, the notion of being judged in relation to mathematics was highly influential in shaping students' orientations toward and relationships with mathematics. Several students noted feeling inferior to family members or classmates who were "naturally" better in math. Some of these emotions were deeply internalized: Kevin, a student who immigrated from Korea in middle school wrote to Math: "you were the stereotype I desperately tried to run away from. I think I told myself that I was 'not good' at math because I was afraid that you would take over my whole identity".

When PSTs mentioned positive associations with math, they were fleeting; students either felt positively about math when they received good grades or as a result of a supportive relationship with a teacher. Several students mentioned at least one teacher by name who helped them to improve their motivation to do math and their sense of ability to succeed in a particular mathematics course. Other positive orientations to math related to completing a problem, as Natalie described feeling like "the heavyweight champion of the world" after finally solving division problems. These positive experiences did not appear to have a lasting impact on their mathematics identities, perhaps in part because they were contingent upon temporary circumstances.

For many students, the conclusion of their letter to math expressed a desire to reconcile their own negative experiences and find ways to help their future students develop positive mathematics identities. They raised concerns about how their own problematic relationships with math would influence their identities as teachers, as Faith writes: "How can I teach my students to love and engage with you when I don't even do that myself?" As illustrated by this and other statements, PSTs may recognize their negative relationships with math, but pathways to rectify these relationships remain out of reach.

"I Didn't Know You Could Manipulate Numbers Like That!"

A primary component of the mathematics methods courses was collaborative work on the Problem of the Week. Problem solving discussions were structured around students' strategies, and instructors strategically paired students to share different approaches to solving the problem. During the whole class discussion, students compared different strategies and agreed on a reasonable solution. Based on our analysis, we saw three key stages that emerged over the course of the semester through students' work with these problem-solving activities.

Initial apprehensions. In the initial weeks of the semester, we found that PSTs continued to demonstrate behaviors that focused on finding algorithms and wanting to be sure to get the correct answer so as to not be judged by their classmates or teachers. Students also exhibited self-protective behaviors, such as adding self-deprecating notes or humorous memes to their submitted rough-draft thinking in an effort to deflect from their feelings of inferiority. This initial period of discomfort was evident in many students' reflections at the end of the semester. For example, Dylan explains:

> When this assignment first started, I felt very uneasy presenting my work to the class. I was constantly comparing myself to the other students… I feared my classmates would judge me as not being intelligent enough for the program. This was clearly reflected in my early Problem of the Week assignments…there is little evidence of work being completed and there is an emphasis on correctness.

This type of response was shared by the majority of the students in class, as they reported finding it difficult to engage with problems and practices that were counter to their prior mathematics learning environments. Students realized, however, that they needed to "unlearn" these deeply ingrained tendencies.

Aha moments. The structure of sharing work collectively in class pushed students to work through their vulnerabilities. Through discussing different strategies and visualizations for solving problems, students were exposed to new ways of thinking about mathematics, which led to a second phase that we refer to as a period of *aha moments*. Students gradually began to place more emphasis on strategies than arriving at a correct answer:

> When we worked on the problem in class I felt like something finally clicked and I realized that my visual model would have been useful if I had spent less time worrying about whether or not it was the "correct" way to solve the problem and instead just stuck it out and

recognized that my ideas do not have to be correct to be worthwhile, they have an inherent worth." (Brandon)

Two problems in particular, *Transparent Algorithms* and *Squares to Stairs*, helped students to see more mathematical meaning and develop deeper conceptual understanding. Both the nature of these problems as well as the timing mid-semester could have contributed to multiple students reaching *aha moments* at this point. Madison described her *aha moment,* stating: "On transparent algorithms, I did not know that you could manipulate numbers like that, straying from the basic, standard algorithms!" *Squares to Stairs* engaged students in recognizing patterns to help visualize figures in linear sequences. Unlike earlier in the semester when students focused on finding an algorithm to solve the problems, students used multiple ways to visualize and solve the pattern. Natalie's *aha moment* noted the importance of representing problems to find solutions: "Because of how we have been socialized, I would have thought that it was an elementary school tactic to visually represent a problem. I saw how my classmates drew out their patterns and I thought 'Why not?'". In these moments, students describe developing increased relational understandings as opposed to their initial instrumental orientations. As these orientations shifted, students also expressed more enthusiasm for problem solving. They began to position themselves as capable of breaking from the procedural rules of mathematics in favor of trying new strategies without a fear of being "wrong".

Transformed relationships to mathematics. During the final phase, students began taking on new strategies and approaches that they learned through their problem-solving discussions. As highlighted in their *aha moments*, working in collaboration with one another helped them to feel empowered to try out different strategies that focused on developing conceptual understanding rather than getting the correct answer. Once Natalie found that it was not indicative of a lack of understanding to attempt multiple strategies, she explained that she "looked for patterns, switched orders, crossed things out and used the process of elimination. I surprised myself and my confidence grew." Similarly, Faith reflects on how she began documenting "discoveries" as a result of her work with her classmates, which helped her "discover something new in every iteration" as she worked towards a solution.

As a result of engaging in problem solving discussions and reflective identity work, students made incredible shifts in their mathematics identities and orientations over the course of one semester. Several students continued to teach math in their field placements beyond what was required, and three students went from thinking they would never want to teach math to expressing interest in seeking certification to teach middle years math.

"I Had Eight Other Minds On the Job."

Looking across their reflections on their experiences engaging in the Problems of the Week, we found that the role of the mathematics learning community was a key mediator in helping students to shift their relationships with mathematics. Students trusted the class community in a way that enabled them to move through their vulnerabilities and in doing so, they allowed themselves to release the security of algorithms and accuracy. Brandon expressed how working with his peers supported this shift: "I felt like I was part of a community of inquiry dedicated to finding solutions instead of being evaluated on my ability to simultaneously learn, synthesize, and enact a new concept."

Further, the experience challenged their preexisting notions of math as individualized and dehumanizing. Students found support in one another and were able to move beyond their initial phase of vulnerability. While before this conceptual and identity work, Kevin purposefully disassociated from mathematics to avoid stereotypes, he described how working with others allowed him to grow: “I always assumed that ‘doing math’ was an individualized process. But incorporating meaningful discourse into the process of ‘inquiring’ into new mathematical concepts has evidently shown me that learning math is really a journey of growth.”

