The notion of in and out of school mathematical thinking is tightly connected to a related notion of mathematical identity (Martin, 2000). Learning to do mathematics, in school, can be viewed as a process of being socialized to participate in that mathematics classroom (Cobb, Wood, & Yackel, 1993). The emerging literature on identity focuses on students' self-understandings, and the understandings that are assigned to them, about their relationships to mathematics (Horn, 2008). One implication of a focus on students' relationships to mathematics is the posing of problems that refer to contexts that are relevant to students' out of school experiences (Nasir, 2002). The mathematics identity literature typically investigates how students are self-positioned, or positioned by others, in relation to the mathematical task at hand (Cobb, Gresalfi, & Hodge, 2008; Horn, 2008, Martin, 2000). However, we should also examine the ways that students, or teachers, position the mathematical tasks, within a context of a mathematics classroom. This paper examines middle and high school student thinking about an effect of sample space task and discusses these results using a lens of in and out of school mathematical thinking.

*Effect of Sample Size*

The empirical law of large numbers, in informal terms, states that if a probabilistic experiment is repeated over and over, a large number of times, the relative frequency of an event will approach its theoretical probability. Alternatively stated, as more trials are repeated, the experimental mean of a random variable approaches its theoretical mean. The earliest version of this law was proved by Jacob Bernoulli in the 17$^{th}$ century and proved in a more general form by Kolmogorov in the 20$^{th}$ century. For example, although a particular casino game might have only a very slight edge in the house's favor, like 51%, the more times that the game is played, the closer the casino's earnings will be to 51% of all of the bets placed. Similarly, the more times one tosses a coin, the closer the relative frequency of tails will be to ½.

Adults have been shown to maintain beliefs in a different law, the "law of small numbers" (Tversky & Kahneman, 1972), by which the empirical law of large numbers is applied to small samples of data. For instance, Kahneman and Tversky (1972), in what has become a classic task, posed the following problem to college students: "There are two hospitals, one small and one large, and over the period of a year, each hospital records the number of days on which more than 60% of the babies born are boys. Is either hospital more likely to yield such days, or should one expect the two hospitals to yield the same number of such days?" Results included only 20% of their undergraduate sample choosing the correct answer, the smaller hospital, while 56% said that the two hospitals would yield about the same number of such days.

Kahneman and Tversky explained these results as an instance of the representativeness heuristic, by which people determine the probability of an event based on how closely it resembles the same parameter in the parent population. Since births generate boys about half the time, people typically indicate that there should be roughly an equal number of boys and girls born in each hospital, regardless of the sample size of hospitals. Bar-Hillel (1982) replicated the hospital problem with college students and obtained similar results. However, when she increased the parameter of 60% frequency of born baby boys to higher percentages, like 70%, 80% or 100%, more students chose the smaller hospital as more likely to have such yields.

*Sampling or frequency distributions*. The hospital problem can be framed in two different ways, as a sampling distribution or as a frequency distribution (Sedlmeier & Gigrenzer, 1997). The sampling distribution format was used by Kahneman and Tversky (1972) as well as Bar-Hillel (1982), meaning that students consider the span of a year and to determine which of the hospitals would be more likely to have days in which 60% of the births were boys. In the frequency format, students are asked which hospital would be more likely, on a single day, to have 60% of its babies born boys. Sedlmeier and Gigerenzer (1997) aggregated results of studies that use alternate forms of this task and found that people are more likely to attend to the effect of sample size when the task is framed in terms of frequency distributions.

*School students' thinking about sampling*. School age children, even when facing the task in the frequency distribution format, also have difficulty with the concept that smaller samples are more likely to be non-representative than larger samples. Watson and Moritz (2000) adapted the hospital problem to a frequency distribution version involving schools, and still, most of the students (61%, n=41) said that both samples were as likely to occur. Fischbein and Schnarch (1997) posed a sampling distribution version of the hospital problem to middle and high school students and found that the students' seeming lack of attention to the significance of sample size was more prevalent among *older* students than younger students. More of the older students committed this error than did the younger students.

Fischbein and Schnarch (1997) also presented students with a second sampling task. They asked students to compare the likelihood of getting at least two heads on three tosses of a coin with the likelihood of getting at least two hundred heads on three hundred tosses of a coin. Again, their results showed that a higher proportion of the older students (11th graders and undergraduates) indicated that these would be equally likely.

Fischbein and Schnarch's counterintuitive results can be explained in terms of a more developed ratio schema among older school age students. Tirosh and Stavy (2000) elaborate this explanation by describing student thinking on this task in terms of the Same A Same B intuitive rule. If the two systems or objects are equal in terms of a quality A, students often indicate that those two objects will also be equal in terms of a second quality B. In this case, since there is an equal ratio of tails to total coin tosses, 2:3 and 200:300, (Same A), students reason that Same A implies equal probabilities (Same B). The hypothesis is that since older students are more adept proportional thinkers, they are more apt to use that strategy in tackling tasks such as these. In gathering the data described in this article, I posed an effect of sample size task in frequency format with the primary aim of further investigating Fischbein and Schnarch's surprising results.

## Methods

This task was part of a larger study (Rubel, 2002), whose main objectives were to explore student thinking about a variety of probabilistic constructs. In this article, I address one discrete subset of that study, captured by the following research question: When given frequency information, what reasoning do middle and high school students use in comparing the likelihoods of two events? Students were asked to respond to the following prompt:

Determine which is more likely, and explain your answer:

a) getting 7 tails on 10 tosses of a coin
b) getting 700 tails on 1000 tosses of a coin
c) they are equally likely

*Data Collection Procedures*

The sample was a convenience sample of 173 students in grades 5, 7, 9, and 11 at an academically rigorous, independent boys' school in New York City. I was a teacher at this school and was familiar to study participants. I visited each of the twelve represented mathematics classes and presented students with information about the process of educational research and the nature of this particular study. Students could choose to opt out of participating in the study, and were given an opportunity to ask questions about the research. Students completed the Probability Inventory during a regular mathematics period. Responses were initially aggregated according to the students' answers, and then were categorized a second time in terms of justification type.

The second phase of data gathering was the clinical interviewing of 33 of the 173 students, stratified to represent each of the age groups and classes (five 5th graders, seven 7th graders, twelve 9th graders, and nine 11th graders). These interviewees were selected primarily on the basis of their responses to the Probability Inventory, so as to ensure the representation of a variety of common answers and justification types to different tasks. Interviews were conducted by the researcher within a week of a student's completion of the Inventory; each interview lasted between twenty-five and forty-five minutes.

Interviews were semi-structured, with the primary goal of gaining greater detail about the specific student's thinking by using "How did you get this?" or "Why does this work?" types of questions.

## Results

Nearly all of the students' responses (95%) can be divided into two categories, that 7 tails out of 10 tosses is more likely, the correct answer, or that the two events are equally likely, the common misconception.

Table 1
*Distribution of Responses*

| | Grade 5 (n=36) | Grade 7 (n=45) | Grade 9 (n=50) | Grade 11 (n=42) | Total (n=173) |
|---|---|---|---|---|---|
| 7 tails out of 10 tosses is more likely | 17% (6) | 13% (6) | 22% (11) | 40% (17) | 23% (40) |
| Equally likely | 78% (28) | 87% (39) | 68% (34) | 55% (23) | 72% (124) |

Only 40 students (23% of the sample) indicated that 7 tails out of 10 tosses is more likely. Students used one of the three justifications for this response, described here in order of decreasing frequency. Many students explained their thinking with some form of the empirical law of large numbers. For instance, one student wrote, "It is easier to get a large number out of a small number than a large number out of a large number." The second most frequent justification was that 7 tails out of 10 is more likely since seven is many fewer tails than 700. Finally, the third justification category related to exactness. These students reasoned that 7 tails out of 10 is more likely since there are eleven possible numbers of tails on 10 tosses, whereas there are 1001 possible numbers of tails on 1000 tosses.

As shown in Table 1, nearly three-quarters of the sample, 124 of 173 students answered that 7 tails out of 10 tosses is as likely as 700 tails out of 1000 tosses. Unlike Fischbein and Schnarch's results, this response was not more common among the older students. Students' justifications to this incorrect answer belonged to two categories. Most of these students offered justifications for their choice based on equal ratios, equal fractions, or equal percentages, using Same A Same B thinking (Tirosh & Stavy, 1999). However, other students used the 50-50 approach (Rubel, 2007), by which they over-generalized the 50% likelihood of a specific outcome in the single event case to an outcome of a broader, compound case. In other words, these students indicated that 7 tails on 10 tosses is as likely as 700 tails out of 1000 tosses because both situations are "50-50."

## Discussion

In addition to the written component of my study, I also conducted cognitive clinical interviews with 33 of the students. In the course of conducting these interviews, I noticed that students often had multiple, contrasting approaches to the same problem and that they themselves characterized those approaches as in-school or "mathematical" versus out-of-school or "real world." In the next section, I give two examples of this phenomenon, using excerpts from interviews with two students about this particular task.

On the written component of the study, Kendall, a 7th grader, penned that 7 tails out of 10 tosses is as likely as 700 tails out of 1000 tosses. However, in his interview, Kendall revealed additional ideas about this task.

Kendall: "I have to say that even though both reduce to the same fraction, it would be more likely that you'd get 7 out of 10 because then your chances – actually, well, if you're going more likely, probably 7 out of 10 because the higher you go up, the less chance you have of being that precise. You know what I'm saying?"

Researcher: " Not exactly."

Kendall: "If I flipped a coin ten times, I'd think, again, not on paper, this is more real life, there's probably more of a chance than what you can do on paper. Ten times, there's more of a chance of getting 7. If you flip it 1000 times, getting 700 is, I mean it's possible. For some reason 7 out of 10 just jumps out at me."

Researcher: "Were you thinking about this since last week?"

Kendall: "That's not what I wrote. I've been thinking about it, what would be more likely. My strategy here is on paper." (Note: in the interview, Kendall had previously mentioned answering questions "the math way.")

Researcher: "The math way?"

Kendall: "If someone just came up to me and asked me this, I would definitely say 7 out of 10 because 700 out of 1000 just seems like more." (long pause)

Researcher: "You're a basketball player, right? Do you ever take free throws and keep track of how many you make?"

Kendall: "Yes. The larger number you get, the larger the amount of error. With the free throw analogy, it's not too hard to get 7 out of 10. In real life, it would be hard to keep up that, I want to say, ratio.

Later in the interview, with respect to a similar task about effect of sample space, Kendall explained, "It's easier to get 7 out of 10 in real life. But if you reduce them it's 7 out of 10. In real life, if I was betting, I would not bet on 700 out of 1000."

Researcher: "What if it were a question on a math test?"

Kendall: "The way I answered it on this. I'd say if you put it into a fraction, it's 7 out of 10. On paper, it makes more sense doing it this way. Usually in math, there's one answer. 7 out of 10 is seven tenths. 700 out of 1000 is seven tenths, and I know that's correct. That's how I would answer on a math test."

This Kendall example demonstrates the significance of a student's beliefs about mathematics and what it means to do mathematics in school. While Kendall explained in his interview the exactness justification as well as the empirical law of large numbers, he characterized those methods as being appropriate for outside of the classroom. Even in the face of these ways of thinking about the effects of sample size, Kendall maintained that the incorrect solution, the one that demonstrated that both fractions are equal, was the appropriate solution for a mathematics classroom.

In another interview, with 11th grader, Ned, we gain some additional insight to such categories of conflicting answers. Ned described the conflict as being between a concise, numerical way of answering the question with an imprecise comparison.

Ned: "The pure math is that they're the same thing. The probability of 7 out of 10 is the same as 70 out of 100. It's like 7 tenths. But if you actually do it 1000 times, it gets less likely to get 700. It's like the *Fight Club*; if you have enough stuff, it's harder to do it.

Researcher: "How's it like the *Fight Club*?"

Ned: "Because he always says, over a long enough timeline, everything goes to zero or something like that. But it's kind of the same thing. On a long enough span, it's going to be harder to get this percentage."

Researcher: "So, are you sticking with this answer?"

Ned: "There are two ways to look at it. I chose this way."

Researcher: "How do you choose if there are two answers?"

Ned: "The way where you say divide 7 by 10 or 700 by 1000. It's always gonna be this – there's no gray. It's less easy to prove the other way, even though I understand that there's another way to look at this."

Researcher: "Let me change the question. How about comparing getting 10 tails out of 10 tosses with 1000 tails out of 1000 tosses?"

Ned: (pause) "That's more like the other way."

Researcher: "What about your way: 10 out of 10 is the same as 1000 out of 1000.

Ned: "Obviously, they're not. Obviously, it's not the same: 1 out of 1 or 1000 out of 1000. So from thinking about it, it's not the same possibility. But on paper, it is. (pause) Ok, so 700 out of 1000 tails and 7 out of 10 tails. How much more likely is 7 out of 10?"

Researcher: "You said they were equally likely."

Ned: "I know, on paper, they're equally likely. But if you're going to say one is more likely, then how much more likely? I want to know how much more. If you can't figure it out, then the way you can figure it out is the way I did it."

Ned positioned the erroneous Same A Same B approach as being "pure math," and then continued to describe an analysis of the situation using the empirical law of large numbers. He seemed to accept the fact that he had indicated two conflicting answers to the same question. Then, in response to an alternate task, selected as way to initiate cognitive conflict (Borovcnik & Peard, 1996), similar to Kendall, he categorizes the Same A Same B approach as being the way to proceed "on paper." When I push him to reconcile this conflict, he persists that "on paper," the two frequencies are equally likely. The mathematical argument posed by the empirical law of large numbers did not allow him to quantify the likelihoods of either frequency, and quantification seems to be a necessary component of correct thinking "on paper," or in school.

## Conclusions

The interview segments dealing with effects of sample size items contained a common theme: there were instances of students at all grade levels who differentiated between a "math answer" and a "real world" answer to a single question. In the case of this particular task, the "math answer" was the incorrect answer, that 7 tails out of 10 tosses would be as likely as 700 tails out of 1000 tosses because of equal ratios. Even though these students' expressed "real world" answers that were, in fact, well aligned with normative mathematics, they favored the incorrect "math answer" because it involved an arithmetic operation.

On paper, it seemed that these students all had the common Same A Same B misconception, that equal ratios imply equivalent probabilities, as discussed by Tirosh and Stavy (2000) and Fischbein and Schnarch (1997). Yet when interviewed, these students revealed a great deal more thinking about the problem than appeared on the written page. This phenomenon has some clear assessment implications. Mathematics teachers, and certainly states and school districts, assess learning and understanding by evaluating students' written responses to pencil and paper tasks. Implicit in that process is the assumption that students will write what makes most sense as an answer to the given question. However, the results reported in this article demonstrate that it is not only possible, but likely, that students have multiple, conflicting responses to a given task, especially when that task is contextualized in terms of a real world phenomenon. This study has shown that students' beliefs about school mathematics, and their sense of what it means to do mathematics in school, can operate as a filtering mechanism by which they designate which ideas are appropriate for written, school responses.

Bringing relevant contexts into the teaching of mathematics is assumed to be useful in that it serves as a way for students to view mathematics as being pertinent to their lives and also that it enhances understanding by facilitating sense making of the various connections between the problem context and corresponding mathematical models or representations. However, the results reported in this article caution us to be careful about these assumptions.

Even more interesting, though, is the question as to why students view a distinction between thinking in the "real world" and thinking in a mathematics classroom. We typically categorize school mathematics tasks as being either context free or related to the "real world." But since the "real world" mathematics tasks that we pose in the classroom are typically stripped of most of their contextual features, perhaps we have inadvertently given students a clear message that the thinking that one does in mathematics classrooms is very different from the thinking one does outside of school.

# CONCEPTIONS OF STATISTICAL VARIATION

Susan A. Peters
University of Louisville
s.peters@louisville.edu

*The need to think statistically stems from the presence of variation. Statistical thinking embodies understanding of how and why to engage in statistical problem-solving processes and understanding of the fundamental concepts that underlie these processes (Ben-Zvi & Garfield, 2004). Variation plays a crucial role throughout statistical problem solving. This paper describes experienced secondary statistics teachers' conceptions of statistical variation, articulated across design, data-centric and modeling perspectives. Results reveal that these advanced learners of statistics hold three distinctly different types of conceptions of variation: Expected but Explainable and Controllable, Noise in Signal and Noise, and Expectation and Deviation from Expectation.*

## Variation and Statistics

Statisticians view students' development of statistical thinking as fundamental to statistics education (e.g., Cobb & Moore, 1997). In general terms, statistical thinking includes knowing why statistical processes are needed and how to engage in the general process of formulating a statistical question, collecting and analyzing data to address the question, and interpreting results to answer the question (Ben-Zvi & Garfield, 2004). Throughout statistical investigation, variation plays a crucial role (Franklin et al., 2007). Failure to acknowledge variation or to anticipate possible sources of variation can render a statistical study meaningless before data collection begins. Identifying potential sources of variation allows some of those sources to be controlled through methods chosen to collect data and thereby increases the likelihood that effects of or relationships among variables of interest can be determined. Variation also plays a central role in the analysis and interpretation of data. Measuring variation and accounting for variability in the selection of distributions or models to fit the data allows assessment of whether independent factors affect dependent factors in ways beyond chance expectation. Variation precludes deterministic conclusions about relationships between independent and dependent factors from being made, leaving only probabilistically conditioned statements for interpreting results about populations of interest. The primacy of variation in statistics leads some statisticians to view statistics as the study of variation (e.g., Fisher, 1925).

The concept of statistical variation is central to the study of statistics and as such warrants attention by statistics education researchers. Reflective of the widespread role of variation in statistics, researchers have studied learners' reasoning about variation in a variety of statistical areas. Synthesizing this body of work, Shaughnessy (2007) identifies and describes eight variation conception types for how learners view variation. Some conception types are limited to particular contexts, such as time-series settings for "variability as change over time", and other types represent developing views of variation. For example, focus on individual data values, such as extremes and outliers, typifies the conception type of "variability in particular values". Students with this view of variation do not exhibit an aggregate view of data and distribution—a view fundamental to sophisticated statistical reasoning like making inferences from data (Konold & Higgins, 2002). The types of conceptions of variation identified by Shaughnessy are important for educators to recognize students' potentially limiting views of variation and students' views of variation in particular areas of statistics. Of equal importance are holistic images of advanced learners' conceptions of variation across multiple areas of statistics to inform developmental paths. This study provides an image of mature learners' conceptions by explicating the conceptions of statistical variation exhibited by experienced secondary statistics teachers.

## Conceptual Frameworks: Perspectives for Reasoning about Variation and SOLO

The breadth of learners' reasoning about variation can be captured by looking at their reasoning from three perspectives. In this study, Prodromou and Pratt's (2006) descriptions of data-centric and modeling perspectives for reasoning about distribution have been expanded and modified to describe perspectives for reasoning about variation. Addition of the design perspective is warranted by the types of thinking associated with reasoning about variation in consideration of design. Thinking associated with design includes strategic thinking to plan and anticipate problems within practical constraints and noticing and acknowledging variation, particularly during selection of investigative strategies (Wild & Pfannkuch, 1999).

Reasoning about variation from the design perspective entails using context to identify the nature of and potential sources of variation and considering design strategies to control variation from some of those sources. Reasoning from the data-centric perspective includes measuring, describing, and representing variation while exploring characteristics of distributions and using those representations to make informal comparisons about the relationships among data and variables. Reasoning about variation from the modeling perspective incorporates modeling patterns of variability in data or modeling patterns of variability in characteristics of data to reason about relationships among data and variables for the purposes of making predictions or inferences from data.

The perspectives provide a framework for considering the breadth of learners' reasoning about variation; the Structure of the Observed Learning Outcome (SOLO) (Biggs & Collis, 1982) provides a framework for considering the sophistication of that reasoning. SOLO is an empirically-derived, neo-Piagetian model of cognitive development that can both describe cognitive development and describe the complexity and cogency of knowledge that results from learning in response to tasks designed to assess understanding (Cantwell & Scevak, 2004). There exists a cycle of three levels of response to describe understanding and cognitive growth: unistructural, multistructural, and relational (Biggs & Collis, 1982). For this study, SOLO provided a useful lens to design tasks to elicit conceptions and complex reasoning indicative of relational reasoning about variation. In particular, the tasks were designed to reveal relational reasoning within each perspective and across perspectives. The relational level corresponds with responses that exhibit integrated reasoning about variation from a particular perspective and integrated reasoning about variation across the three perspectives. In contrast, the unistructural level corresponds with responses that focus on a single aspect of variation, and the multistructural level corresponds with responses that focus on two or more disconnected aspects.

## Data and Data Analysis

Sixteen teachers with a variety of statistical learning and teaching experiences participated in this study. Participants taught statistics for a median of 9.5 years and were selected for their leadership roles in statistics education. The primary source of data for determining teachers' conceptions of variation was a 90- to 120-minute semi-structured interview. During the interview, teachers responded to a set of tasks that required them to reason about variation. Each task statement was purposefully vague to allow teachers to approach the task from design, data-centric, or modeling perspectives—approaches that provided insights into aspects of variation that seemed to be most prominent for them. The collection of open-ended tasks contained tasks that many teachers are not likely to have encountered previously; however, the tasks are approachable with introductory-level statistics knowledge.

Discussion of conception types centers on teachers' responses to the Consultant Task, part of which is shown in Figure 1. The questions and order of questions used with any one teacher were determined by the direction taken by the teacher in response to the task statement. By providing no information about how administrators selected exams, teachers could respond that the samples might be biased, which would lead into reasoning from the design perspective. Because the only summary measures included in the statement are the average scores for each sample, teachers could request additional information about the data to form a conclusion, leading into reasoning from the data-centric perspective. By presenting information about means and asking for a comparison between consultants, teachers could respond by suggesting that they would conduct a test of inference to form a conclusion, which would lead into reasoning from the modeling perspective.

To improve students' test scores on state assessments, administrators from a large school district require students to take practice exams. Two outside consultants create and score the open-ended questions from these exams. Although both consultants use the same rubric to score student responses, the administrators suspect that the consultants do not interpret and apply the rubric in the same way, resulting in differences in scores between the exams scored by the two consultants. The consultants' contract with the district is up for renewal, and the administrators are trying to decide if they should renew the contract. They decide to use the most recent practice exam to compare the scores assigned from each consultant and to decide whether there is a difference in the way the exams were scored. The administrators select 50 exams scored by the first consultant and 50 exams scored by the second consultant. They find that the average score for the 50 exams scored by the first consultant was 9.7 (out of a possible 15 points), while the average score for the 50 exams scored by the second consultant was 10.3 (out of a possible 15 points). What should the administrators conclude about the scores assigned by these two consultants?

*Figure 1.* The consultant task.

After teachers described their strategies for analyzing the administrators' data, they were given standard deviations and dotplots of the data separately to elicit additional reasoning from the data-centric and modeling perspectives. From the summary measures, teachers were asked to describe the distributions they would expect to inform how they described variation and interpreted standard deviation. The task was designed with a discrepancy between summary measures and dotplots; one of Consultant Two's test scores was "misentered"—a value of 150 for a score of 15. The summary measures were calculated using the value of 150, but the dotplot only displayed scores on the interval from 0 to 15. Teachers were asked to estimate values for the mean and standard deviation of the data displayed in the dotplot and to explain how they estimated the values to inform how they used data to reason about variation. They also were asked to reason about what the administrators could conclude, which allowed them to reason about variation within each distribution and between distributions using summary measures and graphical representations of the data. Teachers had additional opportunities to reason about variation from the data-centric perspective in response to additional questions related to the corrected summary measures and dotplot for Consultant Two's scores and questions related to size-15 samples. Teachers' responses to two additional tasks, the Caliper Task and the Handwriting Task, further informed the way teachers viewed variation from the design, data-centric, and modeling perspectives.

Teachers' interviews were video-recorded, and recordings were transcribed and annotated and subsequently used in analysis. A table was created for each teacher, with columns labeled by perspective and containing a list of indicators of reasoning from each perspective. Any time a teacher exhibited reasoning about variation from one or more perspectives, the passage was copied and pasted from the transcript to the column with the corresponding perspective and indicator in the teacher's table. Using the constant comparative method articulated by Glaser and Strauss (1967), teachers' responses were coded using indicators of reasoning about variation from individual perspectives. Teachers' responses were reread and coded to consider the need for further refinement of the list of indicators. During the course of revisiting teachers' responses to tasks, different patterns of reasoning associated with different conceptions of variation began to emerge from the data. As continued comparisons were made through multiple additional passes through the coded data, distinguishing features of different conceptions were delineated. Analysis continued until there no longer existed any conflicts for describing teachers' conceptions of variation.

## Results: Types of Conceptions of Variation

Three types of conceptions of statistical variation emerged from data analysis: Expected but Explainable and Controllable (EEC), Noise in Signal and Noise (NSN), and Expectation and Deviation from Expectation (EDE).

*Conception: Expected but Explainable and Controllable (EEC)*

Individuals with EEC conceptions of variation see variation as omnipresent, explainable, and controllable. Their sense of variation's omnipresence leads them to expect variation in statistical settings, and their view of variation as controllable focuses on design strategies for both observational and experimental studies. Their view of variation as explainable aligns with their focus on context to identify factors that potentially contribute variability in data and with their attraction to experimental designs that allow them to determine causes for variation to establish cause-and-effect relationships.

A view of variation as explainable may be at the heart of privileging experiments over observational studies. A primary advantage of experiments is the capacity to establish cause-and-effect relationships, which provide stronger explanations for variability in data than association alone. Haley, one of the two teachers in the study who exhibited EEC conceptions, has a strong affinity for experiments. Haley seems to be dissatisfied with the limited inferences that she can make from data in the Consultant Task study, which is an observational study. She observes, "I don't understand, if you do a difference of two means, what's that going to prove?" (Haley, Lines 44-46). Haley seems to expect the administrators to want more information than a comparison of means allows—she may be looking for a potential cause for variability in improved scores or alternatively for a potential cause for variability in the form of changed scores. She notes the administrators' stated goal of improving scores and suggests that their design will yield little information towards achieving their goal: "They want—what—what is their goal…they're trying to get to improve students' test scores on the state assessment…The consultants' contract—see I'm not quite sure how that's going to…show improvement. There's no treatment there" (Haley, Lines 58-69). Haley notes that no treatment exists for determining how to improve scores—the administrators did not design an experiment. She seems to struggle with a design that appears to provide no explanatory power for how to improve scores. Haley's critique of the methods employed by others (in this case the administrators) and subsequent consideration of alternative designs that achieve greater explanatory power are characteristic of those with EEC conceptions.

Strategies to control variation are not limited to experimental design. Individuals with EEC conceptions also recommend control strategies for observational studies, including the analog to blocking in experimental design: stratified sampling. For example, when Isaac is asked how he would design the Consultant Task study, he suggests selecting a stratified sample in order to sample exams over the entire interval of scores from 0 to 15. He observes that one advantage of a stratified random sample over a simple random sample is precisely this dispersed effect. Using a stratified sample, he controls variation by imposing greater variation on each set of exams but (presumably) reduces variation overall by considering each stratum separately. Isaac even states that his goal is control: "If I could get a stratified sample, then I could in a sense control that [sample] distribution" (Isaac, Lines 287-288).

As the examples from Haley and Isaac suggest, individuals with EEC conceptions of variation seek to collect data in ways that allow them to discover patterns and relationships in data, with a preference for establishing cause-and-effect relationships. They use their knowledge of context to implement designs that allow them to control and to explain variation, and they tend to do these things naturally and without prompting. The totality of and tightly interwoven nature of reasoning about design issues is unique to those with EEC conceptions of variation.

When individuals with EEC conceptions reason from the data-centric perspective, they tend to view data through a lens of expectation—expectation for random variation if they properly control and explain variation. In the absence of apparent random variability, they seek explanations for aberrations in data. For example, when Isaac has the value of the standard deviation computed with the value of 150 for Consultant Two's scores, he immediately looks for an explanation for the magnitude of the value: "the explanation that leaps to mind is that somebody's just flipping a coin here" (Isaac, Lines 493-494). As Isaac's reaction may suggest, when individuals with EEC conceptions reason from the data-centric perspective, their reasoning often contains elements reminiscent of their reasoning from the design perspective. In working with data, they compare the characteristics and relationships they see with their expectation for randomness. When they reason about variation from the modeling perspective, they tend to view models through a relationship lens. They model patterns of variability to capture relationships among data or among variables and evaluate models according to the extent to which relationships are captured. They also use models to determine or confirm the strength or significance of the relationships among data or among variables.

*Conception: Noise in Signal and Noise (NSN)*

Central to NSN conceptions of variation are views of summary measures, data patterns, and relationships among variables as signals that are sometimes lost within noisy data. Everett and Cheyenne, the two teachers in this study with NSN conceptions of variation, see variation as the noise in data for data that does not precisely match underlying parameters, patterns, and relationships and thus interferes with identifying signals. Their view of variation as noise focuses their attention on exploring data; their desire to find patterns and relationships focuses their attention on aggregate features of data distributions while simultaneously considering individual datum that do not clearly fit the patterns and relationships.

Individuals with NSN conceptions of variation see data exploration as a necessary precursor to inference. They explore data to identify potential signals and to gauge the magnitude of noise in data before attempting to establish the significance of signals. In response to reading the Consultant Task, Cheyenne and Everett both reject making any decision from the means alone. Cheyenne indicates that:

> I would have liked to have taken a look at, um, I guess I'm a graphical person. I like to see the, the spread of the distribution to see what it is. Just looking at the means without knowing anything else about the distribution isn't gonna help an awful lot in making the decision. (Cheyenne, Lines 61-65)

Through stating a need to see the "spread of the distribution," Cheyenne seems to refer to a "distribution around" (Konold & Pollatsek, 2002) a signal for each distribution to determine the strength of each signal and to compare consultants' data distributions. Everett also notes that he would "need to know about the distribution of scores" (Everett, Line 105). Both Cheyenne and Everett mention that an observed difference of 0.6 in consultants' average scores does not seem to indicate a problem; without additional information, they hesitate to conclude any difference exists. What distinguishes Everett's and Cheyenne's reasoning is their desire to have information about the distributions and not just information about specific characteristics of the data, namely values for measures of variation like standard deviations.

Both Cheyenne and Everett exhibit revealing indicators of their conceptions as they reason while exploring data. They explicitly, thoroughly, and flexibly consider variation, in addition to center and shape, when they view data through the lens of distribution. They use the same distributional characteristics to compare distributions, considering variation within and between distributions while contemplating the relationship between data and the populations from which data are drawn. No single characteristic in reasoning about data appears to be exclusive to those with NSN conceptions, but the totality of their facility in reasoning about and from data and their continued focus on data to reason about variation is unique to those with NSN conceptions of variation.

Individuals with NSN conceptions reason about variation from the design perspective using a lens of control. They seek to control variability in data to strengthen signals and to increase the probability for identifying signals of interest. In their design considerations, Cheyenne and Everett do not focus on expectation or explanation. Their desire is to reduce noise in data to isolate a signal in data. Individuals with NSN conceptions tend to reason from the modeling perspective either in conjunction with or subsequent to reasoning from the data-centric perspective. They tend to use models as signals or in determining the significance of a signal, but they typically wait to do so until after they have thoroughly explored data. For example, in addition to considering summary measures, Everett suggests comparing size-15 samples by considering the likelihood of observing particular distributions of scores if the 30 scores were repeatedly combined and randomly divided into two groups. He proposes this data-based exploration before he considers conducting a formal parametric test of inference. Similar to how Everett sought to determine the relationship between consultants' scores, individuals with NSN conceptions tend to view models through the lens of relationships, searching for patterns and relationships among data values or among variables.

*Conception: Expectation and Deviation from Expectation (EDE)*

Views of variation as EDE were most prevalent among the teachers in this study. The most distinctive feature of EDE conceptions is variation juxtaposed with expectation. Those with EDE conceptions often approach statistical situations with some hypothesized expectation stemming from their statistical question or from the context in which their question is set—expectation for particular outcomes or measures (including variability), parameter values, patterns of variability, or relationships among variables. In addition to expected amounts of variation, they view variation as deviation from expected outcomes or measures, of statistics from parameters, of observed data from expected patterns, or of observed data from expected relationships.

Individuals with EDE conceptions of variation approach inferential settings with expectations for relationships among data and among variables, including relationships between statistics and parameters. They attempt to determine if observed statistics are probable given their stated expectations. Every teacher with an EDE view of variation suggested conducting a *t*-test in their initial analysis of the Consultant Task data. For example, Blake suggests using a t-test to compare means and to establish if one mean is significantly higher than the other. For Blake, the question is not whether a difference exists—he expects to see a difference—but whether the observed difference in means deviates from his expectation of zero with low probability.

> You can see that it's nine point seven versus a ten point three, we can obviously, uh, do some sort of *t*-test or something like that on it to, to see if that result is significant… We got the one score was ten point three. We could, everybody could see that that was higher. The issue and the statistic—from a person who's trained in statistics is it significantly higher. (Blake, Lines 56-66)

Although Blake does not explicitly acknowledge that he uses a theoretical *t*- distribution to model the situation, he later notes that "the *t*-test is a nice approximation to the model we're seeing" (Blake, Line 170). He clarifies that to him significance means "not reasonably attributed to chance" (Blake, Line 70). Focus on the difference in means and determining whether the difference deviates significantly from expectation seems to dominate Blake's initial considerations for analysis and the initial analysis considerations for others with EDE conceptions. They invoke comparisons of sample characteristics with theoretical models.

Characteristic of reasoning that distinguishes EDE conceptions of variation from other conceptions is the totality of reliance on expectation and use of models to develop a sense of expectation, to examine deviation from expectation, and to decide whether there is too much deviation from expectation. Individuals with EDE conceptions seem to naturally incorporate models into their reasoning, and they are most adept at reasoning about variation from the modeling perspective.

Individuals with EDE conceptions of variation view design through the lens of control, attempting to design studies that control variability to minimize deviation from expectation and to increase the probability for detecting significant deviations from expectation. They reason from the data-centric perspective using a lens of expectation as they explore data to gain a sense of expectation or to explore whether data conforms to expectation. For example, some sense of expectation for standard deviations can be formed from reading the Consultant Task description. The range is 15, which suggests that the standard deviation must be less than 15. Dustin's and Hudson's strong reactions to a standard deviation value of 20.2 for Consultant Two's scores certainly suggest that the value significantly deviated from their expectations. Hudson says, “holy moly!” (Hudson, Line 563), and Dustin reacts, “Yowza” (Dustin, Line 326). Their strong reactions and the reactions of several others with EDE conceptions were the strongest external reactions in response to the large standard deviation value. Characteristic of EDE conceptions, their affinity for expectation is revealed in their reasoning from multiple perspectives.

## Discussion

This study sought to answer the question of what conceptions of statistical variation experienced secondary statistics teachers, as mature learners, exhibit. Three types of conceptions were observed. Individuals with EEC conceptions see variation as something that needs to be controlled and explained and hence tend to focus their attention on issues of design. In contrast, individuals who harbor NSN conceptions see variation as something that needs to be explored, which manifests in strong consideration of variation during exploratory data analysis. Individuals who conceive of variation as EDE see variation as something that can be expected and modeled, and their reasoning is typified by a focus on models, particularly models related to inference. As their different foci of design, exploratory data analysis, and inference might suggest, individuals with EEC, NSN, and EDE conceptions view variation from primarily the design, data-centric, and modeling perspectives, respectively. The ways in which they reason about variation differ in relation to constructs associated with each perspective. These three types of conceptions reveal identifiably unique views of variation yet do not appear to form a hierarchy with regard to understanding. In a portion of the study not reported here, it was shown that at least one teacher with each conception exhibited reasoning consistent with robust understanding of variation. Several teachers exhibited what appears to be superficial and at times faulty reasoning about variation suggestive of one of the three types of conceptions of variation. Their conceptions appear to still be developing. This study presents mature learners’ views of variation. When considered in tandem with results from prior research, this study offers images of what learners’ developing conceptions might develop into and may offer insights into how instruction can be designed to facilitate that development.

# THE SUBJECTIVE-SAMPLE-SPACE

Egan J Chernoff
University of Saskatchewan
egan.chernoff@usask.ca

*This article will demonstrate that when probabilities are based on the perceived randomness of sequences of outcomes, the probabilities are in accord with, or model, a subjective-sample-space. Further, it will be demonstrated that an individuals' subjective-sample-space is partitioned according to the individuals' interpretation of the sequence of outcomes. Through the employment of a novel theoretical framework, which aligns individuals' verbal descriptions of events with more appropriate set descriptions of those events, it will be revealed that certain individuals' respond to the task of comparing sequences of outcomes via a subjective-sample-space partitioned according to switches. To achieve the above mentioned goals, respondents are presented with different sequences of heads and tails, derived from flipping a fair coin five times, and asked to consider the sequences chances of occurrence.*

## Introduction

A variety of research in psychology (e.g., Kahneman & Tversky; 1972, Tversky & Kahneman, 1974) and mathematics education (e.g., Batanero & Serrano, 1998; Borovcnik & Bentz, 1991; Chernoff, 2008; Falk, 1981; Green, 1983; Hirsch & O'Donnell, 2001; Konold, 1989, 1991, 1995; Konold, Pollatsek, Well, Hendrickson & Lipson, 1991; Konold, Pollatsek, Well, Lohmeier & Lipson, 1993; Lecoutre, 1992; Rubel 2006; Shaughnessy, 1977) is derived from presenting individuals with sequences of outcomes and asking said individuals to consider their chances of occurrence. More specifically, three (theoretical or cognitive) models—Tversky and Kahneman's (1972) representativeness heuristic, Konold's (1989) outcome approach, and Lecoutre's (1992) equiprobability bias—which were developed to account for responses to (what will be denoted here as) the comparative likelihood task, have subsequently dominated the research literature. In general, this article contributes to research in mathematics education (presented above) by introducing a new model to account for responses to the comparative likelihood task. In specific, the main objective of this article is to demonstrate that certain individuals answer the comparative likelihood task according to a subjective partition of the sample space (i.e., via a subjective-sample-space), which is based on an individuals' interpretation of the sequence of outcomes.

## Theoretical Considerations

Individuals, when responding to the comparative likelihood task, reason in (at least) one of three ways: normative, heuristic, and informal. Correct responses are associated with normative reasoning, while incorrect responses are associated with heuristic and informal reasoning. As mentioned, certain models have been developed to account for incorrect responses. More specifically, representativeness (Kahneman & Tversky, 1972) was developed to account incorrect responses derived from heuristic reasoning, the equiprobability bias (Lecoutre, 1992) was developed to account for correct responses also derived from heuristic reasoning, and the outcome approach (Konold, 1989) was developed to account for incorrect responses derived from informal probabilistic reasoning.

*Heuristic Reasoning*

*The representativeness heuristic.* In examining how “people replace the laws of chance by heuristics” (Kahneman & Tversky, 1972, p. 430), the authors produced an initial investigation into the representativeness heuristic. According to their findings, an individual who follows the representativeness heuristic “evaluates the probability of an uncertain event, or a sample, by the degree to which it is: (*i*) similar in essential properties to its parent population; and (*ii*) reflects the salient features of the process by which it is generated” (p. 431). Alternatively stated, and more specifically related to the comparative likelihood task, the determinants of representativeness were broken down into two particular features: similarities between the sample and its parent population and apparent randomness. The authors theorized that events are considered more probable when appearing more representative; and, similarly, events are considered less probable when appearing less representative. Kahneman and Tversky (1972) presented individuals with birth sequences that were considered equally likely, but were hypothesized by the authors to not be “equally representative” (p. 432). Of the three sequences presented—GBGBBG, BGBBBB and BBBGGG—the sequence BGBBBB was considered less likely than GBGBBG because BGBBBB does not reflect the ratio of boys to girls found in the parent population. Further, BBBGGG was deemed less likely than GBGBBG because BBBGGG did not reflect the random nature associated with the birthing of boys and girls in a family.

*The equiprobability bias.* Lecoutre’s (1992) research led to another bias, which should, according to her, “be added to the list” (p. 558) of heuristics and biases from psychology. More specifically, Lecoutre’s research was based on interpreting comparative likelihood task responses that involved a relationship between randomness and equiprobability. Lecoutre (1992) declared, “random events are thought to be equiprobable ‘by nature’” (p. 557). For example, in the comparative likelihood task the two sequences of coin flips HHTTH and HHHTH would be considered equally likely, because flipping a coin is a random process and thus “the two results to compare are equiprobable because it is a matter of chance” (p. 561).

*Informal Reasoning*

*The outcome approach.* “A model of informal reasoning under conditions of uncertainty, the *outcome approach*, was developed to account for the nonnormative responses of a subset of 16 undergraduates who were interviewed” (Konold, 1989, p. 59). Application of the outcome approach demonstrated that incomprehensible statements could be accounted for with a new interpretation of how subjects were reasoning about probability (Konold, 1991). In essence, Konold recognized that normative interpretations and heuristic interpretations of probability did not capture the multivalence associated with the comparative likelihood task, and probability in general. Konold (1995) went further and claimed that multiple models—normative, heuristic, and informal—could conflict in responding to a question such as the comparative likelihood task. Konold et al. (1991), in examining for consistencies over different problems, found “switching among alternative perspective[s] of uncertainty” (p. 360). Further complicating the matter, “different perspectives can be employed almost simultaneously in the same situation” (p. 360) because “people use a variety of frameworks and beliefs concerning uncertainty” (p. 361). To explicate their point, Konold et al. (1993) gave students a most likely version of the comparative likelihood task followed by a least likely version. It was found that for the most likely version some subjects answered using the outcome approach, but for the least likely version subjects answered using the representativeness heuristic. Having demonstrated individuals’ ability to have different problems cue different knowledge Konold et al. (1993) concluded, “in one problem, a person may appear to reason correctly, but in another, this same person may reason in ways that are at variance with probabilistic and statistical theory" (p. 393).

**Abductive Reasoning Considerations**

Consider, for the moment, the following situation: If one studies hard, then one will get good grades. Just because one achieves good grades does not necessarily mean that one studied hard. For example, one may have gotten good grades because one cheated. Thus, it is more appropriate to declare that if one gets good grades the *most probable* or *best* explanation is that one has studied hard, which may or may not be the case. In other words, the observation of good grades does mean that one cannot declare with certainty that studying hard is the appropriate rule used for explanation. However, through abductive reasoning one can hypothesize that studying hard was the reason for the good grades; and if the hypothesis were true, then the achievement of good grades would follow suit. Consequently, there would then exist reason to suspect that studying hard, the hypothesis is true. Similar approaches have been used to develop the representativeness heuristic, outcome approach, and equiprobability bias.

Abduction, also widely known as inference to best explanation, can be characterized as developing a good or the best hypothesis in order to explain observations. In general, facts are used as a starting point, a particular hypothesis—derived from inferences and used to best explain the facts observed—is presented, and if it is the case that if the hypothesis were true it would best or most likely explain the observed facts, there exists reason to suspect the theory hypothesized is true (Lipton, 1991). However, one cannot declare for certain that an individual is in fact answering the comparative likelihood task with, for example, the representativeness heuristic. Further, it cannot be claimed with certainty that individuals, any individuals, employ any of the cognitive models known when answering the comparative likelihood task. Hypotheses, like the representativeness heuristic, the outcome approach, and the equiprobability bias can be seen as (1) models hypothesized to explain observed results, and (2) as new research created through the abduction process when analyzing comparative likelihood task responses. Nevertheless, the models discussed have garnered enough support that they saturate comparative likelihood task research literature; and, moreover, the saturation has occurred to such a degree that often the models are misconstrued as matter-of-fact in declarations such as, "the student was using the outcome approach."

**A New Model: The Subjective-sample-space**

The application of personal theories or informal conceptions is found in many areas of probability education research, including sample space. For example, "to justify the probabilities for the outcomes of dice games, learners construct informal sample spaces" (Speiser & Walter, 2001, p. 61). The inferred structure of personal sample spaces has been used to demonstrate particular anomalies found in probability education research. Speiser and Walter demonstrated that certain individuals found, for example, the outcome (5,6) for the experiment of rolling two dice to be as likely as the outcome (6,6). Further, researchers extrapolated the lack of discernment between pairs to all outcomes (e.g., (3,4) and (4,3)). Consequently, researchers hypothesized—and then concluded—that the sample space employed by certain individuals answering the question consisted of 21 possible outcomes and not 36 outcomes, because individuals treated the outcome (5,6) and (6,5) as one outcome. Alternatively stated, responses to the task explicated a certain structure of the personal sample space used when answering the task. Similarly, the subjective-sample-space models a more nuanced structure of sample space, partitioned according to an individuals' interpretation of the sequence of outcomes, used when answering the comparative likelihood task.

## Task and Participants

Participants in this study were 239 prospective teachers. More specifically, there were 163 prospective elementary teachers enrolled in a methods for teaching elementary mathematics course; and 76 prospective secondary teachers enrolled in a methods for teaching secondary mathematics course. The 163 elementary teachers consist of students in five different classes over two different years, taught by two different instructors. The 76 secondary teachers consist of two classes taught by the same instructor in two different years. In all instances, the task (seen in Figure 1) was presented prior to the introduction of probability to the course.

*Which of the following sequences is least likely to result from flipping a fair coin five times. Provide reasoning for your response. (A) H H T T H (B) H H H T T (C) T H H H T (D) H T H T H (E) T H H T H (F) All sequences are equally likely to occur*

*Figure 1.* Comparative likelihood task implemented in the study.

## Results

Of the 239 participants who took part in the study approximately 82 percent (197/239) correctly chose that each of the sequences presented were equally likely to occur. For elementary teachers the percentage was approximately 81 percent (132/163), and for secondary teachers the percentage was approximately 86 percent (65/76). Alternatively, the 42 participants (roughly eighteen percent) that chose a normatively incorrect answer to the comparative likelihood task were comprised of 8, 13, and 20 participants who chose HHHTT, THHHT, and HTHTH as least likely, respectively. For elementary teachers 8, 7, and 16 chose HHHTT, THHHT, and HTHTH as least likely, respectively. For secondary teachers 0, 6, and 4 chose HHHTT, THHHT, and HTHTH as least likely, respectively. Also of note, within the five normatively incorrect responses to the task, one participant chose HHTTH least likely and zero participants chose THHTH as least likely.

## Theoretical Framework

"Alternative set descriptions of the sample space can act as an investigative lens for research on the comparative likelihood task" (Chernoff, 2008, p. 313). More specifically, Chernoff introduced three alternative set partitions of the sample space—based on switches, runs, and switches and longest run organizations of the sample space's elements—as theoretical frameworks for comparative likelihood task responses. Chernoff's switches partitions of the sample space will be employed as the theoretical framework for analysis of results.

## Analysis of Results

The analysis of results is (recognizing contextual limitations) restricted to response justifications of the 20 respondents (*e* denotes elementary teacher, *s* denotes secondary teacher) who chose sequence HTHTH least likely to occur.

*Response Justifications for HTHTH as Least Likely*

*Response justifications (1): pattern v. randomness & likelihood.*

*(e) Claire*: 1st choice: (F) All have the same likelihood of occurring is what I think. It's random. 2nd choice: (D) The chances of *a nice tidy pattern like these seems unlikely*.

*(e) Michael*: *It's all pretty random but HTHTH seems too perfectly organised*.

*(e) Sayid*: It's *hard to find a pattern, so the ones that are the most random are most likely to happen*

*(e) Sun*: I think *it's not likely for it to follow a pattern*.

*(e) Aaron*: I think *it's [HTHTH] least likely because it has a pattern*.

*(e) Ana*: *random flipping does not produce neat patterns* like this.

*(s) Eko*: *c is least likely as it is patterned. Patterns are less likely to arise from random events,* but b would be the second less likely as there are 3H in a row, but it is not highly unlikely, just more so than a and e

*(s) Jin*: I would think *the odds of getting a perfect HTHTH pattern are slim* (at least one letter would be off most of the time)

The *italicized portions* of the response justifications presented above evidence a connection between pattern versus randomness (read: lack of pattern) and likelihood for all eight individuals. However, individuals' responses, while alluding to randomness, are in fact discussing the appearance or perception of randomness found in the sequences. For example, Aaron's response indicates that HTHTH is least likely because it has a pattern. Further evidenced from the responses and in accord with Kahneman and Tversky's (1972) assertion and conclusion, the more patterned (i.e., less random) the sequence the less likely its occurrence, and the less patterned (i.e., more random) the sequence the more likely its occurrence. For example, and according to Sayid, "the ones that are most random [read: least patterned] are most likely to happen." Whereas the other seven responses (e.g., Sun's response: "I think it's not likely for it to follow a pattern") demonstrate that a neater or tidier the pattern means the less likely the chances of occurrence.

*Response justifications (2): switches & likelihood.*

*(e) Kate*: I believe there is a 50/50 chance that the first flip will be a heads or a tails. Therefore, I believe that **D is least likely to occur b/c the odds of flip a coin from heads to tails is fairly slim**.

*(e) Ben*: I think **HTHTH is low percent because it appears alternately**.

*(e) Ethan*: In my opinion, **'D' is the least likely occur because it is hard that different sides continually appear**.

*(e) Penny*: **it's least likely that every flip will alternate between heads/tails**. However, I think all sequences are equally likely to occur.

The **emboldened portions** of the response justifications presented above evidence a connection between switches and likelihood. More specifically, each of the four responses evidence that the perfect alteration of heads and tails (e.g., HTHTH), that is the maximum number of switches possible for a sequence, would correspond to the least likely of the sequences to occur. According to Penny, "it's least likely that every flip will alternate between heads/tails." The connection between switches and perceived randomness seen in the justifications above aligns with previous research results (e.g., Falk, 1981), which demonstrated frequent switches were indicative of the appearance of randomness.

*Response justifications (3): pattern v. randomness & likelihood & switches.*

> *(e) John*: ***D is least likely to occur because the chances of having the coin*** *land on the opposite side each time* to **create a pattern of HTHTH** ***are very slim***, the longer the pattern the less likely it will be. Also, to get 3 H's in a row [sequence B] is probably next least likely.
>
> *(e) Hurley*: Although there is a 50% chance of getting a H or a T. ***It is very unlikely that you can get a sequence of alternating sides randomly***. The probability of this sequence happening would be the least likely.
>
> *(e) Jack*: With D, an alternating sequence could occur but not necessarily in this order, H + T are more likely to occur at a more random interval.
>
> *(e) Sawyer*: ***(D) is least likely to occur because with a 50/50 chance it is*** **unlikely that the results will be alternating H/T with each coin flip**. *It is more likely that the results would be random*.
>
> *(e) Juliet*: ***I believe that D is the least likely answer because it is too perfect of a pattern.*** Even though there is a 50/50 chance of the coin coming up heads or tails, ***it is very unlikely that it would rotate between the two each flip.***
>
> *(e) Tom*: *because the others are more random they are more likely*, ***but to alternate 1 and 1 each time no, that's like orchestrated fairness…doesn't happen it has to be guided***.
>
> *(s) Rose*: If a coin is flipped five times, **the chance of it going from head to tails, head to tails…is not likely**. ***Rather****, the coin will likely go from tails and head randomly*.
>
> *(s) Bernard*: Although not impossible, ***I think c (the alternating HTHTH) is least likely to occur*** *b'cuz flipping a coin is a random act and option c is not*.

Whereas the first set of response justifications evidenced a relationship between the appearance of randomness (determined through pattern or lack thereof) and likelihood, and whereas the second set of response justifications evidenced a relationship between switches and likelihood, the third set of response justifications evidence a relationship between (1) the appearance of randomness (derived from presence or absence of pattern), (2) likelihood, and (3) switches (or alterations). More specifically, the *italicized portions* above evidence a connection between randomness and likelihood, the **emboldened portions** evidence a connection between switches and likelihood, and the ***italicized and emboldened portions*** evidence the relationship between appearance of randomness, likelihood, and switches. For example, Hurley declares (in part), "It is very unlikely that you can get a sequence of alternating sides randomly." In Hurley's response, for example, the low likelihood, while connected to the perceived absence of randomness due to the pattern, is being determined by the alteration of the coin from heads to tails. In fact, and for all eight responses shown above, the likelihood of the sequence is derived from the absence of presence of pattern, also known as perceived randomness. However, the perceived randomness is derived from the alteration or switches of the sequence. As such, and syllogistically, it is contended that the switches attribute of the sequence element is being employed to determine the likelihood of the sequence. Alternatively stated, it is contended that a subjective-sample-space partitioned according to the switches attribute of the sequence, in this instance, is how subjects are interpreting the sequence element of the comparative likelihood task and subsequently responding to the task.

The justifications provided in participants' responses indicate that the subjective-sample-space they are describing corresponds to an entirely different partition of the sample space than responses are conventionally and traditionally pitted against. According to Chernoff (2008), based upon the verbal descriptions presented, a more appropriate or natural set description, corresponding to the verbal descriptions given, would be to partition the sample space according to switches, as shown in Table 1. When the response that HTHTH is least likely is pitted against the switches partition of the sample space, the response can be considered correct, in that HTHTH is the least likely sequence to occur, because n(4switches)<n(3switches)=n(1switch)< n(2switches). In other words, the event of alternating sides every time does have the least number of outcomes when compared to all of the other sequences, and, thus, would be least likely. As such, and through an alternative interpretation, all eight people represented in *Response justifications (3)* can be seen as 'correctly' answering the task. For example, Rose can be interpreted as correct in declaring that "if a coin is flipped five times, **the chance of it going from head to tails, head to tails…is not likely**." Further, the responses from *Response justifications (2)* when pitted against the switches partition of the sample space can also be considered as correct in their answering of the task. Thus, 12 out of 20—the claim for 20 out 20 cannot be made because what the 'pattern' is derived from was not able to be determined in *Response justifications (1)*—response justifications for HTHTH being least likely to occur can be considered correct when pitted against the switches partition of the sample space.

Table 1. *The Sample Space Partitioned According to Switches (Denoted S)*

| 0 Switch | 1Switch | 2Switches | 3Switches | 4Switches |
|---|---|---|---|---|
| HHHHH | **HHHTT** | HHTHH | HHTHT | ***HTHTH*** |
| TTTTT | TTTHH | TTHTT | TTHTH | THTHT |
| | TTHHH | **HHTTH** | HTHHT | |
| | HHTTT | TTHHT | THTTH | |
| | HHHHT | HTTHH | **THHTH** | |
| | TTTTH | THHTT | HTTHT | |
| | THHHH | HHHTH | THTHH | |
| | HTTTT | TTTHT | HTHTT | |
| | | HTHHH | | |
| | | THTTT | | |
| | | **THHHT** | | |
| | | HTTTH | | |
| n(0S) = 2 | n(1S) = 8 | n(2S) = 12 | n(3S) = 8 | n(4S) = 2 |

## Conclusion and Discussion

If it were the case that individuals are employing a subjective-sample-space partitioned according to the switches attribute of the sequence element, then individuals would think that a perfect alteration for the sequence (i.e., HTHTH) is least likely to occur, which was evidenced through Chernoff's (2008) switches partition of the sample space. As such, there exists reason to accept the claim that the employment of a subjective-sample-space under conditions of uncertainty, in this instance organized according to switches, is taking place when answering the comparative likelihood task, which lends support to the main objective of the article: To demonstrate that certain individuals answer the task according to a subjective-sample-space partitioned according to their interpretation of the sequence element of the comparative likelihood task. However, when abduction is used as a mode of reasoning, minor premises, such as the representativeness heuristic, outcome approach, equiprobability bias, and subjective-sample-space, cannot be declared with certainty. As such, despite conclusions presented, none of the assertions made in this research, nor in related prior research, can be declared with certainty…quite fitting for research in probability.

*When participants in inquiry refer to an object, they may, unbeknown to them, construct the object differently. They thus tacitly attribute different idiosyncratic senses for their respective constructions and consequently draw different inferences regarding the phenomenon under investigation. A single person, too, may shift between alternative constructions of a mathematical object, assigning them different senses, thus arriving at apparently competing conclusions. Only upon acknowledging the different constructions can the person begin to explore whether and how the differing conclusions are in fact complementary. Building on empirical data of students engaged in interview-based tutorial activities targeting fundamental probability notions, we explicate breakdowns such false-contradiction introduces into learning processes yet suggest opportunities such ambiguity fosters.*

'Seeing as....' is not part of perception. And for that reason it is like seeing and again not like.
(Wittgenstein, 1953)

## Objectives

Objects per se do not carry any meaning—all meaning is mentally constructed. The same principle holds for classroom learning materials, be these plastic tokens, spatial–numerical diagrams, or symbolic inscriptions. Yet this fundamental tenet of phenomenology and constructivism—that meanings of objects are mediated by implicit mental structures and are anyhow transparent in the ongoing *Dasein* of goal-oriented activity—may be difficult for a teacher to bear in mind let alone apply successfully in the real-time contingencies of engaged mathematics discourse. Moreover, students are often unaware of the constructed nature of their own mathematical perception of objects and therefore do not differentiate between objects per se (the distal stimuli) and their personal constructions of these objects (the proximal stimuli) (Wittgenstein, 1953). Consequently, teachers and students may be explicitly speaking about the same object yet implicitly ascribing to it diverging meanings and related inferential implications, and therefore their communication fidelity is a priori compromised (e.g., Borovcnik & Bentz, 1991). Nevertheless, a teacher can be well aware that two or more students are seeing a mathematical object differently even though they are using similar lexical labels to index the same object, and a skilled teacher can capitalize on these covert ambiguities to orchestrate productive discursive negotiations (Moschkovich, 2008). Still, teachers cannot always interpret, monitor, foster, or amend students' idiosyncratic constructions so that they accord sufficiently with normative constructions (i.e., so that the meanings are taken-as-shared, Cobb, 2005). Thus, covert communication breakdowns in classroom discourse may be more ubiquitous than one might expect, with interlocutors bearing personal meanings that overlap just enough to preclude overt breakdown.

Yet is such covert polysemy and the communication breakdowns it engenders necessarily detrimental to learning? Here we wish to argue that some covert semiotic "fuzziness" may in fact ultimately support collaborative learning, because it enables interlocutors the ostensible intersubjectivity requisite of mutually supportive discourse, *even as they are seeing objects differently*. Specifically, when students construct differently a semiotic artifact under joint inquiry, they may contribute to a conversation different mathematically valid assertions precisely because they are not cognizant of their different constructions. For example, if you and I are gazing at an array of six dots, I may see it as two rows of three dots each even as you see it as three columns of two dots each. Referring to the array, I might say that, "It is two times three," but then you might disagree that, "It is three times two." Notably the "it" in each of our respective utterances does not refer to the "objective" array itself but to our respective mental constructions of the array. Sorting out disagreement over the meaning of objects thus becomes an opportunity to co-examine the semiotic elements implicit to the conversation, e.g., the unitized groups of dots in the array. Namely, the conversation may shift from arguing over some ill-defined *mis*taken-as-shared 'it' to speaking about how we are seeing 'it,' i.e., to *figuring it out.* So doing, we may discover the semiotic contingencies of our respective statements and formulate a mathematical assertion that reconciles their respective meanings in the form of the targeted mathematical content of the instructional activity, e.g., we may discover that "$2 \times 3 = 3 \times 2$."

This paper examines excerpts from one-to-one interview-based conversations between a researcher and three students, in which the students each sustained throughout a tutorial activity two different framings of a single iconic artifact, which they had been guided to construct so as to model a mathematical system under inquiry. Each framing of the object implied a different expectation for the behavior of this system, and the students' expectations shifted with their framing of the object. We argue that both mental constructions of the object were mathematically correct, if naively worded, and that the students were able to reconcile these constructions successfully only if they were aware of the contingency of their assertions on their implicit framings of the object. We further submit that the ambiguity of the object ultimately supported these students' learning, because it elicited the two key idea elements of the targeted mathematical notion and juxtaposed them for reflection. That is, embedding key idea elements of a targeted mathematical notion within a single semiotic artifact instantiated these elements as co-present in the problem space, thus honing a generative confusion that supported the conjoining of these idea elements into the targeted conceptual composite. Thus we support *embracing diverse perspectives*, in line with the conference theme.

## Theoretical Framework

In his *Philosophical Investigations,* Wittgenstein (1953) sets out by describing a Tower-of-Babel scene, in which construction workers are able to collaborate only because they share referents for their otherwise arbitrary verbal utterances. Thus, if I ask for a "brick" and you hand me a brick, we are capable of co-constructing an artifact, but if you instead handed me a bucket, the premise of our collaboration would be compromised. Yet along with my frustration resulting from this patent miscommunication, we maintain, I may gain a useful realization of the language game underlying human intersubjectivity. Namely, as language breaks down, its normatively obscure equipmentality is disclosed for scrutiny (Heidegger, 1962). To the extent that language, writ large, is the internalized vehicle of human reasoning (Vygotsky, 1934/1962), understanding its semiotic mediation of "objective" situations may be instrumental to reflecting on one's learning process, which necessarily requires the adoption of cultural forms of seeing and referring to aspects of one's personal, unreified phenomenology (Bamberger & diSessa, 2003; Goodwin, 1994; Stevens & Hall, 1998).

In the brick-vs.-bucket communication breakdown, above, one and the same verbal utterance, "brick," differentially referred to two objects in the joint perceptual field. Yet inherent to this miscommunication is that one and the same object was interpreted differentially—the object that you saw as a brick, I saw as a bucket. Such flagrantly conflicted constructions of distal stimuli, though reserved for rhetorical effect in philosophical discourse, may nevertheless underlie—if in a more nuanced caliber—challenges inherent to instructional discourse. In the case of the disciplines where unequivocal definitions are paramount to the production of texts (in the continental, multi-modal sense of 'text'), it thus becomes important to monitor for shared meanings of objects.

Note that the sense that interlocutors ascribe to objects are not necessarily personally available-it is not the case that students are consistently conscious of *how* they are seeing an object, even as they are capable of describing what the object *means* in the context of disciplinary discourse, such as problem solving. Indeed, idiosyncratic constructions of objects may be by-and-large inaccessible ('cognitively impenetrable,' Pylyshyn, 1973), unlike meanings, which may be verbally couched as rationalized inferences pertaining to a phenomenon under inquiry. Nevertheless, the very rationale of scholarly inquiry into students' understanding of instructional materials is the identification and articulation of their personal constructions of objects. This problematique of an analytic endeavor to name the ineffable psychological facets of human discourse has been treated before:

> We do not claim to make clear and explicit what the users of the unclear expression had unconsciously in mind all along. We do not expose hidden meanings, as the words 'analysis' and 'explication' would suggest; we supply lacks. We fix on the particular functions of the unclear expression that make it worthy troubling about, and then devise a substitute, clear and couched in terms of our liking, that fills those functions. (Quine, 1960, pp. 258-259)

Whereas ambiguity of discourse readily suggests *inter*subjective situations, Quine orients us toward *intra*subjective situations. Namely, by virtue of referring to an object by two different labels, one perforce brings out different meanings, demonstrating a phenomenon Quine called *intrasubjective stimulus synonymy*. For example, "For each speaker, 'Bachelor' and 'Unmarried man' are stimulus-synonymous without having the same meaning in any acceptable defined sense of 'meaning'" (Quine, 1960, p. 46).

In this paper, however, we present cases of intrasubjective stimulus *polysemy* and discuss their consequences for mathematical learning. Namely, we demonstrate how an individual student's competing perceptual constructions of a mathematical semiotic artifact initially create cognitive conflict between two inferences that are in fact both mathematically correct. These inferences appear to the student as conflicting, rather than complementary, because the student tacitly equates the objective artifact with its perceptual construction. We highlight the indispensable role of instructional designers and mathematics teachers in both eliciting from students each of the apparently conflicting inferences and facilitating discourse that aims at exposing the different perceptual constructions underlying each inference. The vocabulary, constructs, and definitions necessarily generated so as to achieve these disambiguations are pivotal aims of the instructional process, because these discursive tools help students *synthesize* (Schön, 1981) tacit and mathematical views of the instructional materials. Yet what are the implications of this thesis for teachers' practice?

Guiding students to construe mathematical objects in accord with disciplinary norms is generally an asymmetric process, in which a teacher enables a student to see things as she does and any alternative construction falls by the wayside (Goodwin, 1994; Stevens & Hall, 1998). Yet for some disciplinary content topics, multiple views of problems are intrinsic to mathematical discourse, so that fostering such ambiguity in classroom discourse may play a nurturing, rather than an obstructing role. For example, a sequence of coin tosses—Heads, Tails, Heads, Tails (HTHT)—may be construed as one of sixteen equiprobable elemental events in the sample space of the four-coin-flips experiment (1/16) or, alternatively, as the aggregate event "2 Heads and 2 Tails in any order" that has a 6/16 chance of occurring (on the contingency of mathematical definitions on social contract, see Barnes, Henry, & Bloor, 1996; Ernest, 2008; Weisstein, 2006). A student may sense that one must decide between these two mathematically valid constructions, thinking that HTHT cannot have both 1/16 and 6/16 chances of occurring. Namely, this student would experience a need to decide whether the object—the distal stimulus presented by the inscription "HTHT"—has this value or that value for the property of likelihood, where in fact the student is implicitly referring to different percepts but not articulating the implications of attending or not attending to the internal order of the four singleton events (Abrahamson, 2009).

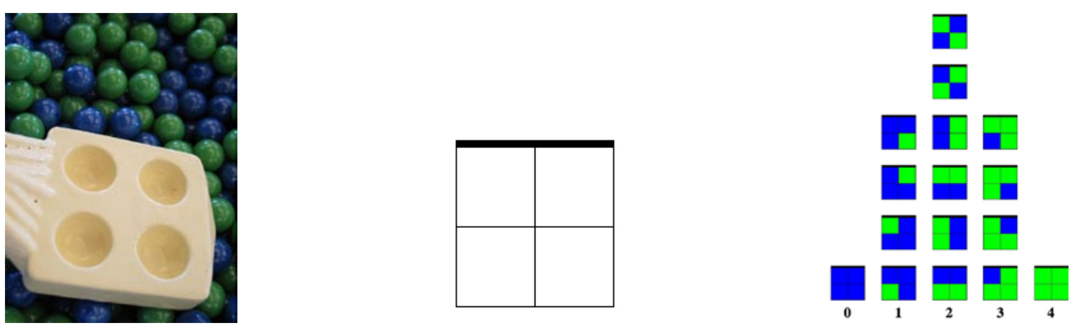
Indeed, in this paper, we present empirical data to argue that one challenge inherent to supporting students' sense making processes is that students are liable to implicitly equate mental constructions with objects per se and thus experience difficulty accepting, let alone reconciling, any competing meanings they may attribute to these objects. That is, when the students think they must make up their mind with respect to the assertions they express about a mathematical object, in fact these different assertions are not necessarily mutually exclusive but possibly complementary, because each assertion refers to a different mental construction of one and the same object. Differentiating these assertions on the basis of their underlying perpetual constructions is crucial for conceptual development in those cases where both assertions are conceptually pertinent. For example, acknowledging the ambiguity of HTHT may help a student understand that the probability of an aggregate event is the sum total of the probabilities of its elemental events (1/16 + 1/16 + 1/16 + 1/16 + 1/16 + 1/16 = 6/16).

## Background, Methods, and Research Focus

The episodes analyzed herein come from a larger corpus of data collected over a succession of cumulative studies conducted as part of the *Seeing Chance* project to understand and promote probability learning (Embodied Design Research Laboratory, UC Berkeley). Specifically, we examine the behavior of 3 out of 28 middle-school participants in Abrahamson (2009). The study took place in a private school in the SF East Bay area (33% on financial aid; 10% minority students), and all three focus students for this paper were ranked by their mathematics teachers as high achieving. The phenomenon of intrasubjective stimulus polysemy that we examine here was typical of all students, yet it elicited longer, richer, and more articulated deliberations from the older and higher-achieving students—perhaps because these students were more self-monitoring and self-exacting in their mathematical reasoning—and hence these study participants help us understand what may be a ubiquitous phenomenon characteristic of all students. Each student participated in a semi-structured clinical interview that lasted about one hour.

The project was conducted in the design-based research approach, which typically examines some conjecture as to an underlying mechanism inherent to a hypothetical learning phenomenon by creating empirical contexts in which to examine this conjecture (Confrey, 2005). Emerging from study cycles of design, empirical implementation, and analysis, in which the researchers tune the learning environment and, reciprocally, their emerging understandings of learning phenomena, are new instructional materials or principles as well as 'ontological innovations' (diSessa & Cobb, 2004), theoretical constructs that capture consistent patterns that the researchers discover in the empirical data. This paper is about intrasubjective stimulus polysemy, an ontological innovation that we are proposing.

Central to the interview was a set of instructional materials designed to elicit students' population-to-sample informal inferences, which are mathematically correct though only qualitative and unwarranted by mathematical argumentation. Students are then guided to construct the expanded sample space of this experiment as a means of creating a context for the dyad to discuss differences in how natural perceptual inclination and formal mathematical analysis couch inferences with regard to probabilistic behavior of random generators. Here we will introduce only those materials that feature in the data under inquiry. The interview begins by showing participants a tub containing many green and blue marbles of equal numbers as well as a *marbles scooper* (see Figure 1a), a utensil for drawing out of the box a sample with a precise number of marbles that are spatially arranged in a particular permutation. Strictly speaking, this is a hypergeometric (without replacement) problem, yet the large population-to-sample ratio enables us to treat it as an approximation for the binomial. Participants are asked to offer their guess for the distribution of outcomes in a hypothetical experiment with this random generator. Next, participants are given a set of blank cards with a 2-by-2 table structurally resembling the scooper (see Figure 1b) and are guided to construct the sample space of the experiment and assemble in the form of the *combinations tower* (see Figure 1c).



*a.* *b.* *c.*

*Figure 1.* (a) The marble scooper; (b) one of many cards for conducting combinatorial analysis of the experiment; and (c) the combinations tower—an assembly of the sample space in a format designed to resonate with students' inferences for the experiment.

Whereas students by-and-large guessed correctly that the plurality of experimental outcomes would be of type “2 green and 2 blue [in any order]” (hence 2g2b), they experienced difficulty in appreciating why analytic attention to the *order* of the four singleton events in each scoop may be advantageous to supporting their guess. Nevertheless, once they had completed constructing the combinations tower, participants appropriated this structure as a warrant for their guess by indexing the relatively greater number of 2g2b elemental events as compared to other aggregate events. In previous publications we attributed students’ reluctance to attend to the combinations’ internal order to a tension between tacit and mathematical constructions of the sample: whereas students naturally couch the experiment in terms of five (aggregate) events (no green, 1 green, 2 green, 3 green, and 4 green), combinatorial analysis requires attention also to the internal order of the four singleton events and therefore produces sixteen (elemental) events.

The current study focused on interview episodes in which participants switch between aggregate- and elemental-event constructions of a compound-event card containing four singleton events. We compared these episodes in an attempt to explore for relations between the participants’ awareness of their constructions and their success in coordinating the tacit and mathematical formulations of the anticipated experimental outcome distribution.

## Results and Analyses

Table 1, below, offers a preview of our results. For rhetorical clarity, we use the familiar duck-rabbit ambiguous figure. (Joseph Jastrow popularized it in the late 19th century so as to illustrate perceptual agency in constructing distal stimuli.) If a viewer is asked to infer the eating habits of this ambiguous creature, yet the viewer is unaware that his mental construction of the image keeps shifting (“duck…no, rabbit!”), then the viewer will not understand his vacillating inferences (“fish…no, carrots!”) and will take this inconsistency as marking confusion. If, however, the viewer can label each mental construction of this object as well as their critical disambiguating features (“beak…ears”), then the viewer will be equanimous with respect to his conflicting inferences (cf. Tsal & Kolbet, 1985).

Table 1. *Inferential Reasoning for an Overtly Ambiguous Figure*

| Distal Object | Disambiguating Features | Proximal Object | Inference for Diet |
|---|---|---|---|
|  | Beak | Duck | Fish |
| | Ears | Rabbit | Carrots |

Table 2, below, presents the less familiar case, from probability studies, of a compound event as an ambiguous figure. A viewer who attends to the particular configuration of green and blue cells in this object may construct it as one of sixteen unique equiprobable elemental events in the sample space. However, a viewer who ignores the internal order of cells in this object and constructs it as 2g2b may interpret it as the aggregate event most likely to occur in the marbles-scooping experiment. If, however, the viewer is unaware of her shifting personal constructions, she will interpret her shifting inferences as marking confusion.

Table 2. *Inferential Reasoning for a Covertly Ambiguous Figure*

| Distal Object | Disambiguating Features | Proximal Object | Inference for Distribution |
|---|---|---|---|
|  | Order | Elemental event | Equiprobable |
| | Number | Aggregate event | Heteroprobable |

Each of the following three 6th-grade students, Lavi, Sima, and Razi, identified the completed combinations tower as resonating with their mathematically correct guesses for the outcome distribution of the marbles-scooping experiment. However, subsequent discussion suggested that their insight was unstably based on a global perception of relations among the combinations-tower columns and that they were still struggling to align their insight with the ambiguous construction of the combinations tower's constituent elements.

*Lavi: "My Mind's Going Back and Forth"*

The interviewer lifts out of the sample space two cards—one of the 3g1b cards and the 4g card—and asks Lavi to compare their likelihoods. The following conversation ensues:

Lavi: There's only four [ways] for getting three [3g1b]. I guess it wouldn't be chance…Oh, I guess it would be chance. And then there's only one way that there can be four [4g].

Res.: So, what do you mean [by] "It's not chance" and "It is chance?"

Lavi: Ah, I don't know, that thought just kind of [popped] into my mind and I just let it come out.

When Lavi says, "It wouldn't be chance," he is viewing the individual cards as representing heteroprobable aggregate events whose chance is indexed by the number of permutations in their respective columns. When he says, "It would be chance," he is viewing these same cards as equiprobable elemental events for which only chance, not logic, would cause greater frequency. The compound event is thus a physical object imbued with different mathematical constructions, and Lavi alternately refers to these competing constructions. However, he does not appear to realize that he is shifting his point of view, so he is confused.

The interviewer repeats the question for another pair of cards. Lavi asks whether he should take these cards to mean "a specific card or an amount of each color" and claims that all "specific cards" are equally likely. The interviewer asks Lavi to compare the cards on the basis of "the amount," i.e., to ignore placement. After some hesitation, Lavi nevertheless asserts, "It is chance," invoking the randomness of the sampling device (on the 'equiprobability bias,' see Falk & Lann, 2008; LeCoutre, 1992). Throughout a subsequent series of questions, Lavi vacillates between viewing individual cards as "ducks" or "rabbits," coming just short of reconciliation.

*Sima: Stuck on Rabbit*

Like Lavi, Sima begins by articulating the equiprobability of the sixteen compound events. She creates the term "color-wise" to refer to the groups and "place-wise" to refer to individual cards and states that "color-wise" the groups have different probabilities but place-wise "they're equivalent." Yet, once the interviewer asks her to compare two cards selected from different columns, she maintains that they have different likelihoods. Subsequently, she appears to experience difficulty in dislodging from the aggregate view and returning to the elemental view—she is "stuck on rabbit" and insists that any 2g2b card is more likely than any 3g1b card.

Only after the interviewer simulates random sampling from these sixteen cards and refers back to the initial experiment is Sima able to reassume equiprobability.

*Razi: Chooses Rabbit*

Like Lavi and Sima, Razy articulates that specific cards are equally likely yet that viewing them by the "number of each color" makes some cards more likely than others. She appears to command greater fluency than Lavi and Sima in shifting between the competing constructions of the events, yet she incurs greater difficulty in articulating the implications of each view for the outcome distribution.

Razi: The majority of the scoops would come out with two blues and two greens.

Res.: A moment ago you told me that each pattern has the same likelihood to show up. Is their a contradiction here?

Razi: Yes and no. Before I said "each specific pattern." Now I'm saying each pattern with two blues and two greens….

Res.: But do you still hold to the fact that each exact pattern has the same chance?

Razi: I am not sure.

Finally, when asked to compare another two cards, Razi becomes entrenched in the aggregate view. It appears that whereas Razi understands that there are two ways to see the object, she feels she must choose between "duck" and "rabbit."

## Conclusion

Students' awareness of their perceptual constructions of ambiguous mathematical objects—their intrasubjective stimulus polysemy—impacts their capacity to generate domain-specific constructs and, in turn, to coordinate tacit and analytic formulations of situated phenomena toward deep conceptual understanding. We have demonstrated this relation for the case of the binomial and will continue to pursue our conjecture as it plays out in the learning of other mathematical concepts.

# EXPLORING STUDENTS' NOTIONS OF VARIABILITY IN CHANCE SETTINGS[1]

Ernesto Sánchez
Departamento de Matemática Educativa

esanchez@cinvestav.mx

Karla Trujillo
Departamento de Matemática Educativa
CINVESTAV, México
trujillo.karla@yahoo.com

*This paper revisits the authors' study of parts of the works of Watson, Kelly, Callingham and Shaughnessy (2003) in a different environment. It explores the notions that some Mexican students hold about statistics variability in chance setting. The study attempts to answer the question: Is it reasonable to classify students' answers according to the level in which they consider randomness, structure and variation? A questionnaire was administered to 327 middle school students, 214 high school students, and 74 college students. The analysis were carried out under; "Pre-structural", "Extreme values", "Structure", "Realist appearance", and "relational" categories. The results indicate a positive correlation between students' educational levels and the categories reported in some literatures.*

## Introduction and Background

One of the first empirical research studies on variation in chance setting was carried out by Shaughnessy, Watson, Moritz and Reading (1999), in which the following questions were asked: 1) what are students' understandings of variability or spread? 2) How can we begin to measure students' understanding of variability or spread? To answer the question, the Gumball task* was modified in such a way as to reveal thinking patterns of students in variability.

It was observed that students' understanding of centers increases with age while their understanding of variability oscillates through the grades. The results buttress the hypothesis that "there is considerable focus on 'centers' in the curriculum throughout school mathematics".

In an experiment carried out by Watson and Kelly (2003) to explore the thinking and progress of students of grades 3 to 9 after some studies on statistics variation, students were asked to predict the possible outcomes of repeated trials of a 50 – 50 spinner. The results among others show "a monotonic decline over the grades in the ability to provide reasonable variation" (p. 391); there is a strong tendency to conclude that the above was "in strict accordance with theoretical probability". As a result, a lesson for teaching of probability was drawn: Expectation must be balanced by variation (p. 393).

Shaughnessy, Canada and Ciancetta (2003) explored the thinking of 84 students of middle school with three tasks which involved repetitive tests. One of the tasks is similar to question 6 of the present work. It was observed that students tend to neglect variability in the context of chance and probability, in the tasks. The reason for this was attributed to the manner in which probability was introduced to the students in their school.

A questionnaire devised to assess students' understanding of variation by Watson et al. (2003) includes items in sampling variation, displaying variation, chance variation, measuring variation, and sources of variation. A coding scheme based on the SOLO taxonomy of Biggs and Collis (1991) was elaborated for that study, and a sample of 746, students in grades 3, 5, 7, and 9 were examined. One of their objectives was "to develop a scale to measure students' understanding of variation in the context of chance and data curriculum" (p. 15). They suggested,

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

among others, for future research that "Trialing the questionnaire with other students, for example in other cultural settings" (p. 19). That suggestion accounts for this work which, in this case, studies Mexican students. However, we have followed another trend of analysis.

## Conceptual Framework

In this work, the concept of variation in chance settings is considered and elaborated within three important stages: the perception of the randomness, the consciousness of the probabilistic structure underlying a situation in a chance context and the understanding of the relation of this structure with the empirical data. A student is said to be *disorder, dispersion or randomness,* centered in if he believes that in a random situation "any data/thing can occur", that is to say, that any data can be obtained. In this case the fact that there is an underlying structure in the data generated is ignored. On the other hand a student is said to be *structure* centered if he expects the data generated to have a particular or regular pattern that conforms to a theoretical distribution (in this case- uniform or binomial), ignoring the randomness. Lastly a student is *variation* centered if he recognizes both the randomness or dispersion and the structure.

In a way of hypothesis a three stage model of evolution of the thinking of the intuitive notion of variation in random situations is supposed. In the first stage the answers are *disorder* centered, that is they show only the perception of the randomness in the data of a chance situation. Later they change to become *structure* centered, when they give evidence of the search expectation of a regular patterned data and, in the third stage and the last stage when answers appear the students consider both the randomness and structure. This last stage is divided in two sub-divisions; in the first, the answers do not give any evidence of establishing relationships between randomness and regularity, in the other, they do.

*Do students' answers pass through the stages of: disorder, structure, and variation while students construct their notions of statistical variation?*

Below, data are explored and elements are sought to support the hypothesis made.

## Methodology

*Participants*

Several groups of students of three levels of the Mexico City's educational systems were polled; 327 students from Middle School, 214 from High School and 74 from College.

*Instruments*

A questionnaire of 12 items was designed, most of which were picked from the questionnaires of Watson *et al.* (2003), while other were the slightly modified version of the same. In this report we will analyze three items, labeled 6, 10 and 11. We will present and describe them briefly.

Item 6. Imagine you threw the dice 60 times. Fill in the table below to show how many times each number might come up.

| **Number on Dice** | **Number of times it might come up** |
|---|---|
| 1 | |
| 2 | |
| 3 | |
| 4 | |
| 5 | |
| 6 | |
| **Total** | **60** |

Why do you think these numbers are reasonable?

*Figure 1.* Problem 6.

Figure 1 shows problem 6. Since this item asks students to suggest a distribution of frequencies of throwing a fair die 60 times, this is a prediction problem: what do you think it might happen?

When one solves this problem it is needed using statistic intuition as well as randomness, probability and variability notions. A disorder centered student will notice only the random nature of the experiment and would answer “any data can occur” or “we can not know”. This kind of answers is valid but not convenient, since ignore the probabilistic structure inherent to the experiment.

A structure centered student will tend to answer with the expectation; these answers are valid as well, but also inconvenient due to the low probability of such result.

“There is, in our brain, a constant tension between the general and specific” (Tal, 2001, p.69). Some variation centered students will notice this tension and solve it by filling out the table with specific numbers different to the mean. Nevertheless, this approach is still incomplete, in the same way that answering with the mean is: the low probability of particular outcomes. Some other variation centered students will be able to solve this tension trying to capture the highest probability possible by an interval around the mean.

Item 10: There is an urn containing 3 balls, each one marked with a letter (A, B, and C). John picks up randomly a ball, writes in a board its letter, and then he replaces it to the urn. John repeats 30 times the experiment. Which one of the following boards do you think John got? Put a mark (a tick) under the board you think is the correct one.

| Ball | Frequency |
|---|---|
| A | 12 |
| B | 7 |
| C | 11 |
| Total | 30 |

[]Board 1

| Ball | Frequency |
|---|---|
| A | 10 |
| B | 10 |
| C | 10 |
| Total | 30 |

[]Board 2

| Ball | Frequency |
|---|---|
| A | 11 |
| B | 18 |
| C | 1 |
| Total | 30 |

[]Board 3

Why did you choose the board?

*Figure 2.* Problem 10.

The problem presented in figure 2, poses to students an informal hypothesis test with three hypotheses to contrast: board 1 is right, board 2 is right and board 3 is right. To make a choice, students should discard options to keep the most adequate one. Intuition is valuable in this case

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

in order to judge each board as a real outcome and decide how likely it is. Board 2 has the highest probability to occur, but this probability is still too low and do not consider the variation concerning the randomness. Board 3 shows a very atypical behavior, since ball C appeared only once and B 18 times. Thus, board 1 is the most reasonable choice.

This approach appeals to common sense as well as abstraction: board 3 represents the class of outcomes with extreme values, and classified as disorder center answers; board 2 represents the existence of structure in random experiences and considered structure centered answers; board 1 represents the class of real outcomes, in which it can be found a reasonable relation between structure and variability: it is realistic.

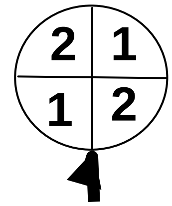
The item 11, (fig. 3) is analogous to item 10. In this case graph A is structure centered (corresponds to a theoretical binomial distribution and ignores randomness); graph B is disorder centered (does not reflect the binomial structure of the experience) and graph 3 is variation centered (shows an adequate balance between randomness and structure). The ideal answer is to identify graphs A and B as made up and C as real.

*Procedures*

Questionnaires were applied to the students by the teacher of each of the groups in the case of Middle and High School. One of the researchers applied the questionnaire to college students.

To classify the answers, the following codification, similar in some aspects to that used by Watson et al. (2003) and based on SOLO hierarchical cycles proposed by Biggs and Collis (1991), was employed: “Realist Appearance” (RA), is used to classify the answers to question 6 if an individual gives a distribution of frequencies, totaled 60 and whose elements fall in an interval of 4 to 16 (90% of confidence), a few college students proposed intervals around the mean and those answers were coded RA (See Trujillo, 2008 for details). Also RA is used to classify an answer of an individual if table one is chosen as answer to question 10. Lastly an answer is classified as RA if I-I-R sequence is chosen in question 11: where “I-I-R” means “Invented, Invented, Realist”. “Without variation” (WV), is used to classify an answer if a uniform distribution is given in question 6 and also if table 2 in question 10 is selected as an answer to that question.

Item 11. Three classes did 50 spins of the above spinner many times and the results for the number of times it landed on the part numbered 2 were recorded. In some cases, the results were just made up without actually doing the experiment. Can you identify what classes made up the results without doing the experiment?



a) Do you think class A's results are made up or really from the experiment? Explain
b) Do you think class A's results are made up or really from the experiment? Explain
c) Do you think class A's results are made up or really from the experiment? Explain

*Figure 3*. Problem 10.

Lastly an answer is classify as WV if R-I-I sequence is followed in question 11: where "R-I-I-" means "Realist, Invented, Invented"

In conclusion, "Extreme values" (EV) is used to classify the answers to question 6 if a distribution whose elements, at least one, is out of the range of 4 and 16, is given. Finally EV describes the answers if table 3 is selected as answer to question 10 and if the sequence I-R-I is followed in question 11. I-R-I means "Invented, Realist, Invented", while NR means "No Response or Inconsistent". Some Middle and High school students gave answers to item 6 totaling a number different to 60; those were coded as Pre-Structural answers (PS).

## Results

The data contained in the questionnaire have been organized to see if it is in agreement with the hypothesis. Simply put: Does statistics variation thinking begin with perception of disorderliness, then structure and finally an integration of both in a notion of statistical variation? If yes, majority of younger students are expected to incline towards choosing "extreme values". On the contrary, it is expected that majority of older students will choose "without variation" or "realistic appearance". The answers to questions 6 and 10 support to a greater extent these expectations.

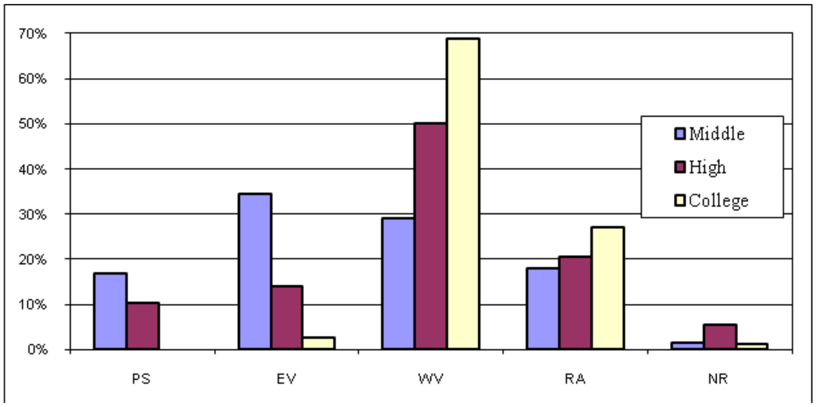


*Figure 4*. Relative frequencies of types of distribution proposed by students in response to question 6.

Notice in Figure 4 that some Middle and High School students gave answers coded ‘pre-structural’ (17 % and 10%, respectively). It could also be observed in graph 1, that the distributions, classified as “extreme values” were proposed with higher frequency by students of the Middle School (34%) than students of high school (14%) and only by a small proportion of College students (3%). On the other hand the distributions classified as ‘without variation’ were proposed with higher frequency as scholar level increases: 29% on High School, 50% on Middle School and 69% College students. The frequencies of distributions classified as “Realistic Appearance” follow an increasing trend: 18% Middle School, 20% High School and 27% College. A remarkable fact is the appearance of intervals as answers between College students (3%), for example, one subject answers:

*$O_1, O_2, O_3, O_4, O_5, O_6$ in such a way that $O_i \in \{0,\ldots,60\}$ y $\sum_{i=1}^{6} Oi = 60$ But I think that $O_i$ = 10 ± 1 or 2. We have a ‘big’ number of repetitions so the trend would begins to arise having in each line a number close to 10, supposing a fair die, it is equally probable any outcome*

It could be observed in Figure 5 that the distribution of the of answers coded as ‘extreme values’ follows a monotonic decreasing behavior (19% Middle School, 7% High School, 4% College). It is important clarify that the answers coded as EV among College students correspond to the choice of every board as a possible outcome. In the case of answers coded as ‘without variation’, lowest and highest scholar levels have similar proportions (47% Middle School and 49% College) while High School students propose answers of this kind in a proportion of 64%. This may be explained by the frequencies of the category ´realistic

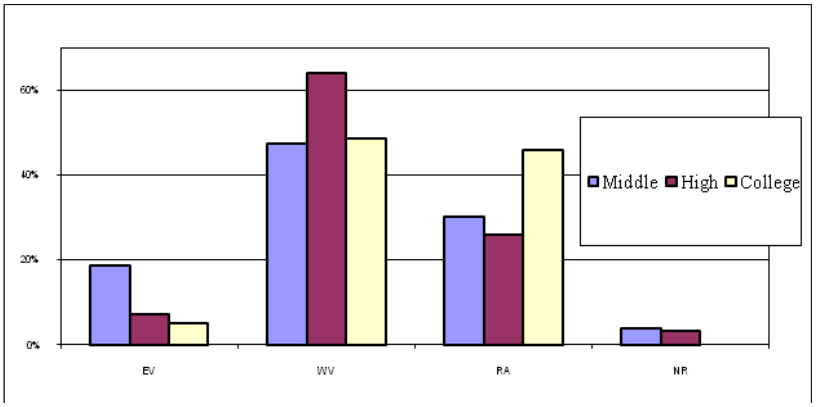

*Figure 5.* Relative frequencies of types of distribution proposed by students in response to question 10.

appearance': 30% Middle school, 26% High School and 46% College. These proportions agree with our hypothesis.

With reference to sub questions of the 11th question, the data were organized as follows: III – mean 'Invented, Invented, Invented' and IIR –'Invented, Invented, Realist', etc.

With reference to the variation evolution model, it is expected that the students of the middle school, accept as realistic the "extreme values". That is, greater frequencies of "*R*" was expected of the students of the middle school, where "*R*" = {IRI, IRR, RRI, RRR}. Also students of high school and college should tend to accept as realist the option "**R" = {IIR, IRR, RIR, RRR}. As can be observed, these expectations were fulfilled to a greater extent.

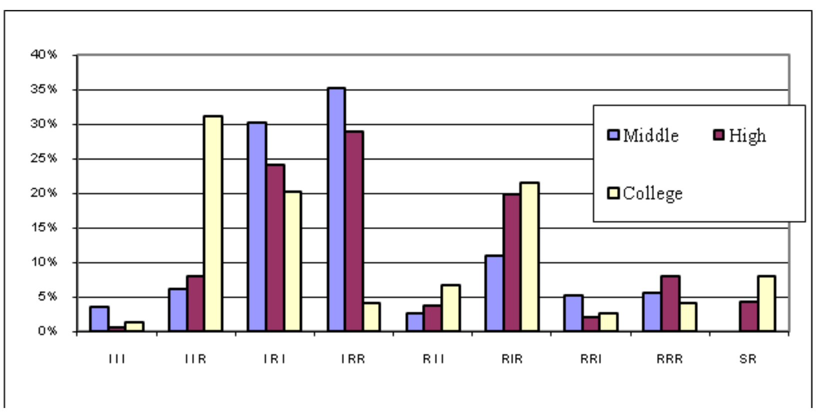

*Figure 6.* Relative frequencies of types of distribution proposed by students in response to question 11.

The options "*R*" and "**R" are focus of attention in the following. The response "*R*", except RRR, was chosen by greater number of students of Middle school than those of High school. On the other hand the response "**R", except IRR, was chosen by greater number of students of High school that those of Middle school. The IRI and IRR have a diminished frequency throughout the grades, which implied greater acceptability of *without variation* in the question 6, as realistic, among the students of Middle school.

The choice of RIR between the two levels is significant; this is possibly due to the fact that greater number of students of Middle school accept as realistic, the distribution with extreme values.

College students respond IIR, the ideal answer, in greater proportion than any other answer or group (31%).

**Discussions and Conclusions**

The results obtained in this work are consistent with the hypothesis that students' answers pass through the stages of: disorder, structure, and variation. Younger students (Middle school ones) tend to notice principally randomness in chance experiences, thus their answers reflect this trend. High school students are strongly anchored on centers may be due to statistics formal instruction, which –in Mexico- has a great emphasis on central measures and neglect variability. College students answers tend to be mostly of the category 'without variation', but ´realistic appearance' answers have an important proportion and some cases are classified as 'relational'

Students are observed to have the tendency of proposing definite numbers and distributions instead of a range of number and a class number of distributions. An important proportion of High school and college students attempt to mix the disorder and structure in question 6; except a few of them, they do this proposing a definite distribution, thereby giving a distribution less probable than the uniform distribution. They were unable to imagine an interval that would form a class of distributions. On items 10 and 11, which ask students identify plausible outcomes, a greater proportion of subjects are able to differentiate possible of reasonable outcomes and discard events with too low probability, than in item 6. This can be due to the fact that problems 10 and 11 do not demand students abandon their idea that prediction consists always in a single number result.

This tendency of thinking in isolated events, instead of a multiple ones could be also attributed to the manner in which courses of probability and statistics are developed. Even though the explanations above revealed the inadequacies in the courses of statistics, it is important to look for cognitive reasons that impede a better understanding of variability.

The three stages earlier discussed: disorder, structure and variation could be characterized through important stages as follow: Recognition of chance, which was observed by Piaget as a very important stage. The second state is the creation of instruments to deal with chance; this mean that all possible results are considered thereby determining the probability of a particular result. The third stage is a combination of disorder and structure through a refined knowledge of probability on: a) a general concepts of events; b) the use of instruments of probability in order.

The magical explanation for a phenomenon is discarded when an event is perceived as a chance. The game of chance is therefore seen as a product of interaction of multiple causes (Borel) or as an interaction of independent processes (Piaget). When a student admits the existence of chance and see a phenomenon as chance, it is natural that such a student will respond that any event can occur, predicting only disorderliness and irregularity. Probability therefore provides a tool that allows one to see structure behind disorderliness. This is witnessed at least in the games of chance. The number of possible results, favorable and its quotient and combinatorial are elements of structure. The students tend to think that the structures determined are not free for all (and indeed they are not) and they serve to make predictions. But the nature of those predictions is far from what the students can believe. The illusion therefore to a process of overcoming of the powers of the disorder, being created that can be adjusted and controlled with the aid of probability.

To be variation minded, one must be able to know the structure (the average, the uniform distribution, etc.) and take into consideration the randomness, dispersion or irregularity of the phenomenon. These two aspects are integrated in proposing an interval of the expected values whose length is determined according to the probability with which the prediction is desired, and that, therefore, it settles down beforehand. To achieve the aforementioned, knowledge of *confidence interval* is useful and desired. Despite college students do know the concept of *confidence interval* just a few of them were able to suitably integrate the dispersion with the structure.

John Tukey (1986) once asked: “What have statisticians been forgetting in principle?” And he answered himself: “That the history of statistics has involved –indeed, very nearly consisted of – successive enforced retreats from certainty. Each step of that retreat has brought further gains…” (p. 588). When a student pass from giving a determined single event to proposing a range of results in prediction problems in a certain way he or she retreats from certainty and started to have statistics thinking.

## Endnotes

# EXPERIENCE AS A POWERFUL TOOL FOR MEANINGFUL LEARNING OF PROBABILITY

Avikam Gazit
Kibbutzim College of Education – The Open University of Israel
aviakm@openu.ac.il

Ordinary problems using standard algorithms do not enable students to understand probabilistic situations meaningfully. Like in other branches of mathematics, students learning probability need to be involved in authentic situations that motivate their way of thinking. Littlewood (1953) declared that a good mathematics riddle (or joke in his words) is worth more than a dozen fair exercises. Probability is very much connected to every day life, but the synthesis between determinism and uncertainty makes it difficult to understand. The theoretical models used in explaining probabilistic thinking sometimes contradict intuition, which is based on every day experiences. Our experiences are deterministic, not continuous, and usually not guided (Rokni, 2001). Using guided experiences concerning probabilistic situations which derive from authentic problems may result in meaningful understanding of probabilistic principles.

## The Research Question

What are the sources of mistakes in solving probabilistic problems and how does experience help lead to meaningful understanding of the correct answers.

*Subjects*

16 pre-service junior high school teachers**.**

*Instrument*

A questionnaire with three authentic situation probabilistic problems:

a. What is the probability of finding at least two people whose birthdays are on the same date, among 30 random participants?
b. There are three doors. Behind one door there is a prize. You are asked to guess where the prize is. After you guess, one of the other two doors is opened and you see that the space is empty. Now you are given the opportunity to change your guess to the remaining door. Will this increase your chance of winning? If so, what is the probability?
c. You have 2 discs: one is red on both sides and the other is red on one side and blue on the other. You choose one disc at random, put it on the table and you see red. What is the probability that the other side of this disc is also red?

*Procedure*

Step I

a. 15 of the 16 participants wrote that the probability of finding at least 2 people whose birthday is on the same date is very small and may be 30/365, because there are 365 days in a year. Only one gave the correct answer based on previous learning of such a situation.
b. All the participants wrote that changing the guess does not increase the probability. The only difference is that the probability changes from 1/3 to ½ in both cases.
c. 15 of the 16 participants wrote that the probability that the other side is red is ½, because there are only 2 discs, one with red on both sides. Only one participant (not the same one

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

who answered item (a) correctly) gave the correct answer using an intuitive explanation based on 4 sides.

Step II

After sharing the results with the subjects, the researcher gave intuitive-logical explanations using demonstration and modeling for the 3 problems.

Step III

Some of the participants experienced cognitive dissonance after hearing the explanation because it did not fit their intuition and/or past experience.

The researcher then performed 3 experiments, one for each question above. The students participated directly and individually in all the experiments:

a. Collecting birthday data.
b. Simulating the 3 door game.
c. Playing a game with 2 discs.

*Results*

After step 3 (the direct experience), all 16 participants were convinced about the correct answer and changed their way of thinking about uncertainty.

# JUSTIFICATION AND CONSENSUS: MATHEMATICAL REFERENTS AND PIVOTAL CUES IN DIVERGENT PROBLEM-SOLVING APPROACHES

Janet G. Walter
Brigham Young University
jwalter@mathed.byu.edu

*Divergent solution approaches in problem-solving emerge in classrooms that support students' enactments of personal agency and small-group collaborative inquiry. University honors calculus students, engaged in building new mathematical understandings, chose specific mathematical referents to substantiate and justify divergent solution approaches to a task especially created to elicit student-generated, meaningful and essential mathematics for finding the volume of a solid of revolution. During class presentations of solution approaches, pivotal cues indicated a change in, or a support for, specific reasoning. Justification was grounded in personally meaningful mathematical referents and was a means for building mathematical consensus among students.*

## Introduction

Classrooms where student inquiry and question-posing are essential elements in mathematics learning present unique opportunities to evidence how mathematical meanings and consensus about those meanings develop when different solution approaches in problem-solving emerge. In the context of such a *thinking classroom,* we characterize four diverse, student-invented solution approaches for finding the volume of a solid of revolution. Our analyses feature the language and notations students choose in building two of those solution approaches, made evident in public presentations to the class, that support mathematical consensus in a thinking classroom. Our purpose is to understand how students reason and build convincing arguments and provide justifications that help others understand divergent solution approaches.

## Theoretical Perspectives

The mathematical work of students engaged in problem-solving may differ greatly between individuals as well as between groups of students. Indeed, Goffman (1959) recognized that "working consensus established in one interaction setting will be quite different in content from the working consensus established in a different type of setting" (p. 10). In particular, if construction of ideas in transitioning from concrete or empirical meanings toward abstraction (Pijls, Dekker & Van Hout-Wolters, 2007; Rivera, 2007), depends, in part, on explanation and critical examination of one's ideas, then retrospective traces of the "way points" (Dimond & Walter, 2006) in mathematics learning may be distinct not only for individuals, but for different learning groups as well. In other words, one may look back at the developmental work in different groups' solution paths and reasonably expect variance in those solution paths.

Individual and collaborative choices in problem-solving may be reflections of the inherent individual characteristic of personal agency. We view personal agency in terms of

the requirement, responsibility and freedom to choose based on prior experiences and imagination, with concern not only for one's own understandings of mathematics, but with mindful awareness of the impact one's actions and choices may have on others… Because people build understanding from experience, it is essential that they have opportunities to

> make personal choices that will foster learning in particular, perhaps unanticipated, ways as they explore mathematics and develop a sense of self as actor and participant. The exercise of agency is what makes mathematical thinking possible. (Walter & Gerson, 2007, p. 209)

We assert that the exercise of personal agency within a community of mathematics learners is made evident as students act and interact, for example, in pursuit of mathematical certainty during problem solving. Powell (2004) defined agency in mathematical learning as learners' individual initiative to define, redefine, build on or go beyond specificities of mathematical situations on which they have been invited to work. We agree with perspectives of personal agency which hold that in order to have the ability to initiate an act a person must be able to make choices based on perception and available information (Bandura, 1997; Holland, Skinner, Lachicotte Jr, Cain, & Delmouzou, 1998; Skovsmose, 2005a). Furthermore, the exercise of personal agency "is manifest in the direction of attention" (Dewey, 1913/2007, p. 8). Such perspectives of personal agency have implications for learning. Dewey noted that thinking is "something to be tried" and that learning is "an active, personally conducted affair" (1916/1944, p. 335) which occurs when a person's "established powers are redirected through intelligent effort...to arouse the person to clearer recognition of purpose and to a more thoughtful consideration of means of accomplishment" (1913/2007, p. 58-59). Acts of purposeful choice in learning may be seen as fundamental, intellectual *tryings* directed toward building understanding (Brown, 2005; Kohn, 1998; Rogers, 1969; Walter & Gerson, 2007). As such, the choices students make are creative acts that direct or redirect established and emerging powers toward the development of mathematical meaning, thinking and learning.

Skovsmose (2005b) noted that there are ethical demands associated with action and responsibility. Mathematics classroom conditions that constrain intellectual tryings by students constrain the exercise of personal agency as well as the exercise of temporally extended agential authority in groups. Synthesizing personal agency with socially constituted conditions, Bratman (2007) suggested that agency may include individual self-governance, intention, planning, and temporally extended agential authority. In our work, temporally extended agential authority emerges when individuals exercise personal agency over time in collaborative pursuit of collective goals. Our perspective on agency underscores social aspects of agency in learning, beyond individual choice and responsibility, and allows us to recognize the critical roles and effects of personal agency enacted by learners working in groups. Indeed, the exercise of personal agency is the genesis of creative acts that shape, and in turn are influenced within, the milieu of lived experience.

Goffman (1959) described performance as "all the activity of a given participant on a given occasion which serves to influence in any way any of the other participants" (p. 15). We use performance as Goffman did because we are interested in how students' mathematical tryings influence one another and the group effort. We suggest that performance in a learning community may be characterized as "an observable, flexible, synchronous process of reasoning, presenting and organizing one's thoughts…[and] begins with an individual choosing to act, which may influence and include actions of the group" (Walter & Gerson, 2007, p. 206).

Interaction was defined by Goffman (1959) as "the reciprocal influence of individuals upon one another's actions when in one another's immediate physical presence" (p. 15). A decade later, Blumer (1969) viewed interaction as "a flowing process in which each participant is guiding his action in the light of the action of the other suggest[ing] its many potentialities for divergent direction" (p. 110). Divergent direction, from our perspective, encompasses the potential for different solution approaches in mathematical problem solving.

In student-thinking centered, investigatory task-based classrooms, all three grounding attributes of our theoretical perspective (personal agency, performance, and interaction) are elemental in student endeavors. Against such a background, we arrived at our initial research question.

## Research Questions

How do university students collectively develop mathematical methods for solving problems? In particular, within the context of our study, we look at how university students collaboratively develop mathematical methods for finding the volume of a solid of revolution when no prior instruction on solution methods was given. How do these students reason to build convincing arguments and provide justifications that are meaningful for others who are trying to understand divergent solution approaches?

## Methodology

Eighteen second-semester honors calculus students, comprising four groups, worked collaboratively on tasks during two-hour class sessions three times per week. Tasks were designed to foster creativity while eliciting conceptually important mathematics as part of a 3-semester teaching experiment at a large private university in the mountain-west region of the United States. Pedagogical decisions were based on the progress and direction of inquiry by students, rather than by textbook organization. During these particular sessions, students worked on one task, the Gel-Pack Mug Task (Figure 1) without prior instruction on solution approaches. This task was especially created to elicit student-generated, meaningful and essential mathematics for finding the volume of a solid of revolution. Although these second-semester calculus students had prior experience with integration techniques and applications, finding volumes of solids of revolution was a new topic. Our analysis here focuses primarily on students' public performances of their small-group invented solutions for the Gel-Pack Mug Task.

*A cold mug consists of a gel pack sandwiched by two cylinders. For manufacturing reasons, we make the gel pack parabolic in cross-section. We are interested in knowing the volume of the gel. For your information, the height of the gel pack is 12 cm. The gel is filled up to the 11 cm mark. The top of the gel pack needs to be 2 cm wide at the top. The inside radius of the mug is 8 cm.*

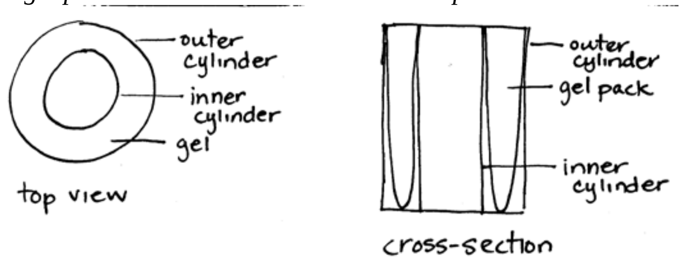

*Figure 1.* Gel-pack mug task.

Each class session was videotaped. Videotape captured and preserved a detailed chronology of interactions, discourse, and mathematical work of groups of 4 to 6 students seated at large hexagonal tables. In addition, whole class discussions and presentations by individual students or small groups of students were also videotaped. Transcripts of videotaped student discourse were created and verified by research team members including graduate and undergraduate research-mentored students. Transcripts are verbatim texts of student utterances. These transcripts were then memoed to record insights and relationships between events and further annotated to reflect gestures, intonations, pauses, and other student activity during student conversations. Interpretations and inferences were substantiated by constant comparison of all data sources, including the videotaped evolution of student written work and notations, homework assignments and completed task write-ups.

In a microlinguistic analysis of student discourse, open and axial coding (Strauss & Corbin, 1998) highlighted differences in students' solution approaches and supported the identification and characterization of the mathematical referents students chose to substantiate and justify their work. Open coding included repeated searches of the video and transcript for student language and notations that indicated student attempts at justification, argumentation, consensus, and proof. Axial coding of students' presentations revealed what we call *pivotal cues* in students' reasoning. Pivotal cues indicated a change in, or a support for, specific reasoning through the use of morphemes such as *because, but, is, like, mean, need, so, then* and *want*. Mathematical referents also surfaced during open and axial coding of students' problem-solving approaches. We defined these emergent mathematical referents as taken-as-shared mathematical objects to which students appealed during consensus building while problem-solving or during public performance presentations of their work. Personal and temporally extended agential authority was evident in the use of pronouns, such as "I" and "we" and language which indicated individual and collective decision-making.

Transcript excerpts presented here are from the three, two-hour class periods that students worked on the Gel-Pack Mug Task. Each excerpt includes, in columns from left to right, video timecodes for ease in referencing particular events and for a sense of temporal breadth (for example D1_1 29:36 would indicate the first day (D1) of student work on the task during the first hour of that class session at twenty-nine minutes thirty seconds into the video), speaker name, transcript, transcript annotations to clarify student discourse and performances, and coding from analysis to support interpretive narrative following each excerpt.

## Data and Analysis

Here, we present brief analyses of two of the four diverse, student-invented solution approaches for the gel-pack task. We begin by noting that all four groups of students came to the conclusion, via different approaches, that the volume of the gel-pack was $264\pi \text{ cm}^3$.

Retrospective traces of each group's work revealed that two groups, students at Table 1 (T1) and students at Table 3 (T3), chose to develop what might be identified as traditional calculus methods to find the desired volume. T1 chose to approach the problem with the shell method and T3 developed the washer method. If students had prior experiences with second-semester calculus content, the graphic presentation of the cross section of the mug may be seen by some as suggestive of these two approaches.

However, students seated at Table 2 (T2) and those at Table 4 (T4) invented distinct, rather unconventional methods for solving the task. Five students at T2, Eric, Justin, Daniel, Jamie, and Julie, developed what they termed the "ratios" method. During small-group problem-solving Justin responded (D1_1 29:36) to Eric by offering a speculative question (Walter, 2004).

| | | | | |
|---|---|---|---|---|
| D1_1 29:36 | Justin | What if you did this? What if you took like kind of saying what you're saying, if you took the ratio of the difference between [pause] of how these two apply to each other. I don't know what I'm saying. And then find the volume of the cylinder and apply the ratio to that. | ["ratio of the difference between"/ratio of parabolic area to circumscribed rectangular area] | [extended agential authority/mindful awareness of Eric's prior suggestion] |
| 29:54 | Eric | I wonder if that would work. | | [personal agency] |

In the ratios method, T2 found that the area of the rectangle circumscribing the parabola was 22 $cm^2$. They set up and evaluated $11\int_{-1}^{1}(1-x^2)\,dx = 14.66\overline{6}\ cm^2$ to determine the area of one of the parabolic faces represented in the cross-section of the gel-pack mug. and then calculated the ratio of the parabolic area to the area of the rectangle (see Figure 1), $\frac{14.66\overline{6}}{22} = .6\overline{6}$. The rectangle, if rotated around the *y*-axis at a distance from the *y*-axis equal to the interior radius of the mug, would form the 11 cm high, double-walled cylinder containing the gel-pack. The double-walled cylinder volume, 1244.07 $cm^3$, was found by determining the volume of the entire cup at a height of 11 cm and then subtracting the volume of the 11 cm high interior cylinder of the cup (D1_1 32:03). During their small group work, and again in public presentation of their solution, T2 stated that the ratio of the area of the parabola to the area of the rectangle would be equal to the ratio of the volume of the gel pack to the volume of the cylinder. Hence, T2 multiplied the area ratio by the volume of the cylinder or "shell containing the gel-pack" to find the volume of the gel-pack (Figure 1).

Meanwhile, students at T4, Danielle, Derrick, Paul and Nels, with remarkable creative insight, invented a method which, unknown to them, demonstrated the Second Theorem of Pappus. The students proceeded, in a compelling manner, to justify to the class their use of specific mathematical referents in their approach to solving the problem. The following is an excerpt from Derrick's portion of the group's performance.

| | | | | |
|---|---|---|---|---|
| D3_1 8:32 | Derrick | As we understand, by finding a volume, like, to find volume it's like length times width times height | [writes V=L x W x H] | [we/pronoun/ extended agential authority] [like/conjunction] [volume of right prism/mathematical referent] |
| 8:45 | | And for us, our length times width, I call it the base of our object, so that was the base of our object, the length times width | [draws a rectangle around L x W and writes "base" below] | [us/our/pronoun/ extended agential authority] [I/personal agency] [it/that/parabolic face of the right prism] |

| | | | |
|---|---|---|---|
| | | | [so/adverb] |
| 8:58 | So all we needed to do was take that, that fourteen point six six six six six seven and multiply it times a height | [writes $V = (14.666667)(H)$ on the board] | [so/adverb] [we/extended agential authority] [needed to do/mathematical necessity] [that/pronoun/ parabolic base area] |
| 9:59 | So we stretched that out | [points to the gel-pack parabolic prism he had drawn–see Figure 2] | [so/adverb] [kinesthetic deformation of gel-pack] |
| 10:01 | That's just like taking the mug and chopping it in half right there and stretching it out | [with a chopping motion draws a vertical line segment across the sketched washer, or top view, cross-section of the gel-pack] | [like/adjective] [process/what we have] |
| 10:06 | And so... so we took this middle radius, the average radius | [draws a circle representing an average circumference on the washer cross-section already drawn on the whiteboard] | [so/conjunction/ process] [we/extended agential authority] |
| 10:14 | ‘cause this is 8 | [draws and labels an inner radius 8] | [‘cause/conjunction] [backing for average radius] |
| 10:16 | and that’s 10 | [draws and labels an outer radius 10] | |
| 10:18 | So we took the radius at 9 | | [so/conjunction/process] |
| 10:21 | And we figured out why we did that. | [sketches an isosceles trapezoid with base lengths 8 and 10 units] | [we/pronoun/ extended agential authority] [nested mathematical referent] |
| 10:22 | Because if you really stretch it out, | [a longitudinal cross section of the gel-pack] | [because/conjunction] [kinesthetic deformation of gel-pack] |
| 10:24 | it looks like this | [points to isosceles trapezoid] | [nested mathematical referent] |
| 10:27 | and there's space unaccounted for | [points to a region outside the left leg of the | [identifies tensions between |

| | | | |
|---|---|---|---|
| | | trapezoid]. | mathematical referents] |
| 10:29 | But if we do it in the middle | [average circumference] [draws the median– a segment connecting the midpoints of the legs of the trapezoid] | [we/pronoun] [process] |
| 10:34 | then it makes up for that extra space | [superimposes on the trapezoid a rectangle with length dimension equivalent to the length of the median and height equivalent to the height of the trapezoid, Fig. 2 | [then/adverb] [resolves tension, reconciles rectangular and trapezoidal referents] |
| | Does that make sense? | | [checks for whole-class consensus] |

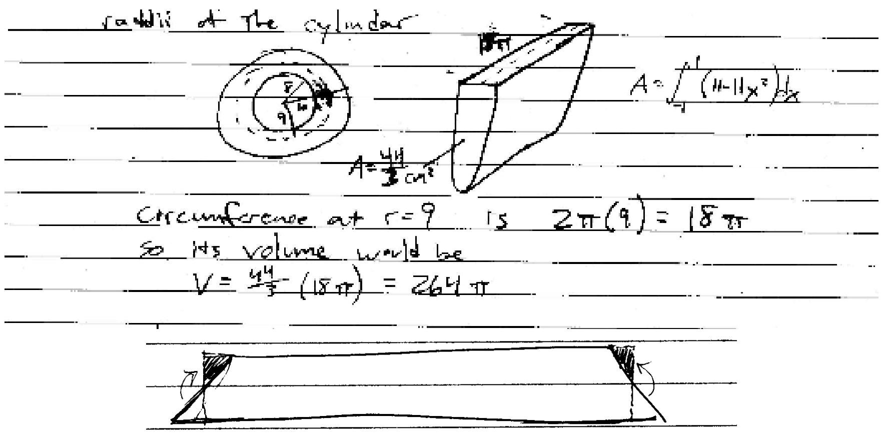

*Figure 2*. T4 mathematical referents and demonstration of second theorem of Pappus.

T4 recognized a parabolic right prism in the structural deformation of the gel-pack. They chose to use the formula for the volume of a prism as a mathematical referent in their invented solution demonstrating the Second Theorem of Pappus. The isosceles trapezoid was a nested mathematical referent to resolve tension between rectangular and parabolic right prisms and to justify the use of the average radius of the gel-pack for the height of the right-prism gel-pack.

## Discussion

These students flexibly used *pivotal cues*, mathematical referents, and collaboratively created notations to meaningfully relate prior experiences with developmental reasoning and mathematical inferences. Pivotal cues note emphases and direction of attention in problem-solving. Selected pivotal cues and purposes as used by these students are presented in Figure 3.

| Adverb | Adjective | Conjunction | Pronoun |
|---|---|---|---|
| So (in the way that follows; in the way that precedes)<br>Like (resembling closely, similar to; in the same way as; as if)<br>Then (immediately or soon afterward; next in order of time or place; as a consequence) | So (true as stated or reported)<br>Like (of the same form; similar, analogous; bearing resemblance; equivalent; possessing the same or almost the same characteristic) | So (in order that; with the result that; on the condition that)<br>Like (as if, in the same way as)<br>Because or 'cause<br>(for the reason that; due to the fact that; since) | I (self as agent)<br>We (nominative plural of I representing a collective viewpoint and temporally extended agential authority)<br>You (second person singular or plural; people being addressed) |

*Figure 3.* Selected pivotal cues in students' presentations of solution approaches.

In these students' work, justification was grounded in personally meaningful mathematical referents and was a means for building mathematical consensus. In subsequent problem solving, each student in the class chose to appropriately and efficiently utilize the Second Theorem of Pappus. We see enacted personal agency and extended agential authority as fundamental for creativity and meaning in students' mathematics. Our analysis expands our awareness of students' use of pivotal cues and mathematical referents in problem-solving. Additionally, we gain fine-grained insight into students' choices for personal instantiations and justifications that ground mathematical inferences. In turn, we begin to recognize more fully how students build convincing justifications for their understandings of mathematical concepts and processes.

*The LieCal Project longitudinally investigates the effects of the Connected Mathematics Program (CMP) and more traditional middle school curricula (non-CMP) on students' learning of algebra. To ascertain the curricular effects, we must attend to aspects of teaching that influence students' learning opportunities. In this paper, we particularly focused on the mathematical tasks to understand the instructional experiences provided when using CMP and Non-CMP curricula. We found that teachers in CMP classrooms implemented significantly more cognitively demanding tasks than teachers in Non-CMP classrooms. Also, teachers are much more likely to encourage multiple strategies in CMP classrooms than in Non-CMP classrooms.*

## Purpose

One of the major goals of educational research, curriculum development, and instructional improvement is to improve students' learning. Advocates of mathematics education reform often attempt to change classroom practice, and hence, students' learning, by means of changes in curricula (NCTM, 1989; Howson, Keitel, & Kilpatrick, 1981; Senk & Thompson, 2003). Historically, curriculum has been used as a means to convey what students should learn (NCTM, 1989) and it has also been used to serve as agents for instructional improvement (Ball & Cohen, 1996). However, curriculum does not always influence classroom instruction (Ball & Cohen, 1996; Fullan & Pomfret, 1977). One of the important factors is how teachers interpret and use the curriculum materials in classroom. The purpose of this study is to examine the kinds of learning provided by classroom instruction using Standards-based and and more traditional middle school curricula mathematics curricula.