Discussion

Our study reaffirms prior findings that suggest PSTs benefit from opportunities to re-learn mathematics from a relational perspective (Ball, 1990) and from engaging in narrative identity work to reconcile their prior experiences with mathematics (e.g., Machalow et al., 2020; McCulloch et al., 2013; Remillard, 1993). Our data also help to illustrate that PSTs’ mathematics identities are complex and intertwined with other social identities that are implicated in how they learn to teach mathematics. Addressing a personified version of mathematics allowed PSTs to unpack how their prior experiences shaped their identities and helped them to problematize their instrumental understandings of math.

Our study provides a unique window into the power of engaging in this type of narrative identity work in tandem with conceptually oriented, collaborative problem solving. We believe that these two processes were mutually supportive in our PSTs’ transformation across the course of the semester, which included beginning to identify as teachers of mathematics (Ntow & Adler, 2019; Lutovac & Kaasila, 2014). The cycle of reflecting on their views of math while working with one another in community rather than individually gave students space to envision a new approach to mathematics instruction. Norms for openness, learning from mistakes, and communication throughout the problem-solving discussions helped students increase their confidence and willingness to adopt new strategies. Further, their reflections on the problem-solving experience itself helped them to see the power of community and express a desire to carry that into their own classrooms.

Importantly, we found that this process takes time and consistent, on-going work to develop a community of practice that allows students to share their vulnerabilities with one another. Although our study focuses on a small cohort of PSTs, we posit that combining opportunities for students to develop relational understandings of math with narrative identity work and community building offers opportunities for teacher educators to support the development of positive mathematics teaching identities in preservice teachers.

More than 50% of PK-12 students in the United States are students of color and/or from historically underrepresented populations (NCES, 2020). Yet for so long, mathematics curriculum has not been representative of diverse student populations or inclusive of their backgrounds and their identities (AMTE, 2015; D'Ambrosio, 2017; TODOS, 2020). Through a focus on the intersections of mathematical modeling, ethnomathematics and cultural and historical practices, this ethnomodeling research study intentionally connects ways to engage and value each and every students' culture and identity while emphasizing essential geometry content. During this presentation, we share results from a study examining how a sequence of geometry-focused ethnomodeling tasks informed secondary mathematics prospective teachers' perceptions of valuing their own as well as their future students' cultures and identities.

Keywords: Ethnomathematics; Culturally Relevant Pedagogy; Equity, Inclusion, and Diversity; Geometry and Spatial Reasoning

For centuries, mathematicians and mathematics educators have debated whether mathematics is culturally bound (Bishop, 1988; D'Ambrosio, 1985) or culture free (Kline, 1980). Oftentimes, mathematics is presented as a "prized body of knowledge" stripped of its rich cultural and historical connotations, and far removed from the lives and ways of many around the world (Naresh, 2015). More than 50% of PK-12 students in the United States are students of color and/or from historically underrepresented populations (NCES, 2020). Yet for so long, mathematics curriculum has not been representative of diverse student populations or inclusive of their backgrounds, cultures, and their identities (AMTE, 2015; D'Ambrosio, 2017; TODOS, 2020). In order to confront the separation between context and content, in recent years there has been an increased interest in integrating mathematical modeling into the K-12 curriculum (Abassian et al., 2019; Niss et al., 2007; NGA & CCSSO, 2010; Pollak, 2016). In addition, a recent international survey of mathematics education researchers calls for increased research in equity, diversity, and inclusion as well as connecting mathematics to other disciplines such as integrated STEAM, familial activities, and leisure activities (Bakker et al., 2021). Mathematics should be accessible and equitable for all students by incorporating cultural diversity into mathematics lessons (AMTE, 2017; NCSM & TODOS, 2016; NCTM, 2018, 2020a, 2020b). Gutiérrez (2018) describes one way to rehumanize mathematics through valuing student's identities and their cultural traditions and practices is through an ethnomathematics perspective. For such efforts to be long lasting, it is crucial that prospective teachers (PSTs) experience this advocacy modeled in their preparation programs so they are prepared for their roles in developing students who contribute to a more equitable and just society (D'Ambrosio & D'Ambrosio, 2013).

Purpose of the Study and Research Question

The purpose of this study was to further extend and connect work by mathematics education researchers, educators, and K-12 teachers in integrating modeling with mathematics. Specifically, the ethnomodeling perspective intentionally connects students' cultural and historical identities to the teaching and learning of geometry.

As supported by NCTM (2020a, 2020b), experiencing geometry in an integrated and active manner can capitalize on the wonder, joy, and beauty of examining the world. The research goal for this study was to engage PSTs in geometry-focused ethnomodeling tasks to develop and understand new insights into honoring and sustaining cultural systems and practices through examples that are grounded in a shared commitment to equity, empowerment, and dignity. This study addressed the following research question:

In what ways can a sequence of geometry-focused ethnomodeling tasks inform secondary mathematics PSTs' perceptions of valuing

- their own cultures and identities?
- their students' diverse cultures and identities?

Conceptual and Theoretical Perspectives

There are many frameworks that inform and connect to this study including ethnomathematics (D'Ambrosio, 1960), culturally relevant pedagogy and teaching (Gay, 2002; Ladson-Billings, 1995), community funds of knowledge (Civil et al., 2002), and culturally sustaining pedagogy (Paris, 2012). Despite the critical contributions of these frameworks to the field, some argue that these frameworks can lack a focus on mathematical content. Previous studies have also created and examined frameworks that connect the mathematical modeling cycle with culturally relevant pedagogy (Anhalt et al., 2018), and with social justice issues (Aguire et al., 2019). An ethnomodeling approach attempts to apply mathematical modeling to bridge domains of ethnomathematics while preserving and valuing aspects of the local culture (Rosa & Orey, 2013). Through such engagements, mathematics teacher educators can help pre- and in-service teachers strategize and build a progression for ways of teaching mathematical modeling with the relevant cultural aspects that help shape critical consciousness for students (Anhalt et al., 2018).