## Background and Theoretical Considerations

*Standards-Based Mathematics Curriculum*

In the late 1980s and early 1990s, the National Council of Teachers of Mathematics (NCTM) published its *Standards* documents, which provided recommendations for reforming and improving K-12 school mathematics. In the *Standards* and related documents, the discussions of goals for mathematics education emphasize the importance of thinking, understanding, reasoning, and problem solving, with an emphasis on connections, applications, and communication (e.g., NCTM, 1989, 2000). This view stands in contrast to a more conventional view of the goals for mathematics education, which emphasizes the memorization and recitation of decontextualized facts, rules, and procedures, with the subsequent application of well-rehearsed procedures to solve routine problems.

With extensive support from the National Science Foundation, a number of *Standards*-based school mathematics curricula were developed in the United States and implemented to align with the recommendations in the *Standards* (see Senk and Thompson, 2003 or NRC, 2004 for details). The Connected Mathematics Program (CMP) is one of the *Standards*-based school mathematics curricula developed with the support of the U.S. National Science Foundation. The CMP curriculum is a complete middle-school mathematics program. The intent of CMP is to build students' understanding in the four mathematical strands of number and operation, geometry and measurement, data analysis and probability, and algebra through explorations of real-world situations and problems (Lappan et al., 2002). Because NSF-funded curricula like CMP claim to have different learning goals and also look very different from commercially developed mathematics curricula, a natural question is: What learning opportunities will a Standards-based curriculum like CMP provide that are different from the learning opportunities provided by more traditional middle school curricula?

*LieCal Project*

The study reported in this paper was conducted as part of a large project titled the Longitudinal Investigation of the Effect of Curriculum on Algebra Learning (LieCal Project). The LieCal Project is designed to longitudinally compare the effects of the Connected Mathematics Program (CMP) to the effects of more traditional middle school curricula (hereafter called Non-CMP curricula) on students' learning of algebra. The LieCal Project is being conducted in 16 middle schools and 10 high schools of an urban school district serving a diverse student population. At the start of the project, 27 of the 51 middle schools in the school district had adopted the CMP curriculum while the remaining 24 middle schools were using other curricula. Eight CMP schools were randomly selected from the 27 schools that had adopted the CMP curriculum. After the eight CMP schools were selected, eight Non-CMP schools were chosen based on comparable ethnicity, family incomes, accessibility of resources, and state and district test results. A total of 725 CMP students from 26 classes and a total of 698 Non-CMP students from 24 classes participated in the study, and these 1,423 students were followed for three years from grades 6 to 8 and into grade 9.

The goal of teaching is to help students learn. To understand the impact of *Standards*-based curricula, then, we must attend to aspects of teaching that appear to have potential to influence students' learning opportunities. Specifically, to help us understand the differences between the instructional experiences provided when teachers use CMP and Non-CMP curricula, in this paper we focused particularly on the instructional tasks posed and implemented by the teachers.

*Instructional Tasks*

Researchers have developed different paradigms and methods that can be used to identify important features of classroom instruction (e.g., see Koehler & Grouws, 1992; Porter & Brophy, 1988; Shulman, 1986). Instructional tasks have been identified as an important construct to study classroom instruction (Doyle, 1983; Stein et al., 1996). The term "instructional tasks" has been referred to by other researchers as "academic tasks," or as "mathematical tasks" (e.g., Cai & Lester, 2005; Doyle, 1983; Hiebert & Wearne, 1993; Stein et al., 1996). Mathematical tasks can be defined broadly as projects, questions, problems, constructions, applications, or exercises in which students engage. Mathematical tasks provide intellectual environments within which students can learn and develop mathematical thinking. Tasks help regulate not only students' attention to particular aspects of content, but also their ways of processing information. However, only "worthwhile problems" give students the chance to solidify and extend what they know and to stimulate mathematics learning (NCTM, 1991). In the classroom, students' actual opportunities to learn depend on the type of mathematical tasks presented and implemented. Regardless of the context, for a task to be worthwhile, it should be intriguing and it should provide a level of challenge that invites speculation and hard work. Most importantly, worthwhile mathematical tasks should direct students toward explicit learning goals by encouraging them to investigate important mathematical ideas and ways of thinking. The NCTM *Standards* (1991, 2000) recommend that students should be exposed to truly problematic tasks in classrooms so that they can practice mathematical sense making. Doyle (1988) argues that tasks with different cognitive demands are likely to induce different kinds of learning. Mathematical tasks that are truly problematic have the potential to provide the intellectual contexts for students' rich mathematical development. Such tasks can promote students' conceptual understanding, foster their ability to reason and communicate mathematically, and capture students' interests and curiosity (NCTM, 1991).

Worthwhile mathematical tasks alone do not guarantee students' learning. They are important, but not sufficient, for effective mathematics instruction because teachers may not implement worthwhile tasks as they were intended. Stein et al. (1996) found that only about 50% of the tasks that were set up to require students to apply procedures with meaningful connections were actually implemented that way. In our LieCal project, we analyzed three distinct categories of mathematical problems: those that appeared in the CMP and Non-CMP textbooks, those that were posed and implemented during classroom instruction, and those that were assigned as homework. In this paper, we report only the results from our analysis of the instructional tasks implemented in the classroom.

## Methodological Considerations

### *CMP and Non-CMP Curricula*

We have conducted detailed analyses of the CMP and Non-CMP curricula, with a focus on the algebra strand. Our preliminary analysis showed remarkable differences between the CMP and Non-CMP curricula. CMP can be characterized as a problem-based curriculum. Take the introduction to equation solving as an example. In one of the Non-CMP curricula, equation solving is introduced symbolically using the additive property (add or subtract the same quantity on both side of the equation, the equality holds) and the multiplicative property (multiple or divide a non-zero quantity on both sides of an equation, the equality holds). On the other hand, in the CMP curriculum, the introduction to equation solving is situated within real-life contexts that are used to help students understand the meaning of each step of the equation solving process (Nie, Cai, & Moyer, 2009).

The extent of the differences is also illustrated in Figure 1 below. Using a scheme developed by Stein et al. (1996), we classified the mathematical tasks in the CMP curriculum and one of the Non-CMP curricula into four increasingly demanding categories of cognition: memorization, procedures without connections, procedures with connections, and doing mathematics. As Figure 1 shows, significantly more tasks in the CMP curriculum than in the Non-CMP curriculum are higher-level tasks (procedures with connections and doing mathematics) ($\chi^2(3, \underline{N} = 3311) = 759.52$, $\underline{p} < .0001$).

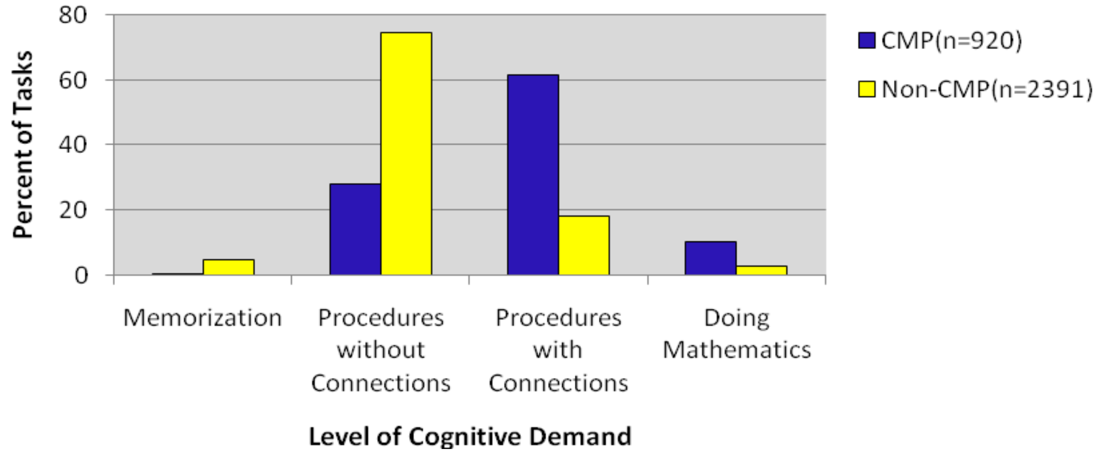

*Figure 1.* Percentages of various tasks in CMP and Non-CMP curricula.

*Classroom Observations*

As we indicated above, the research reported in this paper is part of a longitudinal study of the effect of curriculum on the algebraic thinking of approximately 1400 middle school students from 16 schools in a single urban district as they progressed from grades 6-8. The data was collected over a three-year period during 620 classroom observations. Approximately half of the observations were of teachers using the CMP curriculum. The other half were observations of teachers using Non-CMP curricula. Two retired mathematics teachers conducted and coded all the observations. The coders received extensive training that included frequent checks for reliability and validity throughout the three years. Over the course of the $6^{th}$-grade year, for example, we checked the reliability of the observers' coding three times. These three sessions revealed that the reliability of the coding done by the two specialists was quite high. The reliability achieved during the three sessions averaged 79% perfect agreement using the criterion that the observers' coded responses were considered equivalent only if they were identical (i.e., perfect match). The reliability averaged 95% using the following criteria: (a) If an item or sub-item was "scored" using an ordinal scale, then the specialists' coded responses were considered equivalent if they differed by at most one unit; (b) If an item or sub-item (e.g. representation) was "scored" by choosing from a list of alternatives all the words/phrases that characterize it, then the specialists' coded responses were considered equivalent if they had at least one choice in common (e.g. symbolic and pictorial vs. pictorial).

Each coder observed and coded about 100 algebra-related lessons each year: half in CMP classes and half in Non-CMP classes. Each class was observed four times, during two consecutive lessons in the fall and two in the spring. The coders recorded extensive information about each lesson in a 28-page project-developed observation instrument.

During each observation, the observer made a minute-by-minute record of the lessons on lined sheets. This record was used later to code the lesson. One section of the observation instrument is devoted to the analysis and coding of the mathematical tasks in the lessons. Instructional tasks were analyzed from three perspectives: (1) as intended by the author, (2) as set up by the teacher, and (3) as actually implemented by the teacher with students. The observers in the project coded each of the instructional tasks along four dimensions within each of the three perspectives: (1) Setting; (2) Solution Strategies; (3) Representations; and (4) Cognitive Demand. These dimensions are described in the results section.

## Results

In this paper, we only report the results from the analysis of the tasks actually implemented by the teacher with students. In addition, the difference patterns between the tasks from CMP and Non-CMP classrooms are similar across the three middle school grade levels ($6^{th}$- to $8^{th}$ grades). Therefore, we aggregated the tasks data from all three grades. A total of 646 instructional tasks from about 300 CMP lessons and 744 tasks from about 300 Non-CMP lessons were identified.

*Settings*

We classified the classroom settings in which teachers implemented instructional tasks into three types: whole classroom, small group work, or individual work. The same tasks in a lesson could be implemented in different settings. Nearly 80% of the tasks in CMP lessons and 80% of the tasks in Non-CMP lessons were implemented in a whole classroom setting. About 20% of the tasks in the CMP lessons and 8% of the tasks in the Non-CMP lessons were implemented in small group settings. These two percentages are significantly different ($z = 7.03$, $p < .001$). On the other hand, a significantly larger percentage of the tasks in Non-CMP lessons (57%) than in CMP lessons (41%) were implemented in an individual work setting ($z = 5.89$, $p < .001$).

*Solution Strategies*

We examined whether the instructional tasks implemented in the classrooms were solved using multiple approaches or a single approach. Figure 2 below shows the percentage of tasks that were solved using multiple solution strategies and the percentage of tasks that were solved using a single solution strategy in both CMP and Non-CMP classrooms. A Chi-square test shows that while a larger percentage of the tasks implemented in CMP classroom were solved using multiple solution strategies, a larger percentage of the tasks implemented in Non-CMP classrooms were solved using a single solution strategy ($\chi^2(1, N = 1390) = 122.49$, $p < .0001$).

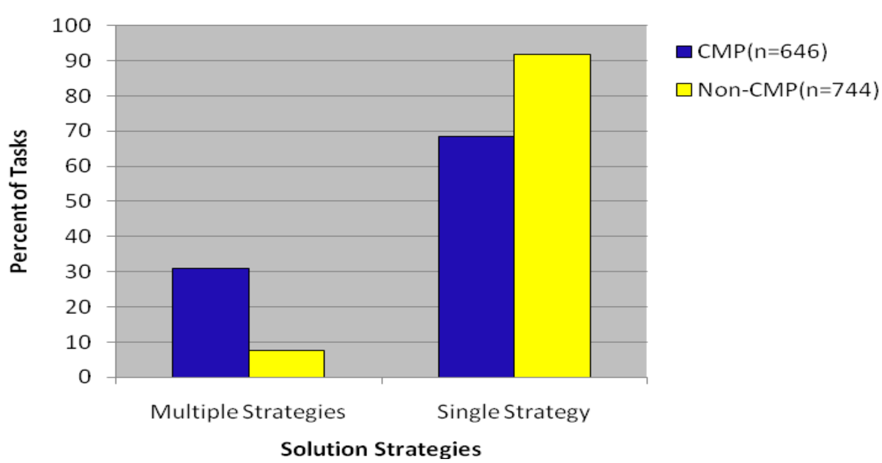

*Figure 2*. The distribution of solution strategies in CMP and Non-CMP classrooms.

*Representations*

The representations used to solve each problem were classified into 7 categories: (1) symbolic, (2) written words, (3) pictorial, (4) tabular, (5) graphical, (6) verbal, and (7) physical manipulatives. Table 1 below shows the percentage of tasks implemented in CMP and Non-CMP lessons using each of the representations. The solution to an implemented task can involve multiple representations. Only a small proportion of the tasks implemented in CMP and Non-CMP lessons were represented with physical manipulatives. The most frequently used representations of implemented tasks in both the CMP and Non-CMP lessons were symbolic, and the proportion of the tasks that were represented using symbolic representations in Non-CMP lessons was greater than that in CMP lessons ($z = 6.16$, $p < .001$). Compared to the use of symbolic representations, the proportion of using other representations is much smaller in both CMP and Non-CMP lessons. We compared the frequencies with which written words, pictorial, tabular, graphical, and verbal were used to represent implemented tasks in both CMP and Non-CMP lessons. We found that the proportion of the instructional tasks that were represented using each of these representations (written words, pictorial, tabular, graphical, or verbal) in CMP lessons was greater than that in Non-CMP lessons ($z = 3.80 – 8.78$, $p < .001$).

Table 1. *Percentages of Tasks With Each of the Representations*

| | Symbolic | Written Words | Pictorial | Tabular | Graph | Verbal | Physical Manipulatives |
|---|---|---|---|---|---|---|---|
| CMP (n=646) | 78 | 20 | 30 | 26 | 23 | 20 | 4 |
| Non-CMP (n=744) | 90 | 12 | 15 | 8 | 8 | 6 | 3 |

*Cognitive Demand*

Using a scheme developed by Stein et al. (1996), we also classified the instructional tasks from CMP and Non-CMP classrooms into four increasingly demanding categories of cognition: memorization, procedures without connections, procedures with connections, and doing mathematics.

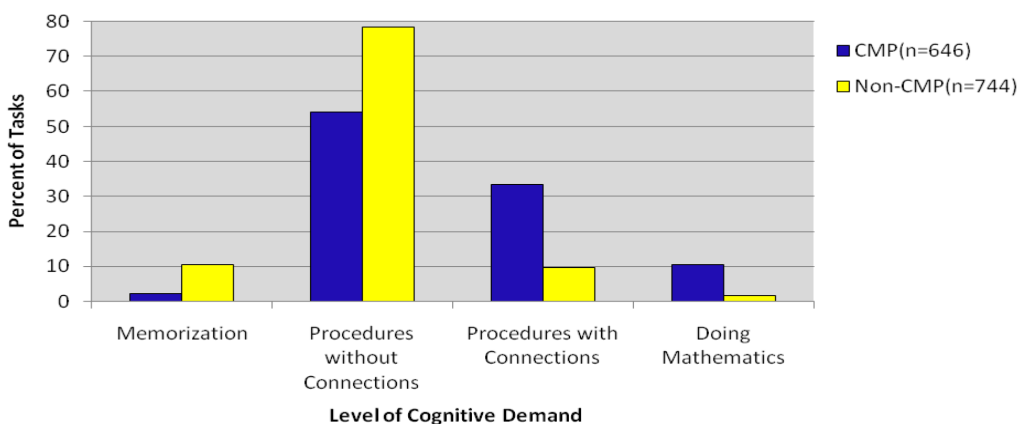

*Figure 3.* Instructional tasks implemented in CMP and Non-CMP classrooms.

Figure 3 illustrates the percentage distributions of the cognitive demand of the instructional tasks implemented in CMP and Non-CMP classrooms. A chi-square test shows that the CMP and

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

Non-CMP percentage distributions are significantly different ($\chi^2(3, \underline{N} = 1390) = 209.42$, $\underline{p} < .0001$). The difference is due to the fact that there was a larger percentage of high cognitive demand tasks (procedures with connection or doing mathematics) implemented in CMP classrooms than in Non-CMP classrooms ($\underline{z} = 13.79$, $\underline{p} < .001$). On the other hand, there was a larger percentage of low cognitive demand tasks (procedures without connection or memorization) implemented in Non-CMP classrooms than in CMP classrooms.

## Discussion

The research reported in this paper is part of a larger longitudinal study conducted in the LieCal Project. The LieCal project was designed to provide (1) A profile of the intended treatment of algebra in the CMP curriculum with a contrasting profile of the intended treatment of algebra in the Non-CMP curricula; (2) a profile of classroom experiences that CMP students and teachers undergo, with a contrasting profile of experiences in Non-CMP classrooms; and (3) a profile of student performance resulting from the use of the CMP curriculum, with a contrasting profile of student performance resulting from the use of Non-CMP curricula. In this paper, we analyzed a single aspect of the classroom experiences that CMP and Non-CMP students and teachers underwent, namely the instructional tasks implemented in the two types of classrooms. The initial analysis of the implemented instructional tasks clearly showed remarkable differences between CMP and Non-CMP classroom instruction. Instructional tasks are more likely to be implemented in small group settings in CMP classrooms than in Non-CMP classrooms, and vice versa for the tasks implemented in individual settings. The instructional tasks implemented in CMP classrooms were more than three times likely to be solved using multiple solution strategies than they were in Non-CMP classrooms. While solutions of instructional tasks in Non-CMP classrooms were more likely to be represented using symbols, solutions of instructional tasks in CMP classrooms were more likely to be represented using written words, pictorial representations, graphs, tables, or verbal representations. In addition, CMP teachers were more than three times as likely to implement high-level tasks during classroom instruction than Non-CMP teachers.

The findings of this study not only show the importance of examining the instructional experiences of students using CMP and Non-CMP curricula, but it also shows the power of focusing on instructional tasks to reveal the instructional differences. Recall that our analysis of the mathematical problems in the CMP and Non-CMP curricula showed that significantly more tasks in the CMP curriculum than in the Non-CMP curriculum are high level tasks (procedures with connections and doing mathematics). Thus it is reasonable to infer that the differences in setting, strategy, representation, and cognitive level of the tasks implemented in CMP and Non-CMP classrooms reflect the differences between the mathematical problems in the CMP and Non-CMP curricula.

The striking and clear differences between CMP and Non-CMP classrooms are of great interest and importance in our longitudinal investigation of the impact of curriculum on students' learning. As part of the parent study, we also collected large-scale, longitudinal student achievement data. In our presentation, we will identify and present important linkages between students' classroom experiences and their learning outcomes.

**Authors' Note**: The research reported in this paper is part of a large project, Longitudinal Investigation of the Effect of Curriculum on Algebra Learning (LieCal Project). LieCal Project is supported by a grant from the National Science Foundation (ESI-0454739). *This paper reports an ongoing study that is aimed at developing an instrument for measuring two particular problem-solving dispositions: (a) impulsive disposition refers to students' proclivity to spontaneously proceed with an action that comes to mind, and (b) analytic disposition refers to the tendency to analyze the problem situation. The instrument is under development and consists of likelihood-to-act items in which participants indicate on a scale of 1 to 5 how likely they are to take a particular action in a given situation. The instrument was administered to 318 college students, mainly pre-service teachers. Statistical analysis indicates that likelihood-to-act items are reliable and that the current version of the instrument has room for further improvement.*

## Motivation for the Study

For many mathematics students, "doing mathematics means following rules laid down by the teacher, knowing mathematics means remembering and applying the correct rule when the teacher asks a question, and mathematical truth is determined when the answer is ratified by the teacher" (Lampert, 1990, p. 31). Students with such beliefs tend to exhibit dispositions such as "waiting to be told what to do," "doing whatever first comes to mind," and "diving into the first approach that comes to mind" (Watson & Mason, 2007, p. 207). In this paper, we use the term *impulsive disposition* to mean the tendency to "spontaneously proceed with an action that comes to mind without analyzing the problem situation and without considering the relevance of the anticipated action to the problem situation" (Lim, 2008a, p. 49).

Some problem-solving episodes found in mathematics education literature can be interpreted as instantiations of impulsive dispositions. For example, consider the following missing-value problem that was posed by Cramer, Post and Currier (1993) to pre-service teachers: *Sue and Julie were running equally fast around a track. Sue started first. When she had run 9 laps, Julie had run 3 laps. When Julie completed 15 laps, how many laps had Sue run?* Thirty-two out of 33 pre-service teachers solved this problem by setting up a proportion such as $9/3 = x/15$. These pre-service teachers are considered *impulsive* if they had applied the proportion algorithm without analyzing the problem situation. In fact, Lim (2008b) found that after a course on rational numbers and algebraic reasoning pre-service teachers, on average, performed better on all four direct-proportional problems but worse on all three non-direct-proportional problems.

As mathematics educators, we are interested in helping students advance from impulsive disposition to *analytic disposition*, in which a student "attempts to understand the problem statement, studies the constraints, identifies a goal, imagines what-if scenarios, and/or considers alternatives" (Lim, 2008a, p. 45). To track this advancement, we need to identify where a student stands in terms of his or her disposition. In other words, we need an efficient and reliable instrument that can "measure" students' impulsive disposition and analytic disposition. In the field of mathematics education, it appears that no such instrument has been developed. In this paper we present a few theoretical constructs related to impulsive disposition, overview the literature associated with assessing cognitive constructs through the use of survey, report our research process, and discuss the results that we have obtained.

## Theoretical Constructs Related to Impulsive Disposition

*Psychological perspective*. In terms of cognitive tempo or response style, a person may be classified as either *impulsive* or *reflective*. Kagan, Rosman, Day, Albert, and Phillips (1964) constructed the Matching Familiar Figures Test to measure children's cognitive tempo. An impulsive is one whose response time is faster than the median and whose accuracy rate is below the median, whereas a reflective is one whose response time is slower than the median and whose accuracy rate is above the median. Nietfeld and Bosma (2003) describe impulsives as "individuals who act without much forethought, are spontaneous, and take more risks in everyday activities" (p. 119) whereas reflectives are "more cautious, intent upon correctness or accuracy, and take more time to ponder situations" (p. 119). In their study on consistency in cognitive responses among adults across academic tasks, Nietfeld and Bosma found moderate positive correlations for response styles among the three types of tasks they investigated: verbal, mathematical, and spatial. The mathematical tasks used in their study were two-digit addition or subtraction problems arranged in a traditional vertical format. Although such tasks are appropriate for measuring cognitive tempo along a speed-accuracy continuum, they are not appropriate for measuring disposition along an impulsive-analytic continuum. Whereas an impulsive tempo is characterized by a fast but inaccurate response, an impulsive disposition is characterized by "diving into the first approach that comes to mind" and not necessarily by how fast an approach comes to mind.

*Problem-solving perspective*. Schoenfeld (1985) has identified four categories of cognition that provide a framework for analyzing problem-solving behaviors: (a) mathematical knowledge base, (b) use of heuristics, (c) monitoring and control, and (d) beliefs about mathematics and doing mathematics. Impulsive disposition can be regarded as an externalization of certain beliefs such as "there is only one correct way to solve any mathematics problem—usually the rule the teacher has most recently demonstrated to the class" (Schoenfeld, 1992, p.359). Impulsive disposition can also be considered as a lack of metacognition—a term introduced by Flavell (1976) as "the active monitoring and consequent regulation and orchestration of these processes in relation to the cognitive objects or data on which they bear, usually in the service of some concrete goal or objective" (p. 232).

*Teaching-learning perspective*. According to Harel (2008), mathematics consists of two complementary sets: (a) *ways of understanding* refer to the products of mental acts while doing mathematics; they include definitions, theorems, proofs, problems, and solutions, and (b) *ways of thinking* refer to the characteristics of the mental acts while doing mathematics. Harel (2007) stipulates that "students develop ways of thinking only through the construction of ways of understanding, and the ways of understanding they produce are determined by the ways of thinking they possess" (p. 272). According to this principle, it is counter-productive to help students develop ways of understanding without helping them develop ways of thinking, and vice versa. Hence, students should be provided opportunities to engage in mental acts (e.g., generalizing, justifying, problem-solving, symbolizing, computing, generalizing, predicting, etc.) that can advance both their ways of understanding and ways of thinking. Lim (2008a) identifies *impulsive anticipation* and *analytic anticipation* as two ways of thinking in the context of problem solving. An important goal of mathematics education is to help students advance from undesirable ways of thinking (e.g., impulsive disposition, authoritative proof scheme) to desirable ways of thinking (e.g., analytic disposition, deductive proof scheme).

### Means for Assessing Impulsive Disposition and Analytic Disposition

One useful way to measure cognitive and psychological constructs is through the use of survey development. The use of surveys can be very informative, as they allow for the quantification of the constructs under study. With such quantification, we can investigate group differences on those constructs and assess how those constructs associate with other behavioral measures. Examples of the use of such measures in the psychological literature are vast, ranging from the measurement of social problem solving (D'Zurilla, Nezu, & Maydeu-Olivares, 2002) to the measurement of decision making styles (Nygren, 2000).

Nygren (2000) constructed the Decision Making Styles Inventory, which measures the degree to which a person makes everyday decisions using an analytical approach, an intuitive approach and an approach which minimizes regret. Analytical decision making involves considering every aspect of the problem before making a decision whereas intuitive decision making involves a reliance on one's gut feeling. These two constructs are analogous to analytic disposition and impulsive disposition.

The goal of this project was to develop a measure of mathematical disposition. We wanted to demonstrate the internal consistency reliability of the survey items. In addition, we wanted to see how well the items in each subscale are inter-correlated, and how well the two items in each impulsive-analytic pair are correlated. Finally, we wanted to assess how scores on such a measure are related to self-reported academic performance in mathematical classes and the participant's teacher training program.

### Research Process

Instrument design, testing, and refining are an elaborate process involving multiple cycles.

*Survey Development*

The initial instrument designed to assess impulsive disposition was a multiple-choice test on ratios and proportions. Students have a tendency to overuse proportional strategies for solving missing-value problems (Van Dooren, De Bock, Hessels, Janssens, & Vershaffel, 2005). The items were designed to determine whether students inappropriately use a proportion to solve missing-value problems that do not involve a direct-proportional situation (e.g., an additive situation, an inverse-proportional situation) or inappropriately use a ratio to compare "non-rate" quantities (e.g., the size of a person's palm, the magnitude of a project in terms of worker-hours).

In subsequent versions multiple-choice items were used for students to choose the action that they would most likely perform in a given scenario. The format was eventually changed from a multiple-choice test to a likelihood-to-act survey which takes less time for students to complete.

The likelihood-to-act survey developed for this ongoing study has undergone two revisions. The first two exploratory versions were administered to about 70 pre-service middle-school teachers and 14 graduate students (mainly in-service teachers) respectively in courses taught by the first author. The version reported in this paper consists of nine pairs of *likelihood-to-act* items, sequenced from A to R. Four pairs (A-J, N-E, O-F, and I-R) involve equation solving; two pairs (B-K and L-C) involve word problems; two pairs (D-M and Q-H) involve fraction division and fraction addition respectively; and one pair (G-P) involves geometry. Figure 1 shows 3 pair of such items.

Two versions of the likelihood-to-act survey were used in this study. All the items in Version

1 are considered “specific” items in that a specific scenario is provided. The nine impulsive-disposition items are based on specific mathematical rules, formulas, or procedures that are supposedly familiar to students.

Please indicate, as honestly as you can, how likely you are going to act in the manner specified in the statement using the following scale:

1. Extremely Unlikely 2. Unlikely 3. Not Sure 4. Likely 5. Extremely Likely

B. When asked to find the cost of 18 cans of specialty soda given that 6 cans of specialty soda cost \$4.10, how likely are you going to begin by setting up a proportion?

K. When asked to find the cost of 20 bottles of mineral water given that 4 bottles cost \$2.10, how likely are you going to study the values of the quantities and predict the answer?

D. When you are asked to find the answer for $\frac{55}{95} \div \frac{11}{95}$ without using a calculator, how likely are you going to use the invert-and-multiply rule?

M. When you are asked to find the answer for $\frac{44}{82} \div \frac{11}{82}$ without using a calculator, how likely are you going to study the two fractions and predict the answer?

I. When asked to simplify an equation (e.g., $10^{3x} \cdot 10^{2y} = 1000 \cdot 10^{3x}$), how likely are you going to begin by applying a formula (e.g., $B^m \cdot B^n = B^{m+n}$) or by following a procedure (e.g., taking $\log_{10}$ on both sides)?

R. When asked to solve $2^{5a} \cdot 2^{10b} = 8 \cdot 2^{5a}$ for $b$, how likely are you going to begin by inspecting the terms in the equation?

*Figure 1*. Three pairs of “specific” likelihood-to-act problems in Version 1.

Version 2 differs from Version 1 in that it contains 2 pairs of “general” items (see Figure 2); the remaining 7 pairs are identical to those in Version 1. “General” items were found to be less reliable in the pilot testing of an earlier version based on a small sample of 14 students. Version 2 was developed to verify this finding. Note that Pair I’-R’ is analogous to Pair I-R, but Pair G’-P’ is substantially different from Pair G-P.

G’. When asked to solve a word problem, how likely are you going to begin by applying a formula or using a procedure that comes to mind?

P’. When asked to solve a word problem, how likely are you going to begin by identifying the quantities in the problem and thinking about how the quantities are related?

I’. When asked to solve an equation, how likely are you going to begin by using a procedure (e.g. combining like terms) or searching for a formula (e.g. $B^m \cdot B^n = B^{m+n}$)?

R’. When asked to solve an equation, how likely are you going to inspect the terms in the equation before applying a standard procedure for solving the equation?

*Figure 2*. Two pairs of general likelihood-to-act problems in Version 2.

*Data Collection and Analysis*

A survey was administered in 13 mathematics classes in the final week of classes of the Fall 2008 semester. To encourage participation, a participant in each class was randomly selected to win a $10 gift voucher. The survey is comprised of two parts: (a) 18 likelihood-to-act items, and (b) either 18 *need-for-cognition* items or 18 *belief-attitude-confidence-in-algebra* items (these items are not discussed in this paper). 318 students were administered the survey, with 257 participants from 10 classes taking Version 1 and 61 participants from 3 classes taking Version 2 of the likelihood-to-act part.

Inter-item correlations were computed using Pearson correlations for the nine impulsive-disposition items and the nine analytic-disposition items. Items that are not significantly correlated with other items in the same category were analyzed to see if they could be improved or should be excluded from the next version of the instrument. Because the items were paired, the correlation between the impulsive-disposition item and analytic-disposition item in each pair was also determined. The reliability for each sub-scale of seven common items was determined using Cronbach's Alpha coefficient based on all 318 individuals. To assess the validity of each subscale, we also performed a 4×3 analysis of variance—four programs (Early Childhood to Grade 4 Generalist program, Grades 4-8 Generalist program, Grades 4-8 Math Specialist program, and B.S. Math program) by three self-reported grade-point-averages for mathematics courses (A, B, and C or below).

## Results and Discussion

*Reliability of the likelihood to act measure*. To compute the reliability of the likelihood-to-act subscales, we used the seven pairs of items common to both versions to create a larger sample—318 individuals. Missing data on any of these items for these 318 students were imputed. At most, one item had seven missing item responses. The Cronbach's Alpha estimate of internal consistency reliability for the seven impulsive-disposition items was 0.64, (95% Confidence Interval: 0.58, 0.70). The reliability of the seven analytical items was 0.63 (95% Confidence Interval: 0.56, 0.69). While these reliability estimates are not very high, it should be noted that each subscale has only seven items. It is well known from classical test theory that the addition of items tends to increase test score reliability. For the next phase, we will focus on developing and testing additional items, s well as improving existing items.

*Impulsive-disposition items*. The correlations among the nine general impulsive-disposition items in Version 1 are presented in Table 1 (ignore the two specific items, G' and I', for the time being). By excluding items L, N, and I, all the correlations among the six remaining items (A, B, D, O, Q, and G) are significant with $p < 0.01$. Items L, N, and I will be replaced in the next version of the instrument. The strong correlations among items A, B, D, O, Q, and G suggest that impulsive disposition is a trait that cuts across the four domains: equation-solving (A and O), word problem (D and Q), fractions (B), and geometry (G).

*Table 1*
Correlations among the Nine Impulsive-Disposition Items

| Item | A | B | L | D | N | O | Q | G | I | G’ | I’ |
|---|---|---|---|---|---|---|---|---|---|---|---|
| A | 1 | | | | | | | | | | |
| B | 0.32** | 1 | | | | | | | | | |
| L | 0.15** | 0.15** | 1 | | | | | | | | |
| D | 0.37** | 0.26** | 0.18** | 1 | | | | | | | |
| N | 0.13* | 0.17** | 0.21** | 0.10 | 1 | | | | | | |
| O | 0.30** | 0.30** | 0.14* | 0.29** | 0.22** | 1 | | | | | |
| Q | 0.25** | 0.17** | 0.09 | 0.15** | 0.12* | 0.21** | 1 | | | | |
| G | 0.24** | 0.31** | 0.13* | 0.19** | 0.17** | 0.28** | 0.23** | 1 | | | |
| I | 0.02 | 0.15* | 0.09 | 0.14* | 0.26** | 0.22** | -0.04 | 0.18** | 1 | | |
| G’ | 0.34** | 0.18 | 0.42** | 0.07 | 0.36** | 0.02 | 0.25 | - | - | 1 | |
| I’ | 0.47** | 0.42** | 0.28* | 0.29* | 0.09 | 0.49** | 0.33** | - | - | 0.19 | 1 |

*Note.* The *p*-values for the correlation of 0.29 for I’ and D is lower than that for the correlation of 0.29 for O and D because the sample size was 61 for I’ and D (Version 2) and 315 for O and D (Versions 1 and 2).
$^{*}p < .05$. $^{**}p < .01$.

As for Version 2 (G’ and I’ instead of G and I), we should retain items A, B, D, O, Q, and I’ and replace items L, N, and G’. Interestingly, the general item I’ appears to be better correlations than the specific item I. A probable explanation is that the participants might have difficulty interpreting Item I because of the equation $10^{3x}\cdot 10^{2y} = 1000\cdot 10^{3x}$ and the meaning of $\log_{10}$.

*Analytic-disposition items*. The correlations among the 11 analytic-disposition items shown in Table 2 are generally less significant when compared to those in Table 1. This finding suggests that the analytic-disposition items are not as effective as the impulsive-disposition items. Items C, E, P, R, P’ and R’ have to be excluded in order for the remaining correlations to be significant. However, items J, K, M, F and H can remain intact for the next version. Hence, the individual items in these five pairs, A-J, B-K, D-M, O-F, and Q-H, seem to be reliable.

*Table 2*
Correlations among the 9 Analytic-Disposition Items

| Item | J | K | C | M | E | F | H | P | R | P’ | R’ |
|---|---|---|---|---|---|---|---|---|---|---|---|
| J | 1 | | | | | | | | | | |
| K | 0.28** | 1 | | | | | | | | | |
| C | 0.05 | 0.14* | 1 | | | | | | | | |
| M | 0.31** | 0.41** | 0.07 | 1 | | | | | | | |
| E | 0.17** | 0.05 | 0.08 | 0.08 | 1 | | | | | | |
| F | 0.22** | 0.16** | 0.21** | 0.17** | 0.19** | 1 | | | | | |
| H | 0.26** | 0.39** | 0.00 | 0.43** | 0.07 | 0.23** | 1 | | | | |
| P | 0.02 | 0.09 | 0.14* | 0.19** | 0.12* | 0.10 | 0.06 | 1 | | | |
| R | 0.21** | 0.18** | 0.10 | 0.14* | 0.23** | 0.08 | 0.08 | 0.34** | 1 | | |
| P’ | -0.01 | -0.14 | 0.21 | -0.05 | 0.35** | 0.06 | -0.33** | - | - | 1 | |
| R’ | 0.20 | 0.07 | 0.44** | 0.09 | 0.15 | 0.31* | -0.01 | - | - | 0.35** | 1 |

*Note*. *$p < .05$, **$p < .01$.

*Correlation between the two items in each pair*. The last column in Table 3 shows the correlation between the impulsive-disposition item and the analytic-disposition item in each pair. A significant negative correlation in Pair Q-H indicates that this pair of items differentiates impulsive disposition from analytic disposition. The significant positive correlations in Pair L-C and in Pair I-R mean that these two pairs of items should not be used in the next version. Note that the five good pairs (A-J, B-K, D-M, O-F, and Q-H) have either negative correlations or very small positive correlations. The lack of significant negative correlations suggests the possibility that impulsive disposition and analytic disposition are not necessarily mutually exclusive. In other words, a person may have two competing dispositions for the same problem situation.

*Table 3*
Comparing the Two Items in Each Pair

| | Mean for the impulsive item | Mean for the analytic item | Difference betw. the two means | Correlation betw. the two items |
|---|---|---|---|---|
| Pair A-J | 3.62 | 3.53 | 0.10 | 0.02 |
| Pair B-K | 3.66 | 3.53 | 0.12 | -0.10 |
| Pair L-C | 3.34 | 3.55 | -0.21 | 0.19* |
| Pair D-M | 4.19 | 3.21 | 0.99 | -0.00 |
| Pair N-E | 3.14 | 3.55 | -0.40 | 0.10 |
| Pair O-F | 3.77 | 3.53 | 0.24 | 0.04 |
| Pair Q-H | 4.00 | 3.33 | 0.67 | -0.16** |
| Pair G-P | 3.40 | 3.84 | -0.44 | 0.12 |
| Pair I-R | 3.77 | 4.09 | -0.32 | 0.14* |
| Pair G’-P’ | 3.86 | 4.07 | -0.21 | 0.24 |
| Pair I’-R’ | 3.37 | 4.28 | -0.91 | 0.16 |

*Note*. *$p < .05$, **$p < .01$.

*Association between training program, self-reported mathematics grade, and likelihood-to-act scores.* To assess the validity of the likelihood-to-act measure, we also performed a 4 (programs) by 3 (self-reported numerical grade) analysis of variance on the analytical and impulsive composite scores. For the analytical subscale, there was a main effect for program ($F(3,270) = 8.233$, $p < 0.001$, $\eta2 = 0.08$). Interestingly, elementary-school generalists (EC-4 program) had higher analytical scores than middle-school math specialists (4-8 Math program) and mathematics majors (B.S. Math program). Middle-school generalists (4-8 Generalists program) also had higher analytical scores than mathematics major. An interaction between self-reported grade and training program emerged only for the 4-8 Math program. Surprisingly, individuals in the 4-8 Math training program who reported a letter grade of B had higher analytical scores than those who self-reported a letter grade of A in their math coursework.

A similar analysis was performed for scores on the impulsive-disposition measure. There was a main effect for training program ($F(3,270) = 4.872$, $p = 0.003$, $\eta2 = 0.05$). Math majors had higher impulsive-disposition scores than did all other groups. There were no differences among the other groups. There was no main effect for self-reported grade and no interaction between self-reported grade and training program. In summary, these results seem to suggest that students with increased exposure to traditional math coursework are less analytical and more impulsive.

## Conclusion

The findings obtained in this study confirm the viability of using likelihood-to-act items to measure impulsive disposition and analytic disposition. Five out of eleven pairs of items have high inter-correlations and will be retained in the next version. The weaker items will be refined for the next version of the instrument. The reliability for the two subscales are 0.64 and 0.63. Our goal is to continue improving the instrument until a reliability of at least 0.75 is obtained.

Analytic-disposition items were found to be slightly less reliable than impulsive-disposition items due in large part to the former being typically less clear than the latter. The specific procedure or rule to which students are drawn can be stated explicitly in an impulsive-disposition item, but not in an analytic-disposition item. There is insufficient evidence in this study to support the claim that general items are not as reliable as specific item. Results from the 4-by-3 analysis of variance reveal an unexpected phenomenon. Students in more advanced but traditional math programs (i.e., B.S. program) were found to have lower analytic-disposition scores than those in the less advanced but reform-oriented mathematics programs (i.e., EC-4 program and 4-8 Generalists program). Future research is needed to account for this phenomenon.

One of the advantages of the likelihood-to-act survey is that it takes less time for students to complete than a mathematics test. Whereas students need to solve a problem in order to arrive at an answer choice in a test item, students only need to understand the problem statement and the action for consideration in a likelihood-to-act item to choose from a scale of 1 to 5 the likelihood level. Another advantage is that participants are less likely to feel threatened because the instrument, as a survey, is not perceived as an assessment of their mathematical knowledge.

However, like any survey, what participants say they will do may differ from what they actually do in a mathematics assessment or in a problem-solving situation. This raises the issue of the validity of the likelihood-to-act survey. Another limitation of the instrument is that an impulsive item is effective only if the students are familiar with the particular rule, formula or procedure that is mentioned in the item. For example, Item B will not be valid if it is administered to an elementary student who has not learned how to set up a proportion. Hence, the validity of a likelihood-to-act survey is limited to the group of students for which it is designed.

The likelihood-to-act items developed in this study were aimed at measuring impulsive disposition and analytic disposition. The idea of asking participants to indicate their likelihood to act may be extended to measure other dispositions such as waiting to be told what to do, relying on the teacher, consulting with peers, and so forth.

# STUDENTS' MENTAL MODELS FOR COMPARISON WORD PROBLEMS

Aaron D. Weinberg
Ithaca College
aweinberg@ithaca.edu

*Comparison word problems have proven to be difficult for students to solve. Previous studies investigated students' solution strategies and described the mental models they used while working on these problems, although subsequent studies questioned the accuracy of some of these models. This study investigates the solution strategies that 210 undergraduate students used as they solved comparison problems. It also uses interviews with 27 students to describe the mental models that tend to lead to correct solutions and explores the role that equality plays in these models.*

## Introduction

Thirty years ago, Kaput and Clement (1979) noted that undergraduate students had difficulty solving the following problem:

> Write an equation using the variables *S* and *P* to represent the following statement: 'There are six times as many students as professors at this university. Use *S* for the number of students and *P* for the number of professors" (p. 288).

Frequently, college students wrote $6S = P$ as the solution instead of $S = 6P$, an example of a *reversal error*. Students had even more difficulty solving problems in which both coefficients in the algebraic expression were not 1. Furthermore, the reversal error was prevalent not only when students were translating words into an equation, but also when they constructed an equation based on a diagram or table of values.

We will refer to problems in which students are asked to translate these types of relational statements as *SP-type* problems. These can be seen as an extension of a class of word problems called *compare problems*, which have been classified (e.g. Riley, Greeno & Heller, 1983) and studied from a cognitive perspective; while *SP-type* problems involve writing an equation, compare problems involve computing a value.

In a pilot study, Weinberg (2007) found that students who were successful at solving SP-type problems seemed to use several strategies that had not been previously reported. The pilot data suggested that students' strategies depended on the specific task they were asked to complete and were associated with their conceptions of equality. The goal of the study reported here is to elaborate on the results from the pilot study and to describe students' problem-solving strategies and mental models as they solve SP-type problems.

## Theoretical Perspectives

Several researchers have attempted to understand why compare problems are so difficult for students. Lewis and Mayer (1987) describe a "consistency hypothesis," which posits that students' approach to solving problems is affected by the word order of the problem. Several researchers (e.g. Verschaffel, 1994) have verified that students have more difficulty and are more prone to make reversal errors when the problem is posed in a way similar to the language used in

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

most SP-type problems.

Clement (1982) interviewed students as they solved SP-type problems and described three strategies/mental models. Some students appeared to syntactically translate the words into symbols, matching symbols to the order of the words. Another group of students appeared to think of the letter as a label (e.g. *S* stands for "students") and the coefficient as an adjective describing the number of objects. The third group of students viewed the multiplication as a "hypothetical operation," operating on the two variable quantities to make them equal to each other. Other researchers (e.g. Hegarty, Mayer & Monk, 1995) have described a *direct translation* approach and a *problem model* approach, with the former corresponding to Clement's syntactic model and the latter describing strategies in which the students formed a meaningful mental model. MacGregor and Stacey (1993) cast doubt on Clement's descriptions, concluding that using a letter as a label was a "post hoc explanation of an equation arising from a model formed without conscious intervention" (p. 230). In addition, they provided data that appeared to refute the hypothesis that students frequently used direct translation, proposing that all students were constructing some kind of mental model. They echoed Rosnick and Clement's (1980) suggestion that students' conceptions of equality may also play a role in the way they solve SP-type problems, although no subsequent research has explicitly addressed this perspective.

Several researchers have described the problem-solving process as involving multiple steps. For example, English and Halford (1995) describe three steps: constructing a problem-text model, a problem-situation model, and a mathematical model. In order to describe mental models and ideas of equality, this study focuses on students' problem-situation models (a student's mental representation of the situation) and the interaction with their corresponding mathematical models.

Previous research has suggested that a problem's word order affects students' responses. Similarly, MacGregor and Stacey (1993) noted that students construct mental models when words are ordered in a variety of ways in the problem. Although the present study does not focus on the problem-text model, it uses word problems in which the word order both matches and fails to match the order of the symbols in the corresponding algebraic representation.

Word problems are situated in a particular task, and different activities involving the same problem situation may cause students to use different strategies and form different mental models. While students are prone to making reversal errors when writing equations, it is possible that their underlying mental models may still allow them to complete other mathematical tasks. Consequently, this study presents word problem situations using three common activities: writing an equation, writing a function, and computing a value.

In order to investigate students' conceptions of equality, the study targets three misuses of the equals sign: the idea that equality is directional (e.g. not recognizing that factoring is equivalent to the distributive property), "run-on" equality (i.e. using the equals sign to connect a string of computations), and the equals sign as a directive to perform an operation (rather than indicating an equivalence).

## Research Questions

1. Are students more successful and less prone to making reversal errors on SP-type word problems when the specific task varies?
2. When solving SP-type word problems, do students' strategies vary depending on the specific task and the number of coefficients? Do students use these strategies consistently

across multiple problems or formats?
3. What strategies do students use *successfully* on each kind of task and problem, and what are the underlying mental models upon which these strategies are based?
4. Are students' conceptions of equality and the equals sign related to either their success on comparison problems or the strategies they use to solve them?

## Methodology

Students in nine sections of first- and second-semester Calculus classes ($n$ = 210) at a northeastern comprehensive college completed a written assessment with four word problems and ten equality problems.

Two of the word problems involved situations that could be described by an algebraic expression with one coefficient that isn't 1 (e.g. $6p = s$) while the others required two coefficients (e.g. $3p = 4c$); one of the latter situations was presented in a diagram rather than words. In one of the *1-coefficient* problems, the sentence described the coefficient before it described the two variable quantities, while in the other the coefficient was described between the quantities; this was done in order to increase the consistency between the word ordering and algebraic representation. Students were randomly assigned one of three formats for each problem: writing an equation to represent the statement (*R*-format), writing an equation that allows them to predict the value of one quantity if they knew the value of the other (*F*-format), or computing the value of one quantity if they knew the value of the other (*V*-format).

The ten equality problems presented students with equations and asked them to decide whether they were correct. Four of the equations were "run-on" expressions (e.g. 2+3 = 5+2 = 7), with two incorporating derivatives and two using arithmetic. Two of the equations expressed relationships that could be seen as "backwards" (e.g., $ac+ab = a(b+c)$), one equated an expression with an integer multiple of itself (i.e., $2x+12 = x+6$), and the remaining equations served as "filler" problems.

All students were invited to participate in an open-ended interview. Fifty-seven students volunteered, and 27 students were selected in random order; the interviews were videotaped and transcribed. In the interview, each student was asked to explain their reasoning on each of the problems. If students had originally seen an *R*- or *F*-format problem, they were asked to compute a value; students who had originally seen a *V*-format problem were asked to create an equation. If a student found the correct equation quickly, they were told that other students had arrived at a different answer and were presented with an equation that incorporated a reversal error.

## Results

Students' performance by format is shown in

Table ***2***. Students were more likely to find a correct value than write a correct equation or a function ($p = 8.58 \times 10^{-42}$) and were more likely to write a correct function than a correct equation ($p$ = .0076). Similarly, students were less likely to make a reversal error when finding a value than when writing an equation or a function ($p = 6.11 \times 10^{-22}$), although were not more likely to make this error on an *R*-form than an *F*-form ($p$ = .099). Students who had both a *V*-form and *R*- or *F*-form on their collection of problems (168 students) were more successful with the *V*-form problems: 69 of these students correctly computed a value but were unable to write an equation or find a function.

*Table 2*
**Performance by Form**

| | *R*-format | *F*-format | *V*-format | Overall |
|---|---|---|---|---|
| Percent of responses that were correct | 36% | 47% | 90% | 58% |
| Percent of responses with a reversal error | 37% | 31% | <1% | 23% |

Students' performance by problem is shown in
Table ***3***. As in previous studies, students were more likely to produce a correct answer on the 1-*coefficient* problems than the 2-*coefficient* problems ($p = 2.17 \times 10^{-10}$). In contrast to previous studies, students were *not* more likely to make reversal errors on 2-*coefficient* problems ($p = .08$). However, 8% of students' responses on the 2-*coefficient* problems were in an additive form with the coefficients paired with the incorrect variables (e.g. $4p+3c$), which may account for some of this difference.

*Table 3*
**Performance by Problem-Type**

| | 1-*coefficient* | 2-*coefficient* | Overall |
|---|---|---|---|
| Percent of responses that were correct | 69% | 48% | 58% |
| Percent of responses with a reversal error | 26% | 21% | 23% |

The strategies students used varied widely between the four problems and the three forms. While a complete discussion of the ways students used each strategy is beyond the scope of this paper, four strategies stood out for being associated with correct answers or suggesting previously undocumented mental models: *ratio, proportion, stepwise,* and *functional*.

*Ratio*

An answer was coded as a *ratio* if it only consisted of a formal ratio (e.g., $3c$:$4p$) or a fraction; typically if the ratio symbol were to be replaced with an equals sign, the student would have made a reversal error. This strategy was used in 24 responses, 21 of which were from an *R*-form, and 23 of which were 2-*coefficient* problems. In several interviews, students who had made a reversal error when writing an equation acknowledged that they were using the equals sign to represent a ratio, suggesting they were using the equals sign as indicating a comparison:

Interviewer: Okay. So then this [points to $3t = 5s$]—was this an equals sign or a ratio sign?

Student: This should be a ratio [writes a colon over the equals sign]—three trucks for every five sedans, 15 trucks for every 25 sedans.

*Proportion*

An answer was coded as a *proportion* if the student set up an explicit proportion (e.g. $c/3 = p/4$). Students used this strategy to solve 82 out of the 840 word problems. Most of these responses occurred when students were computing values (64 problems) and on the 2-*coefficient* problems (67 problems). This was a highly effective strategy, leading to correct answers on 95% of the problems with which it was used.

In interviews, proportional strategies suggested a mental model of *systematic comparison*. That is, the student used the colon (or equals sign) to show that two groups of objects were connected, and that changing one of the groups resulted in a corresponding change in the other group. The student from the previous example above explained this reasoning:

Student: I set *t* equal to trucks then *s* equals to sedans, then it says 3 times, or there are three trucks, 3*t*, for every five sedans, 5*s*. [points to 3*t* = 5*s*].

Interviewer: Okay, so what if there were, let's say, 15 trucks. How many sedans should there be?

Student: Um... that's three times five, five times five [writes x5 below the 3*t* and the 5*s*] so that would be 25? [writes 15t = 25s]

Interviewer: Okay, so 25 sedans? I see... and so—you plugged the 15 in here, and did three times 15? [points to 3*t* = 5*s*]

Student: Three times five. You said there were 15 trucks?

Interviewer: Yeah

Student: So you multiply that times five [points to 3*t*] and that times five [points to 5*s*] because you're doing the same... it's by the same amount you're multiplying this by.

*Stepwise*

An answer was coded as *stepwise* if a student performed two sequential arithmetic operations to produce an answer. This typically involved partitioning a group of objects into smaller equal-sized sub-groups. For example, here is one student's explanation for this strategy:

> What I wanted to do first is find the number of groups of five sedans, and divide that, or get that out of the total. So I divided [165] by five and got 33 groups of five in 165 cars. So if there's 33 groups of five sedans, and then three trucks for every five sedans, I got three times the 33 groups of five to get 99 trucks.

Out of the 840 word problems students solved, 56 were solved using this strategy. Most of these responses occurred when students were computing values (53 problems), and all were used on the 2-*coefficient* problems. As with the *proportional* strategy, the *stepwise* strategy also led to correct answers on 95% of the problems on which it was used.

In interviews, the stepwise strategy suggested a mental model of *partitioning and substituting*, which involves three mental steps. Students described partitioning a group of objects into smaller, equal-sized groups by one ratio term, reconceptualizing the group as a scaling constant, and then reversing the partitioning by multiplying the scaling constant by the other ratio term.

*Functional*

While the *stepwise* strategy involved transforming one quantity into another via two steps, an answer was coded as *functional* if the student transformed one variable quantity into another in a single step:

Student: Well... or would it be... three-fourths? Three-fourths the cows as there are pigs, so... yeah…

Interviewer: So you're saying this [4/3 $p = c$] might be three-fourths instead of four over three?

Student: Yeah, I think three-fourths, just cause there's four pigs, so you'd be four times three-fourths equals the three cows, so it would be... [writes ¾ $p = c$].

Although students used this strategy on all three forms, they used it most frequently when computing a value (75 out of 180 *functional* responses); they used it slightly more frequently on the 1-*coefficient* problems than the 2-*coefficient* problems (104 times vs. 76 times). In interviews, the *functional* strategy suggested a mental model of *transforming*. In contrast to manipulating two quantities so that they are equal in number (a strategy that Clement (1982) refers to as *operational*), the student typically described changing one quantity into another, sometimes describing a transformation of the actual objects (such as cows or pigs) themselves.

It is possible that students who used a single-step transformation in their written work were first writing an equation (such as $3p = 4c$) and then simply "pushing symbols" (yielding $c = ¾ p$; such written responses were coded as *functional-translation*). However, students were significantly more likely to make a reversal error on a *functional-translation* response than a *functional* response ($p = 1.2 \times 10^{-4}$), which suggests a different underlying mental model.

The *proportion*, *stepwise*, and *functional* strategies were the only three strategies that students tended to use repeatedly on written problems (primarily on the 2-*coefficient* problems). This suggests that these strategies may be based on a relatively well-defined mental model that these students viewed as useful. Other students used a wide variety of strategies, frequently using different strategies on problems that were presented in the same format or same number of coefficients. For example, only 57 out of 210 students used the same strategy on the two 1-*coefficient* problems. Out of the 210 students, 68 saw these problems in the same format, and only 30 used the same strategy on both.

*Equations*

Students routinely misidentified two types of expressions as correct: those involving several computations connected by equals signs ("run-on" expressions) and an equation in which the quantity on one side was a multiple of the quantity on the other side (see Table ***4***).

***Table 4***
**Student Responses to Equations**

| Expression | Percent identifying it as correct |
|---|---|
| $f(x) = 2x^3 = f'(x) = 6x^2$ | 88% |
| $g(x) = x^2 = g'(x) = 2x$ | 83% |
| $2 + 3 = 5 + 2 = 7$ | 66% |
| $5 \times 4 = 20 + 3 = 23$ | 36% |
| $2x + 12 = 6 + x$ | 37% |

In the interviews, several students reversed their decision, identifying some of the run-on expressions as incorrect. However, most of these students did not identify *all* of the expressions as incorrect; frequently students would identify all but the first derivative expression as incorrect. These students typically identified the two derivative expressions as "the power rule" and read the arithmetic expressions from left to right, simply asserting that they were correct. Several students expressed the idea that the run-on equations could be both true and untrue:

Student: If you just take it five doesn't equal seven and seven, but if you want to say two plus three equals five, plus two equals seven, take that separately, that's true, but I was just looking at it as five doesn't equal seven...

Interviewer: So in some readings it might be true, and in others...

Student: Yeah.

Students gave multiple reasons for interpreting the fifth expression as correct. Some students interpreted it as a problem to be solved instead of a statement indicating that the two sides were equal. For example, one student noted: "That's just a problem you would solve. It's not really right or wrong, it depends what *x* is.” Other students suggested that you could operate on one side to obtain the other, although you might need to take the multiplication into account. For example, one student asserted that the expression was correct because, “If I take the 2 out, then *x* plus 6 equals 6 plus *x*.”

Surprisingly, students who said that one of the run-on expressions was correct were not more likely to say that any of the other four were correct, suggesting that students may view the equals sign as serving different roles in each of these four expressions. Similarly, there was no association between students’ responses on the fifth expression and their answers on the four run-on expressions.

Students’ responses on the equality problems were compared with their performance on the word problems. There was a significant relationship between getting the run-on arithmetic questions correct and getting two of the word problems correct. However, there were no other significant associations, and there were no associations between performance on the equality questions and the word problems.

Taken together, these results suggest that students don’t have a single conception of equality or the equals sign. Rather, they view the equals sign as representing a variety of relationships and operations. Because their conception of equality is flexible and varies depending on the situation, there is no association between a specific conception (such as a connector for related mathematical expressions) and their response on another problem.

## Discussion

The results of this study provide additional support for the solution strategies previously suggested by Weinberg (2007): *proportional*, *stepwise*, and *functional*. In addition to providing quantitative evidence for the prevalence of these strategies, the study describes new mental models that appear to underlie the strategies. The study also explores the potential connection between problem solving and specific conceptions of equality as well as describing the ways students use the equals sign as part of their mental models.

The *proportional* and *stepwise* strategies led to successful solutions and prevented reversal errors. Both of these strategies involve forms of proportional reasoning. This suggests that it may be beneficial to further investigate students’ conceptions of proportions at the undergraduate level and to attend to the continued development of this type of reasoning.

In addition to describing these strategies, the results suggest several mental models that students may use when working on comparison word problems: *systematic comparison*, *partitioning and substituting*, and *transforming*. These add to Clement’s (1982) description of *operative* reasoning, in which students manipulate both sides of the equals sign to create a true equality. The data suggest that these models may be robust for some students in that they (successfully) used them on multiple problems.

There appeared to be no connection between problem solving strategies and the three conceptions of equality used in the equations on the written assessment. However, equality and the equals sign play a different role in each of these models. In the *transforming* model, it represents an action (much like the role of the equals button on a calculator). In the *partitioning* model, it doesn’t play a significant role, as it is not usually written as part of the solution. In the *operative* model, the equals sign represents a true equality. In contrast, the equals sign represents a comparison in the *proportional model*. However, this comparison is systematic and supports correct computations.

In addition, these models support Clement's (1982) conjecture that students were using literal symbols (i.e. letter representations of variables) as labels instead of true quantities; thus "6*s*" may represent "six students" instead of "six times the quantity *s*". Clement hypothesized that students were using the equals sign as an equivalence relationship. However, when we observe students working within their self-constructed representational systems, we see that the label conception of literal symbols can support productive solution strategies by using alternate interpretations of the equals sign.

While these conceptions of equality or literal symbols may not match the standard way mathematicians use them, difficulties with *SP-type* problems may originate when students attempt to use properties of their (non-standard) representational systems simultaneously with properties of our standard system. For example, they may use the literal symbol as a label and be able to compute a correct answer, but they arrive at erroneous conclusions if they attempt to substitute a value for the symbol or interpret the two sides of the equals sign as being equivalent.

In addition to helping students develop an understanding of proportional reasoning, this study suggests that we should help students understand the standard meaning of algebraic notation and reconcile their mental models and use of symbols with this notation. While there have been numerous studies of students' conceptions of these ideas at the K-12 level, it is important to further develop our understanding of undergraduate students' conceptions so that we can help them build robust conceptions of algebra and become successful problem solvers.

*This study investigated how students with mathematics learning disabilities (MD) or at-risk for MD developed their multiplicative reasoning skills from intuitive strategies to advanced strategies through a teaching experiment. The participants consisted of two fifth graders with MD and one at-risk. A micro-genetic approach with a single subject design was used. Investigators coded and analyzed five strategies children used. Results showed that the participants had fewer strategies than normal-achieving students, but they improved their performance throughout the teaching experiment. The participants increased their use of double counting and direct retrieval, and decreased their use of unitary counting during the intervention.*

Approximately 5% to 8% of school aged children have math disabilities (MD), as defined by poor performance in class and poor standardized test scores (Geary, 1990). Individual variability is one of the most striking features of children's reasoning (Siegler, 2007). Low achieving students usually have fewer strategies than high achieving students, and use less advanced strategies more frequently than high achieving peers on a variety of reasoning tasks (Siegler, 2007). The purpose of this paper is to explore how students with MD develop their strategies of multiplicative reasoning through a teaching experiment.

## Framework

Studies on children's strategic development help people understand how students with MD gradually fall behind their peers by comparing the strategic development of children with and without MD (Geary, 1990). While developing additive reasoning, for example, children normally progress from "count all" (i.e., they simply count the two addends from 1) to "counting on" (i.e., they start counting from the first addend) and "count large" (i.e., they count from the larger addend), and eventually to verbal retrieval (Siegler & Shrager, 1984); however, although both students with and without MD equivalently develop various counting strategies at first and second grades, only students with MD continue to have difficulty in shifting to retrieving correct answers after third grade (Geary, 1990; Geary & Brown, 1991).

However, children's strategic development for multiplication is still much less understood than for addition (Lemaire & Sielger, 1985; Kouba, 1989), especially for students with MD. In multiplicative reasoning, one composite unit is distributed across the other, and children need to be able to coordinate the two quantities (Steffe, 1994). Although normal achieving children in kindergarten can solve some multiplicative problems by directly modeling the problem context and counting all the items one by one (Downton, 2008; Kouba, 1989; Mulligan & Mitchelmore, 1997), it takes time for them to establish a real conceptual understanding of multiplicative reasoning, which is an invariant relationship between two quantities (Piaget, 1965; Vergnaud, 1983).

Early studies (Anghileri, 1989; Brown, 1992; Kouba, 1989; Mulligan & Mitchelmore, 1997; Steffe, 1988) have identified a variety of strategies normal-achieving students use for multiplicative reasoning. These studies have also provided evidence that children's solution strategies begin generally with direct modeling and unitary counting; progress to skip counting, double counting, repeated addition or subtraction; and then, to the use of known multiplication or division facts (Downton, 2008). The general strategic developmental pattern is demonstrated in Figure 1 according to Kouba's data.

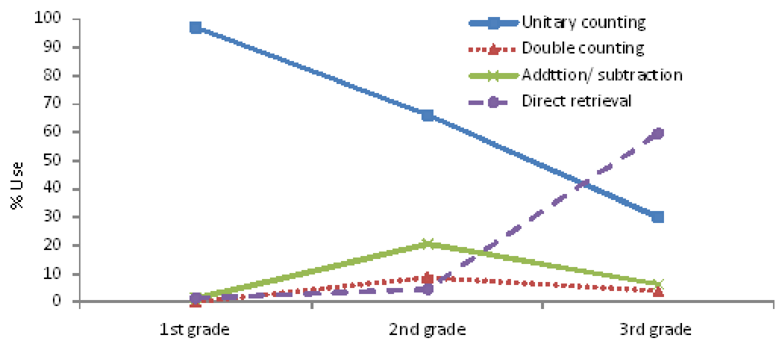

*Figure 1*. Normal achieving students' multiplicative strategic development (Kouba, 1989).

Direct representation and skip counting are two strategies of unitary counting, as they address only one number/counting sequence. Direct representation is at the most basic level (Anghileri, 1989). Kouba (1989) described direct representation as an activity where "children used physical materials to model the problem and some form of one-by-one counting in calculating the answer" (p.152, Kouba). Skip counting is a strategy in which children count by multiples, such as counting "five, ten, fifteen, twenty, twenty five, thirty" for solving "six groups of five" (Kouba). However, skip counting does not suggest a child is able to coordinates the two quantities by tracking *two counting sequences*. An indicator that students are not coordinating the two quantities is that children often do not know where to stop counting (Kouba).

Children's shifting to double counting is a milestone of their development of multiplicative reasoning. Double counting indicates the transition from a unitary counting stage to a binary counting stage (Vergnaud, 1983), where children explicitly keep track of two quantities while counting two number sequences. For example, double counting occurs when a child count "1, 2, 3, 4, 5" with one hand, then counts "1" with the second hand; and then the child continues count "6, 7, 8, 9, 10" with the first hand, then counts "2" with the second hand. Double counting is "an advance over the more basic direct representation because it requires more abstract processing and involves integrating two counting sequences" (p.152, Kouba, 1989). However, no study has investigated whether or not children with MD have double counting strategies.

Afterwards, additive or subtractive strategy occurs when the child exhibits use of repeated addition or subtraction to solve a problem (Kouba, 1989); for example, a child clearly states:

"three plus three plus three plus three" to solve "three times four." And eventually, normal achieving students shift to recalled number facts, which is the highest strategy people use. Kouba explained that this strategy is being used when "the child obtained the answer by remembering the appropriate multiplication or division combination" (p.153, Kouba). Unfortunately, little research has explored if children with MD have the same problems in direct retrieval in multiplication as in addition.

Little is known about how students with MD make their transition from less advanced strategies to advanced strategies in multiplicative reasoning. As such, the purpose of this paper was to explore how a teaching experiment effected on the multiplicative reasoning strategic development for students with MD. Specifically, (1) what strategies students with MD or at-risk used in pretests; (2) did the teaching experiment improve students' performance in solving multiplicative problems; (3) how did strategic development occur during the teaching experiment?

## Method

*Design*

Micro-genetic studies often employ single subject designs (Siegler, 2006). An adapted multiple probe design (Horner & Baer, 1978) across participants was employed in this study to establish a functional relationship between the teaching experiment and students' performance and strategic changes. Specifically, when a stable baseline was observed for one student, treatment was introduced. When improvement for Child A was observed, Child B was introduced to treatment. And when improvement for Child B was observed, Child C was introduced to treatment. In this design, replication of treatment effects is demonstrated if changes in performance occur only when treatment is introduced.

The independent variable was the sessions (the pretests and the teaching experiment). The primary dependent variable was students' strategy use across the sessions. Students' performance in solving multiplicative reasoning problems was also assessed before and during the last session of the teaching experiment.

*Procedure*

This study was conducted within the larger context of the NSF-funded, *Nurturing Multiplicative Reasoning in Students with Learning Disabilities* project (Xin, Si, & Tzur, 2008). Two fifth grade students with MD (Chad and Tina) and a student at-risk for MD (Megan) from an urban elementary school participated in this study. The pretest sessions involved five to six multiplicative problems such as "A platoon must have exactly 7 spaceships. The player received 21 spaceships to begin the first game. How many full platoons can be made?"

The third author, a professor in math education conducted the teaching experiment to the children. The activity was "Towers of Cubes." The goal was for students to figure out the relationships between three quantities: the number of towers, the number of cubes in each tower, and the total number of cubes. Tasks involved multiplicative, partitive, and quotitive division questions such as "Please go and bring me 5 towers of 6 cubes. How many cubes do you have in all?" and "I have 12 cubes in 3 towers. How many cubes are there in each tower?" Although they varied from session to session based on an on-going assessment of students' performance, all tasks shared the common nature of multiplicative reasoning. The instructor explicitly demonstrated double counting to students during the teaching experiment. During the last session of the teaching experiment, the instructor asked students to solve questions similar to those in the pretests, such as “I have 30 cookies in 6 boxes. How many cookies do I have in each box?” Each session lasted 30-50 minutes. The discourse of the teaching experiment was videotaped and transcribed.

*Data Coding & Analysis*

Students’ strategies were coded according to a coding scheme investigators developed based on existing theoretical and empirical literature on solving multiplicative problems and the nature of students’ activities. Five general types of strategies were involved: unitary counting strategies, repetitive addition or subtraction, double counting, direct retrieval, and DK (don’t know). Inter-rater reliability was checked by a team of graduate students who were unaware of the purpose of this study recoding 33% of the transcripts. The inter-rater reliability was 92%.

Graphical presentation of data is important for micro-genetic studies (Sielger, 2006). By visually analyzing data, five dimensions of change were investigated: (1) source of change (what leads children to adopt new strategies); (2) path of change (the sequence of strategies children use while gaining competence); (3) rate of change (the amount of time or experience from the initial use of a strategy to consistent use of it); (4) breadth of change (how widely the new strategy is generalized to other problems); as well as (5) the variability of change (differences among children in the previous four dimensions).

## Results

*Students’ Multiplicative Problem Solving Performance*

All the participants increased their percent of accuracy in solving multiplicative problems from baseline to the last session of the intervention. Specifically, Chad improved his percentage correct from 44% on average of the pretests to 83.33 % during the last session of the teaching experiment; Megan improved her percentage correct from 55% to 87.5 %; and Tina improved from 40 % to 83.33%.

*Students’ Strategic Development*

Figure 2 represented the three students’ multiplicative strategies used during baseline and intervention. Generally, participants increased the types of strategies they used, and they also increased the frequency of advanced strategies used during intervention.

*Baseline.* The baseline data across three students consistently demonstrated the students with MD used very few strategies, and the most frequently used strategy was unitary counting. Chad only used unitary counting strategies for 91.93% of the trials during pretest sessions, and he replied with not knowing how to solve the problem or what strategy to use for 8.19% of all trials. Similarly, unitary counting was the dominant strategy Tina used during the pretest sessions (77.77%); Tina also used repetitive addition strategy (11.11%) and of direct retrieval strategy (11.11%). Megan used more types of strategies than Tina and Chad, but unitary counting was also the dominant strategy for her. She used unitary counting strategies for 41.67% of all trials; she also used repeated addition/subtraction strategies (33.33%), direct retrieval strategies (16.67%), and replied with “don’t know” for 8.33% of the problems. Double counting strategy was not found in any of the three students. Compared to Figure 1 for normal-achieving students (Kouba, 1989), the participants had fewer strategies and more heavily rely on unitary counting.

*Teaching Experiment.* The data from the teaching experiment suggested that students increased the variety of strategies they used; in particular, they increasingly used more advanced strategies. Specifically, double counting strategies appeared in the first session of the teaching experiment for Chad (14.28%) and Megan (7.14%), and in the third session for Tina with

40.91%. Double counting strategies consistently increased and became the most frequently used strategies in the last session across the three students (50% for Megan, 60% for Chad, and 33% for Tina). The appearance and increasing frequency of double counting strategies indicated that children explicitly mastered how to coordinate two quantities in multiplicative reasoning.

In addition, all three children increased their frequency of the direct retrieval strategy used. Chad did not use this strategy during the pretests, but he began to employ it during the second session in teaching experiment (11.11%) and used it with 20% of the tasks during the last session. Similarly, Megan's usage of the direct retrieval strategy increased to 21.43% in the last session of intervention and Tina increased to 16.67%.

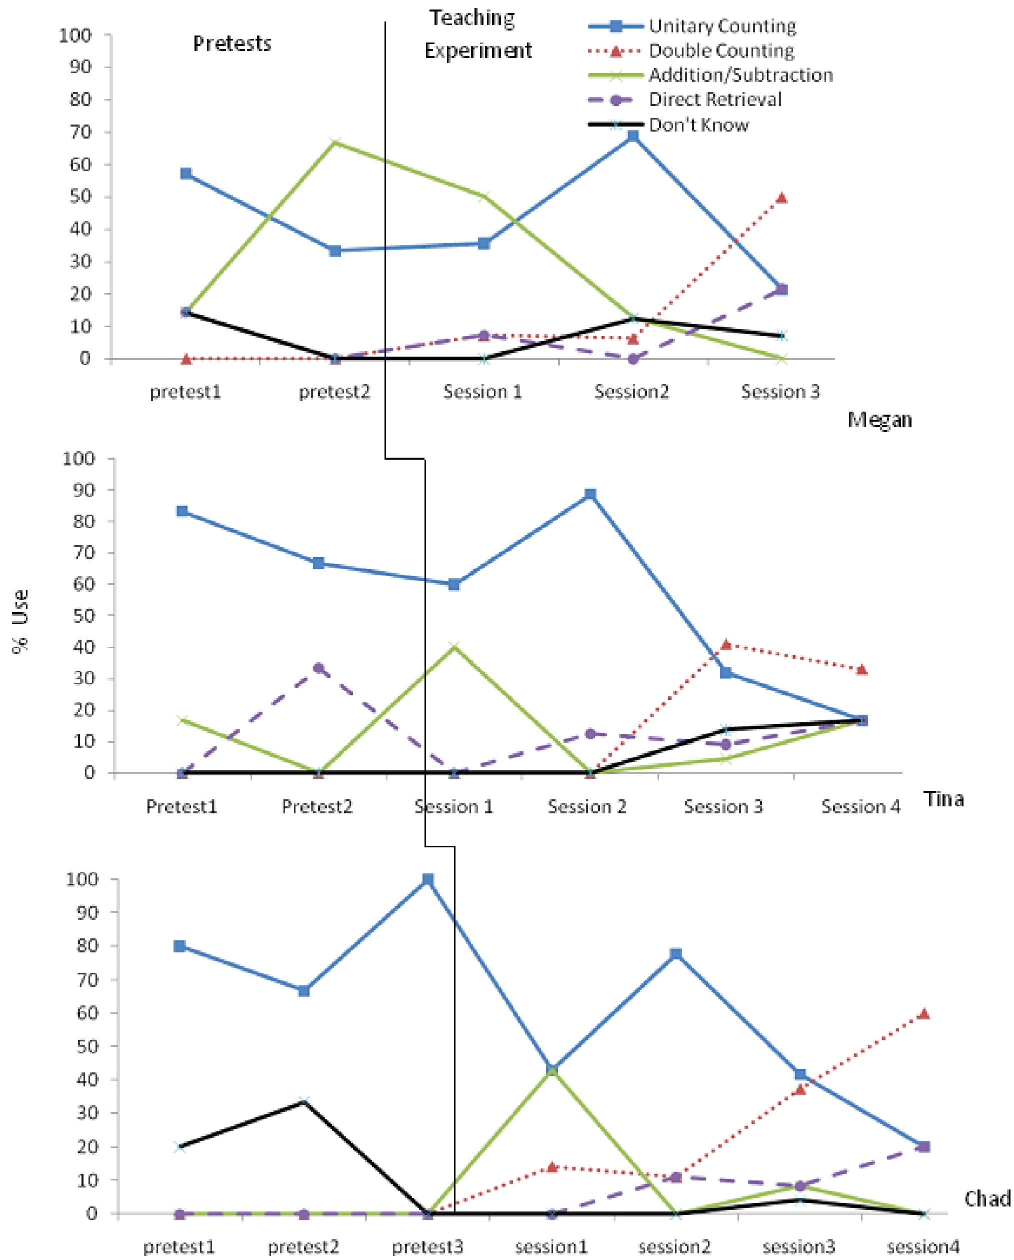

*Figure 2.* Three participants' multiplicative strategic development

On the other hand, the graph suggested that the participants decreased their frequency of using the unitary counting strategies. Chad consistently decreased from 91.93% on the pretest sessions to 20% during the last session. Tina and Megan increased their frequencies of using unitary counting strategies at the beginning of the intervention (Tina increased to 90% in Session 2, Megan increased to 68.75% in Session 2), but decreased the frequency of their usage of unitary counting strategies during the later sessions of the intervention (Tina decreased to 16.67% and Megan decreased to 21.42% in the last session). Similarly, the students also decreased their frequency of using repeated addition/subtraction strategy during the teaching experiment.

## Discussion

The purpose of this study was to explore how students with MD or at risk for failure in mathematics differed from normal achieving students in multiplicative strategy choice, and how these students shift from intuitive strategies to multiplicative reasoning strategies while receiving instruction to improve their multiplicative reasoning. Based on the limited data from the three students, the results suggested the students with MD and those at risk seemed to have fewer strategies and their strategies were less advanced than normal achieving students on the pretest sessions. Nevertheless, after the intervention, students improved their percentage correct in solving multiplicative problems; the frequencies of strategies the participants used changed as well. Five dimensions of change were discussed below according to the framework of micro-genetic studies (Siegler, 2006).

Regarding the *path of change*, the three participants demonstrated the similar pattern with which normal achieving students go through during the multiplicative reasoning strategic development; that is, beginning generally with counting by ones; then, transitioning to double counting, repeated addition or subtraction; and then, to recall of math facts. A short-term increase of their use of unitary counting was found before the participants consistently faded it out. Double counting increased robustly; direct retrieval also increased on a limited basis.

Specifically, unitary counting was the most dominant strategy of all three participants during the baseline sessions (97.93% for Chad, 71.77% for Tina, and 41.67% for Megan). They did not use double counting at all, and used direct retrieval very rarely. These results suggest that the three participants could only keep track of one number sequence while in the fifth grade and that these students did not use double counting to keep track of two number sequences. Whereas early studies (Geary, 1990; Geary & Brown, 1991) found that the major problem for children with MD in additive reasoning was direct retrieval, the current results indicated that the participants with MD seem to have problems both in conceptual understanding and retrieval in multiplicative reasoning.

The baseline data indicated a significant gap between students with and without MD. According to the data in Kouba’s (1989) study, normal-achieving students dominantly use unitary counting strategies at only grade one (97.23%); while they gradually decrease their frequency of employing the unitary counting to 66.16% of all strategies used at grade two and 30.11% at the grade three (Figure 1). The pretest data in this study showed that the three participants used an extremely high percentage of unitary counting strategies. It seemed like that Chad was equivalent to the first-grade level normal students in strategic development; Tina seemed to be equivalent to the second-grade level and Megan was equivalent to the third-grade level. The differential strategy choice may explain why students with MD or at-risk for failure in mathematics have lower performance in solving multiplicative problems than normal achieving students.

The appearance of double counting strategy is an indicator that children conceptually understand the nature of multiplicative reasoning. Children coordinate two quantities by keeping track of two number sequences with double counting. The three participants consistently increased their use of double counting throughout the teaching experiment (i.e., up to 50% for Megan, 60% for Chad, and 33% for Tina). It is noteworthy that normal-achieving students usually increase the frequency of using double counting to 8.74% at Grade 2 and then decrease the use to 3.98% at Grade 3 (Figure 1, Kouba, 1989). This study suggested that double counting appears to be especially useful for children with MD. The explicit demonstrations of keeping track of two quantities strengthened the students' conceptual understanding of multiplication and reduce their cognitive load when processing the problems. In addition, as the students with MD have difficulties in direct retrieving (Geary, 1990; Geary & Brown, 1991); double counting makes it especially suitable for them to explicitly demonstrate the coordination of two quantities, which is the core meaning of multiplication.

Although the three participants increased their use of direct retrieval strategy, they did not get to the level at which normal-achieving fifth grader students perform. Normal-achieving third graders use direct retrieval strategy for 59.66% of all trials (data from Kouba, 1989), but Chad, Megan and Tina only used direct retrieval strategy for 20%, 21.43% and 16.67% of the last session of intervention, respectively. The limited increase indicated that students with MD may need special interventions to help them shift from counting into verbal retrieval

For the *source of change*, an adapted multiple probe design across participants established a functional relationship between the teaching experiment and students' strategic development. Thus it is the "towers and cubes" activity that helps students with MD to adopt new strategies. This activity provides students with manipulatives to solve multiplicative problems. The teacher's demonstration of double counting seems to be effective in teaching students how to coordinate two number sequences, and it may explain the appearance of double counting strategy. During the teaching experiment, the instructor explicitly demonstrated the double counting in finding out the total number of cubes across a specific number of towers. The intervention also emphasized making distinctions between the unit of one (1's) (e.g., total number of cubes) and the composite unit (e.g., a tower of 6). In all, through the "cubes and towers" game, children seem to conceptually develop multiplicative reasoning.

As for the *rate of change*, the participants' use of double counting strategy increased saliently as soon as the occurrence of first use of this strategy during the teaching experiment. The participants' gaining of direct retrieval was slower than the change of double counting.

For the *breadth of change,* the participants could solve problems with various semantic structures; the students were also able to successfully associate the real life problem context in the last session with the multiplicative scheme they learned in the "cubes and towers" problems, and use the advanced strategies (e.g., double counting) to solve problems within new contexts.

And for the *variability of change,* the participants demonstrated some differential patterns from normal achieving students regarding strategic developmental level and transition pattern. Results also demonstrated individual differences among the three participants.

In sum, this study revealed how three students with MD or at-risk for MD in mathematics progress in strategic choices during multiplicative reasoning instruction. Due to the limited generalization of single subject design, a group design study is underway.

# PRECALCULUS STUDENT UNDERSTANDINGS OF FUNCTION COMPOSITION

Stacey A. Bowling
Arizona State University
stacey.bowling@asu.edu

*Existing research on function composition has focused on students' ability to solve function composition problems relative to the student's conception of function. However, little research has examined the mental actions and understandings needed to understand and use function composition meaningfully when solving novel problems. This research addresses this gap, presenting a conceptual analysis of a typical function composition problem, along with the results of a study that investigated three precalculus students' understanding and ability to use function composition to solve novel problems.*

## Background

Educational policymakers often agree on the importance of function composition in high school mathematics, advocating that students in grades 9 through 12 should be able to "understand and perform transformations such as arithmetically combining, composing, and inverting commonly used functions" (NCTM, 1989; NCTM, 2000). However, despite agreement on the importance and desirability of students building a robust understanding of, and fluency using, function composition, little research has addressed students' understanding of this idea. This study begins to close this research gap, analyzing student products and behaviors from task-based clinical interviews in an attempt to gain insights into students' understanding of and ability to use function composition in novel contexts.

Engelke, Oehrtman, & Carlson (2005) found that, in the case of composition problems that require students to find the value of a composition of two functions at a point, most students in their study were able to do so, provided the functions in question were defined algebraically. Engelke *et al.* (2005) conjectured that the relatively high levels of success in such problems were related to the fact that correctly solving these problems required only an action view of function (Dubinski & Harel, 1992). They further conjectured that the much lower student success rate (less than 50%) for problems presented using other representations (tabular, graphical, context) was the result of such representations requiring students to engage in process-level thinking about functions. In general, Engelke *et al.* found that students were most successful in solving function composition problems that could be solved using memorized algebraic procedures.

Carlson, Oehrtman, & Engelke (in review) describe the importance of covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002) and a process view of function in understanding function composition. For a student with an action view of functions, "composition is substituting a formula or expression for *x*." This is quite different from the mathematical reality of a student with a process view of function, for whom "composition is a *coordination* of two (or more) input-output processes; input is processed by one function and its output is processed by a second function."

The present study is part of a larger study that is investigating how precalculus students know and learn function composition, and the impact of students' quantitative reasoning, covariational reasoning, problem solving abilities, and understanding of function on their ability to use function composition to solve novel problems. This report describes three students' ability to use function composition to help them solve static and dynamic problems defined using contextual, algebraic, tabular, and graphical representations.

## Brief Conceptual Analysis of Function Composition

The theoretical perspective for this study emerged from conceptual analysis (von Glasersfeld, 1995; Thompson, 2000) of function composition problems. This approach serves to highlight the mental actions and ways of thinking that are propitious to a robust understanding of function composition. Consider the following problem:

> A rock is thrown into a pond, creating a circular ripple that travels outward from the point of impact at 9 cm/second. Express the area enclosed by the ripple as a function of the elapsed time since the rock hit the water.

To provide an ideal response to this problem, a student must perform a series of mental operations. First, the student must develop a mental image of the situation described in the problem. This mental image must then be made amenable to further mathematical activity. A key component of the process of reconceptualizing a problem in a way that makes it amenable to mathematical activity is what Thompson (1989) describes as *quantification*. This involves identifying an attribute of a situation, conceiving of that attribute in a way that admits a measurement process (which may or may not be explicit), and conceiving of the *quantity*, with appropriate units, that is the result of that measurement process. In this problem, the student must mentally construct quantities corresponding to the elapsed time since the rock hit the water, the radius of the circle formed by the ripple, and the area enclosed by the ripple. As a basis for quantification, the importance of the student's initial mental image of the problem cannot be overstated. The attributes that the student uses to create quantities are not attributes of a problem external to the student, but rather are attributes of the problem as it exists in the mind of the student.

A precalculus student attempting to solve this problem is likely to remember a formula for the area of a circle. As a result, a student's first attempt to write a formula for the area enclosed by the ripple is likely to be $A=\pi r^2$, where *A* represents the area enclosed by the ripple and *r* represents the radius of the circle formed by the ripple. However, the student has been asked to relate the area enclosed by the ripple with an elapsed time, rather than with a radius. A key to the student's advancement toward a solution is the realization that his goal is to relate area and elapsed time. To progress further toward a correct solution, the student must construct a relationship between elapsed time and the radius of the circle formed by the ripple, a relationship similar to $r=9t$, where *r* is the radius (in centimeters) of the circle formed by the ripple and *t* is the elapsed time (in seconds) since the rock hit the surface of the water.

Construction of the algebraic relationships $A=\pi r^2$ and $r=9t$ does not necessarily imply that the student has constructed a dynamic mental model of the problem situation. In fact the student might still possess only a static mental model; such a student might be able to answer a question like "What is the area of the circle 5 seconds after the rock hits the water?" while remaining unable to describe how the area of the circle varies as the elapsed time varies. The student may also still not be able to express a relationship between *A* and *t* using a single formula. The ability to describe how the area and elapsed time vary together requires that students reason about the values of two quantities and how they change in tandem, also referred to as *covariational reasoning* (Carlson, Jacobs, Coe, Larson, & Hsu, 2002).

The problem asked the student to relate the area of the circle and the elapsed time, and to use a *function* to express the relationship. To do so, the student must possess an understanding of the concept of function. Specifically, to provide an ideal solution to this problem, the student must possess a *process conception of function* (Dubinsky & Harel, 1992). A key notion in building a process view of function is that a function is something that accepts input values and produces output values. Prior to constructing the composite function $A = g(f(t))$, the student must conceive of the output of *f* as being a suitable input for *g*. Only then can the student think about "connecting together" the two functions he previously constructed. After the student has mentally connected the functions *f* and *g*, the next step in the "ideal solution" is to think of the composite function as a single function (say *h*). A student who has conceptualized the composite function, *h*, as a single function is able to imagine two processes. The student can imagine the covariation of time and radius, and the covariation of radius and area. He/she can imagine an amount of time being mapped to a radius and that resulting radius being mapped to an area. Typically the student speaks about time being converted to area through a series of two processes.

Certain composition problems present added complexities that warrant further discussion. For example, consider a problem that prompts students to "express the area of a circle as a function of its circumference." Many of the mental actions required for the student to solve this problem are similar to those discussed above. However, this problem incorporates an additional source of complexity: it requires the student to invert a function prior to composing two functions. Inversion is necessary because a student is likely to remember the formulas $A = \pi r^2$ and $C = 2\pi r$, where *A*, *r*, and *C* are the area, radius, and circumference of a circle, respectively. Written in this way, both formulas lend themselves to an interpretation of the radius as the input quantity, with area and circumference the output quantities. To conceive of a function that takes circumference as input and produces area as output, the student must first conceive of the inverse of the second relationship, before composing that inverse with the first formula to create a formula that gives area as a function of circumference.

## Methods and Setting

This study occurred in the context of a precalculus course at a large public university in the southwestern United States. The subjects of this study were three volunteers from a section of the precalculus course that emphasized quantitative reasoning and covariational reasoning. This study consisted of pre-interviews with each student, a single teaching session focused on function composition, and post-interviews. All interviews and the teaching session were videotaped, and all written student products were retained. The videotapes of all interviews and the teaching session were reviewed and transcribed. The transcripts were analyzed in an attempt to gain insights into what the students might have been thinking. Conceptual analysis (von Glasersfeld, 1995; Thompson, 2000) was used in an attempt to answer the question, "What mental actions in the person I'm observing would explain the behavior I seem to be observing?"

Clinical, semi-structured task-based interviews (Clement, 2000; Goldin, 2000) were a key source of data for this research. The pre-interview was designed to gain insights about student knowledge of function composition and ability to work novel function composition problems *before* participating in the teaching session. The interview included tasks related to functions defined by formulas, tables, and graphs.

The teaching session was designed to build on students' knowledge of functions. Students were presented with a problem in which they were asked to develop a function relating two quantities that were not trivial to relate directly. Through interactions with each other and with the instructor, I intended that students build a conception of linking two processes together to create a composite function, which could then be explored, allowing students to reconceptualize this composite function as a single function.

The final sections of the teaching session were intended to allow students to explore function composition using functions defined by tables and functions defined using graphs. The activities using functions defined by graphs included questions requiring students to consider the variation of the output of the composite function in response to changes over an interval of input values.

The post-interview was designed to gain insights about student knowledge of function composition and ability to work novel function composition problems *after* participating in the teaching session. As in the pre-interview, the interview tasks included functions defined by formulas, tables, and graphs. The post-interviews included activities that asked a student to reason about dynamic variation of output quantities in response to changes in the input quantity.

## Results from Pre-Interviews

In her pre-interview, Rachel did not make use of function composition to help her solve problems. For example, when asked to find the area of a square as a function of the perimeter, Rachel stated that she was "not that good at expressing things as functions yet", but that she knew how to find the area of a square. She eventually drew a square, labeled each side of the square as *x*, and wrote $p = 4x$. When asked about a formula for the area, she stated that it would be "*x* squared". However, even after probing, she was unable to construct a formula that related the area of a square with its perimeter.

Rachel was, however, able to meaningfully interpret function composition notation, despite claiming to have not seen it before and having been only briefly introduced to function notation. In a problem involving two functions defined using formulas, Rachel was able to find $g(h(2))$, by finding $h(2) = 5$ and substituting 5 as the input to *g*, but she did not spontaneously use input/output language. When asked to use input/output language to explain what she had done, she stated:

> To do this problem, I was given… I needed to find *g* of *h* of 2, so the input of $h(x) = 3x - 1$ is 2, so I would replace the *x* with 2 as the input, and then whatever I got would be the output, so 5 would be the output of the function *h* with the input of 2… um, and then basically once I got that, I was able to make the output of $h(2)$ the input of $g(x)$.

This pattern of reasoning appeared to continue when solving problems using other representations. When asked to use graphs of *f* and *g* to find $g(f(2))$, Rachel coordinated input and output values, first finding $f(2) = -2$, and then finding $g(-2) = 1$. As she explained it,

> OK, well I know this line is *f*, so to find $f(2)$ I would find 2 on the *x*-axis, which is right here, so I know that $f(2)$ has an output of -2. So now it's asking me to use the output of – $f(2)$ as the input to *g*. So for this line *g* right here, I would find the input -2, which is right here, so I know that $g(f(2))$ has an output of 1.

When questioned about how she was able to find output values that corresponded to given input values, Rachel indicated that she found the appropriate value on the *x*-axis, moving vertically until she intersected the graph of the function, and then moving horizontally until she intersected the *y*-axis to determine the appropriate output value. This suggested that Rachel understood graphs as coordinating values of input quantities with values of output quantities.

Rachel was also able to solve problems involving composition using two functions defined in a table. When asked how she determined which function she evaluated first, Rachel indicated that it was because it was the part "in parentheses", and clarified that she was using "order of operations" rules to make this decision.

The second student, Alicia, solved all of the problems in the interview, but she was often not able to articulate the input and output quantities of composite functions. For example, when asked to express the area of a square as a function of the perimeter, Alicia immediately wrote the equations $A = s^2$ and $P = 4s$. She then solved for *s* in the second equation, "used substitution" (her own words), and wrote $A = \left(\frac{P}{4}\right)^2$. Her solution to this problem did not use function notation, or the word *function*, or input/output language. When asked to write this relationship as a function, she wrote $A\left(\frac{P}{4}\right) = \left(\frac{P}{4}\right)^2$. Asked to explain why she had written this function with $\frac{P}{4}$ as the input, she stated this was because "to get the side by itself, I'd have to divide 4 into the perimeter". This suggests that Alicia was not thinking of a composite function but was still thinking of the function $A(s)$, where in this case *s* was replaced by an expression equivalent to *s*.

Even though she did not spontaneously use function composition in solving these problems, Alicia was able to make sense of problems that used function composition notation. For example, in a problem that required evaluation of composite functions defined by algebraic formulas, Alicia was able to quickly find the correct answer. Her explanation suggests that she solved this problem by thinking of $h(2)$ as the input to *g*: "This just means that you have to do $h(2)$ first, because $h(2)$ is the input to $g(x)$". When asked to explain why she chose to evaluate the functions in the order she did, Alicia stated that this was because of the "order of operations", just as Rachel had stated in the previous interview.

Alicia was also able to solve problems that required composition of functions defined by graphs or tables, using specific input values. For example, Alicia was able to explain how to find $g(f(2))$ using the given graphs. She was also able to solve a series of three evaluations of function composition using functions defined by tables quickly and correctly.

The third student, Hayley, demonstrated weaknesses in her function knowledge during her pre-interview. She was unable to make progress on problems asking her to express the area of a square as a function of its perimeter, or to express the diameter of a circle as a function of its area. Unlike Rachel and Alicia, Hayley was not able to use an "order of operations" interpretation to complete tasks that required her to interpret function composition notation. Instead, she demonstrated a detailed and consistent interpretation of function composition notation. She correctly interpreted the inner function as evaluating a function with a given input, but she interpreted the outer function as a command to multiply. Exactly what she was supposed to multiply varied. For example, one problem presented Hayley with two algebraically defined functions, and required her to find $g(h(2))$. She read this expression aloud as "*g* of *h* of 2", but described the requested operations as "you're multiplying the function *g* times the function *h* of 2". She then proceeded to find $h(2)$ correctly, and then she multiplied the result by the rule for function *g*, giving her an answer of $g(h(2)) = 5x^2$.

When asked to "use the graphs of *f* and *g* to evaluate $g(f(2))$", Hayley's first question was "What point do you want me to use?" Her subsequent response to the task suggested a lack of understanding of what information the graph of a function is intended to convey. The graph of *g* had one point labeled with its coordinates, (-2,1), and the graph of *f* had two points labeled with their coordinates, (2,-2) and (4,3). Hayley gave the written response $g(f(2)) = (-2,1)[(2)(2,-2)(4,3)]$, and gave the following explanation of her response:

> *g* is -2 and 1. Those are the points on the graph, so that's right there, multiplied by *f* of 2, so you're gonna multiply these two points by the number 2, and that's why they're in brackets.

Presented with a table that defined two functions and asked to evaluate composite functions at specific input values, Hayley correctly evaluated the inner (first) function, but her second step was to multiply each of these numbers by the name (*f* or *g*) of the outer (second) function. This suggested a fragile understanding of function notation and function inputs and outputs.

## Results from Teaching Session

The teaching session focused largely on the ripple problem described earlier. Working as a group, the students settled on quantities that were meaningful and measurable attributes of the problem. Having identified quantities, the students created useful formulas relating the values of the quantities. However, students' descriptions of the formulas sometimes suggested that they had constructed vaguely defined quantities and incorrect quantitative relationships. For example, when explaining the correct formula, $f(t) = 0.7t$, Hayley explained that using this formula "you take 0.7, because that's the radius, and multiply it by the number of seconds".

The group members also voiced no concerns with the suggestion that to express the area of the circle as a function of the circle's radius, they could write $A = g(r) = \pi(0.7t)^2$. When probed, Alicia suggested, "You could just do $\pi r^2$". Hearing this, Hayley first wrote $A = g(r) = \pi(0.7)^2$, suggesting that she thought of 0.7 as being the radius. This response suggests that Hayley, and perhaps other group members, were not visualizing the radius as a function of time, and hence they were not visualizing the quantity radius as varying with variations in time.

When using the correct formulas to find the area inside the ripple 6 seconds after the rock hit the water, Alicia correctly described the input and output quantities of both functions, including a description of why she used the output of *f* as the input to *g*. Alicia consistently exhibited a better ability to talk about function input and output quantities than Hayley or Rachel did.

When asked to use graphs of the functions *f* and *g* to find the area inside the ripple 6 seconds after the rock hit the water, Rachel did not refer to inputs or outputs; however, she did indicate with her finger how she would use the graph of radius as a function of time, locating $t = 6$ seconds on the input axis, moving up vertically until she reached the graph of the function, and then moving horizontally until she reached the output axis, where she could determine the radius.

When asked to evaluate composite functions defined by tables, at a given input value, Alicia and Rachel were able to explain how they used the output value from the first function as the input value to the second function. However, Hayley exhibited difficulty similar to her pre-interview. Asked to evaluate $g(g(1))$, Hayley correctly found that $g(1)=2$, but used the word "multiply" to describe what she should do next, and was unsure whether she should multiply 2 by *g*, or perhaps square 2, since she wanted to find $g(g(1))$. With help from her groupmates, Hayley discovered the correct way to solve this problem, and commented that she was seeing the problem differently than she had before.

The group was next asked to use the graphs of two functions to find the output of a composite function at various given input values. All three students were able to describe the process of using two graphs defined on the same set of axes to find specific outputs of a composite function, explaining how to find the output of the first function and use that value as the input to the second function. The students were much less successful in an activity in which they were asked to use graphs to evaluate the output of a composite function over an interval of input values. Since the students had all experienced success in evaluating composite functions at a specific input value, their failure to describe variations over an interval of input values suggests a weakness in their covariational reasoning ability, i.e., they were unable to attend to how the quantities changed together while imagining changes in the input variable.

**Results from Post-Interview Session**

In her post-interview, Alicia was able to describe the input and output quantities for all of the functions used in the post-interview tasks. Alicia was also able to describe the output of the first function as becoming the input to the second function. This suggests that she had developed a more robust conception of functions as accepting inputs and producing outputs.

Just as they had done during the pre-interview, both Alicia and Hayley described the input and output quantities of a composite function in a way that suggests they were still having difficulty conceptualizing the composite function as a single function. For example, when $h(t)$ was defined as $g(f(t))$, both Alicia and Hayley stated that the input to *h* was $f(t)$.

Hayley showed a clear improvement in her ability to use input/output language to talk about functions and function composition over the instructional sequence. In her pre-interview she typically evaluated what she referred to as "the first function" and followed this with a "multiplication" by the second function. However, in her post-interview, Hayley consistently described using the output of the first function as the input to the second, suggesting that she had emerged with a process view of function and had acquired the ability to articulate what it means to compose two functions.

Hayley also showed a significant improvement in her ability to make sense of a function defined by a graph. In the post-interview, she was able to perform evaluations of composite functions, including composite functions that required using the inverse of one of the graphically defined functions. She was able to use input/output language to describe what she was doing, and why she was doing it. However, she was still unable to determine how the output of a composite function varied over an interval of input values, suggesting a continuing weakness in Hayley's covariational reasoning.

In her post-interview, Rachel was successful on problems with real-life contexts or clear procedural solutions. However, she had difficulty completing tasks in situations that had neither a real-life context nor a clear procedural solution. For example, she remained unable to make meaningful progress when asked to "express the area of a square as a function of its perimeter", a problem that had also appeared in the pre-interview. She indicated that she didn't understand why a person would want to do that, since you could just express it based on the length of the side of the square.

## Discussion

All three students exhibited behavior that suggested weaknesses in their covariational reasoning, their quantitative reasoning, and their views of function. In many instances they exhibited a weak understanding of inputs and outputs of functions, and in some cases, the students acted in procedural ways suggestive of an action view of function, rather than a process view. All three students exhibited difficulty reasoning about the behavior of functions over an interval of input values. This suggests impoverished covariational reasoning, as students showed an inability to attend to the relationships between changing input and output quantities in function composition problems.

In many cases, the students in this study also showed a tendency to define quantities based on attributes that were either not measurable or were not well defined. This suggests that these students would benefit from a curriculum that emphasizes conceiving and reasoning about quantities.

Hayley exhibited behavior that suggests she had little understanding of what information the graph of a function conveys. During her pre-interview, her solutions for problems involving graphs were highly procedural, and suggested that her only understanding of graphs involved manipulating numbers that were used to label points on the graph. However, during her post-interview, Hayley demonstrated dramatic improvement in her ability to make meaning of a graph. This suggests that for her and perhaps other students, it would be beneficial to engage students in tasks to support their understanding of the meaning of a function's graph.

# DIFFERENT MOMENTS IN THE PARTICIPATORY STAGE OF THE SECONDARY SCHOOL STUDENTS' ABSTRACTION OF MATHEMATICAL CONCEPTIONS

Ana-Isabel Roig
University of Alicante (Spain)

Salvador Llinares
University of Alicante (Spain)
sllinares@ua.es

*This study reports characteristics of participatory and anticipatory stages in the abstraction of mathematical conceptions. We carried out clinical task-based interviews with 71 secondary school students to obtain evidence of constructed mathematical conceptions and how they were used. We could distinguish both stages in different mathematical conceptions and, furthermore, two cognitive moments in the participatory stage. We argue that (a) the capacity of perceiving regularities in sets of particular cases is characteristic of reflection on activity-effect, and (b) the coordination of information provides the opportunity for changing the attention focus from the particular results to the structure of properties.*

## Introduction

Understanding how mathematical conceptions are constructed can help in thinking about teaching with the aim of encouraging learning. In this sense it is essential to have accurate descriptions of the processes by which mathematical knowledge is developed. This situation generates issues about what it means to know something about mathematical objects, and how the learner develops or constructs that knowledge (Dörfler, 2002). Cognitive theories based on Piagetian stances assume that mathematical conceptions reflect regularities from human actions and mental operations. In this perspective is generated the question of how to explain the way in which learners cognitively construct their mathematical conceptions. For our purposes and henceforth, "construction" refers to the emergence of a new structure through constructing actions (Monaghan, & Ozmantar, 2006; Simon, Tzur, Heinz, & Kinzel, 2004). Simon and his colleagues (Simon et al., 2004) postulate the existence of a mechanism that they call Reflection on Activity-Effect Relationship to explain this construction process. Taking into account the two phases of reflective abstraction (projection and reflection) described by Piaget (2001), Tzur & Simon (2004) point out that in the projection phase, where the actions become the objects of the reflection, learners sort activity-effect records in terms of an established goal distinguishing between records that get closer to their goal and those that do not. In the reflection phase, where a reorganization of knowledge takes place, learners reflect on the relationship between the activity and its effects.

During the resolution of a problem, the student may call-up a mathematical conception already constructed (anticipatory stage), but in the case in which this conception there isn't, student trigger some actions guided by a goal to obtain information to solve the problem (participatory stage). In this context, we adopt Simon et al.'s (2004) account of a construction process trying to provide empirical support to (i) the distinction between participatory stage and anticipatory stage in the abstraction of mathematical conceptions and (ii) a finer description of how proceeds the participatory stage.

## Methodology

### *Participants*

511 students in the last year of compulsory education (15-16 years old) solved a questionnaire with five mathematical problems in the domains of variability, divisibility and generalization. The analysis of the replies to the problems displayed students' diverse behaviours while solving the problems from the perspective of how they used the different mathematical conceptions. These behaviours may be considered evidence of anticipatory and participatory stages in the construction of mathematical notions involved in the mathematical problems posed. To obtain further information about this phenomenon we conducted 40-minute task-based clinical interviews with 71 of these secondary students. The interviews were focused on how the mathematical conceptions were used during problem solving as a manifestation of the conception constructed. Data come from of audio-records and transcriptions of students' justifications and their written replies to the five problems. Figure 1 shows an example of the problems used.

*Job offers for pizza delivery workers have appeared in a local newspaper.*
*Pizza takeaway A pays each delivery worker 0.6 euros for each pizza delivered and a fixed sum of 60 euros a month. Pizza takeaway B pays 0.9 euros for each pizza delivered and a fixed sum of 24 euros a month.*
*Which do you think is the better-paid job?*
*Make a decision and explain why your choice is the better one.*

*Figure 1.* The job offer.

The interviews were carried out after the students completed the questionnaire and the researchers undertook a first analysis of their replies. The aim of the clinical interview was to get the pupils to verbalise their thought-processes used in solving the problems (Goldin, 2000) in order to obtain evidence of how they generated some abstraction processes of mathematical conceptions or used them. The interviewer had a prior interview script constructed considering the characteristics of each problem and the type of answer given by the pupils. In any case, the interviewer could modify her questions in view of the pupil's behaviour, in order to clarify or investigate more deeply the reasoning processes followed.

*Data Analysis*

The students' responses to the problems and the interviews were analysed from a descriptive point of view using a constant-comparative methodology (Strauss & Corbin, 1994) and taking into account the way in which each pupil set up and used elements of mathematics knowledge as tools in order to interpret the situation and then make a decision (Llinares, & Roig, 2007). Characteristics of the abstraction process generated by the students were identified through the way in which they considered the variability of the quantities, the conditions that had to be fulfilled by these quantities and the way in which discerned generalities from the registers of particular data. We interpreted these characteristics from the process involving students' goal-directed activity and the reflection process (Clement, 2000). Next, we considered the characteristics and the interpretations generated according to the stage distinction from the effect of reflection on activity-effect relationship as a coordination of the available conceptions and identified two moments in the participatory stage with similar characteristics in the different mathematical conceptions taking into account how students created records of experience, sorted and compared the records, and identified patterns in those records.

## Results

Table 1 shows the results obtained from the combined analysis of the interviews and the answers of the questionnaire.

Table 1. *Percentages in Different Stages of the Abstraction Process*

| | P1 | P2 | P3 | ***P4*** | ***P5*** | 71x5=355 |
|---|---|---|---|---|---|---|
| | n (%) | n (%) | n (%) | n (%) | n (%) | n (%) |
| *Participatory stage* | 30 (42.2) | 23 (32.4) | 68 (95.8) | 13 (18.3) | 55 (77.4) | 189 (53.2) |
| *Anticipatory stage* | 7 (9.9) | 1 (1.4) | 3 (4.2) | 15 (21.1) | 12 (16.9) | 38 (10.7) |
| Others | 34 (47.9) | 47 (66.2) | 0 (0) | 43 (60.6) | 4 (5.7) | 128 (36.1) |
| Total | 71 (100) | 71 (100) | 71 (100) | 71 (100) | 71 (100) | 355 (100) |

More than 10% of students had anticipated the mathematical conception in the situation (anticipatory stage). On the other hand, 10.7% of students generated particular cases in order to obtain information about the situation (participatory stage). We identified during the interviews how some students coordinated information from particular cases and generated an answer which reflected a certain degree of generalisation which had not been present in their original written answers. This behaviour indicated a change of focus during interview lending to the generation of an abstraction that fits the reflection on activity-effect relationship mechanism, and revealed the existence of two cognitive moments in the participatory stage. We use some answers to problem 1 to explain these two moments: projection (generating a set of registers) and local anticipation (Reorganization, Identification of Regularities and Acceptance of the Generality).

*Projection: Generating a Set of Registers*

In nearly 20% of the total of 355 answers, the students created from the situation some type of set of registers, but had difficulty in coordinating the information available. In "The job offer" problem, 5.6% of pupils used particular cases to obtain information that might help in making a decision. A typical example of the procedure employed to create a set of registers was the following:

- For 10 pizzas delivered, Earnings A = 66€ > Earnings B = 33€ → A is better.
- For 20 pizzas delivered, Earnings A = 72€ > Earnings B = 42€ → A is better.
- …

Here the pupils centred their attention exclusively on the information provided by the set of particular cases. This kind of behaviour, using very low numbers of pizzas delivered, or focusing the attention on only some of the account in the situation, prevents the more or less explicit appearance of the existence of a change in the profitability of the offers as the number of pizzas increases. The following protocol shows an example of this kind of procedure.

E19: *What else did you do? In the end, what conclusion did you come to?*

A: *Well, I saw that in pizza takeaway A they pay better because you are guaranteed the 60 euros, so you don't have to worry about delivering one pizza more or one less.*

The consequence of using very low quantities is that in all cases job-offer A is considerably better than job-offer B. Student E19's attention was centred on the six particular cases considered instead of on the information that could have been obtained by comparing the difference in earnings as the number of pizzas delivered increased.

*Local Anticipation: Identifying and Using a Regularity*

In the course of the interview some of the pupils coordinated the information derived from particular cases in response to prompts from the interviewer which allow them to identify a regularity. Sometimes they made inferences of a general kind from the situation, with no written trace of the activity carried out. On other occasions however the pupils wrote down registers which enabled them to investigate how to compare and relate the particular data, or generated a search for new information. In both cases they were coordinating the information.

An example of this approaching is the way in which E11 perceived during the interview the change of profitability in total earnings, basing the conclusion on a single particular case he had constructed on the written answer paper. On paper, E11 calculated the monthly earnings at each of the pizza takeaways in the case of *"20 pizzas delivered*", concluding that the better-paid job *"is the one at pizza takeaway A because you earn just over twice as much as at B"*. We had considered this kind of answer a manifestation of the Projection moment. During the interview, however, he indicated the following:

E11: *OK. Let's start with the first one. Do you remember what it was about?*

A: *Yes, here it is … you have two job offers, in one it's 6 cents for each pizza, and a fixed amount every month. In the other, the amount for … what they pay for each pizza you deliver, and then the fixed amount every month. And the other, the amount they pay for each pizza delivered is quite high, but the amount they pay every month is lower. I've given an example. I mean, imagine you have to deliver about 20 pizzas a month. So you multiply the 20 pizzas, the pizzas by 6 cents, which is the same as 12 plus 12 and then the 60 euros you get every month, that's 72 altogether. In the other case 20 by 0.9 [by 9 cents] is 18, plus 24, that's 42. So the difference is bigger. So my better offer was A. A was much better.*

E11: *You'd take A, then?*

A: *Yes.*

As the interview continued, the researcher asked him what would happen if a greater number of pizzas were delivered.

E11: *And what do you think would happen if more pizzas were sold?*

A: *Yeah, that's what I was going to tell you, that probably as the number of pizzas increased you would earn more with option B. But with the example I've given you the better offer is A. Maybe with 200 pizzas B is a better offer.*

This reply seems to show that E11 perceives the existence of a change of profitability in the offers as the number of pizzas delivered increases. To find out how he managed to perceive this change, i.e. how the abstraction was produced, the interviewer asked him to explain why he thought it might be possible to earn more in job B.

E11: *Why do you think, then, why do you think you might be able to earn more in job B?*

A: *Because … because for each pizza, eh, you get 3 cents more than at the end of that … as you deliver more and more pizzas, you get, like, 3 cents for each* *pizza. I mean, after a lot, that's more, more money […] In the end, in the end … the more pizzas you deliver you get back the difference you've got here.*

In his answer E11 refers to the difference in the money paid by each pizza takeaway for each pizza delivered, saying *"because for each pizza, eh, you get 3 cents more than at the end of that … as you deliver more and more pizzas, you get, like, 3 cents for each pizza. I mean, after a lot, that's more, more money"*. He therefore perceives that the difference between the fixed amounts offered by pizza takeaways A and B can be compensated by selling a large number of pizzas. This is possible due to the difference in payment for each pizza delivered, and E11 comes to this conclusion via a qualitative analysis of the data without having to carry out calculations for particular cases. The regularity lies in the fact that the difference between the two offers diminishes as the number of pizzas delivered increases (the earnings in A get closer and closer to those in B) and therefore there comes a point at which B is better than A (there has been a change of tendency in the profitability of the two offers). Another relevant aspect of this procedure is the way in which the identification of the regularity is triggered by the researcher's prompt *"What do you think would happen if more pizzas were sold?"*. From a theoretical viewpoint the question functioned as a prompt which moved the pupil's focus of attention from a single case of what a pizza-deliverer might earn towards a consideration of "how the difference between the two amounts earned might vary" depending on the number of pizzas delivered. We have called this change of attention-focus reflection, which makes it possible to identify the regularity by coordinating certain types of information as a consequence of the interviewer's prompts.

On the other hand, once a regularity (change of profitability) has been identified it can enable the students to look for the exact number of delivered pizzas that equals both offers. In this problem the characteristic of local anticipation lies in the "adjustment" of the decision and is revealed when the pupil considers particular cases approaching 120 (which is the number of pizzas delivered that makes the two offers the same in earnings). In his written answer, E22 drew up a table showing various particular cases and the earnings corresponding to each one for both job-offers. In the interview he explains the process he followed.

A: *Look, in the first one they say there are two pizza takeaways, right? A and B, so in takeaway A they give you 60 euros a month, a fixed sum every month, and in B they give you 24, right? So if they give you more in one than in the other, but in … in the first one they give you 0.6 for every pizza you deliver, and in the second one 0.9, right? So that means that for every 10 pizzas you sell it'll be 0.6 times 10, six euros, you move the decimal point, and here it's 9 euros. So for every 10 pizzas you sell … I mean, look, it's here. From 20 to 40 that's 20, right? Well, you go on adding on, and here it says which will pay you better, right? Well, in the first one as it's 60 euros, in the first one if you don't sell many pizzas the chance is you'll get quite a bit of money, right? I mean it's quite a lot, a lot, a lot of money every month. But not in the second one. But in the second one you take more of a risk because you have to sell more pizzas. In the second one they give you more, less money every month, but they give you more money for every pizza you sell.*

E22: *Yes.*

A: *So when you get to 120 pizzas …*

E22: *What did you do? Did you keep trying it, going up and up, seeing how many deliveries…*

A: *Sure, I went 1, 2, 3, 4, 5, right? I kept on multiplying it.*

E22: *Is that the number of pizzas? [pointing to the first row in the table]*

A: *The number of pizzas sold. 5, right? But I saw it was not enough, so I went on adding more and more.*

E22: *Fine.*

A: *I went on multiplying, and here I wrote an equation, right?*

E22: *Yes.*

A: *Say x is the number of pizzas you sell at 0.60, at 0.60 cents plus the money they give you every month, then you multiply, it might only be two pizzas. Two times 0.60, 1.20 plus 60 euros maybe, and so on.*

The particular cases used are organised in a table beginning with the case of “1 pizza delivered”, and increasing by one pizza at a time for the subsequent cases up to the case of “5 pizzas delivered”. From 10 pizzas onwards, he uses the relation *“for every 10 pizzas you sell it’ll be 0.6 times 10, six euros [Job-offer A], you move the decimal point, and here it’s 9 euros [Job-offer B]”*. This regularity is perceived from the comparison between the amounts paid for each pizza delivered. As he states in his written answer:

- *“Every ten pizzas sold in A mean 6€”*
- *“Every ten pizzas sold in B mean 9€”*

The coordination of the information is revealed in the way he looks at the amounts earned for pizzas delivered (going up in tens of pizzas), together with the comparison between the fixed monthly amounts, which lead E22 to realise that job-offer B can be better than job-offer A (i.e. the regularity in the situation seen as a change of tendency). He is searching for the number of pizzas which will make the two offers the same by setting up new registers of particular cases, ten by ten. This “directed” search for the number that will indicate the change of tendency is a manifestation of the coordination of information, in which the particular cases are used as an iterative activity towards a pre-established goal. After calculating the case of 120 pizzas, E22 states that *“If you sell 120 pizzas you earn the same in both places, but if you are going to sell fewer pizzas you should choose A and if you think you will sell more you should choose B”*.

*18A: And in the end I went on doing that and with 120 pizzas you earn the same in both. So if 120 pizzas are sold you would earn the same in both. So you could take either. But from 120 onwards you’d earn more in B. So …*

*19E: So which of the two would you choose?*

*20A: Personally, I’d take A because it’s difficult to sell 120 pizzas. The thing is … but if you want to take a risk and you think you’ll sell more, you’d take B.*

E22 therefore discerns the change of tendency which occurs as the number of pizzas delivered increases, and is able to use it to discover at what number of pizzas the two job-offers pay the same. At the end of the interview he states that “Personally, I’d take A because it’s difficult to sell 120 pizzas. The thing is…but if you want to take a risk and you think you’ll sell more, you’d take B” (line 20). The perception of the change of tendency and the use of this insight into the structure of the situation to find the number of pizzas at which the change occurs enables the pupil to make a decision and justify it appropriately.

## Discussion

The written answers and the interviews provided us with detailed information regarding different manifestations of the abstraction process and the use of mathematical conceptions in secondary-school pupils. The results obtained enabled us to zoom in describing the distinction between the participatory and the anticipatory stages as proposed by Simon et al. (2004), observing a wide range of behaviours in connection with the mechanism that Piaget called "transposing knowledge to a higher level" and "the reorganisation-reconstruction of the knowledge at this level. We identified two different moments in the participatory stage and highlighted the importance of the prompts given during the interviews to students accede to anticipation. The use of different kinds of problems in the same study, together with a broad sample of pupils and the combination of questionnaire and post-reflection interviews made possible to amplify and complement previous characterisations of the abstraction process (Ellis, 2007a; Hershkowitz, Schwartz, & Dreyfus, 2001; Sriraman, 2004). Our findings have enabled us to generate two ideas which may help to explain some aspects of the abstraction process. In the first place, the way in which activity-effect reflection reveals what route is followed from projection to local anticipation and, secondly, the two manifestations of reflective abstraction in the process of problem solving.

Progress from projection to local anticipation stage is based on the capacity to observe regularities (the effect of the activity) and coordinate information in the set of particular cases. The way in which learners use particular cases is evidence of the steps they take when they have not identified a previously-constructed mathematical structure (participatory stage). The use of particular cases is linked to the performance of cognitive actions such as comparing, relating or searching. This kind of actions leads the student to notice the effect of his/her activities and coordinate the information which in turn leads to a change in the learner's attention-focus. Such prompted attention-changes, linked to cognitive actions, are what reflection consists of. A process of this nature has also been identified by Ellis (2007a, 2007b) via different kinds of generalisation tasks in which learners related and associated two situations or properties discernible in two situations, or used repeated acts to search for a relation. In these cases, the prompts proceed from the design of the task or from the interviewer. Our data have shown that in certain cases the existence of some kind of prompt or stimulus (made by the teacher/researcher or the task design) allow to student change through reflection and accede to anticipation (mathematical conception). These prompts favour the change of focus which is itself the beginning of the recognition of some kind of regularity in the set of data (effect of activity).

We argue that it is possible to identify different aspects of the abstraction process using problems from different mathematical domains all of which provides evidence of the general nature of this model. The relationship between the participatory and anticipatory stages in the abstraction process (Piaget, 2001) and the actions of generalisation and the characteristics of what has been generalised (Ellis, 2007b), give greater strength to this way of understanding the abstraction process when learners think mathematically, and locate the focus of attention on the relation between the learner's mental actions while abstracting, the outcome of these acts and their subsequent use. The results obtained therefore have implications with regard to the design of tasks to encourage the construction of an abstraction and the consolidation of the construction. In the first place, the role played by prompts (in the task itself or as made by the researcher/teacher during the interview) would seem to indicate that when abstraction-centred tasks are designed they should take into account the nature of the prompts which will help the learners to coordinate the information and thus go on to local anticipation. This recommendation is compatible with that made by Tzur (2007) following a whole-class teaching experiment. Secondly, in order to give learners the opportunity change their attention-focus and begin to see a set of activity-effect registers as a unified object (the identification of the regularity and/or the general aspect) (Dörfler, 2002) it will be necessary to create opportunities for the development of language-items for the new construction. This characteristic of the task has also been considered relevant in designing tasks to consolidate a new construction (Monaghan, & Ozmantar, 2006). In any event, more research is evidently required to provide information that will be useful in reaching a clearer theoretical understanding of task-design, with all the obvious implications for the improvement of teaching methods.

# ROLE OF PERTURBATIONS IN MAKING SENSE OF FRACTIONS

Zelha Tunc-Pekkan
University of Pittsburgh
zelha@pitt.edu

This study examines the role of perturbations in students making sense of fractions. Steffe and Tzur (1994) define *making sense* as "(a) to construct ways and means of operating in a medium, based on current knowledge, in order to neutralize perturbations induced through social interactions and (b) to become explicitly aware of those potential ways and means of operating through a process of symbolization"(p.111). Therefore, in students' mathematical sense-making, perturbations, social interactions and symbolization are important. In this presentation, I will discuss those three important contributors to learning, using a teaching segment taken from semester-long interactions (17 meetings) conducted with a pair of US $8^{th}$ grade students. I will mainly focus on one of the students, Jasmine, and her actions and operations to discuss her perturbations, the ongoing social interactions, and her use of symbols.

The particular problem that Jasmine attempted to solve was this: "A half-inch candy bar is cut into two parts. If one part is 13/3 as long as the other part, how long are the parts?" It took a total of 15 minutes for Jasmine and her partner to solve this problem. After analyzing the video-recorded interactions among Jasmine, her partner, her teacher (me) and two observers as well as her written work, I inferred that Jasmine was perturbed three times: 1) At the start, she forgot the length of the whole candy bar but operated and produced results without using that information. A possible reason for not using 1/2 inch might be that until this problem, she had solved problems when the length of the candy bar was given as a whole number of inches. When the length of the candy bar was given as a fractional part of an inch, she unintentionally forgot this information and solved the problem with whatever was meaningful to her. She took 16/3 as the length of one of the 16 pieces of the whole candy bar and multiplied it by 13 and 3 to find the lengths of the two parts. She was in a state of perturbation after I (the teacher) reminded her that the length of the candy bar was 1/2 inch. 2) Throughout the interactions, it became clear that she had the question of "how can the same quantity (the whole candy bar) be 16/3 of the smaller part and at the same time sixteen pieces?" The way Jasmine produced 16/3 was notational in that she utilized the denominator of 13/3 to label the other part as 3/3. She then added the number of equal pieces in the two parts, 13 and 3 respectively, and said that the whole quantity would be 16 thirds. It was not because 16/3 was 16 thirds of the 3/3 quantity but it was because all the equal pieces were given in thirds, e.g., 13/3 was given in thirds. She eliminated this perturbation by focusing her attention on the number of equal pieces (instead of using a multiplicative relationship of 16/3 of something is 1/2 an inch, what is the length of that quantity?) and wrote 16 pieces = 1/2 inch. 3) Towards the end of the interactions, she did not realize that when she wrote 1/32*16 the result would be 1/2 inch, the length of the whole candy bar. In addition, when I analyzed the interactions, it seemed that she did not have a goal of finding the lengths of two parts when she wrote 1/32 16/1.

In the poster session, I will present the details of these perturbations and show how Jasmine proceeded in the context of the social interactions that occurred during teaching.

# COLLABORATION AND PROBLEM SOLVING IN AN ONLINE, SYNCHRONOUS ENVIRONMENT

Kate O'Hara
Rutgers, The State University of New Jersey
Katem222@comcast.net

Arthur B. Powell
Rutgers, The State University of New Jersey
powellab@andromeda.rutgers.edu

F. Frank Lai
Rutgers, The State University of New Jersey
fflai@eden.rutgers.edu

Kevin Merges
Rutgers, The State University of New Jersey
merges@rutgersprep.org

*In this study, we observe students working in small teams as they engage in problem solving in a synchronous online environment to understand how they relate to one another, work collaboratively, and communicate their emergent understanding of the problem task without contemporaneous teacher intervention. We present evidence that the students, using the computer as a cultural tool, actively engage in high forms of thinking and reasoning as well as engage in scaffolding as they co-construct mathematical interpretations and ideas.*

The data analyzed for this poster is a subset of a larger data corpus from the *e*Math Project. We are currently conducting our *e*Math Project with two groups of seniors from two different high schools, who meet in a virtual communication environment to solve open-ended mathematical tasks. Our research question emerges from a grounded study in how students collaborate in a synchronous environment carried out without direct teacher intervention. By studying how students communicate and ultimately collaborate within an online environment without direct teacher intervention, we can gain knowledge on how to structure lessons, and more particularly, problem tasks, so as to optimize learning. The theoretical perspective that guides our collection and analysis of data includes sociocultural theory (Vygotsky, 1978), communication (Sfard, 2000), and notions of socially emergent cognition (Powell, 2006) and group cognition (Stahl, 2006). This poster focuses on evidence of how the students communicate their emergent understanding of the problem tasks and coalesce as collaborative learners.

The poster will display evidence of how the students coalesced into a team and collaborated in a virtual environment by presenting clips from the chat window and screen shots of the white board. The screen shots display both edited text boxes and representations the students used to convince one another of their reasoning. Over the course of 13 sessions it is evident that the students improved upon their collaborative skills within the chat window excerpts and whiteboard summaries.

# A COMPARISON OF PART-WHOLE AND PARTITIVE REASONING WITH UNIT AND NON-UNIT PROPER FRACTIONS

Anderson Norton
Virginia Tech
norton3@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

*We report on quantitative methods applied to a pair of hypotheses formed through teaching experiments. In particular, our research affirms conceptual distinctions between part-whole and partitive reasoning with fractions, as theorized in previous literature (e.g., Steffe, 2002). These distinctions include a developmental hurdle in moving from partitive reasoning with unit fractions to partitive reasoning with non-unit proper fractions. Whereas we concentrate on hypotheses arising from scheme theory and teaching experiments, findings relate to fractions concepts identified by researchers employing other methods and frameworks as well (e.g., Kieren, 1980; Mack, 2001).*

## Objectives

Teaching experiments with pairs of students provide opportunities for teachers to closely analyze students' problem solving activities while taking into account student-student interaction (Steffe & Thompson, 2000). Based on students' actions (including verbalizations) teachers can build models of students' reasoning using schemes: hypothetical ways of operating that explain the students' actions. Such models have produced numerous hypotheses with regard to students' learning of fractions (e.g., Olive, 1999; Tzur, 1999; Steffe, 2002; Hackenberg, 2007). We examined some of these hypotheses in a quantitative study that afforded a much larger sample. We recognize that assessing student knowledge with written tests always comes with limitations, but Kilpatrick (2001) reminded us that, as mathematics education researchers, we are also obliged to quantitatively test hypotheses.

Here, we report on results from our examination of one pair of hypotheses, which relate to three particular schemes: the part-whole fractional scheme, the partitive unit fractional scheme, and the partitive fractional scheme. We describe the schemes in more detail in a subsequent section. For now, we note that Steffe (2002) and Olive (1999) learned about these ways of operating from their work with children in the Fractions Project. They theorized that the schemes form a hierarchy (respective to the order listed above) in which each preceding scheme is reorganized to form the succeeding scheme. Based on this idea and our own work with children, we posit the following research hypotheses.

1. In part-whole reasoning there are no operational differences between situations involving unit and non-unit proper fractions.
2. In partitive reasoning there are operational differences between situations involving unit and non unit proper fractions; success with situations involving unit fractions precedes success in situations involving non-unit proper fractions.

In reporting our results concerning these hypotheses, we can also report on the construction of fractional schemes in general, during grades 5 and 6.

## Theoretical Framework

Following Glasersfeld (1995), we define schemes as three-part structures, which include a set of perceived situations that activate the scheme (a trigger, or recognition template), a set of operations to act on the situation, and an expected result from operating. Glasersfeld defined operations—the active and therefore most important component of schemes—as mental actions abstracted through reflection on previous experience. For example, students might abstract partitioning operations from experiences in forming equal shares, folding paper, or otherwise creating equal parts from an existing whole. The partitioning operation results from reflection on the cognitive processes involved in completing such physical activities. Once a student has abstracted the operation, she can apply it to new situations, such as determining how to break a whole candy bar into five equal parts. Iteration—another operation important to working with fractions—involves creating copies of a unit. For example, a student might create three-fifths from one-fifth by iterating a one-fifth piece three times.

### *Part-Whole Fractional Scheme*

Students who have constructed a part-whole fractional scheme conceive of fractions as so many pieces in the partitioned fraction out of so many pieces in the partitioned whole. This scheme relies upon operations of identifying (unitizing) a whole, partitioning the whole into equal pieces, and disembedding some number of pieces from the partitioned whole. However, “a child who has constructed [only] a part-whole fractional scheme is yet to construct unit fractions as iterable fractional units” (Steffe, 2003, p. 242). In other words, a fraction such as three-fifths means three pieces out of five equal pieces in the whole, but it is not yet understood as three iterations of one of the fifths. Consider the tasks illustrated in Figures 1a and 1b.

*Figures 1a and 1b.* Task responses providing indication/counter-indication of part-whole fractional scheme.

Note that one of the tasks involves a unit fraction, whereas the other involves a non-unit proper fraction. The part-whole fractional scheme, as abstracted from researcher interactions with children, theoretically operates on both cases in the same way. The response to the first task correctly indicates one out of six equal parts. On the other hand, the response to the second task (by a different student) serves as counter-indication of a part-whole fractional scheme because the parts in the fraction are not equal in size to the unshaded parts of the bar.

*Partitive Unit Fractional Scheme*

Both a part-whole fractional scheme and a partitive unit fractional scheme generate fractional language, but the difference between the powers of the schemes is evident in resolving the task illustrated in Figure 2. Students with only a part-whole fractional scheme cannot determine the fraction because the whole is unpartitioned.

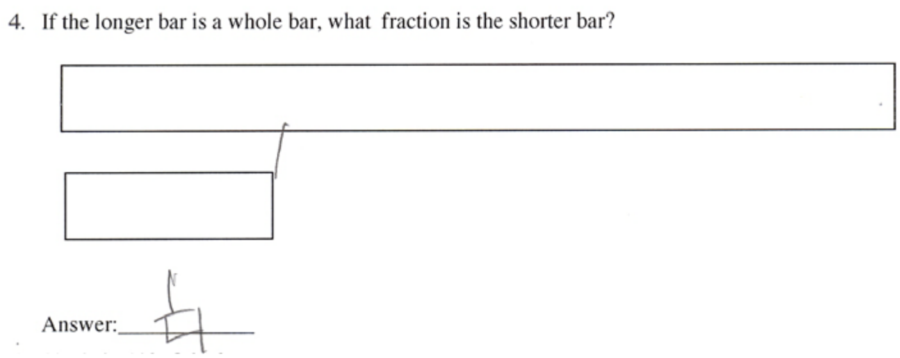

*Figure 2*. Task response providing indication of a partitive unit fractional scheme.

The response in Figure 2 indicates a partitive unit fractional scheme because the student seems to understand (note the mark on the left side of the large bar) that the unit fractional part (small bar) could be iterated four times to re-produce the whole (large bar) and that this number of iterations (four) determines the *size* of the unit fraction relative to the whole (one-fourth). The partitive unit fractional scheme, "establishes a one-to-many relation between the part and the partitioned whole" and involves "explicit use of fractional language to refer to that relation" (Steffe, 2002, p. 292). However, a partitive unit fractional scheme cannot be used to determine the fractional size of a non-unit fraction, because the iterations will not reproduce the whole (unless, of course, the fraction in question simplifies to a unit fraction; e.g., two-sixths).

*Partitive Fractional Scheme*

The *partitive fractional scheme* is a generalization of the partitive unit fractional scheme. Students can use the more general scheme to conceive of a proper fraction, such as three-fourths, as three of one-fourth of the whole. This involves producing composite fractions from unit fractions through iteration, while maintaining the relation between the unit fraction and the whole. It also involves *units coordination* at two levels (Steffe, 2002; Hackenberg, 2007), because the student must coordinate three-fourths as three iterations of the fractional unit and the whole as four iterations of the fractional unit. In order words, three-fourths is a unit of three fractional units, and the whole is a unit of four fractional units. Consider the coordinations indicated by the student response in Figure 3.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

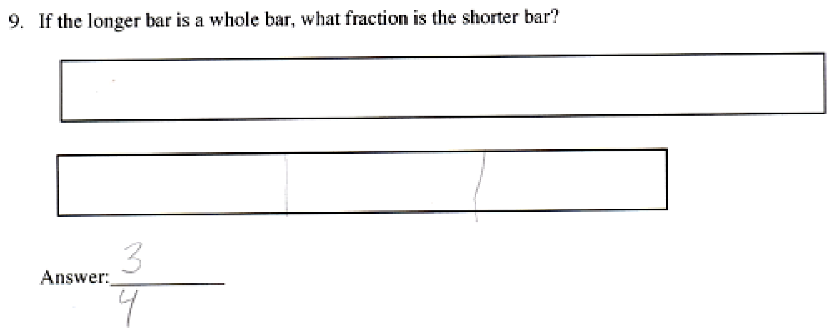

*Figure 3*. Task response providing indication of a partitive fractional scheme.

The response provides indication of a partitive fractional scheme because the student identified the smaller bar as three iterations of a part that, when iterated four times, would reproduce the larger bar (the whole).

*Research on the Progression of Fractions Concepts*

Several teaching experiments contributed to the hierarchy of schemes presented above (Norton, 2008; Olive, 1999; Olive & Vomvoridi, 2006; Saenz-Ludlow, 1994; Tzur, 1999). Collectively, student progress reported in these studies affirms the theoretical hierarchy of schemes and provides some indication of development by grade level. Most students seem to develop part-whole fractional schemes by fifth grade, but other schemes often lag years behind or do not develop at all.

Kieren (1980) identified part-whole relations as one of five subconstructs vital to the understanding of rational number. Although researchers agree that part-whole conceptions are fundamental to understanding fractions (Pitkethly & Hunting, 1996), "teaching efforts have focused almost exclusively on the part-whole construct of a fraction" (Streefland, 1991, p. 191) and this can lead to misconceptions. For example, Olive & Vomvoridi (2006) worked with a student named Tim who conceived of 1/n and n/n as the same thing because he could not consider 1/n apart from the whole before constructing a partitive unit fractional scheme (Olive & Vomvoridi, 2006). "Sparse conceptual structures limit students' understanding; once these conceptual structures had been modified and enriched, Tim was able to function within the context of classroom instruction" (p. 44).

Saenz-Ludlow (1994) emphasized the importance of developing a partitive conception of fractions when she referred to the need for students to understand fractions as quantities. This conception aligns with Mack's description of fractions as "multiplicative size transformations" (2001, p. 269). It also aligns with the *measurement* and *operation* subconstructs identified by Kieren (1980), in which fractions are understood in terms of sizes relative to a specified whole, rather than a simple comparison of numbers of parts in the fraction and the whole.

## Methods

*Data and Assessment*

We administered pre-tests during each fall and post-tests during each spring as part of a two-year professional development study, which took place from 2005 to 2007 in a low- to middle-income small-town school in the mid-western United States. The study involved one fifth-grade classroom and one sixth-grade classroom for each of the two years, with no students involved in both years. Students with missing data were removed for the present analysis, leaving 84 students for the pre-test and 86 students for the post-test. Each test contained nine randomly-ordered items: including items like those illustrated in Figures 1, 2, and 3. We paired the nine items across the two forms of the test so that only the numbers and respective sizes of the fractions changed (e.g., using a one-fifth bar instead of a one-fourth bar for the partitive unit item). We randomly assigned the tests so that each student took each form of the test once, either in the fall or spring.

We designed the items as indicators of particular schemes. That is, responses to each item provided opportunities for students to enact particular ways of operating. When assessing student responses, two scorers looked at the students' work on each single item, and inferred from all markings (e.g., written answers, drawn partitions, shading, calculations) whether there was indication that the student had operated in a way that is compatible with the particular scheme. Responses to each item were scored in the following way:

0: There was counter-indication that the student could operate in a manner compatible with the theorized scheme or operation. Counter indication might include incorrect responses and markings that are incompatible with actions that would fit the scheme. For example, the response illustrated in Figure 2b indicated that the student did not understand the importance of creating equal parts in the fraction and the whole.

1: There was strong indication that the student operated in a manner compatible with the theorized scheme or operation. Indications might include correct responses and partitions. For example, the mark and final answer in Figure 2 indicate the student iterated the smaller bar four times within the larger bar to correctly determine the size of the unit fraction, ¼.

Some items were initially scored as 0.5 and required further inference on the part of the scorers to select a final score of 0 or 1. For example, in response to the task illustrated in Figure 2, a student might have estimated the size of the fraction to be 1/5, with supporting marks indicating he had iterated the fractional stick 5 times. The two scorers reexamined such responses on a case-by-case basis to come to a consensus, and then used that consensus to inform decisions on similar, subsequent cases.

*Measures*

*Part-whole fractional scheme (PWFS).* Two items were used as indicators of students' part-whole fractional schemes. One item involved unit fractions (e.g., see Figure 1a) and the other item involved non-unit fractions (e.g., see Figure 1b). These items were used to test for students' operational differences between situations involving unit and proper fractions (Hypothesis 1).

*Partitive fractional scheme.* Two items were used as indicators of students' partitive fractional schemes. One item involved unit fractions (e.g., see Figure 2) and was used as an indicator of a partitive unit fractional scheme (PUFS) and the other involved non-unit fractions (e.g., see Figure 3) and was used as an indicator of a partitive fractional scheme (PFS). The two items were used separately to test for students' operational differences between situations involving unit and proper fractions (Hypothesis 2).

*Analysis*

Frequencies of student scores were entered into contingency tables and were analyzed using appropriate measures of association for ordinally scaled variables. Our hypotheses test both symmetrical and asymmetrical associations.

Hypothesis 1 was analyzed using a Binomial Test. In this case, a test for no operational differences is concerned with the distribution of students who did not get both items correct. In other words, if there are no operational differences then students should get both items correct or both items incorrect, and the distribution of those students missing one item should not reflect a bias toward either the unit or non-unit proper fraction items.

Hypothesis 2 describes an asymmetrical situation in which partitive reasoning with unit fractions is hypothesized to precede partitive reasoning with non-unit proper fractions. In other words, one variable is an independent variable (e.g., partitive reasoning with non-unit fractions) and the other is a dependent variable (e.g., partitive reasoning with unit fractions). Somer's *D* is an appropriate statistic for testing asymmetrical associations between two ordered variables (Siegel & Castellan, 1988) and was used for Hypothesis 2. Somer's *D* is a measure comparing the number of agreements in order between two variables with the number of disagreements in order. Its value ranges from -1 to 1 with values closer to -1 and 1 indicating a stronger asymmetrical relationship. In the perfect relationship there would be no disagreements. Visually this would be seen in a contingency table as a staircase.

## Results

### *Scheme Hierarchy*

We investigated the scheme hierarchy by examining the overall percent correct for each variable representing the different schemes (see Table 1). In this case, higher percentages were considered to be indicative of those schemes that are, in general, developmentally more stable for the particular grade level students considered; that is, the scheme develops earlier in the hierarchy. Based on the percentages, the schemes align as hypothesized, with the part-whole fractional scheme developing earlier, followed by the partitive unit fractional scheme, and then the partitive fractional scheme.

*Table 1*
Percent Correct for Each of the Items Associated with the Schemes

| Grade 5 | | | | |
|---|---|---|---|---|
| | Pre-test (N = 44) | | Post-test (N = 43) | |
| Scheme | *M* | *SD* | *M* | *SD* |
| Part-whole | .58 | .39 | .82 | .28 |
| Partitive unit fractional | .52 | .50 | .56 | .50 |
| Partitive fractional | .27 | .45 | .58 | .50 |
| **Grade 6** | | | | |
| | Pre-test (N = 40) | | Post-test (N = 43) | |
| Scheme | *M* | *SD* | *M* | *SD* |
| Part-whole | .78 | .22 | .79 | .30 |
| Partitive unit fractional | .70 | .46 | .65 | .48 |
| Partitive fractional | .48 | .51 | .56 | .50 |

### *Part-whole Reasoning*

We hypothesized that when working in part-whole situations there are no operational differences for unit and proper fractions (Hypothesis 1). In other words, the PWFS develops for both situations at the same time. The number of students missing the unit fractional item compared to the non-unit item was found to be statistically the same for the pre-test (Binomial Test, $p = .71$) and the post-test (Binomial Test, $p = .80$) indicating that there is not sufficient evidence to reject the null hypothesis that there are no operational differences between situations involving unit and proper fractions (see Table 2). Because most students were successful with the part-whole items, it would be good to replicate this investigation with a younger sample of students in which an increased numbered of students would not have developed part-whole reasoning.

*Table 2*

Success in Non-Unit Part-Whole Situations by Success in Unit Part-Whole Situations

| | Part-whole | | | | | |
|---|---|---|---|---|---|---|
| | Pre | | | Post | | |
| | 0-Non-Unit | 1-Non-Unit | Total | 0-Non-Unit | 1-Non-Unit | Total |
| 0-Unit | 11 | 13 | 24 | 7 | 7 | 14 |
| 1-Unit | 16 | 44 | 60 | 9 | 63 | 72 |
| Totals | 27 | 57 | 84 | 16 | 70 | 86 |

*Note*. Binomial $\text{Test}_{\text{PRE}}$, $p = .71$; Binomial $\text{Test}_{\text{POST}}$, $p = .80$.

*Partitive Reasoning*

We present frequencies for student success on the PUFS and PFS items in Table 3 for the pre- and post-test. We hypothesized that, for partitive reasoning, there would be operational differences between situations involving unit and proper fractions, and further, we would expect successful operations on unit fractions to precede operations on proper fractions (Hypothesis 2). We found a statistically significant direct relationship between PUFS and PFS for both the pre-test (Somer's $D = .37$, $p < .001$, one-tailed) and post-test (Somer's $D = .40$. $p < .001$, one-tailed) indicating that, in general, for partitive reasoning there are operational differences between situations involving unit and proper fractions; and moreover, in general a PUFS tends to develop prior to a general PFS.

*Table 3*

Success in Non-Unit Partitive Situations by Success in Unit Partitive Situations

| | Partitive | | | | | |
|---|---|---|---|---|---|---|
| | Pre | | | Post | | |
| | 0-Non-Unit | 1-Non-Unit | Total | 0-Non-Unit | 1-Non-Unit | Total |
| 0-Unit | 28 | 5 | 33 | 23 | 11 | 34 |
| 1-Unit | 25 | 26 | 51 | 14 | 38 | 52 |
| Totals | 53 | 31 | 84 | 37 | 49 | 86 |

*Note*. $D_{\text{PRE}} = .37$ ($p < .001$, one-tailed); $D_{\text{POST}} = .40$ ($p < .001$, one-tailed).

## Conclusions

We based our hypotheses on theoretical distinctions between part-whole and partitive reasoning with fractions. These distinctions arose from and are supported by several teaching experiments with children (Norton, 2008; Olive & Vomvoridi, 2006; Saenz-Ludlow, 1994), and they are indicated by the two names given to the partitive schemes. The present study affirms those distinctions by measuring significant differences between students' performance on unit and non-unit *partitive* items, and by indicating no significant difference between students' performance on unit and non-unit *part-whole* items.

Our research findings imply that teachers should recognize that progressing from partitive reasoning with unit fractions to partitive reasoning with non-unit fractions may pose a developmental hurdle on par with the more obvious one of developing improper fractions. To the degree that our results generalize to students at other schools, our findings also indicate grade-level development of fractional schemes, which might inform curricular design.

Percentages of successful performance by students on the items support the theoretical hierarchy of schemes proposed by Steffe (2002) and Olive (1999) and affirmed by numerous teaching experiments. These percentages also indicate that most students have developed part-whole reasoning before entering fifth grade and that most students develop partitive reasoning during fifth or sixth grade. This finding aligns with those of the teaching experiments described in the theoretical framework for our study. Indeed, comparing pre-test and post-test mean averages in Table 1, we find the largest increase on the PFS item, in fifth and sixth grades.

Harvard University
jon_star@harvard.edu

*The present study evaluated the effectiveness of an instructional intervention (schema-based instruction with self-monitoring, SBI-SM) which emphasizes the mathematical structure of problems and also provides students with a heuristic to aid problem solving. One hundred forty eight seventh-grade students and their teachers participated in a 10-day intervention on learning to solve ratio and proportion word problems, with classrooms randomly assigned to SBI-SM or a control condition. Results indicated that students in SBI-SM treatment classes made greater gains than students in control classes on a problem solving measure, both at posttest and on a delayed posttest administered four months later.*

## Introduction

Reasoning with ratios and proportions is widely regarded as a critical bridge between the numerical, concrete mathematics of arithmetic and the abstraction that follows in algebra and higher mathematics. Recent mathematics education policy documents echo this sentiment by identifying proportional reasoning as a "capstone" of elementary mathematics (National Research Council, 2001) and as a foundational topic for further success in mathematics (National Mathematics Advisory Panel, 2008). US students' difficulties in working with ratio and proportion are seen in both national and international assessments. On the 2003 TIMSS assessment, only 55% of US 8th graders were able to solve a routine proportion problem.

The topics of ratio and proportion are frequently encountered in elementary and middle schools in the form of word problems. Word problem solving has proved to be a significant challenge for students, in part because it requires students to understand the language and factual information in the problem, identify relevant information in the problem to create an adequate mental representation, and generate, execute, and monitor a solution strategy. Yet despite their difficulty, word problems are critical in helping children connect different meanings, interpretations, and relationships to the mathematical operations.

There is a rich history in the field of mathematics education of interventions designed to help students become more successful at understanding and being able to solve ratio and proportion word problems (Lesh, Post, & Behr, 1988; Behr, Harel, Post, & Lesh, 1992; Litwiller & Bright, 2002; Lamon, 2007). Although research on ratio and proportion word problem solving was particularly prominent in the 1980s and early 1990s, scholars in mathematics education continue to explore ways to improve students' learning of this important, yet challenging topic. All told, the mathematics education literature provides many compelling examples of methods and curricula that have the potential to enhance students' performance and understanding of word problem solving in the domain of ratio and proportion (Behr, Harel, Post, & Lesh, 1992; Lamon, 2007).

Despite the large literature on word problem solving with ratios and proportions, research on how to address low achieving students' difficulties with word problem solving is somewhat conflicting. In the field of mathematics education, the approach advocated by the NCTM *Standards* (and that is used in most of the NSF-funded reform curricula) is a student-centered, guided discovery approach for teaching students problem solving (NRC, 2001). However, recommendations for this kind of instructional approach are somewhat at odds with the literature on problem solving instruction for low achieving students in the field of special education, which has found that low achieving students benefit far more from direct instruction and practice at problem solving than competent problem solvers (National Mathematics Advisory Panel, 2008). In fact, research conducted in reform-oriented classrooms suggests that many low achieving students (particularly those with learning disabilities) may assume passive roles and may encounter difficulties with the cognitive load of the discovery-oriented activities and curricular materials (e.g., Baxter, Woodward, Voorhies, & Wong, 2002). Yet, despite the robust literature from special education in support of more direct instruction for low achieving students and those with learning disabilities, many in the mathematics education community have strong negative reactions to this instructional approach, in part because of perceived associations and historical links between direct instruction and the development of rote, inflexible knowledge.

The goal of the present study was to design an instructional intervention to meet the diverse needs of students in classrooms using the research literatures from both special education and mathematics education. Our instructional intervention uses a type of direct instruction that involves explicit strategy instruction, which has strong support in the special education literature for increasing the performance of at-risk populations. However, our approach is carefully designed to address three critical concerns with the ways that direct instruction has sometimes been (mis)applied in mathematics instruction.

First, one concern about some direct instructional approaches is that the same procedure (e.g., cross-multiplication) is used to solve all problems on a page. As such, students do not have the opportunity to compare and contrast (and thus learn to discriminate) among different types of problems and approaches, perhaps leading to exclusive reliance (and perhaps rote memorization, without understanding) on a small set of problem solving strategies. Our instructional approach (described below) addresses this concern by exposing students to multiple problem types and strategies and by encouraging reflection on the similarities and differences between problems types and strategies. There is growing evidence from both the education and psychological literature that exposure to multiple strategies facilitates students' learning of mathematics (e.g., Rittle-Johnson & Star, 2007).

A second concern about some direct problem solving instructional approaches is the use of superficial cues such as key words (e.g., *in all* suggests addition, *left* suggests subtraction, *share* suggest division; Lester, Garofalo, & Kroll, 1989) that students are encouraged to use to select an operation or a solution procedure (e.g., "cross multiply"). The use of keyword methods, focusing on surface level features, does not emphasize the meaning and structure of the problem and thus may not help students to reason and make sense of story situations to be able to successfully solve novel problems (e.g., Ben-Zeev & Star, 2001). Our approach moves away from keywords and superficial problem features and more explicitly focuses on helping students see the underlying mathematical structure of problems.

A third concern about some direct instructional approaches is the reliance on a general problem solution method that involves the use of a heuristic and multiple strategies based on George Pólya's seminal principles for problem solving. Pólya's four-step problem solving model includes the following steps: *understand the problem*, *devise a plan*, *carry out the plan*, and *look back and reflect*. However, this method has come under scrutiny for several reasons, including the failure of general heuristics to reliably lead to improvements in students' word problem solving performance (Lesh & Zawojewski, 2007).

Our instructional approach, schema-based instruction (SBI), which is intermediate in generality between key word approaches and general heuristic methods described above, addresses the above-noted concerns with some aspects of direct instruction in that it entails specific problem solving strategies that are linked to particular types or classes of problems (e.g., ratio, proportion). Specifically, SBI in this study includes the following three features.

First, our instructional model uses schema training to help students see the underlying mathematical structure of word problems, which is critical to effectively deploy content knowledge. Schema theory suggests that cognizance of the role of the mathematical structure (semantic structure) of a problem is critical to successful problem solution. Schemas are domain or context specific knowledge structures that organize knowledge and help the learner categorize various problem types to determine the most appropriate actions needed to solve the problem (Marshall, 1995). For example, organizing problems on the basis of structural features (e.g., *rate* problem, *compare* problem) rather than surface features (e.g., the problem's cover story) can evoke the appropriate solution strategy.

One way that problem solvers can access schema knowledge is through the use of schematic diagrams, which have been found to be particularly useful in highlighting underlying problem structure and is deemed by many to be central to mathematical problem solving (e.g., Stylianou & Silver, 2004). It is important to note that a schematic diagram is not merely a pictorial representation of the problem storyline that may focus on concrete, irrelevant details, but rather depicts the relationships between critical elements of the problem structure necessary for facilitating problem solution. Research on the effectiveness of schema training in isolation or combined with schematic representations has shown that it is effective for students of different ability levels (e.g., Jitendra, Griffin, Haria, Leh, Adams, & Kaduvetoor, 2007; Xin, Jitendra, & Deatline-Buchman, 2005).

A second feature of our instructional approach is our focus on multiple solution strategies. Comparing and contrasting multiple strategies is a central feature of mathematics reform efforts (Silver et al., 2005) and is advocated in the National Council of Teachers of Mathematics (NCTM) Standards (2000). An emphasis on having students actively compare, reflect on, and discuss multiple solution methods is also identified as a key feature of expert mathematics instruction (e.g., Silver et al., 2005) and considered to be an important differentiating feature of teachers in countries that have performed well on international assessments such as TIMSS (Richland, Zur, & Holyoak, 2007). Further, two recent studies by Rittle-Johnson and Star (2007; Star & Rittle-Johnson, in press) provide empirical evidence for improving student learning when instruction emphasizes and supports comparing and contrasting solutions. Students who learned to solve equations or to compute estimates by comparing and contrasting multiple solution methods outperformed students who were exposed to the same solution methods but presented sequentially.

Finally, an additional feature of our instructional model is the use of student "think-alouds" to help in the development of self-monitoring skills, a critical component of metacognitive ability (e.g., Kramarski, Mevarech, & Arami, 2002). Teachers model how and when to use each problem solving strategy and work with students to reflect on the problem before solving it. Recent research suggests that instruction that includes a focus on metacognitive skills has an added positive effect on students' mathematical problem solving performance (e.g., Kramarski, Mevarech, & Arami, 2002). As such, our approach emphasizes self-monitoring, an important aspect of metacognitive processes, by having students direct their problem solving behavior to focus on comprehending the problem, representing the problem, planning to solve the problem using appropriate strategies, and reflecting on the solution via the use of "think-alouds."

*Purposes of the Present Study*

The primary purpose of the current study was to evaluate the effectiveness of schema based instruction on ratio and proportion word problem solving. The present study extended prior work of Jitendra and colleagues (e.g., Xin et al., 2005) on SBI-SM in the multiplicative domain in several ways. First, while Xin et al. exclusively focused on students with disabilities and low achieving students, we targeted students of diverse ability levels in general education classrooms. Second, we extended the focus of Xin et al. beyond ratio and proportion word problem solving to also include foundational concepts (ratios, equivalent fractions, rates, fraction and percents) involved in ratio and proportion problem solving. Third, in addition to the schematic diagrams for organizing information (as was used in Xin et al.), we also incorporated multiple solution strategies and flexible application of those strategies. Fourth, instruction was provided by classroom teachers, rather than by research assistants (as was done in Xin et al.).

We hypothesized that students receiving SBI-SM instruction would make greater gains in problem solving performance than their peers receiving "business-as-usual" mathematics instruction (control condition). The following research questions were addressed in this study: (1) What are the differential effects of SBI-SM and control treatment on the acquisition of seventh grade students' ratio and proportion word problem solving ability? (2) Is there a differential effect of the treatment (SBI-SM and control) on the maintenance of problem solving performance four months following the end of intervention?

## Method

*Participants*

Seventh grade students from eight classrooms and their teachers in a public, urban school participated in the study. For mathematics instruction, students in the school were grouped into classes based on three ability levels: Academic (high), Applied (average), and Essential (low). In the present study, each treatment group (SBI-SM and control) included two sections of average and one each of high and low ability classrooms to adequately represent the different levels in the school. The sample of 148 students (79 girls, 69 boys) included those who were present for both the pretest and posttest. The mean chronological age of students was 153 months. The sample was primarily Caucasian (54%), and minority students comprised 22% Hispanic, 22% African American, and 3% American Indian and Asian. Approximately 42% of students received free or subsidized lunch and 3% were English language learners.

All six teachers at the participating school were responsible for teaching mathematics in the different ability level classrooms. The teachers (3 females and 3 males) were all Caucasian, with a mean of 8.58 years of experience teaching mathematics (range 2 to 28 years). Three of the teachers held secondary education certification, four had a master's degree, and only three had a degree in mathematics.

*Design*

A pretest-intervention-posttest-retention test design was used. After matching classrooms in pairs on the basis of ability level, one classroom from each pair was randomly assigned to the SBI-SM or control treatment.

*Materials and Measures*

The SBI-SM intervention unit content provided the basis for solving problems involving ratios and proportions. We identified specific concepts and problem-solving skills by reviewing the textbook used in the 7th grade classrooms and appropriately mapping the relevant topics to the ratio and proportion unit. The unit included exercises to build an understanding of the concepts of ratios and rates that are critical to understanding proportions and for engaging in proportional reasoning as well as to solving ratio and proportion word problems.

To assess mathematics competence on ratio and proportion problems, students completed a researcher-designed mathematical PS test prior to instruction (pretest), immediately following instruction (posttest), and four months following instruction (delayed posttest). The PS test consisted of 18 items derived from the 8th grade TIMSS, NAEP, and state assessments and assessed ratio and proportion concepts and word problem solving knowledge similar to the instructed content. Students had 40 minutes to complete the same 18-item test at pretest, posttest, and delayed posttest.

*Professional Development.* Teachers assigned to the SBI-SM condition attended a 1-day session that described the goals of the study and how to mediate instruction and facilitate discussions and group activities. Teachers in the control condition attended one half-day training session that focused on the goals of the study and the importance of implementing the standard "business-as-usual" curriculum faithfully.

*Procedure*

Students in both conditions received instruction on ratio and proportion and were introduced to the same topics (i.e., ratios, rates, solving proportions, scale drawings, fractions, decimals, and percents) during the regularly scheduled mathematics instructional period for 40 minutes daily, five days per week, across 10 school days, delivered by their classroom teachers in their intact math classes. Lessons in both intervention and control classrooms were structured as follows: (a) students working individually to complete a review problem followed by the teacher reviewing it in a whole class format, (b) the teacher introducing the key concepts/skills using a series of examples, and then (c) assigning homework. Further, students in both conditions were allowed to use calculators.

*SBI-SM*. For the SBI-SM condition, the researcher-designed unit replaced the students' regular instruction on ratios and proportions. Lessons were scripted to provide a detailed teaching procedure (i.e., questions to ask, examples to present) for the purpose of ensuring consistency in implementing the critical content. However, rather than read the scripts verbatim, teachers were encouraged to be familiar with them and use their own explanations and elaborations to implement SBI-SM. To solve ratio and proportion problems, students were taught to identify the problem schema (*ratio* or *proportion*) and represent the features of the problem situation using schematic diagrams. Students first learned to interpret and elaborate on the main features of the problem situation. Next, they mapped the details of the problem onto the schema diagram. Finally, they solved ratio and proportion problems by applying an appropriate solution strategy (e.g., unit rate, equivalent fraction, or cross multiplication). The instructional approach encouraged students' "think-alouds" to monitor and direct their problem-solving behavior along the following dimensions: (a) problem comprehension (e.g., Did I read and retell the problem to understand what is given and what must be solved?, Why is this a *ratio* problem?, How is this problem similar to or different from one I already solved?), (b) problem representation (e.g., What schematic diagram can help me adequately represent information in the problem to show the relation between quantities?), (c) planning (e.g., How can I set up the math equation? What solution strategy can I use to solve this problem?), and (d) problem solution (e.g., Does the answer make sense? How can I verify the solution?)

*Control*. Students in the control group received instruction from their teachers who used procedures outlined in the district-adopted mathematics textbook (Bailey et al., 2004). Each lesson in the chapter on Ratios and Proportions begins with a real-life application of the mathematics to introduce and motivate the day's topic. The text then suggests a direct instruction approach for defining key concepts. Subsequently, several worked out examples are presented to expose students to the target problem types of the lesson, following by a period of guided practice.

## Results

The mathematics problem solving data were first examined for initial group comparability on the problem solving pretest measure by contrasting the SBI-SM with the control treatment, using a 2 group (SBI-SM, control) x 3 ability level (high, average, low) analysis of variance (ANOVA). Next, we assessed the acquisition and maintenance effects of the problem solving skill by conducting separate two-factor analysis of covariance (ANCOVA) with the problem solving pretest serving as a covariate for both the posttest and delayed posttest.

### *Student Learning*

Results of the ANCOVA applied to the posttest scores demonstrated statistically significant main effects for group, $F$ (1, 141) = 6.30, $p$ = .01, and ability level, $F$ (2, 141) = 16.53, $p$ < .001. The pretest was found to be a significant covariate, $F$ (1, 142) = 32.16, $p$ < .001. The adjusted mean scores indicated that the SBI-SM group significantly outperformed the control group. A low medium effect size of .45 was found for SBI-SM when compared with control. Post-hoc analyses using the Bonferroni post hoc criterion for significance indicated that the mean problem solving scores for the ability levels were significantly different (High > Average > Low). No significant interaction between group and ability level was found, $F$ (2, 141) = 2.01, $p$ = 0.14.

In addition, results from the delayed posttest administered four months following the completion of the intervention indicated statistically significant effects for group, $F$ (1, 135) = 8.99, $p$ < .01, and ability level, $F$ (2, 135) = 24.16, $p$ < .001. The pretest was found to be a significant covariate, $F$ (1, 135) = 34.06, $p$ < .001. The adjusted mean scores indicated that the SBI-SM group significantly outperformed the control group. A medium effect size of .56 was found for SBI-SM when compared with control. Post-hoc analyses using the Bonferroni post hoc criterion for significance indicated that the mean problem solving scores for the ability levels were significantly different (High > Average > Low). No significant interaction between group and ability level was found, $F$ (2, 135) = 2.04, $p$ = 0.13.

## Discussion

This study replicates and extends prior work by Jitendra and colleagues and others on the effects of schema-based instruction on students' learning of mathematics. The focus here was on ratio and proportion, a critically important but quite challenging content area for students. Our SBI-SM approach is relatively unique in its synthesis of best practices from the at-times conflicting special education and mathematics education literatures. SBI-SM uses explicit strategy instruction, which has been shown by special education researchers to be effective with low achievers, but with an emphasis on multiple strategies and the underlying mathematical structure of word problems—two features with strong foundation in the mathematics education and cognitive science research literatures.

Our research questions addressed the differential effects of SBI-SM and control treatment on the acquisition and maintenance of seventh grade students' ratio and proportion word problem solving performance. Consistent with our prediction, we found a statistically significant difference in students' problem-solving skills favoring the SBI-SM condition, suggesting that SBI-SM represents one promising approach to teaching ratio and proportion word problem solving skills. In addition, our results indicated that the benefits of SBI-SM persisted four months after the intervention. The effect sizes comparing the SBI-SM treatment with the control group were 0.45 on the immediate posttest and 0.56 on the delayed posttest. It is important to note that our control group received instruction on the same topics and for the same duration of time as the SBI group. At the same time, the effects for SBI-SM were not mediated by ability level, suggesting that it may benefit a wide range of seventh grade students. In sum, our use of direct instruction, but modified to move students beyond rote memorization to developing deeper understanding of the mathematical problem structure and fostering flexible solution strategies, helped students in the SBI-SM group improve their problem solving performance and maintain it over time.

A noteworthy feature of SBI-SM that future experimental research should investigate is its focus on multiple strategies. Prior work in special education has not encouraged the use of such an approach, particularly for low achieving students, because many special educators are skeptical of its benefits. One possible explanation for this skepticism among special educators is the inability of many low achieving students to meet the cognitive overload involved in learning multiple strategies (e.g., Baxter, Woodward, Voorhies, & Wong, 2002). Although ability level did not mediate the effects of SBI-SM in this study, visual inspection of the data suggests that, contrary to prior work in special education, the progress of students in the low ability classrooms was comparable to the performance of low achieving students in the control condition. This finding suggests that the cognitive overload of learning multiple strategies in SBI-SM may not necessarily be a concern, because it did not impede the learning of low achieving students in the SBI-SM condition.

In conclusion, the focus on ratio and proportion problems in the present study extends into middle school and to students with diverse needs the prior work on word problem solving with students with disabilities or low achieving students in other mathematical domains from the elementary and middle school curriculum. The present findings suggest that students can benefit from instruction that emphasizes the underlying mathematical structure of word problems, an important feature of SBI-SM.

# MEXICAN SIXTH GRADE STUDENTS' UNDERSTANDINGS OF FRACTION NOTATIONS AS NUMBERS THAT EXPRESS QUANTITY[1]

José Luis Cortina
Universidad Pedagógica Nacional
jose.luis.cortina@mac.com

Ericka Renata Cardoso
Universidad Pedagógica Nacional
ericka_cardoso@yahoo.com.mx

*We report on a study that consisted of administering tests to 297 sixth grade students from 13 different schools in Mexico. Pupils were asked to identify the quantity represented by common fractions (e.g., 1/2, 1/4, 1/3, 3/4). Results suggest that many students are finishing elementary school with a deficient understanding of fractions: some lagging behind so significantly that they have not developed understandings that allow them to readily and correctly interpret the quantitative meaning of the most common fraction notations, including "1/2." We discuss the implications of these results for students' opportunities to learn mathematics in middle school.*

## Background

Mathematics educators have long been concerned with the ways in which fractions are learned. According to several researchers, students must come to develop relatively sophisticated understandings of fractions in order to have access to important mathematical ideas, particularly those encompassed by the multiplicative field (Lamon, 2007; Thompson and Saldanha, 2003). In addition, studies based on written assessments administered to relatively large samples of students have identified the shortcomings of educational systems around the globe with respect to fraction instruction. For instance, several studies have documented the difficulties experienced by numerous students in grades 5 through 9 when identifying fractions on the number line (e.g., Gould, 2005; Hannula, 2003; Hart, 1989). In the case of the Mexican National Assessment of Educational Quality and Achievement (Backhoff, Andrade, Sánchez, Peon, & Bouzas, 2006) it was reported that 76.9% of Mexican sixth-grade students did not meet the probability criteria $P \geq .67$ of being correct when answering items that involved identifying a fraction such as 3/5 on the number line.

Studies based on assessing relatively large samples of students have typically been useful for gauging the existing limitations of fraction instruction in an educational system, and for measuring longitudinal change. However, these studies have rarely been helpful for developing strategies for improvement, particularly in terms of specifying instructional design and professional development challenges.

The study that we report in this paper was conducted for the purpose of identifying how ready Mexican students finishing elementary school (educación primaria; sixth grade) were to learn the mathematical ideas prescribed in the National Curriculum for Middle Schools (grades 7 to 9; Secretaría de Educación Pública, 2006). In particular, we were interested in documenting differences in how students made sense of a fraction notation of the kind "$\frac{a}{b}$", as a number that expresses quantity. We considered that the way in which a student made quantitative sense of these notations would be consequential in his or hers opportunities to learn the relatively sophisticated mathematical ideas encompassed by the multiplicative field as prescribed in the Middle School Curriculum (e.g., fractions, percents, decimals, ratios, rates, averages and quartiles). It is worth clarifying that such a consideration is consistent with the instructional tenet

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

that students who can attribute quantitatively sound meanings to the numbers that they encounter in instruction will have better opportunities to understand increasingly sophisticated mathematical ideas than those who do not (cf., National Council of Teachers of Mathematics, 2000; Thompson, Philipp, Thompson, & Boyd, 1994).

## Methodology

The study was conducted in the spring of 2006. It consisted of administering a test to 297 sixth grade students from 13 classrooms in different schools. The schools were selected from a pool of about 60, to which the research team had access. Some of those schools were in the highlands of the Mexican State of Chiapas and the rest on the south side of Mexico City. An effort was made to select classrooms with diverse student populations. As a consequence, the sample included classrooms that were in different kinds of schools (Table 1).

Table 1. *Classification of the 13 Classrooms that Formed the Sample by School Characteristics and by Classroom Size*

| | Chiapas N=6 | Mexico City N=7 |
|---|---|---|
| Urban Public Schools | 3 | 6 |
| Private Schools | 1 | 1 |
| Rural Schools | 2 | 0 |
| SES | | |
| High | 1 | 1 |
| Middle | 1 | 3 |
| Low | 4 | 3 |

| | Chiapas N=6 | Mexico City N=7 |
|---|---|---|
| Bilingual Schools | 1 (Spanish-Tzotzil) | 0 |
| Classroom size | | |
| 11-16 students | 3 | 0 |
| 20-25 students | 2 | 4 |
| 28-33 students | 1 | 3 |

The great majority of the students (86.2%) were eleven or twelve years old at the time of the study. There were some students that were ten years old, and others that were older than twelve (Table 2). It is worth clarifying that, in Mexico, the presence of significantly over-aged students is common in elementary schools that serve children living in poverty.

Table 2. *Distribution of the 297 Students in the Sample by Age*

| **Age** | **10** | **11** | **12** | **13** | **14** | **15** | **16** | **18** | **19** |
|---|---|---|---|---|---|---|---|---|---|
| **N** | 3 (1%) | 110 (37%) | 146 (49.2%) | 28 (9.4%) | 2 (0.7%) | 4 (1.3%) | 2 (0.7%) | 1 (0.3%) | 1 (0.3%) |

Prior to designing the test, the National Mathematics Curriculum for Seventh Grade (*primer año de secundaria*; Secretaría de Educación Pública, 2006) was examined (cf. Cardoso, 2008). The purpose of the examination was to identify the kinds of quantitative understandings about fractions that students would have had to develop in elementary school in order to be ready to engage meaningfully with the mathematical ideas prescribed for middle school.

It became evident that the designers of the National Mathematics Curriculum for Seventh Grade did not assume that students who enter middle school would have mastered all the content prescribed in the Elementary School Curriculum. Instead, they chose to review parts of the elementary school curriculum content. For instance, the Middle School Curriculum indicates that teachers should start instruction by helping students identify fractions on the number line, despite the fact that, according to the Mexican Elementary School Curriculum (Secretaría de Educación Pública, 1993), students would have already been taught to do so in fifth and sixth grades.

Based on our examination of the Middle School Curriculum, we conjectured that students would have to enter middle school understanding, at least, the basic rationale of fraction notation; namely, that there is a numerator and a denominator, that each represents something in particular, and that together they express quantity. We also conjectured that students would have to be capable of correctly imagining the quantities represented by relatively common fraction inscriptions as expressing something that would be smaller than, as big as, or bigger than 1/2 and 1. We concluded that without those understandings it would be unreasonable to expect students to meaningfully engage in instructional activities that involved identifying fractions on the number line, as well as others that would come latter in the curriculum.

The test included 19 items. The first 6 involved comparing the fractional amount of milk contained in two milk cartons, in terms of one having more milk than the other, or of the two having the same amount. Students were shown the drawing of two milk cartons, each with a fraction inscription on the bottom (Figure 1). They were asked to mark the level of the milk in each carton, accordingly to the fraction shown, and to indicate which was fuller or if both had the same amount. The fractions that students compared were: 1/3 vs. 1/2; 3/4 vs. 1/4; 1/3 vs. 2/3; 2/4 vs. 1/2; 4/9 vs. 3/4; 5/10 vs. 1/2. All the fractions were relatively common, and all the comparisons could be solved correctly by assessing each fraction inscription as representing a quantity that is smaller than, as big as, or bigger than 1/2. In addition, the items involved a familiar context for students (containers from which liquids are served), although it was probably a context in which pupils were not used to dealing with fraction inscriptions.

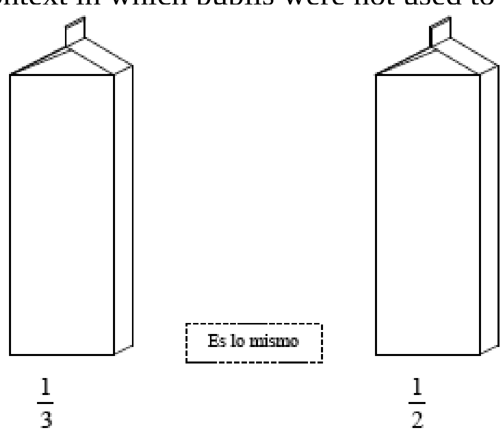

*Figure 1.* One of the milk carton items.

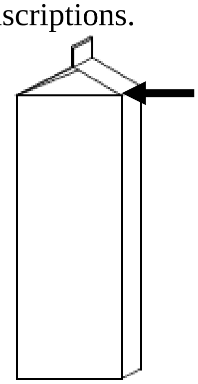

*Figure 2.* The level of the milk when the carton is full.

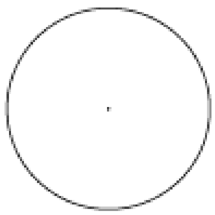
Students were given a detailed explanation of what they had to do before solving the milk carton items. A real milk carton was used to give this explanation. Among other things, students were told about where the level of the milk would be when a milk carton was full (Figure 2). In addition, there were at least three adults[2] present in every classroom in which the test was administered. These adults aided individual students who had doubts about what they were expected to do.

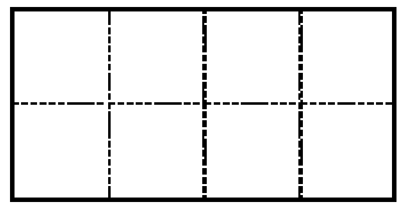
The seventh item involved comparing the amount of milk that was used to make each of three cakes. Students were shown a picture of three identical drawings of cakes, each with one of the following inscriptions on the bottom: $\frac{5}{4}$ *of a liter*, $\frac{8}{9}$ *of a liter*, *liter*. Students were told that the inscriptions showed the amount of milk that was used to make each of the cakes, and were asked to mark the one in which they thought that the most milk was used.

The remaining 12 items were more similar to typical school exercises. Six consisted of circles marked with a fraction inscription on the bottom (Figure 3). Students were asked to shade the area corresponding to the fraction shown. Those fractions were: 1/2, 2/4, 3/4, 1/3, 2/3, and 3/3. The other six items consisted of rectangles marked with a fraction inscription on the bottom (Figure 4). Again students were asked to shade the area corresponding to the fraction shown. Those fractions were: 1/2, 1/4, 3/4, 1/8, 4/8, 8/8.



$\frac{1}{2}$

Figure 3. One of the circle items.



$\frac{1}{4}$

Figure 4. One of rectangle items.

The circle and rectangle items were included for the purpose of identifying possible differences in students' performance when expressing fractional values using representations that are common in schools than when using representations that are not (such as milk cartons). We considered that if a student's performance were to be very different in the two kinds of items, it could be reasonable to conjecture that a poor performance in the *Milk Carton Items* would be the result of the student's difficulties to make sense of the activity. In contrast, if a student's performance in both kinds of items were consistent—in general terms—it would be reasonable to consider that a student's performance in the *Milk Carton Items* reflected his ways of making sense of fraction inscriptions as numbers that express quantity.

## Results

A coding scheme composed of four categories was developed for classifying the tests. The scheme emerged from the analysis of the first 38 tests that were administered. The analysis involved searching out similarities and differences among the test responses that reflected possible similarities and differences in students' quantitative understanding of fractions—similarities and differences that would be important to account for in instruction. The four categories turned out to be useful for classifying 292 of the 297 tests that were administered. Each of these 292 tests was classified, without difficulty, as belonging to one and only one category. The 5 remaining tests (1.7%) were discarded because of inconsistencies (e.g., the test was not completed).

*Category A*

The tests that were classified into Category A (N=59; 20%) were those in which the students responded correctly all the *Milk Carton Items* (or all but one of them), as well as the *Three Cakes Item* and the *Circle* and *Rectangle Item.* These students' responses suggested that they correctly imagined the quantities represented by relatively common fraction inscriptions as expressing something that would be smaller than, as big as, or bigger than 1/2 and 1. Generally speaking, these students seemed to be ready to engage in instruction involving identifying fractions on the number line.

*Category B*

The tests that were classified into Category B (N=57; 19.5%) were those in which the students responded correctly to all the *Milk Carton Items* (or all but one of them), as well as the *Circle* and the *Rectangle Items*, but that responded to the *Three Cakes Item* incorrectly. Specifically, all of them identified the cake with the inscription “1 liter” as the one in which the most milk was used.

The responses on the tests that were classified into this category suggest that the students that answered them properly construed relatively common fraction inscriptions as expressing quantities smaller than, as big as, or bigger than 1/2. However, the responses also suggest that the students might have conceived of fraction inscriptions as expressions that always represent quantities that are smaller than or equal to 1. It is reasonable to conjecture that the students whose tests were classified into Category B may not have been prepared to engage, readily and meaningfully, in instruction involving the mathematical ideas prescribed for seventh grade in the Mexican Curriculum. In order to be prepared, they would have to be supported in understanding why and how a fraction inscription can, legitimately and soundly, express a quantity that is bigger than 1.

*Category C*

The tests that were classified into Category C (N=87; 29.7%) were those in which, throughout the *Milk Carton*, the *Circle*, and the *Rectangle Items*, the students consistently represented the fraction “$\frac{1}{2}$” as “one half”, but misrepresented most of the other fraction inscriptions on the test (Figure 5). These students seemed to have had developed sound quantitative imagery about a limited number of fractional inscriptions (i.e., 1/2 and, in some cases, 1/4 and 3/4).

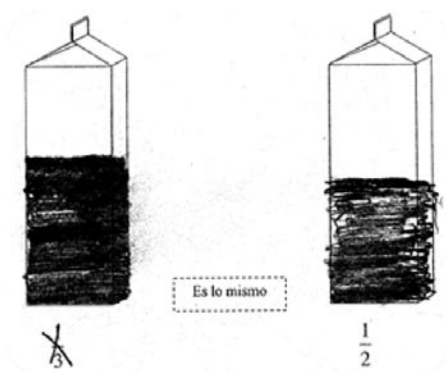


*Figure 5.* Representation of 1/3 as more than 1/2 in a test classified into Category C.

The responses on the tests that were classified into this category (Category C) suggest that the students that provided them might have not yet developed an understanding of the system of fractional notation that would allow them to correctly construe fraction notations whose quantitative meaning they did not previously know. An example of such an understanding would be to consistently conceptualize the denominator of a fraction as expressing a number of equal parts in which a whole was divided, and the numerator as a certain number of those parts. This was not something that the students whose tests were classified into Category C seemed to do. Instead, when encountering fraction notations whose meaning they did not previously know, these students seemed to conceptualize them following the same quantitative rationale they used for interpreting natural numbers: the bigger the number the bigger the amount it represents. For example, in the *Three Cakes Item,* many of these students chose the “8/9 Liter” cake as the one in which the most milk was used, probably because—in the natural number system—8 and 9 represent larger quantities than 5 and 4, and than 1.

It is reasonable to conjecture that the students whose tests were classified into Category C may not have been prepared to engage, readily and meaningfully, in instruction involving the mathematical ideas prescribed for seventh grade in the Mexican Curriculum. To be prepared, they would have to be supported in developing understandings about the quantitative rational of fraction notation that would allow them to, at least, correctly interpret relatively common fractions—whose meaning they did not previously know—as representing quantities that are smaller than, as big as, or bigger than 1/2 and 1.

*Category D*

The tests that were classified into Category D (N=88; 30.1%) were those in which, throughout the assessment, the students did not consistently represent any fraction correctly, including “$\frac{1}{2}$” (Figure 6). The responses on the tests that were classified into this category suggest that the students that provided them might have not yet developed imagery about the quantitative meaning of fraction notations that would allow them to correctly construe them as symbols that express quantity—not even with respect to a limited number of inscriptions. Many of these students seemed to approach all fractions as symbols that followed the same quantitative rationale as natural numbers: the bigger the number bigger the amount it represents.

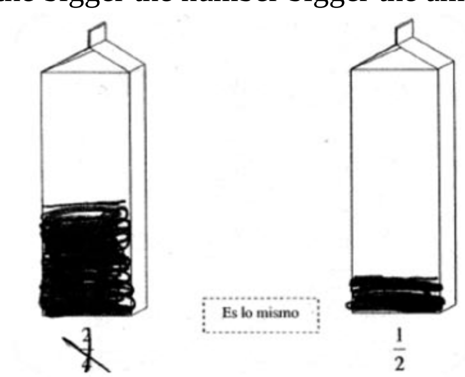

*Figure 6.* Representation of 2/4 as more than 1/2 in a test classified into Category D.

It is reasonable to conjecture that the students whose tests were classified into Category D may not have been prepared to engage, readily and meaningfully, in instruction involving the mathematical ideas prescribed for seventh grade in the Mexican Curriculum. To be prepared, they would have to be supported in developing understandings about the quantitative rationale of

fraction notation that would allow them to, at least, correctly interpret relatively common fractions as representing quantities that are smaller than, as big as, or bigger than 1/2 and 1.

Once the tests were coded, the distribution of students in each classroom—according to the four categories—was identified (Figure 7). It became apparent that there were important differences across classrooms, some with more than half of tests classified into Categories A and B, and others with only a few tests (or no) tests in these Categories. Six classrooms fell into the former group, of which five were in schools attended by students with high or middle SES. Seven fell in to the latter group, of which six were in schools attended by students with low SES (Figure 7). It also became apparent that, despite these differences, all the classrooms had students whose tests were classified into Categories C and D. These observations suggest that the problem of sixth grade students lagging behind in their quantitative understanding of fractions might be widespread across the Mexican Educational System, but more acute in schools attended by children of low income families.

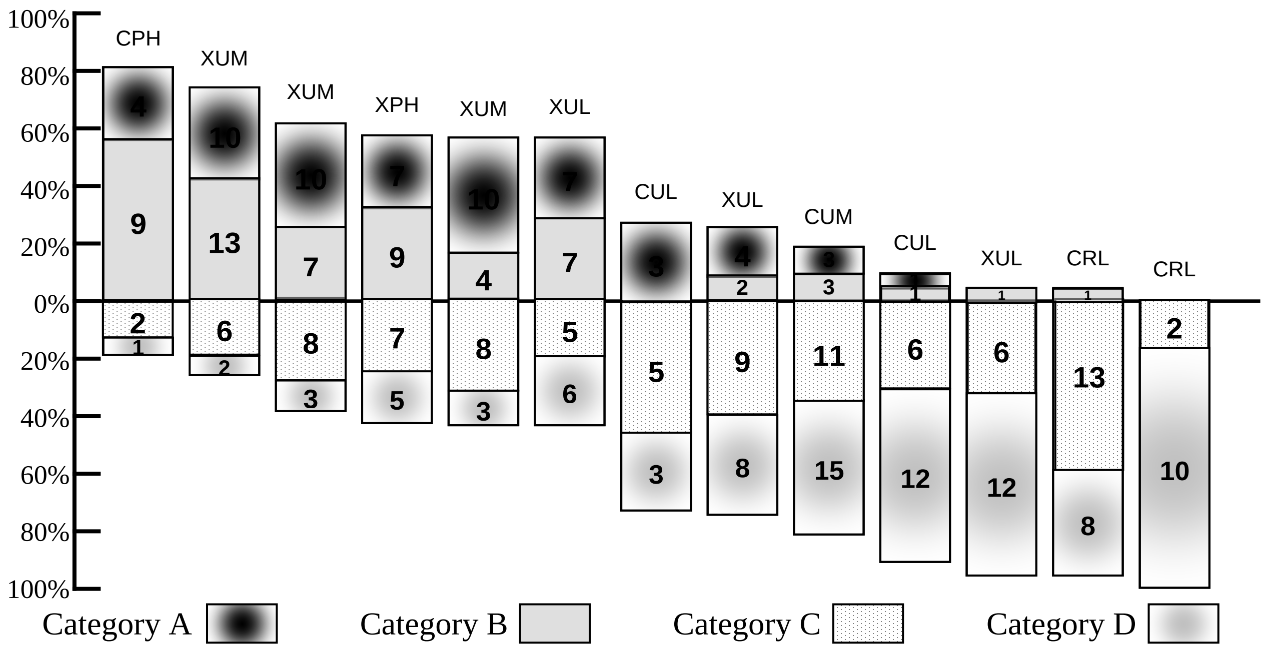

*Figure 7.* The thirteen classrooms by how the tests of its students were classified into the four categories, both in absolute terms (numbers inside the boxes) and proportionally (size of the boxes). The first letter on the label of each classroom indicates the school's location (C: Chiapas; X: Mexico City); the second letter, the type of School (P: private; U: urban public; R: rural public); and the third letter, the typical SES of the students (H: high; M: middle; L: low).

**Conclusions**

Our results suggest that many students in the Mexican Educational System are entering middle school lagging behind in their understanding of fractions as numbers that express quantity. Some students are lagging behind significantly, to the point that they have not developed understandings that allow them to interpret, readily and correctly, the quantitative meaning of the most common fraction inscriptions; in many cases, including “$\frac{1}{2}$”. The results also suggest that the problem is widespread across the educational system, but more acute in socially and economically deprived contexts.

Based on our results, it is reasonable to conjecture that the Mexican Educational System is facing a serious problem regarding mathematics instruction, at least instruction concerning the ideas encompassed by the multiplicative field. It seems that the system is being ineffective in supporting many pupils in developing the mathematical understandings that are necessary if they are to fulfill the learning goals that the system itself has established. As a consequence, many students are being asked to engage in instruction involving mathematical ideas that they are not ready to make sense of. This situation is likely to create frustrating learning experiences in mathematics classrooms for many students. In addition, it can limit students’ opportunities not only to learn the mathematical ideas prescribed for their grade level, but also to make sense of more basic notions.

We are uncertain about how this problem could be solved at the systemic level. However, we believe that it would be worthwhile to develop instructional resources that help Mexican sixth grade teachers identify and respond to the particular challenges they face in their classrooms, regarding fraction instruction. In addition, it would be important to implement professional development programs that help Mexican sixth grade teachers learn about the challenges they face with respect to fraction instruction, and about the resources they can use to meet those challenges.

# THE IMPACT OF PROFESSIONAL DEVELOPMENT ON TWO TEACHERS' UNDERSTANDING AND USE OF REPRESENTATIONS

Susan Sexton
University of Georgia
sextons@uga.edu

Chandra Hawley Orrill
University of Georgia
corrill@uga.edu

*In this study, we consider the experience of two alternatively-certified teachers' experiences in a professional development course. We looked at their abilities to interpret drawn representations and the impact they reported those abilities had on their teaching. We relied on interviews with the participants and videotapes of their professional development experience. Findings indicate that the teachers both made significant strides in their abilities to interpret drawn representations of fraction operations and in their reported use of them in their classrooms.*

## Background

A nationwide shortage of teachers combined with high turnover rates in the areas of special education, mathematics and science (Ingersoll, 2001), have resulted in a practice of recruitment of teachers from non-traditional backgrounds, especially in urban areas. While the interest in research on these teachers has risen, the research in this area is still minimal with questionable results. Nonetheless, results of studies suggest alternatively certified teachers are more willing to work in the critical needs areas with low-achieving students (Zeichner & Conklin, 2005).

This influx of alternatively-certified teachers into mathematics classrooms creates particular challenges given that the vision of classroom mathematics has changed (NCTM, 2000) and these teachers are often sent into classrooms with little more than classroom management guidance. The mandates placed on schools through various national, state, and local accountability efforts have driven the need for teacher professional development (Hill & Ball, 2004), but that professional development is generally designed for teachers with traditional certification and backgrounds. Clearly, the need for professional development of alternatively certified teachers is also great, but little is known about the kinds of support they may need – particularly in their first few years – and whether professional development for regularly certified teachers is appropriate when the alternatively-certified teachers have not had previous opportunities to develop knowledge for teaching (Shulman, 1986; Ball, Lubienski, & Mewborn, 2001). Fortunately, much modern professional development has moved away from the traditional "make and take" model of professional development that focused on development of a single lesson to use in the classroom. Modern professional learning instead often seeks to develop the mathematical knowledge for teaching (Ball, Lubienski, & Mewborn, 2001) of the participating teachers – starting from wherever the teachers are in their current development. This means that these efforts seek to address teacher content knowledge, develop their teaching strategies, and explore student thinking.

Built into this new vision of professional learning and relying on guidelines about high-quality professional development (e.g., Elmore, 2002; Hawley & Valli, 1999; Hill, 2004), the InterMath approach provides teachers with a full semester-long hands-on learning experience designed to engage them in development of content knowledge and pedagogical knowledge simultaneously. To meet the professional development goals, InterMath engages teachers in mathematical problem solving and exploration through the use of software including Fraction

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

Bars (Orrill, undated), wikis, and spreadsheets with which teachers can model and analyze a variety of mathematical situations. In the InterMath class sessions, teachers begin to experience the learning environments advocated in reform documents (e.g., NCTM, 2000). For example, InterMath participants engage in problem-solving by using technology to model and solve a variety of open-ended problems.

For this study, we developed an InterMath course focused on rational numbers. This topic was chosen because of the notorious need for professional development in this content area (e.g., Ball, Lubienski, & Mewborn, 2001; Ma, 1999), the necessity for students to develop strong rational number sense (Lamon, 2007), and its appropriateness for middle grades teachers, which was our population of interest. The InterMath – Rational Numbers course (IM) had three explicit goals: to raise participant awareness of referent units; to provide opportunities for participants to develop understandings of drawn representations for solving rational numbers problems; and development of proportional reasoning skills as they relate to ratio and fraction situations. To meet these goals, we designed the IM course to last 14 weeks with approximately 40 instructional hours.

The data reported here were collected as part of the NSF-funded *Does it Work* (DiW) project which was investigating three critical research questions: (1) What do teachers learn in professional development?; (2) How did teachers' practice change as a result of the professional development?; and (3) How does teacher change impact student performance on assessments? The current study is concerned with the first research question – the impact of the professional development on teacher learning as it relates to this alternatively certified population. Specifically, we wanted to understand the impact of IM (http://intermath.coe.uga.edu) on teachers with emergent mathematical knowledge for teaching who have not taken traditional mathematics education courses. We considered to what extent a single professional development course can impact alternatively certified teachers' learning and their reported practices.

## Framework

### *Learning Environments*

For teachers who have never experienced learning standards-based ways, providing these opportunities to students is difficult (Goldsmith & Shifter, 1997). After all, these teachers "may not have useful images from their personal experiences to guide the creation of a focused and productive classroom culture that emphasizes inquiry and the exchange of ideas" (Goldsmith & Shifter, 1997, p. 25). However, certain learning experiences appear to impact teacher change. For example, teachers consistently report developing the most effective strategies and practices through experiences and collegial interactions (Wilson, Cooney, & Stinson, 2005).

Research has shown that the learner-centered approach of the InterMath course allowed teacher participants to take "ownership of the content and investigations" (Polly, 2006, p. 15). While InterMath courses do not provide a prescription for teaching, the type of learning environment that InterMath offers teacher participants may affect the type of learning environments the teachers provide for their own students. These environments include student-centered mathematical investigations with different learning media such as technology.

### *Understanding and use of Drawn Representations*

Lesh, Post and Behr (1987) discussed understanding as the ability to "recognize the idea embedded in a variety of qualitatively different representational systems", the ability to "flexibly manipulate the idea within given representational systems", and whether one "can accurately translate the idea from one system to another" (p. 36). The authors suggest that to support understanding, teachers need to be able to "diagnose a student's learning difficulties, or to identify instructional opportunities, teachers can generate a variety of useful kinds of questions by presenting an idea in one representational mode and asking the student to illustrate, describe, or represent the idea in another mode" (p. 37).

Lesh, Post and Behr (1987) identified manipulative models, static pictures, written symbols, spoken language, and real scripts as "five distinct types of representation systems that occur in mathematics learning and problem solving" (p. 34). The authors claim that while knowledge and facility with these representations are important, "translations among them, and transformations within them, also are important" (p. 34). Furthermore, the authors discuss that "good problem solvers tend to be sufficiently flexible in their use of a variety of relevant representational systems" (p. 38). This is critical because using mathematical representations may open the classroom to more novel student approaches to the problems, thus, creating a situation in which the teacher has to be able to reflexively interpret and respond to novel student thinking.

## Methodology

Data for this study included videotapes of each session of IM as well as participant "write-ups" for each of 10 investigations. These write-ups outlined not only the solutions to the investigations, but also documented the approach(es) the participants took in working them. The teachers were also expected to create two lesson plans that incorporated InterMath-like approaches into their own classrooms.

In addition to the InterMath assignments, the teachers were also asked to complete a pretest and a posttest. The assessments both drew from a bank of items comprised of those from the "Learning Mathematics for Teaching" middle grades instruments (LMT; SII/LMT, 2004) and items developed by the DiW team. The items developed by the DiW team had been validated through a nationwide effort that included 201 teachers that was further augmented by a set of over 25 videotaped cognitive interviews in which teachers described their approaches to solving the items developed by the DiW team. The DiW assessment reports performance using *z*-scores and forms are equated to allow measurement of growth over time.

To further enhance our understanding of teacher learning in IM, we conducted cognitive interviews with a subset of the InterMath participants about items on the assessments. In this study, we present data from two teachers who participated in the InterMath course. Using mixture Rasch models, we analyzed our participants' performance on the pretest and determined in which of two latent classes each participant belonged. These classes were statistically-identified groups of teachers who shared some aspect of their approach to the items on the assessment. Both teachers were in the same latent class.

Both teachers were interviewed after the pretest and the posttest. Each interview was videotaped using two cameras, one focused on the participant and the other focused on their hands to capture gestures and writing. The interviews were used to capture each participant's discussion about a subset of the assessment items that were of particular interest to the researchers as they aligned with the explicit goals of the course and, for the most part, they relied on drawn representations.

In addition to the pretest and posttest interviews, members of the research team also conducted weekly phone interviews with the InterMath participants. The purpose of the interviews was to gauge teacher perception of the content and teaching of the course. The interviews also gained qualitative information about the teachers' stated beliefs in regards to the teaching and learning of mathematics with respect to the three main foci of the course.

The data were analyzed by a member of the research team to search for evidence of teacher learning – specifically in regards to the three main foci of the Rational Numbers Course: understanding of the referent unit, understanding of drawn representations of fraction and decimal operations, and proportional reasoning. Instances of participant discussion in either the professional development sessions or the interviews were analyzed in which the participants made direct comments to their learning and use of the referent unit, drawn representations, or proportional reasoning. The participants' understanding and use of drawn representations are presented next.

*Participants*

The present study considers two IM participants. The two participants, whose pseudonyms are Brian and Corey, were African-American males teaching middle grades mathematics at the time of the study. Both teachers had alternative certifications and preparations in fields other than middle grades education. Brian was in his second year of teaching sixth grade while Corey was in his fifth year of teaching sixth, seventh, and eighth grades to low-achieving and special needs students.

## Findings

*Pre-InterMath Experience with Drawn Representations*

In our initial interviews with them, both Corey and Brian reported having limited prior experience teaching and learning with drawn representations. Corey, with more years of teaching experience, stated that although he had four years of teaching experience, this was his first year of "actually getting into drawing the lines and actually understanding numbers and operations." Brian, a second-year teacher, discussed his experience of teaching with drawn representations in his first year of teaching as working with "a lot of plane figures, so rectangular prisms, triangular prisms, things like that." Neither provided evidence that they considered the use of drawn representations as a means of modeling mathematical operations.

Items on the pretest asked the participants to consider various models of rational number operations either in the context of student solutions or in the context of finding a solution to a given problem. When presented with number line representations for fraction subtraction, multiplication and division both Corey and Brian displayed confusion and (for Corey) an outright dislike for the representation. When asked why he did not like the number line to model fraction operations, Corey replied "Because it's confusing." He felt that using them to teach with would be "too confusing to [the students], because it doesn't give them a real representation." As he selected his answers on the items, it was apparent that he first found the answer using an algorithm and then found a representation to match that solution. Brian expressed that he was not familiar with modeling fraction operations on the number line and that modeling fraction division with any representation was difficult for him.

Both Corey and Brian expressed general familiarity with array models and had used them for teaching. Corey, in particular, made reference to a "math seminar" he took in the previous school year on learning how to teach with the array model. However, even with this experience, Corey displayed limited ability to interpret array models. For example, in a problem presenting different correct array representations of the same fraction multiplication, Corey chose only two of the three drawings. He based his choice on the one representation that he understood best and whether or not the other two could be rearranged to look like the representation with which he felt most comfortable. In contrast, Brian identified all of the array models as correct and even appeared to understand how the operation was modeled in each representation.

Modeling fraction division with array models proved difficult for both participants. We saw this difficulty in a problem that asked the participants to select the representation that correctly modeled the quotient 2 as it related to the division situation. While Brian initially identified the correct representation, he talked himself away from this choice as he tried to make sense of the representation. Corey, on the other hand, did not find any of the possible representations correct because none of the possibilities represented two wholes – they only showed "parts of a whole." Neither of the teachers understood what the answer, 2, was referring to – they both had a sense that it was two wholes rather than two parts of a divisor.

*InterMath Experiences*

Corey and Brian both reported that they chose to participate in the InterMath course to increase their repertoire of teaching strategies. Corey stated, "I'm always looking for different strategies and different ways to present material. So I'm always trying to learn. I just figured this is a great way to learn more strategies." Brian focused on his students' apparent trouble with rational number understanding stating, "I was actually most interested in the Fraction Bar software because I wanted to be able to have another resource . . . And I knew from last year that fractions was one of the most challenging subjects that my students had."

Throughout the InterMath course, both Corey and Brian were active participants, regularly sharing their thoughts and mathematical ideas with the class. Corey, through the InterMath investigations, started to have a new experience with number lines. "I usually use area models but just looking at some of the stuff that we're doing, I'm starting to feel more comfortable with number lines, as far as fractions." By the eighth week of the course, he shared that "number lines and pictures and everything else have actually helped me expand upon my instruction for my students." Surprisingly, both participants expressed an interest in sharing one particular investigation that involved number line representations with their classes.

While both participants reported finding the IM representations helpful for teaching their students, Brian appeared to be particularly affected by his experiences in the course with modeling operations through drawn representations. In the case of fraction division, an area he expressed having difficulty modeling prior to the course, he noted: "When we went over dividing fractions, I actually the next day went and modeled it for my kids the same way." Unsurprisingly, he explained his pre-IM experience as "just looking at the numbers and, you know, flipping and doing that type of stuff, but never actually seen it modeled visually." Like Brian, Corey reported that he was "taught the algorithm, and you go straight through it and I was comfortable." However, the structure of IM, which included considerable group discussion, provided Corey with access to other teacher participants' mathematical views. "It's more than a few [problems] where somebody else has said or seen it a different way and thought it out and given a darn good explanation and those are the ones that I write down for later."

Both participants provided insight into their teaching through our interviews. Both stated that they were providing more discovery time for their students' mathematical investigations and using questioning strategies. For example, in the eighth week of the InterMath course, Brian discussed his transition:

> "I think at the beginning [my teaching approach] was completely different and now I've really tried to adopt the same kind of approach in terms of asking

> questions, especially last year, when they asked the questions, I'd answer them. I'd give them a straight up answer. . . . So I'm asking them questions to get them thinking about to access where that knowledge is. So I've really changed how I go about the execution of my lesson."

Corey also stated a similar desire to change his teaching approach: "Well, [the InterMath instructor] has a facilitating approach. . . .I'm kind of trying to continuing to emulate that in my classroom."

*Post InterMath Experiences*

At the end of IM, Brian and Corey took the posttest and participated in another interview about that assessment. Both showed qualitative and quantitative improvement on their posttest after having completed IM. During the cognitive interviews, the participants demonstrated improvement in their discussion of the fraction operations problems with drawn representations. In his interview, Brian repeatedly referred back to his experience in IM as he discussed his solutions to different problems. Corey, who was particularly vocal about his dislike of the use of the number line representation before IM, demonstrated fluency and comfort with the representation on the posttest.

Further, both Corey and Brian changed their latent class membership between the pretest and the posttest. Based on our earlier analyses of the meanings of the latent classes, this movement indicates a movement toward more reliance on referent unit knowledge in reasoning about the items on the assessment (Izsák, Orrill, Cohen, & Brown, in review). We interpreted these changes in their assessment performance as indication that the course increased their mathematical knowledge for teaching. Some of the posttest items on drawn representations were identical to the pretest items.

As noted above, the two participants spoke qualitatively differently about those particular problems, indicating a different mathematical point of view and understanding of the representation and mathematical operation used. For example, Corey, who had shared his dislike of the number line model initially, was more confident and comfortable in the posttest noting only that he wished the number line had been labeled. He tied this to his teaching saying, "I'm a little – I'm a stickler on labels also because my children, they will draw something like this, when I actually want to see all the labels." This statement also indicates a possible change in Corey's pedagogical strategies. Before IM, he mentioned he would not use number lines to teach fraction multiplication to his students, however, his comment suggests that he not only taught with number lines during IM, but also required certain features of the number line model to be clear as he assessed his students' work. Corey also explained that he used the array model to help him reason with the number line model stating that thinking about the array model "just gave me a concept of what I needed to be looking for on a number line." Research suggests that while a teacher may be very proficient with one particular model of fraction operations, he/she have difficulty transforming (Lesh, Post & Behr, 1987) that understanding to a different model of the same operation (Orrill, Sexton, Lee, & Gerde, 2008). Corey's statements suggest that he was at least beginning to find connections between the models that were important to his understanding. He also indicated that his work with representations was great and that, "it's showing some dividends in my class."

Brian also provided evidence of increased flexibility in interpreting drawn representations and he attributed that flexibility to his experience in IM. For example when discussing representing fractions he remarked, "And then I remembered after learning it in the class I focused more so on … having one whole and then breaking it into thirds and that third, breaking it into fourths." Brian, like Corey, reported using the representations in his classroom. He stressed that he used them to help the students understand ideas rather than numbers, a focus he had before IM as well.

## Discussion

The data reported here show that the IM experience had a positive impact on these two teachers both in terms of their mathematical knowledge for teaching and their teaching practice. While we would not claim that these results were typical for all InterMath participants, they are encouraging as a sign that a single course can have significant impact on teacher understanding of critical aspects of the content they teach.

While IM did not provide a prescription for teaching, both Corey and Brian remarked on a number of occasions that they had used variations of the problems investigated in the course with their own students. Despite differences in the middle school populations they taught, both teachers reported finding the drawn representations practical and useful for supporting their students. Further, seeing representations modeled by the instructor in the InterMath course supported the teachers in making changes to their own teaching strategies.

In a time of teacher shortages, especially in the area of mathematics, more and more administrators are turning to alternatively certified teachers. Such teachers may lack adequate background in their content knowledge or knowledge for teaching. Professional development is one way in which to help these teachers fill in some of these gaps, as is evidenced by this study. Here, two participants, provided evidence that they not only learned new teaching strategies but also deepened their mathematical content knowledge even though the professional development had not been differentiated for the alternatively certified teachers. To us, this suggests that using a hands-on approach with the instructor modeling desired teaching actions may provide one effective model for supporting alternatively certified teachers in building their vision of what school mathematics should be – one of the critical purposes professional development can serve (Sowder, 2007).

Shandy Hauk
University of Northern Colorado
shandy.hauk@unco.edu

*Interviews with 12 prospective elementary and middle school teachers focused on computation, problem-posing, visualization for problem-solving, and eliciting from participants explanations of the connections among these, particularly explanations that would be accessible to children learning about multiplication. We analyze the nature of participants' conceptions and explanations and discuss implications for teacher preparation.*

## Background

In elementary schools, multiplication of two values is taught as a number of equivalent groups (*multiplier*) times the size of each group (*multiplicand*), with *multiplier* x *multiplicand* as the default order. (Harel, Behr, Post, & Lesh, 1994). Research with children up through middle school age, working with word problems, suggests that their choice-of-operation is strongly affected by the nature of the multiplier (Bell, Fischbein, & Taylor, 1984). For example, given two word problems with the same context but different number types may result in different choices: *Suppose peanuts cost $2 per pound. (a) What is the cost for 3 pounds of peanuts? (b) What is the cost for ½ pound of peanuts?* Students will often identify multiplication as the operation to use for (a) and division for use in (b) (Af Ekenstam & Greger, 1983). Fischbein and colleagues (1985) proposed an intuitive model to provide a theoretical account for this "non conservation of operations" (Greer, 1988): When the constraints of the underlying model are incongruent – for the learner – with the numerical data given in the problem, the choice of an inopportune arithmetic operation may occur. Though Marshall and colleagues (1989) proposed an instructional intervention based on semantic analysis to assist students in learning to match a situation to a useful schematic representation, researchers have expressed concern that such intervention may foster superficial strategies in solving world problems without helping learners to construct conceptual representations situated in the problems (Verschaffel & De Corte, 1993).

Some studies and teaching experiments have approached the learning of multiplication through *problem-posing* rather than problem-solving tasks (Fischbein et al., 1985; Lowrie, 2002). This work supposes that a generative connection to the task might support conceptual engagement during subsequent problem-solving. However, in some cases children's performance on such tasks improved only when the numbers were whole (not fractions). In other studies, researchers have examined how learners connect their solving of word problems to acting on manipulatives to solve problems, in terms of units of quantity (Behr et al., 1997). Such studies have challenged the dominance in school curriculum of the use of a context-independent interpretation of 1-unit (Steffe, 1988). To generate a mental construct, a learner needs to re-present the concept even in the absence of perceptual input (von Glaserfeld, 1982). Thus, neither students' capability in algorithmic calculation nor their competence in acting on manipulative aids cued by problem context reaches the utmost goal of constructing conceptually rich mental schema. Several researchers have worked to describe and explain the process of formation of mental constructions into object-like cognitive entities, such as *encapsulation* (Asiala et al., 1991, after Piaget), *reification* (Sfard, 1989), and *proceptual* thinking (Gray & Tall, 1994). In each case, the role of making connections among object-like cognitive entities is central.

### Theoretical Perspective and Research Question

*Action-Process-Object-Scheme* (APOS) theory (Asiala et al., 1991) describes a hierarchical relationship among types of mental structuring (action, process, object-like entity, and schema) in which learner awareness, perception of totality, and coordination of aspects of a concept (identified by researchers through a genetic decomposition of the concept) are salient features. A style of teaching associated with APOS theory aims to assist students to move from one level to another and to gradually stabilize a developing mental construct. Reification and proceptual theories pay significant attention to the use of symbolic representation. According to Sfard (2000), in the process of reification, naming and symbolizing (creating a signifier) is no less important than the cognitive entity (signified). Gray and Tall (1994) have asserted that a flexible use of mathematical symbolism may compress action/process into object/concept, which in turn may liberate more capacity for cognitive activity and advanced mathematical thinking. Both perspectives, reification and proceptual thinking, value procedural skills in which manipulation on symbolic representations plays a central role in the process of stabilizing a mental construct into a conceptually rich understanding.

For a prospective teacher, the mathematical knowledge needed to *teach* is more than the knowledge needed to *do* mathematics (Shulman, 1986; Ball & Bass, 2000). Also important is a facility in packing and unpacking object-like understandings in order to supply explanation, and make sense of students' thinking, both in planning for instruction and in-the-moment-of-teaching (Hill, Ball, & Schilling, 2008). In particular, we started from the hypothesis that understandings of multiplication by prospective K-8 teachers would be foregrounded if they were asked to describe a particular kind of connection: that between doing multiplication in response to: (a) a symbolic statement (decontextualized) and to (b) a word problem (contextualized).

The study reported here sought to gain insight into the following questions: (1) What are the ways in which prospective grades K-8 teachers may perceive the isomorphic relationship between abstract structures (decontextualized mathematics problems) and concrete structures (contextualized or story problems) for fractions in simple multiplication? (2) What roles in problem-posing and problem-solving might fraction as APOS-object, and fraction multiplication as APOS-object (Asiala et al., 1991) play in understanding multiplication?

### Design and Setting

The 12 women in this study were prospective grades K-8 teachers who had completed the first 2 of 3 semesters of teacher-preparatory mathematics at a comprehensive U.S. university. According to the instructors and textbook authors (Bennett & Nelson, 2000), the courses aimed to teach mathematics with conceptual understanding. One task-based interview with each participant (60 to 100 minutes each) formed the primary data for the study. The interview was framed in a preparing-for-mathematical-teaching context and was designed to bring to the surface participants' understandings of multiplication. Specifically, each participant worked with four numerical prompts,

$$\text{(a) } 4\times 3 \quad \text{(b) } 4\times\frac{5}{6} \quad \text{(c) } \frac{3}{4}\times 6 \quad \text{(d) } \frac{3}{4}\times\frac{2}{5}$$

in interviews that followed five steps: (1) computation, (2) problem-posing, (3) visualization of problem-solving, (4) sketch for visualization, and (5) comparison of ideas and material generated in Steps 1 and 4. All interviews were audio and video recorded and transcribed. Analysis was phenomenological, using constant comparative methods. In recording researcher observations about participants' interactions with tasks and in analyzing their responses we relied on Pirie and Kieren's (1994) method for diagramming a person's progressions through, and folding back among, layers of understanding (e.g., facets of action, process, object, and schema activity). We used these Pirie-Kieren models for participants' problem-posing and associated problem-solving interactions so that the dynamic patterns emergent from the interviewees' efforts could be classified into categories based on the nature of object-like entity understandings.

## Results

During Step 1 of the interview, 8 of the 12 participants made no errors in computing numerical prompts. However, 4 of 12 confounded "multiply across" (e.g., $a/b \times x = a/b \times x/1 = ax/b$), with "cross multiply" (e.g., $a/b \times x = a/b \times x/1 = bx/a$, or $a/b \times x = a/b \times x/x = ax/bx$). Note that at the time of the interviews, all were enrolled in the third semester of their mathematics sequence and studying proportions, including "cross multiplying" to find the unknown value $x$, in a proportional equation like $a/b = x/d$. Though analysis of computational error was not the purpose of this study, participants' procedural skills with decontextualized symbolic prompts in Step 1 may have mediated their efforts to identify isomorphisms in Step 5 of the interview. Subsequently, in Steps 2 through 5 of the interviews, five categories of object-like entities in concept building appeared to be problematic for participants: multiplier-as-operator, fraction-as-multiplicand, fraction as only a part-whole-relation, fraction-as-multiplier, and fraction multiplier acting on a fraction multiplicand.

*Multiplier-as-operator*

All 12 participants posed a complete story and described in words or using a sketch the process of solving for prompt (a) 4 x 3. However, the nature of their understandings varied. In the following excerpt, the interviewer (denoted *Int*) and Ann (all names are pseudonyms) negotiated the personality of multiplier to act on the multiplicand.

> *Ann*: [4×3] probably means that I have four pieces of candy and I have three friends. If I were to say pretend you had three candies, or three piles of candy with one in each pile, so you would have three candies and I want to add four candies to each pile, then I would add 1,2,3,4, 1, 2, 3, 4…then I would end up with the same answer [as 12 candies] and they would represent the same thing both three candies and four candies they are. I am representing candies all the way across. But in the problem that I gave I said that you have three friends and you are giving them each four pieces of candy so the numbers represent different things.
>
> *Int*: So in this case, what does the number three represent?
>
> *Ann*: kids, friends, people.
>
> *Int*: Four is four pieces of candy, and four candies times three people is?
>
> *Ann*: Twelve.
>
> *Int*: Candy or people? Have you ever thought about it?
>
> *Ann*: Yeah, I have never thought of that. Your answer is candy, you end up with 12 pieces of candy. I guess your three doesn't matter like I thought it would. Okay then, the three would represent where you are putting them, like how you are separating them

so how many times you need to use them like when you, often times when you use multiplication you would say four candies and I need to give them to three people, it is just like adding four three times, in relation to addition.

*Int*: Three groups of four?

*Ann*: Exactly. So your three is your groups, your four is your number within those groups.

The participant's perception of multiplier 3 went from "three friends" to "three candies" and then to "three groups" (of four candies). Her struggle in identifying the nature of multiplier concurs with Steffe's (1988) observation about the nature of unit in such contexts. The multiplier 3 is not just for 3 one-units as a number of groups, but also for 3 units (groups) of 4 one-units (candies). In the interview excerpt, Ann's understanding of multiplier-as-operator with natural number may be seen as moving from shaky *process* toward *object*.

*Fraction-as-multiplicand*

In working with (b) 4 x 5/6, two of the participants did not recall an appropriate property of positive integer as multiplier. Beth's story for the prompt 4 x 3 was, "John has grouped four groups of three marbles in each group." Here, the multiplier 4 played an explicit role as operator. However, Beth did not *conserve* the operation (Greer, 1988) in going from 4 x 3 to prompt (b) 4 x 5/6. In Step 3, visualizing her problem-solving, for (b), Beth changed representations and rewrote the whole number multiplier as a fraction, 4 x 5/6 = 4/1x5/6 = 20/6 = 3 1/3, and altered its personality as multiplicative

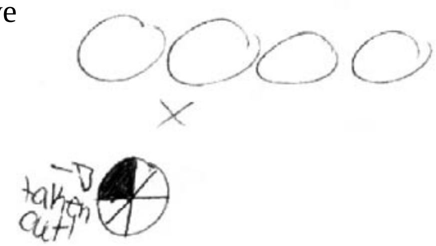

*Figure* 1. Beth's Step 3, visualizing problem solving of 4 x 5/6.

*Beth*: It helps to think about the four as a fraction, so like four over one. That helps because it puts it in, both in the same context.

*Int*: So now we have, an integer times a fraction, any idea where to start?

*Beth*: Um, well you have four wholes. So I am just going to go ahead and draw them here, four wholes. Then we have five [out of six], almost a whole.

*Int*: Okay, now I would like you to compare your sketch to its numerical calculation. The number one and the number five-sixths, which one is bigger?

*Beth*: One. So five-sixths is less than a whole, duh. Let's try that one again. So this [sketch] is not good, we are just going to forget about that.

*Beth*: Okay. We still have four wholes, correct?

The interviewer drew Beth's attention to her story for 4 x 3 and asked her to pose a story for (b) in an analogous way. When the multiplier is a whole number, the multiplication-as-repeated-addition model can also work for a fractional multiplicand.

*Beth*: Oh, could you have four groups of five-sixths, does that work? You would have four of these, so these are all like five-sixths?

*Int*: Does it make more sense?

*Beth*: I think so but I don't know how to explain it…

*Int*: I have four groups. What is inside each group?
*Beth*: Not even one, a part of one.
*Int*: A part of one. How many ones? How many sixths…
*Beth*: Hey, that works.

As proposed by Fischbein et al. (1985), one of the values in 4×5/6 is incongruent to 4×3. In terms of unit types, the numerical prompt 4×5/6, thought of as 4(5(1/6(1))), is one more layer than 4×3, or 4(3(1)). We suspect Beth may not have chosen a useful arithmetic operation because of this incongruence. She may have had, at the time of the interview, a schema of fraction multiplication that was repeated *action*-based, essentially additive, and was the only schema she recalled in the moment.

*Fraction as Exclusively a Part-whole-relationship*

Most of the participants contextualized and visualized a fraction numerical prompt. However, 7 of the 12 participants' understandings of fraction seemed to be confined to the part-whole-relationship personality. Kieren (1980) differentiated part-whole-relationship personality from measure personality for the rational number *x/y*. In the former, some whole is split up into *y* parts and *x* of these parts are taken. The latter sees 1/*y* as a unit to be used repeatedly to determine an *x/y* quantity. In the following excerpt, Cher's conception of 5/6 included five out of six pieces but the idea of 5(1/6), that is of five units of size one-sixth did not appear to come to mind for her.

*Cher*: 5/6… [means] something is divided into six portions, there is five remaining [of 6]
*Int*: How about 6/5?
*Cher*: 6/5, um there were two something that were divided into six [five] pieces, the remainder of what is left is one full one and one of the six [five]…

An understanding of fractions that is exclusively part-whole could be a challenge for participants in tracing the connections between transformation of units in their problem-posing and problem-solving visualization efforts – these multiplication algorithms are mainly based on measure personality. We saw some additional evidence to support this result in Daisy's interview.

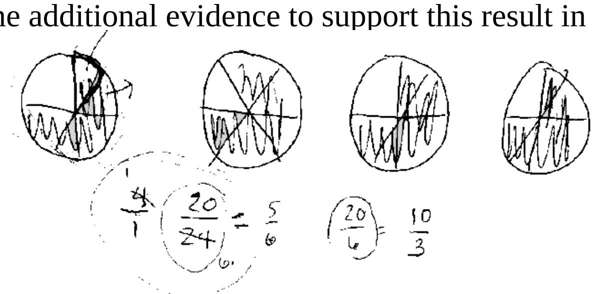

*Figure 2.* Daisy's visualizing problem solving of 4 x 5/6.

*Daisy*: [For 5/6,] there are six pieces so five of them are colored in because it is five of the six pieces and that is where the 5/6 comes in, and then I did four of them for the four times the 5/6. So I know the 20 of the 24 pieces, are colored which would equal 5/6, which doesn't help me out though because I am stuck at – Oh, what if I did four of them, one, 5/6 then I am left with 20/6 which could be reduced to 10/3 but then I don't know that leads me to so...

Daisy's understanding of fraction as part-whole-relation led her to see 4x5/6 as (4x5)/(4x6), or 20 out of 24, which was inconsistent with her computation of 4x(5/6)=20/6=10/3. Mathematically, her computational procedure and sketch matched perfectly. Psychologically, she did not perceive the personality of 6 in 5/6 and in 20/6 as one type of measuring unit, 1/6, derived from partitioning one into six equal parts, or as units of measure 1/6.

*Fraction-as-multiplier*

Several participants called on the symmetric property (axb=bxa) and said prompts (b) and (c) were "exactly the same." The request to create a story where a fraction was a multiplier acting on a whole number, challenged participants' belief in the symmetric property and was, ultimately, not fruitful during interviews. However, prompt (d) 3/4x2/5 involved only fractions, so fraction-as-multiplier was required in some way. In posing a story and/or visualizing problem-solving for (d), 5 of the 12 participants used addition. Elda immediately posed a story for the prompt 4x5/6, but had five unsuccessful attempts on 3/4x5/6. Elda's first attempt was: "If Megan was making a pasta dish and it asked for 3/4 cup of milk and 2/5 cup of salt. How many cups are needed to make the pasta dish?" She immediately realized what she posed involved the operation of addition rather than multiplication. She tried again:

> *Elda*: Megan's pasta dish called for 3/4 cup of milk but she put in 2/5. How much did she forget to put in?
>
> *Int*: Did you mean to put 2/5 *of the 3/4 cup*?
>
> *Elda*: Like, she put in 3 tablespoons instead, how much did she put in?

Later, she contextualized 2/5 as "2/5 cups," though Elda may have tried to express 2/5 *of* the 3/4 cup, in which "3 tablespoons" was about 2/5 of 3/4 cup in her sense. What Elda said might mean a mental structure where 2/5 acted on 3/4 to get "3 tablespoons," or it could be her second attempt was another additive one (in this case, subtraction). In drawing the visualization of her problem solving, Elda tried three times, but each time her strategy involved addition only and Elda seemed to be aware that her attempts did not use multiplication.

*Fraction Multiplier Acting on a Fraction Multiplicand*

Flora created a story for prompt (d) 3/4x2/5 involving the concept of group size and number of groups where 3/4 was group size. However, instead of 2/5 as two groups of measure one-fifth, of something else (i.e., 2((1/5(1)) where the inner 1 represents one whole group of three-fourths), she used "two out of the five" groups. In her drawing, she had five groups of 3/4. She circled two of them and added them together to get 3/2 and said,

> *Flora:* So here are my five groups of three-fourth. And – I want to add these two [groups of 3/4] together. So is, that's the same as three and a half [3/4 x 2/1 =6/4 = 3/2] – No. – Yeah. So that is it. So I need to say two-out-of-the-five somewhere.

Flora saw that 2/5 was not an operator that acted on three-fourths but also clearly articulated understanding of fraction as part-whole: "I need to say two-out-of-the-five somewhere."

Gina also used part-whole relationship to assign context to the multiplier 2/5.

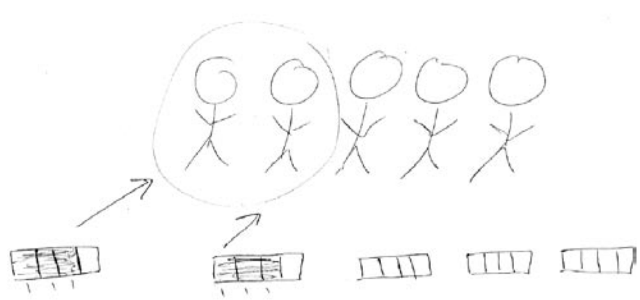

*Figure 3.* Gina's visualizing problem solving of 3/4 x 2/5.

Gina had five candy bars with four pieces in each candy bar and 20 pieces total. Instead of 2/5 acting on 3/4, she had 2/5 act on 5 and 3/4 act on 4 1-units, i.e., 2/5(5(3/4(4(1)))), to have 6 out of 20 pieces as the contextualization for 3/4x2/5. By doing so, there was no need to conceptualize a transformation of units like 1/5 (or 1/4), 1/20, or to form different unit types.

## Conclusion

One can perform actions on an object, physically or mentally, as in Daisy's sketch for visualizing problem solving of 4x5/6, and adopt symbols to represent it like "4x5/6=20/6=10/3," without bringing to mind some properties in the process. An encapsulation of the incomplete process into a sort of *pseudo object* may lead to a "pseudostructural" conception (Sfard, 2000). We hypothesize that all of the 12 participants, like Elda, had experienced *action* of fraction multiplication. But they may not have had awareness of all key properties in the *process*, and therefore did not perceive the process as a totality. A pseudostructural object of fraction multiplication appeared to be sufficient for many to choose an appropriate operation for solving a given word problem. However, the visualization task called for de-encapsulation or unpacking of both *number* and *operation*, from object back to process and action.

De Corte's (1988) empirical study supported the claim of Fischbein et al. (1985) that children's difficulties in solving multiplication word problems may arise when their underlying models are incongruent with the numerical data given in the problem. This study suggests that for adult prospective teachers, a complex version of incongruity is at work. In unpacking both understanding of number and of operations, several sites for incongruity emerge. Cognitively, for the same operation (multiplication) the fraction multiplicative structure is not congruent with whole number multiplicative structure. Teaching with emphasis either on identifying key features from word problems and procedural skills or on concrete experience is, although necessary, not sufficient for learners to construct complexly connected cognitive objects that can be untangled from multiple potential incongruities. This suggests that a richly connected and "unpackable" understanding of multiplication for positive rational numbers may require an equally complex constellation of ways to identify and respond to incongruity. That is, we suggest that this study offers empirical support for the assertion of many that mathematical discourse incorporating procedural skills, problem posing, visualization, and identifying isomorphic corresponding relationships can all play valuable roles in arousing learners' awareness of actions and process, in reifying and encapsulating mental constructs into object-like entities, unpacking or de-encapsulating the same, and using symbolism flexibly to advance mathematical thinking.

Finally, our experience in interviews with prompt (c) and its challenge to participants' belief in the symmetric property leads us to the following suggestion for teacher-educators. In working with prospective teachers, consider working with the abovementioned constellation of activities in the context of multiplication of two fractions (as in prompt (d)) before situations with one fraction; and then address a similar constellation of activities in connecting and unpacking the ideas of *fraction of* and *out of* to move into the context of fraction as multiplier acting on whole number multiplicand (e.g., problems like prompt (c)).

*Although many children can share a continuous whole with two or four people at a young age, students find sharing for three to be problematic. We present results from eight clinical interviews with students age four to eleven. Results show that students use various strategies as they attempt to share a continuous whole among three people. Many students relied on halving, quartering, or parallel cutting strategies. Older students created fair shares for three, often by referring to the "peace sign." We conclude with a discussion of why students may find constructing thirds to be challenging and call for equipartitioning in the early grades.*

## Introduction

The purpose of this paper is to present findings from clinical interviews conducted with the Diagnostic E-Learning Trajectories Approach (DELTA) project. The goal of the DELTA project is to build diagnostic assessments for rational number reasoning concepts for grades K-8. While the larger project involves the study of seven strands of rational number reasoning (multiplication and division; area and volume; decimals and percents; fractions; ratio and rate; similarity and scaling; and equipartitioning), this paper focuses specifically on the equipartitioning strand. Based on extensive literature reviews and syntheses a progress variable and learning trajectory for equipartitioning were developed. The DELTA team has conducted a number of clinical interviews to test and refine our constructs using students from diverse racial and socio-economic backgrounds. This paper will report on a few students as they attempt to partition a circular region into thirds.

## Related Literature

A learning trajectories view was chosen for our synthesis work of the partitioning research. Confrey et al. (2008) have defined a learning trajectory as:

> A researcher-conjectured, empirically-supported description of the ordered network of experiences a student encounters through instruction (i.e. activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time.

Confrey et al. (in preparation) note that learning trajectories are a useful construct for this work, "because of its potential to unpack complexity by revealing characteristics of gradual student learning over time" (p. 1-2). While all students do not progress along the same path, there are certain landmarks and obstacles that we consistently observe students encounter in equipartitioning

Equipartitioning is defined as the cognitive behaviors that lead to the creation of equal sized groups from a collection, or equal sized pieces from a continuous whole, and which result in fair shares (Confrey, 2008). Many students come to school with ideas about how to share a continuous whole (e.g., pizza, cookies, cake) and are able to transfer those ideas to equipartitioning tasks. These informal or out-of-school experiences contribute to students' prior knowledge. One of the first landmarks students reach is the two-split. Previous research has shown that very young children, even pre-schoolers can use a two-split on a collection of items or on a continuous whole (Ball, 1993; Pothier and Sawada, 1983, 1990). Pothier and Sawada (1983) also identify a five-level framework of student's partitioning behaviors, where level one, sharing, is the most primitive behavior and level five, composition, is a more complex behavior. Level four in their framework (oddness) is achieved when students realize that a two-split cannot be used to create fair shares for odd numbers. We have also found that students have trouble with odd splits, especially on a circular region.

While our use of learning trajectories is a more global view of how equipartitioning is situated within the larger framework of rational number reasoning, progress variables show a progression of knowledge from less sophisticated to more sophisticated in specific cases (Wilson & Sloane, 2000). Based on Confrey's synthesis work, the DELTA team has built a progress variable for equipartitioning (Table 1). Based on our review of the literature and empirical work with students, sharing a continuous whole among three and other odd numbers is placed at level 1.6. Despite knowing that students have difficulty in creating thirds, few studies have focused specifically on the tensions students encounter as they attempt to create thirds.

Table 1. *Equipartitioning Progress Variable*

| Case | Description |
|---|---|
| D | 1.8 $m$ objects shared among $p$ people, $m > p$ |
| C | 1.7 $m$ objects shared among $p$ people, $p > m$ |
| B | 1.6 Splitting a continuous whole object into odd # of parts ($n > 3$) |
| B | 1.5 Splitting a continuous whole object among $2n$ people, $n > 2$, and $2n \neq 2^i$ |
| B | 1.4 Splitting continuous whole objects into three parts |
| B | 1.3 Splitting continuous whole objects into $2^n$ shares, with $n > 1$ |
| A | 1.2 Dealing discrete items among $p = 3 - 5$ people, with no remainder; $mn$ objects, $n$ = 3, 4, or 5 |
| A, B | 1.1 Partitioning using 2-split (continuous and discrete quantities) |

## Method

### *Participants*

Clinical interviews were conducted with eight elementary and middle school students. The sample consisted of one pre-school student (Lara), one 1st grade student (Wilson), two 2nd grade students (Ethan and Rhea), and four 6th grade students (Casey, Dora, Keisha, and Bobby). The pre-school and elementary participants were sampled using a convenience sampling technique (McMillan, 2004). The three middle school students attend a magnet school that participates in a university connections program with a local university.

*Task*

In this interview, participants were asked to share circular birthday cakes (made out of play dough) fairly, for two, four, three and six pirates in succession. This order of partitions was suggested by previous research indicating that a) students first share by creating a two-split, and b) even splits are easier for children than odd splits because students can use a half as a benchmark split.

At the beginning of the interview, participants were told that some pirates were having a birthday party and they needed help to share the birthday cakes fairly. Participants were then presented with a circular birthday cake (measuring 6 inches in diameter). A plastic knife and a straightedge were available for use during the interview. Each participant was asked the following questions:

- Can you share the birthday cake fairly for two (four, three, or six depending on which partition the participant was working on) pirates? Show me how you would do it.
- How do you know that each pirate got a fair share?
- Could you show me one $n^{th}$ (half, fourth, third, or sixth depending on which partition the participant was working on) of the cake?
- Is there another way to share the cake?

Note that prior to sharing the circular birthday cake, participants had been asked to share 24 gold coins with two, four, and three pirates. They were also asked to share a rectangular birthday cake with two, four, three, and six pirates.

*Data Collection and Analysis*

The participant was interviewed using a clinical interview method (Opper, 1977; Ginsburg et al, 1983). A specified interview protocol was utilized, with additional questions and probes based on the behavior and responses of the participant. Data collection consisted of videotaping the interview and saving artifacts from the session. Relevant segments from the interview were transcribed for further analysis.

## Results

*Initial Attempts to Create Thirds*

In our work with students, they often times create fair shares for two or four pirates on their first attempt. In these interviews, two students made initial attempts to share for three pirates and realized that strategies they previously used would not be sufficient in this case. Lara began by doing a 2-split on the circle, as shown in the left side of Figure 1. After doing the 2-split, she hesitated about what to do next.

L: There’s not enough play dough.

I: There’s not enough play dough…hmm…Why is there not enough play dough?

L: I can’t cut this one because this one…because this one won’t have a fair half.

I: Ok. You can’t cut this one because… [Lara cuts the half piece in half again]

L: This will be three, but this one has more [Lara places her hand over the larger piece]

Lara knew that her goal was to create three equal-sized pieces, but was unable to meet that goal by starting with a 2-split. Ethan also knew that he needed to create equal-sized pieces. Earlier in the interview, when he shared a rectangle for three, he made two vertical (parallel) cuts.

Although Ethan displayed very strong conceptions for sharing a rectangle for two, three, and four pirates, the same did not hold true for the circle

I: Can you share the birthday cake fairly with three pirates?

E: No. [Shaking his head]

I: You cannot…Why can't you?

E: Because the only way I would really think of it…because an odd number of people…umm…wouldn't be equal. On the others I thought I could do it three ways and I did [Ethan makes the hash marks at the top of the circle—See Figure 2, right side] this, but then this would be a big one, this would be a small one, and this would be a small one [noting that if he were to cut it all of the pieces would not be the same size].

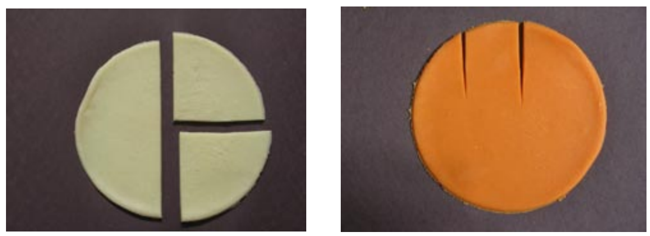

*Figure 1.* Initial attempts to share for three pirates (Lara, left; Ethan, right).

*Sharing for Three After Creating Fourths*

Three students shared the birthday cake by creating quarters and then sharing the remaining piece. Lara and Keisha both created quarters, deal out three pieces and note that the pirates can share the remaining piece. When asked if the pirates have a fair share, Lara notes that they do because they each have the same number of pieces.

[Lara cuts the birthday cake into fourths and puts one piece to the side]

L: We don't need this piece.

I: But what if we want to share the entire birthday cake?

L: The first person can get this one [points to a piece], the second person can get this one [points to a piece], the next person can get this one [points to a piece] and they can all share this one.

I: How can they all share that one?

[Lara cuts the fourth piece into three unequal pieces]

I: Does each pirate have a fair share?

L: Yes

I: How do you know?

L: One, one, one [pointing to the three smaller pieces]

I: What about these? [pointing to the three quarters]

L: One, one, one. One, one, one.

Keisha also began by cutting the cake in fourths, and then hesitated and stated,

K: Three is different. Like you would probably have some left over but then you could cut that.

I: Oh ok. Show me how you would do it because you've got to use up all the pizza. I don't have anywhere I could store it so the three of you would have to use it all up.

K: So these right here will be for that person, that person, and that person [Keisha deals out three of the quarters]

I: Ok

K: You have this left over [referring to the remaining quarter] so you would just cut this into three different pieces but they're kind of not the same shape.

I: Not the same, uh oh

K: Yeah

I: Can we figure out a way to make them the same so they would get the same amount?

K: Yeah you can probably just…

I: How would you do that?

K: I would think of something that's this shape…then…like…how would you put that?

Keisha then thinks about how she could possibly get three equal pieces of the remaining quarter. She notes that she thinks she could get two of the pieces to be the same but that one piece would look different. She concludes this segment by noting that three is hard because it is an odd number.

Wilson also quarters the cake and deals out three of the quarters. When asked if he had used all of the cake, he notes that he has one piece left over. When asked if there was a way he could share the last piece so that no cake is left, Wilson cuts the last piece into four more pieces and deals out those pieces. Since he had four pieces, one pirate received two of the smaller pieces. When asked if each pirate got a fair share, he responded:

W: No. Because this one has four.

I: Can you think of any other way to share for three pirates?

[Wilson takes the extra piece that he had given to one pirate and cuts it into three pieces and deals out each of the pieces.]

Each pirate now has three pieces of cake (one quarter of the cake, plus two smaller pieces).

*Figure 2.* Sharing for three pirates after quartering the cake
(Lara, Keisha, and Wilson respectively).

*Sharing for Three Using Parallel Cuts*

Although equipartitioning by making parallel cuts is sufficient for the rectangular birthday cake, students find that it does not work for the circular region. Rhea recognized that by making two parallel cuts she would have three pieces. When she was asked if each pirate had a fair share, Rhea responds:

R: Yes.

I: They do.

R: Yes.

I: How do you know that each pirate has a fair share?

R: Wait, because this piece [referring to the largest piece] is bigger than this piece [she lays the larger piece on the top piece of the circle] and this piece [referring to the middle piece]. This piece has a big hump like a circle, but this piece [the middle piece] doesn't, it's flat.

I: Can you think of another way to share the cake to make it fair?

*Figure 3.* Parallel cuts (Rhea).

As Rhea thinks out loud of how she may share the cake fairly, she notes that she could cut it in half but that would not work because it would give her two halves.

*Sharing for Three by Creating Equal-Sized Pieces*

Three of the four 6th grade students successfully created thirds on the circle. Two of the students (Bobby and Casey) specifically referred to using the "peace" sign to create thirds on a circle and immediately cut the birthday cake. Although Dora also created fair shares on the circle, her thinking and dialogue about how to create thirds was different from the other two students in this category.

D: It's a little harder to measure on this, but you sort of have to get to the center. Then you have to sort of…it's a little harder to measure the angles.

[Dora uses a straight edge to find the center of the circle and then cuts a straight line from the center to the bottom of the circle]

I: Tell me what you are thinking about the angles.

D: Well…umm…cause you have to get like this…or something like that [Dora makes a radial cut on the circle to create the first third] and it's a little harder to get that right…umm…because there's no other marks on the circle and you have to kind of guess at the angle.

I: So harder than what though?

D: Harder than dividing it in half or getting fourths…Because for the half you just have to find halfway up and then cut across. For the fourth you just…umm…you make sure that you…then you just kind of turn it to make sure that the half is horizontal or vertical, whichever way you cut it. Then cut…like if it's horizontal, cut vertically.

*Figure 4.* Equipartitioning a circle for three pirates (Dora, Bobby, and Casey).

For Bobby and Casey, the peace sign was a tool that they could use to create thirds. Dora however provides some interesting insights about constructing thirds. She notes that the angles are more difficult to construct because essentially she has no benchmark or reference point.

## Discussion

A number of interesting issues arise from students' work on this task. Throughout most of our interviews, students note that three is tricky, or that it will be difficult. But why is it that so many students find three so challenging? Students often state that three is an odd number. So the real question here is how does oddness affect equipartitioning behaviors. Students think of odd numbers as having "one left over." So in the case of three, students recognize that cutting in half does not create enough pieces, but that cutting in half again leaves them with an extra piece. Even when three of the four pieces are dealt, students have difficulty handling the remaining piece. Students are limited in this task because they do not know how to construct a radial cut. When students construct halves or other powers of two, they can usually estimate the midpoint of a side or half of a circle. For thirds, these references are not as fruitful, they have to now locate the center of the circle and use it as a reference point.

Because schools emphasize counting and number properties (e.g., even/oddness, part-part-whole) extensively in the early grades and do not address equipartitioning, many students are unable to use rational number reasoning to justify their behaviors. For example, Wilson noted that each pirate had a fair share because they each had the same number of pieces, although the smaller pieces he cut were different sizes. A tension exists for students between equipartitioning and counting. If counting continues to dominate students reasoning, they will be at a disadvantage when dealing with topics in rational number reasoning.

We also found evidence that for students unfamiliar with the peace sign, sharing among six may lead to the invention of the radial cut earlier than among three. After splitting the circle in half, students are able to use the straight side of the half, locate the center (or the midpoint of that line) and then construct a linear cut. After using this strategy to successfully share among six, Keisha was able to return to her work on three and share the remaining fourth in three equal pieces.

Each of the students in this study provided us with valuable information about how they think about thirds. Although creating thirds is an obstacle that most students encounter, we argue that they should have more experiences with equipartitioning early in schooling so that tensions between counting and rational number reasoning can be negotiated. Providing students with opportunities to engage in equipartitioning early in schools will better prepare them for multiplication, divisions, and fractions.

# WHAT DO ELEMENTARY STUDENTS' SOLUTIONS TELL US ABOUT THEIR STRATEGIES FOR SOLVING A DIVISION WITH REMAINDER

Teruni de Silva Lamberg
University of Nevada, Reno
terunil@unr.edu

Sudi Sudi Balimuttajjo
University of Nevada, Reno
balimutt@unr.nevada.edu

Charles Assuah
University of Nevada, Reno
assuahc@unr.nevada.edu

## Introduction and Theoretical Framework

Student solutions to mathematical problems reveal strategies they use as well as error patterns that reveal conceptions and misconceptions they have about a particular topic. We present an analysis of student solutions to a division with remainder problem (27÷4). We were particularly intrigued by student performance on this particular computation problem because many students in grades 3-5 missed this problem in a pre and post test given as part of a larger professional development project. According to researchers division problem involving remainders is difficult because students do not fully understand the division concept or wrongly interpret computational results (Anghileri, 1996, 1999; Spinillo & Lautert, 2004; Li, 2001; Spinillo & Lautert, 2002; Silver, Shapiro & Deutsch, 1993; Squire, 2002).

## Method

The data presented here is part of a larger three year professional development study. A pre and post test was administered to129 children in grades 3-5 in a western State. The post test results analysis on students' solutions to the division problem with a remainder is presented here. The response samples were made, and analyzed in the following ways:

- Performance was recorded and analyzed across the grades
- Types of errors were identified, coded, and examined
- Types of strategies were identified, coded, and studied for emergent trends
- Different treatments of the remainder were recorded and examined.

## Findings

In summary, students used seven different strategies, made five common errors, and treated the remainder in four ways as outlined below:

| STRATEGIES | | ERRORS | | REMAINDER | |
|---|---|---|---|---|---|
| **Code** | **Explanation** | **Code** | **Explanation** | **Answer** | **Treatment** |
| LD | Traditional long division. | O1 | Computational error. | 6.75 | As decimal |
| DD | Dividend is multiple of divisor. | O2 | No remainder indicated. | $6\frac{3}{4}$ | As fraction |
| EST | Estimation | O3 | Wrong division. | 6r3 | As integer |
| MF | Result is multiple factor of divisor | O4 | Misread division symbol. | Integer | Increased quotient or dropped remainder |
| RAS | Repeatedly add or subtract | O5 | Order of answer reversed. | | |
| DLG | Dividend is dealt or dished out. | | | | |
| PT | Dividend is partitioned. | | | | |

The analysis reveals that 4$^{th}$ and 5$^{th}$ grade students used the standard algorithm, whereas 3$^{rd}$ graders used more pictorial representations to solve problems. This indicates the differentiated approach to the bare division problem, where the upper grades may treat it abstractly and lower grades embed it within some context. In addition, the types of strategies and errors that students made give us insight into different thinking patterns of students.

# REPRESENTING DECIMAL NOTATIONS AS SHADED PARTS OF AREA

Meghan M. Shaughnessy
University of California, Berkeley
mshaughn@berkeley.edu

*This poster reports results from a study of fifth grade students' understanding of representing decimals as shaded parts of area. Evidence from students' responses indicates that students may interpret and represent decimal notations in ways that reflect limited understandings of decimal notation. Educational implications are addressed.*

Rational number has long been described as hard to learn and hard to teach. Area model representations such as rectangular regions are often used to support students' understanding of fraction notation. While area model representations can also be used to represent decimals, little is known about how upper elementary school students understand decimal notations as shaded parts of area. The goal of the present study was to systematically examine students' representation of decimals as shaded parts of area.