Ethnomodeling

Ethnomodeling is the intersection of cultural anthropology, ethnomathematics, and mathematical modeling. Cultural anthropology refers to the aspects of identity connected to language, religion, art, and other aspects of people's daily mathematical practices. Ethnomathematics refers to the understanding of the relationship between culture and mathematics and mathematical modeling approaches that attempt to engage students in real world applications of mathematics. In much of the current literature on mathematical modeling, five perspectives are commonly discussed – realistic, educational, models and modeling, socio-critical, and epistemological (Abassian et al., 2019; Rosa & Orey, 2010). However, each of these would benefit from greater linkage to cultural components, and this is where ethnomodeling connects. One of the primary goals of ethnomodeling is to engage and empower people to mathematize their own realities, and is studied through three lenses - emic, etic or dialogic. In their previous work, Orey and Rosa worked with students and teachers in Brazil, Nepal (e.g., Orey & Rosa, 2020; Rosa & Orey, 2009), where the participants all come from very similar racial and ethnic backgrounds. In this study, the participants at a university in the United States came from diverse backgrounds and experiences.

Geometry

Another key focus particularly for this study was secondary geometry content. Previous studies have shown there is a lack of exposure to deep geometrical thinking, and many teachers need additional support to effectively teach it with depth (Clements, 2003; Driscoll, 2007; Steele, 2013). Geometry has historically been the content domain with the lowest performance on international exams such as The Trends in International Mathematics and Science Study (TIMSS, 2019). Geometry is a critical content domain that spans across our K-12 standards (NGA & CCSSO, 2010). Additionally teaching geometry is crucial in facilitating student opportunities to make connections between and within mathematical content and representations (Desai et al., 2022); and connections with the real world (Jones, 2002; Usiskin, 1980). Through this focus, the intentional connections and integrations of ethnomodeling and geometry afford participants opportunities to link mathematical domains enriched by the wonder, joy, and beauty of geometry in our lives, communities, and cultures.

Conceptual Framework

Previous studies have created and examined a framework that connects the mathematical modeling cycle with culturally relevant pedagogy (Anhalt et al. 2018), and with social justice issues (Aguire et al., 2019). For this study, the conceptual framework illustrated by Figure 1 describes the interaction between the aspects of ethnomodeling and mathematical modeling. The cyclical and iterative process of this framework informed the design and creation of the tasks as well as the process that participants engaged.

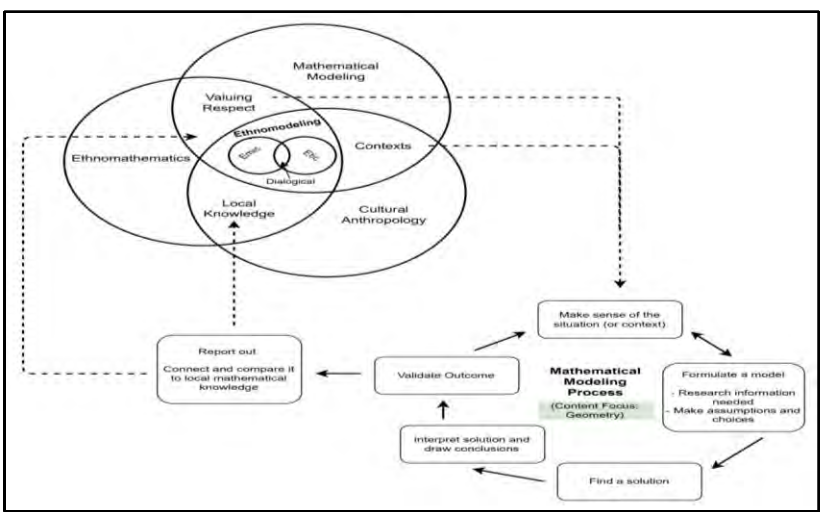

Figure 1: Ethnomodeling Conceptual Framework

Methods

Context

Previous studies have not focused explicitly on the intersection of ethnomodeling and geometry in connection to PSTs perceptions. As such, a qualitative research methodology described by Creswell (2013) was used for the purposes of this study. Within the qualitative methodology, this study was designed as a multi-case study as described by Creswell (2013), Merriam (2009), Stake (1995), and Yin (1994).

This research study took place in a mathematics education methods course in a college of education at a large suburban public university in the southeastern U.S. during the Spring 2022 semester. The participants of this study were secondary mathematics (Grade 6-12) education PSTs, as this aligns to the programmatic and course structure at the university where this study was conducted.

Participants

The total number of PSTs enrolled in this course was 20 undergraduate students from which 18 were participants for this study. Specifically, the research study took place during the first mathematics education methods course that PSTs in this program are required to take. This course was intentionally chosen because it was early in the PSTs' program and is taken prior to PSTs starting their internship in schools, and these were important criteria in helping to best inform the research question. Of the 18 participants, seven expressed interest in being selected as a case participant. In selecting the cases, multiple factors were considered in the following order of importance: (1) As much as possible keeping participants in their chosen groups to maintain natural group dynamics; (2) Heterogeneous representation amongst cases in terms of race/ethnicity; (3) Heterogeneous representation amongst coursework as well as experiences with diversity. Based on these criteria, six participants were selected- Elaine, Lucas, Helina, Diego, Tanh, and Zohar - all participant names are pseudonyms. Table 2 provides an overview of these six participants.

Table 2: Participants

Group #	Potential Cases	Race/ Ethnicity	Gender	Coursework Experience	Experience with Diversity
1	Elaine	White	F	Some	Some
1	Lucas	White	M	Some	More
2	Helina	White	F	Some	Some
2	Diego	Hispanic	M	Some	Some
3	Tanh	Asian-Vietnamese	F	Some	Some
3	Zohar	White-Jewish	M	Some	More

Data Collection and Analysis

All PSTs in the course completed the pre-survey, ethnomodeling tasks, written reflections based on these tasks, as well as the post-survey as these were regular course activities. However, only work completed by the participants chosen as the cases was analyzed as further described in the *Data Analysis* section. Additionally, the case study participants were asked to participate in three interviews. Figure 2 shares a summary of data source collection which is then described in greater detail.