## Methods

Thirty-one fifth grade students drawn from 5 elementary schools in an urban area in Northern California were interviewed individually. Two of the interview tasks are the focus of this analysis. In each task, the student was presented with a rectangular region with a decimal notation written above it. The interviewer pointed the decimal notation and explained that the students' task was to shade that part of the rectangle. Students were asked to explain their thinking. In task 1, the decimal notation was '0.3'. In task 2, the decimal notation was '0.7'.

## Results

Across tasks, four patterns of responses emerged. As shown in Figure 1a, some students interpreted the decimal notation as representing an extremely small quantity and shaded a very small portion of the rectangular region. As shown in Figure 1b, other students interpreted the tenths digit of the decimal notation as representing the number of parts into which the whole should be divided (three in the case of '0.3') and the ones digit as representing the number of parts that should be shaded (zero on the case of '0.3'). As shown in Figure 1c, still other students respected the relative magnitude of the decimal notation in shading; however, they did not partition the rectangular region into tenths and then consider how many parts to shade. Finally, as shown in Figure 1d, still other students partitioned the rectangular region into ten parts of approximately equal size and then shaded three of those parts.

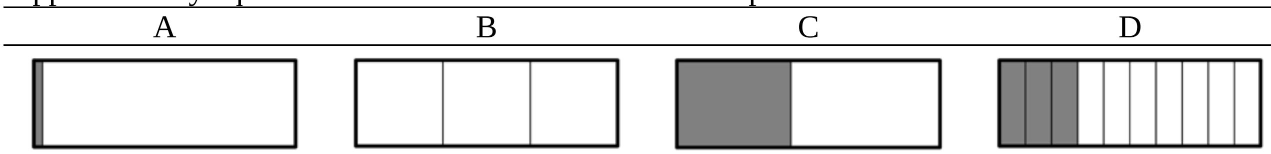

*Figure 1.* Patterns of responses on the '0.3' task

## Discussion

Finding from this student revealed the diverse ways that students may represent decimal notation as shaded parts of area. In my poster, I address implications for instruction.

# FACTORS INFLUENCING A PROSPECTIVE MIDDLE SCHOOL TEACHER'S VALIDATION OF PROOFS: THE CASE OF MARY

Filyet Asli Ersoz
University of Georgia
faersoz@uga.edu

*This case-study examined a prospective middle school teacher's conceptions of proof and the arguments that she accepted as proofs. The factors influencing the prospective teacher's decisions of whether an argument is a proof or not are highlighted in this paper. Some of these factors are familiarity with the statement and certainty about its truth, the closeness of the argument to the participant's own proof and the context of the argument.*

## Introduction

Several mathematicians and mathematics educators advocate proof to be central to mathematics education (Ball et al., 2002; Carpenter, Franke, & Levi, 2003; Hanna, 1995; Knuth, 2002a; NCTM, 2000). To accomplish this goal it is crucial for teachers to be well equipped to teach mathematical reasoning and proof. As Peressini et al. point out "the extent to which mathematical ideas such as proof and justification appear in classroom discourse will be influenced by both the teacher's choice of task and the questions and comments she makes during class, which are, in turn, influenced by the teacher's knowledge of proof" (Peressini et al., 2004, p. 81). However, the results of studies concerning teachers' conceptions of proof are not very promising. The goal of this study was to examine a pre-service middle school teacher's conceptions of proof and analyze her process of validation of proofs (Selden & Selden, 2003) to provide insights into her understanding of a proof and what constitues a proof.

## Theoretical Perspective

Previous research on teachers' conceptions of proof has focused on pre-service elementary school teachers (e.g., Martin & Harel, 1989; Simon & Blume, 1996), in-service elementary school teachers (e.g., Ma, 1999), pre-service secondary school teachers (e.g., Jones, 1997), and in-service secondary school teachers (e.g., Knuth, 2002a, 2002b), as well as undergraduate mathematics majors (e.g., Harel & Sowder, 1998). A common conclusion of these studies is that teachers tend to accept empirical arguments as proofs (Knuth, 2002a; Ma, 1999; Martin & Harel, 1989, Simon & Blume, 1996). In other words they rely on either evidence from examples (sometimes just one example) of direct measurements of quantities and numerical computations or perceptions to justify a claim. To evaluate arguments some teachers focus on the correctness of the algebraic manipulations or form of the argument as opposed to the nature of the argument (Knuth, 2002a), and others accept false proofs based on their ritualistic aspects (Martin & Harel, 1989). Although teachers rate deductive arguments as valid proofs, they still may not find them convincing (Knuth, 2002a). Treating the proof a particular case as the proof for the general case is also common among teachers (Knuth, 2002a; Martin & Harel, 1989). Although familiarity of a statement influence the degree that secondary teachers are convinced of an argument (Knuth, 2002a) this was not found to be a factor in Martin & Harel's (1989) study. However, familiarity might be very subjective. Finally, Jones (2000) concluded that technical fluency does not necessarily mean richly connected subject knowledge.

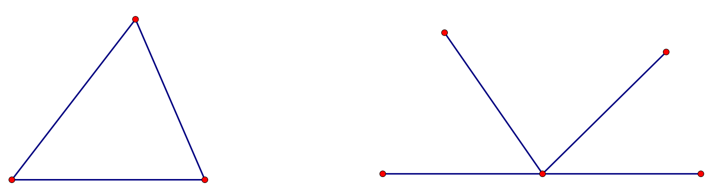
Although past research informs us about teachers' conceptions of proof and agrees that teachers tend to accept empirical arguments as proofs, there is still not a clear picture of the underlying reasons. Furthermore, as Harel and Sowder (1998) point out "despite its dominance, the inductive proof scheme phenomenon is not entirely understood" (p. 252). This paper uses the case of a pre-service middle school teacher to identify some factors that interfere with her acceptance of an invalid argument as a proof.

## Methods

The case analyzed in this paper is one of three participants who had volunteered to be a part of a study investigating pre-service middle school teachers' conceptions of proof. At the time of the study the participants were enrolled in a collegiate level mathematics content course designed for pre-service middle school teachers with a focus on geometry. Two of the objectives of the class as listed on the class website were to strengthen the understanding of and the ability to explain why various procedures and formulas in mathematics work and to promote the exploration and explanation of mathematical phenomena.

One semi-structured interview (Bernard, 2002) was conducted with each participant and their written work was also kept as data source. Each interview started with questions trying to elicit participants' knowledge and beliefs about the nature of proof and the role of proof in mathematics and mathematics education such as "What is your experience with proof?", "What does it mean to prove something?" and "What is the role of proof in mathematics?" Next the participants were asked to prove that the interior angles of a triangle add up to 180 degrees. After that they were given arguments for the same statement and asked to evaluate those arguments

(a) I tore up the angles of a triangle and put them together (as shown below).



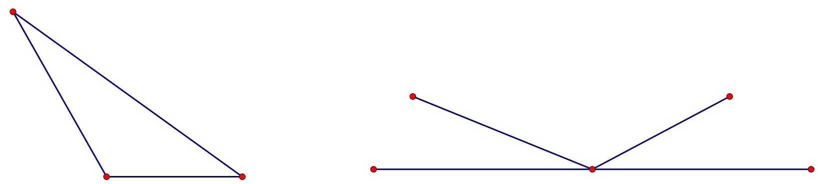
The angles came together as a straight line, which is 180 degrees. Therefore, the sum of the measures of the interior angles of a triangle is 180 degrees.

(b) I tore up the angles of the obtuse triangle and put them together (as shown below).

The angles came together as a straight line, which is 180 degrees. I also tried it for an acute triangle as well as a right triangle and the same thing happened. Therefore, the sum of the measures of the interior angles of a triangle is 180 degrees.

*Figure 1.* Two arguments about the sum of the interior angles of a triangle.
and decide whether they were proofs or not. Two of the three arguments were analyzed for this study and they are given in Figure 1 (adopted from Knuth, 2002b). The following task was to ask the participants what they knew about the sum of the interior angles of other polygons and depending on their answer ask them to figure out an answer and/or prove their answer. The final task was to evaluate arguments for an algebraic statement in order to see if the different nature of the arguments would influence the way that the participants would evaluate them. The task which was taken from a study by Healy and Hoyles (2000) is given in Figure 2.

To analyze the data I went through the entire transcript line by line and the corresponding written work and tried to make conjectures regarding what the participant was thinking. I identified the places where a particular theme was re-occurring and made sure that each conjecture was supported by other relevant things that the participant said throughout the interview. Eventually, I connected these conjectures to a general account of the participant's thinking.



**A1.** Arthur, Bonnie, Ceri, Duncan, Eric, and Yvonne were trying to prove whether the following statement is true or false:

**When you add any 2 even numbers, your answer is always even.**

*Arthur's answer*

$a$ is any whole number
$b$ is any whole number
$2a$ and $2b$ are any two even numbers
$2a + 2b = 2(a + b)$

*So Arthur says it's true.*

*Bonnie's answer*

$2 + 2 = 4$ $\quad 4 + 2 = 6$
$2 + 4 = 6$ $\quad 4 + 4 = 8$
$2 + 6 = 8$ $\quad 4 + 6 = 10$

*So Bonnie says it's true.*

*Ceri's answer*

Even numbers are numbers that can be divided by 2. When you add numbers with a common factor, 2 in this case, the answer will have the same common factor.

*So Ceri says it's true.*

*Duncan's answer*

Even numbers end in 0, 2, 4, 6, or 8. When you add any two of these, the answer will still end in 0, 2, 4, 6, or 8.

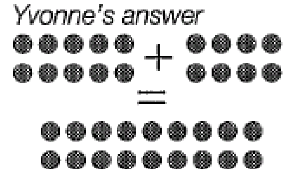
*So Duncan says it's true.*

*Eric's answer*

Let $x$ = any whole number,
$y$ = any whole number
$x + y = z$
$z - x = y$
$z - y = x$
$z + z - (x + y) = x + y = 2z$

*So Eric says it's true.*

*Yvonne's answer*



*So Yvonne says it's true.*

From the above answers, choose **one** that would be closest to what you would do if you were asked to answer this question.

From the above answers, chose the **one** to which your teacher would give the best mark.

*Figure 2.* Seven attempts at proving that the sum of two even numbers is always even.

## Results

This paper reports results for one of the three participants in the overall study. Mary (pseudonym) was chosen because the interview with her seemed to offer richer data in terms of providing insights into and understanding complexities of a pre-service teacher's conceptions of proof. Mary, with regards to her experience with proofs, said that she remembered learning them in high school geometry classes and also mentioned that they have done some simple proofs in their content class. She also mentioned her discomfort with proofs.

*Mary's Conception of Proof*

According to Mary to prove something meant "to show it as a fact and true that it is that way for, in all situations that you say." She explained in response to a follow-up question that "if you are working in general terms, you can, you don't have to test every situation because every situation will follow within those boundaries." Mary seemed to believe that a proof establishes the truth of a statement and to have an understanding of the generality aspect of a proof. She indicated that proofs are important because once something in proven, in other words is shown to be true, then it can be used to solve other problems.

During the interview Mary made a distinction between formal and informal proofs. Although she had a hard time articulating what she meant by formal proof, she referred to textbook proofs as being formal and having "a lot of formal and geometric terms." The way she thought of informal was "kids putting it kind of in their own words and being able to explain it but not necessarily using all the lingo and all the higher knowledge aspect." According to Mary, the ritual aspects of a proof and the level of the knowledge and the language used in a proof determined its being formal or informal. As it will be explained later, this distinction influenced her decisions when she evaluated an argument.

*Mary's Construction of Proofs*

When asked to prove that the sum of the interior angles of a triangle is 180 degrees, Mary was able to construct a valid mathematical proof using the parallel postulate and she concluded that her argument "proves that there is 180 degrees in a triangle." When asked if her proof holds for all triangles she said “yes, because you can draw like, I mean if you wanted to, you could even draw like a right triangle (drew a new picture where the triangle formed was a right triangle), you know what I’m saying, so that one covers right triangles. That (pointed her first picture) is kind of like an almost an equilateral so you could even draw it to where you had like obtuse kinda stuff (drew another picture where the triangle formed was obtuse), it covers anything.”

Without any further information about Mary it could be argued that since she drew extra triangles – right and obtuse – she didn’t understand the generality of her argument or that she needed to check her proof for different cases. However, since she said “it covers anything” it is also possible that she drew those extra triangles to illustrate the generality of her argument and convince the other person about this. In other words, she might be trying to say that it doesn’t matter which type of triangle you draw, the argument holds in any case. This interpretation is also supported by what she said later in the interview "you will still get the same thing because you’ll still get the same transversals just like that (moved her pen along the two transversals in her own second and third drawings) and the same alternate interior angles no matter what (pointed to the right and obtuse triangles that she had drawn) type of triangle you use."

The next proof construction task was about the sum of the interior angles of other polygons. Mary said that they had derived the formula in one of her classes and correctly stated it as “180(n-2)” with n being the number of sides. When asked to prove it she talked about “patterns” and “testing it out on something that you already know like the triangle.” She tested it for the triangle and the pentagon. I tried to challenge her by asking how she would be sure that the formula gives the correct answer for a 12gon, she again referred to patterns. However, all of a sudden, she thought about drawing a pentagon and dividing it into three triangles and wrote 180 into each triangle. She also demonstrated it for a polygon. When I challenged her about how she knew the relationship between the number of the triangles that she created and the number of the sides of a polygon, she said “just by following patterns” and explained that “at some point numbers get too big that you just can’t … you develop a pattern, a consistent pattern, then you can count on it (laughs).” Although Mary could remember a way to prove this statement, she didn't see the generality of that argument, hence relied on her knowledge of patterns for a proof and at the time seemed to be satisfied with this argument.

*Mary's Validation of Proofs*

When Mary was presented with the argument in Figure 1(a) her initial reaction was "I think that's pretty similar to kind of what I did up there. I just didn't cut anything. I just used the parallel postulate to say that." She further stated that it was "accurate" and accepted it as a proof. At the beginning of the interview Mary had said that "when you are trying to prove it or whatever you have to test more than one scenario" however she accepted this argument as a proof. It seems like this piece of knowledge was insufficient to help her see that the argument was "testing only one scenario." One reason might be that she might not have really internalized what she said at the beginning or this argument might not have invoked that knowledge for her. On the other hand, she had also said that "if you are working in general terms, you can, you don't have to test every situation" so she might not have refuted this argument as a proof because she might have viewed it as a "general argument." This is plausible given that she thought that the argument was similar to what she had done. Nevertheless, she labeled it as informal since it didn't involve "any higher math."

Although Mary thought that the first argument was a proof, after examining the argument in Figure 1(b) she seemed to change her mind about it. I think there are two important issues here. Although she thought that the second one was more complete she still did not realize why both of the arguments were empirical. On the other hand, she was aware of the fact that these arguments were not the same as the argument she provided herself (mathematically valid proof) however since she didn't see those as invalid she named them as informal and as not having the "higher knowledge aspects" and as representing "a different level of thinking."

One of the factors that was influencing Mary's decision about the first argument was the relationship she saw between the given argument and her own argument. As it became clear later in the interview another important factor which influenced her decision was her familiarity with this statement. Since she already was familiar with the statement and was confident about its truth, seeing just one case might have been enough for her: "As a mathematician for me or as a math teacher for me this (pointed the first argument) is plenty … I don't think testing one thing when you are trying to figure something out is sufficient I guess, but once you already know like I already know it's a proof or that it's true then this (pointed the first argument) is enough cause I can be ok with that, but for a student like, if I was just trying to figure it out then I would say this (pointed the second argument) would help me a little more because I can actually see that for the different other types of triangles that it works also. … once you know that it's true, I don't think you need all the different examples to back it up but for the initial go at it I think I would want my student to be a little more thorough (pointed the second argument)." In other words, she already knew that the sum of the interior angles of a triangle is 180, so the presented argument was correct or "accurate" for her and being accurate might have been enough for it to be a proof.

Next I presented her the problem about the even numbers accompanied with all the arguments. She first told that she liked Duncan's answer and that it would be closest to what she would do. She also liked Yvonne's "visually because even numbers are always gonna have a pair" and thought that this was explained in words by Ceri. Consistent with the way she identified formal proofs before, she identified Arthur's as the formal one.

An important part of her discussion about these arguments was when she talked about Bonnie's answer: "This (Bonnie's), even though I used the same excuse of patterns, it's, to me it doesn't hold as much water. It's not as, that, like not as valuable to me, just to show patterns (pointed the examples in Bonnie's answer), but I mean cause it works, it proves it, but I guess to a kid they are always gonna say, I mean there's a million ifs, what if this number and this number." The first time during the interview she said "I wouldn't call Bonnie necessarily a proof" and added that "too many what ifs with this one but I agree with it that I agree with what she's thinking that yeah anything any two even number that you add together is gonna be even. That's what she is stating. She needs to go a little further, same as I did, but I couldn't figure it out with those polygons."

Contrasting this episode with earlier episodes of her analysis of empirical geometrical arguments, it can be hypothesized that the nature of the algebraic argument made it possible for her to realize that it was empirical. Although it was not evident in the geometric case that the argument depended on the properties of a particular triangle, it was easier to realize for the algebraic case that the argument only involved numerical computations for a certain number of cases. Hence, Mary could conclude that it was not a proof.

## Discussion and Implications

The case I analyzed in this paper shows there are criteria that one pre-service teacher used to evaluate arguments. Although she did not refute the empirical argument in Figure 1(a) as a proof, I don't think that it can be concluded that she simply believed that showing that something is true for one case constitutes proof. According to Ma (1999) the teachers in her study "ignored the fact that a mathematical statement concerning an infinite number of cases cannot be proved by finitely many examples – no matter how many. It should be proved by a mathematical argument" (pp. 86-87). While this might be a reason for some teachers to accept empirical arguments as proofs, it doesn't necessarily explain why the participant in this study did that in some cases. Whether Mary accepted empirical arguments or proofs or whether she provided an empirical argument when she was asked to prove something depended on other factors as well - factors other than whether she was aware of the fact that empirical evidence doesn't constitute proof. She evaluated arguments according to her criteria of formal vs. informal and the level of thinking used in the argument. It also seemed like she treated arguments differently depending on whether she already knew that the statement was true or not. Furthermore, it was easier for her to realize that an algebraic empirical argument was not a proof as opposed to a similar geometric argument. This study shows that a teacher's decision of whether an argument is a proof or not is not only influenced by whether s/he knows that the argument needs to show that the statement is true for all cases. There seems to be other factors which determine the evaluation of an argument by a pre-service middle school teacher.

An implication of this study for research is that it provides a lens to look through when analyzing teachers' validations of proofs. It points out several factors that researchers need to be aware of and take into account as they look into teacher's conceptions of proof. There are also implications for teaching. Based on the results of this study, it is suggested that rather than trying to prove statements that they are already familiar with students might benefit more from working on statements the truths of which they're not certain about. Furthermore, algebra might provide a better context to introduce proofs where students are more likely to differentiate non-proofs from proofs.

*Researchers have found that students as young as elementary school can engage in mathematical reasoning. However, particular tasks tend to encourage this reasoning. This paper provides insight into the characteristics of tasks that lead to arguments that represent certain forms of reasoning. In this paper we report on arguments built by diverse student groups, of different ages, that were used to justify their solutions to problems from the fraction and counting strands of longitudinal and cross-sectional studies.*

## Purposes of Study

The National Council of Teachers of Mathematics (NCTM, 2000) Principles and Standards document suggests that a primary goal of mathematics education in grades K-12 is the development of reasoning and proof. The document calls for exposing students at all ages to different forms of reasoning, facilitating their ability to choose and use appropriate forms of reasoning, and encouraging them to develop and evaluate their own and others' mathematical arguments and proofs. The focus on reasoning and proof is alighting to the elementary and middle-grades for good reason; reasoning and proof are the foundation of mathematical understanding and necessary for acquiring and communicating mathematical knowledge (Hanna & Jahnke, 1996; Polya, 1981; Stylianides, 2007; Hanna, 2000). While researchers have shown that children as young as eight and nine years old make conjectures, and justify their claims with sound arguments, we are only beginning to understand how students' mathematical reasoning develops and what environments can best support the development of student reasoning (Yackel and Hanna , 2003). Through a combination of cross-cultural and longitudinal studies, we have observed that a mixture of environment/sociomathematical norms, teacher questioning that evokes meaningful support of conjectures, and well-designed tasks contribute to students' success in building convincing arguments. In this paper we report on arguments that represent certain forms of reasoning across ages and from diverse student groups that were used in justifying solutions to problems from the fraction and counting strands of longitudinal and cross-sectional studies. We found that certain tasks tended to elicit particular forms of reasoning across all age groups and populations.

## Theoretical Framework

Stylianides (2007) defines proof as a *mathematical argument* that that builds upon statements or facts that are accepted by the community, utilizes various forms of reasoning shared by the community, and is communicated by a shared meaning of discourse. Other researchers stress the role of discourse in the mathematics classroom in reasoning and proof (Balacheff, 1991; Hanna, 1991; Maher, 1995, in press). Thus the notion of proof is dependent upon the community in which it emerges. As students engage in reasoning and justify this reasoning to the community they begin to develop proofs. A well-defined, well-written task is the impetus from which reasoning emerges and therefore, task design is crucial (Doerr & English, 2006; Francisco and Maher, 2005; Henningsen & Stein, 1997; Maher, 2002; Maher & Martino, 1996; Stein, Grover,

& Henningsen, 1996). Further these tasks can elicit students building multiple representations, as well as, multiple strategies for solutions (Maher, 2002; Fransisco & Maher, 2005; Henningsen and Stein, 1997). Tasks that are open-ended and complex encourage students to rely on their own mathematical resources and make possible the building of new knowledge. In order to promote justifications and reasoning we recommend that students be given sufficient time to work with each other with minimal teacher interventions. We suggest, also, that students later revisit tasks and reflect on their prior work and the explanations of others (Maher, 2002; Maher & Martino, 1996). When tasks are presented to students as strands of related problems that can be revisited over time and in different contexts, opportunities emerge to extend one's ideas, build on the ideas of others, and construct convincing arguments.

## Method of Inquiry

The episodes presented in this paper come from three data sets.[1] The first is a year long study of students' mathematical thinking that was conducted by researchers in a fourth grade classroom in a rural school in New Jersey. The second source of data is an informal after-school math program consisting of twenty-four sixth grade students that was conducted by researchers in a low socioeconomic urban community in New Jersey, drawn from a school consisting of 99% Latino and African American students[2]. The third source is a longitudinal study now completing its 20th year, in which students from a suburban community engaged in strands of mathematical investigations, as a context for research on the development of students' reasoning and constructing of mathematical knowledge and understanding. The three series of sessions were videotaped with at least two cameras. This study uses data from the first seven 60 minute sessions from the fourth grade study and the first five 60-75 minute sessions from the sixth grade study. Data from the third study includes segments from sessions as fourth grade students investigated problems in counting and combinatorics. Because of space limitations, we give examples of two tasks, one from a strand on fractions and the other from cominatorics. The students in the first two studies worked collaboratively on tasks involving fraction relationships. Cuisenaire rods (see figure 1) were available and students were encouraged to build models. Many of the tasks were identical in both studies. The students in the third study worked on

*Figure 1*. Staircase model of rods.

building towers using plastic cubes of two different colors (see figure 2). In all three studies students were encouraged to provide justification for their solutions and to challenge and question the explanations of others.

The video data were transcribed and coded for forms of reasoning. Then, the data sets were compared, and similarities and differences were noted.

## Results

For the purpose of this paper we focus on two tasks. Task 1, Rods, was posed to fourth and sixth graders during a session involving fractions: *If I call the blue rod one, which rod can I call one half?* Task 2, Towers, involved finding all possible towers of a particular height selecting from cubes available in two colors and was posed to students in grades 3 through high school. Students built arguments whose reasoning was both direct and indirect. In particular, for the Rods task, student reasoned using cases, contradiction and upper/lower bounds. For the Towers task, reasoning took the form of cases, induction, contradiction, and recursion. Numerous examples of the above forms of reasoning have been documented (Alston and Maher, 1993; Maher and Martino, 1996, 2000: Francisco and Maher, 2005; Maher, in press; Mueller and Maher, 2007, 2008). Here we offer representative examples that we regularly observe with a wide range of students from a variety of communities.

*Reasoning by Contradiction*

Students used reasoning by contradiction (also known as the indirect method; based on the agreement that whenever a statement is true, its contrapositive is also true) to convince their classmates that there was not a rod whose length was half of the blue rod and that they had built all of the towers of a given (n) height.

*Rods, Grade Four.* While working on the task of finding half of the blue rod, a student used faulty, direct reasoning to name the yellow rod and purple rod one-half. David used a *contradiction* to show that the yellow rod and purple rod were not the same length and therefore could not be named one-half. He used a model of a purple rod and a yellow rod placed next to a blue rod and argued using the definition of one-half, explaining that in order to be called half of the blue rod the two rods would need to be the same length. Alan and Jessica built on David's argument and together formulated a contradiction.

Alan: When you're dividing things into halves, both halves have to be equal—in order to be consider half

Jessica: This isn't half. Those two aren't both even halves.

*Rods, Grade Six*. In the sixth grade Chris reasoned using a contradiction by lining up a train of nine white rods next to a blue rod and explaining that nine is an odd number and therefore it cannot be halved. As Chris' group members offered different arguments, he refined his contradiction five times.

Chris: There is not a rod that is half of the blue rod because there's nine little white rods, you can't really divide that into a half, so you can't really divide by two because you get a decimal or a remainder…"

*Towers, Grade Four*. Stephanie approached the task by applying the procedure of constructing a tower and it's "opposite" to find the 32 unique towers five cubes tall. When explaining her procedure to the class, Stephanie used a proof of *contradiction* to justify her thinking.

Stephanie: With the two [red cubes] together you can make four [towers]. With one [yellow cube] in between you can make three [towers]. With two [yellow cubes] in between you can make two [towers]. With … three [yellow cubes] in between you can make one [tower], but you can't make four in between or five in between [four or five yellow cubes between the two red cubes] …or anything else because you don't have enough … because you can only use five blocks [towers of height five].

*Reasoning by Cases*

For the purpose of this study, critical events were coded as reasoning by cases when students defended an argument by defending separate instances.

*Rods, Grade Four*. David offered an argument by *cases* to show that all of the rods could be organized as either odd or even based on whether or not they could be divided in half. He explained that the white, light green, yellow, black and blue rods were all "odd" since there was not a rod equal to half of their length. He then showed that the red, purple, dark green, brown, and orange rods were "even", using a model to show that two purple rods are equivalent to the length of the brown rod and two yellow rods are equal to the length of the orange rod (in order to demonstrate that these rods had a half).

*Rods, Grade Six.* Justina explained that her strategy of showing that the blue rod does not have a rod that is equivalent to half of its length was to instead find all of the rods that do have a rod equal to half of their length. She drew all of the rods that have a half next to the two rods that make up the half, for example, two yellow rods lined up next to an orange rod. Justina explained that all of the rods in her diagram had a rod that was equivalent to half of their length. She listed all of the cases of these rod combinations and named them "singles". Justina explained, "I was just making half of the color rods, I just made this picture, so like um, half of the orange was yellow, half of the brown was purple, half of dark green was light green, and the same for those two."

*Towers, Grade Five*. After constructing all possible towers four cubes tall when selecting from black and white plastic cubes, Stephanie was interviewed. She explained how she found patterns of towers and searched for duplicates. She then organized her groups of towers according to color categories (e.g., exactly one of a color and exactly two of a color adjacent to each other) in order to justify her count of 16 towers, thus she organized the towers by *cases* (see figure 2). Stephanie used this organization by cases to find all possible towers of heights three cubes tall, two cubes tall and one cube tall when selecting form two colors.

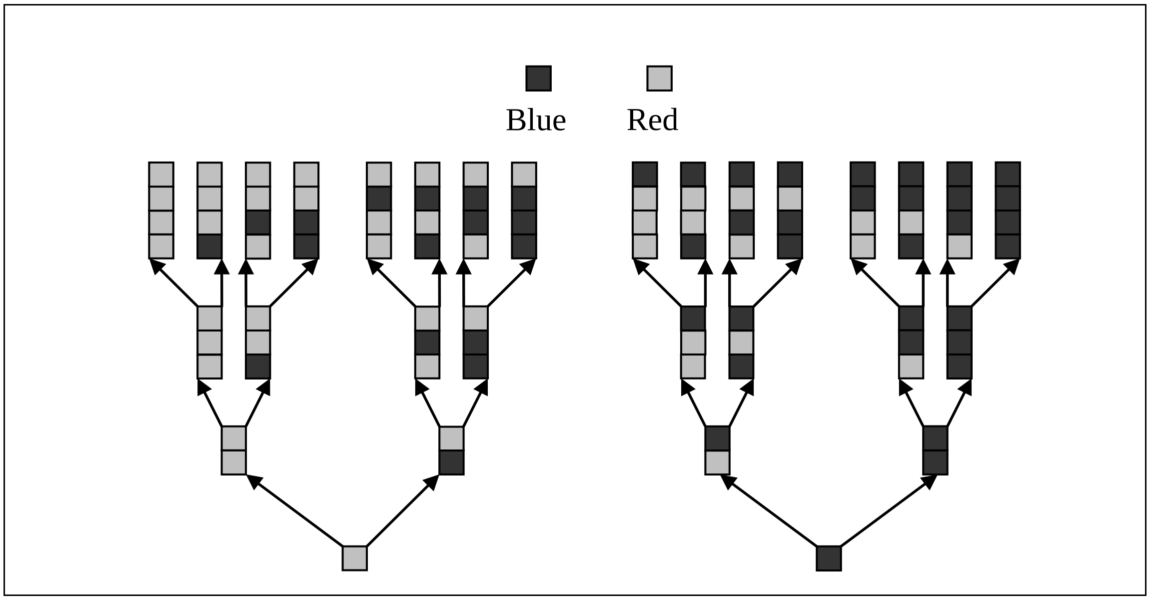

*Figure 2*. Stephanie's extension of the tree diagram introduced during the interview.

*Reasoning using Upper and Lower Bounds*

When reasoning using upper and lower bounds, students displayed the part of the set that was greater than or equal to every element in the set (upper bound) and the part of the set that was less than or equal to every element (the lower bound) and established that there was not an element in the middle.

*Rods, Grade Four*. David began the task of convincing his classmates that there was not a rod whose length was half of blue by offering an argument using upper and lower bounds.

David: I don't think that you can do that because if you put two yellows that'd be too big, but then if you put two purples that's uh, that's uh, that'd be too short.

The researcher asked David if there was any rod between the purple and the yellow, David replied, "I don't think there is anything." When asked to explain further, David showed that the purple rod was one white rod shorter than the yellow rod, and lined up the rods in a staircase pattern in order to illustrate that each rod was one white rod longer than the previous rod (see figure xx). He used this model to show that there is no rod that is shorter than the yellow rod or longer than the purple rod.

*Rods, Grade Six*. In a whole class presentation, Dante explained that instead of using the model of nine white rods lined up next to the blue rod he used a model of a purple rod and a yellow rod. He used the model to show that the purple rod could not be considered to be half of the blue rod because the combination of two purple rods was not equivalent to the length of the blue rod (they were too short). Likewise, the yellow rod could not be named half of the blue rod because the combination of two yellow rods was not equivalent in length to the blue rod. He explained that the yellow rod was one white rod too long to be a half the length of the blue rod and the purple rod was one white rod too short. When asked why this persuaded him that there was not another rod whose length was half of the blue rod, Dante responded, "Because we tried all we can because if usually for the blue piece, it would usually be purple or yellow but yellow would be one um one white piece over it and the pink would be, I mean purple would be one white piece under it."

Chanel backed up Dante's justification using a model that showed the discrepancy of one white rod, using two yellow rods as an upper bound and two purple rods as a lower bound., indicating: "this is blue and the yellow is a little, the yellow is a little bit more than a half and the purple is shorter than a half."

*Reasoning Using an Inductive Argument*

Inductive reasoning was noted when students made generalizations based on individual instances or when the premises of an argument were believed to support the conclusion but did not ensure its truth.

*Towers, Grade Four*. Milin also used cases to organize towers five-tall. He then used simpler problems of towers 4 high and 3 high to build on to towers five high. Next, he organized the towers by "families", using the term "family" to explain the relationship from shorter to taller towers. While his partners based their arguments on number patterns and cases, Milin explained using an *inductive argument*. Milin's explanation in each instance was based on building from a shorter tower exactly two towers that were one cube taller. For example, when asked to explain why from two towers he created four:

Milin: [pointing to his towers that were one cube high] Because – for each one of them, you could add one – No – two more – because there's a black, I mean a blue, and a red- See for that you just put one more – for red you put a black on top and a red on top – I mean a blue on top instead of a black. And blue – you put a blue on top and a red on top – and you keep doing that

Milin then explained, "… and for each one you keep on doing that and for 6 you'd get 64".

*Rods, Grade Four.* David extended the task of finding a rod whose length is equivalent to half of the blue rod by showing that some rods do have a rod that is equivalent to half of their length and some do not. Using the rod staircase he identified all of the rods as "even" or "odd" where odd rods do not have a rod equivalent to half of their length. Thus, David used inductive reasoning by generalizing his solution to show that all of the rods are either even (can be divisible by two) or odd (cannot be divisible by two). The class then discussed the possibility of "cutting" a rod in half to create a new rod and therefore finding half of "odd" rods. Michael used inductive reasoning to broaden the concept of cutting a rod in half to encompass the entire set of rods:

Michael: If you're going to make a new rod, then you'd have to make a whole new set because there'd have to be a half of that rod, too.

David reinforced Michael's argument (also reasoning inductively) by explaining that each time a smaller rod was cut in half, it's half would have to be cut in half and therefore a new set would emerge:

David: Well, what I told you. I thought that, uh, to cut it in half, too, but then I realized that, uh, that you would have to make a whole set…… And make a half for every one.

## Discussion

Our results indicate that both tasks, one dealing with fraction ideas and the other with combinatorics, elicited similar forms of reasoning at multiple grades levels, across different socioeconomic communities. While attending to both tasks students reasoned by contradiction, cases, using upper and lower bounds, and inductively. Although one of the highlighted tasks focuses on fractional relationships and the other combinatorics, they share many characteristics.

In both tasks, students were invited to use manipulative materials but could also approach the tasks with other representations. The building of models naturally led to student collaboration as students were eager to understand each other's models. For both rods and tower tasks, students built models, providing for them a meaningful understanding of the problem. The varieties of representations that the students used to express their ideas were shared in open discussion with others.

Both tasks were open-ended, challenging, and allowed for multiple entry points. They were novel such that a solution was not readily available and therefore students were encouraged to rely on their own resources. Students at all levels of mathematics could engage and realize success. Students had opportunities to be successful in building understanding and communicating that understanding in the arguments they built to support their solutions. Both tasks were open to multiple representations and multiple strategies for solutions. These multiple strategies elicited various forms of reasoning, as in the case of David, who justified his reasoning using three different forms of reasoning (cases, upper/lower bounds, and contradiction).

In addition, the tasks were revisited which allowed students time to reflect on their previous justifications and those offered by their classmates. Thus, when revisiting the tasks students had a schema upon which to build and often revised their justifications and/or used different methods/forms of reasoning.

We suggest that problems, such as these, be integrated into regular mathematics instruction and that students be asked to revisit the same or similar tasks, so that they can build on and extend their approaches, offering opportunities to experience a variety of ways of reasoning. Tasks such as these can serve to engage students in doing mathematics and building arguments. We suggest that strands of open ended tasks that elicit reasoning be integrated in the curriculum at all grade levels.

## Endnotes

# CONCRETE METAPHORS IN THE UNDERGRADUATE REAL ANALYSIS CLASSROOM

Paul Dawkins
University of Texas at Arlington
rdawkins@uta.edu

*As part of a study on classroom communication and study habits in undergraduate real analysis, we investigate one professor's use of concrete metaphors as an instructional tool. We offer a classification of the metaphors according to their function and properties as well as evidence regarding how students understood and used the metaphors in constructing their concept definitions and in constructing proofs. The present findings support these metaphors as an effective communicative and cognitive tool which the students applied appropriately to gain understanding. We also address the biological structural metaphor which these concrete metaphors introduced into the study of real analysis.*

Over time there has been a growing awareness among mathematicians and mathematics educators alike of the dynamic role intuitive understanding plays in mathematical understanding (Fischbein, 1987; Burton, 1999; Oehrtman, 2002). The definition of "intuition" in the context of mathematics is not well defined (Burton, 1999), but most agree that metaphor belongs in this category instead of in the realm of formal knowledge which is centered upon proof. Whatever role metaphor might play in formal mathematics, it is certainly integral to human communication. The real analysis classroom represents a primary intersection between the realm of formal mathematics and communication, so one might naturally ask what role metaphor can or should play in that context.

Oehrtman (2002, 2003) conducted some of the only in depth research on metaphor and communication in the undergraduate classroom. He studied calculus students' work on conceptually complex tasks and observed what metaphors the students employed most commonly. Students' use of metaphor proved to be formative in problem solving, but at the same time problematic by often introducing misconceptions. His framework for understanding the role of metaphor in understanding was primarily informed by the work of Max Black who argues that metaphors can generate understanding by a dynamic interaction of different domains of knowledge. He calls this theory "interactionism" which posits that in metaphor the whole can be greater than the sum of its parts. Black argues that strong metaphors have two key attributes: emphasis and resonance (Black, 1962, as cited in Oehrtman, 2002). A metaphor has emphasis if the metaphorical context couldn't be easily replaced with another without losing meaning. A metaphor has resonance if the parallels between the two contexts are strong enough to allow deep elaboration. Oehrtman references John Dewey's theory of instrumentalism where students use "relevant tools are applied technologically against problematic aspects of situations" (Hickman, 1990, as cited in Oehrtman 2003) to establish the dual role of metaphors both for comprehension and for solving specific problems.

## Present Investigation

During a larger study on classroom communication and study habits in an undergraduate Real Analysis (senior level, proof-based) course, the professor repeatedly used concrete metaphors in her classroom explanations. She not only introduced these metaphors to explain concepts or proofs, but integrated them into her classroom language by repeatedly referring to them in later instruction. The full effect of such metaphors cannot be known because we cannot directly observe student thinking during class lectures nor can we understand how the class would be without these metaphorical explanations since they are integrated into this professor's teaching style. However, in light of their repeated use as a tool of explanation, we investigate the students understanding of the metaphors themselves and their ability to relate them to the course material. In this way we hope to shed light on how students organized their understanding about the mathematics using these metaphors as a tool both to construct understanding and to solve problems which in this context meant to construct proofs.

In order to gain insight into the students' understanding and use of the metaphors, we pursued the following questions:

- How well can the students recall the metaphors and understand how they apply to the concepts? Accordingly, how well do the students understand when the professor would reference the metaphors repeatedly over time to remind students of a given idea or point?
- To what extent do students integrate these metaphors into their concept image or concept definition and use them to articulate or reason about a given concept?
- What, if any, are the misconceptions that arise in student conceptions as a result of the metaphors provided?
- What, if any, are the affective influences of the metaphors upon the students' classroom experience and overall approach to the course?

We borrow our theoretical framework from that of Oehrtman (2002) analyzing the metaphors in terms of Black's classification of metaphors and seeking to gain some view into how students use metaphors as tools to construct understanding and build proofs according to Dewey's theory.

## Methods

The study observed the professor teaching first-semester undergraduate Analysis during two 15-week semesters at a mid-sized (about 25,000 students) university in the southwest. The professor had taught for about 10 years and had taught undergraduate Analysis 2 times prior to the study. She has received several teaching awards and has a reputation among the students as a good but challenging teacher. The course content consisted of analysis on the Real number line covering the cardinality of infinite sets, limits of sequences, limits of functions, and continuity. Each course began with between 20 and 30 students and ended with between 15 and 20 students. Math majors made up most of the cohort because only they are required to take Analysis.

We observed every class meeting keeping record of the written and verbal explanations and discussions. Each semester, we conducted weekly interviews with a set of 4-6 volunteers asking them to:

- recall and explain portions of the classroom discussion,
- give explanations of their understanding of specific concepts, definitions, or theorems,
- write specifically chosen proofs to see their functional understanding of the concepts, and

- report their homework, study, and test preparation habits.

All of the students interviewed were math majors. We also interviewed the professor regularly and she explained her plans for the classroom instruction, provided reasoning behind how she structured her explanations and her emphases, and related any interactions she had with the students which were particularly interesting or meaningful to her.

To understand how students' used the metaphors to construct their concept images, the interviews sometimes invited students to articulate their understanding of those concepts which had been explained using a concrete metaphor. Specifically we observed whether any extraneous aspects of the metaphor were carried over into the mathematics or whether the students would use the metaphor to articulate or recall the ideas. After that, usually at least one week after the metaphor was introduced, they were asked to explain the metaphor, its purpose, and the mathematical concept to which it was applied. This was intended to discover how well-formed the student's understanding of the metaphor was and how effective the professor's repeated reference to the metaphor might be.

## The Metaphors

The extent to which the students would be expected to articulate the metaphor or use it significantly for sense-making depends upon the role the metaphor plays in the explanation and how closely linked it is to the concepts being presented. There were two major roles the metaphors played in the discussion. Some metaphors were used to either clarify the logical structure of the definitions or theorems or to guide the development of proofs regarding their logical structure. These metaphors generally lack emphasis, and have strong resonance in their logical structure and nothing else. This first category shall be referred to as *logical metaphors.* Other metaphors were actually used to demonstrate aspects of the concepts themselves or the structure of definitions. These metaphors on the whole had emphasis, but lacked deep resonance. This type shall be referred to as *mathematical metaphors*. The second category contains those metaphors most likely to be taken into the students' concept images of specific concepts. Thus these are most likely to be used in recall, employed for sense-making, integrated into student language, and introduce misconceptions.

Another form of metaphor appears in the classroom which has minimal conceptual influence. In describing the definition of a cluster point, the professor compared the points of a set to fire ants and said you do not want to be a cluster point for ants. This metaphor falls into the third category which merely introduced concrete language to make a compelling image, but based on which no conclusions were drawn. In this way, the metaphor may influence recall, but is less likely to be used for reasoning purposes. This use of metaphor is the source of the common historical perception which asserts that metaphors are primarily stylistic devices rather than reasoning devices. These could be called *visual metaphors*.

### *Logical Metaphors*

One of the most prominent and well-explored examples of a logical metaphor from the classroom was that of the orange and white tigers. Two sets are defined to have the same cardinality if there exists a bijective (one-to-one and onto) function between them. However the professor reported finding that students would often think two sets did not have the same cardinality if they were presented with a function between them which was not bijective. This misconception hinges upon the students' understanding of the quantifier "there exists" and the orange and white tiger metaphor seeks to clarify the role of this quantifier. The professor defines that a forest is called "special" if there exists a white tiger in it. She then tells the students that someone goes into a forest and finds an orange tiger. She asks if this is enough evidence to say that the forest is not special. Similarly she explains that a function which is not bijective proves nothing about the relative cardinality of two sets

Almost two weeks later on a homework problem, the students were asked to find a function between two sets of the same cardinality (the natural numbers and the even natural numbers) which is injective but not surjective. The students knew the two sets were the same size, so they thought no such function existed. She responded to the students' belief by asking whether her finding a white tiger in a forest proved there were no orange tigers in the forest. One and a half months later, another student was working on a problem trying to disprove a "there exists" statement and the professor asked her, "How do I show there does not exist a white tiger?" The student then replied that, "You look at every single one." The teacher repeatedly referred to the metaphor in the context of "there exists" proofs and it became integrated into her classroom language.

During the second semester, the professor used the white tiger metaphor to explain a sequence convergence proof. She showed how each requirement of the definition was addressed in the proof using the language of the metaphor. The definition requires that for any epsilon, an index be found such that all terms of the sequence after that index are closer to the limit value than that epsilon. The professor expressed this by saying that whatever cage she gives the students, they must find a white tiger which fits in that cage. In this way, the analogy was extended to provide the students with a more global understanding of the structure of the proof.

The professor also used logical metaphors to give clarification to the requirements placed upon definitions. The definition of the limit of a function at a point requires that the point be a cluster point or accumulation point. In her interviews, the professor emphasized how much she wanted the students to know the difference between a limit not existing at a point and when the limit definition simply doesn't apply because the point in question is not a cluster point to begin with. In the classroom, she compared considering the limit at a non-cluster point to finding a tiger and trying to measure its RPM (revolutions per minute). She pointed out that since tigers have no wheels, then the question is irrelevant, just like the question of the limit of a function at a point which is not a cluster point. She later created a parallel metaphor to explain why the function must be defined at a point for it to be continuous at that point. She said that someone asked her if her dog likes her cat when in fact she has a dog, but no cat. Similarly one cannot determine if the limit of a function equals the value at the point if there is no value at the point. Here the logical metaphor works to motivate the need for a condition rather than explain the structure of the situation in question.

*Mathematical Metaphors*

There were several key metaphors which fit into this category. One example compared functions between two sets as arrows being shot by the elements of the first at the elements in the second. Even the language and diagrams used early in the course regarding functions call upon this metaphor by calling the co-domain the "target" and expressing f(a)=b by drawing an arrow from a to b. This language was then used to understand the concepts of one-to-one and onto. One-to-one was thus described to mean no one gets hit with two arrows while onto means that "everyone gets hit." This portion of the metaphor gives an intuitive understanding of the two definitions which is relatively consistent, but the professor then employed the metaphor to explain how to prove that a function is onto. She points out that if onto means "everybody gets hit," then the proof must begin in the target, it must pick any element of the target and show that it "gets hit." The professor follows up by asking the students what it means mathematically for that element to "get hit," namely that f(a)=b. In this way, the metaphor was not only explanatory and concrete, but it was also made functional as it guided the construction of a proof.

During the section of the course about sequences, the professor introduced two key sequences to help the students decide what a function tending to infinity should mean. One function was unbounded, but did not tend to infinity (1,2,1,3,1,4,1,5,…) while the other did tend to infinity, but was not monotonic (2,1,4,3,6,5,…). Both pairs of qualities were chosen by the professor because she had observed students falsely equating the two, namely that unbounded sequences tended to infinity and that sequences tending to infinity were monotonic. The professor built the metaphor around equating sequences that tended to infinity with mammals. The class came to refer to the former as the penguin sequence it looked like it had fur like a mammal, but in fact it was a bird. The second was deemed the platypus sequence because it had qualities most mammals don't such as laying eggs and a bill, but in fact it was a mammal.

A third mathematical metaphor was developed from a student's comment during the second semester of the study. The professor introduced the definition of convergence of a sequence. This definition requires that for any epsilon greater than zero, there must exist a term in the sequence after which every term is closer to the limit than epsilon. As the class was discussing this definition on the first day it was introduced, one student compared the epsilon neighborhood of the limit to a party. He explained that it is not a party unless eventually everyone goes to the party. The professor seized upon this language and began to explain the definition in these terms elaborating the metaphor to include all of the key aspects of the mathematical definition. For two weeks thereafter, her classroom explanations regarding sequences always included some verbal reference to the party analogy.

The final form of party metaphor was as follows: no matter how big your room is, it is only a party if after some time, everyone is at the party. We don't care if there are a few stragglers at the beginning, but only finitely many people can be left outside of the party. Like the arrows metaphor, the professor used the metaphor to explain the general logic of a convergence proof both to motivate each next step and to correspond the pieces of the proof and the definition.

*Structural Metaphor*

The professor's use of specific metaphors had a more universal role in the class beyond the specific concepts which they were used to explain. The most common arena from which the metaphors were built was biology. Biology was the structural metaphor which she used to guide her explanation of the concepts. The professor built her classroom instruction around key examples. Very often before a theorem was introduced or suggested, the professor invited the students to see if they could come up with an example of a convergent but unbounded sequence, a monotone and bounded sequence which is not convergent, a bounded sequence without a convergent subsequence, etc. all of which are impossible. From the students' observations that they cannot in fact manufacture such an example, they discovered the theorems and went on to prove them. To the professor, classifying different sequences and functions according to their properties parallels classifying animals by their properties into species and families. This was also reflected in the classroom language which discussed the "behavior" of mathematical objects.

## Student Responses

There were five major aspects of students' understanding of the metaphors which were of particular interest: recall, application, reasoning or articulating with the metaphor, misapplication, and affective response. Of the 7 students directly interviewed regarding the white and orange tiger metaphor, 5 students could correctly recall it. Some took a minute to reconstruct the logic, but once they knew the context, they could recall the metaphor and explain how it applied. Others could not remember to which specific concept it was originally applied, but could come up with another situation in which it would apply. As part of an ongoing study, one student was asked to recall the metaphor eight months after the class ended and once he remembered it was applied to bijections and cardinality, he could correctly explain it.

One student in each semester spontaneously used "white tiger" language to talk about proof. The first referenced the metaphor to explain the relative difficulty of disproving a there exists statement (showing for every). "When you make a claim about for every, it is usually very difficult to say, you know: the white tiger thing. All the tigers in this forest are orange. Oh, really? You know, find them all and bring 'em here." The fact that the student references this metaphor in the context of a "for every" proof constitutes an extension of the metaphor beyond its original application.

The next semester, another student used the tiger metaphor when explaining rules for certain types of proofs:

> Student: "For these kind of proofs specifically I remember she said you use your scratch work and you look for the white tiger and then you show the white tiger in the proof."
> Interviewer: "Okay and what kind of proofs are those?"
> Student: "Existence proofs."

Of the five students who were asked to articulate their understanding of one-to-one and onto, three used the arrow metaphor's terminology, primarily to talk about onto. When directly asked what metaphor she used, all of them recalled the arrow language. Two students pointed out that because onto means that "everything in the target gets hit," proofs that a function is onto begin with an arbitrary element of the target rather than beginning with a point in the domain. In this way, the students not only had integrated the metaphor into their concept image of onto, but used the metaphor to guide the construction of proofs.

All of the students interviewed referred to the penguin and platypus sequences under those names and understood that they were named for their curious properties that made them atypical examples. It was less common for students to directly be able to explain the logic which paralleled "mammals" to sequences which tends to infinity. All but one of the students recovered the metaphor either from direct memory or reconstruction from their knowledge of the two sequences. None of them gave evidence of using the metaphor to remember which sequence tended to infinity. However the names appeared integral to their memory of the sequences since some would recall a slightly different sequence which had parallel properties such as (2,1,3,2,4,3,…) for platypus or (0,1,0,2,0,3…) for penguin. Two of them were asked about these two sequences by name 8 months after their class ended, and they both could recall the basic behavior of the sequences, explain the metaphor, and explain why they were interesting examples (platypus shows that not every sequence tending to infinity is monotone and penguin shows not every unbounded sequence tends to infinity).

Of the four students interviewed during the second semester about the definition of a sequence converging, three of them used "party" language to explain the definition and the other one could recall the metaphor when asked directly about it. One of them even extended the metaphor. He deemed the term after which the sequence was in the given epsilon neighborhood as the “popular guy” because after he comes, everyone else goes to the “party.” He reported having explained the definition to several other people as they studied together which might mean he extended the metaphor for explanatory purposes. However none of the students were observed to use this terminology in proving the convergence of a specific sequence. One student used this language to explain the proof that limits are unique because we form two separate parties around the two limits. Also, only one student persisted in using this language after the test. The other students began to speak almost exclusively in more mathematical terms and the one who still used party language merely interchanged the terms “party” and “neighborhood,” but did not seem to use the metaphor for sense-making.

Though the professor explained the party metaphor pointing out that it doesn’t matter how big the room is, most of the students during class discussion and during interviews either failed to address the arbitrarity of epsilon or only at the end of the definition that “it works for any epsilon you pick.” It could be that the party metaphor, being primarily concrete, fails to capture this aspect of the definition which led to this weakness in the students’ concept definitions. However any pictorial representation of the limit definition usually includes at most 3 specific epsilon neighborhoods. Thus it remains unclear whether the metaphor was a primary cause of this misunderstanding.

Several students reported that the presence of the metaphors made the class much more enjoyable. There was a uniformly positive affective response to this mode of instruction, sometimes quite enthusiastic. One of the students, despite consistently not being able to recall the metaphors throughout the interviews, at the end of the class reported that they were one of his favorite parts of the course. When asked whether he ever actually referred to the metaphors when solving problems, he said he did not. “[I don’t use the metaphors] really on the test, just as I’m learning it. Like, if I understand I don’t have to think about the analogies, I guess, once I know what is going on.”

Several students recognized the parallels between their study of analysis and biological classification. One student noted the appropriateness of biological metaphors because, “in a sense, what are we trying to do but categorize things... and so basically this is coming down to organization and classification, you know?” Another student similarly described their study of sequences and functions saying they, “classify and group [various examples] into like groups.”

## Discussion

Alibert & Thomas (1991) explain that the sequential structure and presentation of proof often obscure the central ideas. Students may verify a proof to themselves by checking the validity of each line without gaining any global understanding. The professor used the tiger metaphor to point out the global structure of a convergence proof. At least one student then used this metaphor to develop his own proof scheme of “there exist” proofs and another was able to transfer the metaphor to disproving “for every” statements.

The interviews provided evidence that the students did understand the metaphors which were presented in class as they applied to the mathematics. Moreover, even if they couldn’t recall the metaphor by itself, they could recall it in from context in which it was introduced. This implies that the professor’s integration of such metaphors into classroom language was an effective form of communication. Some of the metaphors proved very powerful for recall as evidenced by students being able to recall the penguin and platypus sequences months after the class was over, one without the names of the sequences being mentioned. There was evidence of students using the metaphors for sense-making, namely that they extended the metaphors (tigers and party) or used them to organize their proof approaches (tigers and arrows). Most prominently the students reported a positive affective response to this mode of communication.

The metaphors were primarily used as tools for the students to construct their understanding. None of the students were limited to explaining their understanding by the metaphor and would often acknowledge the less-formal nature of these explanations. The metaphors were not central to the student's concept images because some of them only referenced the metaphor when specifically asked to. They used the metaphors less over time as their concept images were more fully developed. One student even reported directly that he only used the metaphors to gain initial understanding, and then left them behind. No direct evidence arose of students misapplying metaphors or bringing extraneous aspects of the metaphor into their mathematical understanding. All of this supports the characterization of these metaphors according to Dewey's instrumentalism as tools the students used to mediate difficult situations, in this case building a strong concept definition or learning how to prove in the context of real analysis.

These findings stand in contrast to those of Oehrtman (2002) who found that calculus students often used metaphors to reason about problems to the extent that they became mathematically incorrect. It is unclear however whether these differences can be attributed to the relative difference in mathematical sophistication between calculus and analysis students, the difference between a computational versus a proof-based course, or whether the fact that the metaphors in the present study were obviously non-mathematical helped the students to apply them properly. The logical metaphors in the present study were also much less susceptible to misapplication since they weren't applied to the primary concepts being studied, and because they were primarily logical they had a very high degree of resonance.

The present study thus affirms the possibility of effectively employing concrete metaphors in classroom discussion to help students construct their understanding of undergraduate analysis. Moreover, the use of biological metaphors appeared to implicitly provide students with a structural metaphor by which to think about analysis. This is one aspect of the overall model this professor used of which a more full description is forthcoming.

# A JOURNEY WITH JUSTIFICATION: ISSUES ARISING FROM THE IMPLEMENTATION AND EVALUATION OF THE MATH ACCESS PROJECT

Megan E. Staples

*Justification is a practice central to mathematics and mathematics learning. In this paper, we report on results and issues related to justification that arose during the course of a professional development program, the Math ACCESS Project. Justification was one of the three themes central to the project. Data sources included records of project activities, pre-post assessments, and documentation of analyses and the issues that arose while conducting the analyses. Results suggest that the Math ACCESS Project advanced teachers' understanding of justification, but that some important issues were left in an unsatisfactory state. Implications are discussed.*

## Objectives and Purposes

Justification is a central to doing and learning mathematics. This practice requires the articulation of reasoning and is facilitated significantly by the use of mathematical terminology and forms of expression. Students' participation in practices of justification and argumentation expands their mathematical knowledge, as they identify and articulate their own reasoning and gain exposure to others' arguments (Boaler, 1997; Hiebert et al., 1997; National Research Council, 2001; Wood, Williams & McNeal, 2006). In this sense, the practice of justification is a *learning practice* (Cohen & Ball, 2001). Justification is also a core activity in classrooms that support more equitable outcomes in mathematics (Hiebert et al., 1997; Boaler & Staples, 2008).

Supporting student justification in classrooms, however, is challenging (Chazan, 2000; Stylianides, 2007) and researchers have documented that this important practice is absent from many classrooms (Jacobs et al., 2006). Fostering student justification requires a broad repertoire of pedagogical moves (Staples, 2008) supported by a commitment to this practice, appropriate classroom norms, and content knowledge (Knuth, 2002). A further difficulty is that what counts as a justification varies across settings (Stylianides, 2007). It depends on the community's shared background and its purposes. Currently the field of mathematics education has an underdeveloped notion of justification (Stylianides, 2007).

In this paper, we document the design and impact of a professional development program, the Math ACCESS (Academic Content and Communication Equals Student Success) Project. This on-going project has a unique focus – working with teachers in urban settings to understand the language demands of student participation in justification and higher-order thinking in mathematics classes. While important for all mathematics learners, the need for teachers to be able to organize instruction to foster student participation in justification is perhaps heightened in urban areas where students are more likely to be linguistically diverse and have received lower quality instruction at some point in their mathematics careers.

Although there is no standard definition for justification, for the purposes of our work and this paper, we used as a working definition for justification the process of removing doubt about a claim using logical reasoning. We also draw on Toulmin's (1958) framework of argumentation and see justifications as comprised of claims, warrants and evidence, either explicit or implicit.

**Context**

The Math ACCESS Project was designed as a professional development experience for teachers of mathematics working in urban settings. The work was supported by a Teacher Quality Partnership Grant from the Connecticut State Department of Higher Education. The conceptual model guiding the professional development comprises three "pillars": *Appropriate/ Effective Use of Academic Language, Student Justification and Collective Building of Arguments,* and *Access by all Students.* Each pillar addresses a core component of instruction that has a strong research base documenting its value for student engagement and learning, and promoting more equitable outcomes. In this paper, we focus on the second pillar, *Student Justification,* and document and discuss the relevant activities, outcomes and issues from our work with a group of teachers during the ACCESS Summer Institute. See Truxaw, Staples and Ewart (under review) for discussion of the first pillar, *Academic Language*.

Given our goals and the requirements of the grant program, we organized the PD into two main components. The "instruction" comprised a one-week intensive summer institute (40 hours) during July and a half-day (5 hours) session in September. The "follow up" comprised a modified form of lesson study where teachers, organized in grade-band teams, collaborated to develop, implement, and debrief lessons that used pedagogical strategies related to each pillar. We briefly describe some of the institute activities, emphasizing those related to justification.

Our work with respect to *Justification and Collective Building of Argument* focused on the need to provide students with opportunities to engage in *sense-making* (Hiebert et al., 1997) through explanation and justification. Teachers analyzed the cognitive demands of tasks (Stein, Smith, Henningsen, & Silver, 2000), modified existing tasks to prompt higher-order thinking, discussed the validity and completeness of student justifications (Toulmin,1958), examined the language demands of offering justifications (e.g., expressing a general statement), developed strategies for providing formative feedback on student written justifications, and worked in teams to write and implement lessons that promoted higher-order thinking and justification. For example, one activity engaged teachers in examining student work on a test item (from the State tets) that requested an explanation. Teachers analyzed the responses for the claims, warrants and evidence and discussed the validity, completeness, and merits of different responses. Note that this was not easy work. A prerequisite for this work was a clear understanding of the central mathematical ideas needed to solve the problem.

The other two pillars were also critical to the justification work, as these pillars are mutually supportive. Related activities during the Summer Institute included attention to establishing productive classroom norms, providing multiple entry-points into justification tasks, and developing strategies to expand students' math vocabulary and develop student command of certain phrases (e.g., at least, the least, for each person, for every person). For example, a series of activities involved unpacking language demands within mathematics curriculum materials, state testing materials, and student work samples. Participants subsequently learned to write language objectives for mathematics lesson plans (Echevarria, Vogt, & Short, 2004) that focused not only on vocabulary, but also functional language (Schleppegrell, 2007) (e.g., *Students will continue to build an idea of what makes a good explanation by using a language frame: "____ is correct/incorrect because ____."*).

To document the impact of the project and further our understanding of the practice of justification, we address the following research questions:

1. What are the outcomes and effects of the ACCESS professional development activities

for participating teachers?
2. What issues arise as teachers work on understanding the nature of justification and practices related to supporting student participation in justification?

Twenty-four grades 4-9 teachers from one urban area participated in the ACCESS Summer Institute; 20 teachers continued the program during the academic year. Of the 24 teachers, 11 teachers taught the single subject of mathematics (grades 7-9), 10 taught multiple subjects, including math (grades 4-7), and 3 teachers were special educations who worked in mathematics classrooms. Teaching experience ranged from 0 years to over 21 years. The first two authors did the majority of the instruction; all authors are supporting school-based follow-up activities.

Data collection and analysis are ongoing as we are currently engaged in the academic year "follow up." The remainder of the paper focuses on the results from the Summer Institute.

## Methods of Inquiry

This study employed a mixed-methods design to investigate outcomes and effects of the ACCESS Summer Institute activities. Participants completed two pre-post assessments, one primarily targeted content knowledge and the other primarily targeted issues related to academic language (e.g., teachers' awareness of the language demands of mathematics (specifically open-ended prompts) and ability to generate strategies to promote academic language). Across these two assessments, five questions focused on justification, specifically teachers' production of justifications and/or their analyses and evaluations of student justification.

*Instrument Development*

*Content knowledge assessment.* Items for the content knowledge survey were drawn from previously validated sources (e.g., CT State Department of Education; Healy & Hoyles, 2000; *Learning Mathematics for Teaching Project;* Hill, Ball, & Schilling, 2004)) and were selected by a team of mathematics educators to fit the content themes of the project, algebraic and proportional reasoning. The items were field tested for appropriateness and timing. The final instrument included 7 multiple-choice questions and 2 open-ended questions.

*Language assessment.* The second assessment was developed specifically for this investigation to uncover participants' growth related to supporting the development of students' mathematics academic language, especially with attention to ELLs and higher order thinking. Following recommendations of Gable and Wolf (2001), content-validity was sought through the use of research literature and experts' content validation (i.e., mathematics educators, linguistic experts, and methodological experts) that noted the adequacy of the items as representative of the specified key constructs. The final instrument included 6 open-ended questions related to language use, challenges, and strategies. The assessment also included 7 Likert-type questions asking participants to self-report on their perceived knowledge about and confidence in addressing various issues related to language and justification addressed during the PD. The content validity questionnaires and the final instruments are available from authors upon request.

*Data Collection and Analysis*

The data relevant for justification comprised five assessment items and two Likert-scale items. Multiple choice and scaled items were performed using standard statistical techniques (Green, Salkind, & Akey, 2000). The open-ended responses were analyzed using rubrics and additional qualitative analyses were conducted using standard techniques (Glaser & Strauss, 1967). For example, for questions that asked teachers to select from a set of three which student justification they thought was *best*, researchers employed open coding of emergent themes, discussed the themes, and then employed axial coding to make connections among the categories and to refine the coding schemes (Strauss & Corbin, 1990). Coding categories and definitions for each question were developed and tested by at least two researchers. Disagreements were resolved in discussion with a third research as needed. Applying these codes allowed us to look for change on both the group level and the individual level.

## Results and Discussion

Results from the pre-post assessments indicate that the Math ACCESS Project did have a positive impact on teachers' knowledge of content and language-related issues and strategies. We will describe content results briefly and then focus on the justification items.

*Evidence of Overall Impact*

Twenty-four participants completed the pre- and post- content assessments related to content. The results demonstrate increases in content knowledge overall. Scores of 15 participants (63%) increased; scores of 7 participants (29%) decreased, scores of 2 participants (8%) remained the same. Overall content knowledge showed a statistically significant difference in mean scores ($p < .05$). (See Table 1.)

Table 1. *Assessment of Content Knowledge of PD Participants*, n = 24

| Administration | Mean | SD | *t* | df | *P* |
|---|---|---|---|---|---|
| Pre | 9.33 | 3.67 | | | |
| Post | 10.63 | 3.63 | 2.24 | 23 | .035 |

Teachers' self-report on the Likert items also demonstrated significant gains. Nineteen participants completed all questions on both pre and post administrations. The mean score for all 7 items increased from pre to post (between 0.50 and 0.95 points per item), with all items except Item 1 being a statistically significant difference ($p < .05$). A one-tailed t-test showed a significant difference between the pre- and post-results. Overall, these data demonstrate a positive and relatively strong impact of the professional development work with respect to language.

*Evidence of Impact Specific to Justification*

Qualitative analyses of the various assessment items that targeted justification offered additional insights into what the teachers had learned, and not learned, and raised some important issues for our consideration. We focus our discussion on two main issues that emerged as we worked on the idea of justification during the ACCESS Institute and as we analyzed participant data from the Institute. The first pertains to teachers' (and mathematicians') thinking about the *qualities* of a good student justification. The second pertains to the various *types* of justifications that can be offered and evaluating the validity of students' work.

Two assessment items in particular offered insights into how teachers were thinking about the qualities of a good justification, including validity. We describe and discuss each below. These two items demonstrated quite a bit of change between the pre- and post-assessments, but not necessarily towards what we would consider deeper understanding of justification. As will be discussed, we ultimately interpreted our results as indicating that we had raised issues related to justification enough to prompt awareness, new questions, and reflection, but we did not work on the ideas intensively enough to solidify new understandings of what comprises a mathematically valid justification and a high quality justification.

Question 7, adapted from Healy & Hoyles (2000), asked teachers to evaluate two student justifications of a particular claim (see Figure 1). Teachers determined whether each student's response showed that the claim was (always) true and whether it demonstrated *why* the statement was true.

Bonnie and Duncan were trying to prove whether the following statement is true or false: When you add any 2 even numbers, your answer is always even.

| *Bonnie's answer* | | *Duncan's answer* |
|---|---|---|
| 2 + 2 = 4<br>2 + 4 = 6<br>2 + 6 = 8 | 4 + 2 = 6<br>4 + 4 = 8<br>4 + 6 = 10 | Even numbers end in 0, 2, 4, 6, or 8. When you add any two of these, the answer will still end in 0, 2, 4, 6 or 8. |
| *So Bonnie says it's true.* | | *So Duncan says it's true.* |

*Figure 1.* Prompt from assessment item, question 7, adapted from Healy and Hoyles, 2000.

On the pre-assessment, 43% of the teachers (incorrectly) thought Bonnie's response showed that the claim was always true and 61% thought it showed *why* the statement was always true. On the post-assessment, these values decreased significantly to 22% and 35%, respectively. Indeed, we had an extended discussion about a similar problem during the institute. Initially, it was not clear to the teachers why a response such as Bonnie's was inadequate. Several felt that, by showing many examples, the student had demonstrated that the result was always even. Part of the difficulty seemed to be gaining distance from the truth of the result to evaluate the *validity* of the student's *method*. As the teachers knew the result was true, they did not authentically need to be convinced by the argument. In the Institute, we addressed the idea of "proof by example" (commonly known as an empirical proof) and its limitations. We also discussed using examples that exhausted all possible cases as a valid approach. This latter approach seemed akin to proof by example for some of the teachers.

For Duncan's argument, 74% of the teachers on the pre-assessment and 70% on the post-assessment agreed (correctly) that his response showed the statement was always true. (See Table 2.) Despite the similar overall values, we found that many teachers had changed their response to this question.

Table 2. *Percent of Teachers Identifying the Correct Response for Question 7*

| Question | Correct response | Overall N=23 | | Multiple Subject N =12 | | Single Subject N =11 | |
|---|---|---|---|---|---|---|---|
| | | Pre | Post | Pre | Post | Pre | Post |
| 7a. Bonnie's work | | | | | | | |
| Has a mistake | Disagree | 91 | 83 | 92 | 75 | 91 | 91 |
| Shows that it's always true | Disagree | 57 | 78 | 58 | 67 | 55 | 91 |

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Shows why it's true | Disagree | 39 | 65 | 33 | 67 | 46 | 64 |
| 7b. Duncan's work | | | | | | | |
| Has a mistake | Disagree | 96 | 87 | 92 | 83 | 100 | 91 |
| Shows that it's always true | Agree | 74 | 70 | 75 | 58 | 73 | 82 |
| Shows why it's true | Disagree | 39 | 26 | 58 | 50 | 18 | 0 |

Furthermore, the elementary and secondary teachers responded quite differently. Whereas 75% of the multiple-subject (elementary) teachers agreed that Duncan's work showed it was always true on the pre-assessment, only 58% identified it as always true on the post. The single-subject teachers showed the opposite trend, increasing from 73% to 82%. We suspect that there were lingering questions about the distinction between "proof by example" and proof by exhaustion, which perhaps were less clear to the elementary grade teachers. It's interesting to note that the idea of proof by exhaustion may have eluded many secondary teachers initially, and that they better understood this idea at the end of the Institute.

In evaluating whether Duncan's work shows *why* the statement is true (it does not), most teachers, on both the pre- and post-assessment, felt that Duncan's response did demonstrate this. In fact, there was an increase in the number of participants who felt the response did address *why*. Clearly, the participants found this student response compelling. In particular, all single subject teachers agreed that Duncan's work demonstrated why the result held.

Supporting these "mixed bag" results are analyses from the second question (language assessment, Q5). This question included a state test item (open ended problem) and asked teachers to identify whether each of three student work samples a) offered an *adequate* response (which requested an explanation) and b) which of the three they felt was the *best* justification and why. Each of the 3 student explanations had merit and none was complete. We used this question to infer, on the group level, what the teachers seemed to identify as characteristics of a good justification. On the individual level, we analyzed teacher responses for any changes in their thinking about what comprised a good justification.

There is no absolute correct answer to the question of which of the three student responses was the best justification. Indeed, among a group of 12 mathematicians with whom we discussed this problem, at least one mathematician selected each of the three student work samples. To analyze this problem, we coded teachers' responses to identify the characteristics the teachers felt were important for a good justification. There were 4 thematic categories of reasons offered for why a particular response was "best" included the following:

- the detail/explicitness of the response (e.g., I could follow their thinking)
- the student used, or stated that s/he used, a particular mathematical method (e.g., student A used proportional reasoning; he explained he saw the pattern)
- the student understood/had deduced the key mathematical relationships needed to solve the problem (e.g., the student knew there were the same number of red and blue blocks, and half as many green blocks)
- a relative argument (e.g., it made more sense than the other ones)

The second and third bullets perhaps need an additional comment. The second bullet reflects that teachers placed high value on recognizable and potentially named methods or mathematical techniques. Note that the mathematical tools used do not inherently make one justification better than another. Nevertheless, this was valued by many teachers. (It is possible that this was a variation of the first category, being detailed/explicit, namely with respect to the method used.) For the third bullet, we interpreted this to mean that the teachers valued that the student was able to identify the core mathematical relationship that was needed to solve the problem.

As we reflected on these reasons offered, we realized that participants generally did not identify qualities such as the student response being convincing or demonstrating why the result *must be* so. We also noticed the preponderance of responses focused on detail and explicitness, although it was not clear what the teachers wanted the students to be explicit about. It was interesting to note that the attributes of clear and concise only came up once each. This led us to wonder whether teachers generally value explicitness and detail, or the obviousness of student method, more than whether the justification "does its job" as a justification and removes doubt about the validity of the claim. Although it is ultimately a judgment call whether an offered justification serves this function, the lack of attention to any associated attribute by the teachers was concerning to us. We also realized that the prompt might not have elicited attributes of a good justification because the prompt, which asked for which response was best, potentially focused teachers on comparing responses and explaining why one was *better* than the others and not what was absolutely good about the one they selected.

In addition to what the teachers' noticed, we queried the data for evidence of growth between the pre- and post-assessments. We coded individual teachers' responses for whether they evinced some change in their perspective about what comprised a good justification. We coded each as either increased sophistication, stayed the same, or decreased sophistication. A response that was more sophisticated was more specific about the components of the response that were valued and why. It included fewer general claims (it made sense to me) and more specific claims (it made sense because the student explained the pattern he found). We found that 9 respondents increased in their sophistication; 5 stayed same; and 5 decreased.

Consequently, we conclude that the ACCESS Summer Institute heightened teachers' awareness of justification, some important qualities of justifications, and the language issues that might arise when asking students to justify, but the evidence suggests that we were not successful in expanding participants' notions of what a good justification is. Indeed, our assessments show that we made them question their original ideas, but did not do enough work to solidify their understandings in a manner that aligns with the mathematics community.

## Implications and Conclusions

Our work with participants in the Math ACCESS Project confirms earlier findings about the challenges teachers face as they work with justification. Justification is a complex practice the requires content knowledge as well as an understanding of how ideas are logically connected, the limitations of certain modes of argument, and how we determine– with a high level of certainty – whether a claim is true. During the ACCESS Institute, we were successful in raising some issues related to justification, but many more discussions are needed to more fully examine this important learning and disciplinary practice. In particular, sustained discussions about the qualities of a justification, and what one might expect from different students at different grade levels, would be beneficial.

As we reflect on the challenges in organizing professional development activities on justification, we have come to appreciate the power of a system that does not encourage teachers to reflect on or think about justification on a regular basis. On mandated assessments, clear explication of steps is as acceptable as a well reasoned justification (both are considered explanations). Most textbook tasks do not request justification. Planning time is tight, precluding deep thinking about issues of justification and formative feedback to students on justifications they produce. It is nearly impossible for teachers to engage this kind of work and thinking on their own given the incentives and constraints of the system. Without sustained efforts, however, findings that suggest abysmally low participation among students in justification will remain unchanged, as teachers are the linchpins in our system for promoting this important practice.

*In this report, we analyze the heuristics and reasoning that students exhibit as they solve an open-ended combinatorics problem in an online, synchronous environment. While significant research exists on students' mathematical reasoning and heuristics in problem solving, there is little work in these areas as students collaborate to solve problems online. In our analysis, we find that as the students make sense of interpretations of the problem and jointly develop solutions, they display emergent heuristics and reasoning that evolve over the course of their online sessions.*

## Objective

Information-based economies such as in the United States are experiencing an increased demand for individuals who know how to harness information and communication technologies (ICT) to collaborate and to identify and solve complex problems (Reich, 1992). It is important for mathematics educators to acquaint students to environments and learning activities through which they develop abilities and dispositions that allow them to transition to ICT-intensive careers. While much research has been conducted on students' mathematical problem solving (Francisco & Maher, 2005; Schoenfeld, 1985; Silver, 1994) and on Internet-based instruction (e.g., Pena-Shaff, Altman, & Stephenson, 2005; Wallace & Krajcik, 2000), with the exception of a few studies in the learning sciences (e.g., Chernobilsky, Nagarajan, & Hmelo-Silver, 2005; Hiltz & Goldman, 2005; Powell & Lai, in press; Stahl, 2006), little research has been done on Internet-based, collaborative problem solving in mathematics. In light of this gap, it is crucial for mathematics education researchers to investigate how students jointly construct mathematical ideas within online environments.

We have therefore engaged in a longitudinal study to investigate (a) how students use ICT tools to collaborate in mathematical problem solving and (b) what resulting mathematical ideas and reasoning they develop. This study focuses on the latter component of the larger study, and investigates the heuristics and lines of reasoning that students evidence in their interactions as they collaboratively solve open-ended combinatorics problems using an online communications environment.

## Conceptual Framework

The key conceptual terms in this study include heuristics and reasoning. By *heuristics*, we speak of actions that human problem solvers perform that serve as a means to advance their understanding and resolution of a problem task. We do not imply that when problem solvers implement heuristics that they will necessarily advance toward a solution but only that their intent is to do so. Our sense of heuristics includes explicit and implicit general strategies such as categories outlined by Pólya (1945/1973, pp. xvi-xvii, 112-114).

We distinguish heuristics from *reasoning*, which we view as a broad cognitive process of building explanations for the outcome of relations, conclusions, beliefs, actions, and feelings. In agreement with English (2004), mathematical reasoning encompasses such processes as analyzing data, conjecturing, argumentation, forming and justifying logical conclusions, and proving claims. As she describes, these processes make possible such types of thinking as conditional, proportional, spatial, and critical thinking, and deductive and inductive reasoning (p. 13). There is evidence that imagery is deeply tied to mathematical reasoning (Presmeg, 1997; Thompson, 1996), and can affect students' abilities to solve problems, and ultimately, to form generalizations.

## Methods

*Participants and Context*

The fourteen students in this study come from two high schools. Eight of the students, whose mathematics teacher is the fourth author, are from the urban, public high school in Long Branch, NJ (LBHS). The remaining 6 students, whose mathematics teacher is the third author, are from a suburban, private high school in Somerset, NJ (RPS). All of these students are in their fourth year of high school and, in their respective schools, have average mathematical performance.

The students use an ICT tool called the Virtual Math Teams Chat (VMT Chat). Developed by researchers at Drexel University (Stahl, 2006), with support from the National Science Foundation, it is an Internet-based, dual-interaction space with whiteboard and chat windows, which allows users, whether co- or remotely-located, to communicate about mathematics.

For our study during the 2008-2009 school year, we planned for the students to interact online for approximately 18 sessions, each 45 minutes long. During the first half of the year, students would work collaboratively on open-ended combinatorics problems. Students would then switch to solving social choice problems for the second half of the year.

To neither overcrowd nor under-populate each chat room and to facilitate discussion of the problems, we assigned three to four students to a virtual room. Of the four chat rooms, two rooms contained two students from each school, and the other two rooms contained two LBHS students and one RPS student.

To ensure minimal face-to-face communication and that communication among students would occur in the VMT environment, students who were co-located and in the same chat room were placed at desks at opposite ends of their classroom. We also discouraged paper and pencil, as we wanted students to place all of their inscriptions into either the whiteboard or chat windows. These and other procedures were made clear to the students at the beginning of each session through a script that the third and fourth authors read to their students before they began working on the problems.

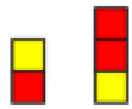
*Data Sources*

Our data sources are the mathematical problem and the persistent archives of the VMT interactions in each of the two interaction spaces.

*Mathematical problem*. During two sessions in October 2008, the students worked on the towers problem, the text of which we present in Figure 1. We chose this mathematical problem for two reasons: (1) its context is familiar to students from urban and suburban communities; and (2) mathematically it affords different solution approaches, ranging from simple listing procedures to more advanced methods involving combinatorial analysis.

Towers Problem

Your team has an inexhaustible set of two colors of cubes. You will use these cubes to build towers. Pictured below are two types of towers: a tower 2-cubes tall and a tower 3-cubes tall.



1. Work together with your teammates to make as many different towers 4-cubes tall as possible when selecting from two colors. Find a way to convince each other that you have accounted for all possible towers 4-cubes tall.
2. How many different towers do you think are possible when selecting from two colors for each of the following situations: 5-cubes tall, 3-cubes tall and n-cubes tall? Work together to determine how many there are for each situation.
3. Work together to write a report of your findings for questions 1 and 2 above. It should include a justification that in each situation you have accounted for all possible towers. You want your report to convince others who are not in your team that your findings are correct. Enter your report into the Summary tab.

*Figure 1*. The towers problem.

*Persistent archives*. VMT Chat records and archives the chat text and whiteboard inscriptions that comprise a chat-room session. These archived sessions are available as Java files (with extension .jno) that can be replayed with a player application. These archived, viewable VMT Chat sessions are one part of the data upon which analyses can be performed. For more detailed analytic purposes, we also produce transcripts of all the actions in the environment. To do so, we use an automated transcriber that translates all the actions in the environment into text. These transcription files can be viewed in a web browser, in a Microsoft Excel spreadsheet, or in a Microsoft Word document as a table. For this study, we used the third method for ease of coding.

*Analysis*

For this report, we analyze two sessions of data from one chat room. This particular chat room contains two students from LBHS and two students from RPS. X lil pit 21 x and johnc250 are from LBHS, and we will refer to them as LP and JC. Cammalleri and 16oncebabyjesus are from RPS, and we will refer to them as CM and SO. During the two sessions, the four students worked on the towers problem. We found this chat room to be particularly interesting because of the way the students interpreted the problem and the solutions that resulted as a result of their interpretation.

To investigate the online, problem-solving actions of learners so as to understand how they build mathematical ideas, heuristics and reasoning, we code for instances in the data of different types of heuristics and evidence of mathematical reasoning (Table 1). These codes were developed inductively for the data.

Table 1

*Codes Used in Chat Room Transcriptions*

| | | | | |
|---|---|---|---|---|
| **H**euristic | **L**isting **S**equentially (HLS) | Using **S**ymbolic **N**otation (HSN) | Using **I**conic **N**otation (HIN) | **L**isting by **C**ases (HLC) |
| Evidence of **R**easoning | **S**tructure of **T**ower **L**isting (RSTL) | **A**rgumentation and **J**ustification (RAJ) | **C**ontributing a **M**issing Solution to Another **P**articipant's work (RCMP) | |

In Table 2, we present an example of one coded time interval from a VMT Chat transcription. In this example, which takes place at 2:49:01, JC (johnc250) has created in the whiteboard a textbox listing a tower. This information can be seen in the first four columns of Table 2, which lists characteristics of an action at a particular time. Note that "wb" under the Type column stands for whiteboard, indicating that this particular action took place in the whiteboard.

In the fifth column, we have coded this moment for the heuristic of using symbolic notation (HSN), as well as for the structure of the tower listing (RSTL) and, as evidence of mathematical reasoning, contributing a missing solution to another participant's work (RCMP).

Table 2

*Sample Coding of Transcription*

| Time | Author | Type | Content | Code and explanation of code |
|---|---|---|---|---|
| 14:49:01 | johnc250 | wb | [johnc250 created a textbox : yellow red red yellow red] | HSN, RSTL, RCMP<br>EC: (HSN) JC uses symbolic notation to list a five cube tall tower. He uses a string of five colors to represent a five-tall tower, with each color being either red or yellow.<br>EC: (RSTL, RCMP) JC creates a textbox containing a tower that CM missed and places it among CM's five-tall towers. JC uses CM's notation to write this tower, and seemingly would have had to enter into CM's logic to not only use CM's notation, but also to discover that CM had not listed this particular tower. |

## Results

With regards to our inquiry into the cognition of the team of participants, our investigation concerns the following guiding question: What heuristics and lines of reasoning are evidenced in students' interactions as they collaboratively solve open-ended combinatorics problems using the VMT Chat? We present our results first with regards to heuristics and second with regards to mathematical reasoning.

*Heuristics*

The VMT Chat environment seemed to afford many of the students' heuristics. During these two sessions, the students seemed to have propensities to use the textbox tool, which is one means to list towers on the whiteboard space. To represent the three-, four-, and five-tall towers in these lists, students used symbolic notation. While CM (cammalleri) used strings of the words red and yellow to represent his towers, LP (x lil pit 21 x) and JC (johnc250) used strings of the letters r and y. In the former case, red and yellow stand for red and yellow cubes, respectively. In the latter case, r and y stand for red and yellow cubes, respectively.

To list their towers, students used three methods: listing sequentially, listing by cases, or both. Listing sequentially specifies instances where each successive tower is related to the preceding tower and where the list contains sequentially two or more instances. At 2:22:55, LP lists six four-tall towers: 1) yrry, 2) yyrr, 3) rryy, 4) ryry, 5) yryr, and 6) ryyr. To get the second tower, yyrr, from the first tower, yrry, it seems that LP shifted rr from the second and third position to the third and fourth position. To get the third tower, rryy, from the second tower, yyrr, it seems that LP switched the positions of yy and rr. To get the fourth tower, ryry, from the third tower, rryy, it seems that LP interchanged the positions of the second r and first y. To get the fifth tower, yryr, from the fourth tower, ryry, it seems that LP changed both ry's to yr's. Finally, to get the sixth tower, ryyr, from the fifth tower, yryr, it seems that LP changed the first yr to ry.

CM lists by cases as well as sequentially. In listing four-tall towers, he used three cases: 1) Towers containing three red's and one yellow; 2) Towers containing two red's and two yellow's, with red in the first position; and 3) Towers containing two red’s and two yellow’s, with yellow in the first position. Within each case, CM lists towers sequentially in a similar manner to how LP listed his towers sequentially.

The heuristic of listing towers sequentially seems to be effective since it allows students to create towers methodically, one at a time. Once a tower is listed, it needs only to be slightly modified to create a next tower. The same process can then be used with this second tower to create a third tower. In this way, students can create a succession of towers in a manner that is not daunting, as the student needs only to make small changes to the previous tower to create a new tower. When used in conjunction with listing by cases, as CM does, it becomes an effective way of listing all of the towers within a case. As we will explain in the next section on reasoning, through his interpretation of the problem, CM was actually able to list all three-, four-, and five-tall towers, save for one.

*Reasoning*

Throughout the two sessions, there is evidence in the students’ whiteboard inscriptions and chat text that they reason mathematically. This is evident in how students structure their lists of towers. When CM lists three-, four-, and five-tall towers, he seems to use knowledge gained from one listing to help with a subsequent listing.

CM lists three- and four-tall towers in two different ways (Figures 2 and 3). Initially, CM starts out by listing three-tall towers, all of which contain either two red cubes and one yellow cube, or two yellow cubes and one red cube. He first lists towers containing yellow in the first position, and then lists towers containing red in the first position. CM follows a similar tactic in listing four-tall towers, all of which contain two red cubes and two yellow cubes. He again first lists towers containing yellow in the first position, and then lists towers containing red in the first position (Figure 2).

*Figure 2*. CM’s initial listing of three- and four-tall towers.

During his second time of listing three- and four-tall towers, CM starts again with three-tall towers. He lists towers containing either two red cubes and one yellow cube, or two yellow cubes and one red cube, but first lists towers containing red in the first position, and then lists towers containing yellow in the second position (Figure 3).

*Figure 3*. CM's final listing of three-, four-, and five-tall towers.

CM's method of sequential listing evolves as he adds an additional case to his listing of four-tall towers: the case of towers with three red's and one yellow. To represent towers in this case, he lists them sequentially and shifts the position of the yellow cube from the last position to a position one place to the left for each new tower, creating the towers red red red yellow, red red yellow red, red yellow red red, and yellow red red red. After listing these towers, using the same cases he used in listing three-tall towers, CM lists four-tall towers containing two red cubes and two yellow cubes. He starts with towers with red in the first position, and then lists towers with yellow in the first position (Figure 2).

CM adapts this method of sequential listing to construct five tall towers, starting with the case of towers with three red's and two yellow's. The first tower he lists is red red red yellow yellow. To construct subsequent towers, he shifts the yellow yellow from its position at the end of sequence to a position one place to the left for each subsequent tower, creating the towers red red yellow yellow red and red yellow yellow red red. Interestingly, CM starts to list towers sequentially after the last tower in that case, and so does not create the tower yellow yellow red red red until later. This can be seen in Figure 3 in the textbox labeled "5 cubes."

In these two instances represented in Figures 2 and 3 of building three-, four-, and five-tall towers, CM seems to reason by analogy. He first builds three-tall towers sequentially and by cases, and then seems to transfer this method to constructing four-tall towers. He then revises his method of sequential listing for constructing three-tall towers, and after doing so, comes up with a new case and method of sequential listing when building four-tall towers, while retaining the older method as well. He then uses these methods to produce five-tall towers.

Reasoning is also evidenced in the way that students make sense of the problem and come to a solution based on their interpretations of the problem. Early in the session, CM seems to infer from the problem statement that it may be possible to construct towers with a single color. He is unsure and asks LP whether this is possible. LP replies, based on his own interpretation of the problem statement, that towers must be four-cubes tall, each containing two colors. From this point onwards, CM continues only to construct towers with two colors and no longer evidences entertaining one-color towers. The other two members of the team who are present at this session also seem to agree with this interpretation, as they also only construct towers with two colors.

Later in the session, LP asks how to answer the question involving *n*-tall towers. CM states that five is the largest number of cubes available and that there are only three red cubes and two yellow cubes. This interpretation helps us to determine exactly which towers CM constructs as well as which towers he omits. We believe that his interpretation stems from our diagram of the two sample towers (Figure 1). The first tower is a two-tall tower containing one red and one yellow cube, and the second tower is a three-tall tower containing two red cubes and one yellow cube. This accounts for the three red cubes and two yellow cubes that CM deems only to be available for constructing towers. Taking into account these restrictions, CM lists all possible towers with the exception of one five-tall tower that JC contributes (Table 2) that also fits within the CM's interpretation of the problem. CM ultimately comes up with six three-tall towers, 10 four-tall towers, and nine five-tall towers. Indeed, with these restrictions, the number of three-tall towers is $C(3,1)+C(3,2)=6$, the number of four-tall towers is $C(4,2)+C(4,3)=10$, and the number of five-tall towers is $C(5,3)=10$.

## Discussion

The results of this preliminary study raise interesting questions about the use of online communication environments as well as the role of teacher or researcher intervention and the development of students' problem-solving heuristics and mathematical reasoning. Indirect teacher or researcher intervention occurs in the design of the online environment and the mathematical tasks as well as in decisions about the composition of the work teams. However, the problem-solving sessions in which CM, LP, SO, and JC participate are mediated by an Internet-based environment and, importantly, without direct intervention of researchers or teachers. Nevertheless, both in the chat and whiteboard spaces, the students engaged in thoughtful discussions and displayed emergent heuristics and mathematical reasoning.

Some of the reasoning in which the students engage is corroborated in the literature. When CM constructs 3-, 4-, and 5-tall towers during the towers problem sessions, he seems to be engaging in reasoning by analogy. English (1997) defines this type of reasoning as "the transfer of structural information from one system, *the base*, to another system, *the target*" (p. 5, emphasis in the original). Indeed, once CM has listed possibilities for three-tall towers, he seems to transfer his strategy from how he lists three-tall towers to how he lists four-tall towers.

CM then starts over and creates a revised version of his original three-tall towers. Afterwards, CM then comes up with an additional case and method for his four-tall towers before. This additional case seems to be influenced by CM's new list of three-tall towers, as well as by how CM's interprets the problem statement. Indeed, the case of four-tall towers containing three red cubes and one yellow cube fits within the constraints that CM imposes on the problem, that there are a maximum of three red and two yellow cubes with which to construct towers. CM then seems to use this new method as well as the method from three-tall towers to list five-tall towers.

Throughout the VMT Chat sessions, there are multiple transfers of structural information. CM's strategy used in his original three-tall tower listing is transferred to his original listing of four-tall towers. CM's strategy used in his revised three-tall tower listing is not only transferred, but also evolved in his new listing of four-tall towers. Finally, CM's strategy for listing four-tall towers is transferred to his listing of five-tall towers.

Some of CM's reasoning goes beyond reasoning by analogy. He not only transfers structural information but also evolves his strategies as he successively constructs three-tall towers, four-tall towers, and five-tall towers. When CM constructs his new listing of four-tall towers, he not only uses his strategies from his revised list of three-tall towers but also evidences an awareness of another pattern. Consider the first two towers listed in his new three-tall towers listing: red red yellow and red yellow red. To get the second tower from the first tower, CM seems to use the strategy of listing sequentially, and switches the positions of the first red and first yellow in the first tower. Note that it is also possible to shift the yellow in the first tower one position to the left to get the second tower. CM may have seen this shifting pattern and could have used it to create the first four towers in his new listing of four-tall towers, where the yellow cube is shifted one position to the left three times (red red red yellow, red red yellow red, red yellow red red, and yellow red red red).

# PROPERTIES OF REPRESENTATIONAL ACTIVITY IN CALCULUS STUDENTS' CONSTRUCTION OF PROOF

Ann R. Edwards
University of Maryland
aedwards@umd.edu

Kellyn Farlow
University of Maryland
kfarlow@umd.edu

Senfeng Liang
University of Maryland
yma2006@umd.edu

The goal of this study is to examine the construction and use of representations in mathematical problem solving, and, in particular, how representations arise and are deployed in their interactional, mathematical, and social contexts. Specifically, we examine students' representational activity while working on proof-based problems in undergraduate Calculus. This poster will demonstrate how reasoning with and through mathematical representations in this setting is interactionally accomplished and identify and characterize qualities of representations that shape those processes of reasoning and proving.

Data include audio-video recordings of a focus group in an introductory calculus course where discussion sections were organized as "workshops" in which students worked in small groups and instructors emphasized the need for explanation and justification. Recordings were content-logged and initial strips of interaction were selected for close interactional analysis. Using these, we developed grounded theoretical categories in an iterative fashion, integrating constructs from the literature, then extended our analysis systematically across the data corpus.

We draw upon two theoretical lenses to examine the students' construction and use of representations: first, we borrow from Speiser, Walter, & Sullivan (2007), who identify a representation as a presentation used to facilitate communication with oneself or others (p. 15); second, we view a representation as a cultural artifact with a local history of production as well as a history embedded in mathematical and pedagogical meanings and conventions (Latour, 1999).

Our analysis reveals three properties of representational activity—complementarity, prospectivity, and generativity—that we find important in understanding the constraints and affordances of representations in their interactional construction and use in mathematical explanation and justification. Complementarity refers to the coordination of multiple forms of representation to support reasoning beyond the affordances of a single representation. Prospectivity describes how representations, due to specific properties embedded in the structure and customary use of a certain representation, can afford prospective attention to and yet also bound the nature of immediate next steps in the problem-solving process. Generativity refers to the productive quality of representational activity for fostering new insights into mathematical situations, in particular across representational systems. This poster presentation will display selected examples of different representations—possessing one or more of these three properties—from the students' work, along with a discussion of the constraints and affordances of such representational activity for students' as they work together to produce proof and justification.

# DOCUMENTING CURRICULUM IMPLEMENTATION: A CASE STUDY FROM UCSMP GEOMETRY

Denisse R. Thompson
University of South Florida
thompson@tempest.coedu.usf.edu

Sharon L. Senk
Michigan State University
senk@math.msu.edu

*For studies of curriculum effectiveness to be meaningful and useful, information is needed about classroom implementation of the curriculum. One challenge for researchers is how to obtain data about implementation that are informative, reliable, and relatively inexpensive to collect and analyze. This paper describes instruments for assessing variations in both content taught and instructional practices and illustrates their use in a study of the field trial of the Third Edition of the UCSMP Geometry curriculum.*

## Introduction

The National Research Council's report, *On Evaluating Curricular Effectiveness* (NRC 2004), recommends that evaluations of curriculum "present evidence that provides reliable and valid indicators of the extent, quality, and type of the implementation of the materials. At a minimum, there should be documentation of the extent of coverage of curricular material" (p. 194). Educators have long recognized that classroom instruction, even for the same course, can vary from teacher to teacher and school to school. Differences often occur because teachers implement curriculum based on their personal teaching philosophy, including what they believe to be the most important content, what expectations they believe are reasonable for their students, and what district and state frameworks form the basis of accountability measures. As Hiebert and Grouws (2007) note,

> The emphasis teachers place on different learning goals and different topics, the expectations for learning that they set, the time they allocate for particular topics, the kinds of tasks they pose … all are part of teaching and all influence the opportunities students have to learn. (p. 379)

The challenge for curriculum researchers is how to collect and analyze implementation data. Clearly, one approach would be for someone to observe a classroom for an extended period of time. However, lengthy observations are expensive. Although such observations might be possible in a study of a few teachers in close proximity, extensive observations are not feasible in moderate or large scale research. Alternatively, a video camera could be placed in a classroom to record lessons. But videos must still be watched and transcribed to be useful – again, an impractical approach except when studying a small number of cases.

The purpose of this paper is to provide insights into two research questions. The first is methodological; the second relates to a particular curriculum evaluation project.

1. What instruments can be used to document teacher implementation of curriculum in a low-cost and reliable manner?
2. What differences exist in how teachers implement and use a new geometry curriculum?

Data to address these research questions are drawn from an evaluation study of the field-trial version of *Geometry* (Third Edition, Benson et al., 2007), developed by the University of Chicago School Mathematics Project (UCSMP). The field trial was conducted in 12 schools

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

from 9 states during the 2006–2007 school year. The schools represented a mix of urban, suburban, and rural environments across the U.S.A. Although comparison classes using the curriculum already in place at the school were present in 9 of the 12 schools, the results reported here are based solely on data from the teachers using the UCSMP *Geometry* (Third Edition) curriculum. Consequently, the results are controlled for curriculum, permitting a discussion of how the instruments and analysis provide insights into variability in implementation.

## Documenting the Implemented Curriculum: Content Coverage and Opportunities for Practice

Some researchers (e.g., Tarr et al., 2006) have used textbook diaries to collect data about the lessons that teachers teach from a particular textbook. This often involves having teachers make notes on a Table of Contents as they use a textbook. Because we were collecting data as part of a formative evaluation, we had teachers record slightly more information for each chapter they taught. For each chapter in the book, teachers completed Chapter Evaluation forms on which they indicated the lessons taught, the number of days spent per lesson, and the questions assigned; they also rated each lesson and set of questions on a scale of 1 (low) to 5 (high), and made comments about various aspects of the lessons. The ratings and comments provided insight to the curriculum developers when revising the materials. The other information provides insights into classroom implementation, and is the main source of data reported in this paper.

*Lesson Coverage: Opportunity to Learn Content*

Benson et al. (2007) contains a total of 114 lessons in 14 chapters. The chapter titles are listed in Table 1.

*Table 1*

Chapter Titles for UCSMP *Geometry* (Third Edition, Field-Trial Version)

| Ch | Title | Ch | Title |
|---|---|---|---|
| 1 | Points and Lines | 8 | Lengths and Areas |
| 2 | The Language and Logic of Geometry | 9 | Three-Dimensional Figures |
| 3 | Angles and Lines | 10 | Formulas for Volume |
| 4 | Transformations and Congruence | 11 | Indirect Proofs and Coordinate Proofs |
| 5 | Proofs Using Congruence | 12 | Similarity |
| 6 | Polygons and Symmetry | 13 | Consequences of Similarity |
| 7 | Congruent Triangles | 14 | Further Work with Circles |

Figure 1 displays the percent of lessons taught as reported by the 12 teachers teaching from Benson et al. (2007) by thirds of the text and overall. Note that the number of lessons is 39 for Chapters 1–5, 45 for Chapters 6–10, and 30 for Chapters 11–14.

Figure 1 demonstrates how implementation of curriculum by teachers using the same text can vary considerably. The percent of lessons taught was relatively similar for Chapters 1-5, with 7 of 12 teachers each teaching at least 90% of the lessons. However, greater variability in implementation was observed in Chapters 6-10, with half of the teachers teaching less than 78% of the lessons. In the final third of the book, three teachers taught none of the lessons; and only three taught more than 40% of the lessons. Overall, the percent of lessons taught ranged from 52% to 92% with a median of 67%.

Although some teachers taught comparable percentages of the text, an analysis of the actual lessons taught reveals differences in students' opportunities to learn specific content. Figure 2 indicates the actual lessons reported taught by all teachers, called Teachers A through L, in the Field Trial study.

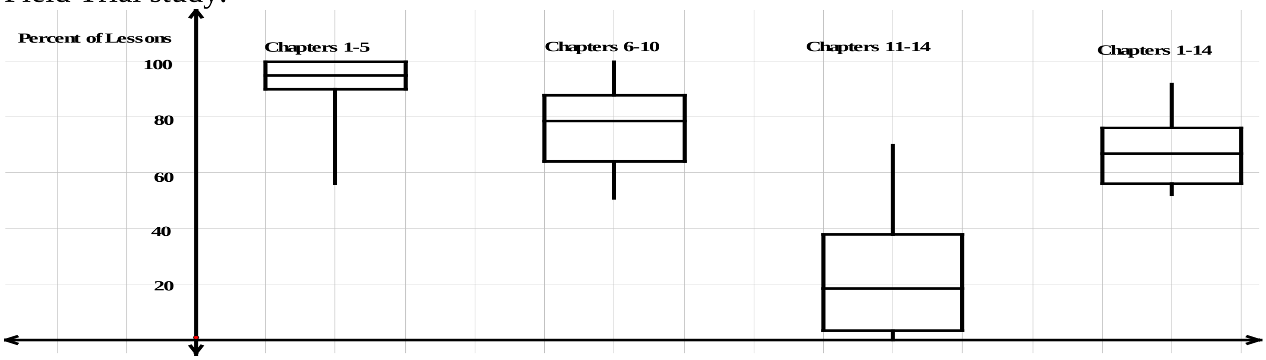

*Figure 1*. Percent of lessons in UCSMP *Geometry* textbook taught by 12 teachers.

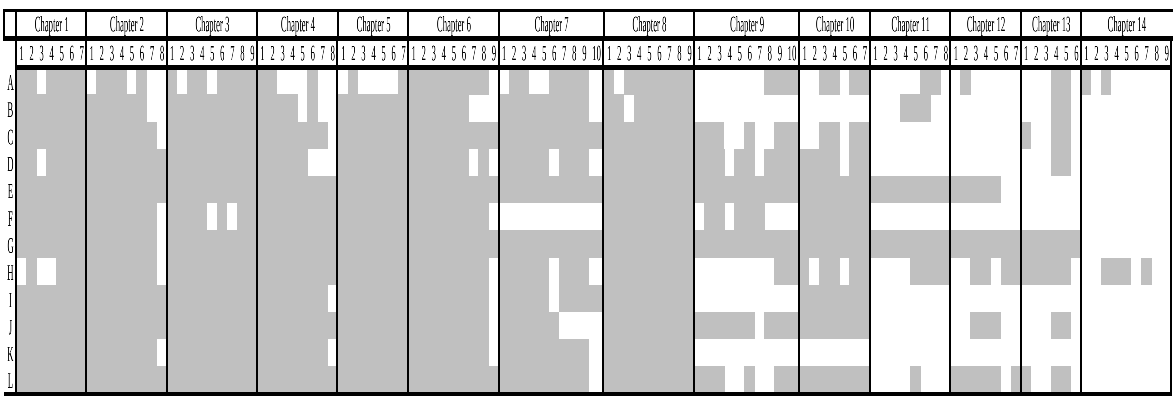

*Figure 2*. Coverage of lessons taught by teachers A-L in UCSMP *Geometry*. A dark rectangle indicates that the lesson was reported as having been taught. A light rectangle indicates that the teacher reported not teaching that lesson.

Although Teachers A, B, F, and K taught comparable percentages of the text (between 52% and 57% of the lessons), each pattern of coverage is different and leads to different opportunities for students to learn geometry content. Teacher A skipped lessons in many chapters but covered some lessons from every chapter in the text. In contrast, Teacher K skipped few lessons but only taught through Chapter 8. So Teacher K's students had little to no opportunities to study three-dimensional figures, volume, or coordinate proofs; even though Teacher A's students studied some lessons from every chapter, they studied fewer lessons in each of the chapters studied by Teacher K's students. Teacher B also taught most of the first eight chapters but then taught some lessons related to proofs with coordinates and trigonometric ratios. Likewise, although Teachers C, D, and I all covered between 60% and 70% of the text, each of their patterns of coverage was different leading to different opportunities for students to learn geometry content.

Examining specific lesson coverage may identify other implementation patterns. For instance, all teachers taught Lesson 1–7, a lesson that focused on using a dynamic geometry drawing tool (DGS). However, although each had regular access to technology, either graphing software such as Sketchpad, or calculators with either Cabri or Cabri Jr, many found the use of the DGS to be difficult and confusing. When another lesson on DGS appeared in Chapter 2, seven of the twelve teachers omitted it. Some teachers came back to the use of DGS later in the year, but an early difficult experience influenced lesson coverage negatively.

*Exercise Coverage: Opportunity for Practice*

Curriculum implementation also includes making decisions about providing opportunities for students to practice mathematics, typically through homework. In the UCSMP curriculum, question sets are constructed with four types of questions. *Covering the Ideas* questions focus on the essential aspects of the lesson; students who complete these questions can use the basic skills and concepts. *Applying the Mathematics* questions require students to use the essential aspects in new ways or in new contexts; students need to take the basic ideas to a slightly higher level. UCSMP uses a modified mastery approach so *Review* questions in each lesson provide an opportunity for students to continue working on concepts throughout a chapter and throughout the text. Finally, *Exploration* questions provide an opportunity for extension and discovery. With the exception of the Exploration problems, the curriculum developers recommend that students generally be assigned almost all the problems.

On the Chapter Evaluation form, teachers listed the questions assigned to students. Figure 3 provides a visual of the variability in implementation of homework assignments.

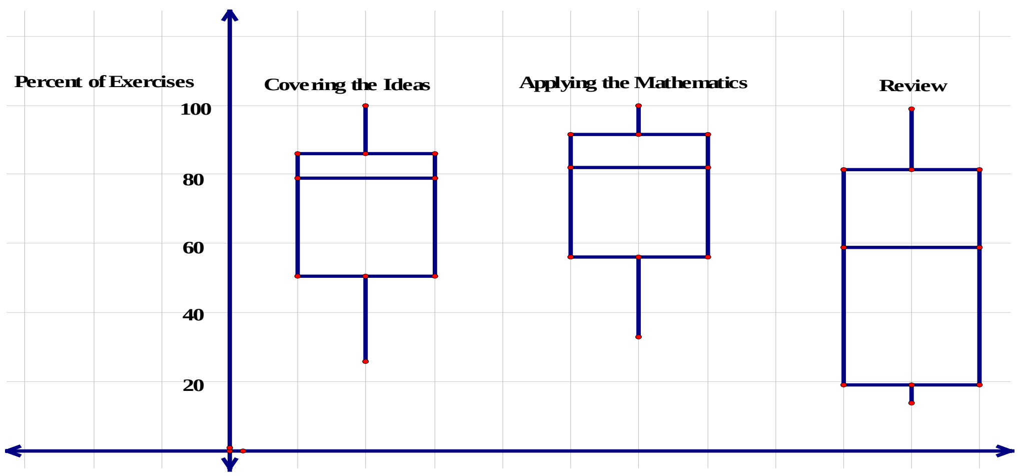

*Figure 3*. Percent of questions assigned by 12 teachers using UCSMP *Geometry*, based only on lessons taught.

Although the median percentage of questions assigned from Covering the Ideas and Applying the Mathematics is roughly 80%, there are major differences in expectations between teachers assigning the maximum percentage of exercises and those assigning the minimum. For instance, two teachers (Teachers D and F) assigned only about a third of the Covering the Ideas questions; eight teachers assigned more than 75% of these questions. Likewise, eight assigned at least 75% of the Applying questions. However, only five of the twelve assigned at least 75% of the reviews; in fact, five teachers assigned less than a fourth of the reviews. Given that review problems are an essential feature of the modified mastery approach used in the UCSMP secondary curriculum, the lack of attention to the review questions raises concerns about the fidelity of implementation of the curriculum in those classrooms. The limited assignment of review questions by some teachers also means that students in their classes may have had less opportunity to achieve mastery than the developers intended.

### Documenting Teachers' Expectations Relative to the Assessed Curriculum

Teachers' expectations relative to the assessments given to their students also provide information about curricular implementation. On all posttests administered as part of evaluations of the UCSMP curriculum, teachers are asked to indicate for *every* item whether they taught or reviewed the content needed for their students to answer the item. This measure provides insight into whether teachers perceive that their lesson coverage provided students with opportunities to master content at a level sufficient for assessment. Even when teachers have taught the same content, based on reported coverage of lessons or assignment of exercises, they sometimes respond differently to these opportunity-to-learn questions.

Two multiple-choice posttests were administered as part of the formative evaluation of the *Geometry* curriculum. The posttests were constructed based on content in the first ten chapters, which the developers expected most teachers to teach. Of the 60 items on these tests, 20 (items 36-55) are from the first four levels of the van Hiele Geometry test (Usiskin 1982). Among the other 40 items, 19 deal with figures and their properties, 4 with transformations, 9 with measurement, 6 with reasoning, and 2 with graphing of lines. Although the 12 teachers in the field trial were using the same curriculum, Figure 4 illustrates that their expectations about the extent to which students had an opportunity to learn the content for the items varied.

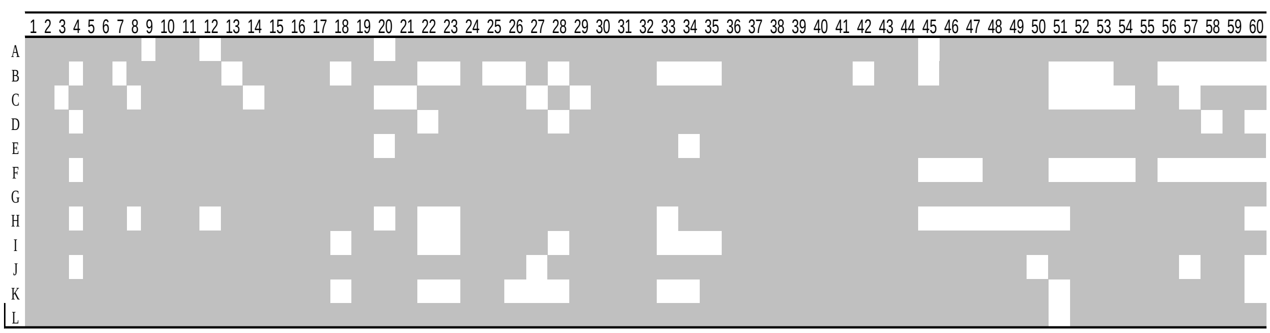

*Figure 4*. *Geometry* teachers reported opportunity-to-learn (OTL) for the UCSMP-constructed posttests. A dark rectangle indicates that the teacher responded "yes" to covering the content on the OTL form; a light rectangle indicates that the teacher responded "no."

Only on 23 of the 60 posttest items (38%) did all teachers report having taught the content needed to answer the items. The number of assessment items for which teachers reported they had taught or reviewed the content needed for students to answer the items ranged from 38 to 60, with a median of 54 items. The documented variability represented in Figure 4 suggests that student achievement data that does not consider teachers' OTL responses on assessment items has the potential to lead to incorrect conclusions. Thus, documenting teachers' views relative to the assessed curriculum is an essential part of documenting curriculum implementation.

**Documenting Instructional Practices Related to Curriculum Implementation**

Data about instructional practices can also be collected from self-reports. At the end of the school year, teachers completed two documents: a questionnaire about instructional practices and a supplement designed to obtain details about curriculum features that might influence revisions to the instructional materials. On the questionnaire, teachers generally checked or circled responses from a set of options, so it required only a few minutes to complete; the supplement required short responses to open-ended questions. Here, we describe questions and present results related to assigning homework and two instructional practices emphasized in the entire UCSMP secondary curriculum—reading and writing mathematics.

Teachers were asked, "On the average, how many minutes of homework did you expect the typical student to do each day?" Choices were 0–15 minutes per day, 16–30 minutes per day, 31–45 minutes per day, 46–60 minutes per day, and more than 60 minutes per day. Five teachers (Teachers A, B, D, F, and H) expected students to complete 16–30 minutes of homework per day, five (Teachers C, I, J, K, and L) expected 31–45 minutes of homework per day, and two (Teachers E and G) expected 46–60 minutes of homework per day. In general, the teachers who expected the least amount of time per day on homework were also the teachers who assigned the fewest percent of the exercises. Hence, the responses to the questionnaire provide a check on the reliability of the data reported about homework on the Chapter Evaluation Forms.

Because reading and writing in mathematics are both prominent features of the UCSMP curriculum, teachers were asked several questions about these practices. Table 2 contains the questions we focus on in this paper and the coding used to create an emphasis index for each. The coded responses were summed to obtain an index of reading emphasis and writing emphasis for each teacher as reported in Table 3.

Again, considerable variability among teachers as well as an individual teacher's relative emphasis between reading and writing in mathematics is apparent. For instance, Teacher A places more emphasis on writing mathematics than reading; for Teacher B, the reverse is true. Several teachers (Teachers D, E, I, and J) have relatively high indices for both reading and writing.

Teachers' responses on the supplement validated their questionnaire responses. When asked to describe how reading was handled, Teacher D replied, "Throughout the year, I gave reading quizzes and the students who read the sections did fairly well. …I expect them to have read the section before we go over the material. I expect them to do a lot of the learning by reading."

*Table 2*
Reading and Writing Questions Asked of Teachers and Coding of Responses

| Reading | Writing | Code |
|---|---|---|
| How often did you expect students to read their mathematics textbook? | How often did you expect students to write explanations to show what they were thinking when solving mathematics problems? | Almost every day = 4<br>2-3 times per week = 3<br>2-3 times per month = 2<br>Less than once a month = 1<br>Never = 0 |
| How often did students read silently in class? | How often did students write complete solutions when they solved problems? | Daily = 3<br>Frequently = 2<br>Seldom = 1<br>Never = 0 |

| | | |
|---|---|---|
| How often did students discuss the reading in class? | How often did students explain or justify their work? | Daily = 3<br>Frequently = 2<br>Seldom = 1<br>Never = 0 |

*Table 3*
Index for Reading and Writing in Mathematics for Teachers Using UCSMP *Geometry*

| Teacher | A | B | C | D | E | F | G | H | I | J | K | L | Median |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Reading Emphasis | 4 | 6 | 7 | 8 | 8 | 3 | 4 | 4 | 10 | 8 | 6 | 8 | 6.5 |
| Writing Emphasis | 7 | 3 | 5 | 10 | 9 | 8 | 8 | 4 | 7 | 9 | 7 | 7 | 7 |

*Note*. For both reading and writing, the maximum = 10 and the minimum = 0.

## Discussion

To address the first research question, "What instruments can be used to document teacher implementation of curriculum in a low-cost and reliable manner?", we have described three survey instruments: Chapter Evaluation forms, Posttest Opportunity-to-Learn Forms, and a Teacher Questionnaire about instructional practices. Each is relatively short and easily completed by teachers. Unlike classroom observation data that may require extensive coding and high inference, all UCSMP survey data are low-inference and can be analyzed and displayed using relatively low-cost software.

In some cases, questions asked on different survey forms can be used to check reliability or to expand perspectives on responses to questions on other forms. Although not discussed here, an end-of-year survey of geometry students also had some questions about content covered and instructional practices, so that responses by teachers and students can be used to validate each others' perspectives. UCSMP researchers also conducted a 2–3 day visit to each field trial school to observe classes and interview the teachers. Data from the school visits generally confirmed the data collected from the surveys. We found that when differences occurred, teachers were often a bit more conservative on the questionnaires than in the interview. For instance, only for Teacher A did the questionnaire responses seem to suggest more frequent use of reading and writing than would have been expected based on the interview responses. Such reliability checks across surveys and between surveys and observations confirm that self-reported data from teachers of the type presented here are quite robust.

To address the second question, "What differences exist in how teachers implement the UCSMP *Geometry* curriculum?", data were provided from a year long field trial conducted with twelve teachers from nine states. Teachers' responses to questions on the survey forms provide a picture of many differing kinds of curriculum implementation. In particular, there is considerable variability from teacher to teacher on the following dimensions:

- Percent of lessons taught, ranging from 52% to 92% with a median of 67%;
- Content studied during the year, including classes where students had little to no opportunity to study three-dimensional figures, volume, or coordinate proofs and classes where all these topics were studied;
- Nature and extent of assigned homework questions, including some classes where teachers regularly skipped the review questions designed to develop and maintain mastery.

- Extent to which they implemented other instructional practices recommended by the curriculum developers, such as emphasizing reading and writing mathematics.

In this paper, we have focused on curricular implementation, not on achievement. However, variations in implementation of the geometry curriculum are accompanied by variations in achievement levels (Thompson & Senk, in preparation). The nature of the data reported here permits detailed profiles of implementation of UCSMP *Geometry* to be constructed. Although space does not permit such profiles to be included here, they can be used to understand class-to-class and school-to-school differences in end-of-year achievement.

As recommended by the National Research Council (2004) and reinforced by the data reported here, achievement results should be accompanied by information about curriculum implementation. As indicated here, students who have studied the same curriculum often have very different opportunities to learn. Without information about curricular implementation, it is difficult to make conclusions about differences in achievement.

# DIPCING A DESIGNING METHODOLOGY FOR UNIVERSITY MATHEMATICS STUDY PROGRAMS

Patricia Camarena Gallardo
Instituto Politécnico Nacional
pcamarena@ipn.mx

Alma Alicia Benítez Pérez
Instituto Politécnico Nacional
abenitez@ipn.mx

*In this paper a research is reported where the research problem is how to design a methodology for the designing of mathematics study programs in engineering careers. In such way that the professor has a clear idea of why each theme included in the program has to be taught. With this basis he can motivate the student, showing him the link between mathematics and engineering subjects and the professor can know what kind of abilities he can develop in the students.*

## Introduction

Mathematics are subjects with a high percentage of reprobation. But this is only a symptom, in this educational problem there are several factors that are of curricular type, caused by the teaching and learning, inferred by the study theme by itself, caused by the cognitive infrastructure of the students, due to social, emotional and economical factors, etc.

Among the great range of problems there are some specific that have something to do with the curricular situations that are mentioned below. When for the first time a professor is going to teach mathematics courses, he finds a list of themes that he understands the best he can, which leads to make different courses in the same study program, one for each professor. If a professor is asked about why these themes are included in the study program, it is common that he can not answer precisely and correctly. As regards to the students, different exclamations are heard from them in the classroom as follows: What is the purpose of studying mathematics? Why do we have to study them?. These questions, at best, are answered by the professor who says that in engineering courses that they will take later they will use them (Camarena, 1984; Camarena, 1988).

From the percentage of students that does not approve mathematics courses and from the teaching experience, it can be said that the few interest that the students have for these science is because they do not see their immediate application, neither the object to use them. An element that affects is the fact that there is not an appropriate curriculum where these mathematics courses are taught, consequently, the professors who teach them do not know why the contents are included in the study programs (Camarena, 1984).

*Objective*

With the background described, the objective research problem is to build a methodology to design mathematics study programs in engineering; in such way that the professor has a clear idea of why each theme that is included in the program has to be taught. With this basis he can motivate the student, showing him the link between mathematics and engineering subjects. Knowing what kind of abilities he can develop in the students.

## Perspectives and Theoretical Framework

The theory in which this research is based is Mathematics in the Sciences Context (Camarena, 1984; Camarena, 1990; Camarena, 1995; Camarena, 2001; Camarena, 2003). This theory has been developed since 1982 in the National Institute Politechnical of Mexico. It takes mathematics learning and teaching in engineering careers as a system, which includes the student, the teacher and the mathematical knowledge. It takes into consideration the interactions among the student, the teacher and the mathematics knowledge, all included in the learning environment where there are social, economical, political and human relations aspects. This systemic look makes five phases of the Mathematics in the Sciences Context theory: Curricular developed since 1984. Didactic started since 1987. Epistemological tackled in 1988. Teachers Training defined in 1990. Cognitive studied since 1992.

Mathematics in the Sciences Context is based in three paradigms: Mathematics are supporting tools and educational subjects. Mathematics have a specific function in each educational level. Knowledge is born integrated.

The educational philosophic assumption of this theory is that the student is trained to transfer mathematics knowledge to the areas which require it, so that he develops competences for his working and professional life. We want mathematics for life.