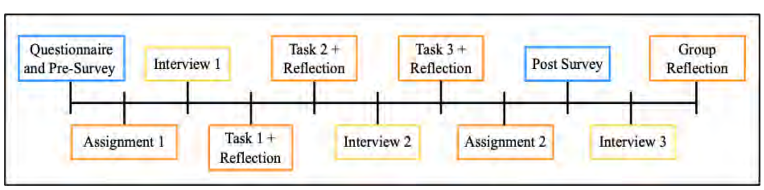

Figure 2: Data Sources Overview

Surveys. PSTs were asked to individually complete one questionnaire and one pre/post-survey. The *Academic and Demographic Background Questionnaire* contained three parts according to recommendations by Siwatu (2007) which state that for studies focusing on multicultural aspects, obtaining information about PSTs' academic and demographic background including items related to their racial and ethnic background, coursework, and experiences in multicultural settings can be helpful in gaining baseline information. Section A of the *Multicultural Efficacy Scale* (MES) (Guyton & Wesche, 2005) was used to gain insights into additional personal and professional experiences PSTs may have had in multicultural settings.

Section B and C of the *MES* was used as the pre- and post-survey. This survey contained 2 parts - Part 1: Attitude Towards Teaching Culturally Diverse Students and Part 2: Efficacy in Implementing Multicultural Teaching Strategies. As the pre-survey was used to establish a baseline for participants' perceptions of how prepared they feel to enact the teaching practices discussed. These results were then compared to the post survey through a matched pairs t-test for dependent samples to assess any changes.

Tasks, Assignments and Reflections. One of the major goals of ethnomodeling is to acknowledge, value, and respect the traditional and local knowledge and to find and develop techniques to provide a translation and contextualization of mathematical ideas. In alignment with these ideas, three tasks and two activities were developed for this study focusing on both valuing and respecting diverse cultures and histories and learning and translating geometrical ideas as well as intentionally emphasizing the iterative process of the ethnomodeling cycle. Each task began with contextualizing the task to give value and respect to the local ethnomathematics practices (*Task Launch*). In the next phase of the task, participants engaged in the mathematical modeling process to mathematize and find a solution to the given problem (*Mathematize and Find a Solution*). In the last phase, the task recontextualized the situation by connecting the task to local knowledge with a particular focus on valuing and respecting the local practices (*Reflections and Connections*).

These tasks were created using examples of ethnomodeling tasks described by Rosa and Orey (2009), and culturally relevant mathematical modeling tasks described by Anhalt and colleagues (2018), as well as built on researchers' previous work (Safi & Desai, 2017). Table 3 provides a brief overview of the ethnomodeling connections (cultural/historical and geometry connections) for each of the assignments and tasks. Following engagement in each task, PSTs submitted an individual written reflection. The assignments were completed individually outside of class and the tasks were completed in small groups of 4-5 PSTs during class time.

Interviews. The six participants chosen as the cases participated in three semi-structured interviews. Figure 2 in the Data Collection and Procedures section shares when in the process each interview took place. Each of the interviews provided participants an opportunity to extend and reflect on their group's work, as well as their own beliefs and perceptions.

Data analysis. The data collected for this study comprised both quantitative and qualitative components. The questionnaire as well as the pre-/post-surveys were analyzed quantitatively using descriptive statistics as well as a matched pair t-test. Task artifacts, task reflections, as well as interviews were analyzed qualitatively through coding and categorizing artifacts by themes based on the Ethnomodeling Conceptual Framework and finding other themes that emerged during the analysis.

Table 3: Assignments and Task Descriptions and Connections

Task	Cultural/Historical Connections	Geometry Connections
Assignment 1: Geometry Around You	Connections to local cultural and historical aspects	Geometry in the world around us
Task 1: City Explorations	Cultural and historical aspects that have influenced city and structural planning	Angles, 3D shapes, Properties of circles, Scale drawings
Task 2: Tiles and Tiling Patterns	Tiles and tiling patterns from around the world with a focus on cultural and historical significance of Mexican Talavera tiles	Geometric transformations, Ratios/ Scale
Task 3: Exploring Connections between 2D-3D Geometry	Connections to Moorish architecture and influence of cultures across time and place.	2D ←→ 3D geometry, Lines/ segments, Parallel/ perpendicular lines, Symmetry, Midpoint, Geometric modeling (HS standards)
Activity 2: Creating your own tile	Connections to own culture, history and identity.	Lines/ segments, Parallel/ perpendicular lines, Symmetry, Midpoint, Geometric transformations, Geometric modeling (HS standards)

Results

The data collection process that included both quantitative and qualitative data is summarized in this section. Specifically, these results are examined through the lens of the *Ethnomodeling Conceptual Framework* (Figure 1) which guided all aspects of this study including the task creation, data collection, and data analysis. The three main components of the ethnomodeling framework include cultural anthropology, ethnomathematics, and mathematical modeling. Following the individual summary of each, the results are synthesized to discuss PSTs' work with ethnomodeling. For the purpose of this paper, we focus the analysis on the individual and group data from Group 2.

Case Descriptions

The primary focus of this study involved aspects related to the identities and backgrounds of teachers and students and as such it would be expected that these PSTs' personal stories impacted the ways they engaged in this study. Group 2 members were Helina, Diego, and three additional PSTs. The group was diverse in terms of gender, race and ethnicity.

Helina identifies as a White female and at the time of this study was a third-year student at the university. This was her third major – prior to this she was an architecture major and then a computer science major. Outside of mathematics classrooms, she has had these discussions and experiences in her K-12 art and undergraduate architectural classes, and also enjoys doing her own research to learn about architectural styles and cultures from around the world. These experiences seemed to greatly influence her contributions to the small group and whole class discussions.

Diego identifies as a Hispanic male, and at the time of this study, Diego was a mathematics teacher at a private school. From all the PSTs in the class, he was the only one with formal K-12 teaching experience. Outside of teaching and learning mathematics Diego shared his other biggest passion is music. Diego was able to bring in his experiences as a current teacher. These perspectives were important in his interactions with the tasks as well as in the interactions and discussions he had with his peers.

Cultural Anthropology

In discussing culturally relevant and sustaining pedagogies and teaching, Ladson-Billings (1995), Gay (2000), and Paris (2012) all reinforce the importance of including students' cultural references in all aspects of learning to promote racial and ethnic equality across diverse communities. Overall, the mean of the participants' beliefs and attitudes towards culturally relevant teaching on the pre- to post-survey increased from $M = 3.37$ to $M = 3.42$, however this difference was not statistically significant at the $p<0.05$ level. For the factors relating to overall efficacy for implementing culturally relevant teaching practices, the increase in mean was statistically significant.

From the first interview with Helina, and Diego, it was evident that they individually shared some tendencies towards wanting to incorporate multicultural ideas in their classroom but not necessarily tied in with mathematical content. By the end of the study, both Helina and Diego shared that the ethnomodeling activities they engaged in opened their eyes towards the importance of incorporating students' identities and cultures in mathematics. This sentiment was also shared by other members of their group who agreed that if engaging in such tasks as PSTs had an impact on their views of their own culture and identity, such tasks were even more crucial to incorporate with K-12 students who are learning the content for the first time.

Ethnomathematics

Ethnomathematics focuses on studying practices of people in different cultures from around the world (Ascher, 2002; D'Ambrosio, 1985). From the beginning of this study, as indicated by the pre-survey data, many of the PSTs had favorable attitudes towards culturally relevant teaching. From their own experiences as K-12 students, Helina and Diego mentioned learning about the integration of multicultural ideas in their world history or world languages classes, or "we would talk about things during Black History Month and things like that but the focus was really on testing" (Helina, Interview 1). Through their engagement in this study, the PSTs were able to experience geometry focused tasks through which they saw a model for integrating such ideas within their future mathematics classrooms. As Group 2 shared in their final reflection,

> Our perceptions changed because we could see that there is so much geometry in the world around us as well as in culture that we can incorporate into our lessons. It has made us all look at a different way to go about how we can include everyone's identities and cultures that we would not have thought of before. (Group 2 Reflection)

In addition to becoming more aware of the geometry that exists in the world around them, this group also shared how the tasks from this study provided them with a model for synergistic integration of both incorporating their own as well as their future students' cultures and identities as well as teaching and learning mathematics.

Mathematical Modeling With Focus on Geometry

Students sometimes perceive school mathematics to be a narrow set of rules and algorithms that have little or no meaning to their lives. This was evident in both Diego and Helina's responses to what they think of when they hear geometry - "shapes, proofs, and the subject that so many students hate" (Interview 1). When mathematical content is devoid of relevancy to students and their lives, there is a decrease in interest and motivation for learning it. Geometric ideas and images surround students in the form of art, architecture, and patterns, and "by integrating geometry, art, and history, we can create opportunities for students to experience the excitement and beauty of mathematics that build on foundational geometric ideas and elevate student interest in mathematics and related subjects" (Desai & Safi, 2020, p. 96). An ethnomodeling approach allows for the focus on both learning about historical and cultural ideas and engaging in the mathematical modeling cycle to further learn about the mathematics of these practices.

Following each in-class task exploration, PSTs individually reflected on their experiences. During their explorations, in their interviews, as well as elsewhere in their reflections they discussed many mathematical ideas their group engaged in. However, when asked to name specific standards, they often left out key ideas. In sharing a specific example of the changes they would make for the future, for Task 2, Helina shared that her group would need to focus on connecting their plan back to the real world context. In creating a plan for tiling their wall, they used reflections which is possible on GeoGebra, however in real life where tiles are one sided this would not work. Diego added that a solution for this could be pre-designing two tiles that are reflections of one another. Such discussions point to the need for integrating real-world contexts into mathematics tasks.

Ethnomodeling

At the beginning of this study, ethnomodeling was new terminology for all of the participants. Many of them had some familiarity with engaging in mathematical modeling tasks in previous mathematics education courses, however integrating that with cultural and historical components was a new approach for them. In their final group reflections when asked how they would describe ethnomodeling tasks to a friend or colleague outside of this study, the group shared "Ethnomodeling is incorporating culture and art into mathematical concepts".

While the group was able to define key components of ethnomodeling, in sharing how these tasks will influence their own practice, the group shared they would use such tasks in introducing concepts before they go on to teaching traditional textbook content. This response calls for a greater need for continued discussions about redefining what it means to do, teach, and learn mathematics in our mathematics teacher education preparation programs.

Discussion and Concluding Remarks

While all the participants agreed that ethnomodeling tasks were necessary to incorporate in mathematics education, there was a consensus that they would need more guidance and examples of how to incorporate such tasks into other mathematical content domains. Research efforts have indicated the need for further ways to explicitly connect students' identity, culture with mathematical experiences - and ethnomodeling can be one way to achieve this goal. As educators, we have a moral responsibility to tell the story of mathematics from multiple standpoints that provide our students an immersion in mathematical experiences informed by cultural and historical perspectives (Naresh, 2015). Through engaging in ethnomodeling tasks, PSTs can learn to value and respect mathematical practices of diverse cultures and traditions as well as become more prepared to engage their students in such geometric tasks. An ethnomodeling approach creates necessary critical dissonance as it pushes on current inequitable and unjust systems, and through this integrated ethnomathematics and modeling approach we can create 'resonant harmony. Through such explorations, PSTs are able to learn mathematical content in de-siloed and connected ways, and naturally find connections between mathematics and other content domains - and explore and share their own experiences. Such experiences also empower PSTs to engage their future students to experience the wonder, joy, and beauty of mathematics in the world around them.

PRACTICE-BASED AND SOCIAL JUSTICE APPROACHES TO MATHEMATICS TEACHER EDUCATION: MOVING FROM DISSONANCE TO HARMONY

Kristin Doherty
Michigan State University
kdoherty@msu.edu

The dissonance in the field between practice-based and justice-oriented approaches to teacher education motivated my review of the literature on the relationship between these approaches, specifically in the context of mathematics teacher education. I reviewed literature to better understand reasons for this dissonance and explore how these approaches might be harmonized within mathematics teacher education. Building on this review, I present a framework for conceptualizing practice-based approaches in justice-oriented ways. I argue social foundations can support preservice teachers in developing a critical lens to apply in their enactment of mathematical practices through practice-based approaches.