This research presents incidence in the curricular phase, where Mathematics in the Sciences Context thinks about the link among mathematics and other knowledge areas of the student, the future professional and working activities and daily life.

In other hand, it is necessary to take into account particular characteristics of mathematics in engineering by the specific methodology to be constructed. Engineering has mathematics as a foundation, because mathematics are engineering language and mathematics make sense to engineering, also mathematics are a supporting tool. Besides having a formative character for the students, that is to say, mathematics develop thinking abilities, critical judgment, scientific heart, etc. Even more, mathematics curriculum in engineering schools requires special attention, since mathematics are not a goal by themselves; in other words, we are not going to form mathematicians (Camarena, 1988).

*Educational Paradigm and Premise*

The methodology for the curricular designing of mathematics study programs in engineering careers is founded in the following educational paradigm: With mathematics courses students will have cognitive elements and tools he will use in the specific subjects of his career. Also, the premise of the methodology is that: Mathematics curriculum should be objective, that is to say, it should be a curriculum based on objective basis (Camarena, 1988).

## Work Method

The work method to follow requires establishing a net between the problematic of mathematics in engineering with the possible ways to tackle them (see first and third columns in fig. No. 1). For such purpose, the problems of mathematics were re-written in terms of research questions in order to clear the working method (see second column in fig. No. 1).

The fig. No. 2 shows, respectively, in column two and three the research questions selection and the way to tackle them, corresponding to the objectives of engineering graduate, as well as the objectives of searched methodology (see first column in fig. 2).

With the co-relation net between research questions and possible ways to tackle them (fig. No. 1 and No. 2), the tendency that minimizes the paths was established and the maximum activities to meet the objectives stated in the research project were taken.

The different activities described were the following:

1. Analyze engineering textbooks.
2. Investigate how mathematics contribute to engineering through the history.
3. Analyze the bibliography of the elements which motivate the high level student.

4. Interviews to engineers in practice.
5. Diagnosis of the students when they go into engineering career.

| Problematic | Research questions | Ways to tackle the questions |
|---|---|---|
| Program as a thematic list of mathematics. | Why mathematics themes are included? | Identify what is needed from mathematics in each engineering theme (textbooks analysis) and determine if it is enough. |
| Where will mathematics be used. | Where do they apply? | Identify what is needed from mathematics in each engineering theme (textbooks analysis). |
| Which is the purpose of mathematics. | Which is mathematics function in engineering? | Determine how mathematics themes in engineering are used (textbooks analysis). |
| Why to study mathematics. | Which is the benefit of mathematics to engineering? | Investigate through history how do mathematics contribute to engineering. |
| There is few interest for mathematics. | How to motivate the student? | Analyze bibliography about which elements motivate the high level student. |

*Figure 1.* Relation among mathematical problems, research questions and how to tackle them.

From these activities and what is expected from them we have two elements groups which are: general for any type of engineering, that is to say, that are independent from engineering; and the ones which depend from engineering which is worked for. In the first category are activities number 2 and 3, while the ones that really depend on engineering are 1, 4 and 5.

| Objectives | Research questions | Ways to tackle the questions |
|---|---|---|
| A graduate efficient to solve problems is searched. **OG** | How mathematics are connected with engineering subjects? | Analyze engineering textbooks. |
| A graduate competent to design is required. **OG** | What is required from mathematics in the professional work of an engineer? | Interviews to engineers in practice about mathematics. |

| | | |
|---|---|---|
| Putting into practice engineering. **OSM** | Which applications of mathematics to engineering? | Analyze engineering textbooks. |
| An objective curriculum is wanted. **OSM** | Where and how mathematics are applied?<br>With which focus and notation? | Analyze engineering textbooks. |
| How to construct knowledge. **OSM** | What is it required so that mathematics are significant for the student? How to give sense to mathematics?<br>How to tie up the cognitive structures of the student? | Present mathematics in engineering context. Determine the knowledge level of the students when they go into the superior level. |

*Figure 2.* Relation among objectives of searched methodology (OSM), objectives of graduate (OG), research questions and ways to tackle them.

*General and Independent Elements of Engineering*

a) The activity which describes: Investigate how mathematics contributes to engineering through the history, lead to make a study consisting of surveys made to historians and books revisions about the historical development of engineering and mathematics. From this there were found results which respond to the research question: which are the benefits of mathematics for engineering?. We founded that mathematics are a supporting tool for engineering and educational forming subject for the ones who study them. At the same time it was tackled the questioning of why to study mathematics, because it supports the foundation of engineering. Notice that the result is consistent with the particular characteristics of mathematics in engineering, and the educational paradigm described for the research development, about mathematics are engineering supporting tools, not leaving behind the formative character offered by them.

b) The second independent element from engineering says that the bibliography about the elements that motivate the superior level students have to be analyzed. For this work several theories were found about the motivation. Among the most relevant references are: Ausubel David P., Novak Joseph D. y Hanesian Helen (1990); Nickerson Raymond S., Perkins David N. y Smith Edward E. (1994) and De Bono Edward (1997). One that makes reference to the age of the student is the cognitive psychology of Ausubel David P., Novak Joseph D. y Hanesian Helen (1990). Although this theory does not specify the educational levels, these can be inferred according to the pupils ages and associate with their corresponding motivators. For the superior level case the facts that contribute to the motivation are mainly the ones which surround the interests of the selected career. Of course this is true as long as the superior level studies have been selected by the student. Several interviews were held with professors, students and engineers, about how the students could be motivated so that they have interest in mathematics, taking into account that they like their career. After analyzing the suggestions it was considered that the most frequent proposal was that applications to engineering have to be given for mathematics themes studied. So, it is necessary to show the link between mathematics and engineering subjects. Notice that it is consistent with the research problem about the motivation of the student through showing him mathematics linked and applications.

It is good to mention that in these two partial studies only the results were presented due to the length of the investigation.

*Dependent Elements of Engineering*

It is evident that the activities: analyze engineering textbooks, interviews to engineers in practice and diagnosis of the students when they go into engineering career, are elements that depend of the engineering entered upon. These will be the ones that determine the methodology looked for.

## Results: The Proposal Methodology Design

In order to fulfill the premise into the educational paradigm frame, a research strategy is proposed in three stages: the central, the preceding and the consequent (Camarena, 1984; Camarena, 1988).

CENTRAL STAGE. Make a textbooks analysis of the specific engineering courses in order to detect mathematics contents, both explicit as well as implicit.

PRECEDING STAGE. Diagnose the knowledge level of mathematics that the students have when they go into the career.

CONSEQUENT STAGE. Interview engineers in practice and researchers engineers about the use of mathematics in their professional work.

*Proving the Proposal*

To establish the feasibility of the proposal we selected electronic engineering area. The experience is reported below.

*Central stage*. In order to realize the first stage, that is, the analysis of mathematics contents, it is necessary to know the profile of engineering graduate that the institution wants, the study plan and the programs (themes and bibliography) of engineering subjects that the student will course. There are three blocks: basic sciences, engineering basic sciences and engineering specialization sciences, as it is established by Asociación Nacional de Universidades e Instituciones de Educación Superior, of Mexico (ANUIES).

With this information, groups of mathematics teachers will be formed, which will analyze engineering subjects. For such activity textbooks will be used directly, in order to get the required mathematics themes, including of course, the focus and depth of the themes, the notation with which they are described and their applications. With the described activity it is established the curricular link between mathematics and basic sciences, also the link between mathematics and subjects of engineering basic sciences, as well as, between mathematics and engineering specialization sciences.

These teacher groups should make a written report of the themes they detected, jointly with the focus required by said concepts in order to take them into account in the didactic proposal.

These teacher groups, who chose one or more subjects to analyze, after having revised engineering textbooks will be competent to teach courses to the rest of the members of the corresponding Teachers Academy, with the purpose of spreading their knowledge about the focus, notation, depth and applications they found in the elected subjects. In the same way, these teachers could elaborate books of mathematics problems and notes about the concepts they detected.

From textbooks analysis, we had detected that from all mathematics used in engineering carriers, a percentage between 70 and 90 percent supports basic sciences and engineering basic sciences, this percent depends of which engineering. The remaining percentage, between 30 and 10 percent, supports engineering specialization sciences.

Also, we detected that engineering basic sciences and engineering specialization sciences have two focus, one theoretical and the other applied. From this, we have mathematics that support theoretical courses and applied courses. In mathematics included in applied courses the professor has to develop, in the student, abilities for modeling and algorithmic handle. While in mathematics included in theoretical courses it is not necessary, but if the professor has curricular time we propose that he develops abilities too. That is to say, whit this analysis the professor can know what kind of abilities he can develop in the students.

*Preceding stage.* Once the contents of mathematics needed in engineering are determined, we will tackle the second stage. Based on the knowledge of this discipline and teaching experience we can determine the necessary requirements for the detected mathematics contents.

In other words, the mathematics link between superior level and middle superior level is established.

From these requirements, the ones supposed to be received by the student in the middle level courses will be selected and the rest should be included in the curriculum of the first years of the career or as preparatory courses.

With this analysis, mathematics entrance profile of the student in superior level is defined. Also, with this selection, a diagnostic evaluation method is elaborated to determine the level of knowledge and abilities in mathematics of the new student in the career.

From the concepts in which most of the students are deficient the following classification will be made:

a) Mathematics themes that should be known by the student and that he can to study by himself with a simple bibliographic orientation.

b) Mathematics themes that the students should be known and to have abilities, should be taken into account to be included as a preparatory part in the elaboration of the curriculum of the first courses of mathematics.

*Consequent stage.* With the end of the second stage the third will be tackled, in which interviews should be held to engineers being in the industry’s practice, that is to say, engineers that are designing. We ask them about the use of mathematics in their work activity.

It is good to make clear that from this information there would be the contents detected from the textbooks analysis and the ones that are not included. The results obtained from this study offer for the curriculum a better hierarchization of the importance that should be given to mathematics themes. While the ones that are not included in the textbooks of engineering careers are the themes and concepts of mathematics that should be considered for post grade engineering studies, establishing the mathematics link between superior level and post grade level. With this stage the link between mathematics of engineering and industry is also established.

After making the mentioned activities and with the reported information by the different working groups, the person who coordinates the elaboration and/or reorganization of mathematics study programs could to group mathematics themes founded in the subjects of the three engineering blocks, as well as, the necessary themes obtained in the second stage.

That is to say, as up to now there are only mathematics themes that are going to be used in their engineering courses, to this should be added mathematics contents necessary to build the logical structure of the knowledge, so that the teaching of the themes make sense.

*Resume*. With the end of the third stage, it can be deduced: the number of subjects to be taught from mathematics. The location of these courses and the link with the other subjects of the curricular map of engineer in question. For each course, the thematic content with its extension, time and depth to be devoted should be determined, as well as, the focus, notation and applications that should be given to them.

Also, it is important to point out that this methodology takes into account the internal and external mathematics link of engineering. In fact, the internal link is established between mathematics and basic sciences, mathematics and engineering basic sciences, as well as, mathematics and engineering specialization sciences, originated from the first stage. In other words, the interdisciplinary subjects of the curricular map now are in fact explicit and known by the professors. While the external link is established between middle superior level and engineering careers, which came out from the second stage of the methodology, as well as, among the latter with post grade and industry, determined by the third stage.

The methodology to design mathematics study programs in engineering has been denominated Dipcing methodology (Metodología de Diseño de Programas de Estudio de Matemáticas en Ingeniería).

In conclusion, we have established the feasibility of the proposal methodology design, Dipcing, because with this methodology, as it can be seen, study programs can be designed where the professor knows why each one of the themes that constitute the program are included. That is, whether they are of direct application to engineering or because they are added to form the logical structure of knowledge. So, the professor knows exactly how linked mathematics with engineering subjects to motive the student. With this, the professor knows what kind of mathematics abilities develops in the student.

## Discussion

From the Dipcing methodology arise support elements for the execution of the study programs, as well as, an updating program for teachers, where among others are included mathematics courses integrated with engineering. Also, arise a didactic strategy to follow in engineering careers, where mathematics should be presented to the students in an integral way with engineering.

*Didactic Aspects*

From the methodology come off in natural way didactic guidelines to be followed by mathematics in engineering careers, among them is the context or link.

The didactic strategy called *mathematics in context* is an ideal way for teaching mathematics subjects, since it offers applications that are not artificial but all contrary they are interesting for the student and they can be easily motivated with this, mathematics in engineering context is not so dry, and it is not out of the student reality and in fact it is ease the teaching learning process (Camarena, 1995; Camarena, 2003).

If the student really likes his career he finds not only a need in mathematics in context but also likes them very much and has a great interest to control them. He can tackle any problem in his future work life. More information about didactic strategy can be find in Camarena (1987; 1993; 1995; 2003) references.

Some supporting didactic materials are found in books of mathematics problems which are guides for the course both for the students as well as for the professors. For more information see Camarena (1998) reference.

Another important element is the use of electronic technology as a didactic support. Nowadays this aspect cannot be dismissed since the students are in direct contact with the computers and on the other side, in their work life they will use this tool.

*Teachers Updating*

Due to the way the study programs are designed and the didactic lead from them, it is observed that the teachers with a mathematical formation should be more prepared in engineering areas they work for. Engineering teachers should receive a stronger preparation than the one they have when they graduate from their career, in mathematics area they teach.

Obviously from this methodology the teachers updating courses should be courses that have mathematics in engineering context, as well as, courses about the teaching and learning process. For more information see Camarena (1990; 2004) references.

## Conclusions

With this methodology, objective mathematics study programs are obtained and they are linked with the subjects of engineering they support, as well as, linked with a middle superior level, post grade and industry. Also, mathematics in engineering context are generated easily and the themes on which the professors must be updated are obtained.

DIPCING methodology helps to make a better professional quality. When *mathematics in context* is presented the significant learning of the student is helped, which will influence durable and motivating learning.

Is good to mention that the Dipcing methodology has been applied in schools of the National Politechnical Institute of Mexico successfully.

# IMPLEMENTATION FIDELITY IN THE MATHEMATICS CLASSROOM

Richelle Dietz
North Carolina State University
rcdietz@ncsu.edu

Krista Holstein
North Carolina State University
kaholste@ncsu.edu

The purpose of this poster is to present the results of an analysis of an extensive literature review of studies and to consider the methodologies used to measure implementation fidelity in mathematics classrooms. This review is part of a long term project to implement a new high school mathematics curriculum and will serve as a basis for its methodology for measuring implementation fidelity. Implementation fidelity is defined as the extent to which a teacher implements a curriculum as the authors intended. If teachers do not implement the curriculum as the authors intend, they could undermine the effectiveness of the new research-based curriculum. Due to the varying conditions across schools and teachers, the need for measuring implementation fidelity is strong. Curriculum evaluators must consider whether the curriculum could "survive or thrive" across sites (NRC, 2004, p. 114).

Curriculum evaluators use various instruments to measure implementation fidelity. However, there are three instruments which are frequently utilized. The first and the most common methodology used to measure implementation fidelity is classroom observation (e.g. Tarr, Reys, Reys, Chavez, Shih, & Osterlind, 2008). Researchers also use surveys (e.g. Schoen, Cebulla, Finn, & Fi, 2003) and teacher interviews (e.g. Remillard & Bryans, 2004) to gather information on a teacher's implementation of a curriculum. In addition, a few researchers consider additional measurements such as homework assignments, chapter evaluation forms, textbook-use diaries, and table-of-contents records. Researchers use these instruments to measure several categories of implementation fidelity, including use of curriculum, teacher instructional practices, verification of teacher-reported data, teacher background information, and teacher beliefs

Through the curriculum evaluations, researchers conclude that professional development, students' comments and questions, and teachers' beliefs and backgrounds greatly influence teachers' level of implementation fidelity. Thus, researchers must be concerned with the effectiveness of professional development, the need for teachers to learn and adapt prior to and during instruction, and the correlation between beliefs and backgrounds and teachers' implementation of curricula. Future research in this project will build on and adapt what is learned from this current research.

# DELPHI METHOD: A DIFFERENT APPROACH OF CREATING MEASURES OF PROFESSIONAL KNOWLEDGE FOR TEACHING

Agida G. Manizade
Radford University
agidam@gmail.com

Margie Mason
The College of William and Mary
mmmaso@wm.edu

*In this paper, we describe a research project in which a new assessment tool was developed and operationalized to measure teachers' pedagogical content knowledge (PCK) of geometry and measurement at the middle school level using the Delpi method. This method, often used in the field of economics, allows a panel of experts to come to a consensus about a given set of tenants or beliefs about knowledge. Delphi methodology provides an opportunity for experts to receive feedback and to modify and refine their judgments based upon their reaction to the collective views of the group. As a result of this study an instrument with an evaluation rubric for assessing middle school teachers PCK in geometry and measurement were developed.*

In selecting the participants for this project several factors were taken into consideration: a) the number of participants, b) their expertise, and c) the difference in their perspectives. When using Delphi method for research it is generally recommended to identify between twelve and twenty participants (Altschuld, 1993; Dalkey, Rourke, Lewis, & Snyder, 1972; Debecq, Van de Ven, & Gustafson, 1975; Edwards, 2003). Researchers picked twenty Delphi study participants based on their expertise. They will be referred as experts from this point on. The experts were selected from the four categories: a) researcher experts, b) mathematics educator experts, c) teacher experts, d) mathematics education leader experts. A detailed description of each group and the selection process will be provided during the presentation. In this study the development and administration of this survey was interconnected. The researchers' role in the data collection process was a) gathering the data from the research literature and creating the initial measures, b) identifying a panel of experts, c) corresponding with experts, collecting their ratings of the measures, and feedback on each measure, and d) analyzing collected data and reporting the results. The qualitative analysis included: a) the review of literature, b) the content analysis of the data, c) the identification of emerging categories of the data, and d) the operationalization of the instrument. The quantitative analysis included: a) calculating reported rating means for each item of the instrument, b) identifying outliers in the reported data, c) recalculating reported rating means of the items, d) conducting factor analysis, and e) establishing reliability, such as test-retest, etc. The researchers decided to use three rounds to elicit experts' suggestions for developing appropriate measures of PCK. The data analysis and data collection were done parallel to each other. The instrument was modified based on experts' feedback, and analyzed according to the categories of the table of specifications developed by the researchers. New categories in the table of specifications emerged from the data, and were used to complete the analysis. More detailed explanation on the development of the table of specifications reliability and validity considerations and other aspects of the Delphi method in the context of developing instruments of teacher knowledge, as well as strengths and limitations of this method will be presented during the talk. The Delphi method used in this project may be further adapted in the context of the broader instrument development process.

# THE VALIDATION OF AN OBSERVATIONAL MEASURE OF MATHEMATICS INSTRUCTION

Temple A. Walkowiak
University of Virginia
twa7s@virginia.edu

Robert Q. Berry
University of Virginia
rqb3e@virginia.edu

Erin R. McCracken
University of Virginia
erm4j@virginia.edu

Sara E. Rimm-Kaufman
University of Virginia
serk@virginia.edu

J. Patrick Meyer
University of Virginia
meyerjp@virginia.edu

In the field of mathematics education, there is a need for viable and valid observational measures of mathematics instructional quality. Examining constructs central to mathematics teaching and learning is essential in order to gain a deeper understanding of these phenomena. Currently, such measures for use in large-scale studies do not exist. The goals of this poster presentation are: to introduce a new measure, the Mathematics SCAN (M-SCAN), and to explain the process of validating the measure for its reliable use.

The M-SCAN focuses on eight dimensions of mathematics instructional quality: structure of the lesson; multiple representations; students' use of mathematical tools; cognitive depth; mathematical discourse community; explanation and justification; problem solving; and connections and applications. The developers of the M-SCAN extended the work conducted by Borko, Stecher, et al. (2005) to create the measure and coding guide.

The validity study was conducted in a large, suburban, mid-Atlantic school district. Sixty third and fourth grade classrooms were randomly selected from a larger sample of classrooms from a federally funded large-scale study. A thirty-minute segment from each classroom was coded using the M-SCAN and three other observational measures: the Reformed Teaching Observation Protocol (Sawada, Piburn, et al., 2000), the Classroom Assessment Scoring System (Pianta, La Paro, & Hamre, 2008), and a time sampling measure of instructional format and content type.

To validate the use of the M-SCAN, the integrated conception of validity proposed by Messick (1995) was utilized. Mathematics education experts provided feedback about the constructs and content of the coding guide. To examine the substantive aspect of validity, the coders' rationales for scores were analyzed in regards to the dimension descriptors. Analyses were conducted to investigate convergent and discriminant evidence with the other observational measures. The development and validation of the M-SCAN aided in establishing reliability. Analyses were conducted to determine generalizability of the reliability findings. Specific results regarding evidence of validity and reliability will be shared at the poster presentation.

# IMPLEMENTATION OF INTEGRATED MATHEMATICS TEXTBOOKS IN SECONDARY SCHOOL CLASSROOMS

Melissa D. McNaught
University of Missouri
melissa.mcnaught@mizzou.edu

*Teachers are the ultimate decision makers with regard to mathematics content taught in secondary school classrooms and research has shown that they rely on textbooks to help with those decisions. The purpose of the study reported here was to gain an in-depth understanding of students' opportunity to learn mathematics from an integrated textbook with respect to the specific content strands contained within the textbook. The results reveal that although teachers provide some attention to each content strand contained within the textbook, the decisions they make about what specific objectives to teach and what to omit results in a different emphasis on each strand than is represented in the composition of the written curriculum.*

## Objectives

The purpose of this paper is to report findings related to curriculum implementation of integrated mathematics textbooks in secondary school classrooms and to discuss implications of these findings. As part of curricular reform, new content has been added to textbooks that bring topics such as statistics, probability, and discrete mathematics to a more central position in the school mathematics curriculum. Moreover, established content such as algebra and geometry is presented in a more integrated fashion than embodied in predecessors to standards-based textbooks. Although we know textbooks are the centerpiece of mathematics instruction in U.S. schools (Grouws & Smith, 2000; Weiss, Banilower, McMahon, & Smith, 2001; Weiss, Pasley, Smith, Banilower, & Heck, 2003), we know little about the relative emphasis teachers place on content embodied in these standards-based textbooks. Teachers may choose to move through the textbook sequentially or not; they may choose to cover most of the chapters of the textbook or not; they may supplement the textbook with materials from other resources or not. All of these decisions affect the extent to which textbooks are implemented and therefore influence the mathematics that students have the opportunity to learn.

This investigation is an extension of a larger study known as the *Comparing Options in Secondary Mathematics: Investigating Curriculum* (COSMIC) project. The COSMIC project is a three-year longitudinal comparative study that addresses questions regarding the impact of two distinct organizations of high school mathematics curricular materials on student learning. During the course of the COSMIC project, the extent to which the textbook is implemented in each classroom is carefully assessed and will subsequently be used in interpreting data analyses that examine student learning under each organization of content. In my investigation reported here, the classroom implementation of an integrated textbook is examined in relation to four content strands: (1) algebra and functions; (2) geometry and trigonometry; (3) statistics and probability; and (4) discrete mathematics.

## Perspective

Although textbooks play a prominent role in the teaching of mathematics in K-12 schools, prior research suggests that different teachers implement the same materials in different ways

(Bowzer, 2008; Chávez, 2003; Tarr, Chávez, Reys, & Reys, 2006). Thus, a difference exists between curriculum as represented in textbooks or other instructional materials and the curriculum that students experience in the classroom (Stein, Remillard, & Smith, 2007). Figure 1 illustrates how the use of the curricular materials and textbooks are only one part of a larger conceptual frame of curricular influences on student learning. Developed by Stein, Remillard, and Smith (2007), this figure models curriculum as "unfolding in a series of temporal phases from the printed page (*the written curriculum),* to the teachers' plans for instruction *(the intended curriculum),* to the actual implementation of curricular-based tasks in the classroom *(the enacted curriculum)"* (p. 321). The oval represents possible factors that influence the transition from one phase of the curriculum to another. For example, teacher beliefs and knowledge mediate the way they interpret the written curriculum and make decisions about what to use from the textbook and what to omit. Within this conceptual framework, I examine the written curriculum in relation to the enacted curriculum.

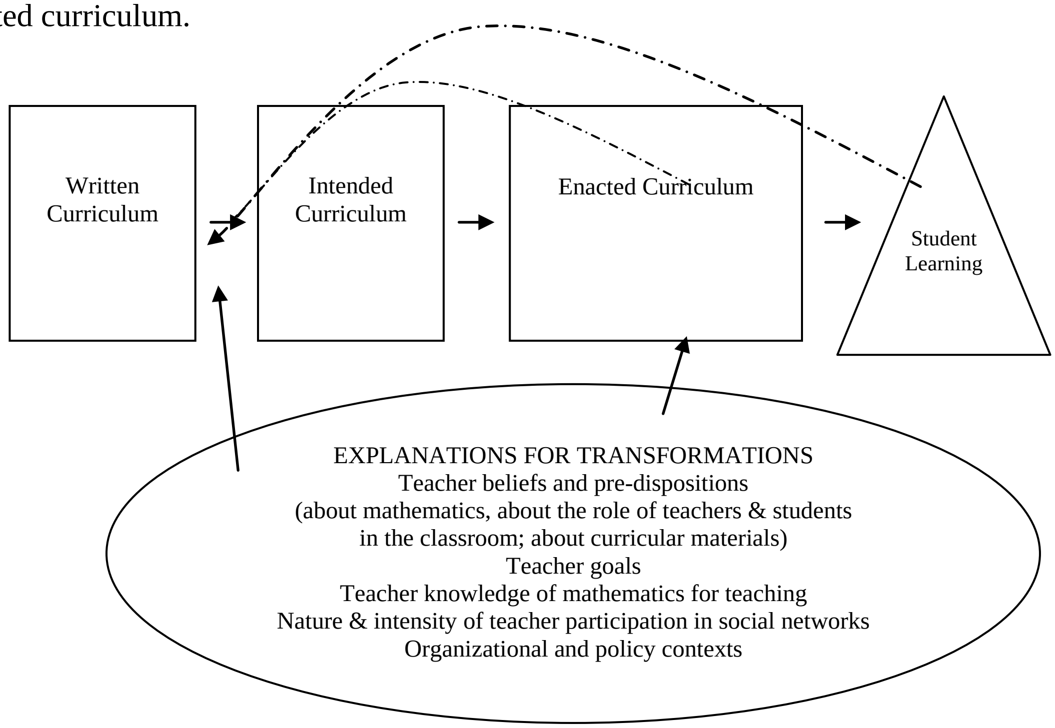

***Figure 3.*****Temporal phases of curriculum (Stein, Remillard, & Smith, 2007).**

## Methods

The purpose of the study was to gain an in-depth understanding of students' opportunity to learn mathematics from an integrated textbook with respect to the specific content strands contained within the textbook. Specifically, the following research questions were investigated.

To what extent do high school mathematics teachers provide students the opportunity to learn the *mathematics content embodied* in an integrated mathematics textbook?

a. What are students' opportunities to learn with respect to the Algebra and Functions strand?
b. What are students' opportunities to learn with respect to the Geometry and Trigonometry strand?

c. What are students' opportunities to learn with respect to the Statistics and Probability strand?
d. What are students' opportunities to learn with respect to the Discrete Mathematics strand?

*Participants*

Teacher participants for the study were 44 teachers from sites included in the COSMIC study, 21 in year 1 and 26 in year 2 with 3 teachers teaching in both years. At each site, all teachers teaching *Core-Plus Course 1* during year 1 and *Core-Plus Course 2* during year 2 were asked to participate. Six school districts in five states participated in the study, all employed a dual curricular option program (an integrated approach and subject-specific approach) allowing students to choose freely between the two options rather than be assigned via past achievement. The school locales varied from rural to urban settings and the student bodies ranged from high-middle socioeconomic (SES) backgrounds to schools where many students were from low SES families.

*Data Sources and Analysis*

*Table of contents record.* On the Table of Contents [TOC] Record, the teacher provided information regarding each lesson of the textbook being used and whether the textbook lessons were altered or adjusted. To gather this information, the teacher was provided an instrument that included a copy of the table of contents of the integrated textbook and was asked to indicate the level of textbook use for each section by choosing one of the following options: (1) content taught primarily from textbook; (2) content taught from the textbook with some supplementation; (3) content taught primarily from an alternative source; and (4) content not taught. Although every unit of each course is integrated around all the strands, the authors have identified each unit as having a primary strand within which connections are made across strands.

The extent to which the textbook was used during instruction and the manner in which it was used is reported utilizing two indices developed from the Table of Contents Records: (1) Opportunity to Learn index; and (2) Textbook Content Taught index. These two indices were calculated for each of the four content strands in the *Core-Plus* textbook: (1) Algebra and Functions; (2) Statistics and Probability; (3) Geometry and Trigonometry; and (4) Discrete Mathematics.

*Opportunity to learn (OTL) index.* The OTL index indicates whether the textbook content is being taught or not taught. Content here refers to the content objectives included in the textbook lessons and includes content taught primarily from the textbook or from alternative sources. The OTL index was computed by summing the frequency of occurrence of the first three options reported across all textbook lessons on a table of contents record divided by the total number of lessons included in the particular textbook. The OTL index essentially represents the percentage of the content in the textbook that students were provided the opportunity to learn for the academic year and aggregated by content strand. The formula below provides a specific example of how the OTL index was calculated:

$$OTL = \frac{6+6+29}{75} * 100 = 54.67$$

For this example, the teacher chose option 1 (content taught primarily from textbook) on the table of contents record 6 times, option 2 (content taught from the textbook with some supplementation) 6 times, and option 3 (content taught primarily from an alternative source) 29 times out of the 75 investigations contained within the textbook. The remaining 34 investigations were marked as option 4 (content not taught) and thus represent content untaught.

*Textbook content taught index (TCT).* The TCT index considers only those lessons whose content was taught in some manner and ignores content students were not given the opportunity to learn. It was determined by weighting each of the first three options provided to the teachers on the table of contents records. The largest weight was given when the first option was identified for a section, *i.e.*, content was taught primarily from the textbook. This was given a weight of 1. The lowest weight was given to the third option, *i.e.*, content taught primarily from an alternative source and it was given a weight of . The second option, taught with supplementation, was given a weight of and omitted sections were assigned a 0. The index was then calculated by summing the weights across textbook lessons and dividing by the number of lessons reported as content being taught in any manner and again multiplied by 100.

$$TCT = \frac{1(6) + \frac{2}{3}(6) + \frac{1}{3}(29)}{75 - 34} * 100 = 47.97$$

Again, this index was reported as a scale ranging from 0 to 100. An index of 100 would represent that every lesson taught was taught neither without supplementation nor from alternative sources. In contrast, an index of 0 would represent that every lesson taught was taught utilizing alternative resources with similar content that substituted for that in the intended textbook. All indices in between would roughly indicate the extent to which lessons were supplemented or replaced. Ultimately, this index reports the extent to which teachers, *when teaching textbook content,* followed their textbook, supplemented their textbook lessons, or used altogether alternative curricular materials.

## Results

Using the Table of Content Records, indices were computed for each year for the entire textbook and in respect to the four content strands. These indices reveal teachers' tendencies to select particular *strands* of mathematics contained within the textbook.

*Overall.* The overall mean opportunity to learn (OTL) index across the 21 teachers participating in Year 1 was 66.60 with standard deviation of 13.23 as represented in the first graph of Figure 2. Across the 26 teachers participating during year 2, the mean OTL index was 57.44 with a standard deviation of 8.57 as represented in the second graph of Figure 2. These indices indicate the percent of content taught *as defined by the textbook* that students were provided the opportunity to learn during each year. Interestingly, although during year 1 the OTL is larger than in year 2, there was substantially more variation among these teachers in terms of the OTL index. For example, during year 1 the lowest OTL index was 42.86 while the highest was 90.91.

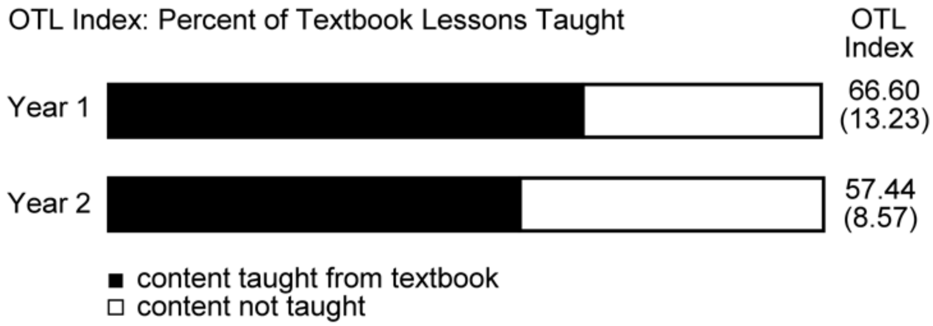

*Figure* 4. Percent of textbook lessons taught disaggregated by year.

Whereas the OTL indices provide information regarding the use of the textbook, the TCT indices narrow the focus to just the content embodied in the textbook that was taught. Figure 3 displays the *Textbook Content Taught* indices. The results show that the content taught across year 1 teachers, approximately 65% of that content was taught directly from the textbook. As shown visually in the second bar, during year 2, less content was taught directly from the textbook (56%) as compared to year 1. Note that the difference was smaller with regard to content supplementation with teachers during year 2 supplementing 29% of the content as compared to 25% during year 1. In general, little content was taught from alternative sources (9% during year 1, and 15% during year 2).

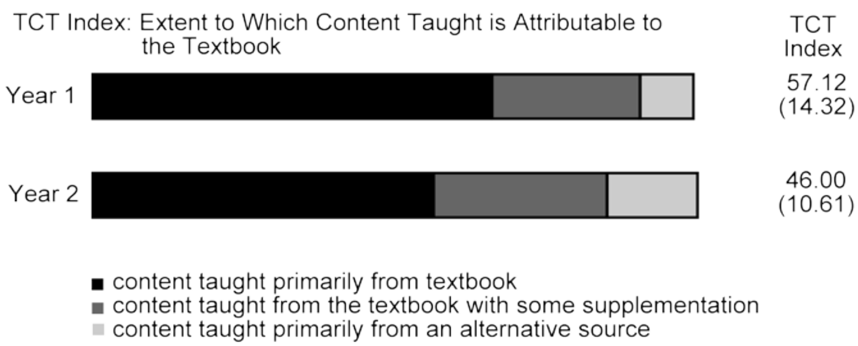

*Figure* 5. Extent to which content taught is attributable to the textbook.

As the overall indices indicate, year 1 teachers using Course 1 materials on average covered approximately 67% of the content contained within the textbook, whether utilizing the *Core-Plus* textbook to do so or not; year 2 teachers using Course 2 materials covered approximately 57% of the content. Given these results, teachers are making decisions regarding what content to teach and what to omit. Using the same Table of Content Records, the OTL index was computed with respect to each content strand contained within the *Core-Plus* integrated textbook.

*Content strand indices.* The results indicate that during year 1, the Algebra and Functions, Statistics and Probability, and Geometry and Trigonometry strands received similar attention. Students were provided the opportunity to learn approximately three-fourths of the content contained within the textbook for each of these three strands. However, within these three strands, the greatest variance existed within the Geometry and Trigonometry strand (Figure 4).

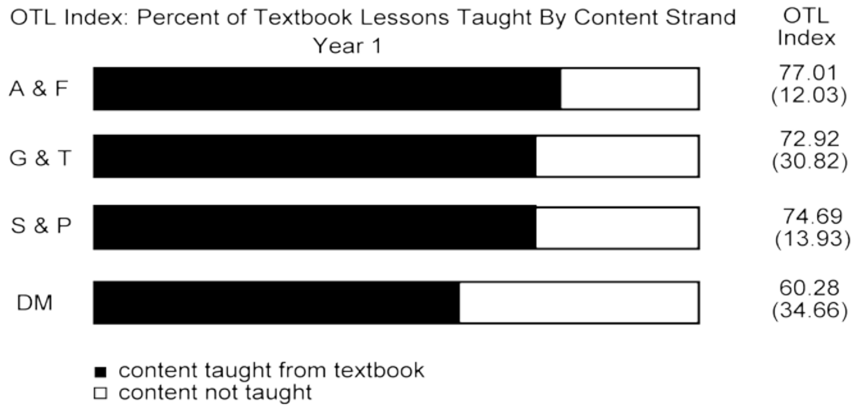

*Figure* 6. Percent of textbook lessons taught during year 1 disaggregated by content strand.

For example, two teachers omitted all units in the Geometry and Trigonometry strand whereas four teachers completed every geometry lesson contained in *Course 1*. The Discrete Mathematics strand received the least attention with only 60% of the material contained in the textbook being taught. Moreover, it is also the strand with the greatest variation. For example, three teachers omitted all units pertaining to discrete mathematics whereas only two teachers completed every discrete mathematics lesson.

Despite the relatively uniform attention given to the various content strands by teachers in year 1, the picture is strikingly different in year 2 (Figure 5). In particular, the Algebra and Functions strand not only received the greatest emphasis but was also implemented in the most consistent manner. Over 90% of the Algebra and Functions content was taught. In comparison, the remaining three strands received much less attention. Only 27% of the Statistics and Probability content was taught. Furthermore, the remaining three strands were implemented with considerable more variation than the Algebra and Functions strand. Similar to year 1, the Discrete Mathematics strand was the least consistently implemented.

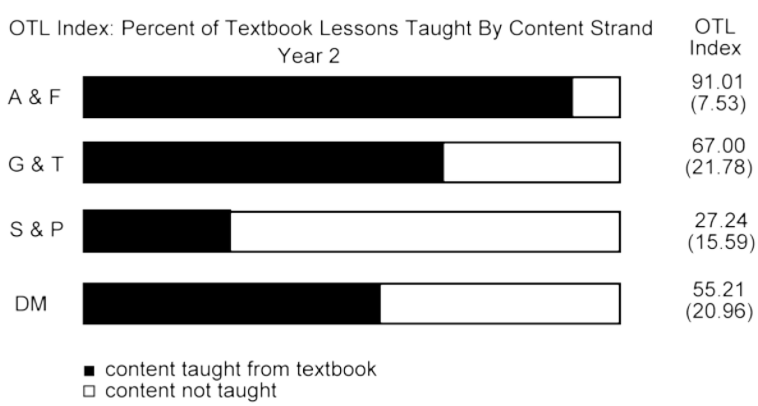

*Figure* 7. Percent of textbook lessons taught during year 2 disaggregated by strand.

*Textbook content taught indices.* Figure 6 displays the TCT indices for year 1 participants. The results show that when teaching content contained in the textbook, teachers relied mostly on

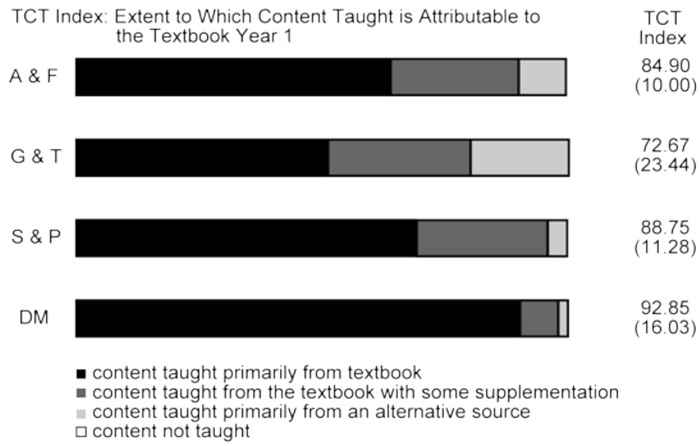

*Figure* 8. Extent to which content taught is attributable to the textbook disaggregated by content strand, year 1.

the textbook when teaching the discrete mathematics content, 90% when compared to 64% (A & F), 51% (G & T), and 69% (S & P). The use of supplementation was similar among the first three strands (26%, 29%, and 27% respectively) although it was greatest within the Geometry and Trigonometry strand. Moreover, teachers' use of alternative materials was also greatest when teaching geometry and trigonometry content (20%) when compared to the other three strands (A& F: 10%, S&P: 4%, and DM: 2%).

During year 2 (Figure 7), the results show that when teaching content contained in the textbook, teachers again relied heavily on the textbook when teaching the discrete mathematics content (71%) and little on alternative resources (2%) but the pattern was similar for the statistics and probability content. However, the discrete mathematics content was implemented more consistently than the statistics and probability content. The pattern of supplementation among all the strands was similar but again was the greatest for the Geometry and Trigonometry strand, 34% as compared to 30%, 21%, and 27%. The greatest use of alternative materials when teaching geometry and trigonometry content was repeated during year 2, 26% as compared to 14%, 7% and 2%.

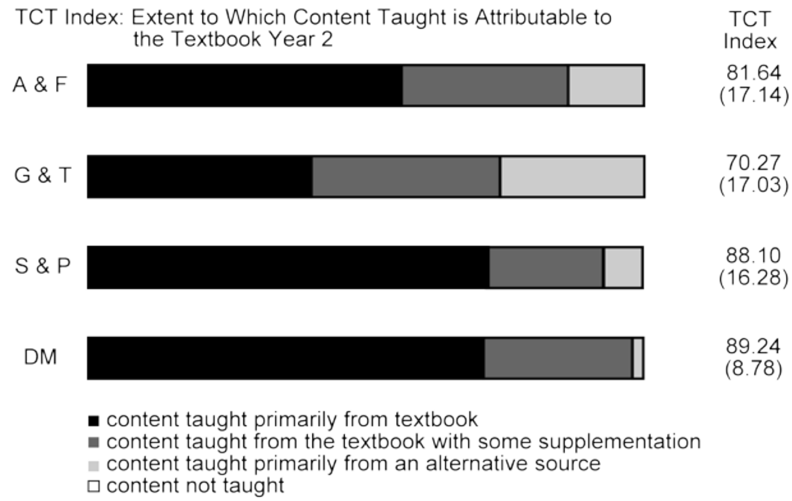

*Figure* 9. Extent to which content taught is attributable to the textbook disaggregated by content strand, year 2.

## Discussion

Teachers do attend to each major content strand included in high school textbooks where the mathematics is organized in an integrated manner, but their daily decision making results in student opportunity to learn being different than that intended in the textbook design. Overall, teachers on average taught less than two-thirds of the content embodied within the integrated textbook during a school year. Interestingly, of the textbook content taught, only 67% in year 1 and 56% in year 2 can be attributed solely to the textbook, with as much as 9% and 15% (year 1 and year 2 respectively) on average being taught from other sources.

Two primary implications of this data are worthy of attention here, one with respect to research and the other with respect to practice. In terms of research, given that during the course of two years, as much as one-third of the content taught includes use of supplementary materials, measures of the impact of this particular curriculum on student learning should be called into question, if this supplementation is not accounted for during data analysis of studies designed to assess its effectiveness in promoting student learning. In terms of practical implications, if textbooks are selected on the basis of content included and emphasized within the textbooks, then those concerned with what mathematics students learn need to be vigilant about how teacher decision-making may not be consistent with the intentions association with the textbook selections. Teachers are making decisions regarding what content to teach and what to emphasize and these decisions impact students' opportunity to learn content. For example, if teachers were utilizing an algebra textbook, the content omitted or deemphasized would most likely be algebraic content. However, when teachers are utilizing an integrated textbook, the content omitted may be from any of the four major content strands contained within the textbook. The results during year 1 revealed that, on average, three of the four strands (Algebra and Functions, Geometry and Trigonometry, and Statistics and Probability) received similar attention while the Discrete Mathematics received the least attention. However, during year 2, the Algebra and Functions strand received considerable attention and it came at the expense of the other strands. Reasons for differential attention may be attributable to the timing of this particular course within a student's education. In other words, this course is the second in a series of four and would most likely be taken during a student's 10th grade year, a targeted testing grade within the requirements of mathematics testing outlined in No Child Left Behind. Consequently, teachers may decide to focus on Algebra and Functions content because they perceive it to be the mostly likely content to be included on the test. This cause of the wide range of attention to strands across the two years suggests an interesting research question to be pursued further.

# MATHEMATICS AS A TOOL: HIGH SCHOOL GIRLS' PERCEPTIONS

*Nineteen high achieving young women in a 10-year longitudinal study were interviewed in high school about their experiences and interests in mathematics. Their perceptions of mathematics included that it was a tool for problem solving, a tool for their education, a tool to increase their self-confidence, a tool for future careers and other real world experiences. Noting that their teachers were instrumental in changing their perceptions of mathematics positively and negatively, none of these young women plans a mathematics major.*

## Background

A longitudinal study of young women selected by their teachers to take Algebra 1 in seventh or eighth grade is now in its tenth year. While some of the young women in the study may be talented in mathematics, we choose the term "high-achieving" to describe their scholarship, motivation, and work ethic. An historical perspective of Girls on Track provides a context to understand the scope of the larger, longitudinal study. Therefore, some of the findings that were previously reported are also presented here. In the first few years of the study, the purpose was to encourage these young women to continue on the advanced mathematics track, taking calculus no later than their senior year in high school. Some of girls continued beyond high school calculus, taking other college mathematics courses during their junior and senior years. Although, many of the young women in our study did continue on the advanced mathematics track, only 2 out of more than 250 young women, planned to or choose to major in mathematics as undergraduates, neither of these girls were in this current study.

In the first three years of the project, 45 of 174 girls were interviewed to investigate how they and their parents perceived their school achievement. Howe and Berenson (2001) reported that there were four characteristics that emerged from these interviews. First, every girl reported strong support from her family in terms of academics. A second factor to emerge was the girls' desire to do well in mathematics. These girls all want to understand what they are doing in math class. The girls discussed the desire to understand and their opinions of their teachers in relation to their wishes to do well. The interviewer did not directly ask about their teachers but the girls gave an opinion that their success and interest in mathematics, in almost every case, depended on whether the teacher helped them understand the topic or concept being studied. The third characteristic to emerge was assertiveness. These are not the type of girls who are passive in class, remaining quietly in the background while the teacher asks the boys the hard questions. Their desire to understand, as well as their desire to get a good grade, prompts them to ask questions in class and to seek help offered by teachers before and after class. When they get lower grades than they want they go to the teacher and ask why they got the low grade and what they can do to bring it up. Finally, these girls believe in hard work. What they all do to bring up a grade or maintain an A, is to work hard or harder. A good math student is *someone who tries hard and does their best*.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

In 2004, 39 telephone interviews were conducted with high school juniors and seniors who were members of cohorts 1 and 2 as middle school students. Berenson, Vouk, Michael, Greenspon and Person (2004) reported results on the girls' generally positive attitudes towards high school mathematics (See Table 1). Of the eight themes, the last three denoted areas in which the girls were not comfortable. These girls' attitudes concerning computer science changed from positive attitudes in middle school to negative attitudes in high school. Using data obtained from school records, we reported the fact that among high school girls in the longitudinal study 119 out of 141 girls was on track to take calculus by the senior year (Berenson, et al., 2004). The 20 girls who took algebra 1 in the seventh grade in 1999-2000 were all on track to take calculus by their junior year in high school.

Table 1. *Cohorts 1 and 2 Attitudes towards Math in High School**

| Attitude | Number |
|---|---|
| Expressed Confidence in Math Ability | 21 |
| Had a Great Math Teacher | 8 |
| Enjoyed the Challenge in Math | 7 |
| Liked Math | 5 |
| Used "fun" to Describe Math | 4 |
| Felt Nervous about Next Math Class | 5 |
| Thought Math was Difficult/Hard | 3 |
| Didn't Like Math Because of the Teacher | 2 |

*N=39

In 2005, we interviewed by telephone 86 girls, aged 16-20, who were juniors and seniors in high school, and freshmen and sophomores in college. Two papers reported at PME in 2006 indicated the mathematics pathways that these high achieving girls took in high school and the relationship between their math course selections and their career choices (Berenson, Michael, & Vouk, 2006). Approximately half of these 86 girls are planning to or have committed to major in STEM careers, and 60% have taken calculus 1 or beyond, four were undecided as to their career choices. We recognize that through high school and the early years of college these career choices are subject to change.

Collapsing categories we conducted a Chi Square test [À$^{2}_{\tilde{5}1}$= 3.897] to compare frequencies of advanced mathematics courses taken and choosing STEM (science, technology, engineering, and mathematics) or non STEM careers. Results indicate that high school girls' taking advanced calculus courses in high school were more likely to choose a STEM career. (Berenson, Michael, & Vouk, 2006). One of the 86 intended to major in mathematics and one in teaching mathematics. When asked to list strengths they will bring to the workplace, this sample of 86 describe themselves as hardworking, determined, organized leaders who are good with people. Disappointingly, only one out of 86 girls described herself as "smart.", when asked what attributes they would bring to the workplace. A quantitative study conducted by Wilson et al., (2006) found that decisions among girls in this longitudinal study to take mathematics beyond Algebra 2 correlated with measurements of mathematics success that include standardized tests, course selection, and course grades.

The results of this ten-year study reveal that high achieving girls in mathematics are confident, hard working, assertive, and have strong parental support for their academic and career choices. Most set high expectations of themselves academically. Half of these girls enjoy mathematics from middle grades through high school, indicating that they enjoy being challenged. Approximately half of this sample of 86 girls is planning to prepare for STEM careers with a majority of choices in the medical field. These high achieving girls are not interested in engineering (with the exception of bio-medical engineering), physics, or computing careers. The girls in this study from cohorts 1-5 are now in college, have graduated from college, or gone on to graduate school.

The current study takes a closer look at the girls' perceptions of mathematics when they were in high school. The design of this study is one of grounded theory and aims to develop a framework of study from the data. According to Creswell (2007), no theoretical foundations are given before the analysis begins. Interviews conducted in late 2004 and during the winter break of 2006/2007 are being used as sources of data. The remaining sections of this paper will discuss the participants, methodology, and discussion of the findings. The study hopes to answer how the high-achieving high school girls in this study perceive the role of mathematics in their lives.

## Participants

For the analysis conducted in this study, we looked at 19 of the high school interviews. The first 6 of these interviews were conducted 2004, these girls are currently juniors and seniors in college. The other 13 interviews were conducted during the winter of 2006/2007. These girls are currently freshman and sophomores in college. These girls were sophomores, juniors, or seniors in high-school. Table 3 outlines the participants, their grade at the time of the interviews, what type of high school they attended, and what their career interests were. The public high school, which is an academic magnet, has a strong focus on preparing students for college. This high school also offers the widest variety in advanced placement courses of all the schools.

Table 2. *Description of the Participants*

| Pseudonym | Grade at time of interview | Career interest | High school at time of interview |
|---|---|---|---|
| Ray | $10^{th}$ | Psychiatrist, Medicine | Public High School Academic Magnet |
| Amy | $11^{th}$ | Veterinarian | Private High School |
| Katya | $11^{th}$ | International Policy | Private High School |
| Zena | $11^{th}$ | Medicine | Public High School Academic Magnet |
| Wendy | $11^{th}$ | Undecided | Public High School Academic Magnet |
| Crystal | $11^{th}$ | High School Math Teacher | Public High School |
| Cara | $11^{th}$ | Nursing | Public High School |
| Ginger | $12^{th}$ | Television or Foreign Affairs | Public High School Academic Magnet |
| Amber | $11^{th}$ | Biotechnology, Science Industry | Public High School Academic Magnet |

| | | | |
|---|---|---|---|
| Kelly | $12^{th}$ | Engineering | Public High School |
| Kim | $11^{th}$ | Paleontologist, Engineer, Graphics Design | Public High School |
| Mia | $11^{th}$ | Music Engineer | Public High School |
| Alison | $12^{th}$ | Biomedical Engineering | Private High School |
| Lisa | $12^{th}$ | Lawyer, History Professor | Public High School |
| Marie | $11^{th}$ | Undecided | Public High School Academic Magnet |
| Rita | $11^{th}$ | Elementary School Teachers, Speech Pathology, Missionary | Public High School |
| Tina | Graduated | Biotechnology Forensics, Pharmacy | Home-Schooled |
| Annette | $11^{th}$ | English, Spanish or Math Teacher | Public High School |
| Vera | $11^{th}$ | Undecided | Public High School |

**Methodology**

During the history of the Girls on Track program researchers conducted several interviews of girls who participated in the summer camp held for middle school girls. Researchers contacted possible participants via e-mail and/or by phone, therefore these interviews represent a small group of girls willing to contribute to the research several years after their camp experiences. The first round of interviews analyzed for this study occurred in 2004, the girls from the first two cohorts were in high school, and a second set of interviews were held in late 2006 and early 2007 when the girls from later cohorts had become juniors and seniors in high school. This research presents the results from 19 different girls. The question asked during the analysis was: how did high-achieving girls perceive mathematics?

All interviews conducted were semi-structured and conducted in person. During the semi-structured interviews, a series of structured questions were asked in each interview with researchers also using open-ended questions to probe more deeply (Gall, Gall, & Borg, 2003). Different interview protocols were used during the two times interviews were conducted. However, all protocols explored participants' experiences, interests, and activities. All interviews were audio-taped. Interviews lasted from 30 to 90 minutes.

The interviews were transcribed verbatim and analyzed using NVivo qualitative software (Weitzman, 2003). Much of the initial analysis of the interview transcripts took place in regular team meetings over the course of four months. Researchers discussed codes and definitions of these codes. They also coded several interviews together. For first and level coding processes, both serial tagging, analyzing each transcript one at a time, and parallel tagging, reading and comparing each response to the same question, were employed by researchers (Baptiste, 2001). Initially, data were labeled, tagged, and coded based on emerging themes in the data (Baptiste, 2001). The codes were created during a separate analysis of data using Wenger's (1998) community of practice framework. The research team was analyzing 12 college girls' interviews, during this coding discussion turned to how the students were discussing their views of mathematics and science in relation to their chosen careers and education. The team then created a series of codes about the girls' beliefs and perceptions of mathematics (Table 4).

To contribute to the validity, reliability and veracity of the study, strategies of verification included using incremental evidence (Morse, Swanson, & Kuzel, 2001), triangulation between researchers (Merriam, 2002), and adequately engaging in data collection so that the data become saturated (Merriam, 2002). In order to address issues relating to reliability, multiple coders were used, coding was checked and refined at both the first and second levels of analysis, and inter-rater reliability was established (Morse et al., 2001).

Table 3. *Codes for Describing Girls' Beliefs and Perceptions of Mathematics*

| Codes | Explanation |
|---|---|
| Mathematics as a tool for thinking and problem solving | Girls like to be challenged, math increases their thinking skills, also some talked about the problem solving skills they developed in higher mathematics courses |
| Mathematics as an educational tool | Advance study in other areas such as Chemistry or Physics, business degrees, as well as in future mathematics classes. Following curriculum requirements and educational goals |
| Mathematics as a tool for STEM career pursuit | Mathematics will help them in their pursuit of STEM related careers. |
| Mathematics as a tool to build confidence in abilities, enjoyment, and satisfaction | The girls are good at mathematics, and therefore, it helps them build confidence in their academic abilities. They also express that they have natural ability and genuinely enjoy mathematics. |
| Mathematics as a tool for connecting to real-life and other fields | The girls talk about liking classes that are connected to other areas. Prefer applied mathematics classes that are relevant for their future majors and career interests. |
| Mathematics as tool for teacher influence on the young women's perceptions of mathematics | The young women describe classroom experiences and teachers in which their perceptions of mathematics was changed. Including their enjoyment and satisfaction in studying mathematics. |

## Discussion

This section will describe each of the six codes in more detail with evidence from the interviews. Because these codes were originally created from college interviews conducted in the winter of 2006 and spring of 2007, they had to be reevaluated for the high school transcripts. For example, the first code, mathematics as a tool for thinking and problem solving, was much more prominent among the college aged girls (Lambertus, Berenson, & Bracken, 2009), but the high school girls discussed their desire to be challenged. The research team saw this desire as being connected with increasing thinking skills. Therefore, the high school interview transcripts have a slightly different focus.

The first code Mathematics as a tool for thinking and problem solving was created to capture the young women's beliefs about how mathematics increases their thinking and problem solving skills. Tina, who was home-schooled and graduated from high school at the age of 15 was taking a year off to do community service, because her mom felt she was too young for college. She continued her mathematical studies, taking calculus for no credit and because she "wanted to keep her mind sharp". The girls liked not only to progress through the mathematics curriculum, but to take challenging courses that improving their thinking skills and prepared them for college. This code also encompasses the idea that the girls like to be challenged and what to be engaged in their learning. Amy talked about the difficulties she has if she is not being challenged. "[I]f you put me in an easy class, I'll just sit there and not do anything…It's got to be challenging enough for me." Ginger, a high school senior, stated that the challenge of a mathematics or science course is what draws her to those courses. This is further demonstrated by the fact that most of the girls, 16, took at least one advanced placement course, and 14 took an advanced placement course in either science, mathematics or a combination of both.

The second code, mathematics as an educational tool has two facets. The first facet being that the girls take mathematics classes that are required and in line with their educational goals. This code is closely tied with the first. The girls are preparing themselves to go to college and are following the curriculum path that will put them in a position to possibly gain admissions to the universities of their choice. For example, Kim stated "I'm in AP Calculus. Last semester I had AB and then this year, I have BC Calculus." A second girl, Lisa, described how she took all the mathematics and science courses available at her school, so that she could "test out" of courses in college, because she wants to focus on history and political science in college. Lisa later stated that she felt taking calculus would "look good to colleges". The girls appear to have spent quite a bit of time thinking about what types of courses and activities would get them into the colleges of their choice. The second aspect focuses on the fact that the girls see mathematics as a way to advance their study in other areas such as physics or chemistry. Kelly expressed that she took calculus before physics so she could take a higher level course than general physics. However, she did not want to take AP physics. Therefore, she was placed into honors and felt that it would be fun and "hard" at the same time.

Mathematics as a tool for STEM career pursuit is the third code. The girls explained the different ways in which the felt their mathematics have helped them or will help them in their pursuit of STEM careers. Because the girls are in high school, we know that their career interests are not solidified. They are probably going to change and several of the girls listed multiple unrelated careers or simply states that they did not know. Amy stated "I'm not really sure, exactly, what I'm interested in. But, I know that I'll need math. It'll be…[math] will definitely be important." Other girls were more confident in their career choices and knew that mathematics would be important in some way. Kelly knew that she wanted to be an engineer. She also had taken steps to prepare for that route. Kelly articulated that she needed calculus in order to pursue an engineering degree; also, she had visited a couple of chemical engineering classes, and observed how mathematics was used. Most of the girls expressed that they would need to use math in their future careers.

The girls are confident in their abilities in mathematics classes; therefore, they talk about mathematics as being a tool for building their self-confidence, enjoyment in math. They gain a level of satisfaction through being able to perform well in challenging mathematics classes. Everyone of the girls in this sample are good at mathematics, and had taken Algebra I in either the 7th or 8th grade. The girls continued down the advanced mathematics track. To date, we know that most the girls either started the Calculus sequence, or completed advanced placement in statistics. In terms of expressing their confidence and enjoyment, the girls gave comments such as:

> I'm taking calculus because I like math (Ginger)
> I'm doing pretty well in them [math classes], so – I like classes that I do well in (Mia)
> I'm really good at calculus and math-based stuff (Lisa)
> I like the way that math works (Annette)

The girls also see mathematics as a tool for connecting to real-life and other fields. They talk about the relevance of mathematics to real problems. They express their enjoyment of being able to apply mathematics to situations that have a direct impact or application. For example, Alison stated that she liked "calculus … better than any of the math that I'd ever done before just because you could see how it applied to real life and how it's important." When the girls were asked about the Girls' on Track camp they stated that they like the mathematics problems because they were applied to real-life problems and situations.

Finally, mathematics as a tool for teacher influence on their perceptions, enjoyment, and continued study was the final code. All of the girls talk about the influences, both positive and negative, of teachers. From examining these particular interviews, we can see that teachers have a large impact on the girls' course choices and their enjoyment of the subject matter. Kim expressed "I love it [BC Calculus] because our teacher, she's an absolutely amazing teacher – she really knows how to teach Calculus." While Katya's enjoyment in Calculus class is because she feels that she has a "really good teacher this year." Her teacher is open to questions and is very good at explaining different concepts.

The girls discuss that a particular course was difficult because the teacher did not explain material well, or that a course was exciting and fun, because the teacher was motivated and excited about the topic. Cara was the girl who expressed that she did not really like math. She verbalized that she did not really enjoy her current math class and that "math is not one of my strong points and I don't really have a good teacher so I don't really like math." When asked what it was that Cara did not like about her teacher, she said that the teacher covered too much material at once, and does not spend enough time explaining the material.

In some instances, a teacher has influenced future mathematics choices of the girls. Mia stated that her teachers influenced what classes she took "they see how well I'm doing in a class and they're like, 'you'd probably do well in this class' or 'you'd probably do better in this class'." Another participant, Marie, stated that she did not register for pre-calculus because her teacher told her there was a lot of geometry involved "I didn't do very good in Geometry, I'm better at Algebra stuff. So I took AFM [Advanced Functions and Modeling] because she [the teacher] said it was a lot of algebra."

## Conclusions

The high school girls expressed the opinions that their teachers were an important factor in their education. The teachers' willingness to help students, answer questions, and explain material all contribute to how the girls feel about their mathematics abilities and their enjoyment of the subject. It also seems to influence the courses the girls take in high school. While teachers may influence their enjoyment of mathematics, these girls perceive the role of mathematics not as a career option but as a tool for their future education and careers. In our study of the high achieving young women, we reported earlier on the college women's perceptions of mathematics and their career interests (Lambertus et. al, 2009). The college girls showed similar enjoyment in mathematics and the use of mathematics as a tool. However, of all the young women interviewed, none of them is studying mathematics. To date, we know of only one participant that has chosen to study mathematics. This leads us to question why these high achieving girls in our longitudinal study do not wish to study mathematics in college.

*Prospective teachers' views of mathematics, proof, and teaching mathematics were examined in a content-focused mathematics education course. Both changes claimed by the participants and small shifts observed by the researchers were noted, along with possibly influential class activities. In addition, an examination of how the participants held their beliefs revealed that they could be tentatively described as isolationist, naïve idealist, and reflective connectionist, similarly to the participants in Cooney, Shealy, and Arvold's (1998) study.*

## Introduction

Previous research suggests that teachers' beliefs about mathematics influence their classroom practices, although not in a way that is straightforward or easily measured (Philipp, 2007). In a previous study, Conner (2007) found that student teachers' conceptions of the role of proof in mathematics aligned with a particular aspect of classroom practice: support for collective argumentation. This paper reports preliminary results about shifts in three prospective secondary mathematics teachers' (PSMTs') conceptions of mathematics, proof, and teaching mathematics over the course of one semester. These participants are part of a cohort involved in a larger study, which will examine these conceptions and changes therein over two semesters and examine their connection to student teachers' classroom practice with respect to support for argumentation. This paper reports on the relevant parts of the following research questions:

- What do PSMTs believe about the nature of mathematics, the role of proof in mathematics, and the teaching of mathematics at the beginning of a two-semester sequence of mathematics education courses (content-focused followed by methods)?
- How do PSMTs' beliefs about mathematics, proof, and teaching change during a content-focused mathematics education course and to what do they attribute those changes?

## Theoretical Perspective

Cooney, Shealy, and Arvold (1998) suggest that we should expect little understanding of the connection between teacher education and teacher practice until we "understand the linkages between our activities in teacher education and the impact of activities on teachers' belief systems" (p. 331). They conceptualize a belief structure as encompassing the ways in which a teacher holds beliefs, providing insights into how consistent teachers' practices may be with their beliefs and how changeable these beliefs may be. At least as important as what PSMTs believe is how they hold these beliefs and how they deal with challenges to these beliefs. According to Cooney, Shealy, and Arvold, a teacher may uncritically incorporate newly encountered ideas into existing beliefs (naïve idealist); may completely reject new ideas that conflict with already held beliefs (isolationist); or may critically analyze ideas, merging aspects of both new and old into a compatible system (connectionist). Considerable research has been conducted on the link between teacher beliefs and practices. A teacher's practice may be connected to his or her view of mathematics, view of teaching mathematics, or some combination of these views. It may also be necessary to examine other related factors to understand the relationships between beliefs and practice. The elementary teacher in Raymond's (1997) study held beliefs about teaching math that differed from her practice, but her practice aligned with her views of mathematics. Borko, Eisenhart, Brown, Underhill, Jones, and Agard (1992) also found inconsistencies between beliefs and practice in their study of a preservice elementary teacher. Philipp (2007) suggests apparent inconsistencies between teachers' beliefs and their practice may be explained by examining contextual factors and the teachers' belief systems. Teachers' belief structures may influence how readily their beliefs change, and previous research has established that teachers' beliefs change slowly, over time, and are not readily changed in one semester (Thompson, 1992).

## Methods

This research was conducted in the context of a mathematics education course, which was designed to help PSMTs think deeply about the middle and high school mathematics they will be teaching. The focus of this class was on mathematical concepts such as complex numbers and trigonometry and mathematical processes such as proof and representation. The course was taught by engaging small groups of students in mathematical investigations followed by whole class discussions. One of the authors of this paper taught the course, and all students in the class ($n$ = 10) agreed to participate in the research. Participants completed a survey (adapted from Yoo, 2008) and participated in semi-structured interviews at the beginning and end of the course to provide a means for us to understand their views of mathematics, proof, and teaching mathematics. Other data included video and audio recordings and field notes of each class session, copies of students' written work, and their responses to weekly reflection questions.

The survey asked students to identify, along a continuum from 1 to 8, their views of various statements about mathematics, proof, and teaching mathematics. Figure 1 shows one of the items on the survey. Each item involved two statements, labeled (a) and (b), and students were asked to select a number between 1 and 8 that reflected their level of agreement with the statements. The first interview involved questions about mathematics, teaching, and proof such as "What does it take to be a good math teacher?" The second interview involved follow-up questions relating to participants' answers to the first interview questions, direct questions about whether participants believed their views had changed, and several tasks that asked participants to validate proofs.

2. The main purpose of proof in mathematics is (a) to show the truth of a mathematical proposition or (b) to explain why the statement is true.

| *Mostly a* | ← *Toward a* | | *Both a and b equally* | | *Toward b* → | *Mostly b* | *Neither a nor b* |
|---|---|---|---|---|---|---|---|
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

Comments:____________________

*Figure 1*. Sample survey item.

Data analysis is ongoing and has involved several passes across the various data sources. For the three focus cases (chosen to be representative of the cohort's initial views of math, teaching, and proof), the surveys and interviews were examined to ascertain individual students' initial and ending views of teaching, mathematics, and proof. Analysis involved identifying pertinent passages from interview transcripts, summarizing what the participants said about each of the relevant ideas, considering alternate interpretations of the participants' statements, and examining the transcripts, written work, and surveys for confirming or disconfirming evidence. The goal was to characterize each participant's views of mathematics, proof, and teaching mathematics.

After each focus participant's initial and final views of mathematics, proof, and teaching mathematics were characterized, changes in views were noted. We noted both changes that were apparent to the researchers and areas in which the participants claimed to have changed their thinking. When possible, we asked participants to identify class activities that influenced their thinking, and we examined those activities to derive characteristics that may have been influential. Future analysis will involve examining other classroom activities for evidence of when the changes may have occurred and what particular activities or conversations may have led to the changes noted by researchers.

## Results

The results reported here are for a subset of the participants in the overall study and are for only one of the two semesters for which data will be collected. David, Kylee, and Helen (pseudonyms) were chosen to be as representative as possible of the range of conceptions of mathematics, proof, and teaching mathematics observed in the participants at the beginning of the semester. All three had completed at least two mathematics classes past the calculus sequence, had taken at least two previous mathematics education classes, and were enrolled in at least two upper-division mathematics classes in addition to this course.

### *David*

David's views of some aspects related to mathematics shifted over the course of the semester, but no evidence was found to suggest that David's views regarding the nature of mathematics changed during the course. He referred to mathematics itself as "independent of human invention" but saw the ways people interact with it as new and innovative; mathematics is already present, waiting to be discovered (David survey 2, question 1). David seemed to utilize the lens of 'practicality' or 'applicability' to determine which mathematical topics are most important. Through the semester, this lens appeared to have been refined from what is applicable in school to what is applicable in life. At the beginning of the semester, he indicated that algebra was the most practical because it "is something that all high school students are going to have to go through at some point" (David interview 1, lines 38–39). David appeared to alter this stance as a result of his study of the concept of area for a class project. This project required him to examine area in depth and consider alternative definitions and possible generalizations of the concept. At the end of the semester David claimed that measurement is the most practical because it is "really easy to relate to real world situations" (David interview 2, line 286).

A second possible modification in David's thinking might be termed a *comprehension of unexpected complexity*. This comprehension is most clear when David recalled a class activity where each student attempted to represent arithmetic fraction operations visually, with the goal of gaining insight into how future students, who are not fluent with a standard algorithm, may think about performing such operations. "Fractions is one of the basic things you learn in math…. That was something I probably would have never… noticed or thought, you know, to see the concept behind" (David interview 2, lines 16, 144–145). This new comprehension seems to be at least partly due to the recognition that teaching a concept involves a level of understanding greater than that typically achieved by students. In addition to possibly gaining a deeper conceptual understanding of fraction operations, there is evidence that David began to generalize the idea of looking deeper in order to “see the concept behind.” He stated, “It’s not just going to be with fractions, obviously, it’s going to be with other concepts that… we just kind of overlook” (David interview 2, lines 148–152).

In both interviews, David emphasized that his reason for becoming a mathematics teacher was first about working with students and secondly about the mathematics. What appeared to differ, however, were his views on what and how mathematics should be taught. David’s comprehension of the unexpected complexity inherent in mathematical topics he understood procedurally developed concurrently with a belief that conceptual understanding should be a primary goal of teaching. Again referencing the work with fractions, he said, “Teaching… is really going into depth about like how to… divide and multiply fractions and what that actually means” (David interview 2, lines 139–141). Additionally, David’s explanations regarding what good teaching looks like became more specific over the course of the semester. In his first interview, David described a good math class as one with “examples on the board, do things like that, but in the end, or maybe the majority of the class time can be spent with students working in groups” (David interview 1, lines 171–173). In this view of teaching, student-led discussion is noticeably absent. In contrast, David referred to the final few weeks of the course as mirroring his ideal classroom: students working on problems in groups and participating in whole class discussion where “what happens is you can get the group that does know it to explain it, and that always helps” (David interview 2, lines 212–213).

There is strong evidence to suggest that David’s views of mathematical proof underwent some revision. At the end of the course he stated, “I used to think of like proof like as a more, like, step-by-step, uh, kind of recipe to follow to prove different things. And now, I kind of see it a little bit more as, um, as using, like, your mathematical knowledge to show something’s true” (David interview 2, lines 462–465). This minor movement in his thinking does not preclude him from later noting that some types of proof have expected structural elements, and, if employing a particular type of proof, one should know and use the traditional elements of that type. Aligning with his current views about mathematics teaching, David stressed that proofs can help students understand mathematical concepts. He pointed to a class activity where several proofs of the same statement were analyzed as one instance that helped to change his thinking in this regard.

*Kylee*

Kylee demonstrated subtle changes in her thinking about doing mathematics, although her view of the nature of mathematics did not change. In both interviews, Kylee stressed her objective view of mathematics, calling it unambiguous in August and, in December, stating that her favorite thing about mathematics was that it can only be interpreted in one way. She does believe that there are multiple ways to solve a problem, but each problem has only one correct answer. The transition with respect to doing mathematics is reflected in her survey responses. Initially, Kylee’s responses indicated that natural mathematical talent and procedures were more important than hard work or using one’s own knowledge to make sense of mathematics, respectively. For example, when asked if she would give up or keep working if a problem took a long time to complete, she leaned toward not finishing the problem (Kylee survey 1, question 16). At the end of the semester she expressed a belief in the value of perseverance: “if you wanna figure it out you can” (Kylee interview 2, lines 215–216). One might hypothesize that the class structure of group investigations and class discussions challenged her thinking and contributed to Kylee's strong belief in hard work. When reflecting on the class she wrote, "I love the open discussions that we have; the thought-provoking questions provided by our instructor(s) are a big part of that" (Kylee week 4 reflection).

Kylee thought her view of teaching changed, although interview and survey evidence provide little support for major changes. At the beginning of the semester, she stated that she knew what to expect in teaching because her parents are both teachers. Student characteristics seemed to play a big part in how she would run her classroom, but she generally remained committed to a more teacher-centered class, expressing a belief that some students need content taught by direct instruction: "I know the 'new-aged' idea of math is to help students understand it on their own, but there are so many things in math that I believe need to be just taught" (Kylee survey 2, question 7). Her comments about what teaching mathematics entails, however, did become more specific over the course of the semester. In her first interview Kylee seemed to focus on general teaching issues such as sharing her love of mathematics, explaining ideas in multiple ways, and helping students stay interested and focused during class. In the second interview, when asked if her thinking had changed, Kylee stated, "it might be a little bit harder than I thought, but not harder in a bad way just a lot more things to think about, … like having to explain things different ways and [being] more prepared for how students may think" (Kylee interview 2, lines 76–80). She pointed to the class activities of fraction operations and generalizing problems as experiences that contributed to changes in her thoughts about teaching. The generalizing activity involved working a number of similar problems in different contexts and determining how all of the problems could be examples of a general problem type. We hypothesize that Kylee's learning experiences during these group activities provided an opportunity for her to think about her views of teaching.

Although Kylee believed that her thinking about proof has changed, she attributed that change to her concurrently taken abstract algebra course. She demonstrated consistency in her overall idea about proof as a means for connecting and building up mathematics: "Proof is like taking ideas you already know and putting them into something, building another idea to make you believe something you already know" (Kylee interview 2, lines 284–287). Despite her emphasis on proof reinforcing facts that are already known, Kylee, over the semester, expanded her view of the purpose of proof to include explaining *why* statements, such as the four color theorem, are true (Kylee survey 2, question 2).

*Helen*

Helen viewed math as a body of knowledge that is waiting to be discovered. This body of knowledge has the characteristic of building upon itself. She also believed that math is not about memorization; it can be applied to anything and that there are many ways to do things in math. Her conception of math with respect to these characteristics seemed to be stable and was expressed in both interviews. Helen believed that her thinking about math changed over the course of the semester. In particular, she stated that she realized that she can have her own way of doing things in math. Previously she had realized that people can do things in math in different ways, but she may not have internalized that she might do things differently from others and still be doing them correctly. She said, "Kylee might do it this way and Bridgett might do it that way but Helen has her own way, too…. their ways are not the only ways that I can do things" (Helen interview 2, lines 245–248). We conclude that although Helen's view of the nature of mathematics did not change, her view of herself in relation to mathematics did.

Helen believed her view of teaching changed over the course of the semester. Precisely how her thinking changed is difficult to determine, but it seems to relate to her conception of group activities. Helen's view of teaching at the beginning of the semester seemed to be that a teacher should be the one presenting the information to the students with the students having the responsibility to ask questions and participate in class. In an attempt to explain the change in her thinking, Helen said, "I've been accustomed to like a teacher standing at the board and lecturing whereas this semester…. it was more of like, you know, let's work as a group, let's figure this out as a group or let's figure this out as a class…. I think this class has really helped because it makes me like maybe want to teach the class … like half a little bit of lecture, half a little bit of like let's do group activities" (Helen interview 2, lines 142–150). Experiencing a class in which students were expected to construct their understandings by interacting with other students around carefully chosen tasks seemed to have influenced Helen's view of the activities that are included in teaching. Helen's survey answers also reflect this change in her view of teaching. Originally, she said the goal of instruction is equally (a) to transmit established mathematical facts and procedures to students and (b) to guide students to construct mathematical knowledge and understanding on their own. At the end of the class, she indicated that the goal of instruction is mostly (b), explaining, "The teacher has to allow the students to try on their own and to guide the students to the information, not tell them the information" (Helen survey 2, question 7).

Helen's view of proof seemed to stay relatively consistent over the course of the semester. She saw the importance of proofs in mathematics but did not like them or feel that she was good at proving. For Helen, a large part of proving was related to understanding – understanding why a mathematical statement is true and understanding what the mathematical statement means. Her response to the survey question 'The main purpose of proof in mathematics is (a) to show the truth of a mathematical proposition or (b) to explain why the statement is true' was 4, (a) and (b) equally, both at the beginning and end of the semester. From her statements and work with proof tasks in the second interview, Helen's clear emphasis was on understanding each step of a proof when validating it. She had difficulty understanding one of the statements within an argument she was examining in the second interview and stated, "if I understand that one step it will probably be really convincing and I'll probably like that proof the most" (lines 790–792). In fact, she did find that argument most convincing and labeled it a proof, but only after the interviewer provided more information that helped to explain that particular part of the argument to her.

## Discussion

As we examined the activity of our three focus participants, we found some similarities in the conceptions held by the students, the kinds of changes or shifts we observed in their conceptions, and the class activities that the students reported as influencing their thinking. Our analysis considered mathematics, proof, and teaching mathematics separately. Our initial hypothesis was that this course, which focused on mathematics, might be influential in relation to mathematics and proof, while the next course, which focuses on pedagogy, might be more influential in terms of teaching. However, all three participants reported changes in their thinking about teaching, while only one suggested that this course influenced his thinking about proof.

David, Kylee, and Helen believe that math is 'out there' and either has already been discovered or is waiting to be discovered. They talked about math as a known entity, although David and Kylee both referred to mathematicians developing new ideas or new mathematics. Helen suggested that each person re-discovers math for himself or herself. David's perspective on what was important about math seemed to broaden, and we found shifts in all three of their perspectives on math in relation to teaching and learning. Helen's view of herself in relation to math shifted from a belief that mathematics problems can be done in multiple ways to a belief that she may personally have a valid method that differs from those of her peers. Kylee shifted from a view that espoused ability as more important in doing math to one that emphasized more sense making and hard work. David saw more complexity in what he had before considered to be simple mathematical ideas. Essentially, David's view of mathematics in relation to the rest of the world changed; Helen's view of herself in relation to mathematics changed; and Kylee revised her view of what it means to do and learn mathematics.

All three focus participants were concurrently enrolled in an abstract algebra course. This proof-intensive course may have influenced their thinking about proof more than our mathematics education course. Kylee directly stated that her thinking about proof changed during the semester, but in response to the abstract algebra course rather than the mathematics education course. David described a change in his thinking about proof over the course of the semester, although we might describe it as a maturing in his views of proof from an initial view of proof as step-by-step to a current view as a more global process dependent on understanding. He conceived of the purpose of proof as to show why a statement is true, although he also talked about proofs as showing that a statement is true. Both Kylee and Helen also spoke about the importance of understanding when writing proofs.

The most interesting shifts during the semester occurred within the three participants' views of teaching mathematics. All three felt that their thinking about teaching changed over the course of the semester, and we believe it was the nature of the class activities that most clearly influenced those changes. David and Helen both changed in their view of group activities. David saw more potential for learning to occur through group activities. Helen professed more willingness to use group activities, and perhaps saw more of an opportunity for learning to occur in them. Even though we do not believe Kylee changed from her view of the job of the teacher as explaining and presenting information to students, Kylee and David both attended more to the complexities of teaching mathematics during their second interviews. Their initial comments about teaching could be applied to teaching almost any subject, but they specifically commented on the complex nature of the knowledge needed for teaching math in their second interviews. Kylee and David both pointed to the fractions activity as influential in their thinking about teaching, while Helen attributed changes in her perspective to her experience as a learner in a class that was, for her, unique. Previous studies have pointed to the notion that teachers are influenced by their own learning experiences as students (Thompson, 1992). This, along with Helen's, and to some extent Kylee's and David's, report of experience suggests that even one course taught in a way that is significantly different from the rest of their experience may allow them to begin to think differently about teaching.

Despite some similarities in views of mathematics, proof, and teaching mathematics, we believe these three participants hold their beliefs in very different manners. Choosing Cooney, Shealy, and Arvold's (1998) vocabulary, we believe we can tentatively describe David's belief structure as reflective connectionist, Kylee's as isolationist, and Helen as a naïve idealist. Though his core beliefs, such as his metric of practicality, inform his subsequent beliefs and actions, David showed a willingness to refine these subsequent beliefs based on reflecting on his experiences and interactions, such as his concept analysis of area and work with the fractions activity. Isolationists generally believe that there is always a right or wrong, a belief Kylee repeatedly expressed in reference to mathematics, and that truth comes from authority figures rather than rationality. Because her parents are both teachers, it is likely that many of Kylee's views on teaching derive from her parents. She does not seem willing to challenge what her parents, as her authority figures, may have told her. Generally, her responses to the survey questions seeking to understand her beliefs about mathematics, teaching, and proof were quite consistent from August to December. Her only major shift concerned her own perseverance in completing mathematics problems. This possible shift in her thinking about her own interactions with mathematics does not seem to have influenced her thinking about teaching others, providing more evidence that she holds her beliefs as an isolationist. Helen seems to be a naïve idealist, wanting to bring the new ideas that arose from her experiences in class into agreement with her original ideas based on her classes with her favorite high school teacher, leaving her with the conclusion that she would teach half with lecture, half with group activities. Rather than making choices between teaching methods or reconciling differences between her original views and those arising from new experiences, Helen embraced all as good.

## Implications

The small shifts in conceptions that we saw over the course of only one semester suggest that experiencing a course taught differently may influence students' beliefs about teaching and learning. Although their beliefs about the nature of mathematics and the role of proof in mathematics did not change, each participant's views of some aspect of mathematics and teaching changed. Carefully designed mathematics education courses that provide PSMTs with experiences that mirror the ways that they will be expected to teach may allow them to reconsider or extend their initial beliefs about teaching mathematics.

We initially hypothesized that this course would provoke changes in the PSMTs' beliefs about proof based on comments made by students who had completed the course in previous semesters. Since our participants did not seem to experience comparable change, we examined our course activities, comparing them to previous semesters. We concluded that we did not address proof and proving as explicitly as in previous semesters. This leads us to suggest that more explicit attention to proof might be necessary to provoke students to reconsider their conceptions of proof. Given the small shifts in conceptions of proof in this semester, it may be necessary to attend to proof much earlier in teacher preparation programs.

The results reported here tell only part of the story. At this writing, data are still being collected about the PSMTs' conceptions of math, proof, and teaching. We describe the changes that we saw as shifts in thinking, and we will continue to examine how stable these shifts are, given their individual belief structures, during another mathematics education class and their student teaching practicum.

# PROMOTING EFFECTIVE GRAPHING CALCULATOR USE: REVEALING UNINTENTIONAL PRIVILEGING

Allison W. McCulloch
North Carolina State University
allison_mcculloch@ncsu.edu

Matthew P. Campbell
North Carolina State University
mpcampbell@gmail.com

James P. Hedges
North Carolina State University
james.p.hedges@gmail.com

*This paper reports on an exploratory case study aimed to identify the ways in which an algebra one teacher privileged the graphing calculator and the ways in which her goals were interpreted and ultimately practiced by her students. The study employed an adaptation of an existing framework (Pierce & Stacey, 2002, 2004) highlighting the mathematical, technical, and personal aspects of graphing calculator use. The authors suggest the consideration of each of these aspects as important for future research on the complex issue of privileging in the promotion of graphing calculator use.*

## Background

Graphing calculators are a mainstay in the U.S. high school mathematics curriculum and because of that considerable research has been done on the effect of graphing calculators in the math classroom (Ellington, 2003; Burrill et al., 2003). In a national survey completed in 2000, it was revealed that over 80% of high school mathematics teachers in the United States reported that they used graphing calculators in their classrooms (Weiss, Banilower, & Smith, 2001) and due to the current state of standardized tests in our country that percentage has likely risen in the last nine years. Given the pervasiveness of graphing calculators in the culture of our high school mathematics classrooms, it is necessary to understand the ways in which and the reasons why students incorporate them as tools in their mathematics learning and problem solving.

Studies have shown that the ways in which technology is used in the context of a mathematics classroom are formed by a shared understanding about the appropriate modes of use that are developed over time by the members of the classroom community, the teacher and the students (Doerr & Zangor, 2000; Goos et al, 2003; Kendal & Stacey, 2001; McCulloch, in press; Pierce & Stacey, 2004). Of these studies, those that aimed to understand and describe effective graphing calculator use have largely been set solely in the context of the classroom, failing to reach beyond and examine how promotion in the classroom might impact student decision making with regards to their graphing calculator use in independent situations (Burrill et al., 2003). Furthermore, the classrooms in which these studies are typically situated are the equivalent of pre-calculus or calculus classes (Burrill et al., 2003). However, since most statewide algebra exams require the use of graphing calculators many students first encounter them in algebra one. As such, it is important to examine how effective use is promoted, understood, and then applied in independent situations in these classrooms.

The study described here was set in a year long algebra one class in a large urban high school. It is different than previous work in that we look at an algebra one teacher and her students, both in and out of the classroom. This particular teacher incorporates graphing calculators regularly because she wants her students to become “effective graphing calculator users”. We aim to identify the aspects of graphing calculator use that this teacher deems consistent with effective graphing calculator use, the aspects that she actually promotes in her classroom practice, and the ways in which her goals are interpreted and ultimately practiced by her students in independent situations.

## Framework

Pierce and Stacey (2002, 2004) have offered a series of frameworks for analyzing both the cognitive and affective aspects of effective use of calculators with computer algebra systems (CAS). They have identified four aspects of CAS use: mechanical, technical, personal, and mathematical. The mechanical aspect refers to knowledge of the actual calculator hardware. The mathematical aspect refers to the mathematical knowledge that is drawn upon during problem solving. These two aspects act as the extremes in a continuum of knowledge that students must draw upon when using CAS. The interaction between the mechanical and mathematical aspects is what Pierce and Stacey (2004) refer to as the technical aspect. The technical aspect is synonymous with knowledge of the machine software, meaning it is the knowledge of how to get the machine to complete the mathematical actions you want it to carry out. For example, to solve an equation using a table requires both the mathematical knowledge of how a table could be used to determine a solution and the mechanical knowledge of how to create a table on the CAS. Finally, the personal aspect refers to attitudes toward CAS use and judicious decisions regarding its use. It is through the personal aspect that decisions regarding CAS use are made. Since the tools available on graphing calculators are a subset of the tools available on CAS, it is appropriate to draw upon Pierce and Stacey’s work to frame this study.

The purpose of this study was to begin to understand the intricate ways in which the promotion of graphing calculator use in the classroom might impact students’ use in independent situations. We aim to go beyond the generalities of attitudes toward graphing calculator use and look carefully at the actions and words associated with its use by both the teacher and the students, in and out of the classroom. Specifically we aim to examine interaction between the mathematical, technical, and personal aspects of graphing calculator promotion and usage. As such, Pierce and Stacey’s (2004) framework for effective use of CAS was adapted for graphing calculator use. This framework captures both the technical and personal aspects of graphing calculator use (see table 1). Pierce and Stacey (2002) have also explicated a framework for the mathematical aspect of CAS and graphing calculator use, which they refer to as *algebraic insight*. The algebraic insight framework identifies the “part of symbol sense that is most affected by the availability of having CAS” (p. 622) (i.e. algebraic expectation and ability to link representations). Given the context of this study, the algebraic insight framework is an appropriate lens through which we can view the mathematical aspect of graphing calculator promotion and usage.

Table 1. *Framework for aspects of effective use of graphing calculators**

| Aspects | Elements | Common Instances |
|---|---|---|
| 1.Mathematical (Algebraic Insight) | 1.1 Recognition of conventions and basic properties | 1.1.1 Know meaning of symbols |
| | | 1.1.2 Know order of operations |
| | | 1.1.3 Know properties of operations |
| | 1.2 Identification of structure | 1.2.1 Identify objects |
| | | 1.2.2 Identify strategic groups of components |
| | | 1.2.3 Recognize simple factors |
| | 1.3 Identification of key features | 1.3.1 Identify form |
| | | 1.3.2 Identify dominant term |
| | | 1.3.3 Link form to solution type |
| | 1.4 Linking of symbolic and graphic representations | 1.4.1 Link form to shape |
| | | 1.4.2 Link key features to likely position |
| | | 1.4.3 Link key features to intercepts and asymptotes |
| | 1.5 Linking of symbolic and numeric representations | 1.5.1 Link number patterns or type to form |
| | | 1.5.2 Link key features to suitable increment for table |
| | | 1.5.3 Link key features to critical intervals of table |
| 2. Technical | 2.1 Fluent use of program syntax | 2.1.1 Enter syntax correctly |
| | | 2.1.2 Use a sequence of commands and menus proficiently |
| | 2.2 Ability to systematically change representations | 2.2.1 Plot a graph from a rule and vise versa |
| | | 2.2.2 Plot a graph from a table and vise versa |
| | | 2.2.3 Create table from a rule or vise versa |
| | 2.3 Ability to interpret GC output | 2.3.1 Locate required results |
| | | 2.3.2 Interpret symbolic GC output as conventional mathematics |
| | | 2.3.3 Sketch graphs from GC plots |
| | | 2.3.4 Interpret GC non-response |
| 3. Personal | 3.1 Positive Attitude | 3.1.1 Value GC availability for doing mathematics |
| | | 3.1.2 Value GC availability for learning mathematics |
| | 3.2 Judicious Use of GC | 3.2.1 Use GC in a strategic manner |
| | | 3.2.2 Discriminate in functional use of GC |
| | | 3.2.3 Undertake pedagogical use of GC |

*Adapted from Pierce and Stacey (2002, 2004)

## Methodology

The focus of this study was a single high school algebra one class, both the teacher and the students. Since the purpose was to gain insight from all members of the classroom community about how graphing calculator use was being promoted and actually used, data was collected from both the teacher and the students before, during and after the unit of study.

*Data Collection*

The classroom teacher, Ms. Kersee (a pseudonym) identified a unit of study (solving equations) that she would be teaching during the fall semester and in which she planned to integrate the graphing calculator. The class was video taped every day during the unit (13 days). In addition to classroom video, both survey and interview data were collected from Ms. Kersee and each of her students. Ms. Kersee was interviewed both prior to and upon completion of the instructional unit. The purpose of these interviews was to gain an understanding of the ways in which she planned to promote graphing calculator use (prior) and believes she did promote its use. Students' perceptions of her promotion of the graphing calculator and their actual use were captured using both survey and interview data. A survey designed to identify how each student typically used the graphing calculator, their comfort level with different modes of the graphing calculator, and their perceptions of the teachers promotion of graphing calculator use was administered both prior to and after the instructional unit. Finally, the students participated in an interview at the completion of the unit, a portion of which was task-based. The student interviews were intended to provide insight into how and why the students used their graphing calculators in private situations and how consistent their use was to the ways in which they perceived use was promoted in their class. All interviews were both video and audio recorded. Video of the graphing calculator screen was also captured when calculators were used during the interview process.

*Participants*

Ms. Kersee is in her 14th year of teaching high school mathematics. She has spent her entire career at one high school, a large urban high school in the south eastern United States. During her 14 years she has taught at least one section of some version of algebra one every year. She was asked to participate in this study based on the recommendation of school administrators as a “very good teacher” that is known for “using technology well” in her classes (She was honored as teacher of the year during the 2007-2008 school year). Ms. Kersee has a B.A. in secondary mathematics education and is currently pursuing a master’s degree in educational leadership.

The class at the focus of this study is an algebra one course that meets 90 minutes each day for an entire school year. The class is comprised of 21 students, all of whom had been unsuccessful in a previous algebra course. Due to excessive absences only 17 of the students (8 female, 9 male; 15 Black American, 1 Mexican American, 1 White American) completed this study. These include 2 freshman, 7 sophomores, 6 juniors, and 2 seniors. A special programs teacher was in the classroom full-time due to the number of students who have instructional and testing modifications related to learning disabilities or other exceptionalities. Ms. Kersee expresses very firm beliefs on how students in such a class need to learn mathematics. Beyond the development of an environment of high standards and accountability, Ms. Kersee looks to incorporate new teaching methods that incorporate different learning styles and highlight different methods of solution.

## Observations and Preliminary Inferences

Ms. Kersee labels herself as being committed to professional development, a claim that is verified through her actions as a professional. She has been self-motivated to learn new methods of using calculators, specifically graphing calculators, in the classroom. While she admittedly does not know all of the instructional capabilities of the graphing calculator, she continues to search for new ideas. Without any technical, instructional, or financial support from her school or district, she explores Internet tools and other materials offered by Texas Instruments (TI) or other publishers. In the place of costly workshops and conferences, Ms. Kersee has taught herself how to use the graphing calculator through what she refers to as “playing around.” In order for her students to benefit from what she feels is a powerful tool and to address a shortage of available calculators in the school, Ms. Kersee wrote two grants to obtain a class set of TI-84 calculators, which students use in class and are allowed to check out to bring home in certain situations.

Ms. Kersee incorporates the graphing calculator into her algebra one course because of the value she places on effective calculator use as a benefit on state and in-class tests. She has also observed the positive impact of the calculator’s availability on students’ confidence. In the instructional unit in which this study was situated (solving equations), Ms. Kersee identified the use of tables to solve equations as a skill that she intended to promote as a solution method that was as legitimate as using “by hand” methods. Indeed, she stated that she hoped her students that struggled with computational errors would use tables instead of “by hand” methods on both their classroom based and standardized tests.

For the purposes of this paper we have chosen to focus on a very small sliver of Pierce and Stacey’s (2002, 2004) adapted framework, one particular technical aspect (constructing a table from a rule) and the mathematical and personal aspects related to it from both the teacher's and the students’ points of view. Specifically, we focus on Ms. Kersee’s goal of having her students learn to use graphing calculator produced tables to solve equations, how she actually carried out this goal in her classroom, and some preliminary observations with respect to how her words and actions influenced student decision making regarding graphing calculator use in independent situations.

*Graphing Calculator Promotion in the Classroom*

Ms. Kersee introduced the use of tables to solve equations on the tenth day of the instructional unit. The previous nine days had been focused on solving one and two step equations, special equations (e.g. identity and no solution), solving literal equations, and word problems. This, the tenth day, was the day before the unit test and Ms. Kersee’s goal was to provide her students with another method for solving equations. She opened the class by stating, “Today I’m going to show you another way to solve equations.” She began by using a large poster that displays the TI-84 plus calculator, on which she pointed to the buttons that would be used in the lesson. After identifying these keys on the graphing calculator Ms. Kersee put an example problem on the board, 2x - 3 = x + 4, and solved it "algebraically." Next, while using the overhead display of her own graphing calculator, she instructed the students to enter the left and right side of the equation into $Y_1$ and $Y_2$, respectively. She reminded the students that the solution of the equation will be "the X that makes it a true statement." To find the solution, Ms. Kersee told the students to "search until our $Y_1$ and our $Y_2$ is the same." Then she identified x = 7 as the solution to this equation.

On the board, Ms. Kersee checked the solution found on the calculator by substitution, and reiterated that the table process is "another way to solve an equation." The students were then given four equations to try to solve on their own ($7-2x=x-14$ , $2(4-2r)=-2(r+5)$ , $(2/3)(6x+3)=4x+2$ , and $3.2h=9.3-3.2h$ ). After the students worked the examples independently, she returned to the board and "checked" solutions given to her by the students "algebraically" by hand, without using or referring to the table. After finishing the second equation, a student asked Ms. Kersee why she did not "plug in" the solution to check. She responded, "To check your answer, you plug it in. I was doing it algebraically to show if you work the steps, you still get the same answer." After they had gone over all four examples, Ms. Kersee assigned a review for the test the following day. No mention of the graphing calculator was made when discussing the review assignment.

The following day, as they went over the review assignment all problems were worked out on the board and no mention was made of the new solving method. However, as Ms. Kersee passed out the tests she reminded the students that “when you are solving equations you can use any method. And don’t forget you can do that to check.” Further, she explained, “If you use your calculator to solve a problem on your test, you don't have to show any work, just make sure you write down that you used your calculator so I know where you're getting your answer from."

*Student Graphing Calculator Use*

Though Ms. Kersee stated that the students were free to use any method on any problem, preliminary analysis indicates that the students did not all interpret her goals as she intended. In some cases, the students did not understand how the new method of solving, using the tables, could even be used to meet those goals. Though there are many, we have chosen to highlight two examples of this misinterpretation of goals here: (1) the interpretation that tables are to be used to check, not to solve, and (2) the interpretation that tables can only be used when solving an equation with variables on both sides.

*Tables used to check, not solve.* Though Ms. Kersee introduced the table solving process as another method to solve, she only used it to solve one equation with the class. She then gave the students four examples to try on their own, when they came back as a whole group to share their solutions, she checked them by working the problems out by hand on the board. These actions have been interpreted by some students as a message that this process should be used to check, not solve equations. For example, when she was asked how she thinks Ms. Kersee wanted her to use her graphing calculator in this chapter one young lady responded, "Actually, I mean, she would have wanted us to use it. But, I think she ... I mean, she would want us to use it a lot but like maybe on problems that she went over with us to tell us to use it. So, if it wasn't the problem she went over that said use calculator, I guess she wouldn't really expect us to use the calculator." She went on to share a problem on her test for which she used a table. She explained, "I did it by hand and then by the tables, to check…how she showed us." Similarly, a young man shared that he used the tables to check his work as well. When discussing his test he said, "I used these (points to table) to see if it is right." Later when he was asked to solve a problem he first did it by hand and then used his graphing calculator to check his solution (see figure 1 below). The conversation follows:

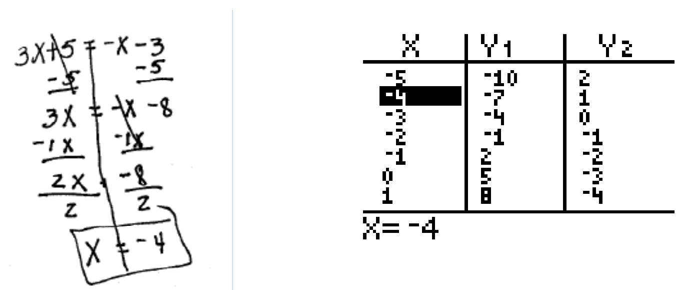

*Figure 1.* Student's "by hand" work and corresponding table used to "check".

| | |
|---|---|
| Interviewer: | Okay. So is your answer correct? |
| Student: | It [the graphing calculator] says it wrong. |
| Interviewer: | It says it's wrong, huh? Can you tell me what the answer should be? |
| Student: | Negative seven, negative seven. |
| Interviewer: | But, so that tells you that it's wrong, since it says negative seven and one, right? |
| Student: | Yeah. |

Interviewer: So when you look through here, can you tell what the answer is supposed to be? It's not negative four.
Student: Yeah.
Interviewer: Can you tell what it is?
Student: Uh, no.

This particular student not only had interpreted that the table was intended to check his work, but even though the solution was in his viewing screen he did not know how to use the table to determine the solution to the equation.

*Tables can only be used when solving equations with variables on both sides*. As described above, in her introduction of using tables to solve equations Ms. Kersee worked one example with the students using the overhead graphing calculator, which was followed by having them try four examples on their own. All five of these examples were of similar form; each had variables on both sides of the equal sign. In more than one case we saw that this choice of examples influenced students' beliefs about the types of problems for which using graphing calculator produced tables are either appropriate or that Ms. Kersee would deem valuable. For example, one student was explaining how he used his graphing calculator to solve a set of tasks. The interviewer noticed that he did not use the table on an equation that had a constant on the right hand side, but started to use his graphing calculator when their were variables on both sides. The interviewer inquired about this decision. Their conversation follows:

Interviewer: Okay, how come, this one you decided to use the table? What's different about these two problems?
Student: Oh, because this one here, when it looks like that, I can't put it in the table
Interviewer: When it's like that?
Student: Yeah.
Interviewer: What do you mean…
Student: Like, for, like, two equate--one equation's one side, one equation one side.
Interviewer: Oh, so there's a variable on both sides...
Student: Yeah.
Interviewer: ...and that's why you used the table. Okay. I understand. Can you use the table on a problem like this one, too? [pointing to an equation with a constant on the right]
Student: No you can't.

Due to the examples used in class this particular student either didn't know how enter an equation with a constant on one side into the graphing calculator to use a table, didn't think it was possible to do, or didn't think his teacher wanted him to use it on those types of problems. Regardless, his misinterpretation about when it is appropriate or even possible to use tables to solve equations was influenced by the examples presented in class.

## Discussion

Previous research has shown that students' graphing calculator use is influenced by the ways in which it is privileged in the classroom (e.g. Kendal and Stacey, 2001; McCulloch, in press). The preliminary results of this study support these claims, but also point to the complexity of the issue of privileging. Ms. Kersee's language, both in interviews and in classroom observations, indicates that she values the graphing calculator as a tool with which one can solve equations. Her intention was to send a message to her students that graphing calculator solving methods are as valued in her class as by hand methods. However, it is clear that the message that she intended to send to her students regarding her goals for them was not the message they received. It appears that the examples she chose and the way in which she discussed them might have influenced the ways in which her students interpreted her goals.

Though the focus of this paper was narrow, one particular technical aspect and the mathematical and personal aspects related to it, it is apparent that in order to build an understanding of how teachers actions influence the development of effective graphing calculator users, we must look at all three of these aspects together. If we had focused on just the technical aspect of how to actually create at table we would have missed how Ms. Kersee's value statements regarding using the graphing calculator to check might have been interpreted by her students. Furthermore, had we not focused on the mathematical aspect of interpreting the tables we might have missed the fact that some students interpreted that the tables were only appropriate to use on equations with variables on both sides. These findings bring about an important feature of the methodology for this study, data collection both in and out of the classroom for both the teacher and the students. Future research that aims to describe student decisions regarding technology use should include data from all angles in order to construct a complete picture.

It appears that the personal aspect of graphing calculator use is an important one. Its role was evident in every decision made by both Ms. Kersee and her students. Pierce and Stacey describe the personal aspect of graphing calculator use to include attitude toward graphing calculator availability and judicious use of the graphing calculator. However, based on both observations here and previous research (e.g. McCulloch, in press) it appears that there is more at work within the personal aspect. It seems as if the personal aspect includes not only attitudes, but also values, beliefs and even emotions and not only of one's self, but those perceived of others as well (e.g. students perceived Ms. Kersee's values). To better understand student decision-making regarding technology use future research should be designed to further operationalize the personal aspect and its relationship to the technical and mathematical aspects.

The overarching purpose of this study was to identify the aspects of graphing calculator use that this teacher deems consistent with effective graphing calculator use, the aspects that she actually promotes in her classroom practice, and the ways in which her goals are interpreted and ultimately practiced by her students in independent situations. This case provides evidence that issues of privilege with regards to technology use are complex, often misinterpreted, and in need of further research.

## Acknowledgements

We would like to thank the Ms. Kersee and her students for so generously offering their time for participation in this project.

*The objective of this research is to gain knowledge about some of the beliefs activated within the framework of the mathematical-argumentation processes that arise in the classroom setting. We are interested in analyzing the evolution of those beliefs and explaining them in view of the possible reasons subjects have for holding those beliefs, their personal motives and the contexts within which the beliefs take shape. In this research our interest lays in discovering the beliefs that arise spontaneously in class, which is the reason why the research was undertaken in the natural classroom scenario, where researchers limited their participation solely to observation.*

## Interpretative Framework

For purposes of this paper, the researchers considered that:

- The beliefs of a subject S are representations (Goldin, 2002) that possess an apophantical function (Duval, p. 98, 1999) to which S associates:
  A degree of probability (0,1] to their truth (Villoro, 2002)
  And a degree of personal relevance (that can start at zero), which relates to the importance the subject attaches to the belief, in turn producing in the subject a conative, affective, interest or expectations-related charge (Villoro, 2002; Schoenfeld, 1992, p. 358).
- The beliefs lead the individual holding them to respond consistently in favor of the belief held under different circumstances (cf. Villoro, 2002. Schoenfeld, 1992.). This condition enables assuming, with fair well-founded basis, that behind a regular or uniform behavior practice lies a guiding belief –or system of beliefs.

The truth or verisimilitude of a belief may be based on reasons—and in this case the subject is said to be convinced to a certain extent of that truth, yet it can also or only be based on affective aspects or on the interests of the subject holding the beliefs. In the latter case, the subject’s belief is said to be based on his/her ‘motives’ (Villoro, 2002).

Unlike formal logic, in the domain of beliefs the veracity load is not based on dichotomic principles. The subject professing a belief can associate to that belief a truth likelihood that ranges within a continuum from complete certainty of its veracity (“belief in the strong sense”) to uncertainty (“belief in the weak sense”) (Villoro, 2002).

The types of beliefs present in mathematics classes are (Schoenfeld, 1992; Thompson, 1992): (a) beliefs and value judgments of students and teachers concerning their participation in classroom mathematics activities, with the how and why they participate; foremost here are those related to teaching and learning; (b) Meta-mathematical beliefs; foremost among which are those that deal with the ways of justifying in mathematics, validation criteria and the semiotic systems involved; (c) ‘Mathematical beliefs’; foremost are beliefs in the truth or verisimilitude of the mathematical statements and those dealing with the validity or plausibility of a mathematical argument (in the broadest sense of the terms) (Goldin, 2002).

## Methodology and Data Collection

This is an ethnographic case study of the instrumental type (Stake, 1995) and of a longitudinal nature, undertaken of three primary education centers (two public schools and one private school) in Mexico City. Data collection and interpretation consisted of the actions listed below, although such actions were not necessarily carried out sequentially:

1. Design and application, within the context of a pilot study, of a school-type test for third and sixth grade students, dealing with proportionality problems and of a questionnaire for their teachers;
2. Interviews of the teachers from the three schools, dealing with their beliefs concerning mathematics and its teaching;
3. Observation of sixth grade classes on the subject of proportionality (ten observations of one teacher from each school, undertaken throughout the school year). The classes were video-taped using two video-cameras, one of which focused on the teacher and the other on the students;
4. Transcription of all video tapes taken; and
5. Analysis of the data collected in the video tapes as compared with the data from written records. Given the nature of the study, project researchers limited their classroom involvement solely to observation. During the classes observed, the teacher usually uses the official mathematics textbook as a guide. The didactic proposal of such official mathematics textbooks focuses on solving exercises and problems. Consequently in this study, a classroom argumentation consists of a process of social interactivity among teacher and students, in which reasons are presented in order to sustain the solution of problems raised in the classroom.

## Interpretation and Results

For this paper, the authors chose a single episode of one of the classes observed (Lesson 80). The episode corresponds to the participation of a student (Mar) who stands out, not just because of the mathematical quality of her interventions, but because of the strength of her beliefs and the determination with which she attempts to convince the teacher and her classmates of her ideas. Below readers will find a chart analysis that highlights the most significant steps in Mar's participation and in her interaction with her teacher (T). In italics, readers will find the possible beliefs and the epistemic states (certainty, presumption, conviction) that are eventually associated with those beliefs. The Annex to this paper contains the text of the exercise and several lines (L.) that are representative of the extract transcribed.

---

- *T:* "How can we prove who swam the fastest?" *Mar*: "By proportionality" (L.14-20)

The T asks about the strategy and the student (Mar) answers.

Mar's belief that proportionality is the method that must be used to solve the problem.

- Preparation of Table 2 (L. 23)

Mar constructs a proportionality table. She uses the distances covered by the competitors as her point of departure and calculates the times that Be would have registered 'had he swum the same as' –or at the same speed as- when he swam the 50 meters.

Table 2 provides Mar with the elements needed for her to know that she stands on more solid ground.

The logic behind Mar's reasoning is unknown, but several feasible options exist:
i. Solution and confirmation argument. In this case Mar has a clear strategy, but initially she does not know what the solution will be. To find the solution, she goes to the blackboard and begins to analyze the simplest case –that of Be, because the distance he swam is divisible by the rest of the distances, so constructing the proportionality table is easy. This is a feasible option given that in the video she does not initially propose a result. Also the teacher has asked for a strategy, which is what Mar provided.
With her participation, she seeks to convince the T and the group of the method used.
ii. Presumption and confirmation argument. Presupposes a conclusion based on a few quick calculations that Mar carried out prior to her presentation at the blackboard, where she proves that her presumption is correct.
She has confidence in the method and is to a degree certain of the answer.
iii. Argument dealing with a hunch or intuition. This appears to be the least feasible option because in the video Mar is doing operations while the T is posing the initial questions.
In this possible case, Mar is persuaded of the solution and has confidence in the method.

- *Mar*: "… in order to find … the amount of time it took them". (L. 29-33).

Mar compares pairs of reasons possessed by a common term (distance), which reduces the problem to a linear comparison of two amounts (times). Her idea of speed consists of 'the one who swam the same distance in the least amount of time'. There does not seem to be any relative thought, rather it is absolute based on additive procedures.
Mar appears convinced of her procedure and of her interpretation of speed in the register. It is likely that her conviction and decision to externalize it increased after having drawn the table.
Mar conveys her beliefs about her role as a student and about self-confidence.

- *Teacher*: "I think the amount is wrong …" (L. 34-52).

Some of the possible explanations for the T's behavior include:
i. The T had another type of strategy in mind. This option is fairly likely given that the T showed signs throughout the entire course of her preference for general, parsimonious and symbolic strategies. The manner in which she closes the solution (L 65) and the way in which she later solves the exercise (in Solution 2) are also evidence in favor of the assumption. (L. 64-68).
ii. The T did not understand Mar's strategy. Possibly because she was distracted thinking about another way of approaching the problem (in the video, she is seen to do calculations in her book while Mar is at the blackboard) or because Mar did not explicitly state her conclusion.
Nonetheless one must admit that the T truly masters this type of strategy, in addition to the fact that it is precisely the type of strategy recommended by the textbook for the exercise. Hence her distraction was probably the result of her having other plans and expecting another type of intervention from her students.
The T makes it possible for observers to perceive some of her meta-mathematical beliefs ('the more general it is, the more mathematical it is' (Hersh, 1993)) and some of her ideas about the teaching of mathematics. Her intervention also reveals the techniques of the maieutics art that she resorts to and the underlying credences.

- *Mar*: "It's just that … you didn't understand me" (L. 58).

Perhaps the T's attitude in L (34-56) served to spur Mar on to reinforce her arguments, explain her conclusion (L 62) and increase the certainty of her beliefs.
Mar gives indications—by way of persuasive rhetorical resources—of how sure she is of her

belief in the result found and the method used. Her ideas about her role as a student and the role of her T can be perceived. She proceeds in response to her own interpretation of the T's behavior: if the strategy is not understood, then it has to be clarified.

- *Mar*: "I think Be was faster, so if we have Be taking 50 seconds for 50 meters, then he would have swum differently …" (L. 58-62).

Mar allows observers to more clearly see the logical structure of her procedure: She makes an assumption ('Be is the fastest, based on certain mathematical elements) and verifies that it is correct on the blackboard. This is a presumption and confirmation argument (possibility ii, previously alluded to). Mar's argument is to a certain extent logically complex, given that she applies –implicitly- an exhaustive reasoning of the type:

(dC) If B(dC) then B>C,

which can be translated as

For all distances (d) covered by Competitors (C), if B had swum them all at the same speed as he did for the 50 meters, he would have swum faster than anyone else.

In solving school-type problems, Mar is both intuitive and talented which is why she knows—perhaps implicitly—that the simplest assumptions generally work, as is the case in this exercise. Her reasoning appears to enhance her certainty that her conclusion is indeed correct, that the method used is valid and pertinent, and she attempts to share her conviction with the T and her classmates.

- *T*: "¿… how many seconds did it take A…?" (L. 64).

The T does not institutionalize Mar's solution and her question suggests a change of strategy (her question cannot be answered using the strategy proposed by Mar). She thus prompts for a new manner of solving the problem (based on quotient d/t) (L. 64-66).

The T calls on her authority and the obligations she feels she must honor as a teacher: to lead her students to 'discover' methods and processes they would be unable to arrive at alone. Once again she demonstrates her disposition for the pedagogical resources offered in maieutics.

*Chart 1*. Comments on student's and teacher's interactions.

Chart 1 identifies several of the student's beliefs, as follows: inter alia, her confidence in the conclusion of the exercise and in the validity of the solution (mathematical beliefs), and her firm conviction that the 'table' strategy is the most suitable for solving the problem (meta-mathematical belief). Observers can also distinguish her ideas regarding her role as a student, the role of the teacher and self-referred beliefs.

As regards the teacher, one can perceive her certainty about the teaching of mathematics based on usage of general formulae, a certainty which she underscored throughout the course and which appears to orient her standardized didactic practices. Also of note to observers was her confidence in the maieutics of Socrates, as revealed in her carrying out of daily routine pedagogical duties.

The beliefs highlighted in the extract chosen can be explained from the standpoint of different levels. One takes into account the possible reasons that led the subject to believe. Another considers a person's own motives, interests and preferences. While yet another looks to the socio-cultural context within which such credences were generated, in other words the background and circumstances that led a person to believe (cf. Villoro, 2002). The foregoing concepts are used below in analyzing the beliefs identified.

*Mar's Beliefs*

Toward the end of her intervention, Mar gave indications that she had confidence in the conclusion and in the value of her procedure. It is plausible to think that her belief underwent a change as the solution process evolved. She may have had a hunch at the beginning that then became a presumption as a result of some of the calculations she did in her head. The student ended up providing a high degree of probable truth to the result and her certainty was substantiated by firm and conclusive—for her—reasons, although her reasons did not receive the inter-subjective backing of her Teacher. The fact that she was so very sure of the veracity of her conclusion could also have been derived from the treatment and objectification that she undertook in one of the registers (tabular) that she is so certain of (personal motives) and from the fact that the procedures she used are usually recommended in the Textbook (context).

Mar showed that she was sure of the truth of the conclusion. However, it is very much possible that that was not the vector of her argument, rather her certainty was about the pertinence of the strategy she chose ('table'). What convinces her of the strategy and why does it convince her?

Several reasons can be cited, to wit: that she has proof of reliability or that she has evidence that the exercises in the textbook can usually be correctly solved using the same type of strategy; or those relative to the characteristics of the method per se in which, as in informal procedures, it is possible to signify each step and operation involved, which makes it possible to objectify the mathematical notions and obtain treatments imbued with meaning and sense.

Surely Mar bases her certainties on personal motives and intentions as well. Throughout the course her special disposition for and liking of tabular registers was apparent, and this denotes the importance and appreciation she attaches to that method.

Mar's belief in the strategy could also have been induced by the classroom context. In that context the textbook affords a prominent role to that particular solution method, as did Mar's own teacher in the previous course (a teacher well respected by Mar, her classmates and the entire school). Moreover tables and tabular registers used as a means of problem solving are well known by all her classmates, thus Mar can share the method with them.

*The Teacher's Beliefs*

The teacher's scarce acceptance of Mar's proposal and the emphatic support she attached to the introduction of quotient (s/t) as the means to solve the problem analyzed (L.64-66) does not seem to be either circumstantial or casual. As previously stated the Teacher showed (at every opportunity that we observed) a marked interest in use of general rules and mathematics laws, even taking her own initiative to introduce them. Through her attitude during Mar's participation—where Mar resorts to what is in the teacher's opinion a particular, ad hoc, hypothetical and inconclusive argument—the Teacher deliberately or involuntarily conveys to her students that she is firmly convinced of her own didactics and of her conception of mathematics focused on use and mastery of general mathematics rules. Surely, the teacher has her own reasons that support this didactic position (symbolic formulae are efficient and universal; they work in practice and are easy to apply and learn). It is also very likely that her reasons are driven by her motives, values and intentions (that her students go beyond that called for in the official curriculum, that they get better grades in official evaluations or that algebra pose less of a problem for them), and by aspects having to do with the context (the school's plans may place a high priority on this type of strategy, or that may be the way she learned mathematics).

It is quite clear from that previously stated that the disagreements between the student and her teacher have to do with the strategy chosen and the beliefs underlying that choice. Teacher and student appear to have their own reasons and motives for supporting the ideas of which they are convinced, and what was witnessed in class was the asymmetrical struggle between them, each aiming to implement her own ideas.

During the confrontation, meta-mathematical meanings and beliefs were constructed concerning how to proceed in mathematics, how to go about expressing a justification and what type of register should be used. Another belief that was built has to do with who makes the decisions in class. There is little doubt that the students took note of all of this and constructed their personal interpretations based on their own belief nodes and networks. As part of an accommodation process, the reference frameworks will be changed by the experiences filtered through the frameworks themselves.

## Final Remarks

The interpretative belief model introduced in this paper is supported by the epistemological position that considers beliefs to be a part of a subject's stock of truths. That is to say, that knowledge is a proper sub-set of a subject's beliefs. The model is furthermore supported by a didactic position according to which in a successful learning model as students progress they associate meaningful mathematical deeds with levels of confidence and certainty that increase in line with the generality and conclusiveness of the reasons to which they have access (epistemically).

The interpretative framework used makes it possible to identify different types of beliefs that arise in the classroom setting, focusing on mathematical and meta-mathematical beliefs. The framework also made it possible to analyze changes of epistemic states and values as they are conveyed by the actors with regard to those beliefs. In the class being studied, in particular terms, the model enabled interpreting the evolution of a single mathematical belief of one student, and her confrontation with the teacher's position.

Of interest in the study are questions such as precisely what are students convinced of in mathematics class? How are they convinced of it? And what roles are played by conviction and certainty? In the case analyzed, one student seeks with great determination to persuade her teacher of the pertinence of a particular strategy for solving an exercise, showing that not all students can be dissuaded easily, contrary to that stated by Hersh (1993). Her case also provides evidence in favor of another point. Although arguments must be constructed in the mathematics classroom to convince people of the truth of conclusions and to explain them (consistent with that reported by De Villiers (1991) and as occurs with the experts proof (Hanna, 1996)), there is also a desire to convince people of other issues, such as the suitability of a particular type of register or of a method to solve problems (as also occurs with expert rigor criteria (Tymoczko, 1986).

## Annex. Lesson 80, Episode 2, Solution 1

1. *T:* Who swam the fastest? (repeats several times)
2. *A:* Beto … Catalina … Beto …
(*The Ss, and Mar* in particular, do operations in their notebooks)

| | Distancia | Tiempo | | |
|---|---|---|---|---|
| | | Horas | min | seg |
| Am | 100 m. | 0 | 2 | 0 |
| Be | 50 m. | 0 | 0 | 50 |
| Ca | 150 m. | 0 | 2 | 51 |
| Da | 1500 m. | 0 | 40 | 0 |

(Table 1. Textbook)

10. *T:* Can we know just like that?
14. How can we prove who swam the fastest?
17. *Mar*: By proportionality …
19. *Mar*: To see if, for example, 50 m. were covered in 50 sec., for 100 they would have had to take (pause) one minute and forty seconds.
20. *T*: You're relating distances to times, right?

| m. | min | seg |
|---|---|---|
| 50 metros | | 50 seg |
| 100 | 1 min | 40 seg |
| 150 metros | 2 min. | 30 seg. |
| 1500 metros | 25 min. | |

23. (Table 2. Drawn by *Mar* at the blackboard; does the operations in the book that she has in her hand, erases them and writes the results in the table on the blackboard).
29. *T:* How can we compare those amounts?
31. *Mar:* (asks to participate) seeing this (points to table 2, that she drew on the blackboard) with what they did, to find what's missing … and their times.