Keywords: Preservice Teacher Education, Teacher Educators, Social Justice

Problem Statement and Objectives

The dissonance in the field between practice-based teacher education (PBTE) and a teacher education oriented toward social justice (SJTE) motivated my review of the literature on PBTE and SJTE, with connections to mathematics teacher education (MTE). I reviewed the literature to better understand reasons for this dissonance and to explore if and how these approaches could be harmonized within MTE. The following research questions guided my analysis: (1) For what reasons have mathematics teacher educators adopted practice-based approaches? (2) What opportunities and challenges have mathematics teacher educators experienced when implementing PBTE with respect to issues of social justice? and (3) How can PBTE and SJTE be harmonized within MTE?

PBTE emerged as a response to a persistent problem in teacher education, the *problem of enactment* (i.e., the struggle amongst beginning teachers to bridge theory and practice) (Kennedy, 1999). This problem motivated teacher educators to conceptualize a professional knowledge base for teaching and the practices involved in the work of teaching (i.e., *high-leverage practices*), and make this learnable to PSTs through opportunities to examine and enact the practices (i.e., *pedagogies of enactment*; Grossman et al., 2009) before entering the profession (Ball & Bass, 2002; Ball & Cohen, 1999; Ball et al., 2009; Grossman et al., 2009; Holmes Group, 1986). However, as teacher educators adopted practice-based approaches, some worried these could be reductive and reinforce the status quo of whiteness (Philip et al., 2019), while others have leveraged practice-based approaches for supporting the enactment of justice-oriented pedagogy (e.g., Schiera, 2019 & 2020). This tension between different lenses of PBTE first motivated my exploration into the dissonance (Doherty, 2022; Doherty, in press). In this conference proceeding, I will build on those ideas and tie them more specifically to mathematics teacher education. My motivation for addressing the dissonance between PBTE and SJTE is to show these two approaches can be more powerful together than as stand-alone initiatives. In other words, harmonizing these approaches within MTE can better support PSTs to operationalize justice-oriented mathematics pedagogy.

Theoretical Framework

Literature Review

Differing conceptualizations of PBTE across time and across scholars seem to be one contributing factor to the dissonance between PBTE and SJTE. Forzani (2014) documents these various conceptualizations and asserts, "what teacher educators and education researchers have meant by 'practice' and 'practice-based' teacher education has varied from one era to the next" (Forzani, 2014, p. 357), and adds, "there seems to be little consensus about what it means or should mean" (Forzani, 2014, p. 358). For instance, Philip et al. (2019) describe PBTE as a reductive, prescriptive, and decontextualized approach that "amplifies oppression," whereas Schiera (2019 & 2020) leverages practice-based approaches for bridging justice in theory with practice and acknowledges these practices are contextually situated. Schiera (2019) noticed PSTs struggled to operationalize justice-oriented pedagogy, particularly in a world made by and for whiteness, and practice-based approaches can support PSTs in navigating this and acting on injustices through their teaching practice.

Studies have investigated different combinations of PBTE, SJTE, and MTE, but fewer have studied the integration of all three. For instance, studies found practice-based approaches (particularly, *pedagogies of enactment*) improved PSTs' readiness and competency to teach mathematics content (see Boerst et al., 2011; Campbell and Elliott, 2015; Ghousseini and Herbst, 2016; Lampert et al, 2013; Tyminski et al., 2014). However, these were not paired with a justice-oriented focus. Some studies harmonized PBTE and SJTE within other content areas other than mathematics, such as social studies (e.g., Schiera 2019 & 2020) or multiple subject areas (Calabrese Barton et al., 2020; Kavanagh et al., 2020). Kavanagh and colleagues (2020) found approximations of practice can improve teacher *responsiveness* to students' contexts; and Calabrese Barton et al. (2020) identified *justice-oriented high-leverage practices* they observed from teachers' instructional practices. While pedagogies of enactment (such as approximations of practice) can help operationalize pedagogy, naming practices (such as justice-oriented high-leverage practices) can contribute to a professional knowledge base of the work involved in teaching for social justice. While these studies were not specific to MTE, an empirical study by Campbell and Elliott (2015) discuss PBTE in relation to MTE, with a closer connection to SJTE. Campbell and Elliott (2015) situate their work in sociocultural theory and leverage approximations of practice for supporting PSTs in being more responsive to students, which they call part of "ambitious and equitable mathematics teaching." While the studies referenced above are notable in attempts to harmonize some combination of PBTE, SJTE, and MTE, there were no peer-reviewed published studies that I could find that wholly integrate all three. I found reductive dichotomies of theory and practice combined with different lenses of PBTE and SJTE contributes to reductive dichotomies of PBTE and SJTE within MTE.

Conceptual Framework

In this section, I present my framework for integrating PBTE and SJTE within MTE, with connections to dissonance and harmony. In music, harmony results when more than one note is played simultaneously to produce a sound arguably more powerful than the sound each stand-alone note could make. By harmonizing PBTE and SJTE within MTE, the field can realize a teacher education that is more powerful than trying to implement them as separate, stand-alone initiatives. Schiera (2019) explains integrating PBTE and SJTE entails learning to develop a critical consciousness and applying that lens to act on inequities in practice (e.g., in genuine mathematics teaching contexts). Schiera (2019) draws on Ball's (2018) notions of *discretionary* *spaces* which explains practice is never absent from belief and disposition and teachers have the power to disrupt or reinforce patterns of inequity through their teaching. Schiera explains,

> These processes of representation, decomposition and approximation could be interrogated with critical conceptual tools (Grossman et al., 2009) to investigate whether and how the enactment of a practice might reinforce or interrupt inequities. In the field, researchers and practitioners together can also investigate the ways that they enact practices in culturally responsive ways. Researchers can also look to decompose actions social justice educators take in discretionary spaces, following Ball's (2018) model, to learn further about how teachers at all stages of development respond to inequities in the moment (Schiera, 2019, p. 943).