33. *Mar*: "Amalia swam 100 m in 2 min., but here she's
got 1 min. 40 sec. (points to the amount in table 2 on
the blackboard)
34. *T:* One hundred meters in how long? I think the
amount is wrong. Check it ….
36. *T:* Can someone tell her what's going on with
42. Amalia?
48. *T:* There's a mistake there sweetheart, erase it!
*Ale*: The thing is that where it says 150 meters it's 2
52. minutes 51 seconds…
(Upon the teacher's instructions, Mar erases the
entire table she had drawn on the blackboard. The
teacher then dictates, with the help of the Ss, the
56. table in the Textbook).
*T:* How can we compare this time and these
58. distances? … Who swam the fastest?
*Mar:* It's just that, I had already done the table but
59. you didn't understand me …
60. *T:* Ah ha! Now I understand you! (astounded)
61. *Mar:* I based it on what Beto did …
62. *T.* In other words … the table was just for Beto!
*Mar:* It was to see, … because I think that Beto was
faster, so if Beto took 50 seconds for 50 meters, then
63. he would have swum differently …"
64. *T:* Very good.
*T:* What can we do to find out how many seconds it
65. took Amalia, Catalina and Darío?
66. *Di*: Divide the distance by the time.
*T*: Divide the distance by the time! Of course!
(emphatically).

# U.S. AND CHINESE TEACHERS' PRACTICES AND THINKING IN CONSTRUCTING CURRICULUM FOR TEACHING

Yeping Li
Texas A&M University
yepingli@tamu.edu

*By focusing on teachers' preparation for teaching fraction division, this study examined eight US and Chinese mathematics teachers' practices and thinking in lesson plan development. Both lesson plans and interview data were collected and analyzed. The results presented a contrast picture between US and Chinese teachers' practices and thinking in constructing curriculum for teaching. While Chinese teachers' lesson plans presented a well-structured and detailed picture, US teachers' lesson plans were brief and more like a reminder for what to teach and relevant teaching procedure. Although both Chinese and US teachers thought that lesson planning is needed, the nature of their thinking differed and helped explain cross-national differences in their lesson plans.*

## Background

Results from several cross-national comparative studies suggest that students from East Asia outperform U.S. students in school mathematics. High quality classroom instruction has been taken as one important factor contributing to Asian students' achievement, including China and Japan (e.g., Stigler & Hiebert, 1999; Watkins & Biggs, 2001). Researchers tend to seek factors that may contribute to the quality of teaching in these countries, including curriculum materials, teachers' knowledge, and teachers' work outside of their classrooms (e.g., Li, Chen, & An, 2009; Ma, 1999). One key factor might be teachers' lesson planning and interactions that happen before and after their classroom instruction (e.g., McCutcheon, 1980; Stigler & Hiebert, 1999). If teachers can design well-thought-out and high quality lesson plans, as a process of curriculum planning at the micro level, they build a solid base for classroom implementation. Quality instruction is, therefore, more likely to occur. However, not every teacher tends to agree on this idea, especially in the United States (see O'Donnell & Taylor, 2006). The value of lesson planning and its role in developing high-quality lessons are still contested in teachers' views and practices. Further studies are needed to explore teachers' practices in lesson planning and their thinking behind their practices.

As part of a larger research project, this study was designed to investigate Chinese and US teachers' practices and thinking in lesson preparation. In particular, this study focused on teachers' curriculum construction for teaching the content topic of "division of fractions". As addressed by Li, Chen and An (2009), division of fractions (DoF) is a complex content topic that is included in elementary school mathematics for sixth grade in China, sixth and/or seventh graders in the U.S. Although fraction division is procedurally straight forward, it is a conceptually rich and difficult topic. In textbooks from many education systems including China and the United States, fraction division is a content topic that has been given various conceptual treatments (e.g., Li, 2008; Li, Chen, & An, 2009). The topic presents a rich context to explore possible variations in teachers' thinking and lesson planning.

By focusing on this content topic of DoF, a case study approach was used to focus on eight mathematics teachers' lesson planning from different schools in China and the U.S. Through collecting rich data around these eight teachers' lesson planning on the topic of fraction division, this study was designed to address the following two questions:

1. What are the characteristics of Chinese and US teachers' daily lesson plans on the topic of fraction division?
2. What may Chinese and US teachers normally do and think when developing lesson plans?

## Theoretical Perspectives

Studying teachers' lesson planning is not a new endeavor. In the United States, the importance of investigating teachers' lesson planning and their thinking was recognized more than two decades ago (e.g., McCutcheon, 1980; Peterson, Marx, & Clark, 1978). The results from studies on U.S. expert and novice teachers' cognition indicated that variations in teacher's planning relate to their classroom teaching behavior (e.g., Hogan, Rabinowitz, & Craven, 2003). Cross-nationally, it is reported that Chinese teachers' lesson plans differed from their counterparts in the United States (e.g., Cai & Wang, 2006). Yet, much remains to be understood about teachers' practice and thinking in constructing curriculum for classroom instruction. In particular, this study aimed to examine teachers' planning practices through analyzing teachers' daily lesson plans. Interviews with participating teachers were also used to explore teachers' thinking behind their practices and to triangulate the lesson plan analysis.

In analyzing individual lesson plans, both content and process are important aspects of lesson plans (Cai & Wang, 2006). While the content aspect focuses on what to teach, it translates into a teacher's interpretation and specification of instructional objectives and content treatment for teaching. Likewise, the process aspect focuses on how a teacher plans to teach, and it translates into the teacher's planning of lesson activity and its structure with the use of different strategies and problems. Moreover, students should be an integral part of a teacher's consideration in lesson planning. It is also important to examine how a teacher may anticipate possible students' learning difficulties and progress in the process of lesson planning (e.g., Shimizu, 2008). Thus, a three-dimension framework was developed for analyzing teachers' plans of individual lessons as outlined below:

Content aspect: the content scope to be covered in one lesson, instructional objectives, important content points of teaching, difficult content points of teaching, and materials/tools to be used.

Process aspect: activity segments and structure, use of instructional strategies, use of problems and representations.

Student aspect: the places in lesson plans where the teacher considers students, the nature of teacher's considerations about students in lesson plans.

## Method

*Participants and Context of the Study*

This study focused on four US schools and four (out of seven) Chinese schools participating in a larger research project that aimed to investigate Chinese and US mathematics classroom teaching. With local mathematics education experts' help, the eight schools were selected with comparable variations in school quality and reputations in these two education systems. While the four US schools were located in one state, the four schools in China were in two different provinces. With one teacher from each school, a total of eight teachers participated in this study.

The schools and participating teachers were all informed that the data collection was only for the research purpose. As part of the research project, the teachers' lesson plans on the topic of fraction division were requested and collected. All eight teachers were interviewed about their practices and thinking in constructing curriculum for mathematics classroom instruction.

*Types of Data Collected*

In the larger research project, all participating schools were site-visited and participating teachers were given semi-structured interviews about their lesson preparation and teaching of the content topic of DoF. As the topic of DoF was treated differently in Chinese and US textbooks (Li, Chen, & An, 2009), the complete instruction of the topic presented different arrangements with different amount of time required in these two education systems. Thus, all the data collection was focused on the first several lessons that participating teachers prepared and taught the content topic of DoF. However, video-taped teachers' lesson instruction was not included for analysis in this study. The data used for this study included the following:

1. Eight participating teachers' daily lesson plans on the topic of fraction division.
2. Semi-structured interviews with the eight teachers about their practices and thinking in constructing curriculum for mathematics classroom instruction. In particular, teachers were asked such questions as instructional goals for planning the lessons on DoF, difficult content points for students in teaching this topic, their perceptions of lesson planning, and normal procedure in lesson planning.
3. Field observations of these eight elementary schools and these teachers' daily working environment.

*Data Analysis*

All the data for this study were analyzed in the original Chinese or English languages, and then translated the Chinese into English if needed. To address our first research question directly, we analyzed these eight teachers' lesson plans. Because there were some variations among these teachers in terms of their teaching pace and what was planned after the first lesson, the variations made teachers' plans for the first lesson on the topic a default choice for comparison.

Our analysis of teachers' lesson plans then followed the framework outlined above. The data analysis was a process that integrates iterative lesson plan examination and code development, together with extensive discussions between two coders. A consensus in data coding was reached after discussions. By referring to the codes used in Cai and Wang's study (2006), teachers' first lesson plans were categorized in terms of their content and process features. Teachers' considerations of students' possible responses and difficulties were also examined.

To support the above data analysis and address the second research question, we analyzed the interviews with all these eight teachers to reveal their lesson planning routines, and to capture the ways in which these teachers came up their ideas in constructing curriculum for lesson instruction on this content topic as well as their thinking about lesson planning. In particular, we focused on teachers' perceptions of the process of lesson plan development, their perceptions of important factors influencing their development of lesson plans, their instructional objectives, and the difficult and important points of teaching this content topic. The interview data can allow us not only to triangulate our analysis of teachers' lesson plans on the content topic, but also to examine teachers' perceptions and beliefs of the role of lesson planning in developing effective classroom instruction. The field observation was also incorporated to support our analysis of the interview data in terms of teachers' lesson planning practices in the school.

## Results

Information about these eight teachers and their schools were obtained through interviews and school site visits. Table 1 shows that participating teachers were all experienced teachers, with at least eight years' teaching experiences. However, all participating US schools let teachers use their own classrooms for lesson preparation and teaching. In contrast, all schools in China provided teachers with office space for lesson preparation that is separate from classrooms.

*Table 1*
Information about Eight Participating Teachers and Their Working Organization

| Teacher | Years of teaching | Teachers' office arrangement | Normal practices in lesson planning |
|---|---|---|---|
| CH-T1 | 10 | Subject-based teacher office | Mainly individual preparation, periodically group lesson preparation |
| CH-T2 | 10 | Grade level-based teacher office | Use common lesson plan prototype, then modify by individual teachers |
| CH-T3 | 19 | Grade level-based teacher office | Used to be group preparation, now mainly individual preparation |
| CH-T4 | 11 | Grade level-based teacher office | Use common lesson plan prototype, then modify by individual teachers |
| US-Ta | 9 | The teacher's Classroom | Individual preparation |
| US-Tb | 12 | The teacher's classroom | Individual preparation |
| US-Tc | 8 | The teacher's classroom | Individual preparation |
| US-Td | 8 | The teacher's classroom | Individual preparation |

Related to the teachers' working office arrangement, all four US teachers had their lesson planning on their own, whereas all Chinese teachers reported the combination of individual and group works for lesson planning activities. Although variations existed across these Chinese schools in terms of how group efforts were formally utilized, individual work did not prevent teachers from having informal discussions about teaching and planning from time to time.

In general, although the four Chinese teachers were from four different schools in two provinces, their lesson plans shared many similarities. Based on the unified curriculum standards in China, all their lesson plans contained clear and same instructional objectives taken from teachers' instruction reference book. The complete instruction of DoF was arranged in the Chinese curriculum for the sixth grade and would take at least two weeks (Li et al., 2009). All four teachers' first lesson plans focused on the conceptual understanding of why the computation of fraction division works. Although the format of lesson plans varied across these two provinces, all lesson plans had a clear teaching process that includes reviewing the previous knowledge, introducing new content, and summarizing and practicing.

In contrast, the US teachers' lesson plans presented a diverse picture. Although these teachers were from four different schools, their lesson plans were surprisingly brief and varied in content and instruction arrangements. In fact, only three teachers had some kinds of lesson plans available to share. And one teacher (Tc) actually made her lesson plan as filling in a small box for each day on a monthly planner. All these teachers were teaching DoF to seventh graders and planned to use one lesson period (about 40 to 50 minutes per lesson period) to cover the topic.

In analyzing features of these teachers' lesson plans, we thus focused on their first lesson plans on this topic. Similarities and differences among these participating teachers' lesson plans were evidenced along the three dimensions specified in the framework, i.e., content features, process features, and knowing about students. The following three sub-sections are structured to present findings in detail.

*Content Features of Teachers' Plans for the First Lesson*

In analyzing seven (there was no lesson plan provided by one US teacher - Td) teachers' first lesson plans, five content features were identified in their lesson plans: content topic specification for the lesson, instructional objectives, teaching emphasis, difficult points of teaching, and instructional materials or tools. Table 2 summarizes content features included in these seven teachers' first lesson plans.

*Table 2*

Content Features of Seven Teachers' First Lesson Plans

| | Content specification | Instructional objectives | Teaching emphases | Difficult points | Materials |
|---|---|---|---|---|---|
| CH-T1 | + | + | | | |
| CH-T2 | + | + | + | | + |
| CH-T3 | + | + | + | + | + |
| CH-T4 | + | + | + | | |
| US-Ta | + | + | | | |
| US-Tb | + | + | | | |
| US-Tc | + | + | | | + |

*Note*. "+" means that the item was presented clearly in that teacher's lesson plan.

Table 2 shows that all seven teachers' first lesson plans included both content topic specification for the lesson and its instructional objectives. However, while Chinese teachers tended to include more information such as teaching content emphasis, US teachers' lesson plans basically did not contain further information except one teacher (Tc) specified what materials need to be prepared for instruction. The following sub-sections will provide further detailed information.

*Content specification.* In specifying the content topic, three Chinese teachers (T1, T2, and T3) provided an item (e.g., a fraction divided by a whole number) at the beginning of their lesson plans to explicitly state the teaching content, while one (T4) placed the content topic directly as the lesson plan's title. In contrast, all three US teachers used the content topic simply as the title of their lesson plans.

*Instructional objectives.* Next, all four Chinese teachers provided instructional objectives in their lesson plans. They all thought that understanding the meaning of DoF and correctly doing the algorithm of a fraction divided by a whole number are major objectives in the first lesson. Moreover, they included both understanding (why it works) and mastering the computation of a fraction divided by a whole number (how to do the computation) as for correctly doing the algorithm. The four teachers included three same instructional objectives, but expressed varied ideas in their specifications of other instructional objectives. For example, T1 specified the objective of understanding the relationship between fraction multiplication and fraction division based on the meaning of division. T4 indicated the need to develop students' inquiry and enhance their confidence. Two teachers (T1 and T3) included as an instructional objective to develop students' ability to compare, analyze, and generalize results.

In contrast, the three US teachers included simple objective statement. Two of them simply used the title as the lesson's objective, while the remaining one used "dividing fractions" as content topic and "to divide fractions and mixed numbers" as objective.

*Teaching emphases and difficulties.* Three Chinese teachers (T2, T3, and T4) from the same province further specified teaching emphases and difficulties in their lesson plans. They used the same form of lesson plan, which was designed to place teaching emphases and difficulties together in the same item. While T2 and T4 addressed teaching emphasis explicitly, T3 did not separate teaching emphasis from difficulties. For those plans including teaching emphases and difficulties, they were similar in their specifications of teaching emphases and difficulties. For example, T2 indicated "teaching emphases" as the computation of a fraction divided by a whole number, T4 indicated as the meaning of fraction division and the computation of a fraction divided by a whole numb, while T3 mentioned the meaning of fraction division and the computation of a fraction divided by a whole number as both "teaching emphases" and "teaching difficulties". However, such content specifications were absent in the US teachers' lesson plans.

*Teaching materials.* Table 1 shows that two Chinese teachers (T2 and T3) and one US teacher (Tc) mentioned "teaching materials" besides the textbook. T2 planned to use concrete materials (e.g., rope), and T3 planned others (e.g., small blackboard). The US teacher (Tc) listed several materials as supplies, including ruler, scissors, tape, and colored pencils.

*Process Features of Teachers' Plans for the First Lesson*

In general, lesson plans were considered as scripts for what teachers will do in classrooms (e.g., Cai & Wang, 2006). Although these teachers' lesson plans varied in many ways, the four Chinese teachers' lesson plans shared a similar structure of instructional process. In particular, all lesson plans except one (T3's) were outlined as containing four steps: (1) reviewing previous knowledge, (2) introducing new knowledge, (3) exercises and practicing, and (4) summary and assigning homework. In contrast, the three US teachers' lesson plans were brief and varied dramatically. In fact, Tc' lesson plans contained no process information at all, while Ta and Tb filled in blanks on a pre-set one-page lesson plan. However, Ta wrote one sentence for each of four activities in a list, like "Recall any previous knowledge of dividing fractions" as activity 1. The lesson plan looked more like a reminder for a sequence of lesson activities. Tb listed six fraction division computations and corresponding word problems, together with two exercise sheets for students. Given such limited information available on US teachers' lesson plans, the following sub-sections will focus on process features presented in Chinese teachers' lesson plans.

*Reviewing previous knowledge.* As explained in the last section, all four Chinese teachers' lesson plans contained two instructional objectives: to understand the meaning of fraction division and to master the computation of a fraction divided by a whole number. Subsequently, these teachers, except T3 whose lesson plan did not have a reviewing step, planned relevant knowledge review. In particular, two teachers (T2 and T4) planned the review of the meaning of whole number division, while T1 planned to review multiplication of fractions.

*Introducing the new knowledge.* All four teachers planned the part of "introducing new knowledge" in detail. A difference was observed as T2 and T4 placed the meaning of fraction division as part of reviewing and then introduced the computational rule as "new knowledge". Others (T1 and T3) included both the meaning and the computational rule of DoF in the step of "introducing new knowledge". For introducing the meaning of DoF, T1 used the word problems of whole number division provided in the textbook, whereas T3 provided a fraction division expression and used the equation of multiplication to introduce the meaning of fraction division.

Pedagogically, all four teachers were consistent in planning to ask students to discuss the computational rule in groups and to report their findings. In order to help students' learning, three teachers (T1, T2, and T4) planned to provide students some hints first by showing concrete manipulative or pictorial representation. With the use of concrete or pictorial representation, each teacher expected students to predict the answer for the problem. Although these four teachers' lesson plans varied in terms of the degree of their details, they all showed the use of pictorial representation in proving the computational rule and the use of multiple ways for coming up the algorithm.

*Exercises and practicing.* After introducing the new knowledge, all four Chinese teachers provided exercises for practicing. T1 included exercises for understanding the meaning and mastering the algorithm, others mainly focused on the computation. All four teachers provided exercises for practicing the algorithm. With the exception of T2 with one type of exercise provided for practicing the algorithm, others planned to provide multiple types of exercises for doing the algorithm.

*Summary and assigning homework.* All four teachers ended their lesson plans with a summary and assigning the homework. In particular, these teachers designed specific questions in their lesson plans to ask students in order to check whether or not students' learning achieved the lesson's instructional objectives.

*Knowing and Predicting Students' Responses and Difficulties*

Three teachers (except T3) planned to organize and use students' group discussion about the fraction division algorithm. Moreover, T4 explicitly predicted possible solutions that students would generate through group discussion. Based on the solutions that students would make, the teachers planned to generalize for developing characteristics of each algorithm.

*Teachers' Thinking about Lesson Planning*

To my surprise, all eight teachers said that they always had lesson planning and considered that lesson planning is important and useful to them. These teachers' responses presented a picture different from cross-national differences in teachers' lesson plans reported above. Further analyses of teacher interviews were carried out to reveal details.

For US teachers, lesson planning mainly referred to "getting ready for a lesson". It involved knowing what to teach and how to teach a lesson. Although these teachers would use textbooks, they would use textbooks mainly as resources and for getting exercise problems. It was important for them to know students' learning style, what may make their learning difficult, and to think about how to connect mathematics with real world. While all four US teachers thought that they had enough time to plan for their lessons, they were not sure whether they were satisfied with their lesson preparation until they taught students.

For Chinese teachers, lesson planning was a process necessary for students and teachers. Lesson planning for students meant to plan lessons from the student's perspective. Teachers should think what students have already learned and how the teachers provide students a good learning approach. Lesson planning for teachers meant that the teachers can deepen their own understanding of content through the lesson planning process and develop their teaching. In this regard, studying the textbook is very important to develop a deep understanding of the content topic in terms of instructional objectives, emphases, and difficulties. Studying textbooks can also help teachers make knowledge connections between the current content topic and others. Moreover, lesson planning is for teachers to think about how to teach cleverly and use teaching strategies. Teachers can thus develop teaching from the process of lesson planning.

## Discussion

Overall, the study presented contrast results between US and Chinese participating teachers in their practices and thinking in constructing curriculum for teaching. Chinese teachers' lesson plans presented a coherent and detailed picture, not only in terms of what these teachers considered as important for their students to learn among these teachers, but also in structuring these contents together for classroom instruction in individual lessons. Their lesson plans resulted from these teachers' intensive study of textbook content in relation to their students' situation. In contrast, US participating teachers' lesson plans were very brief, if they made one. Lesson plans were developed more like a reminder for what to teach and its teaching procedure. Because these US teachers tended to pay more attention to students and their learning but not a lesson's content treatment, their lesson plans presented a picture that is consistent with these US teachers' thinking about lesson planning. Although this study is limited with a few participating teachers, the findings provided a valuable glimpse of what may help contribute to the quality of classroom instruction in China. To Chinese teachers, the value of lesson planning is beyond what it is for classroom instruction. It is also a valuable professional activity for teachers themselves.

# BECOMING A TRIPLE A GEOMETRY TEACHER: THE CASE OF ROSE

Brenda Strassfeld
New York University Steinhardt School of Culture, Education and Human Development
bs49@nyu.edu

*Factor analysis was used to analyze data that was collected from 520 high school mathematics teachers' questionnaire responses to 48 Likert type statements. The analysis revealed a three factor solution: disposition towards activities, a disposition towards appreciation of geometry and its applications, and a disposition towards abstraction. These results allowed for the classification of teachers into one of eight groups depending on whether their score was negative or positive on the three factors. Knowing which group a teacher belongs to would allow for appropriate professional development activities to be undertaken as was done in the following case study where techniques for scaffolding proofs were used as an intervention for a teacher who was in Group 2 with a positive disposition towards activities and appreciation of geometry and its applications but with a negative disposition towards abstraction.*

## Theoretical Framework

Beliefs play a central role in shaping the practice of teaching (Ernest, 1989, 1991; Raymond, 1997, Thompson, 1984, 1992). Questionnaires that included both statements that required responses on a Likert scale and open-ended questions are used to measure beliefs (Leder and Forgasz, 2002). Thompson (1984) used the method of case studies to report on teachers' beliefs about mathematics, mathematics teaching, and their criteria for judging effectiveness of instruction. Case studies give deeper insights into beliefs.

Students take their "cues" from their teachers. Classroom experience affects students' beliefs about mathematics. Teachers need to examine their own beliefs about proofs, in particular in order to understand how they may influence their students (McCrone, Martin, Dindyal, & Wallace 2002; Schoenfeld, 1988; Senk, 1985). If teachers strongly convey the idea that proofs are necessary to fully understand and appreciate the fundamental geometrical principles being taught, students may become more interested and involved in learning about and doing proofs. Otherwise, doing proofs becomes a dry, rote classroom drill. As earlier researchers have reported, doing formal proofs should come after students have made some sense of the underlying geometrical and mathematical ideas through hands-on explorations (Battista & Clements 1995; Freudenthal, 1971).

## The Study

One of the questions that I wanted to follow up after the preliminary questionnaire was: What happens in a class where a teacher is required to teach geometric proof but has scored negatively on factor 3: a disposition towards abstraction? Could something be done to help a teacher overcome a negative disposition towards abstraction?

In my position as a mathematics specialist-consultant, I was carrying out professional development in Rose's school and the principal suggested that I observe Rose's class in which she was about to start teaching geometric proof. This provided an opportunity for me to delve further into these questions, using Rose as an 'opportunistic sample'. It was in the position of observer participant that I was present in and observed Rose's class seven times taking extensive field notes.

Rose who has an undergraduate degree in mathematics education had taught ninth and tenth grade mathematics in a small urban high school for two years. She was in her late twenties, when I started to work with her. She is enthusiastic in the classroom and she exhibits good classroom management skills.

I met with Rose each morning to discuss her lesson plan for the day and after each of these classes to conduct a debriefing with her. During these sessions I made several suggestions, such as always listing all six corresponding parts of congruent triangles on the board when referring to them and marking them on the diagrams. She implemented these suggestions and others described below in her class almost immediately. This study was presented to Rose so that she could concur or refute any inferences made.

I observed Rose's class several times. I also had the results of the factor analysis and my intention was to find a way to make her comfortable teaching students about proof. The intervention is described below, along with her responses to a further follow-up questionnaire. When she taught with the movable cards containing statements and reasons which were part of the intervention she felt more at ease.

Rose was at the end of her third year of teaching. During the previous year, she had been one of the respondents to the questionnaire. Her scores on the three extracted factors were positive on factor 1: *a disposition towards activities*, positive on factor 2: *a disposition towards appreciation of geometry and its applications*, and negative on factor 3: *a disposition towards abstraction*.

## Rose in Her Second Year of Teaching

Based on Rose's factor scores I went back to look at her actual responses to a number of statements on the questionnaire.

She responded *disagree slightly more than agree* to the following statements:

4. Learning to construct proofs is important for high school students.
6. Geometry should be included in the curriculum for **all** students.
13. High school students should be able to write rigorous proofs in geometry.

This indicated to me that Rose was concerned about teaching average or below average students how to do proofs.

Rose responded *agree slightly more than disagree* to these statements:

1. I enjoy teaching geometry.
2. Learning geometry is valuable for high school students.
9. Geometry should occupy a significant place in the curriculum.
10. High school geometry should not contain proofs.
21. I enjoy doing geometric proofs.

These responses appear to show that Rose believed that geometry is worth learning and that she did enjoy teaching geometry as long as she did not have to teach students how to do proof. She herself likes doing proofs.

Rose responded *strongly disagree* to the statements:

16. My students enjoy doing geometric proofs.
44. I enjoy teaching my students how to do geometric proofs.

Rose responded *moderately agree* to the statement:

48. I enjoy proving theorems for my students.

These responses and the conversations that I had with her led me to conclude that she was uncomfortable about teaching students how to do proofs. The fact that she enjoyed proving theorems for students and doing proofs gave me a glimmer of hope that she might reconsider teaching proofs if she was armed with the appropriate tools and therefore more confident.

**Rose in Her Third Year of Teaching**

By her third year of teaching, Rose had a desire to teach mathematics to upper grade students and so she sought and accepted a position at another small urban high school whose students were supposedly "more academic" than at Rose's first school. I was doing short-term professional development at the school where I worked with three of the four mathematics teachers. The principal asked me to work with both Rose and another teacher who were both starting a unit on proof in geometry. Although I observed both teachers and suggested similar interventions this study focuses on Rose because she was an identified respondent to my questionnaire.

Teaching students how to prove theorems involves all of the problem-solving that teachers do in their 'work of teaching' (Ball, Bass, & Hill, 2004; Kazima & Adler, 2006). These include: Using mathematically appropriate and comprehensible definitions; designing mathematically accurate explanations that are comprehensible and useful for students; working with students' ideas; making judgements about the mathematical quality of instructional materials and modify as necessary and assessing students' mathematics learning and take next steps. Rose exhibited these problem solving skills in her teaching of other aspects of geometry. Could Rose incorporate these skills when teaching proof? I believed I could share a method of teaching students how to do proofs that would be appealing to Rose. The method is described below.

**Congruent Triangles**

The students in the class were learning how to prove geometrical results. They were mostly tenth graders who had already learned definitions and properties of triangles and quadrilaterals in the ninth grade or the beginning of the tenth grade.
Rose used the concept of congruent triangles as a vehicle for introducing students to proving conjectures.

The following is a snapshot of the type of questions Rose asked on the first day of the unit: "What makes triangles congruent?" Students respond that the triangles have to be exactly the same. Rose then drew a picture of two triangles on the board. How can I show that triangle *ABC* is congruent to triangle *DEF* (See Figure 1) based on the information given?

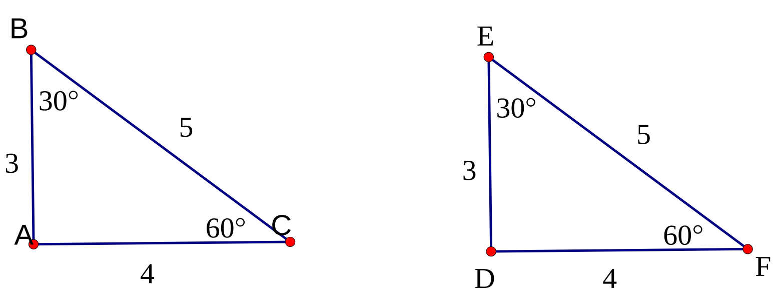

*Figure 1.* Rose's example of congruent triangles.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

The students recognised that the triangles were congruent from the given information. No student noticed that these triangles couldn't really exist because in a 30-60 triangle the length of the side opposite the 30 degree angle is equal to half the length of the hypotenuse. Bills, Dreyfus, Mason, Tsamir, Watson, and Zaslavsky (2006) asserted that when selecting instructional examples the teacher should take into account 'learners' preconceptions and prior experience'. Zaslavsky and Zodik (in press) studied what considerations went into teachers' choices of examples. They found there was a tension between the desire to construct real-life examples and mathematical accuracy. A random choice of example could lead to an impossibility. When Rose and I discussed her example she was surprised at what she had done. She expressed a desire to be more careful about her choice of examples in the future.

Another question that Rose posed was whether the information given was sufficient to prove triangles congruent: She drew the diagram shown in Figure 2 and asked students, "In the square ABCD, is ΔABC congruent to ΔADC?"

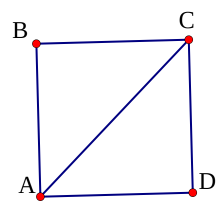

*Figure 2.* Rose's second example.

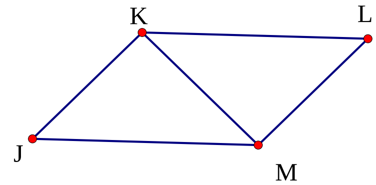
Her students had to remember the properties of a square in order to answer this question. They knew the sides were all congruent. Rose wanted the students to focus on SSS congruent to SSS. Rose had the students rely heavily on the visual aspects of the problem. I suggested that she have the students investigate the other congruence relationships. I loaned her Michael Serra's book *Discovering Geometry: an Investigative Approach* (2003). She prepared a hands-on lesson for the investigation: Is ASA a Congruence Shortcut? Rose gave each group of students a work sheet with a line segment and two angles drawn on it and asked them to construct a triangle. The students used scissors and tape to cut out the segment and angles and paste them together to form a triangle. She had the groups compare their results. Rose placed the results up on the bulletin board.

Rose kept telling me that she was anxious about having the students do actual proofs. I gave her three worksheets from a set of worksheets I had received from Sandra Gundlach, a teacher, who had presented them at a conference. The first one had six statements to prove along with a diagram for each (See Figure 3). The next two sheets had mixed up answers to each of the proofs from the first sheet. I brought in envelopes with the given, the "to prove", and the diagram for each of the six proofs taped onto the outside and the cut up statements and reasons inside.

5. Given: $\overline{KL} \cong \overline{JM}$
$\overline{JK} \cong \overline{LM}$
Prove: $\angle J \cong \angle L$



6. Given: $\overline{JK} \parallel \overline{LM}$
$\overline{JK} \cong \overline{LM}$
Prove: $\overline{KL} \cong \overline{JM}$

*Figure 3.* Last 2 examples from sheet 1: Proving triangles congruent.

Rose took proof #1 (See Figure 4) and enlarged the cut up statements and reasons. She taped them to the blackboard, wrote the given and to prove statements, and drew the accompanying diagram. Some of the students had difficulty with how to use the definition of midpoint. Rose used coloured chalk effectively to illustrate. My suggestion was to use Geometer's Sketchpad to demonstrate angle bisectors in proof #2, but the technician was not available to bring a laptop to Rose's classroom. (I mention this here to make the point that even if a teacher wants to use technology it is not always readily available.) Students complained that one angle looked bigger than rather than equal to the other angle. (Sometimes such arguments are productive but in this case time was wasted).

D is the midpoint of $\overline{AB}$ $\quad$ $\overline{AD} \cong \overline{DB}$ $\quad$ $\angle A \cong \angle B$ $\quad$ Given

$\angle ADC \cong \angle BDC$ $\quad$ $\overline{CD} \cong \overline{CD}$ $\quad$ $ACD \cong \Delta BCD$ $\quad$ Given

Def of midpoint $\quad$ SAS

*Figure 4.* Proof #1 mixed up answers.

Rose used a metaphor of identical twins to help the students understand that corresponding parts of congruent triangles are congruent. "If the twins are identical, what can you say about their eye colour, their height etc.?" The students responded, "They are the same." "So if the triangles are congruent by SSS, SAS or ASA, what can you say about the other parts of the triangles?" The students were able to understand this concept. In the United States some teachers abbreviate the statement *corresponding parts of congruent triangles are congruent* – CPCTC. Unfortunately many students use the abbreviation but fail to remember what it represents.

Some students struggled with the logical sequencing of the steps. In proof #4 they placed the statement G is a midpoint of EI in the middle of the proof. One student, Gary said, "You have to look at cause and effect." This was a useful insight.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

Eventually Rose used the same format for proofs that she found in the text. She assessed how the students were doing by giving them a quiz where all the statements and reasons were written in mixed-up order on the page and the students had to put the proof together correctly. She was pleased with the results.

**Some of Rose's Response to the Follow-Up Questionnaire**

Rose's responses to the follow up questionnaire were:

1. What do you most love about geometry and why?

*I love geometry proofs. I feel they help students think logically. A proof is like a jigsaw puzzle where everything must fit and when it is complete it's a nice accomplishment. Proofs make students realize that nothing in geometry can be taken for granted there always has to be a reason.*

Rose's response indicates a positive experience with proofs, but I knew from conversations with her that she was worried about teaching proofs. Her next response gave me a glimpse into why she was anxious about teaching students how to do proofs.

2. What is your most memorable experience or experiences as a student in a geometry class?

*My teacher explained the topics very thoroughly. However eliminated geometry proofs from the curriculum. I feel this turned me off from proofs for quite some time.*

4. Is there any topic or topics that are in the current geometry curriculum that you believe should be eliminated? Please explain why.

*I believe constructions should be eliminated from the curriculum, time does not allow for it.*

This question was included to try to find out what teachers do not value in geometry. The way the curriculum is arranged in Rose's state, geometry is part of integrated courses. Constructions are taught in the first course and proofs are taught in the second course. There is no context for the unit on construction. It is left to the last lessons of the course. Rose cannot do justice to the topic and therefore wanted to see it eliminated.

5. Do you include real world applications in your geometry course? What are these and why are they included?

*Geometry is a topic in mathematics that lends itself to real world application. I tell my students geometry is something that is used in every field in the working world. Construction works as well as carpentry works need to know geometry. Individuals who work in advertising need to think about space when they make up an advertisement. Police officers need to use geometry when they are on a chase or when a shooting occurs. This year I took my students outside in the courtyard and we went around looking at the building and trying to find quadrilaterals and explain their properties and purpose by looking at them as well as their purpose in the building.*

I was able to understand Rose better from her responses to this short open-ended questionnaire. Her own experiences with proof in high school (Raymond, 1997) influenced her belief that it would not be easy to teach students how to prove. Rose did not understand the relationship between constructions and proof (Schoenfeld, 1988) and felt that teaching constructions should be eliminated from the curriculum. The curriculum emphasises the procedure for constructions. Since Rose's high school teacher did not teach proof to the class she may have had the students working aimlessly at constructions which is what Rose did in her own class and felt it was a waste of time. In Rose's responses, the *formal, intuitive,* and *utilitarian reasons* for studying geometry can be found.

## Case Study Conclusions

Rose's factor scores on the questionnaire placed her in group 2. Rose had a fear of teaching students how to do proofs. From her response to question 2 above we find that because Rose's teacher did not teach her how to do proofs when she herself took a geometry class, she was reluctant to now teach her own students how to do proofs. From another perspective, Rose left her first high school teaching job in order to teach at a school with more academic students. Not all of her students at the second high school were as academic as she expected. She might have believed that many of them were not capable of doing proofs. I created an intervention by showing her an approach to teaching proofs that fitted well to her disposition to work in a hands-on manner and use manipulatives since she had a positive score on factor 1. She used the intervention successfully in her class and has now requested to teach two sections of this course in the coming year. She has also taken an intermediate level training course in Geometer's Sketchpad during the summer in order to become more adept at using it in her class when she is teaching geometry (Cinco & Eyshinskiy, 2006).

In this one case, by looking at the factor scores I was able to find an appropriate intervention for the teacher. Can one look at the factor scores of other respondents and introduce them to interventions that would help them in their teaching of geometry? We can't generalise Rose's success to others since Rose was already implementing most of the aspects of problem solving in her work as a teacher (Ball, Bass, & Hill, 2004; Kazima & Adler, 2006).

Rose believed that she has a professional responsibility to continue learning and perfecting her craft. Beswick (2007) refers to this belief as "*commitment to seeking out 'second voices' and is related to a propensity to reflect on one's practice with a view to continual improvement*" (p. 115). She attributed the notion of "second voices" to Lerman (1997). Rose was willing to incorporate suggestions made to help improve her practice. Teachers who are unwilling to listen to "second voices" may not be able practice their espoused beliefs.

## Follow-Up: Rose in Her Fourth Year of Teaching

During Rose's fourth year of teaching I observed her class at the beginning and towards the end of her unit on proof. She again used investigations to verify conjectures about when triangles are congruent (Serra, 2007). She displayed the results of these investigations on the classroom walls. She also used the cut out statements and reasons that I had shown her the previous year. She increased the number of proofs that her students did using this method. Her questioning had improved. She had the students planning out their proofs. She asked, "Why does this belong here? Why can't it be placed earlier in the proof?"

On examinations she included matching up statements and reasons instead of cutting them out. She then had the students put the matched up pairs into a formal proof. Some of her students were finally able to complete proofs on their own.

# INVESTIGATING IN-SERVICE TEACHERS' BELIEF MODELS

Dionne I. Cross
Indiana University-Bloomington
dicross@indiana.edu

Over the last few decades more emphasis has been placed on the role teachers play in the learning process. Teachers organize and shape the learning context and so have enormous influence on what is being taught and learned. With this recognition, the mathematics education community began to invest more time and resources into teacher research. Specifically, mathematics education researchers, educational psychologists, and those involved in teacher education have become increasingly aware of the influence of teachers' beliefs on their pedagogical decisions and classroom practices. This collective case study reports on an investigation into the relationship between mathematics teachers' beliefs and their classroom practice, namely, how they organized their classroom activities, interacted with their students, and assessed their students' learning. It also examined the pervasiveness of their beliefs in the face of efforts to incorporate reform-oriented classroom materials and instructional strategies. The participants were five high school teachers of ninth-grade algebra at different stages in their teaching career. This study contributes to the body of literature by illuminating the clustered organization of these teachers' beliefs into an interdependent belief network. This network is presented as hypothesized models reflecting the derivative nature of the teachers' sets of mathematical beliefs. The researcher sought to understand the teachers' beliefs from their own descriptions and experiences to identify dimensions of the phenomenon not covered by preexisting theory (Ezzy, 2002).

The qualitative analysis of the data revealed the teachers' beliefs about the nature of mathematics served as a primary antecedent for their beliefs about pedagogy and student learning. Findings from the analysis concur with previous studies in this area that reveal a clear relationship between these constructs. In addition, the results provide useful insights for the mathematics education community as it shows the diversity among the in-service teachers' beliefs (presented as hypothesized belief models), the role and influence of beliefs about the nature of mathematics on the belief structure and how the teachers designed their instructional practices to reflect these beliefs. Implications for teacher education will also be presented.

# CONFRONTING PRACTICE: CRITICAL COLLEAGUESHIP IN A MATHEMATICS TEACHER STUDY GROUP

Lorraine M. Males
Michigan State University
maleslor@msu.edu

*This study investigates the development of "critical colleagueship" (Lord, 1994) by eight middle-grades mathematics teachers participating in a teacher study group as part of a project focused on improving mathematics classroom discourse. Analysis of the action research phase of this project indicated that aspects of critical colleagueship, such as self-reflection, openness to new ideas, the capacity for empathetic understanding, and the ability to reject flimsy reasoning were exhibited by the teachers. These aspects were manifested in three interaction patterns ranging from the common patterns of praise and advice-giving to the uncommon pattern of teachers engaging as challenging colleagues.*

## Background

With the current climate of educational reform in the United States and with teacher quality seen as critical to success (Wilson, Duffy, Fiori, Halladay, & Mapuranga, 2006), understanding how teachers learn through professional development and how contexts promote this learning is crucial. Although professional development has been labeled as "the ticket to reform" (Wilson & Berne, 1999, p. 173), there is little in terms of empirical evidence of the effects of professional development on practice or on student learning (Elmore, 2002).

According to the "consensus on effective professional development" learning is a collaborative activity and "educators learn more powerfully in concert with others who are struggling with the same problems" (Elmore, 2002, p. 8). Therefore, professional development should be designed to include the development of teachers' ability "to work collectively on problems of practice within their own schools and with practitioners in other settings, as much as to support the knowledge and skill development of individual educators" (Elmore, 2002, p. 8). Similarly, Wilson and Berne (1999) determined that a common thread in "highly regarded" projects was the "privileging of teachers' interaction with one another" (p. 195). These projects all had similar conceptions of professional development and were "aiming for the development of something akin to Lord's (1994) '*critical colleagueship*'" (p. 195). All of the professional development projects studied had difficulty building "trust and community while aiming for a professional discourse that includes and does not avoid critique" (p. 195). Unfortunately, this is contrary to the culture of teaching, in which teachers have a great deal of autonomy and are not often asked to explain their actions (Wilson, Miller, & Yerkes, 1993).

## Purpose of Study

Because of the lack of empirical evidence documenting the benefits of collegiality, there is a need to explore the concept of collegiality. There is also need for research that examines groups of mathematics teachers in order to gain insight into collegiality as it applies to mathematics teachers. This study has two purposes, one of which is methodological. It aims to answer the following questions: a) What are some of the ways that critical colleagueship is exhibited by mathematics teachers participating in a teacher study group as part of a project focused on teachers engaging in action research to improve mathematics classroom discourse? and b) Is it possible to identify the aspects of critical colleagueship exhibited by mathematics teachers by observing a group of mathematics teachers?

## Theoretical Framework

For a broader transformation, collegiality will need to support a critical stance toward teaching. This means more than simply sharing ideas or supporting one's colleagues in the change process. It means confronting traditional practice – the teacher's own and that of his or her colleagues – with an eye toward wholesale revision (Lord, 1994, p. 192).

In an effort to explain how teachers learn, Lord (1994) proposed his idea of *critical colleagueship* based on research about teacher collegiality. Critical colleagueship involves not only working together, sharing ideas and supporting each other, but also confronting unproductive practices and pushing one another to confront these practices. According to Lord, the elements of critical colleagueship are:

1. Creating and sustaining productive disequilibrium through self reflection, collegial dialogue, and on-going critique.
2. Embracing fundamental intellectual virtues. Among these are openness to new ideas, willingness to reject weak practices or flimsy reasoning when faced with countervailing evidence and sound arguments, accepting responsibility for acquiring and using relevant information in the construction of technical arguments, willingness to seek out the best ideas or the best knowledge from within the subject-matter communities, greater reliance on organized and deliberate investigations rather than learning by accident, and assuming collective responsibility for creating a professional record of teachers' research and experimentation.
3. Increasing the capacity for empathetic understanding (placing oneself in a colleague's shoes). That is, understanding a colleague's dilemma in the terms he or she understands it.
4. Developing and honing the skills and attributes associated with negotiation, improved communication, and the resolution of competing interests.
5. Increasing teachers' comfort with high levels of ambiguity and uncertainty, which will be regular features of teaching for understanding.
6. Achieving collective generativity – "knowing how to go on" (Wittgenstein, 1958) as a goal of successful inquiry and practice. (p. 192-193)

## Methods

*Participants and Context*

The participants included two university researchers and eight middle-grades (grades 6 – 10) mathematics teacher-researchers (TRs) from seven different schools in the Midwest United States. These middle and high schools were in a variety of communities (rural, suburban, urban) and included students from a range of socioeconomic levels. The teachers were also "purposefully selected to vary gender, context of teaching situation, certification level, years of teaching experience, extent of involvement in professional development, and reasons for entering the teaching profession" (Herbel-Eisenmann, Drake, & Cirillo, 2009). For more about the participants, see Herbel-Eisenmann, Drake, & Cirillo (2009). All of the TRs volunteered to be a part of this project[1]. The participants were involved in regular project meetings ranging from three-hour meetings to full day and overnight retreats. The data for this study is transcripts from 10 of the project meetings, all of which came from the action research phase of the project.

*Data Analysis*

This study draws on discourse analytic methods (Fairclough, 1992; Chouliaraki & Fairclough, 1999). First, the corpus was reviewed and summarized in broad terms (Fairclough, 1992), using codes that reflected the topic of the discourse. These topic codes were then used to choose transcripts that contained discourse in which the teachers shared with one another. Once the transcripts where chosen each transcript was broken up into episodes by topic or theme. These episodes were then broken up into question/advice blocks. Each of which was coded for who was doing the questioning, and who was being questioned, and the type of question(s) asked (clarification, elaboration, probing, challenging). Additionally, notes were taken on how these question/advice blocks related to the components of critical colleagueship (i.e., pushing someone to reject flimsy reasoning, evidence of openness).

## Findings

In the analysis of the 10 transcripts, three patterns of interaction surfaced: praising colleague, advising colleague, and challenging colleague. Due to limited space, I have chosen to describe the praising and advising colleague using a single transcript that exhibits both of these interaction patterns. I will then discuss the challenging colleague by exploring a different transcript. It should be noted that these interaction patterns did not always emerge in isolation; however in most cases one interaction pattern lasted for multiple teacher turns. All teacher names are pseudonyms. Since the purpose of this study was to identify the teachers exhibiting the aspects of critical colleagueship, I have chosen to indicate the researchers by using initials.

*Praising and Advising Colleague*

The praising colleague interactions were those in which teachers' engaged in dialogue that included a multitude of praise, usually directed at the teacher who was presenting their work. This interaction rarely involved questioning and the questions that were posed were mostly clarification questions. Similarly, the advising colleague interaction involved little questioning. However in addition to questioning in this interaction, the teachers offered advice (solicited and unsolicited) to the presenting teacher. This transcript is a representation of the types of praising (bold) and advising (italics) interactions in the data. The underlined text indicates utterances that include aspects of critical colleagueship.

In the following transcript one of the TRs, Robert, shared his action research progress. He showed videos from two lessons (one from the beginning and one from the end of the project).

BHE: So what did other people notice in what you heard happen in that period of time if Robert's goal is to be having kids talk more, right?

Robert: Contribute more of their ideas in classroom discussion.

Mike: I **liked** how you didn't give any cues when you were, when you were writing down answers. I mean there was no evaluation going on.

Cara: I **really liked** the idea that you gave it to them the day before and had them if they didn't understand it or needed something, they had to write down a question. And **I like the fact**, I mean I have so many kids that come up to me and say, you know three of them just put it down in front of you and just stand there. And then it's, I don't get it. And so by your asking them to write down a question ahead of time really made them get into the thinking of it. I thought that was **a really neat strategy** and one I'm gonna take.

Robert: It's stolen from...

Cara: That's what you got to do and **I like that a lot**. And **I like** the problem because, and I guess I relate to Robert, well, because we're both teaching sixth grade and that's the exact concepts that I work with all the time, is that it depends on the size of the whole on what the fraction is.

Stacey: **You're successfully getting them more engaged** in **meaningful ways**.

Robert: I mean honestly things that you've enjoyed in class that, more opportunities to provide kids with activities like this I could always use. Cause I'm willing to try them now where before I wasn't going to try them.

We can see that in lines 04, 06, 14, and 18, different teachers praise Robert for the good things they see in his teaching using words such as “like” and commenting on the “neat” things he is doing. In addition, in line 18 Stacey uses the word “successful” to describe Robert’s progress.

Although this interaction between the teachers did not seem to be what one might define as critical, many of the aspects of critical colleagueship were exhibited. Throughout this excerpt the aspects of empathetic understanding and openness are exhibited. Cara indicated that she had similar situations to Robert and not only is she placing herself in his shoes (lines 08) she explicitly aligns herself with Robert in line 15 where she stated “I relate to Robert.” Openness to new ideas is reflected in both what Robert says and in what other teachers say during this interaction. In line 12 Cara explained that Robert had a “really neat strategy” and she claimed that she was “gonna take” it. An even more explicit instance of openness to new ideas is exhibited by Robert. In line 20, Robert asked for more ideas from the other TRs because “I’m willing to try them now where before I wasn't going to try them.”

We continue the transcript form the same meeting where we left off.

Cara: Do you like what you’re doing better?

Robert: Yeah. Like I said, it was more fun. I don’t know if, I mean I think they get, like I said I'm asking them to do something that's different than the norm. So they ask. Like I said the one girl did ask, why does each problem that we do have to have a discussion or a lot of discussion.

Gwen: I've got students that ask that too. Why do we have to talk so much?

Kate: *It might be interesting to ask them too what their reaction is to talking about them more.*

Cara: *I have done that. It’s very interesting. For example, I've gone to that no hands policy and I just said, why do you think I've gone to this policy? And it was very interesting for them to say different reasons.*

MC: Robert, you said in the past I wasn't willing to try this. And I was wondering is, do you think that's accurate that you weren't willing to or do you think it's more that you didn't know what other possibilities there were?

Robert: I guess I don't know. At that time, even if these were posed to me I'm pretty, you know I might think they're pretty cool or whatever, but if you haven't known I was pretty passive in my behavior. But I was at a transition point where I didn't want to teach anymore. So I was pretty frustrated in my job that I was doing. You know I was seriously looking at other things to do. And then you know I just kind of had a change of heart, changed grade level, and then

42 this kind of came up too.
43 MC: So then it was that you were more willing it sounds like. So what about the
44 participation here made you more willing?
45 Robert: Gosh, I don't know. Maybe. Probably accountability to everyone else. Just
46 change. Seriously. And that we're all going through the same stuff too. We're
47 all in the same, same problems, same issues. Yeah and just having materials
48 to use that were pretty user friendly and I was able to understand you know
49 what the objectives were and stuff.
50 Holly: *I would say Robert, even just since we started the project I think there's more*
51 *resources on the NCTM's illuminations website that are more by topic so*
53 *that's a richer resource even in the last few years. And I find that like two or*
53 *three times a week to see if there's an open ended thing.*

We see in this excerpt that the TRs also provided Robert with advice. In line 28, Kate advised Robert to talk with his students about discussing problems, and in line 30, Cara offered him an example of how he might be able to do this. Later in the discussion in line 50, Holly also gave Robert some advice on where he might be able to find rich resources.

This excerpt also illustrated the aspects of critical colleagueship. Cara (line 30) continued to exhibit empathetic understanding and so did Gwen (line 27) by commenting that she also had students ask similar questions. We also see Robert engaging in self-reflection (lines 23, 36, 45) and in lines 36 and 45, discussing his openness. Robert shared his progress with the other teachers and seems to be engaging with the difficulties he experienced and the ways in which he was able to change is practice. He also talked candidly about how his willingness to try new things changed. Interesting is the fact that when MC asked Robert about his willingness to try new things prior to the project, one can see that the project encouraged his openness. He stated in line 36 that he was the type of person that “was pretty passive in my behavior.” Then, in line 45 Robert talked about the project and how it had encouraged his openness because of “the accountability to everyone else” and the fact that “we’re all going through the same stuff.”

*Challenging Colleague*

The least frequent type of interaction was that of the challenging colleague. In these interactions teachers asked elaboration, probing and challenging questions. This interaction happened only when one particular TR presented to the group. Bold is used to identify utterances that were challenged or challenging and the underlined text indicates utterances that include aspects of critical colleagueship.

In the following excerpt a different TR, Owen, discussed his action research project, which was to identify his students as procedural or conceptual by giving them an assessment.

01 Owen: So to me, using the Pythagorean theorem to find a distance **is more of a**
02 **conceptual response,** because it connects back into something they already
03 know. So whether or not they learn the Pythagorean theorem in a procedural
04 fashion, or a conceptual fashion, right. **Okay, are they relying on their**
05 **procedural understanding of the Pythagorean theorem**?
06 Stacey: **How are you going to determine that?**
07 Owen: Well **I do** the Pythagorean theorem when I’m supposed to be doing
08 distance formula, I do the Pythagorean theorem.
09 Holly: **What do you do?**
10 Gwen: **What do you mean do?**

Owen: We ah, they get a grid paper and I have them draw a right triangle, and they make the squares off to the sides.
Gwen: The question would be, when you are teaching them distance, you just taught as, a triangle Pythagorean theorem. **So, you never actually gave them a problem where they did this?**
Owen: Oh **no, we did**, there are homework problems like this.
Gwen: In class, **did you show them using Pythagorean theorem to solve the problem**?
Owen: **Yes. That's the way we did them**.
Gwen: So **you couldn't say**, that a kid said, oh this is how you did it, so that's how I'm supposed to do it. **So how is that different than, I know the distance formula**, so that's how I'm going to do it?
Owen: Because the distance formula **is** an exterior entity which **they have no actual understanding of**. All they have is their memorization of what the distance formula is as opposed to having them draw a triangle, which connects a problem they are presented with, back to something else they are already familiar with. Well no kid is going to come out, with a one hundred percent we would assume.
Kate: **Well they might, but you might have a lot of people who are**,
BHE: **They have a lot of variation.**
Owen: Right. Yeah.
Stacey: **I don't think that's the issue**, I think **the issue is whether or not you can really make the initial statement, this is procedural, this is**, and I'm one of the, I'm a big, big advocate of conceptual, so you know that about me. You are trying to talk about conceptual and **you're not giving conceptual tasks, it's hard to justify the claim** that this is procedural or this is conceptual.

In this transcript we see that Owen is asked questions that require him to elaborate, justify his reasoning, and reflect on his own thinking about his action research project. Owen is asked fairly quickly in his presentation (line 06) how he plans to determine whether students have conceptual or procedural understanding, and then in lines 09 and 10 both Holly and Gwen asked Owen to explain what he means by doing the Pythagorean theorem. As Owen continued to present his ideas, Gwen asked many questions (lines 13, 17, 20). It is important that these questions be looked at together because as individual questions they may seem to be only asking Owen to clarify how he taught the concept of the distance formula. However, these questions are challenging Owen to consider alternate explanations for the results he may get from his students. Gwen and others are attempting to push Owen to think about his reasoning, which they believe to be faulty. This is evident by phrases such as "So you never actually…", "So you couldn't say…", and "So how is that different than…" In lines 29 and 30, both Kate and BHE posed issues for Owen to think about that challenge his plan to identify students. In line 33, Stacey not only challenged Owen but also Kate and BHE. In response to the issues they were discussing with Owen, Stacey stated "I don't think that's the issue." Stacey then continued to challenge Owen's action research project and stated that "it is hard to justify the claim that this is procedural or conceptual."

The challenges that the teachers posed for Owen brought about other aspects of critical colleagueship, although perhaps not fully realized, that were not exhibited in the praising or

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

advising colleague interactions above. In this challenging colleague interaction the teachers pushed Owen to reject what they believed to be flimsy reasoning. They provided him with countervailing evidence and sound arguments to encourage him to reconsider his project objectives. However, Owen did not seem to be open to these ideas as evidenced by how he continued to explain his reasoning in the same way without incorporating ways to address the issues posed by the teachers.

## Discussion

This study is only the first step in unpacking critical colleagueship. According to Wilson and Berne (1999), critical colleagueship may help to explain how teachers learn. Although this study does not claim to draw a link between the aspects of critical colleagueship and teacher learning, it has provided us with what some of the aspects of critical colleagueship sound like in a particular mathematics teacher study group. This study is a necessary step in determining whether this type of collegial development does in fact explain teacher learning since it is first necessary to determine whether these aspects can be observed in a teacher study group. From a methodological standpoint, this study did in fact illustrate that it is possible from observing a mathematics teacher study group to identify some of the aspects of critical colleagueship. The teachers in this study exhibited openness to new ideas, capacity for empathic understanding, self-reflection, and were working towards aspects of rejecting flimsy reasoning by providing their colleagues with sound arguments and countervailing evidence. However, there are many aspects that were not identified in this study. The question remains as to whether these aspects (e.g., increasing teachers' comfort with high levels of ambiguity and uncertainty and sustaining productive disequilibrium) were simply not exhibited by the teachers in this group or if these aspects are not observable. Since this analysis included only 10 project meetings, it is possible that observing more meetings across a longer period of time might illuminate more than was possible here.

This study also raises more questions about how collegiality develops and specifically how it develops within a mathematics teacher study group. First, why was it that the teachers engaged as challenging colleagues around only one teacher's sharing? Although we may like to believe that personal relationships, status, and personality do not play a role in the development of critical colleagueship, it appears that they do. Even though the teachers in this study seemed to feel comfortable sharing and collaborating with each other, it is possible that the existing relationships and issues of status (teaching experience, certification level, mathematical knowledge, and experience with reform curriculum) may have had an impact on how critical colleagueship developed. Further research is needed to examine how status in a teacher study group affects collegiality. Also, the question remains as to how the context of mathematics allows for the development of critical colleagueship. Future research should examine the mathematical aspects of the teacher talk within study groups.

## Implications

This study has implications for further professional development work. According to Wilson and Berne (1999), effective professional development opportunities were those that involved something akin to critical colleagueship. This study group was one of those opportunities. Although the teachers in this group have not mastered all the aspects of critical colleagueship, they were well on their way to developing these types of relationships. Needless to say, critical colleagueship does not develop over night. This project was a four year project and the meetings analyzed for this study were from the fourth year of the project. Special care was taken in this project to promote trust and to help the teachers feel comfortable sharing. The types of interactions discussed above are less likely to develop in traditional professional development settings where teachers are not given opportunities to collaborate with the members of their group on a regular basis.

Regarding action research, the context of the study groups examined in this study, Atweh (2004) made a compelling argument for the use of action research in mathematics classrooms. Action research can be a catalyst for teacher learning since the learning process involves prior knowledge, experience, and reflection, all of which are a part of the action research process. This type of research also affords teachers the professional status and autonomy they deserve. "If teachers are to enjoy the status of autonomous professionals they should feel that they are in control of the processes of knowledge generation as well as knowledge application" (Atweh, 2004, p. 203). This study adds to the argument for doing action research. Teachers, just like students, need good tasks and environments in order to be able to engage in good discussions. The action research project proved to be a good venue for the types of discussions that promoted the teachers to engage as critical colleagues. It was through these projects that the teachers were able to share their classroom practices, including their successes and their struggles, and give and receive constructive feedback.

## Endnotes

1. This data was collected as part of an NSF grant (#0347906) focusing on mathematics classroom discourse (Herbel-Eisenmann, PI). Any opinions, findings, and conclusions or recommendations expressed in this article are those of the authors and do not necessarily reflect the views of NSF. We would like to thank the teachers for allowing us to work in their classrooms.

# TEACHERS' CONSTRUCTION OF DYNAMIC MATHEMATICAL MODELS BASED ON THE USE OF COMPUTATIONAL TOOLS

Aarón Reyes-Rodríguez
UAEH
aaronr@uaeh.edu.mx

Manuel Santos-Trigo
Cinvestav-IPN
msantos@cinvestav.mx

*To what extent does the use of computational tools offer teachers the possibility of constructing dynamic models to identify and explore diverse mathematical relations? What ways of reasoning or thinking about the problems emerge during the models construction with the use of the tools? These research questions guided the development of the study that led us to document the process exhibited by high school teachers to model mathematical situations dynamically. In particular, there is evidence that the use of computational tools helped them identify and explore a set of mathematical relations dynamically. In this process, the participants had opportunity of fostering an inquisitive approach to models construction that values ways of formulating conjectures or mathematical relations and ways to support them.*

## Introduction

Models construction plays a fundamental role during the development of mathematical knowledge. In particular, the modeling cycle that involves examining the phenomenon to be modeled, identifying and discussing assumptions and elements to construct the model, and exploring and validating the model provides useful information to frame an instructional approach to foster teachers' practices and students' mathematical thinking. In this context, we argue that a central activity in students' process of developing mathematical concepts and solving problems is the construction of models that are used to identify, explore and support mathematical relations. Goldin (2008, p. 184) states that "…A model is a specific structure of some kind that embodies features of an object, a situation or a class of situations or phenomena – that which the model represents". How a model is constructed? How can one evaluate the pertinence of a model? What is the role of the use of computational tools in the construction of models? To respond to and discuss these questions, we identify an inquisitive or inquiry approach as a crucial activity associated with the modeling process.

> Mathematical modelling is the process of encountering an indeterminate situation, problematizing it, and bringing inquiry, reasoning, and mathematical structures to bear to transform the situation. The modelling produces an outcome –a model– which is a description or a representation of the situation, drawn from the mathematical disciplines, in relation to the person's experience, which itself had changed through the modelling process. (Confrey & Maloney, 2007, p. 60)

Teachers need to problematize their instructional practice in order to construct instructional routes. In this process, it is crucial that they get engaged into an inquisitive approach to examine the situation (formulation and discussion of questions) in terms of mathematical resources and strategies that lead them to the construction of models. A model then, is the vehicle for teachers to identify mathematical relations and to solve problems. We contend that the development and availability of computational tools offer teachers and students the possibility of enhancing their repertoire of heuristics strategies to deal with mathematical relations embedded in models. It is also important to recognize that different tools may offer distinct opportunities for them to represent and approach mathematical problems. For example, with the use of dynamic software, such as Cabri-Geometry or Sketchpad, some tasks can be modeled dynamically as a mean to identify and explore diverse mathematical relations or conjectures. Thus, tasks or problems are seen as opportunities for teachers and students to engage in the construction of models. In this process they pose and pursue relevant questions as a mean to identify and represent relevant information that guides that construction. In this study, high school teachers worked on a series of mathematical tasks in which they had the opportunity to construct and explore mathematical models. Those models provided them relevant information to think of and design their instructional routes. They were encouraged to use dynamic software during the process of constructing and refining the models.

## Conceptual Framework

Kelly and Lesh (2000) have recognized that researchers, teachers, and students rely on models to represent, organize, examine, and explain situations. For instance, researchers construct models to analyze and interpret teachers and students' activities. Teachers use models to describe, examine, and predict students' mathematical behaviors, while students use models to describe, explain, justify, and refine their ways of thinking. Thus, a model is conceived of as a conceptual unit or entity to foster and document both the teachers' construction of instructional routes and the students' development of mathematical knowledge.

In this context, it becomes important to identify not only the basic ingredients or elements of a model; but also to characterize the process involved in the construction of models. Doerr and English (2003, p. 112) define models as "systems of elements, operations, relationships, and rules that can be used to describe, explain, or predict the behavior of some other familiar system". That is, the models construction involves examining the situation or problem to be modeled in order to identify essential elements that are represented and scrutinized through operations and rules with the aim of identifying and exploring mathematical relations. Here, we are interested in documenting cognitive behaviors that the problem solver (teacher or student) exhibits during the interaction with the task. Thus, it is important to distinguish phases or cycles that explain relevant moments around the teachers or students' process of models construction. In particular, ways in which teachers or students refine or transform initial models of the situation or phenomenon into more robust or improved models to deal with the situation.

In order to identify the essential elements embedded in a task or phenomenon it is important to comprehend initially the situation or problem (Polya, 1945). Understanding phenomena or situations that involve real contexts demands not only the recognition of the key elements around the problem or dilemma; but also ways to represent them mathematically. This phase is crucial to construct the model that will be explored through mathematical resources and strategies. The exploration stage leads us to search for different approaches and media to examine the model and eventually to solve the problem. The next stage is to interpret and validate the solution in terms of the original statement or problem conditions. In this process, it is important to analyze and discuss whether the model used to solve the problem or situation represents a tool to approach a family of problems or situations.

Is the model of the situation appropriate? Is the solution reasonable and consistent with the problem statement? Can the model be improved? Can the model be extended? What are the mathematical resources, concepts and strategies that were relevant during the construction and exploration of the model? These types of questions are crucial to evaluate the strengths and limitations of the model and to extend the model scope (Niss, Blum, & Galbraith, 2007).

Figure 1 represents a modeling cycle that shows relations and operations that allow transferring features of the phenomenon into the model construction. How can the use of computational tools influence and help the problem solver construct and explore mathematical models? Zbiek, Heid, and Blume, (2007, p. 1170) suggest that in experimental mathematics, computational tools can be used for:

(a) Gaining insight and intuition, (b) discovering new patterns and relationships, (c) graphing to expose mathematical principles, (d) testing and especially falsifying conjectures, (e) exploring a possible result to see whether it merits formal proof, (f) suggesting approaches for formal proof, (g) replacing lengthy hand derivations with tool computations, and (h) confirming analytically derived results.

In particular, the use of dynamic software could play an important role in constructing dynamic models of situations or tasks. The models represent configurations made of simple mathematical objects (points, segments, lines, triangles, squares, etc.) in which, some elements of the models can be moved within the configuration in order to identify and explore mathematical relations. As a consequence, the same process of model construction and exploration incorporates new ways to represent, formulate, and explore mathematical relations.

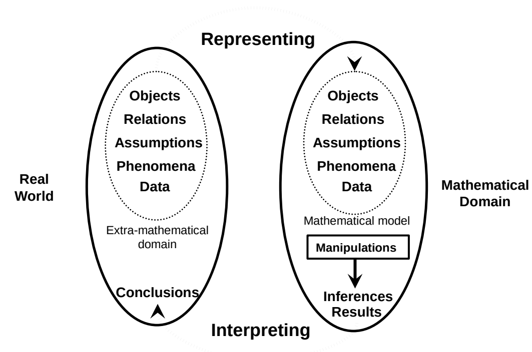

*Figure 1*. Modeling cycle.

inquisitive approach to the tasks. In this process, the teachers worked as a part of the community not only to solve the problems; but also to have opportunities to review mathematical contents that emerged while solving the tasks. The problem solving sessions were recorded and each team handed in a report that included the software files. The researchers took notes and discussed the advantages in using the tool during the diverse problem solving phases. In this report, we focus on analyzing the work shown by the community while dealing with a problem embedded in a real context. Thus, the unit of analysis is the work shown by the six participants as a group during the sessions. The task discussed throughout this report is representative of the type of problems that the community addressed during the development of the sessions.
In general, the participants had experience in using computational tools and they were encouraged to use them during their interaction with the tasks.

*The task.* Figure 2 shows a car going on a straight highway. Aside there is a palace and the driver wants to stop so that his friend (the passenger) can appreciate the facade of the palace. At what position of the highway should the driver stop the car, so that his friend can have the best view? (Adjusted from Vasíliev & Gutenmájer, 1980).

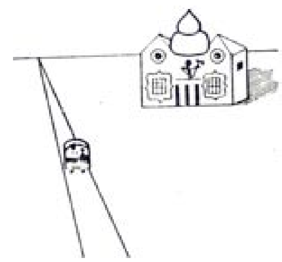

*Figure 2.* The palace.

**Presentation of Results**

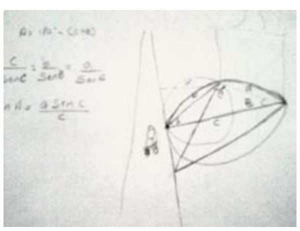
We organize and structure the results in terms of identifying essential phases around the process of model construction that the participants exhibited during the interaction with the task. These phases include the initial comprehension of the statement of the task; the identification of basic elements to construct a model of the problem; the exploration of the model and the formulation of conjectures; ways to support mathematical relations and conjectures, interpretation of results and validation and extension of the model.

*A. Understanding the task statement: An inquiry approach.* This phase was important to comprehend the task and to identify and discuss a set of assumptions that led the community to identify the elements to be considered in the model construction. To this end, the community posed and discussed the following questions: How can we identify that for a distinct position of the car, the passenger has different views of the palace? What does it mean to have the best view? Is it sufficient to consider the position of the passenger on the highway as a reference instead of the car to determine the best position? It was observed that the figure provided in the statement of the task helped them to visualize and eventually represent the problem. They relied on the figure to assume that the observer could be identified as one point that is moved along a line (the highway). Here, the community also discussed if the provided information was sufficient to solve the task since there was no quantitative data involved in the statement.

Initially, the community identified two ways to characterize the best view of the facade: One that related the distance between the observer and the facade (less distance better view) and the other that focused on relating the best view to the angle that is formed between two points on the facade and the observer. The former interpretation was chosen by the community and became a source or a departure point to construct the model of the situation. At this moment, the task was thought of in terms of the basic elements (line, angles, segments, etc) as a way to construct a mathematical model.

*B. Model construction.* The initial analysis of the statement led the community to construct a dynamic model of the situation by representing elements of the task (highway, facade, and observer) through geometric objects (lines, segments, points, angles). In this context, Sophia proposed to represent the highway with a straight line and the passenger a point of that line, and a segment as the base of the palace's facade. Why can the facade of the palace be represented through a segment? Some of the participants argued that the best view means to compare angles that relate the wide of the palace (represented by a segment) and the point that represents the observer. In general, the participants agreed that Sophia's representation included the relevant information of the task. It is important to mention that in order to explain what happens to the angle for various position of the point (the observer) they recognized that it was necessary to identify and notate explicitly the main objects embedded in the problem (points, angles, line, segment). Here, some teachers initially used paper and pencil to sketch a problem representation but later, the use of the tool (dynamic software) became important to visualize the angle variation for different positions of the observer.

*C. Model exploration and conjectures.* At this stage, there appeared two ways to represent the statement: One in which some participants used paper and pencil and relied on trigonometric relations to construct and explore the model (Figure 3, left); and the second approach in which the use of the tool guided the model exploration. Thus, the participants who decided to use the software, started to observe the behavior of some attributes of triangle APB (area, perimeter, and angles) when point P was moved along line L. Here, by assigning measurements to those attributes, both the areas and perimeters of the family of triangles did not reach a maximum value. In particular, Sophia and Jacob noticed that when point P was situated on a position that was collinear with point A and B, then the angle APB measured zero degrees; but when point P was moved to the right of the collinear position the measurement of angle APB increased for some positions and then the angle value decreased.



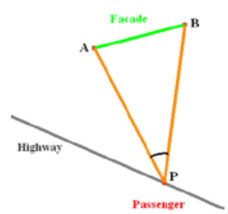


*Figure 3.* Paper and pencil representation (left) and a dynamic model (right).

Thus, they focused on determining the position for point P on L in which the angle APB reaches its maximum value. There appeared two ways to identify the maximum value of the angle. One in which some of the participants directly visualize the numbers displayed while moving point P along the line L (Figure 4); and another in which the participants construct a graphic representation that involves the distance AP and the corresponding value of angle APB (Figure 5).

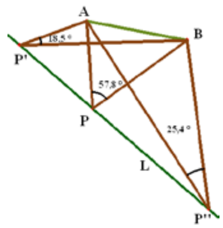

*Figure 4*. Identifying various positions for point P and the angles formed with end points of segment AB.

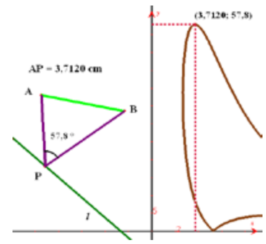

*Figure 5*. Graphic representation of the variation of the value of angle ABP when point P is moved along line L.

The participants were aware of the need of looking for an algebraic or geometric argument to justify the position of point P where the angle reaches its maximum value. In this process, Daniel and Emily decided to draw the circle that passes through points P, A, and B. Based on this construction, they realized that when point P is moved along line L, then the circle that passes through points P, A, and B seems to be tangent to line L at the position where angle APB reaches its maximum value (Figure 6).

Based on this information a conjecture emerged: *To identify the point where angle APB reaches its maximum value is sufficient to draw a tangent circle to line L that passes through points A and B. That is, the tangency point of the circle and line L is the place where the observer gets the best view of the palace*. How can we construct the circle that passes through A and B and is tangent to line L? Emily posed this question to the rest of the participants during the class discussion. Sophia and Jacob suggested that it was relevant to identify relevant properties of the tangent circle assuming its existence. That is, if the tangent circle exists, what properties should it have? Here, it was recognized that the circle must lie on the perpendicular bisector of segment AB and also that its centre must also be on the perpendicular to line L that passes through the tangent point. Thus, David drew a perpendicular line to L that passes through point P and the perpendicular bisector of segment AP. These lines get intersected at point D. What is the locus of point D when point P is moved along line L? With the use of the software the locus was determined (Figure 7). Thus, the intersection point (C) of the locus and the perpendicular bisector of AB was the centre of the tangent circle. Here, to draw the circle they drew the perpendicular from point C to line L, and the distance from point C to line L was the radius of the tangent circle (Figure 7). During the class, it was also argued that the locus of point D when point P is moved along line L is a parabola, since point D is on the perpendicular bisector of segment AP and it holds that d(P,D) is always the same as d(D,A) (definition of perpendicular bisector). Here, the focus of the parabola is point A and the directrix is the line L.

Sophia and Jacob constructed the tangent circle to L that passes through point A and B by drawing initially the perpendicular bisector of segment AB. Later, they situated a point C on that perpendicular bisector and drew a circle with center point C and radius the segment CA. They also drew a perpendicular to line L that passes through point C. This perpendicular and the circle get intersected at point D. What is the locus of point D when point C is moved along the perpendicular bisector of AB?

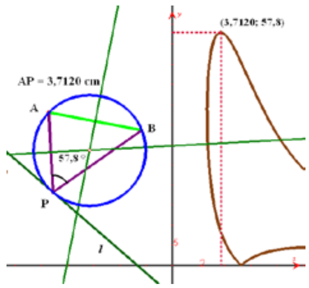

*Figure 6*. The circle that passes through point P, A, and B seems to be tangent to line L when angle APB gets the maximum value.

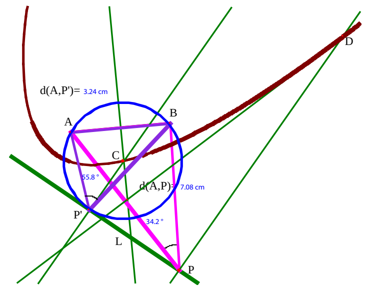

*Figure 7*. Drawing a tangent circle to line L that passes through points A and B.

Again, the use of the software showed that such locus was one branch of a hyperbola. The locus intersects line L at point P. The perpendicular line to L that passes through point P intersects the perpendicular bisector of segment AB at point C'. Thus, to draw the tangent circle to L that passes through points A and B it was sufficient to draw the circle with center point C' and radius segment C'P (Figure 8).

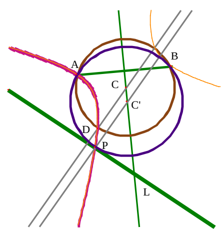

*Figure 8*. Using a hyperbola to construct a tangent circle to line L that passes through points A and B.

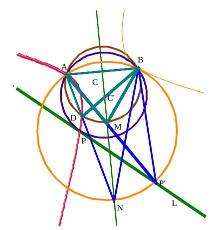

*Figure 9*. Providing an argument to show that angle APB reaches the maximum value.

*D. Interpretation and model validation.* During the class discussion, the participants recognized that the problem of finding the best view was reduced to construct a tangent circle to a line that passes through two given points; however, it was important to provide a mathematical argument to validate that the tangency point was the position where the angle gets its maximum value. To present the argument they relied on figure 9: Point M and N are the intersection points of the perpendicular bisector of segment AB and circles that pass through points ABD and ABP' respectively.

Thus, to compare the values of angle ADB and angle AP'B is the same as comparing angles AMB and ANB. This is because angle ADB is congruent with angle AMB and angle ANB is congruent with angle AP'B. It is also observed that d(A, N) becomes equal to AP when D coincides with point P (tangency point), otherwise d(A, N) is always larger than AM. Therefore, the tangency angle is the angle with maximum value. To evaluate the appropriateness and feasibility of the model the participants changed the original position of the essential elements (highway and facade) and they observed that the model also allowed them to identify the best view of the facade. Including the case in which the facade (segment AB) and the highway (line

L) are parallel, here the best view appears at the intersection of the perpendicular bisector of segment AB and line L.

The participants observed that the domain of the solutions lies on the interval between the intersection of the perpendicular from the extreme of the facade that is closest to the line (highway) and the intersection point of the perpendicular bisector of segment AB and the highway (Figure 10).

*Figure 10*. The model's domain.

## Discussion and Remarks

The model approach used to guide the development of the problem solving sessions helped the participants to focus on key aspects associated with the development of mathematical thinking and practice. For example, firstly, the participants, working as a part of a community, realized that the process of initially comprehending the problem statements is crucial not only to identify essential aspects of the situation, but also to recognize a series of assumptions needed to construct a model of the task or problem. Secondly, they recognized that the model exploration phase represents a departure point for the problem solver to examine the model from distinct perspectives with the aim of identifying a set of relations or conjectures. Later, the conjectures that emerge, during the model exploration phase, need to be supported with mathematical arguments. Finally, the model used to solve the problem needs to be examined in order to evaluate and contrast its pertinence and possible extension to be used in isomorphic or related tasks.

In this context, there is evidence that the use of the tool helped the participants to initially construct a dynamic model of the task. Thus, moving a point (P) on a line (highway) led them to identify and relate the "best view" with the angle formed between the ends of a segment (palace) and that point. How can we measure the angle for distinct positions of point P? How can we identify the angle with a largest value? The teachers used the software to measure the angle for various positions of point P to observe that there was a position where the angle's value was the largest. This visual and empirical approach became important to think of other ways to represent the angle variation. The graphic solution involved a functional approach in which the use of a Cartesian system helped them relate the distance from one end of the segment (AB, the palace) and its corresponding angle. Thus, the graphic approach became relevant to visually identify the point where the angle reaches its maximum value. In addition, moving the point P on the line helped the participants to observe particular behaviors of other objects (circles, segments) within the representations. For example, the teachers observed that the circle that passes through the three points (A, B, and P) becomes tangent to the line when the angle APB reaches its maximum value. Thus, the solution of the task was reduced to draw a circle tangent to the line and the tangency point was the desired point. Again, analyzing relevant properties of the possible solution led them to construct the perpendicular bisector of segment AB and the perpendicular line to L that passes through point P. The locus of the intersection point of those lines when P is moved through line L generated a parabola. Here, the parabola was the key to find the solution of the task. The participants were surprised that a conic section was used to find the point where the observer gets the best view of the palace. They also recognized that the dynamic representation of the problem became important to identify two mathematical results: (a) given a line L and a segment AB that is not parallel to line L, then there is a point P' on the line where the circle that passes through points A, B and P' is tangent to line L. Here the angle AP'B is the angle with the maximum value, (b) given a line L, a point P on that line, and a segment AB that is not parallel to L, then the locus of the intersection point of the perpendicular bisector of segment AP (or BP) and the perpendicular line to L that passes through point P when point P is moved along line L is a parabola. The modeling phases, described in this report, provided useful information to identify a potential route for students to approach mathematical tasks with the use of the tool. Thus, the construction of the dynamic representation, the quantification of attributes (measures of segments, angles, etc.), the identification of loci and the graphic representations are key activities that can help teachers and students to identify and explore interesting mathematical relations. In addition, the use of the tools is also relevant to search for arguments to support those results.

In short, during the modeling processes the participants had an opportunity of identifying and discussing assumptions and essential components that were relevant to construct a dynamic model of the task. The exploration of the model, through an inquisitive approach, led them to formulate a set of conjectures and relations that were important during the solution process. To reach the solution, they relied on empirical, numeric, visual, and algebraic approaches to support and validate conjectures. In this context, the use of the tool seems to help the teachers to experience themselves diverse routes to reconstruct basic mathematical results. These routes are key ingredients for teachers to identify instructional strategies that can foster their students' development of mathematical thinking.

# TWO FOURTH-GRADE TEACHERS' DIFFERENT USE OF MATHEMATICS TEXTBOOKS: COGNITIVE DEMANDS

Ji-Won Son
University of Tennessee
sonjiwon@utk.edu

*This study explored how two fourth-grade teachers transformed problems and teacher questions in terms of cognitive demands in teaching. This study also examined factors influencing their textbook use. Analysis results revealed that although two teachers used the same textbook, they used it differently. One teacher closely followed the textbook and thereby maintained the higher level of student thinking. However, the other teacher lowered the cognitive level by using teacher questions that focus on procedure and finding the answer. Teachers' different teaching goals for learning were identified as a significant factor that leads teachers to use the same textbooks differently.*

## Introduction

Historically, curriculum materials or textbooks have been a key agent of policies to regulate mathematics practice in ways that align instruction with the reformers' ideas. Unlike objectives, assessments, and other mechanisms that seek to guide curriculum, textbooks are concrete, and provide the daily information of lessons and units: what teachers and students do. Textbooks are, therefore, often used as a means to shape what students learn (Dow, 1991). Accordingly, research on teachers' textbook use and influential factors has been done over the course of two decades and has provided a substantial number of categories of teachers' textbook use patterns and factors that influence them (e.g., Freeman & Porter, 1989). However, most of the previous studies on textbook use focused on the maximal extent of coverage, such as to what extent teachers use textbooks in planning and teaching school subjects. Therefore, they provided three or four different textbook use patterns such as a textbook-follower, a textbook-adaptor, and a textbook-ignorer. However, these findings do not help us understand how teachers use their textbooks to provide different students' learning opportunities.

According to the *Professional Standards for Teaching Mathematics* (NCTM, 1991), opportunities for student learning are not created simply by putting students into groups, by placing manipulatives in front of them, or by handing them a calculator. Rather, the level and kind of thinking in which students engage with mathematical problems, what Stein and Smith (2000) called, "cognitive demands" of mathematical problems *determines* what students will learn (p. 19). Yet, there are a few studies looking at how teachers use their textbooks in terms of cognitive aspects. Although several studies have examined teachers' practices in terms cognitive demands (e.g., Stein, Grover & Henningsen, 1996), they did not consider the teacher-text relationship (i.e. how the cognitive demands of mathematical tasks presented in *textbooks* were changed when teachers planned and implemented these task during instruction).

This study therefore explored whether and how the cognitive demands of the textbook versions of problems and questions were changed when teachers moved content from text to teaching and what factors influenced their textbook use. In particular, this study examined whether and how two teachers used the same textbook differently in terms of cognitive demands.

## Research Questions

The purpose of this study is to examine two fourth-grader teachers' textbook use in terms of cognitive demands of problems and questions and influential factors. The detailed research questions are as follows:

1. How do two teachers use their textbooks in terms of the cognitive demands of problems and questions?
2. What factors influence teachers' use of the same textbook?

## Conceptual Framework

In order to examine teachers' textbook use in terms of cognitive demands, this study refers to Stein and Smith (2000)'s study. A problem in this study means a mathematical object to be solved or answered that requires logical thought, whereas a question is a pedagogical object suggested in the textbook or used by teachers during instruction that directs the student to think in certain ways, reflect on their math work (i.e., teacher questions). According to Stein and Smith, *cognitive demands of problems* mean the kind and level of student thinking required when (students) engage in problems; *cognitive demands of questions* means the kind and level of student thinking required when (students) engage in teacher questions (Stein, Grover & Henningsen, 1996).

Problems and questions presented in textbooks and those used by teachers during instruction can be categorized into two different levels of cognitive demands—problems (and questions) requiring high-level cognitive demands on students and those requiring low-level cognitive demands on students as Table 1 shows.

*Table 1*

Two Types of Problems and Questions in Terms of Cognitive Demands of Student Thinking

| | High-level | Low-level |
|---|---|---|
| Characteristics | • Require complex and non-algorithm thinking.<br>• Require students to explore and understand mathematical concepts<br>• Require students to analyze the task and possible solution strategies<br>• Usually are represented in multiple ways (e.g., visual diagrams, manipulatives, symbols)<br>• Require making connections among multiple representations.<br>• Require engagement with the conceptual ideas that underlie the procedures. | • Involve either reproducing previously learned facts, rules, formula, or definitions<br>• Are algorithmic. Use of the procedure is either specifically called for or its use is evident based on prior instruction, experience<br>• Do not require students to make connections to the concepts or meanings that underlie the procedure being used.<br>• Are focused on producing correct answers<br>• Do not require students to give explanations,<br>• Focus solely on describing the procedure that was used. |
| Example | Use a diagram to illustrate how the fraction 3/3 represents the same quantity as the decimal 0.6 or 60% | Find an equivalent fraction. ½= ( )/6<br>Completing multiplication tables |

A mathematical problem demanding high-level cognitive processes requires students to recognize transformed versions of a formula they have already learned. The focus for high-level problems is on comprehension, interpretation, flexible application of knowledge and skills, and assembly of information from several different sources to accomplish work. In contrast, a problem involving lower cognitive demands requires students to use memory: Students are required to reproduce or recognize information they have already seen or they have to use algorithms to generate answers to a set of problems. The focus for low-level problems is on memory, formulas, or algorithms to accomplish work. This study employed this framework in analyzing problems and teacher questions in textbooks and those used by teachers in teaching.

## Methods

*Participants and Textbooks*

Two fourth-grade teachers participated in this study. Brad had 7 years of teaching experience at the elementary school while the other teacher, Karen had four years of teaching experience. They worked together at the same elementary school and in the same grade in the U.S. (all names are pseudonym).

*Math Trailblazers* (Wagreich et al., 2004) was used by the teachers. *Math Trailblazers* is one of many commercially published texts revised to reflect changes called for by the NCTM *standards*. Problems and questions in this textbook were analyzed based on Stein and Smith's framework above before conducting the study. The vast majority of the problems and questions presented in the textbook were categorized as high level problems and questions that require students to use *procedures with connections* to meaning, concepts, or understanding and *doing mathematics* (Hiebert, 1999). For example, a typical problem presented in *Math Trailblazers* (Grade 4, Wagreich, et al, 2004, p. 922) is: "Look for patterns in the number sentences and find another equivalent fractions." This problem requires students to focus on the relationship between numerators and denominators and use the patterns, as opposed to simply following the rule, in order to find other fractions equivalent to one half. Questions presented in the teacher's manual of *Math Trailblazers* were also categorized as requiring students to engage in thinking, reasoning, problem-solving, justifying, and communicating about mathematics. These questions include the language like "look for", "explain"," justify".

*Data Collection and Analysis*

In order to examine how two fourth-grade teachers interact with the textbook and what factors influence their decision-making, I observed and interviewed each teacher while they were teaching a fraction unit across two semesters. During the observation, I took field notes focusing on problems and questions the teachers or students worked on. Post-observation interviews were tape-recorded. In the analysis of two teachers' textbook use, audio-taped interview data, the transcripts of interviews, documents related to teachers' use of textbooks (teachers' lesson plan from the teacher's manual and my observation notes), and my observation were used. Based on Stein and Smith's (2000) framework, each problem used by teachers was classified into either high-level or low-level. The interview data were analyzed in order to explore possible reasons why teachers used the same textbook differently. First, interviews were transcribed into printed text. I then read the transcripts carefully. While I obtained a general sense of the information through that reading, I tried to make a list of emergent ideas from the reading of the data (e.g., Miles & Huberman, 1994).

## Results

Analyses of the two teachers' use of the textbook revealed that there were similarities between these teachers on the dimension of the mathematical problems they set up. The same

mathematical problem was used in both classes and was set up in essentially the same manner. However, different from Brad, Karen lowered the cognitive demand level of the textbook problems by using teacher questions that focus on procedure and finding *the* answer the ways in which students actually went about working on the problems differed in the two classes. During instruction, Karen shifted the emphasis from meaning, concepts, or understanding to using procedures. She took over students' thinking and reasoning and specified explicit procedures for finding equivalent fractions. As class went over, Karen's questions became much narrower, asking students to fill in the blank rather than construct an answer (e.g., "two times two is?). Karen attempted, and rarely managed, to surface students' mathematical thinking using her questions. In this paper, I will describe how Karen transformed the cognitive demand of textbook problems when teaching the topic of equivalent fractions using *Math Trailblazers*. In particular, I will use the lesson "equivalent fractions" in Karen's class, which I observed in Brad's class.
*1. How do two teachers use their textbooks in terms of the cognitive demands of problems and questions?*

Before observing her class, Karen gave me a copy of her lesson plan, reproduced as Figure 1, which came directly from the teachers' manual of her textbook. Brad closely followed suggestions presented in Figure 1.

1. Ask students to use their fraction chart from Lesson 3 to find all of the fractions that are equivalent to ½. List these on the board or overhead.
2. Ask students to compare the numerators and the denominators of the equivalent fractions in order to look for patterns.
3. Ask students to suggest other factions that are equivalent to 1/2
4. Write number sentences on the board or overhead showing the equivalencies
5. Students look for patterns in the number sentences
6. Students use the patterns (multiplying or dividing the numerator and the denominator by the same number) to find fractions equivalent to 3/4, 1/3, and 2/5.
7. Students use the patterns to complete number sentences involving equivalent fractions
8. Students complete *Questions 1-5* on the *Equivalent Fractions* Activity Pages in the Student Guide as independent practice
9. Assign Homework *Questions 1-15* on the *Equivalent Fractions* Activity Pages in the Student Guide. Students will need their fraction charts to complete this assignment

Source: From *Math Trailblazers Fourth Grade Teacher's Lesson Guide* (p. 924), by Wagreich, P., Goldberg, H., Bieler, J.L., Beissinger, J.S., Cirulis, A., Gartzman, M., Inzerillo, C., Isaacs, A., Kelso, C.R., & Peters, L(2004), TIMS Project, Dubuque, IA:Kendall/Hunt.

*Figure 1*. Summary of lesson activities in lesson.

Like Brad, Karen used activities suggested in the lesson guide. Karen asked students to look at the fraction chart they used in the previous lessons and find all of the fractions that were equivalent to one half. Like Brad's class, students in Karen's class easily came up with the equivalent fractions. As suggested in the lesson guide, Karen asked students to arrange these equivalent fractions in an order such that a denominator gets bigger. As in Brad's class, students arranged them and Karen wrote them on the board, such as. Karen again asked students to write this arrangement of these equivalent fractions down underneath the word "equivalent fractions" in students' notebook. In the meantime, she told them that all of these fractions are the same size.

As students finished writing down equivalent fraction sentence, Karen asked students to find patterns by comparing the denominators. Students noticed two patterns, "counting by twos" and “even”, but they did not come up with the answer that Karen expected, which is multiples of two. In this instance, Karen interacted differently from Brad. While Brad gave hints, waited until students volunteered to answer, and had students discuss the incorrect answer, Karen told her students the expected answer. This interaction with students exemplifies how teachers decrease the cognitive demand of problems during instruction. Henningsen and Stein (1997) reported that teachers often decrease the cognitive demand of student thinking by taking over student reasoning and telling students how to do the problems.

For the rest of the lesson, I repeatedly observed this pattern. For example, after having students find the relationship between the numerators and between the denominators of fractions equivalent to one half, Karen asked students to look at the numerators and denominators together of each of equivalent fractions and find patterns. Several students responded, but none provided her expected answer. Karen again said to students “the numerator is half of the denominator, isn’t it?” Indeed, Karen’s telling was more obvious when students did not figure out patterns in the number sentences. She wrote four number sentences on the board and said:

> I have on the board four number sentences. Four number sentences. The first one, one half equals two fourths. The second one, one half equals four eighths. The third one, one half equals five tenths and the fourth one is one half equals six twelfths. Look at that pattern in these number sentences, first by looking at the numerators and then by looking at the denominators. What do you see?

This problem requires students to focus on the relationship between numerators and denominators and use the patterns, as opposed to simply following the rule, in order to find other fractions equivalent to one half. One student answered but his answer did not show the relationship between numbers and denominators. The same mistake occurred in Karen’s class as in Brad’s class. In both Karen’s and Brad’s classes, when students were asked to find the relationship in the number sentences as above, students tended to compare the denominator of the first fraction and the numerator of the second fraction, and find the relationship. For example, in Karen’s class, one student found the relationship for the first number sentence, such as “If you take two and times it two you get four”. Karen responded to this study as follows: “Is this what you were saying? One times two is?” Karen paused and students said “two”. Karen again said, “two times two is?” and paused. Students said “four.”

Although Karen set up problems finding the relationship and used it to find other equivalent fractions, as students became confused, Karen gave the pattern as a rule that students needed to follow, which requires low level of student thinking. Karen said, “Here is the rule. Get your pens ready. If you multiply both the numerator and the denominator of a fraction by the same number, the result will be an equivalent fraction”. Karen asked students to copy out the rule in their notebook, and repeatedly stated the rule while students were writing the rule down. During an interview, Karen mentioned that “students need to memorize it to apply it”; contrast with Brad who said that “students need to make a discovery for themselves.” By using the rule, Karen tried to have students see patterns in the rest of number sentences. For example, Karen asked students to take a look at the third number sentence and see whether the rule works. Some students nodded their heads to say yes and some kids shook their heads for no. She said:

> That’s what the rule says. Multiply both the numerator, that’s my numerator and the denominator by the same number. The result will be an equivalent fraction and I said over here that one half equals five tenths (interview, 04/27/2007).

Karen led the students through four number sentences involving equivalent fractions, all the while focusing on the procedure. For example, for the fourth number sentence, Karen repeatedly asked, “Three times what equals six?” Karen paused and students said “two.” Karen asked again, “Four times what equals twelfths?” and paused. Students said “two.” Karen’s questions became procedure-oriented, required only multiplication facts. The conversations that Karen had with students during this portion of class revealed what her goal for the lesson was: writing equivalent fractions by applying the rule.

Like Brad, Karen asked students to explain and justify their answers. For example, Karen also asked students to see if it is true that one third equals two sixths. However, in her class, it was sufficient and acceptable for students to rely on the rule. Consider the following Karen’ remark: “We said it’s true if we could multiply both the numerator and the denominator by the same number to come up with the answer. What number do I multiply one times two is equal?”

Karen ended up the lesson by asking students to create the number sentences involving equivalent fractions such as “one times two is two and six times two is twelve”, which is expressed as in a numerical form. Karen called out one student. But the selected student said, “I don’t know how to do this”. Karen called out other students. A few students could make the number sentences described above. Karen used the same mathematical problems as those used in Brad’s class for an introductory teacher activity and student exercise. Therefore, the problems set up in Karen’s class focus students’ attention on the discovery of patterns and the use of the patterns for finding equivalent fractions, which demands complex thinking and a considerable amount of cognitive effort. However, the questions most frequently used in Karen’s class were “what number do we multiply?” which require only multiplication facts. In Karen’s class, the procedure of “how to do it” was stressed above all else. In an interview, she confirmed her typical questions as below:

> I think probably the question that I asked over and over again and maybe not in this exact word is “What number should I multiply both the numerator and the denominator by to find the equivalent fraction?” I probably said that a hundred times (interview, 04/27/2007).

Her remark “a hundred times” shows not only how frequently she used this type of questions during the class but also how she was aware of her frequent use of this type of questions in her class. Students in Karen’s classroom were rarely pushed to elaborate on their answers. If students’ responses reflected the correct answer, the teacher did not raise follow-up questions to make students’ mathematical thinking explicit. If students’ responses reflected the incorrect answer, teachers paraphrased the answer, changing it to make it more “accurate.” Although *Trailblazers* provide a lot of suggestions in the lesson guide for how teachers should approach questioning or approach discussing concepts, Karen did not use those questions. She shifted the emphasis of their work from meaning or understanding to the use of procedure without connections, and decreased the cognitive demands of teacher questions in ways that require lower level of student thinking.

*2. What factors influence teachers’ use of a textbook?*

Karen supplements the lessons from *Trailblazers* with practice problems. While Brad claimed to be a “follower” of *Math Trailblazers*, Karen claimed to be “modifier” of the textbook. She reported that, in total, 50% of lessons came directly from *Math Trailblazers* and the rest 50% came from other resources such as other textbooks. She said that she supplements the textbook with more practice problems from other textbooks, in particular, an old textbook, *Houghton Mifflin Mathematics*. During an interview, Karen said:

> I’ve used old textbooks. I find that in the *Trailblazers* series there is a lot of introducing the concepts but not a lot of mastering the concepts… We have some old texts [*Houghton Mifflin*] like that has more practice than the *Trailblazers* does....*Houghton Mifflin* has some from when I was in school so 1980’s. The Trailblazers series provide a lot of explore, look at, manipulate but it’s very shallow in the practice areas as you can see from the lesson that there’s I don’t know ten problems or seven problems (interview, 04/27/2007).

Together with her use of lower level teacher questions, frequent supplementing of the standards-based textbook with more practice problems reduces the cognitive demand of student thinking. Why did Karen transform her textbook in that way? What factors account for Karen’s transformation? During the interview, Karen provided the rationales for why she added practice problems out of her obligation to meet the Grade Level Content Expectations (GLCE) for Michigan. In addition, Karen’s notion of how students learn also is a factor that influences her use of the textbook and her teaching practice.

*Conflict between Teachers’ Goal and Perceived Goals of the Textbook*

Karen believes that she should cover all the content presented in the GLCEs. Karen described her use of the textbook as follows:

> When I start out at the beginning of the year, I lay out the content expectations that the state has mandated then I try to match up the text with the GLCEs. So when I get to each unit I have to first make sure that I’ve covered all of those content expectations. Because that’s what the state says we have to do. The district has said, this is the text we’re using and that the Trailblazers series. But the district also has said that the Trailblazers series does not cover all of the Michigan grade level content expectations. So therefore you must supplement. So when I’m planning I take a look at the lessons that are in the Trailblazer series and I see which ones of those cover the grade level content expectations and then I look at all the holes that are left over and start using other resources (interview, 04/27/2007).

Karen’s obligation to the contents of the GLCEs influences her pedagogy. During an interview, Karen said:

> When I was at a math meeting a year and half ago we were talking about the new content expectations, what 4th graders are required to know….The curriculum director at the time said, these things are suppose to be taught to mastery and here was this huge group of experts saying, we’re introducing the concepts but the children are not practicing it enough to say that we’ve mastered it….So I’m working really hard on trying to make sure that I can pull from anywhere that I can find practice stuff to make sure my kids are going home and

> working on it on their own, working on it with friends here, that their parents are informed about what we're doing and also working with them at on it (interview, 04/27/2007).

Indeed, "mastery of the concepts" can be interpreted in various ways. Some may think it only from procedural aspects, such as proficiency in computation, whereas others consider it from both conceptual aspects and procedural aspects of the mathematics contents. Considering the recommendations in the GLCEs, definition of mastery requires both conceptual understanding and computational skill (Mcthighe & Wiggins, 2005; Wormeli, 2006). However, Karen seems to recognize the definition of mastery from the procedural aspects. This understanding may cause her to lead instruction more procedure-oriented and emphasize application of the rule in her class.

*Procedural fluency as a Teaching Goal*

Indeed, Karen's obligation to meet the GLCEs is in keeping with her notion of how students learn, as evidenced by the focus of her questions on procedures—on *how* rather than *why*. Karen put more emphasis on application of the rule than on sense-making or meaning in learning mathematics. Karen articulated her goals as "proficiency in writing equivalent fractions" and "mastering the concepts and applying it" in general. This differs from the evidenced by teachers in the first pattern which matches the category "understanding-oriented". Together with Karen's view on the emphasis of Grade Level Content Expectations, her learning goal seems to push her to supplement the textbook with more practice problems and change the emphases from understanding to following rules to solve problems in her classroom.

## Discussion and Implications

Although Brad and Karen used the same textbook, Brad maintained the cognitive demand of the textbook problems by using higher level teacher questions, whereas Karen decreased the level by using lower level teacher questions. The reason behind this different use of textbook is their different teaching goals for student learning. While Brad wanted students to develop the underlying ideas between equivalent fractions, generate the rule and apply the rule to find equivalent fractions, Karen wanted students to follow the rule to find equivalent fractions. She believed that practice makes perfect. Different teaching goals led them to use the same textbook in different ways, which in turn provided different notions of knowing mathematics and doing mathematics. This study suggests that the extent to which teachers' ideas about how mathematics is learned matches the teaching and learning philosophies of the textbook contributes significantly to their use of curriculum.

This study provides implications for policy makers, curriculum developers, professional developers, and teacher educators. For example, for professional developers, this study suggests that they should provide opportunities for teachers to learn and participate with their textbooks in professional development and should provide teachers with opportunities to change their notions of learning and teaching mathematics. Research has documented the challenges that many teachers face when they try to conduct lessons that take into account and productively build on student responses (e.g., Ball, 2001). All teachers need support. In particular, teachers like Karen need to teach about mathematics as a field of inquiry, not as a body of procedures. They need to learn to think about the goals of learning mathematics as greater than the mastery of computational skills. Teachers cannot make fundamental changes in their teaching without several kinds of support, such as time and assistance in examining and evaluating their own assumptions about how children learn mathematics and comparing their assumptions to those represented in standards-based curriculum. Reformers and policy makers must find ways to communicate about change in a way that makes sense and respects where teachers are, while still helping them realize that they are being asked to rethink what they do, and in a way that provides guidance for that change.

# MATHEMATICS TEACHERS AND PROFESSIONAL LEARNING COMMUNITIES: UNDERSTANDING PROFESSIONAL DEVELOPMENT IN COLLABORATIVE SETTINGS

Matthew P. Campbell
North Carolina State University
mpcampbell@gmail.com

*For professional learning communities (PLC) to be used as a form of mathematics professional development (MPD), more work needs to be done to identify the extent to which mathematics teachers in PLCs engage in the activities that address their content and pedagogical needs. This paper reports on a study that investigated mathematics teachers' attempts to implement principles of PLCs. Based on the findings, the role of PLCs as the sole source of professional development for mathematics teachers is questioned. Suggestions for future research on collaborative MPD and its benefits for the design and replication of professional development interventions are offered.*

## Background

The rapid growth of the field of literature on mathematics professional development (MPD) is due to the realization that teachers should be better prepared to be able to improve their own instructional practices (Sowder, 2007). As a result, recent studies have attempted to identify effective MPD initiatives and find a set of features that are commonly part of these successful programs (e.g., Yoon et al, 2007; Garet et al, 2001). This search has led to findings that professional development experiences that are sustained (Garet et al, 2001), practice-based (Ball & Cohen, 1999), and allow for teacher involvement in the decision making process (Yoon et al, 2007) are successful in terms of the high value that teachers place on the experience as well as resulting increases in student achievement. Additionally, research has shown that the opportunity for collaboration is both valued by teachers (Garet et al, 2001; Arbaugh, 2003) and plays a role in supporting inquiry and problem solving (Loucks-Horsley et al, 1998). Given the recent focus on professional development, especially in collaborative settings, it is important to define the work of teachers in groups in order to identify what influences teacher learning and aid in the design of effective MPD.

Professional learning communities (PLC) provide both an organizational framework and a set of requisite dispositions and activities for teacher learning. PLCs are defined as sustained collaborative opportunities where teachers focus on student learning and critically reflect on their shared practice (e.g., McLaughlin & Talbert, 2006; DuFour & Eaker, 1998). In such communities, teachers are empowered to make changes to their practice by inquiring into the best methods of instruction and developing and testing new hypotheses (Louis, Marks & Kruse, 1996). Additionally, the decisions to make changes are based on data from the classroom to determine new and appropriate teaching strategies (DuFour & Eaker, 1998). Studies have shown positive changes in the practice of teachers (i.e., student-centered instruction, high expectations for student learning) in PLCs (McLaughlin & Talbert, 2001; Vescio, Ross & Adams, 2008).

However, not all collaborative groups of teachers engage in the type of examination of practice found with PLCs. Research studies have shown communities of teachers that share values and set expectations for their work with students but avoid the conflicts that can arise during the critical reflection on practice (e.g., Wells & Feun, 2007). As a result, teachers tend to stick with the teacher-centered, traditional methods that are prevalent in schools (McLaughlin & Talbert, 2001). While structural changes such as the availability of meeting time for teachers are important for the work of a collaborative team (Louis, Marks & Kruse, 1996), such changes are relatively easy and are less effective in impacting instructional practices. As a result, the attributes of PLCs are special in the bigger picture of teacher collaboration.

Many MPD interventions claim to rely on collaboration, specifically the shared values and norms for critical reflection that are part of PLCs (e.g., Borko et al, 2008; Lachance & Confrey, 2003; Arbaugh, 2003; Kazemi & Franke, 2004). However, a team's inclination to engage in critical reflection is not the only component of most collaborative MPD interventions. Many programs aim to promote the use of instructional practices such as cognitively demanding tasks, mathematical technology, and *Standards*-based curricula. As a result, certain features are commonly incorporated into collaborative MPD such as video study, task analysis, student work analysis, and engaging with mathematical content and technology. These activities are important as Kennedy (1998) found that a strong content focus in professional development programs had a positive impact on student learning. Additionally, research has linked increases in student achievement to teachers' mathematical and pedagogical knowledge (e.g., Hill, Rowan & Ball, 2005) and their attention to student reasoning (e.g., Carpenter et al, 1999). Ultimately, mathematics teachers are faced with unique challenges that must be addressed with specific forms of professional development activities.

PLCs only provide a general guideline for the organization, activities, and individual and group dispositions necessary to make meaningful change to instruction, regardless of subject. Additionally, there is little documentation of the nature of the work that teachers do while working in PLCs (Vescio, Ross & Adams, 2008). In order for PLCs to serve as an effective form of MPD, more work needs to be done to identify the extent to which mathematics teachers in PLCs engage in the activities that improve their content and pedagogical knowledge and, ultimately, improve student achievement.

The study described here investigated two teams of teachers attempting to implement principles of PLCs as part of a district-wide intervention. The goal of this study was to discover both teams' success in implementing these principles and to what extent the presence of features that are commonly found in effective MPD was evident in their work. From those findings, the author questions the role of PLCs in the professional development of mathematics teachers and highlights other factors that could be attributed to a group of teachers' inclination to engage in activities found in effective MPD. As a result, the author offers suggestions for future research on collaborative MPD and how findings from such research could be used to inform the design and replication of MPD.

## Framework

When comparing the literature on professional communities, PLCs, and collaborative MPD, there are differences in terms of the activities teachers do, their content focus, and what teachers ultimately take away from the experience. Further, some types of collaborative settings rely on many of the characteristics of another type. For instance, PLCs rely on a focus on student learning, experimentation, and inquiry but also rely on the shared values that comprise more traditional collaborative groups. Collaborative MPD interventions often consist of specific activities that focus teachers' attention to students' mathematical thinking. However, the productive use of these types of classroom artifacts relies on the shared practice, results orientation, and comfort with critical reflection, traits which are attributed to PLCs.

As a result, a conceptual framework has been developed to illustrate both the hierarchy and the links among different types of collaborative work (see Figure 1). The framework refers to three stages: Collaboration, Teacher Learning, and Specialized Growth. By using the term stages, it is implied that the features of each type of collaborative setting serve as a necessary foundation for subsequent types of work.

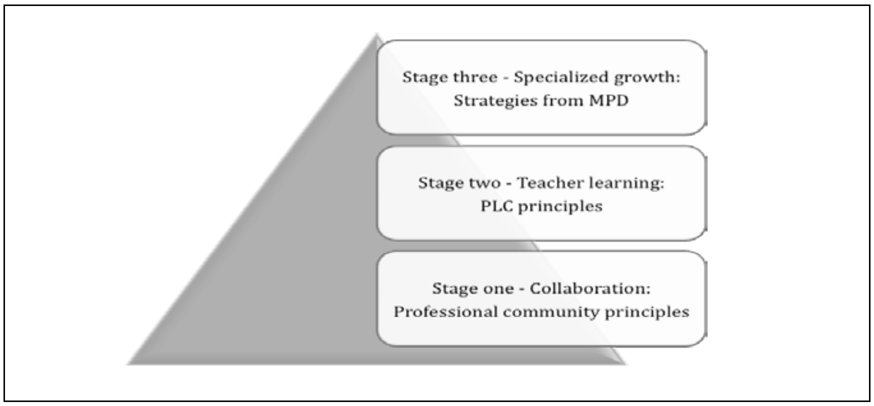

*Figure 1.* Conceptual framework: Stages of mathematics teachers' collaborative work.

To better describe the attributes and features of these three stages, elements have been identified for each. The Collaboration stage consists of three elements: beliefs on collaboration, shared values and goals, and shared role. The Teacher Learning stage consists of three elements in addition to those in the previous stage: collective inquiry, assessment of practice on basis of results, and focus on student learning. Finally, the Specialized Growth stage has three elements: content focus, use of artifacts of practice, and planning and implementing reform-inspired instructional practices.

Each stage also refers to the type of growth that teachers experience at each stage. At the Collaboration stage, teachers worry about logistical and other non-instructional issues, resulting in unchanged practice and, thus, no growth. Teachers at the Teacher Learning stage function as a PLC and, in turn, focus on issues of curriculum, instruction, and assessment resulting in a general pedagogical growth. At the Specialized Growth stage, teachers are focused not only on teaching but are also focused on content, fostering specialized growth in both mathematics content and pedagogy.

Previous work has documented the factors attributed to fostering a group of teachers' movement toward becoming a PLC (stage one to stage two). While structural features such as the availability of meeting time are beneficial toward the growth of a group, other factors such as the empowerment of teachers to be involved in the decision-making process (Louis, Marks, & Kruse, 1996), a focus on issues of curriculum and instruction instead of issues of behavior and policy (McLaughlin & Talbert, 2006), and the use of classroom data to drive decision-making (DuFour & Eaker, 1998) help develop a group of teachers into a PLC.

The transition of a PLC consisting of mathematics teachers to a group engaging in the types of activities found in effective MPD (stage two to stage three) is not as clear. While many MPD interventions claim to value and rely on collaboration and the traits of PLCs, researchers or facilitators drive many of the decisions for activities and content. In order for true PLCs to serve as a source of professional development for mathematics teachers, the role that PLCs play in the specialized growth of teachers must be better defined.

## Methods

*Context*

The study reported in this paper investigated the collaborative interactions of two teams of high school mathematics teachers. The study took place in a large, urban school district in the southeastern United States. A goal of improving high school graduation rates as well as a mission to stay current with movements in the field of education resulted in the district adopting the idea of PLCs to be implemented throughout its schools. Specifically, the district promoted the principles for PLCs described by Rick DuFour and his colleagues (DuFour & Eaker, 1998). Workshops for district teachers were held to present these principles of collaborative learning. Knowing the benefits of teacher collaboration, district administrators hope PLCs eventually serve as the arena for the professional development for all teachers. As a result, attempts have been made to ensure that teachers are given adequate time to work collaboratively and that they develop the skills needed to function as member of a PLC.

*Participants*

Both teams' involvement in the study was the result of their positive response to participating after interest was gauged from schools across the district. Additionally, both teams were focused on issues in Algebra I classes, which provided some control in the study. The two teams were housed at different schools in the same district, Brantley High School and Elmwood High School (both pseudonyms). Both teams met on Tuesday mornings for 45 minutes each week as part of a scheduling change at the school level. Each team was in their first year together, though PLCs had been in the district for two years prior and some teachers from each team had previously worked together in that capacity.

The team at Brantley High School consisted of five teachers, three female and two male. Four of the teachers had five or fewer years of teaching experience and all five teachers had between two and four years of experience teaching Algebra I. The team at Elmwood High School included four teachers, three female and one male. There was generally more teaching experience on this team, with three of the four teachers having taught for at least ten years. Two of the teachers had taught Algebra I for 13 years each. However, the other teachers are in their first year of teaching the course.

*Data Sources*

Data was collected for this study using three sources: team meeting observations, individual surveys, and individual interviews. While the team meeting observations provided the most information about the team's interactions, the interviews and surveys allowed for triangulation of data to ensure consistency of observed phenomena across different environments.

The researcher observed, audio recorded, and took notes on four of each team's weekly meetings over a span of two months. The researcher did not provide any input regarding the agenda for each meeting nor did he provide any feedback after meetings. The teachers participating in the study were also given two surveys consisting of demographic information, goals for their collaborative interactions, and a set of Likert scale questions regarding teachers' experiences with their team and the activities in which they engage with their teams (adapted from McLaughlin & Talbert (2001) and Wells & Feun (2007)). The teachers also participated individually in two interviews over the course of data collection. The first interview was designed to allow teachers to elaborate on their experiences with their team as well as other forms of professional development. The second interview was designed for a different goal as teachers interacted with mathematical tasks and corresponding student work to explicate their dispositions when analyzing tasks and student work.

*Analysis*

For each data source, coding sheets were developed to pair positive indicators of effective group interactions with a corresponding element. For example, the mention or use of common lesson plans, activities, or assessments would be positive indicators for the collective inquiry element of the Teacher Learning stage and working through mathematical tasks or discussing algebraic concepts would be positive indicators for the content focus element of the Specialized Growth stage. By then combining the results across all data sources, consistencies could be noted in order to identify the strengths and weaknesses of a team at each element and, thus, each stage of the framework. These strengths and weaknesses, as well as any inconsistencies across the three data sources, were further examined as possible factors associated with fostering or inhibiting mathematics teacher learning.

## Results

The analysis of data from both teams yielded results regarding each team’s implementation of the principles of PLCs and the extent to which they engaged in activities commonly found in effective MPD. Since, in this context, PLCs had been setup to serve as a form of professional development, this section will highlight each team’s performance as well as factors that can be attributed to each team’s success or difficulties at each stage of the framework.

*Brantley High School*

Based on teachers’ responses regarding collaboration as well as the full use of their available time to meet as a group, it is clear that the team at Brantley High School valued the benefits of collaboration. A common goal for all of the team members was the sharing of ideas and sharing the responsibility on items such as test creation and other materials. However, the roles and responsibilities were not evenly distributed amongst team members, as two teachers were new to the team, which could have impacted their willingness to take a more prominent role.

Despite uneven participation, the team was able to thoroughly engage in activities that are recommended for PLCs. The team made significant changes to their curriculum in response to changes in the course’s cumulative state exam and its effect on student achievement. Among other commonly used materials, the team administered common chapter tests, which were used for data analysis and decision-making. In all, the team focused much of their time on issues of curriculum and assessment and, in turn, student learning. The team’s success has even been used as a model for other teams in their school attempting to implement the same PLC principles.

Despite the team’s success in implementing the principles of PLCs, there was little to no evidence of any of the elements of the Specialized Growth stage in their team meetings or individual responses. Aside from an occasional discussion of algebraic topics with respect to their curricular changes, there was no time spent with mathematical content, artifacts of practice such as video or student work to supplement the assessment data on which they relied, or planning the use of mathematical tasks or technology. In this case, while the team at Brantley was very effective at implementing the PLC principles, they did not engage in the materials and activities based in mathematical content and pedagogy as recommended in MPD literature.

The team at Brantley's success at implementing the principles of PLCs could be explained by the fact that four of the five team members attended at least one of the PLC workshops offered by the district. As a result, it seemed that the team implemented those principles literally, assuring that activities such as common planning, data analysis, and refining curricular materials were a fixture in their collaborative work. However, such a determined focus plus the fact that most of their other professional development experiences were focused on general issues such as classroom management might explain the group's inability to engage in the types of activities that are common in MPD. Without much previous professional development based in their content area, it is not too surprising that these teachers were not self-motivated to incorporate mathematical content and pedagogy into their collaborative interactions.

*Elmwood High School*

For the team of Algebra I teachers at Elmwood High School, while the teachers did seem to share goals for student achievement, there was less evidence that they valued their collaborative interactions. The members of the team seldom cited the value they placed on collaboration and the team also often cut meetings short, even though the meeting time caused no conflicts with the school day. Despite these problems, there was an expectation that all four members of the team participate in the group discussions and bring ideas and materials to share.

At the same time, however, the teachers on the team at Elmwood did not engage in a shared practice. While the team followed a common curriculum and pacing guide, they would only occasionally use common chapter tests and classroom materials. Additionally, the team spent very little time reflecting on their practice or drawing conclusions from classroom data. Much of the team's time was focused on issues not pertaining to curriculum, instruction, or assessment, instead resorting to discussions on class size and student behavior. As a result, this team was not successful in implementing PLC principles at the time of this study. In essence, the team at Elmwood High School was functioning as a traditional collaborative team by sharing values and materials but not taking a critical look at their instructional practice.

Even though much of the team's time was unfocused, when the team did discuss issues of curriculum and instruction, there were many instances that served as indicators for elements in the Specialized Growth stage. During team meetings, teachers worked through mathematical tasks that teachers were going to use in class. The team also referenced curricular resources and other literature on mathematics content and pedagogy. Some of the team's time focused on the use of graphing calculators in the classroom. As a result, the team at Elmwood showed more evidence of engaging in the types of activities that are common features of effective MPD despite their deficiencies as a PLC.

The Elmwood team's performance was far different than that of the Brantley team. However, like the Brantley team, some factors were identified that may be attributed to their effectiveness in implementing the PLC practices and the extent to which they engaged in activities found in effective MPD programs. Only one of the teachers on the Elmwood team attended a PLC workshop offered by the district, which could explain the team's lack of emphasis on principles such as shared practice and data analysis. Moreover, the lesser value that this team placed on collaboration in comparison to the Brantley team could make it difficult for the team to accomplish much at the teacher learning level. Such a claim is consistent with literature on professional communities and PLCs and is in line with the idea of stages found in the framework. However, the team's ability to begin to implement features of professional development commonly found in mathematics-focused programs seems to defy the idea of stages. Upon closer examination, several factors could be attributed to their use of these specialized activities. First, three of the four members had graduate degrees in mathematics education or educational leadership. Given this fact, the professional development of these teachers was much more focused on mathematics content and pedagogy. The individuals on the team also shared a willingness to change the way they teach but did not seem to have the norms to address these issues as a group.

## Discussion

The goal of this study was to evaluate the effectiveness of PLCs in terms of the specialized growth of mathematics teachers and offer recommendations for future research on and design of collaborative experiences for mathematics teachers. The grounds for this study are based in literature on collaborative professional development, specifically research on collaborative MPD. In such work, teachers benefit from the activities and dispositions that come from working as a PLC. However, facilitators provide the direction for these groups toward the specialized growth that impacts mathematical instructional practices and, in turn, student achievement. In order for collaborative MPD to be effective and replicable, the role of PLCs in the professional development of mathematics teachers must be better understood.

The implementation of PLC principles as a professional development intervention should be questioned based on the results of this study. One team was not successful in implementing the principles, which could lead to doubts about the methods used in such a widespread implementation. The other team was successful at implementing the PLC principles but showed no evidence of engaging in the activities or discussions that are commonly found in successful MPD programs, leading to doubts about the real benefits that mathematics teachers can take away from these collaborative experiences.

The results of this study also raise questions about the conceptual framework considered in this paper. The team at Elmwood was not effective in implementing the principles of PLCs but did show evidence of some of the activities that are commonly found in MPD, which would be characteristic of teams at the Specialized Growth stage. Given this team’s ability to incorporate a content focus while struggling to incorporate collaborative norms, such a framework could be reconsidered across two dimensions (collaborative norms and content focus) instead of the one-dimensional approach taken in the original framework. Ultimately, this framework could be used to inform the design of collaborative MPD as an emphasis is needed on both the collaborative norms and the content focus of a group’s interactions in order to lead to the specialized growth of mathematics teachers’ instructional practices.

This study looked at a small number of teams for a relatively short amount of time. However, the findings from this study can inform future research on the collaborative work of mathematics teachers. Future research should look at more teams for a longer period of time to get a more representative account of the growth of teachers in collaborative settings across subjects, schools, and districts. Based on the results of this study, it is also recommended that future research studies take measures of teachers’ content knowledge, pedagogical knowledge, and beliefs on content, collaboration, and reform-inspired instructional practices using the tools, instruments, and assessments available in the field. The results of this study suggest that individual teachers’ knowledge and dispositions could affect the collaborative work of a group. Similarly, researchers should also take into account any ambient factors that surround a collaborative team, such as existing professional development programs, graduate coursework, or the implementation of new curricula. The results of this study suggest that these experiences can impact the work of a collaborative team. By better explicating these factors, the design of MPD interventions can take a broader scope by considering all of the attributes of effective programs and allowing for more efficient replication.

# DEVELOPING TEACHERS' FLEXIBILITY IN ALGEBRA THROUGH COMPARISON

Christopher Yakes
California State University, Chico
cyakes@csuchico.edu

Jon R. Star
Harvard University
jon_star@harvard.edu

*We describe a one-day professional development activity for mathematics teachers that promoted the use of comparison as an instructional tool to develop students' flexibility in algebra. Our analysis indicates that when teachers were presented with techniques for effective use of comparison, their own understanding of multiple solution methods was reinforced. In addition, teachers questioned their reliance on one familiar method over others that are equally effective and drew new connections between problem solving methods. Finally, as a result of experiencing instructional use of comparison, teachers began to see value in teaching for flexibility and reported changing their own teaching practices.*

## Introduction

Recently, Star (2005, 2007) proposed a new conceptualization of procedural knowledge, highlighting the critical importance of strategic flexibility as an instructional outcome for school mathematics. Star (2005; Star & Seifert, 2006; Star & Rittle-Johnson, 2008) defines strategic flexibility as knowledge of multiple approaches for solving mathematics problems and the ability to select the most appropriate strategy for a given problem.

Consider the domain of linear equation solving. What does it mean to be a flexible solver within this domain? A standard algorithm exists for solving linear equations; this algorithm is often explicitly taught as the optimal approach. For an equation such as $3(x+1)=9$, the standard algorithm would involve first distributing the 3, then collecting and isolating like variable and constant terms to opposite sides of the equation, and finally dividing both sides by 3 to solve for *x*. However, this is not the only strategy for solving linear equations; for this particular equation, it may in fact be more efficient to divide both sides by 3 as a first step. A flexible solver not only knows both strategies but also chooses to use the more efficient approach on this problem. This choice reflects expanding knowledge of *when* the divide step is appropriate to use. In addition, if the problem were altered slightly to $3(x+1)=10$, a flexible solver (particularly a middle school student) might realize that dividing by 3 on both sides, though possible, might not be the optimal solution method, since 10 is not evenly divisible by 3. Flexible strategy knowledge reflects better *conditionalized* knowledge of when to use strategies.

Flexibility as an important outcome is alluded to in several recent policy documents, including the National Research Council's [NRC] "*Adding It Up*" report (2001), the *Curriculum Focal Points* from the National Council of Teachers of Mathematics [NCTM] (2006), and the recently issued report from the National Mathematics Advisory Panel (2008). Flexibility also appears to have a strong metacognitive component. Flexible solvers engage in metacognition when they think critically about a problem and choose to use a more efficient or effective solution strategy to solve it, when they compare multiple solution methods to problems and note why one seems better than another, when they tap into their repertoire of multiple solution procedures, and when they even realize an opportunity or need for efficiency.

*The Development of Flexibility*

Drawing on the literature in cognitive science and mathematics education, Star and colleagues have identified comparison as a particularly effective means for promoting the development of flexibility. Rittle-Johnson and Star (2007) found that middle school students who learn to solve equations by studying multiple worked examples, presented side by side, become more flexible than students who see the same examples but presented one per page. Similarly, Star and Seifert (2006) found that students who were asked to solve previously completed equations using a different ordering of solving steps become more flexible in their knowledge of equation solving strategies. These results from Star and colleagues on the benefits of comparison can be summarized by the following three instructional practices that have been found to positively impact students' strategy flexibility in mathematics.

First, research on comparison indicates to-be-compared solution strategies should be presented to students side-by-side, rather than sequentially. Side-by-side placement allows for more direct comparison of solution strategies and facilitates the identification of similarities and differences between strategies. A side-by-side comparison helps students notice and remember the features that are important to each or both solution strategies (Rittle-Johnson and Star, 2007).

The second practice is for teachers to engage students in comparison conversations. Discussion of and comparison of multiple strategies helps students justify why a particular solution strategy or solution step is acceptable and helps students make sense of why certain strategies are more efficient than others for particular problems (Silver et al., 2005). Teachers can help guide comparison conversations to ensure that students are able to make connections among strategies that they would not always be able to make on their own.

The final recommended practice is to provide students with the opportunity to generate multiple solution methods to the same problem, either by investigating multiple solution methods of the same equation or by creating new equations to solve by a given method. In general, knowledge of multiple solution strategies seems to help students more readily consider efficiency and accuracy when solving problems. Additionally, by generating multiple solution methods, students are encouraged to move away from using a single strategy and, rather, other, possibly better strategies that work for the problem (Star & Seifert, 2006; Star & Rittle-Johnson, 2008).

*The Present Study*

The goal of the present study was to design and pilot a professional development activity for inservice secondary mathematics teachers, focusing on improving teachers' flexibility via the three comparison practices described above. Our professional development activity had two goals. First, we sought to make teachers aware of the three comparison practices described above. Research has linked these practices to students' flexibility, so our primary goal was for participating teachers to learn how to implement comparison in their own classrooms.

However, the success of our efforts to change teachers' practices would clearly be dependent on the flexibility of the teachers themselves. For example, teachers attempting to orchestrate a comparison conversation with a group of students would be better able to direct the conversation along a fruitful path if they understood the nuances of different solution methods and problems, e.g., if they were flexible. Furthermore, a flexible teacher has the ability to spot a potentially interesting and innovative approach to a problem during a class, and will offer it for classroom discussion to highlight the specific aspects of this unique approach. Conversely, less flexible teachers, those with only a superficial knowledge of procedures, may have the tendency to teach only one method for solving particular problems, and disregard students' innovative solution methods as unimportant digressions. Thus, a secondary goal of our professional development activity was to impact participating teachers' flexibility, by implementing the comparison practices in the professional development. Teachers must themselves see value in flexibility before they will regard it as an important instructional outcome for their students—and in order for flexibility to be valued, teacher participants must be consistently presented with problem solving situations in which they can develop and exercise their own flexibility.

## Method

In June of 2007, a two-week professional development institute for 24 middle and high school algebra teachers was held at California State University, Chico. The teachers were participants in a 5-year project; the results reported here are from the first year of the project. The focus of the professional development institute was algebraic reasoning and pedagogical strategies for use in algebra classrooms. The professional development activity focusing on comparison was implemented during one eight-hour day.

The comparison practices were introduced to the teachers by giving a brief presentation on the notion of flexibility and the comparison practices. This introduction was followed by a series of problem solving activities where groups of 3-4 teachers were given two similar math problems (P1, P2) and two suggested strategies (S1, S2) for solving the problems and asked to solve both problems using both strategies. Teachers were then asked to create a poster with all four combinations of problem and strategy (P1S1, P1S2, P2S1, P2S2) that they would then present to the remaining participants. The purpose of the presentations was to model the first two comparison practices -- that is, to present different solution methods side-by-side and to facilitate comparison conversations among the other participants. This activity format was used several times over the course of the two-week institute. Below we show the various problems and strategies that groups of teachers were asked to present. They will be referred to hereafter as Topics 1-7.

1. Systems of Equations: Solve the following systems by (S1) substitution, and (S2) linear combinations:
   (P1) $\begin{array}{l} 4x-3y=2 \\ 2x+5y=8 \end{array}$ (P2) $\begin{array}{l} y=3x-2 \\ 5x+2y=8 \end{array}$
2. Linear Inequalities: Find the solution sets for the inequalities by (S1) moving the variable to the right-hand side of the inequality and (S2) moving the variable to the left-hand side of the inequality:
   (P1) $3-5x>10$ (P2) $x \geq 3x-2$
3. Solving Proportions 1: Solve for x by (S1) using cross multiplication, and (S2) multiplying both sides of the equation by a single value:
   (P1) $\frac{2}{x}=\frac{16}{5}$ (P2) $\frac{x}{6}=\frac{5}{9}$
4. Solving Proportions 2: Solve for x by (S1) using cross multiplication, and (S2) comparing the ratio of the numerator to he denominator:
   (P1) $\frac{x}{14}=\frac{16}{8}$ (P2) $\frac{x}{14}=\frac{3}{8}$
5. Finding Linear Equations: Determine the equation of the line passing through the two points by (S1) using the slope-intercept form of the linear equation, and (S2) using the point-slope form of the linear equation:
   (P1) (0, 4) and (5, –2) (P2) (–2, –2) and (6, 1)

6. Simplifying Fractions: Simplify the expressions by (S1) dividing numerator and denominator by successive common divisors, and (S2) writing out the prime factorization of the numerator and denominator:
   (P1) $\frac{38}{98}$ (P2) $\frac{2a^2b}{6ab^3}$

7. Finding the Least Common Multiple: Find the LCM by (S1) generating a table of multiples, and (S2) writing out and using the prime factorization:
(P1) 18, 30 (P2) $4x^2$, $x^2 + x$

The data reported below was taken from recollections of the facilitators but also from teachers' responses to a written open-ended survey administered at the conclusion of the comparison activity and discussion. This survey contained two prompts: "Reflect on the comparison activity in regards to your teaching," and, "Reflect on the comparison activity in regards to your own mathematical ability and understandings."

**Results**

We describe the discussions that took place during the professional development comparison activities in order to illustrate that using comparison with teachers gave insight into teachers' own flexibility, and moreover helped to develop an appreciation for flexibility as an instructional outcome. As we point out, these discussions were both mathematical and pedagogical in nature.

*Observing the Activity*

*Topic 1: Systems of equations*. This topic was chosen since it is a very familiar topic within which teachers would see value in using comparison techniques to teach flexibility. Many indicated they had already used modified comparison techniques when teaching solution methods for systems of equations, noting that the typical textbook teaches solution methods as totally separate, rarely indicating a connection between any two. However, many teachers noted while they present different solution methods, they do not allow their students to have conversations about the solution methods, nor do they let them have a choice as to which method to use to solve a given problem.

In this specific example, teachers found that the set of equations that featured an equation in slope-intercept form is easier to solve by substitution then the other system, and more cumbersome to use for elimination due to the re-arranging of the equation that had to come first. Many remarked that this example addressed a difficulty for students; if a student does not properly rearrange an equation for setting up the elimination method (i.e. having all variables to one side and lined up in order of *x* terms and *y* terms, for example), or for setting up the substitution (placing the equation into slope-intercept form), then they will incorrectly solve the problem. Many teachers noted that literally having side-by-side comparisons of solution methods might help students see that elimination is often more efficient when the least common multiple of either the coefficients of the *x* terms (or the *y* terms respectively) is easy to find.

*Topic 2: Linear inequalities*. One of the most fruitful of the comparison discussions concerned solution methods for solving linear inequalities. The intent of the two problems and the two solution methods in Topic 2 was to emphasize that problems involving inequalities can be solved by moving the variables to either side of the inequality, as opposed to the more common way students are taught to solve equations, which involves isolating the variable on the *left* side. We had hoped to show that the potential for error when dividing by a negative in working with inequalities and of forgetting to 'flip' the inequality could be taken care of by being flexible in working with inequalities. Indeed, this is what the discussions indicated.

During the discussion of the solution methods in Topic 2, several teachers commented on the fact that they always ask students to move the variable to the left side of the inequality. In fact, many of the same teachers admitted their own difficulties in trying to solve the problems by moving the variable to the right side first. Such comments clearly showed that throughout the activity our teachers were forced to consider their own flexibility in solving problems. A significant portion of this discussion was focused on the difficulty with the negative sign depending on which side of the inequality the variable was on. For instance, when solving the inequality, $3-5x \geq 10$ , by moving the variable to the right, $3-5x \geq 10 \Rightarrow 3 \geq 5x+10$ , the coefficient of the variable is positive, and so there is no need to worry about making mistakes in dividing by negatives and forgetting to flip the inequality. Of course, the ability to do this requires flexibility in understanding how to read inequalities in both directions.

*Topic 3: Solving proportions*. Our intent in Topic 3 was to allow our teachers to discuss the strategy of cross-multiplication for solving proportions and to compare it with other strategies. Many teachers report that cross-multiplication, although a useful strategy for solving proportion problems, is often incorrectly used by students who lack an understanding of why it is a valid strategy. Moreover, the overreliance of students on this strategy indicates a lack of flexibility in their understanding of what a proportion can represent, and subsequently of the lack of tools for solving such problems. One possible strategy for solving Topic 3 Problem 1 $\frac{2}{x} = \frac{16}{5}$ by multiplying both sides of the equation by a single value would be to multiply both sides of the equation by $(5x/16)$. Our teachers needed some instruction in this solution strategy, which they indicated was not completely intuitive to them. In fact, teachers reacted quite negatively to this strategy, both in terms of how students might view this approach ("We don't expect our students to be able to do that"), and also in terms of their own comfort with and willingness to use this strategy ("that seems like too much work"). More generally, in the discussions of both Topics 3 and 4, our participants revealed their own reliance on cross-multiplication as the 'best' strategy to use when solving proportion problems, and perhaps a little reluctance for investigating other means of solving them.

*Topic 5: Finding linear equations*. In presenting this topic, we wanted to learn about our participants' flexibility in finding linear equations. In particular, finding the equation in P1 (see above) is perhaps easiest by using the slope-intercept form (S1), since one of the given points is the *y*-intercept. Our teachers picked up on this and indicated so in the discussions. Many of our teachers seemed more in favor of using the slope-intercept form to solve either case, by first finding the slope, then substituting the coordinates of one of the points for *x* and *y*, and lastly solving for *b*. In using the point-slope formula strategy (S2: using $y - y_1 = m(x - x_1)$ ) to solve P1 and P2 of Topic 5, many teachers commented that it takes just as much work and just as many steps to use it to solve Problems 1 and 2. In other words, in their view, the fact that the point $(0,4)$ is given in P1 does not offer any advantages when using the point-slope formula. But perhaps surprisingly, some participants were more in favor of the point-slope formula in both cases. For example, one person remarked, "Many students like the point-slope form because there's no *y*-intercept. They don't need to solve an equation [referring to solving for *b*]. It takes less steps. [Students often wonder,] "What does it really mean that I'm solving for *b*?" This comment suggests that teachers feel that students can use the slope-intercept form of the equation of a line without understanding what solving for the variable *b* means in the context of the problem.

*Topic 6: Simplifying fractions*. The discussion of Topic 6 served as an exemplar of how solving problems side-by-side and directly comparing the solution methods can lead to a better understanding of the mathematics involved and when different methods are appropriate. In this topic the relationship between factoring and then cancelling common factors in the numerator and denominator, and "successively dividing" numerator and denominator by the same values are examined as two different methods for simplifying fractions. The impetus for such an exploration comes from seeing the 'cancelling factors' strategy appear in the text when solving fraction simplification problems, with no real explanation as to why it is a valid solution strategy.

In the case of simplifying the fraction found in P1, $\frac{38}{98}$, it was more or less obvious to teachers that each number is even, so a common factor of 2 may be 'divided out' from numerator and

factors of the numerator and denominator share. When participants saw the differing solution methods to P1 side-by-side,

$\frac{38}{98} = \frac{19}{49}$ and $\frac{\cancelto{19}{38}}{\cancelto{49}{98}} = \frac{2 \cdot 19}{2 \cdot 49} = \frac{2}{2} \cdot \frac{19}{49} = 1 \cdot \frac{19}{49} = \frac{19}{49}$,

they were better able to draw the connection between "canceling out" common factors and factoring. The observation was made that the process of canceling out a common factor is covering up several steps involving factoring and division. But when shown side-by-side, connections can be drawn between the two. If armed with the flexibility to rewrite the expression in P2 as $\frac{2 \cdot a \cdot a \cdot b}{2 \cdot 3 \cdot a \cdot b \cdot b \cdot b}$, and then to divide out common factors, a student may have better success in solving such a problem. In this example, teachers saw the importance of teaching multiple methods and drawing connections between the two. Again, the connection between factoring and dividing common factors and "canceling out" common factors was more readily seen when solution methods were presented side-by-side.

On the pedagogy side of the discussion, the presenting teacher's reference to the solution by cancelling common factors as "cross-cancelling" became a source of interest. What exactly does the word "cross" refer to in this method? Is it the misuse of a word? A conflation of meanings? Does "cross" refer to the "crossing-out" procedure used once the numerator and denominator are factored? One person remarked that in general, "cancelling out kind of 'sounds like' you should get zero." Here, teachers were trying to rectify the language commonly used with the mathematical steps involved in the problem solving method. Such pedagogical talks sparked specifically by comparison discussions were common.

*Topic 7: Finding the least common multiple*. The final topic was chosen as an illustration of the potential disconnect between a common method for finding the least common multiple [LCM] of integers and the method later commonly taught for variable expressions. In particular, many students first construct lists of the multiples of the two integers and then find the first number that appears on both lists as the LCM. However, this method has its limitations when applied to two variable expressions such as $4x^2$, $x^2 + x$. Consequently, a method involving prime factorization and then finding common factors must be introduced as students progress to such expressions.

The participants saw that when they tried to apply the "listing" method to the variable expressions, it was not clear how they would actually do so. For instance, participants started by writing a list such as $\{4x^2, 8x^2, 12x^2, \ldots\}$, and quickly realized that they would need to factor in more factors of *x* as well, as in $\{4x^2, 4x^3, 4x^4, \ldots\}$. Eventually, participants saw that it would be nearly impossible to write an exhaustive list of all the varying multiples of $4x^2$, and furthermore they were uncertain how to organize their lists to obtain the LCM of $4x^2(x+1)$. This example illustrated the need to understand the connection between the procedure of listing factors, used primarily with numbers, and the prime factorization method that is taught for finding the LCM of variable expressions. Once more, when teachers had a chance to explore the content they teach and the methods they know in the context of comparison, they were able to challenge their own understanding of concepts and procedures in new ways.

*Teachers' Comments on the Post-Activity Survey*

Recall that participants were asked to complete a written survey following the professional development activity. Teachers' responses generally indicated an increasing appreciation of the potential of comparison for improving students' flexibility. One teacher noted, "If students look at several ways of doing the same problem, they can start to generalize what's really going on." Similarly, another teacher noted the potential power of the comparison conversation, noting, "[The discussion] is a great tool to get students to defend their ideas and explain their reasoning." One teacher began to see how comparison could be used to help students review and consolidate material at the end of a unit: "If I were to use this comparison as a review or a recap of the concepts, the students would then be able to engage in fruitful conversation about the various methods." In addition, another teacher noted how comparison could be used for students to check their work: "Comparison would also be a way for students to check their own work, because they should get the same answer for both methods."

However, other teachers noted the challenges of implementing comparison effectively in their own teaching. As one teacher noted, "Comparison is a tool I have already used in various lessons, but I do not question my students successfully. I tend to want to lecture and give them my comparisons instead of asking them what they notice." More generally, teachers seemed especially daunted by the difficulties of facilitating a classroom discussion where students would be allowed to share their own thoughts when comparing multiple strategies. Several teachers noted their own tendency to do most of the talking in their classrooms and their trouble with allowing students to discuss ideas. Another concern noted by teachers was whether students might be confused by seeing multiple methods; as one teacher noted: My worry is that some students will be confused if I introduce more than one way to solve a problem on the same day."

In addition to commenting on the potential impact that comparison can have on students' knowledge, teachers also commented on the ways that the professional development activity influenced their thinking about their own teaching and learning of mathematics. One teacher noted, "I learned that in my own thinking and strategic competence that I already have a mental map of comparison strategies which helps me quickly decide upon a certain strategy to solve a particular problem…[The discussion] allows students to take ownership of their own learning." Similarly, another teacher noted, "In all of the textbooks, there is the sequential set of examples and students often become confused… I know that when I was learning math, I often fell back on one way of solving a problem. I think this did not allow for a better understanding of the topic because I was so focused on one solution method. This one-way method put up a sort of roadblock in my understanding." Similarly, another teacher noted, "I realize that intuitively I choose a method that is best/most efficient/easiest for me when I work on the board, but I have never taken the time to express why or even let the students suggest why."

## Discussion

The results of this small study suggest that using comparison in a professional development institute can provide teachers with an adaptable instructional tool as well as a chance to examine their own flexibility as problem solving. Survey results suggest that introducing comparison techniques to teachers increased awareness of student flexibility. As a result, teachers began to see that flexibility is a valuable instructional goal that can be incorporated into their curriculum. In addition, teacher discussions during the professional development indicated that teachers expanded their own flexibility. Teachers reported that they were challenged to see the connections between different solution methods, and subsequently questioned why they taught a certain solution method over another. The current study suggests that the three recommended instructional practices described above represent a practical way to begin to teach for flexibility in the algebra classroom.

Future studies on the use of comparison with teachers should focus on effects of teachers' use of comparison in their classrooms, including direct observations of teachers' practices to determine when and how teachers are implementing the practices described here. In addition, a more detailed study of the correlation between mathematics teachers' knowledge of multiple strategies and the effectiveness of their use of comparison in the classroom would be educative. Furthermore, the work of Star and colleagues (e.g., Rittle-Johnson & Star, 2007) suggests that simply changing the method of presentation to side-by-side is not enough; students must have the opportunity to engage in comparison conversations and to try to derive their own problem situations for comparison to be effective. Hence, a comparative study on the impact of comparison in the classroom both with and without the discussion component would more strongly inform teacher best practice for developing flexibility using comparison.

*In this paper we provide an analysis of the work of a video-based case development team whose goal was to produce didactic objects to be used the professional development of secondary mathematics teachers. In order to generate artifacts for use in the creation of the cases, the research team conducted a classroom intervention in an Algebra I classroom. The daily videotapes, copies of all the student work, and interviews with the teacher comprised the resources for the case development effort. As design researchers, we engaged in interactions of design and research as we tested and refined our development efforts. An important aspect of the work is its focus on the unifying mathematical concept of covariation.*

## Introduction

In this paper we analyze the work of the Case Design Project [Cadept][1] that is part of the TPCC [Teachers Promoting Change Collaboratively] [2] Project. As background, the larger TPCC project entails multiple stages of research and development employing a design research perspective (cf. Brown, 1992; Cobb, Confrey, diSessa, Lehrer & Schauble, 2003). Following this design orientation, the TPCC research team first addressed the need for a strong mathematical basis for teachers by engaging them in a series of three graduate-level courses called Extended Analysis of Functions [EAF]. The mathematical content of the EAF courses focused on developing a coherent understanding of the secondary mathematics curriculum from the complementary perspectives of (1) functions and quantitative relationships (with covariation being a foundational idea for both) and (2) representational equivalence. In addition, these courses were designed and implemented as a model of the type of interactions and discussions that supported the mathematical thinking being developed during the course.

Next, the work of the grant was extended to the school setting as groups of teachers enrolled in the EAF courses met weekly in the format of Professional Learning Communities [PLC's][3] with the goal being that of reflecting on practice as it related to the big mathematical ideas of the courses. Our intent was that PLC meeting agendas would be tightly linked with issues that emerged in the EAF courses. As a result, the relevance of the issues to the teachers' classroom practices provided the link between the courses and teachers' classrooms (cf. Zhao & Cobb, 2006). Each PLC was assigned a facilitator from the TPCC project with the expectation that within a three-year period each PLC would become self-facilitated. The appointed facilitator initially set the meeting agendas and conducted these meetings. The means of support used to initiate teacher reflections typically included (1) teacher developed student interviews, (2) Japanese-style lesson study or (3) sharing a self-recorded video of a teacher in the PLC teaching a particular lesson in his classroom.

During the preliminary analysis of both the EAF courses and the PLC's, the research team realized that its work was not supporting the teachers' ability to formulate an *image*[4] of the practices that were being promoted in the project. The teachers also had difficulty imagining the kind of interactions that would support students in understanding the big mathematical ideas from the EAF courses. Examples of teachers' difficulty in understanding the ideas promoted in the project emerged particularly during PLC sessions. When discussing student interviews the teachers conducted, their focus was on students' answers and not how the students thought about obtaining their answers. When a teacher would share a video recording of a teaching segment from her classroom, other teachers' were (1) either hesitant to share their opinion so as not to offend the teacher or (2) focused on classroom management issues. In their discussions, little focus was placed on student thinking.

In order for the TPCC research team to better understand these perceived difficulties and then create conversations that would address the difficulties, it decided to generate artifacts for use in the professional development settings. The goal was to create video-based cases in which teaching took the form of a long-term coherent approach to significant mathematical ideas in a classroom setting where students' current ways of reasoning were at the forefront of decision making and planning. As a result, the Case Development Project [Cadept] was developed. The goal of Cadept was twofold. First, the members of the Cadept design team wanted to create potential didactic objects[5] (cf. Thompson, 2002) that could be used with teachers to reflect on teaching in relation to student learning; and second, these objects needed to provide comprehensive understandings of the struggles teachers encounter as they attempt to implement what they understand to be the big mathematical ideas in their classrooms.

In order to generate the artifacts necessary for creating the potential didactical objects, the TPCC research team determined that it needed to conduct a classroom intervention[6] with one teacher in order to produce a record of her attempts to teach a conceptually oriented course. The team selected a ninth-grade Algebra I course for non-honors students —students with whom the team would later work in Geometry and Algebra II. The teacher, whom we call Augusta[8], was a full participant in the classroom intervention. Augusta was chosen as the teacher for the experimental classroom because she was comfortable taking risks and trying out instruction for which the eventual outcome was unclear. She also was willing to collaborate with the TPCC research team in the process of designing the course. In addition, Augusta's principal was eager to have this project in his school. This, therefore, removed some potential institutional constraints. During the year of the intervention, each class session was videotaped for two purposes: for our own understandings of the struggles that teachers face, and for potential use in generating artifacts.

The development of the cases was an iterative process of ongoing analysis, modification and refinement. Much like Simon's (1995) *Mathematics Teaching Cycle* the TPCC research team engaged in both *meta* and *mezzo* levels of design and revision during which it focused on both the design of the professional development courses for the teachers and the design of activities for the classroom.

Against this background, we next document the evolution of the need for the classroom design intervention. We follow by documenting the research and design cycle that was employed in the development of video-based cases from Augusta's classroom. We then give a summary of the current state of our work. We conclude with an analysis that provides implications of our work for other university collaborators and the field at large.

## The Evolution of the Need to Design a Classroom Intervention

As noted earlier, the need to generate classroom artifacts emerged from ongoing analyses of work in both the EAF courses and the PLC's. Further, the teachers' curricular knowledge—their understandings that corresponded to textbook material they felt compelled to teach and their image of problems that students must know how to solve—overwhelmed their ability to imagine teaching a series of lessons that developed ideas relationally, coherently, and longitudinally independent of their text. As a result, the research team decided to conduct a classroom design intervention with one teacher to produce a record of that teacher's attempts to teach a conceptually oriented course.

It was conjectured that the record of Augusta's classroom would provide a data source for us to use in documenting the process of both the teacher and her students' learning conceptually oriented mathematics. In addition, the team conjectured that the struggles emerging as part of this learning would also be documented. As a result, our design was focused on (1) Augusta's reconceptualization of Algebra I, (2) students' mathematical learning, (3) appropriate instruction to teach what Augusta reconceived so that students could learn it, and (4) the means of support for Augusta's transformation.

## The Artifact Collection Process

In addition to the daily-videotaped classes, the TPCC research team also created an electronic record of the lesson designs for the year, videotaped daily debriefing sessions with Augusta after the class period, audio recorded weekly collaborations with Augusta, made copies of all student work, and videotaped student interviews with the research team. This extensive data corpus not only provided the resources for use in understanding the difficulties associated with teaching conceptually oriented mathematics, but it also provided artifacts that could be used in the design of potential didactic objects. As a result, the Cadept team's initial design conjectures for the artifacts was focused on (1) instances of Augusta's coming to conceptualize an instructional sequence to promote students' mathematical learning, and (2) means of support for Augusta's transformation. It is therefore important to note that the intention of the design was not to focus on Augusta per se; but rather on the generation of artifacts which could be used to focus other teachers' attention on Augusta's reconceptualization of her teaching practices. The motivation for focusing the design of the case study on Augusta's reconceptuatlizations and teaching practices were based on the observations made from the PLC and EAF courses.

This was a highly interventionist and time-intensive process. As part of this process, frequent exchanges occurred between Patrick Thompson and Augusta both after class and during their Saturday planning sessions. The goal of these exchanges was to support Augusta's ability to reason logically with the innovative materials while using the student's ways of reasoning as an important aspect of planning. In addition, these meetings assessed the effectiveness of the materials in developing student thinking and Augusta's understanding of these materials. The meta-level goal of these exchanges was to gain insight into Augusta's difficulties as she was teaching with these innovative materials while getting her input into subsequent design.

## The Design of Video-based Cases

As the TPCC research team reflected on the unfolding "story" from Augusta's classroom and on the changes in Augusta during the teaching of the Algebra I course, it saw the video as a potential source of didactic objects for professional development. The team determined that the video would make a compelling case for other teachers. In particular the research team identified appropriate instances from the classroom video to choose as segments that would form the basis of the cases. The Case Design Project [Cadept] was therefore developed to create a series of video-based artifacts to be used in a professional development setting. These video artifacts would be part of a larger package of artifacts that included problem sets for the teachers, curriculum critique and development, and analysis of student work. These materials were being designed to provide opportunities for the teachers to reflect on their practices by examining Augusta's classroom.

The initial exploration of the data yielded six potential cases: (1) covariational reasoning, (2) linear functions, (3) systems of equations, (4) sums of functions, (5) factoring and polynomials, and (6) quadratics. As the design team worked, each case required condensing the classroom video into sequences of short video stories that could be supported with additional resources from Augusta's classroom. The video was edited both to make these stories of practical viewing length, and also to emphasize specific plots. These plots involved the students struggling with mathematical ideas, the teacher struggling with implementing those ideas, the development of discourse in the classroom, and the cognitive development of the students including significant mathematical benchmarks and shifts.

## Pilot Studies as Part of the Design Cycle

As noted, the design team took a *design research* perspective in its development process. As a result, selected video segments were piloted with teachers throughout the development process. For example, the third EFA course served as one pilot study. The goals of this study were to draw teachers' attention to student thinking and the subtleties of covariational reasoning and instruction. Initially, the teachers in the functions course did not focus on content nor student understanding. Their original focus was on Augusta's classroom management. Their assessment of the success of the lesson was directly related to how well the students' behaved. Moreover, the teacher's focus was on Augusta rather than on the students she was teaching to. They did not discuss the students' thinking, nor notice the role of Coordinating Quantities Tool[8] in the lesson. They viewed the tool as a "nice activity." When they broke into groups to watch individual video clips, their discussions indicated that they did not have a theory of learning or a notion of an epistemic student. It was only after discussion and probing by Patrick Thompson (the teacher of the functions course) that the teachers attempted to focus on student thinking. As a result, were able to articulate evidence as they built models of student thinking. As an example, they were able to examine one student's use of the Coordinating Quantities Tool to make conjectures about her ways of reasoning about the coordination of the two quantities. Also, the teachers' image of covariation changed. They shifted from shape thinking[9] to covariational reasoning.

Throughout the study, it was apparent that simply changing the curriculum or improving teacher's content knowledge would not provide a sufficient stimulus for change. These issues must be addressed in the context of exploring classrooms (cf. Zhao, 2007). Zhao makes a strong argument for the necessity of "conceptualizing the relations between teachers' learning in the setting of professional development and their instructional practices in the classroom" (p. 3). She argues that

> [r]egardless of researchers' continuous efforts to design and support teachers' professional development, changes in classroom mathematics instruction do not always occur as intended. Thus, an immediate and pragmatic challenge posed to

> teacher educators necessarily involves how to design professional development activities so that teachers can relate what they learn to their classroom practices and, as a result, become willing to engage in changing their current ways of teaching. (p. 4)

In order to address this conundrum, the design team therefore focused its pilot efforts on understanding the relation between the classroom-based video artifacts and the teachers' reactions with respect to their practice.

As a result, the research team constructed an epistemic model of teachers' images of the classroom. The model included the fact that teachers would not attend to student thinking without readily available evidence and someone pressing them to hold to that evidence. Further, the text emerged as the dominant resource for planning. Also, possible distracters in video emerged. For example, teachers paid more attention to classroom management issues than to the intended focus of the video segments. The epistemic model of teachers' image of Augusta's classroom was used as a factor in choosing the story that was to be told of the important issues to be discussed around the video based cases. As a result, selected video segments were continually piloted throughout the development process. The iterative process was crucial in the success of our final design.

## Results of Analysis, Conclusions and Implications

Numerous scholars in the field of mathematics education have advocated the importance of teachers having strong knowledge of the content they teach (cf. Ball, 1990; Bransford, Brown, & Cocking, 2000; Grossman, 1990; Ma, 1999; National Research Council, 2001; Schifter, 1995; Sowder, et al., 1998). This sentiment is echoed in the *No Child Left Behind* legislation that articulates a demand for highly qualified teachers who display mastery of subject matter. There is, in fact, general agreement in both the political and educational arenas that knowledge of content is a necessary condition for an effective mathematics teacher.

However, we have learned that this knowledge is necessary, but not sufficient. Being able to take newly acquired knowledge and transpose it into a new image of teaching is challenging at best. As we have noted, teachers must also develop *images of good teaching*. These images must be grounded in the teaching of significant mathematics where student thinking guides instructional decision-making. Here we have argued that the investigation of a well-designed video-based case can provide the context in which to make explicit the complexities involved in innovative mathematics classrooms. In doing so, we provide a context in which to examine the use of video-based cases in supporting teachers' professional growth, including their understandings of issues of both mathematical content and pedagogy. It is in this context that opportunities for teachers to reflect on their teaching practices arise.

However, investigations of classrooms provide both potential resources and pitfalls. Teachers view classrooms through the lens of their prior beliefs, thereby negating any efforts for issues of teaching and learning to be made explicit through their observation. For this reason, teachers' discussions of classrooms often take on the characteristics of "storytelling" during which the teachers in professional learning communities share their interpretations of accounts from the classrooms. The judgments they make about what they observe and experience can become traps that prevent professional growth. Overcoming this can be a formidable task. We therefore cannot assume that the issues that are focused upon during collaborations will be made explicit and then acquired naturally through teaching.

However, the effectiveness of video-based, multi-media cases has been documented by

Richardson and Kyle (1999) who state that "the use of multimedia cases significantly impacts teachers' cognitions" (p. 131) They note that the power lies in the cases' ability to present "a visual, moving picture of teaching in a real-life classroom" (p. 136). Video-based cases also allow easy access to numerous facets of the classroom to facilitate in-depth investigation of issues of content, the teacher's decision-making process and students' diverse ways of reasoning. Through their investigation and critique of a case, teachers have the opportunity to develop and refine their skills in critiquing, evaluating and creating learning experiences. Their image of teaching is changed as a result.

The critical aspect of this process is the guiding and framing of the experience by the facilitator. Just as we view the role of the teacher as critical in supporting students' developing understandings of mathematics (or any other content area), we view the role of the facilitator as critical in supporting teachers' understandings of what it means to teach mathematics effectively. We do not believe that the cases are transparent carriers of meaning. Nor do they have agency. They are, in fact, tools to be used in the course of teacher collaborations (cf. Kaput 1994; Miera, 1998; van Oers, 2000). The goal is then to create the settings in which these cases can become genuine didactic objects. For this reason, our next cycle of design and research will focus on the development of facilitators' guides. However, like Carpenter and colleagues (Carpenter, Blanton, et al), we do not believe that forms of professional development can be codified and handed over as a means of scaling up. Therefore, the next steps in our design process will involve cycles of design and revision while working closely with other university collaborators.

Although our process is still ongoing, we claim to have documented evidence to support the following guiding principles:

1. *The thoughtful design of a video-based case is essential in creating effective means of supporting teacher professional growth and development because it provides a bridge between the professional development setting and the classroom.*
2. *Video-based cases must support the larger goals of any collaboration.*
3. *The strength of a video-based case is limited by the quality of instruction and the nature of the student discourse captured in the video.*
4. *Video-based cases can only become didactic objects when thoughtful consideration has been given to their design and use.*

In order for the cases to meet these guiding principles and therefore support teachers' ability to re-conceptualize their practice, they need to provide resources to support the teachers' construction of an image of a conceptually oriented mathematical conversation with students. A conceptual conversation is one that has a diminished emphasis on technique and procedure while having an increased emphasis on images, ideas, reasons, goals, and relationships. People conversing conceptually speak in ways that make their meanings, ideas and ways of thinking clear to others in the conversation. To avoid speaking in ways that could possibly hide their meaning, these individuals are aware of possible interpretations of their words another may have which are different from the meaning that they intended. The design, testing and refinement of our cases and the supporting material can therefore provide this opportunity. This is significant in that it offers a means of supporting teachers' transitions in professional development setting.

## Endnotes

1. The Case Design Project Team [Cadept] is composed of Kay McClain, Scott Adamson, Ted Coe, Carlos Castillo-Garsow, Sharon Lima and Patrick Thompson.

2. The research team is composed of Patrick Thompson (Principal Investigator), Scott Adamson, Ted Coe, Carlos Castillo-Garsow, Sharon Lima, and Kay McClain. Research reported in this paper was supported by National Science Foundation Grant No. EHR-0353470 under the direction of Patrick W. Thompson. Any conclusions or recommendations stated here are those of the authors and do not necessarily reflect official positions of NSF.

3. We use the term Professional Learning Communities to denote the cohorts of teachers within the schools who met on a weekly basis to discuss issues related to the college course. An analysis of the development of the cohorts into communities is beyond the scope of this paper. We therefore realize that we are taking liberties with the term *community* and do not intend to imply that we have conducted analyses to confirm that these cohorts actually transformed into communities (cf. Dean, 2005; Wenger, 1998).

4. By "image" we build from what Maturana (1978) describes as a conceptual system through which we may anticipate another system's behavior. These images are highly related to what Cobb has in mind when he speaks of an envisioned practice as a goal of instructional design.

5. Elsewhere, we have used the phrase didactic object to refer to "a thing to talk about" that is designed with the intention of supporting reflective mathematical discourse (see Thompson, 2002). In doing so we note that objects cannot be didactic in and of themselves. Rather, they are didactic because of the conversations that are enabled by someone having conceptualized them as such. In this sense, a didactic object is a tool, but one designed to produce desirable conversations.

6. We make a distinction between a classroom intervention and a classroom teaching experiment or a classroom design experiment. In the intervention, the goal of the TPCC research team was to elicit certain ways of reasoning and certain struggles from both the teacher and the students.

8. The Coordinating Quantities Tool (or finger tool) makes use of the index finger on each hand by asking students to track the changes in the quantity of the independent variable with a horizontal movement while simultaneously tracking the quantity of the dependent variable in a vertical movement.

9. Thompson makes a distinction between "shaping thinking" and covariational reasoning. In shape thinking, students can imagine the shape of a graph from the scenario such as the distance of a bungee jumper from a bridge as he bounces back and forth. The graph is then a static trace of an event that has occurred. Covariational reasoning requires the student to think about how two quantities vary in relationship to each other or co-vary.

# DEFINING VISIONS OF HIGH-QUALITY MATHEMATICS INSTRUCTION

Charles Munter
Vanderbilt University
c.munter@vanderbilt.edu

*By synthesizing what has been learned with regard to critical dimensions of mathematics classroom teaching and learning, and investigating the ways teachers and other school personnel characterize high-quality mathematics instruction, this study defines the notion of 'instructional vision' and provides an initial categorization scheme. Motivating this work is the need to reliably document change in participants' instructional visions within an ongoing study of the institutional setting of mathematics teaching, in which we hypothesize that improvement in teachers' instructional practices and student achievement will be greater in schools where teachers and instructional leaders have a shared vision for high-quality mathematics instruction.*

## Background

The Middle School Mathematics and the Institutional Setting of Teaching (MIST) research team is working for four years with four urban school districts serving ethnically and economically diverse populations as 'co-designers' of support structures and strategies for meeting ambitious goals for reforming mathematics instruction at a district level. All four of our participating districts have recently formulated and begun implementing comprehensive initiatives for improving the teaching and learning of middle-school mathematics, including the adoption of mathematics reform curricula and the provision of professional development aimed at developing instructional practices in which teachers place students' reasoning at the center of their instructional decision making.

Our aim is to investigate, test, and refine a set of conjectures and formally test a set of hypotheses about support structures that potentially enhance the impact of professional development on middle school mathematics teachers' instructional practices and student achievement. Our conjectures and hypotheses pertain to seven sets of support structures: 1) teachers' professional networks; 2) shared vision for high quality mathematics instruction across teachers and instructional leaders; 3) quality of instructional leadership; relationships of 4) accountability and 5) assistance between teachers and instructional leaders (including principals, assistant principals, department chairs and mathematics coaches) and among teachers; 6) alignment across district units with respect to high-quality mathematics instruction; and 7) particular supports for providing equitable learning opportunities to all students.

It is the second of these hypotheses that motivates the work represented in this paper: Improvement in teachers' instructional practices and student achievement will be greater in schools where teachers and instructional leaders have a shared vision for high-quality mathematics instruction. Eventually, the goal is to establish a means of tracking shifts toward both increased sophistication and 'sharedness' in individual leaders' and teachers' instructional visions. However, in order to determine the extent to which groups of individuals *share* an instructional vision, we must first be able to reliably assess accounts of personal visions of high-quality mathematics instruction. With this paper I define *visions of high-quality mathematics* and describe the initial categorization scheme resulting from preliminary data analysis.

## Theoretical Perspectives

*Professional Vision*

Charles Goodwin (1994) presented a comparative analysis of practices in two professional settings, an archeological field school excavation and the 1992 California trial of four policemen charged with beating Rodney King. He argued that both the senior archeologist and the defense attorneys (with the help of an "expert witness"—an LAPD sergeant who was not present for the alleged beating) utilized particular complex discursive and representational practices to build and contest professional vision, which he defined as "socially organized ways of seeing and understanding events that are answerable to the distinctive interests of a particular social group" (p. 606).

Sherin (2001) extended the idea of professional vision to her work in documenting the evolution of one mathematics teacher's perspective of classroom events. Her teacher, David Louis, had been teaching for five years at the time that Sherin and her colleague began observing and videotaping his classroom and meeting weekly with him to watch excerpts of those video recordings. During the most recent year-and-a-half, Mr. Louis had attempted to change his instructional approach to one of supporting the development of a community of learners (Brown & Campione, 1996; Rogoff, Matusov, & White, 1996). In addition to their weekly video viewing sessions, Mr. Louis and the researchers also participated monthly in a video club with David's colleagues. Over the course of her 4-year collaboration with Mr. Louis, Sherin documented how his interpretation of classroom events captured on video from his classroom changed from a focus on his own pedagogical actions (i.e., what he should have done differently) to one on student ideas and the nature of mathematical discussions (i.e., accounting for what had actually transpired in classroom events of interest). Adapting Goodwin's notion, Sherin suggested that this marked a shift in his professional vision—a "new interpretation strategy" (p. 90) focused more on the aspects of classroom activity to which researchers rather than teachers typically attend.

However, in his conception of professional vision, Goodwin was much less concerned with how individual actors had come to the point of being able to enact the practices of a professional vision than he was in examining how the enactment of a professional vision is accomplished. Although he recognized that the practices must be learned, his conception of professional vision was much more collectively and historically oriented, arguing that "the ability to see relevant entities is not lodged in the individual mind, but instead within a community of competent practitioners" (p. 626). In her account of Mr. Louis's interpretations of classroom events, Sherin explicitly made the leap from archaeology to mathematics teaching, but in doing so mapped Goodwin's (collective) professional vision within archaeology onto (individual) ways of interpreting events in the mathematics classroom.

Though Sherin's analysis of Mr. Louis's shift in perspective might not have adhered faithfully to Goodwin's conception of professional vision, there is much to be learned from her account. Sherin adapted Goodwin's notion of "professional vision" to describe one individual's way of seeing and interpreting classroom events. Across time, she documented which aspects of the classroom the teacher emphasized as being important with respect to mathematics instruction and learning, and the rationale behind his choices. It is this perspective on the classroom that I refer to as simply a "vision"—specifically, a "vision of high-quality mathematics instruction" (for which I will use "instructional vision" synonymously). Just as Sherin was able document an evolution in Mr. Louis's way of seeing and interpreting classroom events, the motivation for the work reported in this paper arose from a need to reliably document change in the visions of high-quality mathematics instruction among our study participants (including mathematics teachers, principals, mathematics coaches, and district leaders) to provide a means for determining the extent to which groups of participants move toward a shared instructional vision. To achieve this goal, it is therefore necessary to build a framework for considering the ways teachers and other participants characterize high-quality mathematics instruction.

*Dimensions of High-Quality Mathematics Instruction*

A considerable body of literature provides insights into one or more important aspects of mathematics teaching and learning, often investigated and reported as discrete elements of the practice. However, few attempts have been made to glean a coherent set of distinct aspects that adequately delineate crucial dimensions of the practice. In the following paragraphs, I summarize three such attempts, namely those of Franke, Kazemi, and Battey (2007); Carpenter and Lehrer (1999); and Hiebert and colleagues (1997). By examining how the various summaries fit together, my intention is to provide an initial frame for the analyses presented later in the paper.

Franke, Kazemi, and Battey (2007) described three features of mathematics classroom practice they viewed as most central: 1) creating and shaping mathematical *classroom discourse*; 2) establishing classroom *norms* for doing and learning mathematics; and 3) building *relationships* with and among students that support participation in the mathematical work of the classroom. The authors further detailed specific aspects of each feature. For example, with respect to classroom discourse, Franke and colleagues stressed four core ideas and practices, including revoicing student thinking (O'Connor & Michaels, 1993) to highlight particular mathematical ideas, to introduce mathematics vocabulary or to position students in relation to each other and their arguments; employing tasks that provide for multiple strategies and rich discussion; identifying and building on the resources English language learners bring to mathematical discussion; and encouraging students to interrogate meaning (Rosebery, Warren, Ogonowski, & Ballenger, 2005) behind mathematical assumptions and ideas, which contributes to developing classroom norms around questioning and challenging. Regarding classroom norms, the authors stressed the importance of distinguishing between social and sociomathematical norms (Yackel & Cobb, 1996), and attending to the consequences such norms have for student learning and defining what it means to 'do mathematics.' Lastly, the authors described the importance of teachers building relationships with students in terms of understanding children's thinking, and also in ways that lead to opportunities for participation, "which requires getting to know students' identities, histories and cultural and school experiences, all in relation to the mathematical work" (p. 243).

Carpenter and Lehrer (1999) described three dimensions of instruction, the examination of which they viewed as critical for enabling students to engage in mental activities necessary for learning mathematics with understanding: *mathematical tasks, tools* and *normative practices*. First, the authors suggested that through task sequencing that is based on children's thinking rather than mathematical structure, the learning of concepts and skills can be integrated. Important in this vein is that tasks be viewed as problems to be solved, not exercises to be completed, and that they be couched in meaningful contexts. Secondly, the authors suggested that tools, such as paper and pencil, manipulatives, calculators, computers and symbols, be used to represent mathematical ideas and problem situations. They argued that "connections with representational forms that have intuitive meaning for students can greatly help students give meaning to symbolic procedures" (p. 25). By considering the use of such tools, which can be introduced by either students or the teacher, students begin to abstract the mathematical ideas behind their manipulations, so that they gradually no longer need the physical representations. But the authors also argued that it is not the tasks and tools alone that will support learning with understanding. Lastly, Carpenter and Lehrer pointed to the role of classroom normative practices, which influence the use and interpretation of tasks and tools and “govern the nature of the arguments that students and teachers use to justify mathematical conjectures and conclusions” (p. 26). A key norm the authors highlighted is that students be expected to regularly discuss alternative strategies and why they work. This practice, they argued, will not only motivate the kinds of reflective mental activity previously described as students come to participate in what has been established as common classroom practice, it will also provide opportunities to make relationships explicit as the class examines how various methods are alike and different.

Predating the work described above was Hiebert et al.’s (1997) book, *Making Sense: Teaching and Learning Mathematics with Understanding*. Based on research conducted by the eight authors in various mathematics classrooms, Hiebert and colleagues identified and devoted a chapter to each of five “dimensions” of mathematics classroom instruction and activity: 1) the nature of classroom tasks; 2) the role of the teacher; 3) the social culture of the classroom; 4) mathematical tools as learning supports; and 5) equity and accessibility. Within each of these dimensions, the authors discussed essential “core features,” necessary for supporting students’ understanding of mathematics. Like the authors whose work is discussed above, Hiebert and colleagues attempted to describe a set of features of mathematics classroom instruction they viewed as critical for providing opportunities to learn mathematics with understanding—the dimensions that ‘matter.’ Additionally, the authors viewed their framework as potentially meaningful to those engaged in the practice of mathematics instruction, suggesting that it could be “used by teachers to reflect on their own practice, and to think about how their practice might change” (p. 3).

| Hiebert et al. (1997) | Carpenter & Lehrer (1999) | Franke et al. (2007) |
|---|---|---|
| Nature of Classroom Tasks | Tasks or activities students engage in and the problems they solve | |
| Role of the Teacher | | |
| Social Culture of the Classroom | Classroom normative practices | Establishing norms for doing and learning mathematics |
| Mathematical Tools as Learning Supports | Tools that represent mathematical ideas and problem situations | |
| Equity and Accessibility | | Building relationships for doing and learning mathematics |
| | | Supporting discourse for doing and learning mathematics |

*Figure 1.* Summary of central aspects of mathematics instruction identified in three works.

In Figure 1 I list the critical dimensions of mathematics classroom instruction identified in the work summarized above, mapping those identified by Carpenter and Lehrer and those of Franke et al. onto the dimensions described by Hiebert and colleagues. The ‘gaps’ in these lists should not be interpreted as omissions; they are typically a consequence of arrangement and classification choices. Since all of the authors acknowledged a systemic relationship among their dimensions, it is not surprising that in any one of these classification choices, dimensions identified as central by the other authors can be found. Two particular instances worth noting in this regard are Hiebert et al's “role of the teacher” and Franke et al.’s “supporting discourse for doing and learning mathematics.” Much of what Carpenter, Franke and their co-authors wrote about pertained very much to the role they envisioned a teacher playing. For example, both teams described the importance of the teacher’s influence on the establishment of classroom norms. Likewise, Franke et al.’s discourse dimension was represented in multiple places throughout the others’ summaries as they discussed the importance and role of communicating about mathematics in the classroom. Although it is to some extent a matter of reorganizing and renaming, I will argue below that the labels on the dimensions are meaningful in that they can represent points of view, or ways of seeing and valuing aspects of a mathematics classroom.

## Research Questions

As stated above, my immediate goal was to build a coding scheme for assessing participants’ visions of high-quality mathematics instruction. Therefore, my question regarded the ways teachers, principals, and others characterize high-quality mathematics instruction. In particular, which aspects of mathematics classroom instruction do they choose to highlight? To what extent do practitioners’ characterizations of classroom instruction map onto the critical “dimensions” described in the literature?

## Methodology

Participating school districts were purposively sampled to represent districts with ambitious goals for mathematics instruction reform to meet the needs of diverse populations. While differences exist among the strategies the districts are attempting to implement for accomplishing their goals, in general, all four districts are working to support mathematics instruction in every classroom that emphasizes rigorous tasks, problem-solving and sense-making, productive discourse, fair and credible evaluations, and clear, high-level expectations for all students.

In each annual data collection we document aspects of the institutional settings in which our participants work, the instructional practices and mathematics content knowledge for teaching of approximately 30 middle school mathematics teachers per district, and the extent to which structures such as those listed above have been established to support the ongoing improvement of mathematics teaching in 6-10 representative middle schools per district. Annual data sources are varied, but include 45-90 minute interviews with each participating teacher, principal, mathematics coach and district leader on issues related to the institutional settings in which they work, as well as their vision of high-quality mathematics instruction.

The data analyzed for this paper come from the interviews conducted in year one (January 2008) with middle school mathematics teachers, principals, and, in districts that employ them, mathematics coaches. I examined transcripts from every participant (teachers, principals and coaches) at each of eight schools (two from each district). These schools were theoretically sampled (Strauss & Corbin, 1998) to provide wide variation in the ways participants talked about mathematics instruction, as indicated in case summaries written for each school. The interviews were conducted and audio-recorded by members of the project team and later transcribed. As is the case with ‘unstructured interviews,’ (Burgess, 1984), they followed a set of guiding questions (that were customized for each district), but were conducted flexibly, intended to afford opportunities for conversations rather than a rigid sequence of questions.

The interviews probed at a number of issues related to mathematics instruction and the institutional setting in which participants work, including participants' understanding of the district's plans for improving mathematics instruction, their vision of high-quality instructional leadership, their informal professional networks, professional development activities in which they participate, the people to whom they are accountable, the sources of assistance on which they draw, and the curriculum materials they use in the classroom. An additional purpose of the interviews—and the focus of my analyses in this paper—was to document teachers', principals', and coaches' visions of high-quality mathematics instruction. Specifically, we asked participants the following question: "If you were asked to observe another teacher's math classroom, what would you look for to decide whether the mathematics instruction is high quality?" Depending on the participant's response, we asked, "Why do you think it is important to use/do _____ in a math classroom? Is there anything else you would look for? If so, what? Why?"

The purpose of this particular question was twofold. First, it was an attempt to circumvent the say-do problem (Gougen & Linde, 1993), a well-known obstacle in the social sciences in that self-reporting typically does not yield reliable data concerning participants' own practices. Thus, in asking our participants to imagine and talk about the activities in a classroom of some hypothetical other, our thinking was that we could release the participant from some of the pressures of accurately describing his/her own classroom and practices, and tendencies to foreground more socially desirable aspects of classroom instruction to the exclusion of those perceived as less desirable . Secondly, and more importantly, in asking teachers (and principals and coaches) to place themselves in the role of observer, we hoped to ascertain aspects of the lens with which each participant would actually view a mathematics classroom, or the way they interpret classroom events (Sherin, 2001). That is, we could interpret their responses to mean, "this is what matters in a mathematics classroom"—the aspects of the classroom on which they focus to determine the quality of instruction. This in turn would enable us to not only establish the kinds of things they might attend to when observing a mathematics classroom (e.g., what the teacher does, what the students are doing, the nature of the mathematical tasks, the nature of classroom discourse, etc.), but also to attribute some measure of depth or sophistication to their criteria.

Focusing in particular on the portion of the interviews including the question and probes mentioned above, I collected more than 200 statements from 54 of 222 participants (8 principals, 41 teachers and 5 mathematics coaches). Following Strauss & Corbin's (1998) open coding technique, I classified these statements (or concepts) into categories based on shared properties, such as whose behavior the statement pertained to (e.g., teacher, students, or both) or which aspect of the learning environment was emphasized (e.g., nature of classroom tasks, structure of lessons, etc.).

My initial classification was guided by a provisional list of codes (Miles & Huberman, 1994) drawn from Hiebert and colleagues' (1997) identification of essential dimensions of mathematics classroom instruction discussed above. I employed these dimensions and their accompanying core features as an initial framework for categorizing mathematics teachers' and instructional leaders' descriptions of what they would look for in a classroom to determine whether what they observed was high-quality instruction. Hiebert and colleagues' framework represented a reasonable starting point for my purposes, since the authors viewed it as a tool that could be used by those engaged in the practice of mathematics instruction for reflection and change. Thus, in initially adopting these authors perspective, I was not merely imposing a priori a researcher's tool on practitioners' views, but attempting to combine etic and emic accounts to create tools in which both communities find relevance and meaning.

## Results

Approximately half of the lines of talk I collected from interview transcript resembled the kinds of ideas expressed in the dimensions proposed by Hiebert et al. Many participants commented on the types of problems they would hope to see students working on (the nature of classroom tasks), what they thought the teacher should be doing (the role of the teacher), or how students would be interacting with other students and the teacher (the social culture of the classroom). Approximately five participants commented on the need to differentiate instruction based on students' individual needs (equity and accessibility), and two participants' remarks pertained to the importance of technology or means of representation in the classroom (mathematical tools as learning supports). Since my primary goal was to describe participants' visions of practice, I decided to drop the category pertaining to mathematical tools because it accounted for so few of the participants' responses, and retain the other four dimensions proposed by Hiebert *et al*. But a considerable number of responses were left unaccounted for. Therefore, I sorted the remaining statements into groups that appeared to share a focus. One set of concepts pertained to student and teacher talk (i.e., classroom discourse—a dimension identified in the framework of Franke *et al.*), one to lesson structure, another to assessment, and another (the largest) to student engagement.

In summary, in order to establish a means for describing participants' instructional visions, I have relied on both our interview data and previous work in identifying important aspects of mathematics classroom practice to identify categories to which teachers' and leaders' instructional visions might pertain. This analysis resulted in eight categories or, in Hiebert and colleagues' language, "dimensions": 1) the role of the teacher; 2) classroom discourse; 3) the organization/purpose of activity (i.e., student engagement); 4) social culture and norms; 5) the nature of classroom tasks; 6) role of student thinking; 7) lesson structure; and 8) equity and accessibility.

## Discussion

With this paper I have attempted to define a construct important to the ongoing MIST project, that of instructional *visions*. In the spirit of Simon and Tzur's (1999) efforts to generate "accounts of mathematics teachers' practice," my aim was to categorize and understand teachers' visions of high-quality mathematics instruction "in a way that accounts for aspects of practice that are of theoretical importance to the communities of mathematics education researchers and teacher educators" (p. 254). Thus, guiding my analysis was this question: What is the minimum number of dimensions of classroom activity and instructional practice that makes a difference? This question represents a two-pronged endeavor. One the one hand, I wanted my final categories to reflect what previous researchers have identified as important aspects of mathematics classroom instruction. On the other, I needed the final categories to sufficiently and meaningfully account for patterns I perceived in our data.

Along each of the eight dimensions listed above, we have elaborated a conjectured trajectory for participants' instructional visions in terms of depth and sophistication of their descriptions (the presentation and discussion of which is beyond the scope of this paper). Over the 4-year duration of our research team's work in school districts, we will use (subsequent refinements of) these trajectories to document shifts in individuals' visions of high-quality mathematics instruction, and the extent to which members of various district units move toward a shared instructional vision.

*This paper examines the use of a laboratory-class-based professional learning experience for mathematics teacher developers (MTDs). An 8-day institute focused on mathematical knowledge for teaching (MKT) featured a laboratory class a means of providing a common experience for observation and discussion. In a follow-up study 2 years later, the MTDs recalled several features of the institute and reported that it had influenced their current thinking and practice. In particular, the MTDs identified several features of the laboratory-class-based experience as significant: (a) observing the instructional practices of another MTD, (b) experiencing a potentially novel model of professional development, (c) investigating MKT, (d) working with MTDs of different backgrounds, and (e) exploring student understanding.*

Recent reports have cited an urgent need for improving both the quality and size of the mathematics teacher workforce in the United States (see, e.g., Business-Higher Education Forum, 2007; National Science Board, 2007). Part of this improvement entails mathematics teachers shifting their practices away from teacher-centered models of instruction to a focus on students' mathematical understanding and developing students' ability to solve problems, communicate, and work together. Undertaking a task of this scale requires a cadre of competent mathematics teacher developers (MTDs), those who are charged with the initial and ongoing professional education of mathematics teachers.

MTDs are a diverse group of professionals that includes community college and university faculty from both mathematics and mathematics education departments, privately practicing professional developers, and school district leaders who offer workshops for teachers. Although some MTDs do not have degrees in education or consider themselves teacher educators, they do teach courses designed for teachers. Sztajn, Ball, and McMahon (2006) described the literature

[1] This paper is based upon work supported by the Center for Proficiency in Teaching Mathematics and the National Science Foundation under Grant No. 0119790. Any opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect the views of the National Science Foundation.

We are grateful to Kathleen Banchoff not only for facilitating one of the focus groups but also for helping us formulate the protocol for those groups and for sharing her extensive experience in using the focus-group research technique. Tom Ricks, Shelly Allen, Patricia Wilson, and Jeremy Kilpatrick contributed to the design of the survey and focus group protocols. Ricks and Allen also each facilitated a focus group session.

Kilpatrick also provided invaluable feedback on several drafts of this paper.

on MTDs' professional learning as essentially nonexistent. Similar to the shifts recommended for teachers, it is becoming clear that those who work with teachers need to also "undergo shifts in their knowledge, beliefs, and habits of practice that are more akin to a transformation than to tinkering around the edges of their practice" (Stein, Smith, & Silver, 1999, p. 262).

But how do MTDs acquire their expertise? Along with the investigation and development of professional development models for mathematics teachers, attention must also be given to models of professional development for MTDs (Sztajn et al., 2006). In this study, we investigated a model of professional development for MTDs that featured a laboratory class.

In summer 2004, 65 MTDs from across the country gathered in Ypsilanti, Michigan, to attend an 8-day institute entitled "Developing Teachers' Mathematical Knowledge for Teaching". The institute was organized by the Center for Proficiency in Teaching Mathematics (CPTM), an NSF-funded project led by researchers from the University of Michigan and the University of Georgia. The central feature of the institute was the observation of six consecutive sessions of a university-credit mathematics content course entitled Mathematical Content and Applications for the Teaching of Elementary School Mathematics. Sixteen preservice elementary teachers enrolled in the course, which was taught by Deborah Ball from the University of Michigan.

To better understand how a laboratory-class-based model may facilitate the professional development of MTDs, we examined the 2004 CPTM Summer Institute and its laboratory class to address the following research questions:

1. When asked to recall their participation in a laboratory-class-based professional development experience, what do mathematics teacher developers report as being significant?
2. What features of a laboratory-class-based professional development experience do mathematics teacher developers report as influential in their current practices?

## Theoretical Perspective

The professional development of MTDs, like that of other teachers, should attend to the work of teaching (Ball & Cohen, 1999; Smith, 2001). This work includes the cycle of teaching: planning for instruction, enacting the plan, and reflecting on the plan (Smith, 2001). Although this cycle oversimplifies the teaching process, it highlights three of its significant aspects.

Current literature on effective professional development also suggests classrooms should be used as a laboratory to explore teaching and learning (Lappan & Rivette, 2004). Hiebert, Morris, and Glass (2003) proposed an experimental model for preservice teacher development, called *lesson experiments*, whose laboratory-like structure parallels Smith's (2001) three-part cycle of teaching. In this model, preservice teachers treat the development and enactment of lessons as an experiment. First, they develop research questions, plan activities, and formulate hypotheses about what students might learn during those activities. Second, they implement those activities and collect data that will help them test their hypotheses. Third, when the lesson has concluded, they examine and interpret their data, developing conclusions and reformulating their hypotheses. By learning how to learn from their practice, participants in lesson experiments will continue to sustain professional growth throughout their careers.

Hiebert et al. (2003) recommended those who teach teachers should also learn about their practice through lesson experiments. By incorporating systematic inquiry within the cycle of teaching, the lesson experiment model fulfills what Cochran-Smith (2003) called the need for teacher educators' practices to have an *inquiry stance*. This stance includes "a way of learning from and about the practice of teacher education by engaging in systematic inquiry on that practice within a community of colleagues over time" (p. 8).

The ultimate goal of professional development for teachers at any level is to improve their students' mathematics learning, yet it is difficult to link the effect of one professional development experience with students' performance over time. Smith (2001) noted:

> If the goal of these efforts is to change knowledge, beliefs, and habits of practice so as to have an impact on students' learning, then changes in what teachers know, how they think about teaching and learning, and what they do in their classrooms might foreshadow future changes in learning outcomes for students. (pp. 51–52)

In this study, we sought to better understand changes in the MTDs' thinking and practice since attending the institute by asking them to reflect on their experiences with different features of the institute.

## The 2004 CPTM Summer Institute

In this section, we first describe several goals that guided the design of the institute activities. Then we provide more detail about the laboratory class and sessions related to it.

### *Institute Goals and Design*

*MKT.* As indicated by its title, the institute's central theme was mathematical knowledge for teaching (MKT). Bass (2005), who led discussions of mathematics at the institute, defined MKT as "the mathematical knowledge, skills, habits of mind, and sensibilities that are entailed by the actual work of teaching" (p. 429). From this theme, the designers posed two questions to focus institute activities:

> 1. What mathematical knowledge and practices play a central role in the everyday work of teaching?
> 2. What are promising approaches for helping teachers learn mathematics for teaching and and learn to use it in their work? (Sztajn et al., 2006, p. 154)

Institute designers used a variety of strategies to support MTDs' discussion and analysis of MKT. These strategies included assigning a particular focus for laboratory class observations, distributing scholarly articles on MKT, and, when appropriate, connecting MKT to group discussions.

*MTD diversity*. The institute designers selected institute participants that would reflect the diversity of backgrounds held by MTDs. In doing so, they hoped to encourage the group to collaboratively develop a professional identity (Sztajn et al., 2006). In addition, the designers sought to better understand how MTDs of different backgrounds "attend to learning opportunities" (p. 154–155). To accomplish this task, the designers used focused observations and participant journals as ways to capture MTDs' observations and reflections during the institute.

*Professional development of MTDs.* The designers also strove to understand how to help MTDs sustain their learning and professional growth. Using their knowledge of the professional development of K-12 teachers, they identified five guiding principles for the design of the institute:

> (a) learn in and from practice; (b) share with each other and from their professional experiences; (c) participate in some aspects of the design of their professional

> experiences; (d) choose professional development opportunities to work on that are most meaningful to them; and (e) be treated as professionals. (Sztajn et al., p. 155)

Efforts to reach these goals were evident throughout the various institute activities.

*The Laboratory Class*

The laboratory class could “be compared to a shared specimen for observation and manipulation” (Sztajn et al., 2006, p. 156). In this model, the MTDs, as the participants, acted as “a research team developing hypotheses and looking for evidence to support or refute claims and assumptions” (p. 156). Although the laboratory class provided a site for inquiry, it also created an environment that encouraged the MTDs to work within a community to generate knowledge and theorize their practice. Specifically, the laboratory class and its supporting sessions paralleled the three-part teaching cycle—planning, teaching, and reflecting—and incorporated features of Hiebert, Morris, and Glass’s (2003) lesson experiments.

*Planning.* Each morning, the MTDs would review and discuss the plan for the upcoming laboratory class session. Although Ball had already created a plan for that lesson, she gave the MTDs an opportunity to make suggestions. Part of the MTDs preparation for their observation involved solving and discussing the mathematics problems in the lesson. This prompted them to hypothesize how students might approach the activities and what difficulties students might encounter. This planning activity was essential for focusing MTDs’ observations of the lesson.

*Teaching.* The MTDs sat in elevated rows on either side of the class to observe the two-hour laboratory class in which the planned lesson was taught. To provide further focus, the institute designers directed the MTDs to specifically consider the teaching, the learning, or the mathematics being taught in the lesson. During the observation, the MTDs looked for confirming or disconfirming evidence to support or refute their predictions.

*Reflecting.* After each observation of the laboratory class, the MTDs reconvened first in small groups and then as a whole to discuss and reflect upon what they observed. Ball met with the MTDs to discuss what had occurred, the rationale for her instructional moves, and her plans for future class sessions. The MTDs revisited their original thoughts about the lesson and discussed how students approached the activities and what seemed difficult for them.

## Method

To understand what influence, if any, the CPTM Institute had on participating MTDs’ thinking and subsequent practice, CPTM researchers designed a two-part follow-up study. First, institute participants were invited in fall 2006 to complete an online survey that elicited information about their current practice, their impressions of the institute, and input for an upcoming reunion for institute participants. Of the original 65 participants, 46 submitted responses to one or more of the online survey questions.

The second part of the follow-up study consisted of four 90-minute focus group interviews at the reunion in January 2007 with a total of 32 participants from the institute. By encouraging participants to explain and discuss their responses, these interviews enabled the collection of rich data not attainable through the survey alone (Kleiber, 2004). The focus group discussions addressed the institute experience (including specific attention to the laboratory class), the participants’ current practice, and MKT.

Although responses in the online survey and focus group were to questions that dealt with a wide gamut of institute issues, we focused specifically on those that concerned the laboratory class. We examined transcripts to identify specific features of the laboratory class recalled by participants and the changes in practice that they reported had occurred as a result. Through several iterations of this process of examination, two dominant themes emerged pertaining to the laboratory class, along with some other themes that were mentioned less frequently or not described as explicitly. Once the themes were identified, we used them to code the data.

## Results

We have organized our results into three sections. The first two address the dominant themes: (1) the opportunity to observe and emulate instructional practices that the participants thought to be effective, and (2) the identification of features of institute design that affected their institute experience and their view of professional development. The third section summarizes some of the other themes, which included opportunities to investigate MKT, explore student understanding, and work with MTDs of different backgrounds. We address both research questions within each section.

*Observing Effective Instruction*

Many participants cited the instruction that took place in the laboratory class as prominent in their view of what they learned at the institute. Although a variety of aspects of this instruction received particular attention from the participants, we detail the three most frequently cited. First, Ball constantly pushed her students to think deeply about the mathematics they studied and the pedagogical decisions she made during class. In a focus group discussion, Sally (all names are pseudonyms) called this technique “the press” and gave examples of the questions Ball asked to focus students on their mathematical thinking: “‘Why are you saying that? What do you mean by that?’” Ball often asked students about her pedagogical decisions, encouraging them to think more deeply about what they were learning. Rachel (focus group) described this behavior as “making [one’s] practice explicit” and reported that she had become “a much better teacher” by adopting this practice. At times, Ball would push the preservice teachers to consider both the mathematics and the accompanying pedagogy by prompting them to write in class journals. Paul (focus group) remarked on this technique:

> I always had students write a lot about things. But I do that a lot more now than I ever did. And getting at them to understand or explain the whys of what’s happening, to get at that greater depth of the thing, I find that that’s very difficult for most students.

By focusing on creating mathematical explanations, asking significant questions, and identifying connections between representations, Ball was able to push the students to consider more deeply the mathematics and pedagogy they would need in their own practices.

Second, Ball used mathematically rich problems whose exploration required large amounts of class time. In his focus group, Andrew (focus group) described his reaction to this practice:

> There was … an enormous amount of time talking about one problem. This elaboration of discussion where people were able to go down all kinds of different paths, some of them down to dead ends and so forth…. It was a really eye-opening experience for me.

The participants reported using some of these problems in their classrooms. More importantly, some noted having redesigned their courses to include fewer problems with more time for exploration allotted to them.

Third, Ball established classroom norms necessary for the students to explore and discuss their mathematical thinking. Molly (focus group) described this practice as providing “a really rich classroom environment where [students] knew it was okay to make a mistake and that everyone was going to learn from that.” As a result of observing the instruction at the institute, Julie (focus group) reported that she spends "a lot more time socializing my students and talking on the first day." She continued to describe how she stresses to them the importance of spending significant amounts of time on problems, finding multiple solutions, and, at times, becoming frustrated.

Although we have identified three general elements of Ball's practice that participants deemed to be significant, this description may oversimplify what she did in the laboratory class. In her focus group, Suzanne described the complexity of Ball's instruction eloquently:

> Her work is often so nuanced. … You can't make a list. That's sort of just a beginning step. But I have thought many times since then: What is it that she did? What were some of the things? And yet I feel like I'm just scratching the surface.

*Institute Features*

In the follow-up study, participants described how the laboratory class, as a feature of the institute, stimulated their thinking about their own professional development as well as the professional development they provide for others. Several participants noted the importance of having a common experience that enabled "deep discussions about the issues we face in preparing teachers of mathematics" (Helen, online survey) by providing something that "we could dig into together" (Jen, focus group).

Of particular significance, participants frequently stated the importance of interacting with Ball before and after laboratory class sessions and her openness to their input. This interaction enabled them to feel like "active participants in her instruction" (Lauren, focus group). Edward (focus group) was drawn in by the interaction with Ball, coupled with the "real time nature" of the laboratory class, commenting:

> There were all of these unpredictable variables that come into play, what inputs [Ball] used and how those influenced her thinking, and how transparent she was about that, how she invited our involvement in that. And so, we were simultaneously going through the same process.

This shared process, which Robin described as an opportunity to "learn in the moment" (Focus Group D) was also cited by other participants as an important feature of the laboratory class.

Several participants reported changes that they had attempted to make based upon their experience with this professional development model. Martha took her class of 25 preservice teachers to a fifth-grade classroom to observe a lesson, focusing on how students learn. Lauren (focus group), citing the importance of having focused observations, no longer allows the teachers with whom she works to interact with students during classroom observations. Several participants reported using video to create the common experience for their own students that was found to be so valuable at the institute. However, Sandy (focus group) noted that, because the use of video was not instantaneous, "you lose something."

*Other Themes*

Although participants discussed the themes detailed above more frequently and explicitly, other themes could be detected within the data. First, some participants cited the importance of exploring MKT at the institute. Considering their own practices, they also noted the teachers with whom they work needed to develop a deeper knowledge of the mathematics they teach. When discussing how to address this need, some recalled their experiences in the laboratory class. In particular, they focused on the importance of having multiple representations for a mathematical concept. Molly (focus group) stated:

> I … remember all the different representations, none of which I would have thought of in a million years, and then how [the students] even struggled to communicate what is was they were doing and why they were doing it. … Giving them a chance to go back and really reflect on that was so important.

Some participants provided examples of how MKT had become a theme in their current work. For example, Andrew (focus group) described how the focus on explanation in the laboratory class carried over to his own practice: “I confess I got kind of hung up on this idea of explanations in these courses that I’ve been teaching.” He went on to describe how he has been trying to elicit explanations from his students that are similar to those that teachers need to produce on their own.

Other participants described their attempts to focus on deeper mathematical knowledge in their work. This shift in focus involved the creation or redesign of their mathematics content courses for teachers and, for Robby (focus group), a move to make his examinations “explanations-based.”

Second, in addition to exploring MKT, participants noted the importance of working with MTDs of different backgrounds while at the institute. By assembling a group incorporating the diversity of MTDs, the institute organizers created an environment in which all could learn from each participant’s unique insights. The participants of our study referred to the diversity of the MTDs and how the laboratory class structure brought out a variety of viewpoints. Jonathan (online survey) described the various perspectives as “critical”, stating that it had “a powerful impact on all of us, that there was not agreement, or even common understanding among those in the ‘same’ workgroup.” Robbie (focus group) cited the presence of diverse viewpoints as a way to bring out “some kind of opposition or polemic” in the group discussions, an element that he claimed facilitated his learning. Erica (focus group) had a similar view, stating that the presence of divergent views forced her to reflect upon and justify her perspectives.

Some participants reported that the interactions with MTDs of different backgrounds affected their subsequent practice. For example, an unidentified participant (notes from focus group) reported having “more confidence to interact with mathematicians about the body of knowledge that I possess & where our worlds intersect.” Julie (notes from focus group) expressed a similar sentiment, stating, “I valued at the institute the input of research mathematicians and work with them seeking deeper understandings of that which I teach.”

Finally, the participants reported that the laboratory class and the student journals that students produced in conjunction with the course provided an opportunity for them to develop hypotheses of student understanding. Considering the utility of understanding student thinking, Kelly (focus group) remarked, “If we can capture student thinking on problems so that we know how they typically respond, then that’s very informative for the next time you teach.”

For some participants, this focus on student understanding carried over into their work. At the institute, Erica had become particularly intrigued by her interpretation of a student-produced representation and how it differed from the student’s interpretation. In one focus group, she had reported that her subsequent thinking and attempts to reconcile that this difference led to her developing a “Building Hypotheses of Student Understanding” theme for her methods courses. Many participants also reported adopting the practice of using student journals after the institute as a way to monitor student understanding.

## Discussion

Comparing the goals for institute held by institute designers with the experiences that participants recalled about it revealed some parallels. The institute designers intended for the participants to investigate MKT (the institute theme), learn from peers with varying professional backgrounds, and learn in and from the practice of MTDs. MKT was a prominent topic in the online survey and focus groups. When asked questions that focused on the laboratory class, however, the participants spoke much more on the practice of the laboratory class instructor rather than on MKT. It was not that MKT was unimportant to the participants, but rather that they mentioned it less frequently in the context of discussion of the laboratory class. This relative lack of attention might be attributed to a struggle to articulate their understanding of MKT. In addition, many aspects of Ball's instruction recalled by participants, such as the focus on explanation or the importance of a deep understanding of mathematics, could be considered an embodiment of MKT in action.

One feature of the institute that participants reported as influential in their thinking and practices was the laboratory class. The laboratory class, through its combination of participant observation of and reflection on a common experience, allowed the MTDs to progress in how they thought about the work of MTDs. Making the laboratory class the central feature of an intensive institute experience appears to have helped the MTDs change their thinking and practice. The responses of MTDs suggest that variations of this laboratory class experience could be incorporated into professional development for mathematics teachers.

# MEDIATING INFLUENCES OF TEACHERS JOINTLY PLANNING A LESSON

Teruni de Silva Lamberg

juliemamador@gmail.com

*This study examines what mediated teachers thinking processes when jointly planning a lesson. The findings reveal that how teachers thought about standardized testing and state standards influenced how they took into account the cognitive, language and social development of students. In addition, the mediation of the facilitator, that involved the tension between creating a product and engaging in discussion, influenced the level of conversation that took place.*

## Background

Teacher lesson planning that supports learning is a complex process (Ball, 2000). Teachers need to consider the students they will be teaching, the mathematical content to be taught, and the methods through which the information will be delivered. Understanding the thought processes that teacher engage in for planning lessons can give professional developers insight on how to support teachers to improve their teaching practices. Lesson study has been advocated by researchers (Lewis & Tisuchida, 1997; Stiegler & Hiebert, 1999) as a viable means for teachers to examine and improve their teaching practices. In lesson study, a group of teachers jointly plan and teach lessons. We adapted the idea of teachers jointly planning a lesson in our work with teachers. Therefore, we present an analysis of what mediated teacher's thinking processes when jointly planning a lesson. Lesson study involves a group of teachers identifying a goal within a content area and jointly planning activities to teach a lesson (Fernandez, Cannon, & Choksh , 2002). Lewis, Perry and Murata (2009) point out that the innovation mechanism of lesson study must be understood as opposed to focusing on the surface features of lesson study (c, Fulla, 2001; McLaughlin & Mitra, 2001).

## Theoretical Perspectives

Lesson planning provides teachers with an organizing structure to conceptualize outcomes, and identify means of delivering instruction in order to influence student learning (Bage, Grosvenor, Williams, 1999; Panasuk & Sullvan, 1998; Yinger, 1979). Therefore, understanding what teachers consider when planning lesson is necessary for supporting teachers to improve their practice. Simon (1995) pointsout that effective lesson planning should involve thinking about the mathematical goals, learning trajectory that students might follow and designing tasks to support learning. However, the plans must be flexible so that the teacher can adapt tasks based on assessment of student thinking. This process involves taking into consideration children's cognitive development in order to support their mathematical thinking. Furthermore, this also means that teachers must consider the context in which they teach. Specifically, they must consider how to support mathematical thinking and language development (Bransford, Darling-Hammond, & LePage, 2005) within the social setting of the classroom. How teachers think about students' cognitive, language, and social development influences how they plan lessons and also the eventual outcome of the lesson.

Planning a lesson that takes student learning into account involves thinking about multiple variables. Joint lesson planning involves using problem solving skills. Particularly, it involves

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

working with non-routine problems. This means, the teachers have to define what they want their students to learn and figure out a topic and tasks. The potential for teachers' growth in learning comes from the messy process of solving the non-routine problems. Polya (1957) identified the process of problem solving as involving several phases such as understanding the problem, developing a plan, carrying out the plan, and looking back. Carlson & Bloom (2005) identify *resources, control, methods, heuristics and affect* as dimensions of problem solving process.

## Research Question

What mediated teachers thinking processes when jointly planning a lesson?

## Methodology

This paper examines data gathered as part of a larger three year Math Science Partnership Project involving collaboration among 5 school districts and 22 schools in a western state. There were three different professional development sites. The data analyzed in this paper is from one site. Five teachers participated in a professional development session where they engaged in developing a lesson, teaching it, and debriefing afterword. These teachers had participated in two and a half years of professional development in math education. Therefore, teachers had experience thinking about current research and teaching methods.

Four female teachers and one male teacher in grades 3-7 participated in the study. Additionally, a facilitator who was a district leader and part of the professional development team oversaw the process and incorporated guiding questions with the focus of completing the lesson plan. The first author serving as the project director, sat in during the lesson planning process. The teachers in the study applied to be part of this three year program. Teachers were randomly selected based on their interest, and commitments to serve as a teacher-leader.

The teachers involved in this study took part in a lesson study session, led by a facilitator. The facilitator focused on the completion of a Lesson Study Planning Sheet on a computer. Teachers were asked to complete the following elements: *Learning Activities and Questions*, *Expected Student Reactions*, *Teacher Response to Student Reactions? Things to Remember*, and *Evaluation*. Under the heading of Learning Activities and Questions the following elements existed: Process Standards, Standard, Big Mathematical Ideas, Objectives, Activities, and Possible Homework.

The data presented in this paper was the first 1 and ½ hour segment of the four-hour video tape recording of a lesson planning session that was part of a lesson study group. The data was transcribed and coded using Strauss and Corbin (1990) constant comparative methods. We first transcribed the data and made initial notes of observations. Then we coded the data based on emerging themes. Once the data was coded we looked at patterns in the data to determine what teachers considered when planning the lesson.

## Results

How teachers thought about the state testing and standards influenced the topic they chose to plan a lesson on. Furthermore, the level of conversation was mediated by the facilitator. The facilitator's focus on helping teachers to help students do better on standardized testing, and her focus on keeping teachers on task to develop a product (lesson plan) within the time frame allocated, mediated the level of conversation that took place. A brief excerpt of transcript from the beginning stages of the joint lesson plan is presented here. The teachers were examining the geometry state standards and standardized testing item specification sheet in order to decide on a topic for planning the joint lesson. This transcript illustrates the conversation that took place.

T4 Let's say we are all developing a lesson. And, maybe we have a lesson on linear measurement, and maybe that one lesson would be dealing with inches, feet, yards and miles. You know I mean. It would just be on one thing. And then in a separate lesson you can say we also use….Then they can put it all together. I just think if you teach it all at once with third graders they are going to get very confused. Don't you think? If they can use those units?

T1 It says standard and non-standard. I know I have looked at these before, but I can't remember.

Facilitator Okay, select and use appropriate units, measure to a required degree of accuracy and record results. Estimate and use measures and devices to measure. (Reads standards)

T3 I think the item specs the hint. It says inches and cm. so I think that is all we need to worry about.

Facilitator Another thing to look at and I hate to tell people this, but seriously, is the matrix to see how many questions they are going to be asked about cm and m and if there is only one question….you have to think about how much time

Teachers discussed sequencing of the lesson and what they might be capable of understanding. However, the conversation shifts to focusing on state test.

T3 You know, we did that. The first we got serious about cramming for the (state test). We went through and looked for what they had asked the year before and there were concepts we did not cover. And when we got it back it was really fun because the kids didn't do really bad on the ones we did not cover.

T1 Where is the matrix?

Facilitator: It is on here. Look at this, it tells you. It defines the terminology and it tells you how much they should be… and that is in the vocabulary that is underneath the old standards and we moved it to a glossary because this wasn't satisfactory.

Facilitator: This like unit, inch, meter, pound, it at least defines it a little bit.

Facilitator identifies vocabulary that will be on the state test. T3 teachers comment reveals that teacher cover content only that will be tested.

….

Facilitator: Okay, now what topic do you guys want?

T1 Okay, I posed a topic, now, somebody else.

T3 I agree with you, measurement is frustration in fifth grade, so it is no better in sixth grade because they are still banging their heads against the wall in fifth grade so as soon as they get in middle school they probably have problems. And when I do things around the house with my kids, measurement is still a problem in high school.

Teacher discusses the difficulty that students experience when learning measurement across grade levels.

Facilitator: And it is, to me, am I wrong, or do early elementary not measure as much as we used to. Get your ruler out and measure this….can you jump one inch, or one mile?

T3 Well I think, it has changed a lot.

T1 There is crazy stuff, this one question in here has a sticker star placed in the middle of a ruler and it is an inch and they are counting up from the beginning and it is clearly an inch. I mean it is crazy, weird stuff. (Examine curricular materials)

F2 How about we do a measurement lesson at grade three in your classroom?

T1 All right.

Facilitator suggests that they do a lesson on measurement. As teachers start sharing stories from classroom the facilitator makes a comment to get teachers back on the task of creating a lesson plan.

T5 They read the ruler backwards.

T1Let me show you. Here it is. (shows paper) This is three inches according to my students.

T5 We talked about this in the teachers meeting the other day that you need to step and this was one of the most missed questions in our data. So, what do you need to do to teach them to zero in, or compare the beginning to the end? Ours had a truck with wheels and some kids measured the distance between the wheels instead of the end of the truck, you know? And so we discussed what kinds of things do you have to do in a lesson to remedy your kids missing those lessons? Well, one is you have got to give them practice measuring things not with the beginning of a ruler.

T4 And two, when you are working on in the overhead you are showing them about starting at zero and you do it intentionally and you are modeling and then you just kind of place it down starting from and they will say that to you. OH Mrs. W, Mrs. W, you are not starting at zero! And then I could say, well, does it matter if I am starting at zero and here is when you could say this is at

T1What is a third grade standard we are looking at.

T2 You wanted the vocabulary right?

F2 No, I am going to be ornery and keep you guys or we won't get done.

T5 What she was talking about measurement.

F2 I know, I know. Do you actually want linear measurement or do you want to do something else?

(reading standards)

…

T1 Here is 3.3.1. compare, order and describe objects by compare attributes for area and volume/capacity. Or 3.3.2. select and use appropriate units of measurement required to a degree of accuracy.

T3 We can do both, can't we?

F2 Mm, there is no reason you can't cover both, I mean depending on the standards.

T3 I mean not covering all of both of them, but touching on both of them.

T1 We could very well be touching on both of them.

T3 Usually when you are doing that you are doing multiple anyway.

T5 You know what this is a question I guess I should have asked back when we were looking at our standards, but volume is not mentioned , I don't think, in sixth grade standards and they put it in seventh grade and it used to be in sixth grade standards. Now, I am hearing volume in third grade standards?

T3 Not any more. I don't think.

T5 Didn't you just read volume?

T1 Area and volume/capacity and like I said, I am confused about how much differentiation to make between volume and capacity. Do I strictly say, volume is the amount of space and capacity is the amount it will hold? And volume is measured in square units and capacity is measured in liters, gallons, bla, bla, bla?

T4 I really didn't even differentiate in fifth grade, I don't think.
F2 Remember too, we are talking about one lesson and how much you are going to be able to teach in one lesson. Not everything you are going to be teaching because you may not actually be teaching both of those in one lesson.
T1 Right.
F2 For our purposes and narrowing it down.
T4 Let's look at some lessons and see what we can find that comes to fit us close and then start modifying it.

This vignette illustrates that teachers not only looked at the state standards to make decisions about the focus for the lesson content. They also examined the specific number of items on the test specification sheet that was available on the internet to determine what topic to teach. The data illustrates that preparing students to be successful in standardized testing mediated how teachers interpreted the task and also made decisions. In addition, teachers also considered students ability levels and sequencing of lessons. For example, T4 pointed out that if you teach too many concepts together the students might get confused. Teachers relied on their classroom teaching experiences to make sense of what students might do such as reading the ruler backwards and T5 shared that measurement was a most missed question in their school data.

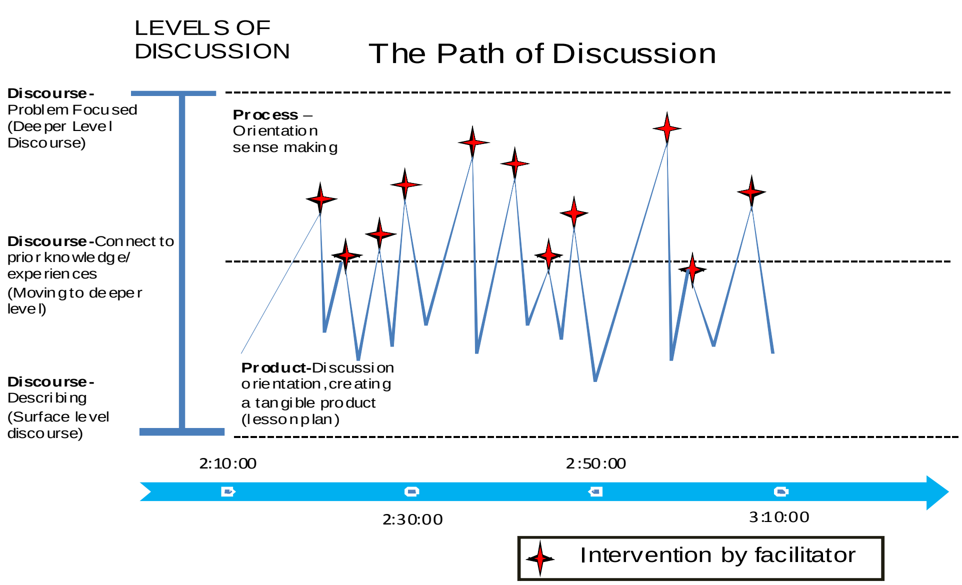
Teachers shared stories from their classroom experiences of teaching measurement and stated that measurement is a frustration in fifth, sixth grades and even middle school. During this process, the teachers were seeking to find a topic that would be beneficial for all teachers at different grade levels present in the lesson planning session. Sharing stories of difficulty in teaching measurement involved the process of beginning to define a problem that students have with measurement. The conversation had shifted from originally reading the standard and test matrix and item specification to talking about students. The facilitator interjected at this point to get the teachers back on task to develop the lesson plan. She even asked the teachers if they wanted to stay with the topic or do something else. This comment shifted the focus away from linear measurement to talking about volume and capacity. Again, the conversation shifted to reading out loud what the standards stated about volume and capacity in the state standards. As a result, the conversation shifted to a lower level of description. Once, teachers started to discuss their own experiences in the classroom and confusions about the topic the conversation shifted to a deeper level of thinking. For example, a teacher commented that teaching volume was more difficult than linear measurement. During this time, the facilitator reminded teachers not to get off track but to focus on one lesson.

The facilitator's actions were mediated by the need to have a finished product in form of a lesson plan within the allocated time for the planning session. The activity of the group shifted to looking at curricula to plan the lesson. The facilitator's interjections resulted in teachers changing the activity of discussion to focusing on developing a product. As teachers started looking at lesson activities, the facilitator was reading ideas from the state standards of other topics they could focus on. The facilitator told the teachers they could choose another topic other than geometry because the topic was taught earlier by the teacher and the geometry standards were not "meaty enough". Therefore, the conversation shifted again to another topic. One teacher was doing her master's project on problem posing and division and suggested that they work on problem posing. Eventually, teachers decided upon a lesson that involved problem posing involving division. They developed a lesson that involved students writing a division problem so that others could solve them. The teachers decided to create bags for group of students so that they could create their own problem. Their goal became to help students develop problem solving skills by posing problems.

**Discussion**

The first one and a half hours of the 4 hour lesson planning session involved finding a topic to plan a lesson. This process involved defining the problem in order to plan a lesson. The first phase of problem solving involves understanding the problem (Polya,957). Carlson et. al (2005) point out that that defining a problem is an important part of the problem solving process. Therefore, this process should be messy because it involves working with a problem that is not defined.

Lesson planning can be compared to the problem solving process. What we found interesting in the data was the tension between the facilitators role in keeping teachers on task of developing a product, verses allowing teachers to engage in discussion. When teachers began to relate a problem about their students and share stories from the classroom, the facilitator refocused teachers on the task of creating the lesson plan. The intervening comments changed the direction of the conversation that was taking place. Many times, discussion about what took place in their classrooms was viewed by the facilitator as an "off task" behavior. The conversation shifted to a descriptive level of reading standards or looking at activities. Whereas, when a teacher shared stories such as the difficulty they have teaching volume and capacity as opposed to measurement, they were posing problems to the group for discussion that required a deeper level of thinking. Carlson, Bowling, Moore & Ortiz (2007) point out that a facilitator needs to "*decenter*" in order for meaningful conversation to take place. Figure 1 illustrates the trajectory of conversation that took place.



Lesson study is a widely used form of professional development. Understanding what happens and how problems get defined can provide professional developers insight on how to support teachers during lesson study. Lewis et. al (2009) had pointed out that the innovation must be understood as opposed to the surface features being implemented. In this 1 1./2 hour discussion, a deeper discussion of defining the problem did not occur. Allowing teachers to share stories from their classroom, discussing what the standards mean in relation to their students can be a process of identifying a significant problem in order to find a solution. Eventually, a lesson on problem posing involving division was planned. The lesson did take into account student reasoning. Further research is needed on how teacher define problem during lesson study.

# REFLECTION-ON-ACTION OF MIDDLE SCHOOL MATHEMATICS TEACHERS

Na-Young Kwon
University of Georgia
rykwon@uga.edu

Chandra H. Orrill
University of Georgia
corrill@uga.edu

*In this study, we examined the reflection-on-action of four middle school mathematics teachers from the perspective of Cohen and Ball's instructional triangle (1999). We addressed questions of how teachers reflect on their students' understanding differently. The four teachers were asked about their students' thinking while watching video clips taken from their lessons. Findings indicate that the teachers showed differences assessing and interpreting students' thinking, differences by teaching experiences, and changes over time in ways they talked about the interaction between materials, students, and teachers as they related to students' understanding.*

## Introduction

In his discussion of the characteristics of practical knowledge, Schön (1983) noted, "There are actions, recognitions, and judgments which we know how to carry out spontaneously; we do not have to think about them prior to or during their performance (p. 54)." However, we sometimes think about what we are doing, and that is reflection. Two important forms of reflection are: *reflection-in-action*, which involves thinking about actions while engage in them and *reflection-on-action*, which involves thinking about processes after actions (Schön 1983). We are interested in teachers' reflection, in particular, reflection-on-action, because a growing body of literature suggests that reflection can help teachers understand the relationship between their cognition and teaching practice (Artzt & Armour-Thomas, 2002).

While there are a number of definitions for reflection in the literature, for this study, we consider reflection to involve teachers' analysis of teaching and students' learning. This is consistent with the *Mathematics Teaching Today* (Martin, 2007), which emphasized the analysis of teaching and learning as one of the professional standards. The Mathematics Teaching today, which is newer version of the NCTM teaching standards, asserts that teachers need to engage in this kind of reflection because it helps them develop deeper understanding of students' learning and development and impacts the ways in which they plan their lessons. Because of the potential for shaping teachers' practices, we assert that reflection is a part of the professional knowledge of teachers.

Research on inservice teachers' reflections has examined how reflection affects teachers' practices as well as their learning. In one line of reflection research, Sherin and her colleagues (Sherin, 1998; Sherin & Han, 2004; and van Es & Sherin, 2008) suggested the concept of *teacher noticing* as an important aspect of teacher learning that develops as part of the reflection process. Teacher noticing includes "(a) identifying what is important in a teaching situation; (b) using what one knows about the context to reason about a situation; and (c) making connections between specific events and broader principles of teaching and learning" (van Es & Sherin, 2008, p.245). Sherin and her colleagues found that teachers commented more on students' understanding and were able to recall more detailed information of classroom events over time as they worked as a group in video clubs. These are considered desirable outcomes of engaging in this kind of reflection activity.

In contrast to Sherin and her colleague's work, this study focuses on individual teacher's reflection. While we relied on video, we did not set up a learning community among the teachers and, in fact, did not engage the teachers in professional development as an intentional activity. Rather, we report the effects of engaging teachers in reflecting on classroom activities as part of a research effort. In further contrast to Sherin and her colleague's work, the researcher in these interviews directed the teacher's attention to particular events in the classroom rather than allowing the teachers to determine which incidents they wanted to discuss.

In this study, we examine four inservice teachers' individual reflection-on-action in the context of being interviewed for a larger research study. Our goal was to understand the development of the teachers' reflections over time in terms of their discussions about student thinking and to consider how the teachers differ in their reflection on student thinking. To this end, we examine teachers' reflections on their students.

## Theoretical Framework

We used Cohen and Ball's instructional triangle (1999) as a metaphor for thinking about teachers' reflections (see Figure 1). The triangle indicates that the learning environment is comprised of the interactions among the teacher, the students, and content as embodied in the instructional materials.

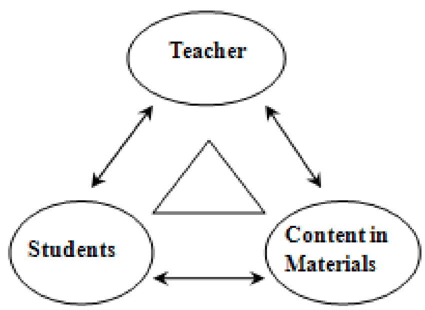

*Figure 1*. Cohen and Ball's instructional triangle.

The triangle forms the basis of our analysis because when teachers reflect on their lessons, they think back to the situations and interactions on the lessons so that the triangle of interactions can be a metaphor for thinking about teachers' reflection. That is, we take the perspective that reflection on these interactions is a critical element for improving the interactions and in helping the teacher begin to think about how the three elements of the triangle interact. Our underlying assertion is that a teacher with better reflective thinking will be more likely to connect a reflection on student understanding to the content and to her/his own actions as the teacher in the learning environment.

## Methodology

In our previous work, we examined one teacher's reflection and its change over time (Authors, 2007). In that study, we found that the teacher moved toward incorporating more discussion of the interaction between teachers and materials in her reflections on student understanding. In the present study, we replicated our analysis on a larger sample of teachers who participated in the NSF-funded Coordinating Students' and Teachers' Algebraic Reasoning (CoSTAR) project.

*The CoSTAR Project*

The CoSTAR research project focused on broad questions about mathematics teaching and learning by considering students' and teachers' knowledge, interactions, and sense-making of shared events. The CoSTAR data included daily videotaped observations of each teacher working with a single class of students using *Connected Mathematics Project* (CMP; Lappan, Fey, Fitzgerald, Friel, & Phillips, 2002) materials for an entire unit of instruction at a time (typically 6-8 weeks). The CoSTAR team interviewed teachers using the classroom video clips and student interview video clips.

*Participants*

The four participants were mathematics teachers at Pierce Middle School[1], which had recently replaced traditional instructional materials with the standards-based CMP materials. Three of the teachers were experienced mathematics teachers each having over 10 years of teaching experience. The fourth was a new 6th grade teacher who had some experience teaching 7th grade CMP while serving as a long-term substitute in the year prior to her case study. The data analyzed for this study came from our first case study with each of the teachers, though Ms. Moseley[2] had participated in a two-week pilot study before these data were collected. Ms. Moseley and Ms. Reese were teaching 6th grade and in their second year of implementation of the materials during this study while the 7th grade teacher, Ms. Bishop, was in her third year of implementation at the time of data collection.

*Data Collection*

Each teacher was interviewed weekly for the duration of her case study. In each interview, the interviewer used video clips from class sessions and student interviews. The video clips were selected by the interviewer and the investigator who was interviewing the students in the same classroom. In each case, the focus of the effort was on developing a deeper understanding of how the students and teachers understood the shared events of the classroom.

The interviews were videotaped using two cameras—one focused on the teacher and the other focused on either the computer on which the student interview and classroom clips were shown or on any written work or gestures the teachers made during the interview. These videos were then transcribed verbatim and these transcripts formed the basis of our analysis.

For each participant, we selected three interview transcripts—first, middle, and the final—from each of the cases to investigate these teachers' reflection patterns. The transcripts were the primary data analyzed for this study; however, the interview videos and classroom videos were used to clarify any points of confusion from the transcripts.

*Data Analysis*

Data analysis occurred in two steps. In the first step, the first author separated the transcripts into three categories based on the questions the teachers were asked: questions about teaching, questions about students, and questions about curriculum and materials. Questions about logistics of the research itself were separated out as well. For this study, as in our earlier research, we chose to focus only on interactions that arose from questions about students.

In the second phase of analysis, we used a modified version of the categories developed by Wallach and Even (2005): (1) *Assess*, (2) *Describe*, (3) *Interpret*, (4) *Justify*, (5) *Extend*. *Assess* instances were those in which the teachers evaluated students' ability. *Describe* instances were verbatim descriptions of actions without any analysis. *Interpret* instances were the teachers' analyses of what their students were doing. *Justify* instances provided a rationale of the teachers' beliefs about what was happening. *Extend* instances included interactions in which the teachers reflected on their teaching, the content, or the curriculum materials.

Each researcher coded all of the instances in the subset of data concerned with student questions within the three selected transcripts for each teacher. A single paragraph could have one or more instances within it and each instance was assigned to one of the five categories. Inter-rater agreement was achieved on both the instances and the categories for each instance. We discussed each instance about which there was disagreement to achieve a 100% agreement on the coding. Finally, we used *inductive analysis* (Patton, 2002) to compare the four teachers' reflection on students' understanding.

## Results

Initially, we only considered the relative percentage of instances of each category for each teacher (see Table 1). However, the relative frequency of each kind of instance was insufficient for understanding the teachers' reflection-on-action. Hence, we examined each instance in various ways to further understand the teachers' reflections.

### *Positive/Negative Comments*

As shown in Table 1, Ms. Moseley and Ms. Bishop generally increased in their frequency of Assess instances, but Ms. Reese and Ms. Archer decreased overall. Hence, we cannot say that there is a pattern in general. Nonetheless, we found an interesting result in those teachers' Assess instances. During interviews, Ms. Moseley provided 17 positive comments (80%) of the total 21 assess instances and Ms. Bishop offered 12 positive comments (80%) of the 15 assess instances. Most of these positive Assess instances focused on students' understanding or things that the students were able to do. For example, "She got the right percent though, so that is good" (Ms.

Moseley, 4/08/03 interview) and “I think she understood the concept” (Ms. Bishop, 9/24/03 interview). In contrast, in their Assess instances, Ms. Reese and Ms. Archer talked about their students’ misunderstanding or things that the students were not able to do. For example, “She’s misunderstanding that they’re different sizes” (Ms. Reese, 3/27/03 interview) and “Yeah… he would’ve found some stuff out. It wouldn’t have come out right” (Ms. Archer, 5/25/04 interview). Of Ms. Reese’s 16 Assess instances, 11 were negative (69%). Ms. Archer’s Assess instances included 12 negative comments (67%) out of the 16 Assess comments analyzed.

The positive or negative comments showed up in different patterns of the frequency of *Assess* instances. Ms. Moseley and Ms. Bishop who focused on students’ understanding positively showed a kind of increasing pattern in the percentage of instances of Assess. On the other hand, Ms. Reese and Ms. Archer who commented on negative students’ understanding showed a decreasing pattern in the instances. We claim that the decreasing pattern of the instances of *Assess* of Ms. Reese and Ms. Archer aligned with an increase in their discussion of their students’ understanding in contrast to focusing on students’ mistakes. Further, we assume that the teachers who evaluate their students positively make more efforts to understand their students’ mathematical thinking unlike the teachers who assess their students negatively focus on students’ misunderstanding or their mistake.

*Novice/Expert Teacher*

We had one teacher, Ms. Archer, who was in her first year full-time teaching at the time of data collection in contrast to the other three teachers who all had more than 10 years of experience. The case of Ms. Archer was curious in that she used many descriptions and a few interpretations to explain her thoughts about her students’ understanding at the first interview. However, by her later interviews, she changed to have fewer descriptions and more interpretations, making her similar to the other teachers. This may be because she was nervous about being questioned about her students and her practice or it may be related to her limited pedagogical content knowledge (Shulman, 1987), which necessarily limited her ability to interpret classroom instances. Ms. Bishop’s shift from Description to Interpretation suggest that providing this novice teacher with opportunities to watch and analyze her students’ work with the mathematics in their classroom supported her in moving quickly to being able to analyze and interpret her students’ work. If this is common in other settings, it could suggest that simply reflecting on student understanding can help develop a kind of professional knowledge for teaching much faster than it might develop without this reflection.

*Change in the Instances of Extend*

In this study, Extend instances included a wide variety of comments including reporting, evaluating, reasoning, reconstructing the teacher moves as they related to their students’ understanding, and assessing aspects of the curriculum materials. In the first interview, Ms. Archer provided the highest percentage of instances of Extend. However, the ratio of comments on her teaching decreased in later interviews. In our analysis, we found that Ms. Archer shifted over time to include less reasoning more reconstructing in her comments. Despite the decrease in Extend comments, we found that the Extend instances changed to reconstruct her thinking about teaching as it related to her students rather than just reasoning about her teaching practice itself. Building from our theoretical framework, we assert that this is a more sophisticated focus as the teacher began to attend to the interactions between the elements of the interaction triangle rather than simply focusing on each element independently. Given that the instructional environment is shaped by these interactions, having the teachers attend to them should impact teacher practice.

All four teachers showed changes in their instances of Extend from reporting or reasoning their teaching to considering various aspects including evaluation of their teaching or curriculum materials. For example, in their first interviews, the teachers commented specifically much on a few aspects such as reporting and reasoning; however, in later interviews, the teachers generally reflected on various aspects of teaching while they were talking about student thinking (see Table 2). This implies that these teachers' reflections improved in the sense that the teachers noticed more aspects of teaching and situations in their teaching as they gained experience in analyzing the video clips. This experience allowed them to not simply focus on their students' understanding and report their teaching actions, but also to evaluate and reason about their actions and the curricular materials as they related to student understanding. Again, building from our theoretical framework, this showed a movement to looking at the interactions between what they did, what the curricular materials included, and how the students understood the mathematics of interest. In other words, it built the teachers' professional knowledge in ways that allowed them to coordinate their understanding of how the three elements of the classroom work together and reconstruct their teaching with their students in the context.

*Increased Incidents of "no idea"*

We anticipated that, over time, the teachers would become clearer and less hesitant in explaining their interpretations about students' understanding. However, in our analysis, we found the opposite to be true for these teachers. This shift in the instances of *Interpret* occurred for all teachers, indicating that experience was not a factor in this aspect of our analysis. In the initial interview, the teachers provided interpretations of their students' mathematical understanding, but in later interviews, they often said "I don't know how he/she gets this" or "I have no idea." Perhaps, as they became more aware of individual student thinking through viewing these videos, the teachers were beginning to question their preconceived ideas about student understanding. In contrast, it could be that the teachers were becoming more comfortable with the interviewers and felt safe admitting when they did not understand a student's thinking. Regardless of the underlying cause in the increase of "no idea" comments, it was clear that the teachers did not always know how to interpret the students' thinking. We expect that reflection built into the regular practices of teachers might impact the teachers' abilities to interpret student thinking; however, the duration of this study was too short to test this assumption.

## Discussion

The data presented here suggest that the teachers who participated in this project began to change in the ways they reflected regardless of their years of teaching experience. While not large, these changes indicated that these teachers gained more insights about students' understanding as they gained experience in analyzing student understanding. The role of the researchers in this study is important because the researchers persisted in asking questions about students' understanding each week and selected video clips to support the teachers in discussing student understanding. This forced the teachers to reflect on their students' understandings week after week for the six to eight weeks of the unit. Without the researchers, the teachers likely would not have reflected on the students' understanding. We assert that the consistent interviews supported ongoing development of teacher knowledge that would not have occurred without the intervention. However, it should be noted that this study was not intended as a professional development study, rather the changes in reflection appeared to be the products of the teachers' changing in their reflection abilities simply through regular engagement in reflection.

Consistent with Sherin and Han's study (2004), we found that our teachers also shifted to focus more on student conceptions than pedagogies over time. This is especially interesting given that our context was quite different from theirs in that our study focused on one-on-one interactions between the teacher and the researcher rather than group interactions among teachers. Also, in our study, the researchers selected the classroom events on which the interviews focused whereas in Sherin and Han, the teachers attempted to interpret their students' mathematical thinking and, in the process, they struggled to explain their interpretations. These results suggest that reflection may be the critical aspect in promoting attention to student understanding as a product of the classroom interactions. Further, the video clips used in this study played a role of useful sources to engage teachers in reflecting on. This suggests that teachers can quickly develop relatively the ability to analyze student mathematical understanding if they were provided appropriate sources for reflection.

Clearly, further research is needed to understand the impact of reflection on teaching and learning. Reflection, as a form of professional knowledge, involves teachers' analyzing their own practice and using the conclusions they draw from the analysis to drive their future teaching. In this study, we examined teachers' reflection-on-action as prompted in one-on-one interviews. Our findings suggest that professional development may consider ways of using reflection and ways of engaging teachers to reflect on in order to raise teacher awareness of the interactions among the three elements of the interaction triangle.

## Endnotes

1. All names are pseudonyms.

2. The pseudonyms for teachers used in this study are consistent with those used in other publications of the CoSTAR project.

# SUPPORTING TEACHERS TO INCREASE RETENTION

Axelle Faughn
Western Carolina University
afaughn@email.wcu.edu

Barbara Pence
San Jose State University
pence@math.sjsu.edu

*U.S. national reports have identified the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education. However, providing high quality mathematics education for all students goes beyond the recruitment of knowledgeable teachers. This paper offers an examination of the role that professional development plays in the work and retention of new teachers and/or teachers in hard-to-staff settings. Based in California and including 10 sites and more than 250 teachers, first and second year results from data collected through large group surveys, online logs and site level focus groups helps to explain why the attrition rate over the first year of the study dropped from 20% to 11%.*

## Introduction

The preparation, support, and retention of mathematics teachers in grades 7–12 merits careful examination. Several U.S. national reports have pointed to the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education (National Academy of Sciences, 2007; Glenn Commission, 2000). However, providing high quality mathematics education for all students goes beyond the recruitment of mathematically knowledgeable teachers to encompass issues of teacher preparation, support, professional development, and retention. Analyses of teacher employment patterns reveal that new recruits leave their school and teaching shortly after they enter. Ingersoll, using data from the School and Staffing Survey concluded that in 1999-2000, 27% of first year teachers left their schools. Of those, 11 percent left teaching and 16 percent transferred to new schools (Smith & Ingersoll, 2003). Earlier research revealed that teachers with the highest qualifications tend to leave first (Schlecty & Vance 1981). This "revolving door" is even higher in large urban districts; for example, 25% of the teachers new to Philadelphia in 1999-2000 left after their first year and more than half left within four years (Neild and other 2003). In Chicago, an analysis of turnover rates in 64 high-poverty, high-minority schools revealed that 23.3 percent of new teachers left in 2001–2002. In California, 10% of the teachers working in high-poverty school transferred out in 2006–2007 (Posnick-Goodwin, 2008).

Reasons for the attrition of new teachers and teachers in high-poverty schools are often related to "working conditions" and lack of support (Ingersoll, 2001; Smith & Ingersoll, 2004; Johnson et al., 2004), though pay also plays a role (Hanushek, Kain, & Rivkin, 2001). This support includes both professional and collegial support such as working collaboratively with colleagues, coherent, job-embedded assistance, professional development, having input on key issues, progressively expanding influence and increasing opportunities (Johnson, 2006). Preparation, support, and working conditions are essential to teachers' effectiveness and their ability to realize the intrinsic rewards that attract many to teaching and keep them in the profession despite the relatively low pay (Johnson & Birkeland, 2003; Liu, Johnson, & Peske, 2004; Lortie, 1975).

Most of the research on the "support gap" has dealt with elementary teachers and national data. To focus attention on the retention and the impact of support and professional development

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

on mathematics teacher retention, both those who move and those who leave teaching altogether, a study was developed in the Fall of 2006 by the California Mathematics Project. This study is entitled California Mathematics Project Supporting Teachers to Increase Retention (CMP STIR) and was funded by the California Postsecondary Education Commission under the Improving Teacher Quality Grants to address both dimensions of teacher retention across California. The project focuses on teachers from schools and/or districts eligible under the No Child Left Behind guidelines who are in their first five years of teaching or teachers in hard-to-staff schools.

A major component of the project is research that would extend and deepen the knowledge base on mathematics teacher retention. Since the base for this study of support and sustainability of mathematics teachers involves 10 CMP regional sites, its design is complex, diverse, and builds on a 25 year-old professional development network, thus embracing a diversity of perspectives on the retention of mathematics teachers through support and professional development.

This paper will include an overview of the project, an outline of the research design and the results of the first two years. Results will include project as well as site specific analyses, and reflect upon opportunities and challenges.

## Research Design and Methodology

The project is multifaceted in both the range of professional development models and the research design. In general, CMP STIR is a 5 year intervention project with the first three years focused on systematic and sustained support, year 4 supports leadership development, career advancement and school and district support, and year 5 emphasizes collaboration, communication, and dissemination. Although specific dimensions of the professional development vary from site to site, the general model for the first three years is (1) intensive professional development and (2) systematic and sustained academic year support. The intensive PD consists of Institutes and follow-up, content, and communities of practice, while the support may include coaching, lesson study groups, school site networking, data driven reflection, access to resources, district and/or school support.

To study the major question of teacher retention, the project design consists of both quantitative and qualitative data. Overall, the research design encompasses project level longitudinal data, site level data, and case studies in three of the sites. The project level component includes baseline data, annual surveys and exit surveys. The site level data involves baseline data providing a history of attrition for each site across a five-year period from 2002–2007, teacher content knowledge, student achievement data, site yearly reports, teachers' monthly logs, focus group interviews, administrator interviews, and exit interviews. The case studies include classroom teacher interviews and observations for both project teachers and control teachers.

Project level, site level, and case study observations and interviews are linked through the inclusion of similar questions, such as a question about confidence and one about competence are found in the annual survey, the focus group questions, the log prompts and the case study interviews. The question of how much longer the participant expects to teach and why is also found in each level. Since most of the data collected is self-reported, triangulation helps provide validity and reliability. Yearly data allows us to trace trends within and across years. Tracking and understanding teacher retention patterns as related to professional development relies on site level models and input. Site level perspective provides the basis for on-going discussions and a serious element of reality. In this paper we choose to focus project findings by describing the unique features of one particular site's model, California State University Bakersfield (CSUB) in Kern County, and relate this site's results regarding opportunities and challenges translated at the site level. At CSUB, teachers are supported in taking one course per quarter in the Master's of Arts in Teaching Mathematics (MATM). The Department of Mathematics being very collegial, this model not only impacts subject matter content knowledge, but also allows for effective collaborations among participants while working together on course work, or sharing teaching ideas and other concerns with one another and the faculty in an atmosphere of nurtured community. The heavy technology focus of most courses such as Dynamic Geometry, Discrete Mathematical Models, or Numerical Approach to Calculus, engages teachers in first-hand experiences with educational technologies they are then able to transfer to their own classroom. This choice of support model draws both from the program coordinators' knowledge of the District's needs, and from the nature of the MATM. Kern County recruits heavily from the upper Midwest. These teachers generally obtain their teaching credential along with their baccalaureate degree, whereas in California, the credential generally requires an additional year of post-baccalaureate courses. Thus, many teachers obtaining their credential outside of California fall behind in graduate credits and end up at the bottom of the pay scale. Historically, these teachers would earn a graduate degree in Counseling or Administration and leave the math classroom. Furthermore the collegial, technology intensive and constructivist nature of the MATM meets some of the immediate needs of these individuals by breaking their classroom isolation while providing the tools to implement new teaching strategies with their students. Early in the data collection, one teacher shared with us "I already know what the unsuccessful lesson feels like. I hope to learn the successful strategies that will make my lessons work!"

In addition to this intensive course work, participants at CSUB have the option to attend yearly summer institutes aimed at addressing specific pedagogical content knowledge needs. These needs are self-identified during the school year to promote a model of professional development that is not only Content Knowledge and Community centered, but also focused on Teacher, and Assessment and in-line with the recommendation from the "How people learn" framework (Bransford & Brown, 2003). In summer 2007, 20 participants attended a "Meaningful Algebra" one-week intensive workshop that addressed the key California algebra standards, developing activities adaptable to any algebra book, modeling instructional strategies that teachers can use in their classrooms, and providing research-based information about learning. In summer 2008, 6 participants attended a Proportional Reasoning workshop during which Susan Lamon's books on teaching ratios and fractions for understanding (Lamon, 2006) as well as integrated-type curriculum supported the teachers' inquiries and discussions. Other support and engagement activities for participants include attending additional technology-based workshops and conferences, engaging in leadership positions at their school, self-reflecting on teaching practices through action research projects, and presenting at regional conferences.

## Results

Project sites work with teachers from schools and/or districts across California. Locations of the sites range from Northern California to the border of Mexico and include urban and rural communities. Each site is expected to work with at least 27 teachers. Data from the initial survey conducted in the Fall of 2007 included 266 teachers with site participation ranging from 17 in a small costal community to 60 in an urban setting. Each site also identified teachers for a project level control group that consists of 83 teachers across the state. The CSUB site currently serves 25 teachers in 17 high-need schools. Even though all participants are in their first five years of teaching mathematics, demographics vary across the group from newly graduates, to second career, with some individuals more seasoned in serving the district.

Baseline retention data for the state-wide project was collected in the site proposals which included a five year study of retention. That is, for mathematics teachers who were teaching in June, how many returned to teach in September. Each site compiled this data for the period of 2002–2007. Across this time period the attrition rate was consistently 20% both across years and sites. In addition to the attrition, the need across the five years, as reflected in the number of mathematics teaching positions reported each September, showed an increase of more than 60%. That is, the 600 math teaching positions reported in 2002 grew to 982 teachers in 2006. One site was able to trace individual teachers across the five years. The attrition rate for this site was 40% when the new teachers were tracked across the five-year period. In no case did the baseline data reflect how many left teaching and how many moved to another teaching position or administrative position.

Initial surveys included a baseline for retention expectation which provided a sharp contrast with the pre-project baseline data. In 2007, the participating mathematics teachers across the 10 sites reported that 94% expected to continue teaching for at least 3 years and 81% expected to teach for at least another 6 years. Additionally, the individuals in the 6% who expected to teach for only one or two year more were those who anticipated retiring or moving into administrative roles. Expected retention was traced through multiple instruments. Similar retention expectations were reported in the focus groups administered during the intensive professional development of 2007. A log prompt completed in March 2008, however, signaled an increase in expected attrition ranging from 10% to 20%. Actual first year attrition results varied from 4% to 29% with an average across the sites of 11%. What happened in these teachers lives that changed their expectations? Data collected across the multiple instruments and levels are designed to help understand these changes but the exit interviews conducted at each site are especially important. For example, since the CSUB project started in 2007, 5 participants have withdrawn due to conflicts of interest but are still teaching in the district, and 2 participants discontinued their participation to a change career: one went back to his prior engineering career after being unable to follow through with his alternative license, while another followed her parents' advice to pursue a profession in Law. The increase in expected attrition identified in the spring log coincided with a time when budget cuts where announced throughout the state and teachers were receiving Reduction in Force notices, especially those new to teaching.

Across all sites, beginning in September of each year, six electronic logs are collected throughout the academic year. Due to serious follow-up by each site, the response rate was very high varying from 53% to 100% with an average of 78% across sites and logs. The first two logs addressed teaching goals and support for classroom teaching. Results from these responses reflected the impact of the professional development with 84% indicating that the professional development affected their goals and/or supported their classroom teaching. Logs 3 and 6 looked at their perceived success as a teacher and the success of their students. In log 3, the teachers looked at opportunities and challenges and whether their students were as successful as they would like. Only 13% of the participating teachers were satisfied with their students' achievement. But, when they talked about the opportunities and challenges, student achievement became both a challenge and an opportunity. Instead of deciding to leave teaching or looking only at the challenges, the majority discussed the opportunities for learning how to teach. The final log asked the participants to describe a lesson that they especially liked and the support they received in developing this lesson. Seventy-nine percent attributed contributions to the lesson from the professional development and/or community developed through the professional development.