The *SJ-PBTE Framework* (socially just practice-based teacher education framework) introduced in Doherty (in press) describes leveraging social foundations with practice-based approaches (see Figure 1). It builds on Schiera's (2019) ideas and is supported by Bowman and Gottesman (2013) who also argue for grounding PBTE in social foundations. The framework involves identifying high-leverage practices for mathematics instruction, that are made learnable to PSTs through pedagogies of enactment, situated in social foundations that support PSTs' development of a critical consciousness to apply as a lens in the enactment of the practices. The framework has connections to TeachingWorks (2022b), which acknowledges teaching is not neutral and supports grounding teacher preparation in pedagogies of enactment that support PSTs in noticing and disrupting patterns of inequity through their practice. This involves identifying the work of teaching (i.e., high-leverage practices) and how the work can advance justice, and making this learnable to PSTs through pedagogies of enactment. For instance, for *each* high-leverage practice, TeachingWorks (2022a) offers explicit statements describing how the practice can advance justice. For example, the description of the high-leverage practice, *Implementing norms and routines for discourse*, contains the subheading "How does implementing norms and routines for classroom discourse and work advance justice?" which explains content area norms and routines can help students construct and share knowledge but "often reflect dominant power and privilege." Thus, TeachingWorks (2022a) cautions that norms and routines should center student voice and in ways that do not marginalize others. Using the framework within MTE thus involves identifying high-leverage practices (1) as conceptualized within mathematics spaces and (2) specific only to mathematics, and offering similar statements that describe how the practice can reproduce or disrupt injustices in the mathematics classroom.

Another approach to using the framework might involve engaging PSTs in *pedagogies of investigation* (Grossman & McDonald, 2008) about Freire's discussion of the *banking approach* to education (as related to *traditional* mathematics), alongside *reform* mathematics (NCTM, 1989) as moving closer (but not fully) to Freire's *problem-posing* and *co-intentional education,* where students share in the co-construction of knowledge and use mathematical argumentations with justifications to decide what counts as truth rather than the teacher readily confirming answers. Pedagogies of investigation can be interwoven with *pedagogies of enactment* (Grossman et al., 2009) to provide PSTs scaffolded and mediated opportunities to carry out this work. Although not every scenario can be approximated (because teaching and learning is contextual), I argue approximating within various contexts that center student voice can help PSTs learn to be more responsive to students when later placed in other contexts. This is supported by Kavanagh et al. (2020) who found teachers' responsiveness to students improved through approximations of practice. I argue approximations and field teaching experiences should be mediated by teacher educators and mentor teachers to support PSTs in disrupting inequities that arise within the *discretionary spaces* (Ball, 2018) of mathematics instruction.

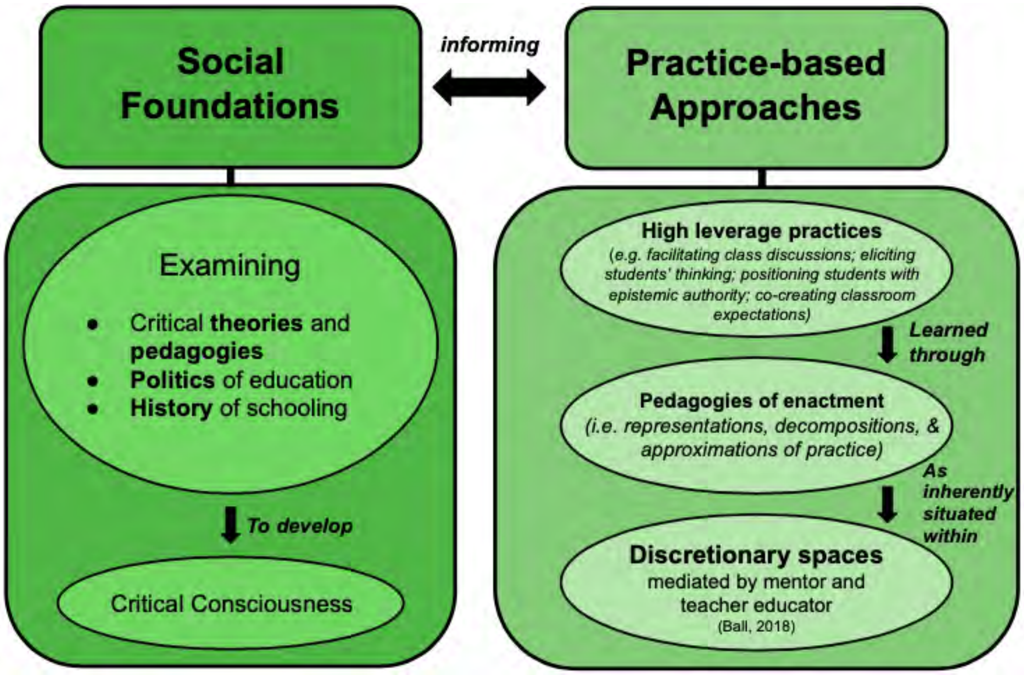

Figure 1: SJ-PBTE Framework

Discussion

Learning to teach mathematics in ways that enact ambitious and justice-oriented pedagogy is complex work, which is why I argue for supporting PSTs through a practice-based approach. Without practice-based approaches to support PSTs, many struggle with figuring out how to operationalize justice-oriented pedagogy (Kavanagh & Danielson, 2019; Schiera, 2019). Schiera explains, "SJTE critiques [PBTE] for reproducing social structures that perpetuate inequities (Philip et al., 2019). Such divergent starting points make it difficult to find common ground from which [PBTE] and SJTE begin to collaborate. This leaves novices… alone to figure out how to become 'comfortable' with practice while being 'mindful' of justice amid the complicated process of learning to teach" (Schiera, 2019, p. 2). Although broad in design, the SJ-PBTE Framework shows the potential for a socially just, practice-based teacher education situated within MTE. Because of the complex work of teaching (Ball & Forzani, 2009) and even more complex work of harmonizing these perspectives, this integration itself will be complex. The framework has implications for the field to develop more empirical studies that integrate PBTE and SJTE within MTE. It also has implications for the field to identify *justice-oriented high-leverage mathematics practices*, similar to those described in Calabrese Barton et al. (2020). Mathematics education is a highly influential field, as it serves as an academic and economic gatekeeper (Martin et al., 2010). Due to its strong influence on society, helping beginning teachers learn to enact equitable mathematics pedagogy is important work for social justice initiatives, and I believe practice-based approaches can support this.

Supporting our teachers means that we must continually improve our teacher preparation programs. This improvement is influenced by various sources (e.g., state policies, university culture, program environment, faculty, needs of local schools, research). An overlooked perspective on teacher preparation programs is students' voices. We conducted a multi-stage survey to inquire into students' perspectives about their mathematics teacher preparation program. We discuss mathematics teachers' beliefs about the strengths and weakness of their preparation program. Findings from both stages indicated that students experienced disconnects between what they expected to get out of certain courses and what we, as faculty, expected them to learn. Although these are not novel issues, they are pertinent issues related to improvement of teacher education and serve as the impetus for conversations around programmatic improvement.

Keywords: Systemic Change, Teacher Beliefs, Teacher Educators

Pre-service secondary mathematics teachers take a variety of mathematics, education, and/or mathematics education courses in their programs (Darling-Hammond et al., 2005). The courses and structure of the program are heavily tied to the institutional context. Local institutional contexts are always looking to improve their programs to enhance the recruitment and retention of students, as well as improve the overall teacher education experience. Student voices and perspectives are an important, yet often overlooked, component in the process of instructional changes related to improving these programs (Allen & Peach, 2007; Fielding, 2001). In this work, we share findings from student voices and perspectives on their beliefs about how their program is preparing them or has prepared them to be teachers. Our research question was: *What do preservice and inservice teachers believe about how their program is preparing them to be teachers or has prepared them to be teachers?* The goal of this research is not only to learn students' perspectives on their education, but to understand what needs they have even after leaving our programs. What role does teacher education play in professional development post-graduation? To situate this, we will also describe the specifics of our mathematics teacher preparation program. First, we summarize relevant literature. We then discuss our methods and findings.

Literature

There is much literature on teacher preparation programs, oftentimes using student achievement to discuss successful programs (e.g., Boyd et al., 2009; Koedel et al., 2015). More recently, though, focus has shifted to standards for mathematics teacher preparation that are not solely about student achievement. In 2017, the Association of Mathematics Teacher Educators (AMTE) published the *Standards for Preparing Teachers of Mathematics*. To assess candidates, AMTE recommends assessing mathematical knowledge relevant to teaching, mathematics teaching practice, and dispositions. Regarding programs, AMTE recommends assessment of stakeholder engagement, program curriculum and instruction, effective clinical experiences, and recruitment and retention. An overall assumption within these standards is that "those involved in mathematics teacher preparation must be committed to improving their effectiveness in preparing future teachers of mathematics" (AMTE, 2017, p. 2).

Thus, given these important standards and recommendations, the teacher education field needs to know how these standards are communicated to students in teacher preparation programs. Having teachers reflect on their instructional practice is a well-documented successful strategy for teacher education (e.g., Etscheidt et al., 2012); we aim to use reflection in this work at the programmatic level.

Methods

Research Design and Context

Our research question was: *What do preservice and what did inservice teachers experience in their mathematics teacher preparation program?* To answer this question, we conducted a two-phase exploratory convergent parallel design study (Creswell & Creswell, 2017; Tashakkori & Teddlie, 1998), wherein we designed a survey to collect both qualitative and quantitative data in Phase 1, and results from both data sets are used to compare or relate our findings for an overall interpretation. We then sent a follow up survey in Phase 2 to ask targeted qualitative open-ended questions from the three themes that emerged from the qualitative data in Phase 1.

In Phase 1, we sent a survey to our current undergraduate middle-grades and/or secondary mathematics education students and former graduates from these programs from the last 10 years. Participants either graduated from or are currently enrolled in a university in the southeastern United States which is a UTeach replication site. Preservice teachers seeking certification to teach middle grades and/or secondary mathematics have multiple majors. Students can either major in Mathematics or Middle Grades Mathematics. In some cases, students will choose to major in both. Mathematics certification also requires an additional major in Science and Mathematics Education (SMED). All of the mathematics courses are taught by mathematics education or mathematics faculty within the Mathematics Department. The SMED courses are taught by education faculty in the School of Education. Although there is not a formal connection between mathematics and education courses, the faculty in both units try to provide a cohesive experience. In the mathematics courses, the focus is strictly on content whereas the education classes focus on the various aspects of teaching.

Data Collection

We used alumni email lists and current student departmental email lists to ask for participation. Sixty-nine participants filled out the Phase 1 survey (15 current students and 54 former students). The survey collected demographic information, open-ended responses, and Likert-scale questions. The demographic information was gender identification, race, ethnicity, first-generation college student status, majors, minors, and classification (former student, senior, junior, sophomore, first-year). The quantitative data were 5-point Likert-scale questions (strongly agree to strongly disagree) where participants were asked how their program was preparing or has prepared them to: 1) teach mathematics in a student-centered way; 2) inquire into my students' mathematical thinking; 3) assess students' mathematical knowledge; 4) prepare mathematics lessons; 5) solve mathematical problems; 6) support diverse students and diverse student thinking; and 7) make connections between mathematics content. Example open-ended questions for former students were: 1) Please describe your teaching style and why that is your approach to teaching mathematics; 2) What about our program, in regard to your [mathematics /

education] courses, [did / did not] prepare you for your current position? Current students were asked similar questions, rephrased to be applicable to them.

In Phase 2, we asked specific questions based on the results from Phase 1. Specifically, we asked:

1. Describe how the content you learned in your courses is connected (or not connected) to the content you teach in your classes. Please discuss both mathematics and education classes, and be as specific as possible.
2. What is your definition of good mathematics pedagogy? Where have you experienced this as a student and as a teacher?
3. Concerning your response to the previous question: Describe how often and in what ways your teaching does or does not espouse (live up to) this definition of good mathematics pedagogy.
4. Classroom management is often something that teachers feel least prepared for. Please describe a specific issue you have had with classroom management during your time as a teacher. Why did you feel prepared or unprepared to deal with it?