As we conduct research to gauge the effects of our intervention on teacher retention and support, each site gains valuable feedback on the model of professional development offered, which in turn helps refine the support provided. At CSUB, self-reported needs seem to be met by STIR, whereas a greater support from the school site is requested regarding assistance in instructional approach and curriculum. Some participants, even though they acclaim the community found at the university, still suffer from isolation at their site and express frustrations regarding workload, curricular pace, and lack of parental, administrative or collegial support. At times these frustrations seem enhanced by a new awareness of what teaching for understanding could potentially look like, and the evident discrepancy with their school environment or the reality of their classrooms, as one of our teachers points out, “There is a disparity between what I know how to do in my classroom and what I actually do. Much of the difference is caused by a lack of time to prepare, and lack of chance to reflect on what was done. This disparity is the cause of building frustration.”

As we enter the second year of intervention, online feedback also reflects enthusiasm for the program. The Summer Institutes have helped some implement successful lessons in their classrooms. Some have turned what they learn in graduate school into enrichment activities for their students, especially through history and technology. Teachers welcome the opportunities provided to use technology in their classrooms as they have become very familiar with it as users in their university courses. The MATM is technology-focused; mathematical concepts are discovered and discussed through inquiry-based activities encouraging participants to try new teaching strategies with their students as one teacher sums it up: “I have used Geometer’s Sketch Pad with my LCD projector onto my classroom whiteboard. I learned how to use the program in my class thru the CMP STIR program. Likewise, I have used my knowledge developed from the program about cooperative learning exercises with my classrooms. Overall, my students have been very pleased about how the classroom lectures are conducted and how much more they are involved compared to previous math teachers.” Some mathematics faculty teaching in the MATM have become role models for these beginning teachers who express a desire for their students to access deeper conceptual understanding of the material. Teachers also want guest speakers to enhance classroom motivation, feel empowered by their participation in STIR, and supported by a learning community that exists beyond the MATM courses; confidence levels have increased. Recently, teachers started asking for “more”: more classroom games enhancing students’ motivation; more enrichment ideas; more on-site support; more insights on how to teach lower-level mathematics; more involvement from administrators and parents.

Focus Groups are group interviews conducted at each site during the summer intensive professional development. The purpose of the Focus Group interview is to talk with a randomly selected group of participants during the intensive PD about their experiences to date, and to obtain data that might not surface by other methods. All of the Focus Group interviews are conducted by the same person and last between 45 to 70 minutes. Responses are coded and the data is compiled for all sites. Due to group dynamics, not every participant answers every question. In some cases, several teachers would nod in agreement to a response, visual affirmations that are not recorded while most of the verbal responses are transcribed during the interview.

The 2007 Focus groups included 59 participants consisting of 28 middle school teachers (including 3 special education teachers), 20 high school teachers, two pre-service students not assigned to a school, a middle school/high school coach, and a special education teacher of grades 4–6 (data for seven teachers are missing). When responding to “why are you participating?” and “what did you hope to gain?,” participants often responded with what they had already gained through networking with each other and with institute leaders: ideas for working with students, as well as for teaching and understanding mathematics conceptually. Ideas that linked to the classroom and time allocated for planning with colleagues were identified as successful aspects of the institute. Three key challenges emerged: how to transfer what was learned to the classroom, how to balance home, institute, coursework, and summer school, and how to address mathematics content that was challenging. As a result of the institute, many were realizing the importance of teaching conceptually, with concerns that they won’t be able to implement it with fidelity. Several teachers shared that they felt comfortable with the lecture method and that changing would be a challenge for them. Accordingly, they want the site to support them in the classroom through regular observations and coaching.

About 85% of the respondents said that teaching would be a lifelong career. In response to why they went into teaching, most said they liked the idea of teaching and helping others, liked helping students specifically, and influencing them with positive experiences in math. Other reasons included making an impact, coming from a family of teachers, and liking mathematics. About 10% mentioned that teaching was a second career. Most indicated that they would be interested in a leadership positions if they did not have to leave the classroom, such as become department chair or give presentations. A few talked about going into administration or becoming a college instructor.

For the 2008 Focus Group interviews, another group was randomly selected to participate. Future plans still showed high retention expectations with 88% expecting to be lifelong teachers and 5% expecting to leave teaching in 5 years. One-third of the participants mentioned an improvement in their classroom teaching. Regarding changes in the delivery of instruction, 35% identified higher level cognitive demands of students in questioning and problem solving. In terms of content, teachers reported deeper understandings of math, and greater accessibility to new mathematical ideas. Table 1 below shows changes in confidence that the participants can make a difference in student learning of mathematics, and competence in their knowledge of mathematics.

| Year/Level | 4 | 3 | 2 | 1 | 4 | 3 | 2 | 1 |
| 2007 | 15 | 32 | 12 | 0 | 14 | 34 | 12 | 0 |
| 2008 | 31 | 26 | 1 | 0 | 23 | 29 | 6 | 0 |

Support, networking and community are reflected in the responses to what has been gained to date as well as from prompts that looked at support provided, most useful support, what was gained in summer of 2008, and unexpected benefits. The following is a quote from the last log of 2008 that resonates with many of the Focus Group responses:

> It was great to work together and talk about what worked and what didn't. It was great to hear about the "aha" moments when they caught on that the number was always approximately 3. We discussed many ways of teaching this concept and it was very useful for us to bounce ideas back and forth to see what has worked or not worked in the past.

## Conclusion

This project is only in its second year but critical questions are being addressed. The key issue of the role of professional development on teacher retention shows reductions in mathematics teacher attrition for teachers in their first five years of teaching or teachers in hard-to-staff schools. Through the multiple levels of data collection and the triangulation of the data, dimensions related to this connection are surfacing. They include increased teacher perceived content and pedagogical knowledge and the development of professional mathematics teacher communities. Another major theme that has emerged across the sites and will need to be examined in future years is the issue of teachers' confidence in and competence with learning and teaching essential mathematical understandings.

As we look ahead, a greater presence at the school site will be necessary for the CSUB model. This need may be addressed through seeking administrators' involvement in supporting the program, focusing the teachers' thesis on action research projects, and moving into the leadership phase to help broaden the community. On-site leadership positions are already assumed by some of the participants. Additionally, 6 potential leaders were identified and/or expressed interest in leadership and participated in the San Joaquin Valley Mathematics Project Winter Leadership Retreat this winter. They shared very positive impressions with us: "The retreat was one of the most positive experiences of professional development I have ever participated in". Further leadership opportunities will include an involvement as workshop leaders in the induction program for beginning teachers, and presentations at regional conferences.

To conclude, success of a retention initiative takes root in a variety of needs: the need to know your District and its teachers—a necessity that often relies on established, long-term relationships between the university and district leaders; the need to offer sustained support as opposed to punctual interventions in order to break the isolation of beginning teachers and create a sustainable community; the need to establish relevance in the professional development activities proposed by engaging participants in deep introspection of their own knowledge gaps; the need to involve all actors of the community to prevent miscommunication from annihilating attempts made towards change; the need to nurture the community created by moving its members forward into roles and responsibilities they are ready to take on; and last but not least, the need to refine even successful models to keep the momentum.

*A U.S. federally funded nationwide field trial in 118 school classrooms of algebra 1 implemented Texas Instruments TI-Navigator™. The year 1 control group implemented the treatment in the second year. The purpose of this paper is to describe the professional development program and evaluate the summer institutes for both cohorts of teachers.*

## Purpose and Context

Teaching reforms and innovative interventions require carefully planned professional development programs to support implementation (Clarke, 1994). Large-scale research efforts in education often utilize teacher training as part of the intervention in order to effect change in student outcomes. *Classroom Connectivity in Promoting Mathematics and Science Achievement* (CCMS)[1] is a national research study examining the impact of classroom communication technology on student achievement, dispositions toward mathematics and science, and self-regulated learning. The intervention for this project consists of professional development to support algebra 1 and physical science teachers' implementation of a modern classroom connectivity technology, the TI-Navigator™ that allows classroom teachers to wirelessly communicate with their students' handheld devices. The research design is a randomized cross-over field trial in 118 Algebra I classrooms. Cohort 1 teachers attended a summer institute and implemented the intervention in the first year. Cohort 2 was a control group in the first year using graphing calculators and implemented the TI-Navigator™ in the second year of the study. This paper reports the practices and findings related to the professional development (PD) efforts for the mathematics teachers in the CCMS project.

## The Connected Classroom

Connected classrooms in this study were equipped with the TI-Navigator™, a system connecting each student's handheld graphing calculator with the teacher's computer. Four handhelds are wired to a hub. The students and teacher communicate wirelessly via the hubs through an access point connected to the teacher's computer. Using the *Quick Poll* feature, the teacher can pose an individual question, and *LearningCheck*™ is a feature by which several questions can be sent to the calculator. Student responses may include multiple choice, true/false, and open-ended responses. The results can be displayed as bar graphs using a projector. A third feature is *Screen Capture* by which the teacher can take a “snapshot” of all calculator screens. The teacher can hypothesize about and diagnose errors or display a selection of screens to the class to foster class discussion of students’ work. The fourth feature of the system is *Activity Center* in which a coordinate system can be displayed. A typical Activity Center lesson might include the teacher displaying a line with the assignment, “match my line.” Similarly, the teacher can ask students to send the equation of a line through a given point parallel to or perpendicular to a line entered by the teacher. Finally, the teacher can aggregate data collected by students, display it on the screen, and send the lists to students to analyze. Activity Center is typically used to develop conceptual knowledge. Quick Poll and Learning Check are typically used as tools for formative assessment. Screen Capture may be used for either of these purposes. The teacher has immediate information that may lead to adjustment of instruction. Using any feature, the teacher can engage the class in discussion diagnosing incorrect responses that can be displayed anonymously. As aggregate class results are shown to the class, students receive immediate feedback in a private non-threatening way that can encourage them to reflect and discuss their understanding or methods of solution in small groups and with the class as a whole (Roschelle, Penuel, & Abrahamson, 2004).

## Perspectives on Professional Development

Various models of professional development are described in the literature (Guskey & Huberman, 1995; Loucks-Horsley, Love, Stiles, Mundry & Hewson, 2003; Rodriquez & Knuth, 2000; Smith, 2001). Well designed PD programs are teacher-driven (Borko & Putnam, 1995; Little & McLaughlin, 1993) and focused on documented learning needs for students (Fullan, 1993; Howey & Collinson, 1995). Loucks-Horsley et al. (2003) offer a framework for professional development in science and mathematics that includes a commitment to a vision and standards, analysis of student learning, goal setting, planning, execution, and evaluation in the context of classrooms, with consideration of teacher knowledge and beliefs.

Clarke (1994) describes ten important research-based principles of successful professional development: 1. Determine initial teacher interest in the topic of professional development and provide an element of individual choice; 2. Develop collegial working groups within schools with broad community and administrative support; 3. Identify and manage possible classroom, school, and district level barriers; 4. Model actual classroom approaches to help teachers develop better understanding of the change; 5.Request teacher commitment to active and sustained participation in their individual classroom context; 6. Acknowledge the importance of classroom practice on teacher beliefs by encouraging teachers to validate the practices in their own classrooms; 7. Provide time for reflection and opportunities for group discussion and feedback; 8. Allow teachers to develop ownership by encouraging the development of their professional judgment regarding implementation; 9. Acknowledge the slow and incremental process of change and celebrate small successes; 10. Encourage goal setting for continued professional development. The CCMS Summer Institutes aimed to enable expansion of teachers’ professional knowledge base including their pedagogical content knowledge, their subject matter knowledge and their beliefs, experiences and habits (Borko & Putnam, 1995; Eraut, 1995).

### CCMS Professional Development

Given the complexity of teaching with the TI-Navigator, a significant initial professional development program was required. We designed a weeklong summer institute for the summer before a teacher's implementation of the TI-Navigator. Given what we know about the need for regular continuing professional development (Loucks-Horsley et al., 2003), the teacher participants meet one day before subsequent Teachers Teaching with Technology ($T^3$) International Conferences for targeted CCMS professional development and attended the three day conference. Web-based follow-up training tutorials on graphing calculators and TI-Navigator were available on the $T^3$ website, and a project listserv was made available to the participants as an opportunity for questions and discussion.

In technology-laden training, an unwarranted focus on the technical aspect of making the technology work is appealing. Yet an equal emphasis on the pedagogy of using the technology is extremely important. Important components of the summer institutes included: a) focus on student learning in algebra 1; b) extensive hands-on practice in both 'student' and 'teacher' roles; c) curriculum-specific applications; d) the pedagogy of the connected classroom, especially self-regulated learning and formative assessment; e) experienced teacher-instructors who use the technology in their own secondary mathematics classrooms; and f) differentiation and practice based on the teacher's technology ability level. Discussions about pedagogy for using the technology were built into the workshops in a practical, hands-on manner. The goal was to teach theory through real-life examples of classroom activities. Often these were introduced spontaneously as the participants played the part of students for the workshop instructor's "expert teacher," as s/he illustrated how to use features of the connected classroom system. In this way, the context became sensitive to specific classroom needs of the participating educators (Pink & Hyde, 1992).

The model used for the Summer Institute was based on lessons learned in the $T^3$ PD program founded at The Ohio State University in 1988 (with NSF support) that closely parallels the Clarke (1994) principles stated above. The $T^3$ trained instructors were secondary school teachers who had used the technology in their mathematics classrooms and modeled the methods from their classroom experience. In addition to the three primary $T^3$ instructors who assumed responsibility for the PD planning and delivery, three other $T^3$ instructors who were also classroom teachers provided support during practice sessions. This enabled the differentiation of practice sessions based on technology ability levels. Following the $T^3$ model, we held daily debriefing sessions so that adjustments could be made for the next day. Mathematics content for the institute was from typical Algebra 1 curricula. Activities included in the institute were technology-focused, hands-on instruction and practice in "student" and "teacher" roles. Participant products for the week were lesson projects and presentations.

Finally, faculty lectures infused theoretical and pedagogical focus on productive classroom discourse, formative assessment (FA), student self-regulated learning strategies and the teacher's role in supporting self-regulation, and learning environments from *How People Learn* (HPL) (National Research Council, (NRC), 1999). Self-regulated learning (SRL) is consistent with mathematics education reform. For example, in *Adding It Up*, Kilpatrick, Swafford and Findell (2001) call for strategic competence, adaptive reasoning, and conceptual understanding as well as procedural fluency as components of mathematical competence. Among contexts that support SRL are multiple representations and rich mathematical tasks, classroom discourse, environmental (classroom) scaffolding of strategic behavior, an evaluation system that emphasizes feedback, and self and peer evaluation (Pape, Bell & Yetkin, 2003). Among the components of contexts that support SRL are teacher's higher order questions, teacher press for student involvement, teacher press for elaboration, explanations and justifications, soliciting multiple answers or solution methods, mastery orientation, and scaffolding and social support (high expectations, respect, and inclusion of all students in the learning process) for student achievement (De Corte, Verschaffel, & Eynde, 2000; Pape, 2005).

Another component of faculty lectures was HPL "centerednesses" for the design of learning environments. *Learner-centered* environments "pay careful attention to the knowledge, skills, attitudes and beliefs that learners bring to the educational setting" (NRC, 1999, p. 133). These environments are termed "culturally relevant," or "culturally responsive," and include "diagnostic teaching." "*Knowledge-centered* environments take seriously the need to help students to become knowledgeable" (p. 136). They "focus on the kinds of information and activities that help students develop an understanding" (p. 136) of the algebra content. *Assessment-centered* environments "provide opportunities for feedback and revision and what is assessed must be congruent with one's learning goals" (pp. 139-140). Included are formative assessments and appropriate summative assessments. *Community-centered* environments include "the classroom as a community, the school as a community, the degree to which students, teachers and administrators feel connected to the larger community" (pp. 144-145). Using a TI-Navigator with pedagogically sound techniques has the potential to support a learning environment with these centeredness characteristics.

The last component of faculty lectures was formative assessment. Cowie and Bell (1999) define formative assessment as "the process teachers and students use to recognize and respond to students' learning and enhance it *before it is complete.*" In addition to the timeliness of the formative assessment process, Black and Wiliam (1998) direct attention to the "*teacher use* of assessment information to modify and improve their teaching effectiveness." In an analysis of more than 40 studies, high quality formative assessment was linked to significant learning gains (Black, Harrison, Lee, Marshall & Wiliam, 2003). Black et al. identified enhanced feedback loops, active student participation, teacher modification of instruction based on knowledge of student learning, and increased motivation and engagement as important characteristics of successful formative assessment studies.

## Participants and Data Collection

The Institute was designed to last one week. For Cohort 1 in the first summer, 30 participants attended the first week, and 30 participants attended the second week. Out of 60 total teachers, 42 were female (70%) and 18 were male (30%). For Cohort 2 in the second summer, 27 mathematics teachers participated in week 1 and 20 attended week 2. Of the 47 teachers in the second summer, 35 were females (74%) and 12 were males (26%). Each day of the Summer Institute was videotaped to document the progress of the PD. In addition, participants completed an Institute Evaluation Survey in the afternoon of the last day of the Institute.

## Evidence of PD Instruction

The videotapes from the Institute provide evidence of teacher-instructors incorporating pedagogical issues into their instruction. In the segment below, one of the instructors described insisting on student explanations and justifications. He then described how to use Quick Poll for teacher error analysis during or after class.

Instructor 1 (I 1 discussing the Screen Capture feature): Before I show it to the class, I could group all the 'good' wrong answers to the top. I could ask, "How did someone get such and such. I could have kids defend. Why is 3 the correct answer? Have them tell why do you think it is. Why is it not? Having kids starting to talk mathematics . . . I can take a picture of the entire record. When I have a question and I want to know who is really with me on this topic, . . . I can capture this entire [class] snapshot to look at later during my conference period. Also, in addition to [surveillance], saving a [Screen Capture] picture is crucial for us deciding which kids need remediation, which kids need intervention, who do I need to focus on, all this educational stuff we have to be concerned about. We can save it to look back at later. In the heat of the battle of the classroom we might not be able to address every single misconception. [July 31, 2006; year 2, day 1]

On another day the teacher-instructor reinforced pedagogical strategies of speaking mathematically in class discussion, classroom discourse, and engagement.

Participant 1 (P 1): We have to reset our window.

I 1: Ahh – This is a great discussion because I would hope the kids would say our window [on the calculator] is not right now. What do we need to change our window to?

P 1: Something above 84.

I 1: So we have students in the calculator change the window to something above 84. Now we have a discussion. I want to pause for a second. Why do you think it might be more powerful to have every student look at this graph versus the teacher standing up here just graphing "watch."

P 2: Ask them what they thought.

P 3: And you could do a Quick Poll of what they thought.

P 4: That way you would have everybody engaged.

I 1: You said the magic word, engaged! They are taking active participation in the activity. . .

I 1: (summarizing a few seconds later) Obviously we are talking about discourse, and this is great discussion. In the Navigator world this is what should be going on in your classroom. It is different from the days when the teacher lectures and the kids sit there . . . and write stuff down. . . . So we get engagement. [August 2, 2006; Year 2; Day 3; PM]

In the brief episode below, one instructor emphasized the importance of planning good pedagogy, speaking mathematically in classroom discourse, and student error analysis and revising incorrect answers. In discussion a participant turns the topic by asking about indicating the correct answer for a Quick Poll. Another instructor discussed the potential for increased argumentation if the correct answer is not indicated.

I 2: When it comes to your presentations on Friday, keep everything in mind. You should use all of this technology in a pedagogically sound way. [I 2 asks a question followed by a brief participant response; I 2 continued:] That's the discourse; when we get to the point where we can talk about mathematics and talk about error analysis and get kids to revise their incorrect thinking and get their incorrect thinking to be correct. I use a little trick: I say give me a good case for why we choose 'false;' or make a good case for choice 'c.'

P 5: If they saw the correct answer [bar] in green, there would be no discussion. If you set the system so the correct answer is not indicated we can go back later to see the correct answer.

I 3: Certainly there is tremendous discussion without knowing the correct answer, because the kids argue more vehemently. Sometimes, I seed my questions so the obvious [apparent] answer is the wrong one. [August 1, 2006; Year 2; Day 2; PM]

**Institute Evaluation Survey Results**

The Institute Evaluation Survey was administered at the end of each summer institute (see Table 1). Overall, participants rated the Summer Institute very highly on a Likert-type scale with means on appropriateness of content of 4.5 and 4.8. Participant's perceived usefulness of the pedagogy and their self-confidence in using the TI-Navigator exhibited means of 4.1.

Table 1. *Institute Evaluation Survey Results*

| Construct | Cohort 1 (N=60) | | Cohort 2 (N=47) | |
|---|---|---|---|---|
| | *Mean** | *SD* | *Mean* | *SD* |
| Appropriateness of institute content (5 items; see Table 2) | 4.54 | *.70* | 4.76 | *.54* |
| Perceived pedagogical usefulness (8 items; see Table 3) | 4.10 | *.85* | 4.08 | *.81* |
| Perceived self-confidence in components (15 items) | 4.09 | *1.18* | 4.10 | *1.02* |

*Note: 1 – strongly disagree; 5 – strongly agree

Table 2 presents participant responses to specific items about the appropriateness of institute contents. Appropriateness included materials and discussions about pedagogy. These resulted in the indicated levels of comfort and confidence that they can teach with the TI-Navigator. Across the two cohorts, the percents of participants who agreed or strongly agreed ranged from 87% to and impressive 98%.

Table 2. *Participant Responses about Appropriateness of Institute Contents*

| Statement: single item | Cohort 1 % somewhat agree or strongly agree | Cohort 2 % somewhat agree or strongly agree. |
|---|---|---|
| The content of this institute was at the appropriate level | 90 | 93 |
| The institute materials were useful and helped me learn how to teach more effectively with the TI-Navigator | 98 | 98 |
| The institute helped make me feel more comfortable about using this TI-Navigator technology in my classroom | 95 | 98 |
| The discussions about how and why to teach with the TI-Navigator (i.e. pedagogy) were valuable to my everyday teaching | 87 | 98 |
| As a result of this institute. I will be able to use TI-Navigator technology in my teaching | 98 | 98 |

Table 3 presents participants rating of their learning of various specific pedagogical issues. The statement in the item stem reads: “As a result of this institute, I have a better understanding of the following pedagogies.” In Cohort 1, 77% to 90% agreed that the institute had helped their understanding. In Cohort 2, 74% to 89% agreed that the institute had improved their understanding of various pedagogical issues.

Participants were asked to respond to the components with the item stem: As a result of this institute, “I have a better understanding of the following TI-Navigator components.” Regarding the primary component uses: Create a class, Quick Poll, LearningCheck, Screen Capture, student inquiry/data aggregation, Activity Center, Class Analysis, send lists applications and programs. Participants agreement (combining somewhat agree and agree strongly) over the two summers ranged from 87% to 100%. On other facilities: network manager, sending internet data to the class, percent of agreement ranged from 22% to 48%, and collecting files was 83% and 89% agreement for cohorts 1 and 2, respectively.

Table 3. *Participant Ratings of their Improved Understanding of Specific Pedagogies*

| As a results of this institute, I have a better understanding of the following pedagogies: | Cohort 1 % somewhat agree or strongly agree | Cohort 2 % somewhat agree or strongly agree |
|---|---|---|
| Classroom discourse to reveal student strategies | 83 | 89 |
| Formative assessment | 74 | 68 |
| Strategies to support developing self-regulated learning | 83 | 77 |
| Questioning strategies | 77 | 83 |
| Critical junctures when I might use the TI Navigator | 82 | 96 |
| Classroom norms that foster understanding and development of strategic behavior | 77 | 80 |
| Mathematical explanations and justifications | 85 | 74 |
| Uptake of correct and incorrect student responses | 90 | 89 |

## Conclusion

A professional development program patterned after the $T^3$ model was designed for the national field trial research study of implementation of the TI-Navigator in Algebra 1 classrooms. An important component of the professional development was teacher-instructors modeling their use of TI-Navigator based on their classroom teaching experience. The teacher-instructor roles were supplemented with faculty lectures on applying theory to classrooms. Additional professional development activities were designed to implement the principle of ongoing PD. Participants met for CCMS specific learning one day per year and attended the $T^3$ International Conference. Additional online training and a listserve for participant communication were made available.

The summer institutes were evaluated highly. Participating teachers generally agreed that they had learned facility with the TI-Navigator, pedagogical issues and that the institute activities were appropriate. Future work will undertake an evaluation of annual daylong PD activities and use of the project listserv.

## End Note

# REFRAMING FAILURE: HIGH SCHOOL MATHEMATICS TEACHERS' LEARNING ABOUT STRUGGLING STUDENTS THROUGH PARTICIPATION IN WORKPLACE COMMUNITIES

Nicole A. Bannister
University of Washington
nbannis@u.washington.edu

*This paper examines teachers' developing understanding of student failure in freshman mathematics classes. The question organizing my inquiry was: How do high school mathematics teachers who are engaged in equity-oriented reforms learn about struggling students in their workplace communities? I found that teachers' conversations shifted away from personal reflections and moved toward understanding the classroom systems that contribute to student failure. Teachers' learning was signaled by changes in their framing of student failure. By joining concepts of frame analysis and learning in a community of practice, this study contributes conceptual tools for understanding teachers' learning at the level of mechanism.*

Teachers' ideas about student ability directly shapes the culture of learning in their classrooms. If teachers believe that student ability is fixed, then there is little they can do about students' learning difficulties. If, on the other hand, teachers have a more developmental view, believing that ability is dynamic, they are more likely to adapt their practice and send students messages that encourage persistence in the face of difficulties (Weinstein, 2004). Yet teachers vary in the extent to which they adapt their practice to the diverse learners they encounter (Stodolsky & Grossman, 2000). When faced with underprepared students, teachers often feel a tension between upholding subject matter standards and meeting learners where they are (Horn, 2007). Teachers' conceptions of struggling students are thus important sites for their reconceptualization of student ability. Research suggests that teachers' participation in a strong teacher community has the greatest potential for yielding the kinds of teacher learning that produces equitable student outcomes, though what that learning is or how it might be taking place is largely unaccounted for in the literature (Gutiérrez, 1996; Horn, 2005; Little, 2003; McLaughlin & Talbert, 2001). As such, the overarching research question organizing my inquiry was *how do high school mathematics teachers who are engaged in equity-oriented reforms learn about struggling students in their workplace communities?*

## Rationale

My study targets high school mathematics because mathematics consistently plays a gatekeeper role for students (Moses, 2001; NRC, 1989; Schoenfeld, 2002): "More than any other subject, mathematics filters students out of programs leading to scientific and professional careers […] Mathematics is the worst curricular villain in driving students to failure in school" (NRC, 1989, p. 7). What is most disturbing is the fact that a disproportionate number of poor and minority students compose this group, a disparity that is quantified in the "achievement gap" that plagues our nation. By targeting high school mathematics, I situate my study in the context of a critical gateway/gatekeeping subject.

I focus my study on teachers engaged in equity-oriented reforms for two reasons. First, in keeping with the prior reasoning, a specific portrait of teacher learning about equity-oriented reforms concerning struggling students can directly speak to single-system attempts to change disparities in student achievement by educators. To achieve this goal, I selected a group of teachers who not only chose to engage in equity-oriented reforms but who also had some success with their efforts to improve equitable outcomes. This particular group is made more exceptional as a case of teacher community because it was designed for optimizing teachers' learning (e.g., attending to issues of equity through conversations about curriculum and pedagogy became a part of teachers' daily work) and had considerable external support by our research team. Second, there is presumably a greater impetus for teachers engaged in equity-oriented reforms to question their assumptions and practices, rendering their learning about students, teaching, and subject matter more visible. I make this assumption because a major goal of equity-geared reforms is providing all students with rich opportunities for making sense of essential mathematics ideas. It follows that the conditions surrounding teachers' enactments of reform, such as instruction and classroom culture, must also align with this goal in order to yield equitable outcomes. As such, my focus on teachers who are collectively engaged in equity-oriented reforms is a strategic choice for increasing observable instances of teachers' sensemaking on struggling students.

## Theoretical Framework

*Teachers' Learning in a Community of Practice*

Teachers' participation in their professional communities is a social endeavor. This activity catalyzes a dual process of participation and reification, which is the fundamental process through which learning happens (Wenger, 1998). This learning-as-a-social-phenomenon stance influences my more general conception of teacher community, meaning that the communities do not necessarily have a certain level of functioning, improvement-oriented stance, or meet some other criterion. In other words, these teacher communities are "neither intrinsically beneficial nor intrinsically harmful. Rather, they constitute the *places* in which organizational and individual learning unfolds" (Coburn & Stein, 2006, p. 28, emphasis in original). As such, by adopting a *community of practice* perspective – which Wenger (1998) characterizes as communities where members are mutually engaged in an activity, held together by a joint enterprise, and have a shared repertoire of customs for praxis – I identify *learning* as change in participation within that community. This definition of learning recognizes the co-construction and distribution of knowledge across teachers and takes the wider social context into consideration (Kelly, 2006). Individuals' learning can be conceptualized as movement from legitimate peripheral participation by newcomers to fuller forms of participation by old-timers: "As they progress they acquire the skills, the identity, and the ways of acting and interacting valued by the community" (Coburn & Stein, p. 44; see also Kelly, 2006; Lave & Wenger, 1991; Wenger, 1998).

This theoretical framing is critical for this paper because it places my study of an equity-oriented teacher community in a broader community of practice landscape, which means that the community in my study is not privileged for its equity orientation. In other words, when looking *across* teacher communities, an equity-oriented community is not more or less of a community *as an entity* than another teacher community; when looking *within* the teacher community itself, the community's equity-orientation does not lock it into one state of being (i.e., "strong learning" or "mature"). More importantly, such a framing allows for an equity-oriented description with the understanding that such a description is not necessarily unitary or consistent. Rather, a community of practice framing helps me see such communities for what they are: key sites for negotiation of the meaning of equity-oriented reifications about students, (Coburn & Stein, 2006), which makes observable instances of teachers' learning around these issues more likely (Kelly, 2006). To be clear, this means that it is possible for the community in my study to look like a developmentally mature, strong teacher learning community in one instance, and then perhaps an evolving weak community in the next instance (Grossman, Wineburg, & Woolworth, 2001; McLaughlin & Talbert, 2001); I will need to look well beyond the labels – including equity-oriented – to make sense of teachers' learning through interactions in their workplace communities. This framing provides a value-neutral basis for my analysis of teachers' learning because it allows for the nonlinear, dynamic, zigzag nature of teachers' learning about students, teaching, and subject matter through interactions in their workplace communities.

*Frame Analysis as a Means for Capturing Learning*

My study aims to understand teachers' learning about struggling students in a community of practice context, and so I need conceptual tools that will help capture learning as changes in participation within teachers' interactions – changes that may be subtle, ambiguous, and most certainly complex. I turn to theoretical and empirical work on frame analysis for ways of making sense of this interactive learning process as it unfolds (Benford & Snow, 1986; Goffman, 1974; Snow, Rochford Jr., Worden, & Benford, 1986). Frame analysts look at the interactive process by which frameworks are created in social interactions, and focus on "how people use interpretive frames strategically to shape others' meaning-making processes in an effort to mobilize them to take action" (Coburn, 2006, p. 347). I take framing interactions to be evidence of learning because these processes – processes such as framing (e.g., prognostic, diagnostic, and motivational), reframing, offering counterframes, aligning to frames, and frame amplification (Benford & Snow, 1986; Snow et al., 1986) – mark and describe changes in participation in a community of practice. As such, examining the ways teachers engage in framing interactions in relation to struggling students stands to result in more manageable units of teacher interactions for the analysis of their learning (Evans, 2002; Russell & Munby, 1991).

## Methods

This research takes place in the context of a larger project, *Adaptive Professional Development for High School Mathematics Teachers* (Ilana Horn, Principal Investigator), a design-experiment project situated in part at Septima Clark High School (all names are pseudonyms), a diverse, large, urban comprehensive high school in a large northwestern school district in the US. Our research team worked with the Clark mathematics teachers using a mutual appropriation approach – that is, we collaborated with the teachers to create activities that fit theoretical principles about equitable mathematics teaching while serving the teachers' goals (Cole, 2006). Our precepts included pedagogical principles about equitable mathematics teaching, such as the use of pedagogical strategies to engage learners in important mathematical ideas (Boaler, 2002, 2006; Horn, 2006; Moses, 2001). In addition, we used learning principles for teachers, such as prioritizing providing teachers with collaborative time in the school day to make sense of new practices in their classrooms (Horn, 2005, 2007; Horn & Little, under review; Little & Horn, 2007). For this paper, I examine teachers' learning about struggling students in context of their interactions during this collaborative time.

During the 2004-2005 school year, I followed the interactions of the mathematics department at Clark in my role as a research assistant on the project. I observed classrooms, attended department meetings, and provided classroom support to teachers. One teacher in particular, Susan, struggled with issues related to students, teaching, and mathematics. She asked for my help, and so I provided her with additional classroom-based support several days per week, such as co-planning instruction, doing mathematics, modeling teaching, making sense of student work, and interpreting student interactions. However, even with my classroom-based support Susan still faced a crisis: over 75% of her freshmen students were failing her first-year mathematics course. This crisis caused the other teachers of first-year mathematics to examine their pass rates, and the results were stunning: more than 50% of students taking the first year ($9^{th}$ grade) mathematics course at Clark were failing. The Clark teachers were in a panic over this crisis and asked our research team to help them make changes to their existing curriculum and pedagogy with the aim of improving all the success of all students.

Realizing the ambitious nature of the Clark teachers' plans for implementing starkly different pedagogical and curricular equity-oriented reforms, our team designed an intervention for the 2005-2006 school year to support their reforms. We created the "Freshman Team" intervention by providing the four teachers of first year mathematics with an extra planning period (in addition to their personal planning period) so that they would have dedicated time during the school day to collaborate around issues of teaching and curriculum. We also helped Clark find a new teacher trained in equity-geared teaching practices who could take on the "missing" four first year classes, in addition to being a part of the collaborative team and having her own personal planning period. We aimed our intervention at freshman mathematics because it is – and was at Clark – in this course where students are historically most likely drop out of high school mathematics, a group disproportionately represented by poor and minority students. Clark's principal supported this intervention by crafting the master schedule so that all five team members had a common overlapping planning period. The Freshman Team met during every sixth period, and was composed of five teachers: Susan, Zack, Rose, Julie, and Linda.

Through active participant observation, I collected a variety of qualitative data about the teachers' work, including audio records and fieldnotes of the Freshman Team's weekly meetings, artifacts of classroom practice, records of professional development activities, and teacher interviews. In addition, I have the "headnotes" I collected through my experiences working at Clark that allow me to build connections between events and have a deeper knowledge of the place and participants (Emerson, Fretz, & Shaw, 1995). I crafted a case study around the Freshman Team at Clark because this method will help me concentrate my investigation and analysis on the complexities and particulars of teachers' learning around about struggling students in context of equity-oriented reforms (Merriam, 1998). By conducting an in-depth analysis of the Freshman Team teachers' learning around issues of struggling students I am able to use the case of Clark to theorize about teacher learning inside of a community of practice more generally, which responds to a need for case studies of this nature (NAE, 2008).

*Data Analysis Procedures*

I began my analysis by content logging all of the recorded Freshman Team meetings in chronological order. Then, I systematically examined the content log and timeline resources with my unit of analysis: the *episodes of pedagogical reasoning* (EPRs) (Horn, 2005) that are related to struggling students. Horn (2005) defines the EPRs to be

> units of teacher-to-teacher talk where teachers exhibit their reasoning about an issue in their practice. Specifically, EPRs are moments in teachers' interaction where they describe issues in or raise questions about teaching practice that are accompanied by some elaboration of reasons, explanations, or justifications. (p. 215)

My decision-rule for locating EPRs is based on topical shifts that are related to struggling students. Identifying these episodes allowed me to systematically reduce the larger data corpus into smaller portions of Freshman Team meetings that are the most proximal and relevant to teachers' learning about struggling students.

Next, using my theoretical framework, I coded the transcripts from the most proximal and relevant episodes of pedagogical reasoning based on teachers' sensemaking around struggling students, and in particular, noted instances where teachers use interpretive frames strategically to shape others' meaning-making processes and in what way these frames are being used (e.g, prognostic framing versus diagnostic framing, reframing versus counterframing, etc.). Once the data were coded, I looked for themes that helped make a case for teachers' learning (or not) around issues of struggling students. I then generated findings based on my analysis of a strategically reduced data set.

## Results

I examined teachers' learning about struggling students through a close analysis of one conversation that emerged as significant from the larger data analysis process. This conversation took place at the end of the first term (January 2006) after the research team initiated an activity to support an investigation into the reasons for students' failure. On this day, teachers used their two-hour meeting time to go to the counselor's office as a group to review the student history files of their students they identified as struggling students. They did this activity in conjunction with another planned "make-up packet" intervention for their struggling students.

The teachers used the first 90 minutes of this meeting for review of student histories. During this time, Zack privately commented to a member of our research team that he did not understand the value and utility of this review. At the end of this review, Zack, the Team-designated facilitator of this meeting, prompted the group to debrief this activity by asking the following question: "Did you find anything interesting out, and what are you gonna use it for?" Rose responded to Zack's question first, and launched the debriefing with a finding about student transitions:

> I found a lot of transitions for ELL and special ed kids, and that kids are having trouble with these transitions. […] They don't get any support when they transition out, which doesn't make any sense to me. I don't know if there's anything we can do about that, because that seems like the time when the kids need the most support.

Rose's report suggests a call to action around supporting struggling students through important transitions (motivational framing). Julie went next, and reported that she thought that one of her struggling students was just a lazy kid: "my perception is that he's lazy, not getting it, troublemaker." But then she found evidence contradicting her perception in his records:

> You know, he had pretty good grades up until, you know, this year. So I know he can do the math. His test scores show that he can do the math. Or at least he tests well, you know. So, you know, kind of gives me new glasses to look at him through.

Julie demonstrates a change in participation in the community of practice (learning) by her demonstration of a change in her framing of a problem of practice about one of her struggling students. Her view shifted from one that linked a struggling student with laziness (diagnostic framing) to a more multidimensional view that this student is capable of doing mathematics, and by extension, indicates her agency in helping this student reclaim this capability (prognostic framing). What is more, even though it was Linda's turn to reflect when Julie finished speaking this thought, Rose interrupted the sharing out process to say, "Maybe something recent happened with that kid. Maybe that's a good thing to try to find out!" Rose's comment opened the conversation back up on Julie's student (motivational framing and frame amplification), which generated discussion around supporting him and other students like him (prognostic framing).

The debriefing continued in this manner, where each teacher reported and reflected on what she or he found. Zack was the last teacher to report out. I interpreted his reflection as an account that confirmed and amplified what he already knew: struggling students are students who have poor work habits and perform poorly, and always have. Based on his report, I infer that though Zack believes teachers amplify the struggling student problem with practices like social promotion, the main problem is mostly attributed to the ways in which students work in class. As an analyst, I interpreted Zack's report as one that frames the problem of struggling students in a way that primarily locates the problem of student failure with the behaviors of the students (diagnostic framing). Despite Zack's negative outlook on this exercise and his framing of the struggling student problem, Rose responded to Zack's comment by wondering about kids who have been failing for ever and ever and ever. What happened? What do you do? How did they get so behind? They must not understand anything that's going on. This statement oriented and opened up the conversation to an alternative framing of the struggling student problem (reframing using prognostic/motivational framing). Linda aligned with and extended Rose's potential reframing by saying that students "must get just so used to it," which implied that it must be really difficult for struggling students to overcome a history of failure, or to believe that success is possible (frame alignment using motivational framing).

Lisa – the external professional development specialist funded by our project – then made a conversational move that connected this conversation to status ("the first thing that popped into my head is status") and asked, "How much does he believe that he's not capable if he's been being told the same thing over and over and over again?" I interpret Lisa's statement as a move to align with and extend Rose's and Linda's reframing with status (students fail because they get multiple messages that they are not capable), which also served as a contrast Zack's framing of the problem (students perpetually fail because of their work habits). Lisa's comment "finished" the "community" reframing by linking the struggling student problem to status (frame bridging), which further served to engage teachers' agency with this problem.

I claim that Freshman Team aligned with a community-based "status reframing" that was built by Rose, Linda, and Lisa. This reframing locates the problem inside teachers' classrooms, giving the Freshman Team agency over the problem. The data show how teachers' participation in this conversation on sensemaking around struggling students shifted away from Zack's framing that locates the problem inside the student, and moved towards alignment with the community-based framing started by Rose. What is more, teachers' participation in this conversation shifted away from personal reflections, and moved toward understanding the within classroom systems that contribute to student failure. Taken together, I argue that these shifts show changes in teachers' participation in a community of practice (Wenger, 1998). This indicates that the Freshman Team learned through this conversation about the conditions that contribute to student failure and how to better support them. In other words, these teachers' learned about struggling students through participation in their workplace community in a way that led to their reconceptualization of student ability, an important process for adapting their practices and changing the culture of learning in their classrooms (Weinstein, 2004).

## Discussion and Implications

In this paper, I examined teachers' conversations in their workplace communities for the purpose of understanding the nature of teachers' learning about struggling students. I found that teachers' participation in a workplace community conversation brought about alignment toward or away from a developmental framing of student ability. I interpreted these shifts in framing as a marker of teachers' learning about their struggling students. Theoretically, this analysis contributes to our understanding of teachers' learning about struggling students through participation in their workplace communities. By connecting the conceptual tools of frame analysis with analysis of teachers' learning in a community of practice, this study contributes to the development and use of conceptual tools for understanding teachers' learning at the level of mechanism, which responds directly to the need for more literature clearly explaining what teacher learning is within a workplace group or how it might be taking place (Grossman, Wineburg, & Woolworth, 2001; NAE, 2008).

This study also serves to highlight emergent issues that warrant further study, such as the effects of teachers' roles within the workplace community and looking at individual teachers' learning alongside group learning. For example, Rose consistently made conversational moves that pressed the group for deeper understanding and opened up the conversation for alternative framing, such as when she commented about Julie's student ("Maybe something recent happened with that kid"). This comment engaged Julie's agency with that student, which changed the group's sensemaking around Julie's student, thereby helping Julie and the rest of the Freshman Team learn that there is something more that can be done to support that student. I theorize that Rose's participation in the conversation catalyzed a collaborative reframing process that resulted in teachers' learning.

Furthermore, I hypothesize that Zack's ambivalence towards this exercise – an exercise connected to the equity-orientation of the group – and his consistent orientation to diagnostic framing for problems of practice closed off this learning opportunity for him. For example, at the end of the debriefing, Zack remains uncertain about the utility of their shared activity, and makes a comment about struggling students who get "passed along" in spite of their failure. His participation appears relatively constant, which indicates little visible learning around issues of students in this conversation. My hypothesis brings up an emerging analytic issue concerning Zack's learning opportunities alongside an analysis of his learning. In addition, analysis of group dynamics alongside individual learning has not yet been done and will help us better understand the relationships between individual and group learning. Though these emergent issues raise questions that need to be addressed in my future work, this analysis highlights the possible levers for bringing more teachers into a developmental view of student ability.

# EXAMINING THE INFLUENCE OF LEARNER-CENTERED PROFESSIONAL DEVELOPMENT ON ELEMENTARY MATHEMATICS' TEACHERS ENACTED AND ESPOUSED BELIEFS

Drew Polly
University of North Carolina Charlotte
drewpolly@gmail.com

## Background and Literature Review

American students continue to perform poorly on tests of mathematics achievement (National Center for Educational Statistics [NCES], 2000; 2004). Analyses of student scores on large-scale tests have gone beyond identifying student performance shortcomings, and have identified specific factors that influence student achievement. Studies have shown that students' mathematical learning can be positively influenced by allowing students to explore hands-on tasks that focus on students' higher-order thinking skills (Wenglinsky, 1998). Further, students' learning has been linked to specific pedagogies, such as posing questions about students' mathematical thinking (Fennema, Carpenter, Franke, Levi, Jacobs, & Empson, 1996). While these practices echo the recommendations for mathematics education reform (National Council for Teachers of Mathematics [NCTM], 1989, 1991, 2000; RAND, 2003; Schoenfeld, 1992), the enactments of these pedagogies are still rare in today's classrooms.

How do we support teachers' enactment of these pedagogies? A recent synthesis of research about teachers' enactments of mathematics curricula suggests that numerous teacher factors, such as content knowledge, pedagogical content knowledge, beliefs and their interpretation of the curriculum influences how learner-centered activities are enacted in classrooms (Remillard, 2005). Teachers must be given opportunities to develop an understanding about these pedagogies while also participating in experiences that develop each of the teacher factors mentioned above.

*Professional Development's Role in Improving Student Learning*

In the past decade, professional development leaders have presented theoretical perspectives about how teachers learn (Cohen & Ball, 1999; Putnam & Borko, 2000; Richardson, 1996) and recommended principles for effective professional development programs (e.g. Guskey, 2003). These recommendations include:

- focusing on issues related to student learning (Hawley & Valli, 1999);
- allowing teachers to take ownership of their learning (Hawley & Valli, 1999; Loucks-Horsley, Love, Stiles, Mundry, & Hewson 2003);
- addressing specific content and pedagogies (Desimone, Porter, Garet, Yoon, & Birman, 2002);
- providing opportunities for teachers to reflect and learn from their own practice (National Partnership for Educational Accountability in Teaching [NPEAT], 2000a, 2000b; Putnam & Borko, 2000);
- allowing teachers to collaborate with each other and with project staff (Sparks & Hirsch, 2000); and
- providing ongoing and comprehensive activities (Loucks-Horsley et al., 2003; Richardson, 1996).

In essence, these documents call for learner-centered approaches to professional development (NPEAT, 2000a, 2000b).

In mathematics education, promising approaches to learner-centered professional development (LCPD) have been advanced. These programs allowed teachers to focus on student learning by having them watch videos of their own classroom instruction (Sherin & van Es, 2005) examine student work samples (Carpenter, Fennema, & Franke, 1996; Fennema et al., 1996), collaborate with university faculty to develop and implement reform-based curricula into their classroom (Silver, Smith, & Nelson, 1995; Silver & Stein, 1996), and make instructional decisions based on their analysis of student work (Fennema et al., 1996; Schifter & Simon, 1992).

While learner-centered principles have been widely embraced, empirical research is needed to examine how LCPD programs influence teachers' classroom practices and their students' learning. Typically, professional development research includes only teachers' self-report about their perceptions, experiences and intentions to apply their new knowledge and skills in their classroom (Guskey, 2000). While this information is useful, teachers often overstate how they intend to use what they have learned from professional development in their classroom (Buck Institute for Education, 2002). LCPD research must study participants' enactments of pedagogies emphasized during workshops.

## Methodology

Based on the need to examine teachers' enactments of pedagogies emphasized in a professional development project, I conducted a naturalistic study (Patton, 2002). Two research questions guided this research:

1. To what extent (and how) do teachers enact the practices emphasized in a learner-centered professional development during their mathematics teaching?
2. How do teachers' enactments of the practices emphasized during learner-centered professional development compare with their espoused and intended practices?

*Context*

Two teachers participated in this naturalistic, qualitative study (Patton, 2002). Both teachers taught in an urban elementary school located near the downtown area of a major city in the southeastern United States. Seventy-nine percent of students at the school qualified for free or reduced lunch. The participants, along with colleagues from other elementary schools in the district, took part in a professional development program designed to prepare them to integrate learner-centered mathematical tasks and associated pedagogies into their classrooms. During the program, teachers completed mathematical tasks while the project staff modeled learner-centered pedagogies, worked with related technologies, examined cases from the Developing Mathematical Ideas curriculum (Education Development Center, 2006) and discussed how to address the state mathematics standards by having students complete mathematical tasks.

*Participants*

*Shantel.* Shantel, an African-American female, has been teaching the 5$^{th}$ grade for 13 years. During the study, Shantel taught three departmentalized mathematics classes daily: one with students in the Early Intervention Program (EIP) and two with students at grade level (AGL-1 and AGL-2). During her baseline interview, she indicated her intention to use professional development-related practices in order to change her teaching in what she referred to as a "good way" to help her students learn.

*Keisha.* Keisha, an African-American teacher, has completed six years of teaching, including four years as a 4th grade teacher. Keisha finished her specialist degree in Educational Leadership in August, 2005, and described herself during her baseline interview as “a lifelong learner.” In her first year, Keisha did not teach mathematics, so this year was Keisha’s third year of teaching 4th grade mathematics. Keisha frequently characterized herself as a “different” teacher because she used manipulatives, games, songs, videos and other instructional strategies to teach mathematics to her students.

*Data Collection*

Data were collected related to intended (i.e., what they planned to do), enacted (i.e., what they were observed doing), and espoused practices (i.e., what they believed they did). Teachers were observed when they indicated their intent to implement practices consistent with the professional development goals and were interviewed to identify their intended and espoused practices. During each implementation a video camera and a wireless microphone were used to record the classroom activity. Further, I recorded field notes about the students’ work and the teachers’ interactions with the students. I interviewed each teacher after the observations about their intended and espoused practices.

*Analysis*

The Video Analysis Tool (VAT; http://vat.uga.edu) was used to code instances of the six instructional practices emphasized during the professional development (i.e., tasks, questions, algorithms, technology, student communication, and mathematical representations) using a lens that codified the extent to which they implemented the pedagogies. The lens (Figure 1) was constructed based upon scales that were developed during prior research studies (Fennema et al., 1996; Hufferd-Ackles et al., 2004) and was refined after initial pilot testing. Interview data were analyzed using inductive analysis. The instructional practices in the scale were used as primary codes during the analysis of the interviews.

| **Practice** | **The teacher…** |
|---|---|
| Mathematical Tasks | 0- does not provide opportunities for students to work on mathematical tasks<br>1- provides opportunities for students to work on tasks that do not use resources (e.g. manipulatives or technology) and involve completing a procedure given by the teacher<br>2- provides opportunities for students to work on tasks in which students use appropriate resources and follow a procedure given by the teacher<br>3- provides opportunities for students to work on tasks in which students use appropriate materials, choose their own approach and provide a solution |

## Findings and Discussion

Several patterns from the data analysis warrant further discussion: These are discussed in this section.

*Little evidence was found to indicate that participants' enacted practices aligned with the professional development intended practices.* Consistent with prior research studies (e.g. Cognition and Technology Group at Vanderbilt [CTGV], 1997; Doyle, 1988; Henningsen, Stein, & Grover, 1996), a majority of the enacted tasks did not align with the professional development goals. Both teacher-participants implemented didactic tasks that did not include resources or used them for rote procedures rather than to complete the tasks. One explanation for teachers' enactments of low-level tasks might be their desire for their students to have success in mathematics. Previous studies about the enactment of mathematical tasks (Doyle, 1988; Henningsen, Stein, & Grover, 1996; Kim & Stein, 2006; Tarr, Chavez, Reys, & Reys, 2006) found that teachers often provided rote procedures, skills-based practice problems and explicitly told students how to complete the tasks in order to ensure students' success.

*Subsequent implementations were more likely to feature learner-centered tasks and high-level questions.* Professional development researchers examining teacher questioning of students' mathematical thinking reported that teachers needed time to make substantive changes to their teaching practices (Richardson, 1994; Orrill, 2001) and to recognize instances where questioning would be appropriate (Sherin & van Es, 2005). In the present study, both participants asked more high-level questions during their latter enactments. The increase in high-level questions as the study progressed may be evidence of the cumulative impact of ongoing professional development activities. During the workshops, teachers observed high-level questioning strategies modeled by the professional developers, reading and watching teachers' implementation episodes and discussing questioning approaches. It seems likely that initial attempts to apply target strategies were influenced by limited familiarity and few opportunities to practice. Thus, with ongoing workshop and planning support, paired with prior opportunities to apply the methods with their students and emerging familiarity and comfort, teachers were more likely to demonstrate learner-centered practices in their classrooms.

*Participants' espoused practices did not align with the professional development goals.* During this study, teachers' interpretation of the professional development goals rarely matched the actual goals. While teacher-participants' reported that each of their implementations would align with the professional development goals, few were consistent with the project goals. Prior studies reported similar results: researchers observed teachers as they employed didactic instruction, but teachers' indicated they were implementing reform-based mathematics instruction (Peterson, 1990; Wilson, 1990).

*Although scaffolding influenced classroom enactments, didactic components were evident even during highly scaffolded tasks.* Tharp and Gallimore's (1988) application of Vygotsky's Zone of Proximal Development to teacher learning contended that teachers require extensive support and guidance when first learning new pedagogies. This support can be scaffolded and gradually removed when teachers are able to independently enact these new pedagogies. Studies of enacted curriculum (Remillard, 2005; Kim & Stein, 2006) found that teachers were more likely to implement learner-centered curriculum when instructional materials adequately supported instruction. The present study confirmed teachers' need for support; classroom implementations were most closely aligned with the professional development goals on tasks that were scaffolded by the professional developers (i.e., tasks the professional developer modeled or co-planned with the participants).

## Implications for Future Research

*Scaffolding Implementation*

While the scaffolding tended to increase the likelihood of learner-centered task implementation, the teachers did not receive the type of progressive guidance recommended by Tharp and Gallimore (1988). The workshops transitioned from directly adopted, to co-planned to independently planned tasks, but participants varied in the order in which they implemented those tasks in their classrooms. Participants may have been more likely to adopt the professional development practices if their first implementation was directly adopted from workshops and subsequently followed by co-planned lessons and independently planned lessons. Perhaps initial enactments might be more effective if focused on directly adopted tasks modeled during the initial workshops and scaffolded via on-site support. Research is needed to examine the benefits and tradeoffs involved in explicitly imposing and scaffolding tasks developmentally.

*Clarifying Links between the Enactments and Student Learning*

Future studies should examine how evidence of student understanding and measures of student learning, are influenced by the enactment of learner-centered tasks. The progressively scaffolded approach suggested previously may complement this line of research. Implementation of adopted tasks might promote consistent student learning outcomes (e.g., similar types of student-generated mathematical representations, communication about students' mathematical thinking, and representations of mathematical work). As teachers assume increased ownership of the implementations by co-planning and independently planning tasks, and begin personalizing their approaches consistent with learner-centered tenets, student learning outcomes might then demonstrate greater variation. Research that attempts to link the implementation of learner-centered tasks to student learning outcomes must start by examining measures of student learning that are embedded within the tasks themselves.

## Conclusion

This study provides evidence that scaffolding teacher's implementations increases the likelihood of the enactment of learner-centered tasks—especially after teachers gain greater familiarity through professional development workshops and have opportunities to practice the methods with their students. However, even highly scaffolded tasks were sometimes implemented didactically. Due to the inconsistency between teachers' self-report and their observed behaviors, in situ observations are needed to sufficiently examine participants' implementation of professional development practices. Further, professional development researchers must continue to examine the links between teacher learning, teachers' implementations of their new knowledge and skills, and student learning outcomes.

# EXAMINING THE IMPORTANT FEATURES OF LESSON STUDY

Diane Hobenshield Tepylo
University of Toronto
dtepylo@oise.utoronto.ca

Joan Moss
University of Toronto
jmoss@oise.utoronto.ca

*This study examined similarities and differences in the learning of two teachers in the context of Japanese Lesson Study. The goal of this project was twofold: 1. To assess teacher change as a result of participating in Lesson Study: 2 To uncover mechanisms in Lesson Study that support teacher change. Both teachers began the lesson study with comparable mathematical knowledge; both came from the same school, used the same textbooks and faced similar challenges in terms of student learning profiles and attitudes, but only Brenda demonstrated significant changes in her practice. An analysis of the transcribed video data revealed that Brenda spent more time than Francis examining student work from the practice lessons and also appeared to focus more on her students' developing understandings than Francis did. The implications arising from this limited but detailed study are explored.*

## Background

Lesson study is becoming an increasingly popular professional development method for mathematics educators despite a lack of evidence of its effectiveness in a North American context and little research into the processes by which lesson study might lead to improved teacher practices and student learning (Lewis, Perry, & Murata, 2006). In lesson study - a professional development method credited with improved student learning in Japan over the last 50 years - teachers cyclically plan a lesson together, observe the lesson implemented in a real class, scrutinize student learning, and then re-teach an improved lesson (Stigler & Stevenson, 2001). Lewis, Perry & Murata (2006) argue that there is a need for formative evaluation to summarize the essential processes, and to determine the mechanisms by which lesson study can lead to teacher professional development and ultimately to improved student learning.

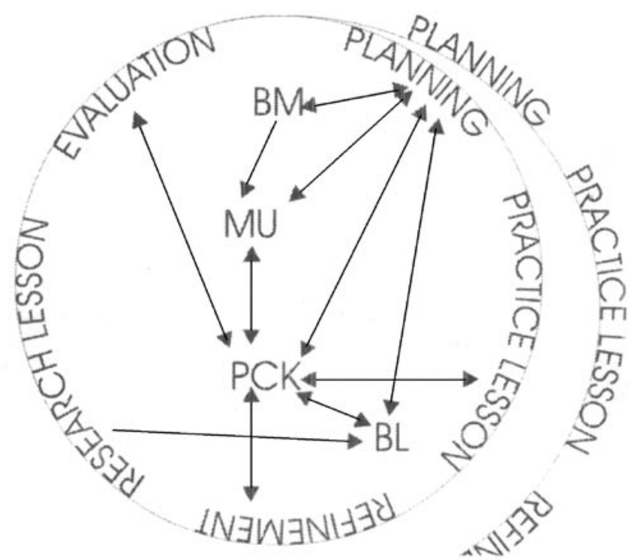

***Figure 1.*** **Theoretical model guiding study.**

This study introduces a methodology for examining lesson study mechanisms and teacher learning outcomes associated with improved student learning in mathematics: teacher beliefs, classroom practices and mathematical knowledge. A literature review suggested a tentative model (see Figure 1) of how these closely-interconnected concepts might interact during lesson study to affect teacher implementation of reform mathematics.

The circle captures the cyclical stages of lesson study, beginning with planning. The spiral arm conveys the potential generative nature of lesson study, building and learning from previous cycles, resulting in gradual improvements in mathematics teaching. Improved mathematics instruction in this research implies changes in teacher beliefs, knowledge, and practices towards those associated with reform mathematics teaching. These changes include teacher's use of authentic learning tasks that promote multiple solutions or strategies, instruction that builds connections between mathematical ideas through classroom discourse, and teaching that adapts to the student understandings (Ross et al., 2002; Sherin, 2002).

In order to make these desired changes in mathematics teaching, research has documented the increased knowledge demands on teachers, both of mathematics and mathematics teaching (Ball et al., 2004). In this research, mathematical understanding (MU) has been defined as the ability to see connections between mathematical concepts and flexibly apply this knowledge to new situations –a synthesis of Woodruff's (2007) flexible understanding and Hill, Schilling, and Ball's (2004) subject knowledge. In contrast, pedagogical content knowledge (PCK) refers to the teacher's ability to choose the most appropriate instructional strategies and representations and ability to anticipate and interpret student's understanding and misunderstandings (Hill et al., 2004). The proposed model suggests planning activities—discussing problematic mathematics topics and considering possible teaching strategies—will affect both mathematical understanding and pedagogical content knowledge.

The model proposes that planning activities affect beliefs about mathematics (BM) and learning (BL); as teachers explore rich mathematical tasks and reflect on teaching strategies to overcome traditional student misconceptions, they need to explicitly examine their beliefs. Changing teacher's beliefs about mathematics and beliefs about learning are considered central to reform teaching. Traditional mathematics instruction implies a belief that mathematics is a static field comprised of set procedures leading to set answers. In contrast, reform mathematics envisions mathematics as a dynamic field emphasizing problem solving continually enhanced through conjecture, exploration, analysis, and proof (Smith, 1996).

The proposed representation also expects that the practice lesson —one of the more unique features of Lesson Study— will build teachers' pedagogical content knowledge as teachers observe student conceptions (and misconceptions) of the activity. Similarly, the model predicts that, as teachers collegially elaborate their comprehension of student understandings and adjust the lesson during the refinement stage, teachers will further develop pedagogical content knowledge. It is anticipated that the focus on student learning during the research lesson will build teacher knowledge of student understandings and reinforce teacher pedagogical content knowledge. As this knowledge increases, it will affect mathematical understandings, beliefs about learning, and all stages of subsequent lesson study cycles. The spiral in the model can also represent the gradual, yet continual enrichment of these conversations.

## Context and Methodology

To evaluate this model, teachers' mathematical understanding (MU) (specifically of fractions), pedagogical content knowledge (PCK) and beliefs about mathematics (BM) and learning (BL) were probed prior to, during and following the lesson study. Before and after the lesson study, the teachers individually solved problems using a talk-aloud protocol and were individually interviewed to assess their knowledge of fractions, mathematics teaching, student understandings, as well as their beliefs about mathematics and learning. Additional data were collected by recording all lesson study sessions and by having teachers complete short reflections on the lesson study process and their own learning.

This present study comes from a larger study of four teachers conducted in a small-town elementary school in the rural school district where the first author works. The school, with approximately 450 students, is a dual-track school in an economically-depressed area, resulting in classes in the regular stream having a high proportion of special needs students. The first author worked with the teachers as a participant researcher, as the group explored lesson study for first time. The group met formally ten times within a five-week period, with many more informal meetings in the hall, the staffroom, and during a shared half-hour commute each day. Two formal meetings occurred during school hours, with coverage provided by administration. The remaining lesson study sessions occurred after school and at lunch. The teachers, eager to demonstrate the lesson study process to their colleagues, arranged a public lesson, attended by two staff from their school, six teachers from other schools, and two special assignment teachers from the board office.

In the larger study, more than 25 hours of interview and session transcripts were read closely in their entirety to identify themes and categories using peer and participant **reviews** to develop validity and manage subjectivity (Bogden & Biklen, 2003; Macmillan & Schuster, 2001). Matrix queries within NVivo 7 (Network Solutions E-Commerce, 2007) investigated relationships among the different stages of lesson study and codes identifying changes in teacher beliefs and knowledge. This paper contrasts the learning of two teachers; Brenda who made significant changes in her practice, and Francis who became more rigid in some of her teaching. Both worked in the same school, teaching grade 5/6 and 6 respectively. Both used the same textbooks and faced similar challenges in terms of student learning profiles and attitudes. Interview and session transcripts were re-examined to identify differences during the lesson study that would explain the variation in teacher change. As tentative hypotheses developed, the video and audio sessions were rechecked in search of discrepant evidence.

## Results

*Pre-Lesson Study Mathematical Understanding (MU)*

Both Francis and Brenda were confident completing their pre-lesson fraction knowledge assessment. Francis answered every question correctly except one, and using a mixture of procedures and intuitive strategies, she moved flexibly between graphical, verbal and formal representations to solve the problems. She used sophisticated counting strategies such as counting by arrays, and quickly caught any calculation or reading mistakes by checking the reasonableness of her answer.

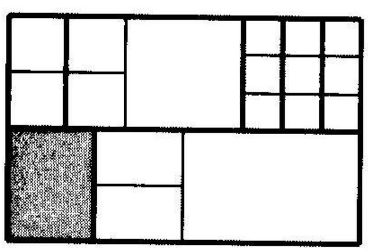

***Figure 2.*** **What fraction is shaded?**

Brenda also answered almost every question, struggling only on the more unusual conceptual-based questions such as determining the shaded fraction of a complex shape such as Figure 2 (where she estimated rather than find the determining the specific fraction). She used arrays to determine fractions of the cookie set and easily converted percents to fractions, hesitating only at 0.33. She immediately recognized it as an important fraction, but needed to use 3/10 as a benchmark to determine it was 1/3. She ordered fractions instinctively, without once using a procedure for finding common denominators.

*Pre- lesson Study Pedagogical Content Knowledge*

To assess the teacher's PCK , the teachers were asked to anticipate how students would answer the fraction items that appeared on the teacher interview. While both teachers were confident in their own ways of solving these questions, neither Francis nor Brenda was able to identify mathematical misconceptions that students might have. Francis could only identify areas where students might have difficulties with the presentation of the material, noting for example her students might ask, “How come this number has two decimals?” where one dot was the period at the end of the sentence. When asked how her students would think about specific questions, Francis initially answered in absolutes—students would or would not be able to answer: “I think that half of my students would know this.” Brenda’s conception of student understanding was limited to whether, in her view, they understood each step of the procedure required to solve the problem.

*Pre-Lesson Study Beliefs about Mathematics and Teaching*

The first author observed one of each teacher’s mathematics classes before the pre-interviews and the lesson study. In Francis’s class, students were observed answering teacher questions in a number sense activity followed by students making up questions for the last answer. Of the 40 minutes observed, 35 minutes focused on the teacher asking closed questions with only one right answer. In her initial interview, Francis reported that three days a week her class worked on new skills. On Wednesdays her class worked on consolidating number facts, and on Fridays the class would work in homogenous groups to solve problems. Francis also noted that her students benefited from, and enjoyed drill and practice activities:

> It’s probably old school but I do believe that practice can make perfect and I think it’s lacking but I don’t think it does them any harm to practice.

Brenda reported that, for the most part, she followed the textbook, supplemented by a skills duotang. During the observed class, Brenda provided a teacher-centered lesson on creating nets, asking closed questions to review terminology, and provided detailed hints for students to create nets. In her interview she noted that she liked traditional math and had difficulty with students explaining their work:

> I’m the type of person that I just liked to do math. I don’t want to explain, I don’t want to talk, so I’m awful;… Every time I’m telling them [to explain their solution], I feel like a hypocrite, because I know I hate it. That’s why I don’t really like teaching math, because I like doing, I like thinking about it.

*Post Lesson Study: Changes in Teachers*

Despite their similarities before the lesson study, Brenda’s and Francis’ teaching practices and thoughts on teaching appeared to diverge significantly by the end of the Lesson Study experience. In post interviews, Brenda reported that that since the Lesson Study she had begun to ask her students questions to probe their understanding, such as “How do you know?” Do you have a different way of explaining that?’ She also reported that she began to value class discussions about student thinking—in sharp contrast to her earlier comments about hating such discussions. In addition, when asked to describe student strategies, Brenda revealed a much more analytical approach than she described prior to participating in the lesson study. For example, in describing a specific lesson involving ordering of fractions, Brenda referred to an example where students had to consider which of two fractions was the greater, 20/15 and 10/4. Brenda noted how some students were able to reason by either drawing pictures or converting to mixed fractions. She also noted that several students reasoned erroneously asserting that 20/15 was bigger because both the nominator and denominator were bigger.

In another example, where students were asked to find equivalent fractions, Brenda described students’ grouping of cookies. When asked whether she thought more students would use the grouping strategy or divide the numerator and denominator by the same term, she initially responded that they would most likely divide—the strategy that she would have used. However, she then reconsidered from the students' perspective:

> I think the dividing strategy. Or would they? They had a hard time going from a lot to less. They had more success paper folding and drawing lines—thinking I am going to group this. I think you have to present it both ways the abstract and the physical.

Brenda summarized changes in her teaching from as moving from search for the perfect resources to a focus on student understanding:

> I am going to think about what they did, or I am going to look at their work. I am just going to read this rather than think of more practice for them, because that's not reaching them. It's okay to sit back and think about, and read about data management or stem and leaf graphs. It's fine if you don't bring something new everyday. It's fine if you just go over where they are coming from.… Not just more practice. Mulling over. What's going on in their brain?… We put away the textbook and just discuss. I've done a lot of that, and I get a lot more out of them.

In contrast, Francis reported much less change in her teaching: during post interviews she seemed at times to be more insistent on traditional mathematics instruction than she had appeared to be prior to the Lesson Study. She insisted on the dominance of rules and the need to practice set procedures. Even though, as part of the Lesson Study, she had been involved in teaching three lessons with the goal of fostering students' conceptual understanding of equivalent fractions, at post interview she asserted that finding common denominators was the only way of adding fractions—this traditional method is no longer even in the grade six curricula. She said that students did not need to explore why rules worked:

> I think a lot of my students had the rule... I don't know that we are so concerned with [the understanding why]. I thought that the lesson was very good for a lot of students to show that they had an understanding of the material. They had an understanding of the rule, of the abstract.

### Accounting for Differences in Teacher Changes: A Focus on Student Work

Given that Francis and Brenda began the lesson study with similar knowledge and beliefs and taught similar students in similar classrooms, what differences in their lesson study participation might explain their different outcomes? An analysis of the transcribed video data revealed that Brenda spent more time than Francis examining student work from the practice lessons. She also appeared to focus more on her students developing understandings than did Francis.

After each lesson study session, the student work was distributed to teachers to examine. The video record showed the other teachers browsing the student samples for five minutes and then proceeding to discuss their notes on the lesson. In contrast, Brenda is visible studying the work even after the discussion begins. For example after the first practice lesson, Brenda examined the student artifacts for 20 minutes, at times appearing to sort the work into categories. When Brenda participated in the discussions she did so by referring to the student work she was trying to analyze. For example, in one point she directed the group's attention to several students' strategies including that of Paul and Adele:

> Paul: He was adding one to the top and four to the bottom [to determine equivalent fractions to ¼]. I was thinking, "Where did that come from?" I would have never thought like that.
>
> Adele: Its not a fraction until you cut it up.

The video of the debrief session for the second lesson shows a similar pattern in regards to Brenda's interest and focus on student work.

In contrast, video analyses show that Francis examined the student work for less than three minutes after each practice lesson but then was the most active participant in the discussion with more than ten turns in each discussion. During the debrief of the first practice lesson, Francis listed the students who "just didn't get it at all" and several times during the lesson study meetings and post interview she reported that it was attention rather than misunderstanding that led to students poor achievement. She described students who did not attend to the class review of a worksheet and noted " It's not that they are totally confused with things but they dismiss so much."

An examination of the lesson study video indicated that Francis differed from Brenda in how she used the materials in her own classrooms, outside of the formal observation lessons. Francis tried some of the problems in her class, and reported to the group the students who could or couldn't solve the question, and the frustration students experienced when the teacher refused to immediately tell them "the" "right" answer.

When probed "What were your students thinking" by the first researcher, Francis detailed the students who wanted detailed procedures, while Brenda responded she had no idea what her students were actually thinking. Francis moved on to other topics, but Brenda persevered. At the next group meeting, Brenda reported that she had covered equivalent fractions in her class for three periods days before she could see what the students did not understand, and before the students could actually do the work. She indicated that "It's so hard when you are there by yourself and trying to observe," but her comments suggest that she had set up a feedback loop within her own class. In these lessons, she analyzed student responses to questions to determine their thinking and how instruction should proceed.

## Conclusion

Lesson study consists of a complex web of activities that have the potential to support professional development. Although limited, this study comparing the changes in two teachers over three months suggests that concentrated examination of student knowledge and their developing understandings is an important mechanism of lesson study. While longitudinal studies of larger groups of teacher are necessary to determine if this focus on student thinking leads to long-term teacher change, this study suggests that teacher knowledge and focus on student conceptions through Lesson Study is a powerful supporter of teacher change.

This central finding of this study has implications for North American teachers undertaking lesson study. While a focus on student understanding is an integral component of the Lesson Study process, North American teachers may not always be amenable to a careful focus on student understanding (Fernandez, Cannon and Chokshi, 2003). In this study only Brenda spontaneously examined student work in detail and this attention was followed by significant changes in her teaching beliefs and practices. The results of this admittedly small study appear to be aligned with the findings of Franke, Carpenter, Levi, & Fennema (2001) where the focus on student understandings is an important element of teacher change.

# DEVELOPING AS MIDDLE GRADES MATHEMATICS TEACHERS: CAREER CHANGERS

Agida Manizade
Radford University
agidam@gmail.com

Elaine Wiegert
Clemson University
ewieger@clemson.edu

*This qualitative study examined the career paths of 12 career changers who completed a field-based Master of Arts in Teaching program to become middle level mathematics teachers. Researchers examined the sources of mathematical knowledge for teaching mathematics as well as the affect on their mathematics teaching of the context in which these teachers learned and used mathematics in their previous careers.*

## Background

The findings presented here are the result of a pilot study for a larger, multi-state longitudinal study that examines the development of career changer mathematics teachers are the middle and high school level. This was a qualitative study of 12 career changers who became middle level mathematics teachers. Teachers were graduates of a Master of Arts in Teaching (MAT) program at a research university in the southeastern portion of the United States. The program had a heavy emphasis on field experience. The purpose of this study two fold. The first goal of the study was to investigate the sources of professional knowledge that career changers use in their teaching of middle level mathematics. In this study researchers sought to describe sources of professional knowledge such as *knowledge for practice, knowledge in practice and knowledge of practice* (Cochran-Smith & Lytle, 1999; Sowder, 2007) necessary for career changers to teach middle level mathematics. The second goal of the study was to determine how these career changers develop their vision of what they need to know to teach middle level mathematics, their mathematical content knowledge for teaching, their understanding about children's thinking about and learning of mathematics, their pedagogical content knowledge, and their sense of self as a mathematics teacher (Sowder, 2007). Data sources included surveys, interviews, classroom observations, and licensure examinations. In this paper, the researchers report the results on the development of the aforementioned types of knowledge and sources of development of such knowledge.

## Theoretical Framework

*Problem Statement*

The teacher shortage in the United States is a two-fold problem. As student enrollment is increasing and teacher attrition rates are also increasing (Ingersoll, 2000, 2007). In its recent report, *Teacher Attrition and Mobility: Results from the 2004-05 Teacher Follow Up Survey* (2007) the National Center for Educational Statistics (NCES) reported that in 2004-05 269,600 teachers left the profession. This number represents 8.4% of the teaching force in that year. In California, it is estimated that approximately 33 1/3% of the teaching force is approaching retirement age and that 25% of teachers leave the profession in their first five years (CFTL, 2001). Ingersoll (2000, 2007) reports that the attrition rate for mathematics and science teachers is not significantly different from that of the all teachers combined. Because of current attrition rates and retirement rates of mathematics teachers at all levels, there have been several attempts to increase the number of teachers entering the profession. These attempts include programs for

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

mid-career changers such as Troops to Teachers, programs for recent college graduates with degrees in content areas such as Teach for America, and programs that provide an alternative route to certification, for example the South Carolina Program for Alternative Certification for Education (PACE) program and the American Board for Certification of Teacher Excellence (ABCTE). The National Science Foundation (NSF) funds programs such as the Noyce Scholarship and Fellowship program to encourage science, technology, engineering, and mathematics (STEM) majors to pursue careers in mathematics and science education. Many universities offer Master of Arts in Teaching (MAT) programs for career changers who are seeking second careers in education. A major goal of these projects is to encourage career changers who have experienced successful careers in occupations in which mathematics was used to seek second careers as mathematics teachers at the middle and high school levels. Researchers report that the inservice and preservice professional development of mathematics teachers is an important aspect in the improvement of mathematics education in public school systems. (Ball & Cohen, 1999; Elmore & Burney, 1999; Nelson & Hammerman, 1996; Sykes, 1999; Thompson & Zeuli, 1999) In this study, we seek to understand how novice teachers develop their mathematical knowledge for teaching in the context of a field-based MAT program designed for career changers who seek certification in middle level mathematics.

*Prior Research*

There has been significant research in the area of teachers' professional mathematical knowledge and its development (Ball & Cohen, 1999; Borasi & Fonzi, 1999; Hill, Ball & Schilling, 2008; Ma, 1999; Simon, 1997; Spillane, 2000; Sowder, 2007). Researchers have defined professional knowledge for teaching mathematics in various ways. For example Ball and Hill (2008) refer to mathematical knowledge for teaching as "the mathematical knowledge that teachers use in the classroom to produce instruction and student growth" (p.374). Spillane (2000) discusses procedural knowledge as well as principled knowledge for teaching mathematics that focuses on the conceptual knowledge that provide a basis for procedural knowledge (p.144). Simon (1997) describes the intersection of eight areas of knowledge for teaching mathematics. The aspects of knowledge for teaching mathematics described by Simon (1997) include knowledge of and about mathematics; knowledge of a meaningful model of mathematics learning; knowledge of the way students develop relevant mathematical concepts; knowledge of a meaningful model of mathematics teaching; knowledge of students' interaction with mathematics; knowledge of goal setting for students; knowledge of what student learning might occur; and knowledge lesson planning that is consistent with one's model for teaching mathematics. Ma (1999) discusses at length the fundamental knowledge of mathematics that is required for teaching elementary mathematics. In the *Mathematical Education and Development of Teachers*, Sowder (2007) synthesizes the research on the professional development of mathematics teachers. In particular, Sowder uses the framework proposed by Cochran-Smith and Lytle (1999) which identifies *knowledge-for-practice, knowledge-in-practice,* and *knowledge-of-practice* to make sense of the body of research on the development of professional knowledge for teaching mathematics. Knowledge – practice is defined as the shared knowledge already know by others such as those that provide teacher education and professional development experiences. Is knowledge is acquired as a result of formal professional development activities (p. 250). Knowledge – in – practice is defined as the particular knowledge of teaching known "as embedded in practice and in teachers' reflections on practice" (p.268). This type of knowledge is acquired when teachers reflect on their own practice. Knowledge – of – practice is the knowledge that teachers develop while practicing their craft in their own classrooms and school sites while investigating the interaction of learning, knowledge and theory.

Several researchers have studied mathematics teachers who have had successful careers in other fields in which mathematical concepts were applied (Adler & Davis, 2006; Ensor, 2001). In particular, Adler and Davis have researched diverse populations of mathematics teachers, career changers in the UK and teachers with insufficient training in South Africa and how their knowledge for teaching mathematics develops. Adler and Davis studied the works of Hill, Ball, & Schilling, (2008). with respect to unpacking mathematical knowledge for teaching mathematics with respect to mathematics courses required for inservice teacher professional knowledge. It was determined that mathematics courses required for inservice teachers in South Africa did not require teachers to unpack knowledge for teaching mathematics, even though this unpacking of mathematical knowledge is required to teach reform mathematics. Of particular interest to this study are the works of Bernstein (1996) and Ensor (2001) have studied the conceptualization of mathematics for teaching. The Bernstein and Ensor studies lead to the questions, what effect does the context in which one learns and applies mathematical concepts have on ones ability to teach middle level mathematics and how do career changer mathematics teachers learn from their professional communities about teaching mathematics

## Research Questions

The participants in this study became mathematics teachers after successful careers in engineering, accounting, retail sales, applied sciences, and the military. Career changers who become mathematics teachers face many challenges. Some of these challenges are similar to those who completed the traditional route to teacher certification others are very different. The researchers are interested in tracking the development of the professional knowledge for teaching mathematics for this unique population of career changers. The research questions for this study are:

1. What are the sources of professional knowledge such as *knowledge for practice, knowledge in practice and knowledge of practice* (Cochran-Smith, M. & Lytle, S., 1999; Sowder, J., 2007) necessary for career changers to teach middle level mathematics?
2. How do career changer mathematics teachers learn what they need to know for teaching mathematics?
3. In what ways do career changers develop:
    a. their vision of what they need to know to teach middle level mathematics:
    b. their mathematical content knowledge for teaching:
    c. their understanding about children's thinking about and learning of mathematics;
    d. their pedagogical content knowledge; and
    e. their sense of self as a mathematics teacher (Sowder, 2007).
4. How do career changer mathematics teachers learn from their professional communities about teaching mathematics?

## Methodology

*Participants*

There were 12 participants in the study. Each of these participants has experienced a successful career in which mathematics concepts were applied on a regular basis. Participant undergraduate degrees included civil engineering, electrical engineering, architectural design, marketing, economics, meteorology, statistics, business management and marketing. As candidates in the MAT program, these teachers were required to complete a minimum of 250 hours in field-based internships in addition to the traditional student teaching experience. The extent of the field experiences required of this program are consistent with Ensor's (2001) recommendation that extensive field experiences are important in the development of best practices in the mathematics classroom.

Participants in the study ranged in age from 22 – 50. Three of the participants in the study were males, the remaining nine participants were female. There was one African American participant in the study. After successful completion of the MAT program, participants had completed a minimum of one year of teaching middle level mathematics.

Participation in the study was voluntary. Participants were recruited from recent graduates of an MAT program. Respondents received no incentives for participation in this study.

*Data Collection*

The researchers collected data through surveys completed by candidates in the MAT program and recent graduates of the MAT program. Video-tapes of the candidates conducting instruction in a simulated classroom, a requirement of the first semester Middle Grades Mathematics Methods course is the second source of data for this study. Another video tape of their teaching was collected during the regular academic year after completion of their teacher-training program. Data was also collected from interviews with participants after they have completed a minimum of one semester of teaching in a middle grades mathematics classroom. Participants Praxis mathematics exam scores were also provided.

*Data Analysis*

The researchers considered participants Praxis scores as indicators of their mathematical content knowledge. To analyze the video lesson plans collected in this study researchers used Instructional Quality Assessment Classroom Observation Tool Rubrics created by Lindsay Clare Matsumura, Helen Garnier, Sharon Cadman Slater, and Melissa Boston. The interviews were transcribed, coded, and analyzed. The researchers noted common themes that immerged from the interview data and survey results. These themes included but were not limited to the following themes: a) teachers vision of what they need to know to teach middle level mathematics; b) their mathematical content knowledge for teaching; c) their understanding about children's thinking about and learning of mathematics; d) their pedagogical content knowledge; e) their sense of self as a mathematics teacher; and f) identified sources of professional knowledge to teaching. With every new theme, the researchers re-evaluated prior interview data and survey results.

## Preliminary Results and Discussion

Preliminary research finding of this pilot study include the following:

1. Based on survey data and interviews, the researchers found that all participants relied heavily on their prior professional training in the field outside of education to bring rich contextual examples into their classrooms.
2. Ninety percent of participants also reported that mathematics methods classes as well as classroom management classes (that they took as part of the teacher training) were most important for their transition into a classroom. They felt that pure "mathematics classes were very helpful". However, teachers wished they "had an opportunity to take more mathematics methods classes." Their sense of self as a "mathematics teacher" versus "mathematics user" continued to develop during these formal classes and as they spend more time in the field.

3. Based on the interview data, several participants who worked in schools with established ‘communities of practice’ were influenced by these communities. These teachers/career changers had significant growth of knowledge-in-practice, and knowledge-of-practice. However, two participants reported that they “stayed away from majority of their teacher fellows in order to avoid constant complaining about students, school, administration, etc….”
4. During the interviews, all teachers reported that they developed foundation of their mathematical content knowledge during formal mathematics classes at the university. They continued working on this content knowledge after graduating from each of the academic programs
5. Based on the preliminary video analysis, career changers vision of what they need to know to teach middle level mathematics changed with time. 90% of participant started their teaching practice with a behaviorist approach to teaching mathematics. They focused on students’ correct answers and attempted to create a “perfect sequence of procedures or steps” for students to remember. Over time teachers focused on their own understanding of children’s thinking about mathematics and their own pedagogical content knowledge. The classroom focus also shifted towards learning environment with opportunities for problem solving.

*Limitations*

One of the main limitations of this study is the fact that the sample for this study was a convenience sample. In addition, one of the researchers was the instructor for the mathematics methods class in which the participants participated during their formal class work for the MAT. Participants in the study were overwhelmingly female Caucasians. The results of the study cannot be generalized because of the small sample size and lack of diversity of the sample. This was a pilot study. The researchers intend to collect additional data through classroom observations after career changers first year of teaching. This classroom observation data analysis was not included in the current report.

*Final Thoughts*

Additional research is needed to better understand the transition STEM majors, career changers experience when becoming middle school mathematics teachers. In this pilot study, we observed and described some of the patterns in such transition. However, we are interested in learning more on how these middle grades teachers contextualize their prior knowledge in their daily teaching practice. We are also interested in knowing in what ways will the analysis of classroom observations (that researchers collected) contribute to the project findings.

# LANGUAGE DEMANDS OF MATHEMATICAL THINKING: AN INVESTIGATION OF THE MATH ACCESS PROJECT

Mary P. Truxaw
University of Connecticut
mary.truxaw@uconn.edu

Megan E. Staples
University of Connecticut
megan.staples@uconn.edu

Randy Ewart
University of Connecticut
statsdude@earthlink.net

*This study investigated the design and impact of a professional development project, Math ACCESS (Academic Content and Communication Equals Student Success) with a unique focus – working with teachers to understand the language demands of student participation in higher order thinking and justification in mathematics classes, particularly related to supporting linguistically diverse students in urban schools. The results demonstrate increases in teachers' content knowledge, perceptions of knowledge and confidence related to supporting students' development of academic language, and awareness of challenges and strategies related to vocabulary and language development for ELLs as well as other students.*

## Objectives and Purposes

In this paper, we document the design and impact of a professional development (PD) project, Math ACCESS (Academic Content and Communication Equals Student Success). This on-going project has a unique focus – working with teachers to understand the language demands of student participation in higher order thinking and justification in mathematics classes. There is evidence that promoting the development of academic language and engaging students in the practices of justification and argumentation support students' learning of mathematics (e.g., Brenner, 1998; National Research Council [NRC], 2001). These practices may be particularly important for supporting lower attaining students (Boaler & Staples, 2008) and the growing population of English language learners (ELLs) (Brenner, 1998; Moschkovich, 2002).

The development of students' academic language is a central function of schooling (Schleppegrell, 2007). A key aspect of this work is to help students move from everyday, informal language toward academic language and use of the mathematics register (Halliday, 1978; Pimm, 1987). This goal is pertinent for all students, but particularly so for students whose first language is not English (Cummins, 2000; Schleppegrell). Too often, attention to language in mathematics classrooms focuses on vocabulary. Language-related instruction should move beyond simple vocabulary; it should include attention to how language is used to express mathematical ideas (functional linguistics) and the development of the mathematics register (Moschkovich, 2002; Pimm; Schleppegrell). Most classrooms, however, do not support such practices. Many teachers remain unaware of the language demands involved in learning mathematics, especially with attention to justification and higher order thinking.

Developing command of academic language is not only a valued end in and of itself, but it also supports students' learning (Halliday, 1978; Pimm, 1987; Schleppegrell, 2007). Language and thinking are intertwined; we use words to think and reflect; when we name something, we can come to understand it in a new way (Vygotsky, 2002). Building on students' everyday language and *bridging* to academic language is a key strategy to develop mathematical proficiency (Echeverria, Vogt, & Short, 2002). Math talk is dense. Phrases like "Given that the sides of the triangle are…" and "For all x…" are not structures used in everyday language. We must help students understand these meanings (Pimm, 1987).

The need for teachers to be knowledgeable of the linguistic demands of learning and doing

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

mathematics is perhaps heightened in urban areas where students are more likely to be linguistically diverse. In particular, intermediate level ELL students who demonstrate *Basic Interpersonal Communication Skills* (BICS), but who have not yet achieved *Cognitive Academic Language Proficiency* (CALP) (Cummins, 2000), are at risk of not being able to access necessary academic language to support justification and higher-order thinking. These students may be socially fluent, yet may need strategic linguistic support for cognitively challenging mathematical tasks (Janzen, 2008). Attention to these areas can help to ensure that students who vary in prior mathematical background, language ability and other characteristics will have more equitable access to math learning opportunities (Cohen & Lotan, 1997).

As noted, teachers often remain unaware of the language demands of doing mathematics beyond a consideration of vocabulary. In a recent review of the literature related to teaching ELLs in content areas, Janzen (2008) emphasized the need for further research on PD that can help teachers to develop "understanding of the relationships among language, content, teaching, and context, and how they can implement that knowledge in their disciplinary fields" (p. 1031).

To provide a sense of the complexities involved, consider an open-ended prompt that asks grade 4 students to find a way to purchase *at least* 40 buns that costs *the least* amount of money, given particular package sizes and prices. The task includes potential for cognitive challenges, but also contextual and linguistic challenges beyond vocabulary. These may include unfamiliarity with "everyday" words and phrases (e.g., package and purchase), as well as other words that are germane to the mathematical work they are expected to engage. For example, phrases such as "*at* least" and "*the* least" may *seem* familiar, but may be misinterpreted or not understood, and lead to very different mathematical work. Students must make sense of what is required of them mathematically and must be able to represent their mathematical thinking and processes in written form—ideally, including justification in the response. The intersection of language, content, and context are complex for students and challenging for teachers to teach.

Given these complexities, it is important to consider how the mathematics education community might expand teachers' pedagogical expertise in these areas. There are examples of PD that have attended to the development of language, though they typically target the teaching of ELLs in *any* content area (e.g., SIOP, Echevarria, Vogt, & Short, 2004). Conversely, there are examples of PD that foreground mathematical justification or higher order thinking (e.g., QUASAR, Silver & Stein, 1996), but that do not include explicit attention to language issues. There are limited examples of projects that attend to both language and cognitively challenging math (e.g, *Project Challenge,* Mitchell, 2007 and the *Center for the Mathematics Education of Latinos/as,* CEMELA, 2009). Given the importance of these areas for student learning, there is a clear need to develop and provide research-based PD for teachers that addresses these issues.

## Context

In response to these needs and issues, we created a conceptual model to guide the development of a professional development program. The model comprises three "pillars": *Academic Language and the Mathematics Register, Student Justification and Collective Building of Arguments,* and *Access by all Students.* Each pillar addresses a core component of instruction that has a strong research base documenting its value for student engagement and learning, and promoting more equitable outcomes. In this paper, we focus on the first pillar, *Academic Language*, and document and discuss relevant activities, outcomes, and issues from our work with a group of teachers during the ACCESS Summer Institute.

The Math ACCESS PD program was supported by the *Teacher Quality Partnership Grant* program from the Connecticut State Department of Higher Education. We partnered with two K-8 public schools, one public high school, and one private high school in an urban district. In this district, 45% of the students speak a language other than English at home, 94% of students qualify for free/reduced lunch, and 96% of the students are categorized as “minority students” (Connecticut Strategic School Profiles, 2008).

Given our goals and the requirements of the grant program, we organized the PD into two main components. The “instruction” comprised a one-week intensive summer institute (40 hours) during July and a half-day (5 hours) session in September. The “follow up” comprised a modified form of lesson study where teachers, organized in grade-band teams, collaborated to develop, implement, and debrief lessons that used pedagogical strategies related to each pillar. Space precludes an in-depth discussion of each pillar and the corresponding activities. We provide an overview and discuss in more depth some of the instructional activities that targeted promoting academic language during the summer institute.

The first pillar, *Academic Language and the Mathematics Register*, focuses on the role of language in mathematics, specifically, developing students’ academic language and their ability to respond to open-ended prompts. Our learning objectives for the teachers focused on helping teachers recognize language-related aspects of math prompts that may be challenging for students and generate and/or purposefully select strategies that support students in managing the language demands. Examples include: expanding students’ math vocabulary, having command of certain phrases (e.g., at least, the least, for each person/for every person), and helping students develop proficiency with explanations and justification. Towards these ends, we developed a range of activities, including: providing background in the Sheltered Instruction Observation Protocol (SIOP) model (Echevarria, Vogt, & Short, 2004); unpacking language demands within curriculum materials, state testing materials, and student work samples; writing language objectives for math lesson plans that focus not only on vocabulary, but also functional language (Schleppegrell, 2007) (e.g., *Students will continue to build an idea of what makes a good explanation by using a language frame: “___ is correct/incorrect because ___.”)*; and modeling explicit attention to language during algebraic and proportional reasoning content instruction.

An example activity that demonstrates the intersection of language, content, and sense-making was designed around the prompt: *Before, tree A was 8’ tall and tree B was 10’ tall. Now, tree A is 14’ tall and tree B is 16’ tall. Which tree grew more?* (Lamon, 2006). Lamon notes that proportional reasoning problems are filled with language challenges because “the same words that we use to discuss whole number relationships, take on different meanings in different situations” (p. 33). In this case, the phrase “grew more” had more than one interpretation, allowing teachers to wrestle with language related to absolute and proportional reasoning.

Activities related to the other two pillars were also critical, as these pillars are mutually supportive. Throughout the Institute we focused on scaffolding, norm setting, appropriately challenging each student, and particular teaching-learning strategies. The teachers analyzed cognitive demands of tasks (Stein, Smith, Henningsen, & Silver, 2000), modified existing tasks to infuse higher order thinking (HOT), discussed and analyzed qualities of good justifications, analyzed student work, and worked in teams to plan and implement HOT lessons.

The following research questions are addressed in this research project:

3. What are the outcomes and effects of the ACCESS professional development activities for participating teachers?
4. What issues arise as teachers work at the intersection of academic language and justification?

This paper focuses primarily on the first research question, with particular attention to the first pillar, *Academic Language*. We are currently engaged in the academic year “follow up” so data collection and analysis are ongoing. Please see Staples and Truxaw (under review) for focus on the second pillar, *Justification,* related to this project.

## Methods of Inquiry

Twenty-four grades 4-9 teachers participated in the ACCESS Summer Institute; 20 teachers continued the program during the academic year. The 20 continuing teachers included 11 teachers who taught the single subject of mathematics and 9 teachers who taught multiple subjects. Teaching experience ranged from 0 years to over 21 years. The first two authors did the majority of the instruction; all authors are supporting school-based follow-up activities.

This study employed a mixed-methods design in order to investigate outcomes and effects of the ACCESS PD. Participants completed two assessments at the beginning and completion of the Summer Institute in order to assess the following: a) the growth of teachers’ content knowledge and b) change in their ability to identify and generate strategies to support the development of students’ academic language, especially among ELLs. Assessments included both content questions and teaching scenarios where situations are analyzed and action is proposed.

Items for the *content knowledge assessment* were drawn from previously validated sources (e.g., CT State Dept. of Education, 2008; Healy & Hoyles, 2000; *Learning Mathematics for Teaching Project*, 2008) and were selected by a team of mathematics educators to fit the content themes of the institute, algebraic and proportional reasoning. The items were field tested for appropriateness and timing by administering them to non-participating elementary and secondary mathematics teachers. Based on these results, the final items were selected. The final instrument included 7 multiple-choice questions and 2 open-ended questions.

The *language assessment* was developed specifically for this investigation in order to uncover participants’ growth related to supporting the development of students’ mathematics academic language, especially with attention to ELLs and higher order thinking. We identified the key constructs of the survey based on the themes of the institute. Following recommendations of Gable and Wolf (2001), content-validity was sought through the use of research literature and experts’ content validation (i.e., mathematics educators, linguistic experts, second language learner specialists, and methodological experts) that noted the adequacy of the items as representative of the specified constructs. The final instrument included 6 open-ended questions related to language use, challenges, and strategies, and 7 Likert-type questions asking for self-reported knowledge of language issues addressed during the PD. The content validity questionnaires and the final instruments are available from authors upon request.

Analysis of the multiple choice and scaled items were performed using standard statistical techniques (Green, Salkind, & Akey, 2000). The open-ended responses were analyzed using standard qualitative methods (Strauss & Corbin, 1990). For example, for questions that asked teachers to identify the linguistic demands of a problem, researchers employed open coding of emergent themes, discussed the themes, and then employed axial coding to make connections among the categories and to refine the coding schemes (Strauss & Corbin). Coding categories and definitions for each question were developed and tested by at least two researchers. Disagreements were resolved in discussion with a third research as needed. Applying these codes allowed us to look for change on both the group level and the individual level.

## Results and Discussion

Results from the pre-post assessments indicate that the Math ACCESS Project did have an impact on teachers' knowledge of content and language-related issues and strateigies. We will describe content results briefly and then focus on the language-related results.

*Evidence of Reaching our Objectives Related to Content*

Twenty-four participants completed the pre- and post- assessments related to content—algebraic and proportional reasoning. The results demonstrate increases in content knowledge overall. Scores of 15 participants (63%) increased; scores of 7 participants (29%) decreased, scores of 2 participants (8%) remained the same. Overall content knowledge showed a statistically significant difference in mean scores ($p < .05$), as shown in Table 1.

Table 1. *Assessment of Content Knowledge of PD Participants, n = 24*

| Administration | Mean | SD | *t* | df | *p* |
|---|---|---|---|---|---|
| Pre | 9.33 | 3.67 | | | |
| Post | 10.63 | 3.63 | 2.24 | 23 | .035 |

*Evidence of Reaching Our Objectives Related to Language*

The analysis of our data indicates that there were (Institute-compatible) observed changes in teachers' proficiencies identifying language-related issues and planning in ways that would promote the development of academic language. A summary of related results follows.

*Teachers' self-assessment of knowledge.* We asked teachers to self-assess their knowledge of various issues by rating themselves on seven 7-point Likert item questions (1= not at all knowledgeable; 7=expert knowledge). For example, they rated their knowledge of *Generating strategies to support students in managing language demands of CAPT and CMT-like open-ended prompts.* Nineteen participants completed all items on the pre- and post-assessments. The overall pre-assessment mean was 4.09; the post-assessment mean was 4.77 (4=moderately knowledgeable; 5=very knowledgeable). A one-sample *t*-test was performed, showing a statistically significant increase in total mean scores for all participants ($p < .05$). Similarly, mean scores for each of the 7 individual items increased from pre- to post-assessment. These data demonstrate a positive and relatively strong impact of the PD with respect to language.

*Open-ended items related to language challenges and strategies.* In addition to the Likert items, the Language Assessment included 3 open-ended questions that provided evidence of change with respect to the teacher's ability to identify challenges related to language and/or strategies to address challenges and support the development of academic language.

*Developing academic vocabulary.* Question 2 asked participants to identify 3-5 general strategies they might use to help students build understanding of mathematical vocabulary. Taken as a group, participants increased the number of strategies they generated to address vocabulary in the classroom and specifically increased the number of *ACCESS related* strategies (i.e., strategies associated with the 3-pillars; e.g., "Think-pair-share activities to build vocabulary," was considered *ACCESS related*; "flashcards," was *not*). Table 2 shows the mean number of strategies per teacher and the percent of those strategies identified as *ACCESS related*. We also include results for single subject teachers as compared with multiple subject teachers as we found some interesting differences among these two groups.

Table 2. *Language Survey Question 3 – Strategies to Address Vocabulary*

| | All n=20 | | Single subject n=9 | | Multiple subject n= 11 | |
|---|---|---|---|---|---|---|
| | Pre | Post | Pre | Post | Pre | Post |
| Mean # strategies per teacher | 3.2 | 3.3 | 2.9 | 3.5 | 3.6 | 3.1 |
| % ACCESS related strategies | 33% | 50% | 16% | 40% | 50% | 72% |

The mean number of strategies per teacher increased for all participants and for the single-subject subgroup; the mean number of strategies per teacher decreased for multiple-subject teachers. However, perhaps more important than the number of strategies (especially since the prompt suggested a specific range of 3 to 5 strategies), was the inclusion of *ACCESS related* strategies. These percentages increased overall, as well as for the two subgroups. Sixty-five percent of the teachers added at least one *ACCESS related* strategy.

*Identifying challenges and strategies in open-ended math prompts.* In question 3, participants were given an open-ended prompt designed for grade 7 or 8 students. Participants were asked to identify words and/or wording that might be challenging for students and then describe why the words would be challenging. Responses were coded for increased detail or specificity if they included additional words or phrases and/or included increased detail in their description of the challenges (e.g., adding the word "explain" [not included in pre-assessment] accompanied by, "Students may need some language support to be able to explain the process they followed to come up with the answer.") The results suggest that, overall, the participants increased detail or specificity related to challenges of language for this specific prompt: 12 participants (60%) showed an increase; 2 participants (10%) showed a decrease; 5 participants (25%) had similar detail and/or specificity, and 1 (5%) had missing data. There were slight differences in results for single-subject versus multiple subject teachers—55% of single subject participants showed increases; 67% of multiple subject participants showed increases.

Question 4 included an open-ended prompt designed for grade 4 students. Participants were asked to identify a) features of the problem that would be challenging to ELLs and b) strategies the teacher could use to help students understand and answer this type of problem. Data were coded for increased specificity and detail, as well as by thematic category. For Question 4a (challenges of the prompt), results were mildly positive: 10 participants (50%) showed an increase, 4 participants (20%) showed a decrease, 5 participants (25%) showed similar level of detail, and 1 participant (5%) had missing data. Most notably, teachers seemed to show increase in responses that included specific words, short phrases, and symbols *and* were accompanied by reasons why they may be challenging (e.g., use of prepositional phrases or relational words). This demonstrated some movement beyond simply identifying vocabulary words.

For question 4b (strategies), results related to increase/decrease of strategies were mixed: 7 participants (35%) showed an increase; 5 participants (25%) showed a decrease; 7 participants (35%) showed equal numbers, and 1 participant (5%) had missing data. While the number of strategies did not show marked increases, the thematic coding revealed some interesting trends. Forty percent of the teachers' increased the explicit mention of language in the strategies they described. Interestingly, the increase in strategies related to language was much higher for single subject teachers (55%) than for multiple subject teachers (22%). To further make sense of the strategies, those coded as specifically mentioning language were subcoded thematically. This coding revealed a decrease in responses involving simple definitions and an increase in responses where the teacher described building meaning about language. This showed a shift toward *ACCESS related* language awareness.

**Implications and Conclusions**

This research reported on PD designed to help teachers understand the language demands of student participation in higher order thinking and justification in mathematics classes—with particular attention to linguistically diverse students in urban schools. Recognizing that it is not a simple matter for teachers to change their practices (Darling-Hammond & Bransford, 2005), combining multiple themes seems ambitious. However, it is this very recognition that PD is too frequently unconnected to complex issues and practices of real schools (Kazemi & Hubbard, 2008) that suggests to us its timeliness.

Although the Math ACCESS project is ongoing, the preliminary results suggest that this model of PD has promise for increasing teachers' knowledge of the language demands of student participation in higher order thinking and justification in mathematics classes. The results demonstrate measurable increases in teachers' content knowledge, perceptions of knowledge and confidence related to supporting students' development of academic language, and awareness of challenges and strategies related to vocabulary and language development for ELLs as well as other students. Thematic analysis demonstrated subtle shifts in perceptions about language use in mathematics classrooms. For example, some of the teachers moved from suggesting rote strategies for learning definitions of math words to providing evidence that they were beginning to grapple with contexts and functions of language (Schleppegrell, 2007); this suggests a shift toward thinking that language is not separate from mathematics, but rather, can be integrally involved with the process of *doing* mathematics.

An additional interesting finding concerned differences in results between single subject teachers (predominantly secondary math) and multiple subject teachers (predominantly elementary). While there were clear group differences in certain results, the differences were inconsistent—that is, for some questions, single subject teachers showed more improvement and for other questions, multiple subject teachers showed more improvement. We conjectured that some of the differences in results may relate to teachers' background experience, expertise, and comfort with content or language. For example, multiple subject teachers were likely to have more extensive backgrounds in language-use, though they may not have considered applications of language to mathematics. Secondary teachers, on the other hand, were likely to have deeper content area expertise, but less experience with language. Questions that have arisen for us include: How do interactions of single subject and multiple subject teachers over the course of the PD impact their perceptions of and competencies with content or language? How do prior knowledge and background influence teachers' openness to ideas? Considering impact of these differences is worthy of further investigation.

As we consider the implications of this research, it is useful to note that these results relate only to the Summer Institute. The project is ongoing, with regular follow-up work in the schools. With this in mind, we look forward to further uncovering important distinctions between "knowledge" and "knowing" (Cook & Brown, 1999; Kazemi & Hubbard, 2008). The results reported here relate predominantly to the teachers' *knowledge* from the PD; as we continue to work with these teachers and document their practice, we will be better able to say how the knowledge translates to *knowing in teaching practice*. This translation from knowledge to knowing in practice has the potential to transform teaching and learning.

# MODELING THE COLLECTIVE INQUIRY PROCESS IN MATHEMATICS TEACHER EDUCATION

Cassondra Brown
San Diego State University
cas_brown97@yahoo.com

Susan Nickerson
San Diego State University
snickers@sunstroke.sdsu.edu

*Starting with the notion that teachers learn as teacher educators model effective mathematics pedagogy, we examined what teacher educators model from the perspective of researcher, teacher educator, and teachers. Using the NCTM Professional Teaching Standards as a starting point of our analysis, we highlight the idea that teachers were not only engaged as learners of mathematics in a classroom community but also as professionals in a community of mathematics teachers. Here we redefine and elaborate on the NCTM Professional Teaching Standards as they apply to mathematics teacher education with respect to teachers' engagement in a community of mathematics teachers.*

## Introduction

The NCTM Professional Standards for Teaching Mathematics (1991) express the vision of teachers who are well prepared to teach mathematics using student-centered instruction. This vision highlights the importance of teachers' ability to select tasks that engage students' intellect and deepen students' understanding, orchestrate mathematical discourse, use technology and tools to pursue mathematical investigations, make connections to previous or developing knowledge, and guide individual, small group and whole class work. As recognized in the mathematics teacher education literature, such a shift in the classroom environment requires changes in the core dimension of mathematics instruction that are not easy to accomplish, may take several years, and require appropriate professional development (Clarke, 1994; Friel & Bright, 1997; Fennema & Nelson, 1997; Loucks-Horsley, Hewson, Love, & Stiles, 1998).

It has been argued that teachers' instructional practices are shaped by their own learning experiences long before entering teaching in what Lortie (1975) calls an "apprenticeship of observation". Thus, a major difficulty for teachers working to transform their teaching practices in accordance with the NCTM Professional Standards for Teaching Mathematics is that many teachers' experiences as learners of mathematics stand in stark contrast. One way to help teachers make this transition is to engage them as learners in inquiry-oriented mathematics communities where student-centered mathematics teaching is modeled.

The results reported here are part of a larger study in which we investigate modeling by teacher educators in teacher education courses for practicing teachers. An analysis of the data revealed that the teachers are not only engaged as learners of mathematics in a classroom community, but also as professionals in a community of mathematics teachers. In this report, we redefine and elaborate on the NCTM Professional Teaching Standards specifically with respect to modeling professional practice by mathematics teacher educators. We illustrate this elaboration with an example.

## Theoretical Perspective

We view learning as situated within practice. We presuppose that novices develop while embedded in a community alongside experts. Such engagement provides learners with multiple opportunities to build a conceptual model of desired practice. With respect to mathematics

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

teacher education this suggests that learning the teaching profession stems, at least in part, from the teaching teachers see and experience as learners and the activity they engage in as professionals. Thus, in mathematics teacher education modeling instructional practices is essential to learning about the practice of teaching since from this perspective the learning of and development of any practice emphasizes the influence of participation, observation and listening in as practice is modeled and mediated by culture and communication.

The constructs of perceptual lived experience, intent participation, apprenticeship and cognitive apprenticeship share a situated perspective on learning from the milieu. They all suggest that knowledge is developed and deployed in activity and is not separable from or ancillary to learning and cognition (Brown, Collins, & Duguid, 1989). In mathematics teacher education, teachers have the opportunity not only to learn mathematics, but also the practice of teaching mathematics from the mathematics instruction they experience as learners. When student centered instruction is modeled, teachers have the opportunity to understand their mature roles as professionals and develop a conceptual model of effective inquiry-oriented teaching.

## Literature

The NCTM Professional Standards for Teaching Mathematics (1991) suggests learning to teach is a process of integration of theory and practice, and teachers should be afforded opportunities to comment and reflect on their own learning and teaching. The current reform movement in mathematics education has a strong underlying theme of the professionalism of teaching. Reform recommendations suggest that teachers ought to collaboratively plan instruction, reflect on practice, create and reflect on new practices, and support one another's professional growth, (NCTM, 1991). This collaborative work of teachers allows teachers to share what they have learned from their experiences as practitioners and then act on what they learn through discussion to enhance their effectiveness as professionals so that students benefit (Astuto, Clark, Read, McGree, & Fernandez, 1993, Hord, 1997). Communication and collaboration such as this among school faculty and staff are important aspects of what researchers call a "professional learning community" or PLC (Dufour & Eaker, 1998; Astuto, Clark, Read, McGree, & Fernandez, 1993, Hord, 1997).

A professional learning community is characterized by a supportive and shared leadership, collective creativity, shared values and vision, supportive conditions and shared personal practice. A major component of the PLC is the collective inquiry process. Dufour and Eaker summarize Ross, Smith, and Roberts' (1994) description of the collective inquiry process:

1. Public reflection–members of the team talk about their assumptions and beliefs and challenge each other gently but relentlessly.
2. Shared meaning–the team arrives at common ground, shared insights.
3. Joint planning–the team designs action steps, an initiative to test their shared insights.
4. Coordinated action–the team carries out the action plan. This action need not be joint action but can be carried out independently by the members of the team. At this point, the team analyzes the results of its actions and repeats the four-step cycle.

For mathematics teachers this includes discussion and reflection about teaching, student learning and the evaluation of both, sharing insights about mathematics teaching and student thinking gained through practice, collaboratively lesson planning and so on. However, engaging in this collaborative process is not automatic. In reform-centered mathematics teacher education the hope is that the teachers are enculturated into a professional learning community of mathematics teachers. In what ways can mathematics teacher educators foster the enculturation of mathematics teachers into the collective inquiry process of a professional learning community of mathematics teachers?

In what follows we report on research conducted in mathematics teacher education courses for practicing teachers. The courses in this study provide teachers the opportunity to deepen their understanding of the mathematics they teach, and engage in activities that are important to the enculturation into collective inquiry process of a professional learning community of mathematics teachers as it is modeled by mathematics teacher educators. In this report we describe our analytical framework and discuss an emergent framework for how mathematics teacher educators model the collective inquiry process and how it parallels the NCTM standards. We further discuss implications for instruction.

**Method**

The mathematics courses for practicing teachers discussed in this report are a part of a university-based professional development group. As with many mathematics professional development programs, the goal is to move teachers forward in their thinking about content and student learning so teachers can work to help increase student achievement in mathematics (Nickerson, 2000; Sowder, 2007). These professional development programs are designed to provide extra preparation for teaching mathematics, not only by communicating pedagogical knowledge, but also by providing opportunities for teachers to deepen their content knowledge by collaboratively reflecting on their teaching and student learning. However, as the focus of this study is on modeling the collective inquiry process the results will focus on the latter.

In this study we observed the mathematics professional development of three cohorts: a primary elementary cohort (grades k-3), an upper elementary cohort (grades 4-6), and a middle school cohort. The classroom data was collected in two consecutive classes for each of the three cohorts. All class sessions were videotaped and a researcher was present at all sessions and took field notes. The videos of the classroom sessions were reviewed to create a descriptive timeline of classroom events to aid in analysis. The teacher educators were interviewed pre and post observation and several participants were interviewed to enable the coding and subsequent creation of an integrated data set of complementary perspectives. Starting with the NCTM teaching standards the classroom sessions coupled with the timeline analyzed in a cyclical process of coding and search for confirming and disconfirming evidence (Strauss & Corbin, 1990) to delineate the categories of modeled instructional acts. Once we developed what we thought to be an exhaustive group of codes, we coded a few episodes separately and compared codes for inter-rater reliability. The coders were in agreement 78% of the time and discussion resolved discrepancies. The primary cause of discrepancies was related to sub-codes of the categories.

## Analytical Framework

The NCTM Standards (1991) advocate a shift in the mathematics classroom environment from an emphasis on mathematics as an individual pursuit that privileges the memorization of algorithms and procedures to an emphasis on mathematics as a collaborative endeavor among members of the classroom community where logical reasoning and argumentation are used to solve problems. In Table 1 following, we provide a brief summary of the NCTM Professional Teaching Standards as they are described by under four headings: tasks, discourse, environment, and analysis.

Table 1. *Brief Summary of NCTM Professional Teaching Standards (1991)*

| | |
|---|---|
| 1) Pose worthwhile mathematical tasks | **Tasks** are the projects, questions, problems, constructions, applications, and exercises in which students engage. They provide the intellectual contexts for students' mathematical development. |
| 2) Orchestrate class discourse<br><br>3) Promote student discourse<br><br>4) Encourage the use of tools to enhance discourse | **Discourse** refers to the ways of representing, thinking, talking, and agreeing and disagreeing that teachers and students use to engage in those tasks. The discourse embeds fundamental values about knowledge and authority. Its nature is reflected in what makes an answer right and what counts as legitimate mathematical activity, argument, and thinking. Teachers, through the ways in which they orchestrate discourse, convey messages about whose knowledge and ways of thinking and knowing are valued, who is considered able to contribute, and who has status in the group. |
| 5) Create a leaning environment that fosters the development of each student's mathematical power | **Environment** represents the setting for learning. It is the unique interplay of intellectual, social, and physical characteristics that shape the ways of knowing and working that are encouraged and expected in the classroom. It is the context in which the tasks and discourse are embedded; it also refers to the use of materials and space. |
| 6) Engage in ongoing analysis of teaching and learning | **Analysis** is the systematic reflection in which teachers engage. It entails the ongoing monitoring of classroom life-how well the tasks, discourse, and environment foster the development of every student's mathematical literacy and power. Through this process, teachers examine relationships between what they and their students are doing and what students are learning |

The NCTM Professional Teaching Standards served as a lens for examining how the mathematics teacher educators' support the teachers' improved participation in a mathematics classroom community of learners. From this emerged parallel categories to describe the mathematics teacher educators' interactions with the teachers modeling the collective inquiry process of mathematics teachers during the class sessions.

**Results**

Starting with the NCTM Professional Teaching Standards as a basis for our analysis, the classroom observations and video were used to redefine the categories of interaction of the mathematics teacher educators with the teachers to shed light on how the teacher educators model the larger practice of the teaching profession. One of the results that emerged was that in the mathematics courses for practicing teachers in this study, the teachers were engaged on two levels, as learners of mathematics in a classroom a community and as professionals in a community of mathematics teachers. In this section we redefine and elaborate on the NCTM Professional Teaching Standards in terms of mathematics teacher education as they are modeled in mathematics courses for practicing teachers with respect to the collective inquiry process of a community of mathematics teachers.

The mathematics teacher educators model the collective inquiry process of a professional learning community of mathematics teachers by engaging teachers in activities that are a part of the practice of teaching mathematics. The activities were often related to evaluating and reflecting on student learning and teaching, lesson planning, and thinking about student thinking, understanding and learning and so on. These activities were mediated by the mathematics teacher educator and provided opportunities for teachers to increase their participation in the collective inquiry process in a community of mathematics teachers. Table 2 characterizes the mathematics teacher educators' instructional acts that have the capacity to foster the enculturation of mathematics teachers into the collective inquiry process.

In this section of the results we will describe a classroom episode from the middle school cohort and discuss the mathematics teacher educators' interactions with teachers as they engaged in an activity that has the capacity to promote teachers' enculturation in the collective inquiry process. Here the teacher educator is Karla, the teachers are the participants in the mathematics teacher education and the term student is reserved for the children that the teachers teach.

The mathematics teacher educator, Karla, began the class by asking the teachers to discuss in their groups the student work that they brought from their own students and choose a few examples that they thought would be interesting to share with the class. The student work the teachers brought was drawn from a predetermined task that all of the teachers in the class tried with their own students, called "try-ons" in this context. This particular try-on was a banquet hall problem that stated as follows:

A banquet hall has a huge supply of various shaped tables (square, trapezoidal and hexagonal). Only one person can sit on each side of a table, except the longest side of the trapezoid table, which can seat two people. The same shape tables must be used for each banquet. The banquet rooms are long and narrow, so the tables can only be put together as shown  , . For a given table shape, develop a rule or formula for the number of people that can be seated at 1 table, 2 tables, 5 tables, 100 tables, or n tables. (Adapted from Burns 1992)

*Figure 1.* Try-on task.

As the groups discussed their students' work, Karla walked about the room, listened in on the groups' conversations and briefly joined the discussions of each group in turn. Much of the discussion in groups focused on trying to understand what the students were thinking, the reasonableness of the students' approach, common approaches the students took, etc. After a few minutes Karla asked the teachers if they need more time to discuss. A show of hands suggested that the teachers needed more time. Karla decided to let them continue their discussions for a few more minutes and continued to listen in and discuss with groups. After a few more minutes Karla brought the class back together so the teachers could discuss the task as a class. Ms. K shared a student's work related to using tables to determine linear relationships. Karla placed the student's work on the document camera and asked Ms. K what she could tell the class about this the work. (See Figure 2.)

Square

| Tables | 1 | 2 | 5 | 100 | n tables |
|---|---|---|---|---|---|
| People | 4 | 6 | 12 | 202 | Add 2 each time |

Trapeziod

| Tables | 1 | 2 | 5 | 100 | n tables |
|---|---|---|---|---|---|
| People | 5 | 8 | 17 | 302 | Add 3 each time |

Hexagon

| Tables | 1 | 2 | 5 | 100 | n tables |
|---|---|---|---|---|---|
| People | 6 | 10 | 22 | 402 | Add 4 each time |

*Figure 2.* Student work shared in the professional development class.

Ms. K explained that the student could determine the number of seats at the banquet by her rule of adding a certain number for each table added, but could not generalize that statement with a formula. Ms. N, a teacher in Ms. K's group, further elaborated on the student's work and explained that the student could reason about the situation additively but had not yet transitioned her thinking about repeated addition as multiplication or make use of variables to further generalize the situation. Karla pointed out that the student is making use of a recursive relationship to solve the task but not the functional relationship.

Ms. N expressed that they chose to share that example of student work because many of their students thought about the task in a similar fashion. They discussed another student's work where the student did use multiplication to do the task but did not generalize the linear relationship with a function and was unsure how to think about n tables. This particular student chose n to be 200 and found the number of seats available if there were 200 tables. Karla stated if we had to order the students in their level of understanding it seems this student seems to exhibit a little less understanding than the one in their last example. Karla noted that the students were from 6th grade and that they might not expect that all students at this level would be able to could come up with a function to express the relationship. Karla then asked the teachers to think about what would be next for these students to push them further in their thinking if they were going to be their teacher next year. Ms. N suggested that they could give the kids practice translating words into variable expressions; and once they have practice with that they could go back to the banquet hall task and ask them how they could use their experience translating words into variable expressions to determine the number of seats when there are n tables are put together. Karla reiterated what Ms. N said and Ms. K added that the practice could start with simple translations that yield expressions like 2x and 3x and so on. Karla suggested another possibility could be to ask the students express the relationship in words and later connect the words to the algebra. Karla then opened the floor for additional question or comments before moving on.

Using the NCTM Professional teaching standards to describe classroom episodes like the one above was problematic with respect to tasks, discourse, environment, and analysis because the while some mathematics learning may have taken place the teachers were primarily engaged as teachers of mathematics and not learners. In order to characterize the interaction of the mathematics teacher educators and the teachers we elaborate on the professional teaching standards as it applies to modeling the collective inquiry process.

*Tasks*

In the episode described above the primary focus of the task was not to provide intellectual contexts for the teachers' mathematical development as learners, but to motivate the development of the teachers' understanding of the students' mathematics through discussion, exploration and experimentation. With the try-on task, the mathematics teacher educator modeled the coordinated action and analysis of the collective inquiry process.

*Discourse*

While like in the NCTM professional teaching standards the discourse during this episode reflected the ways of representing, thinking, talking, and agreeing and disagreeing that mathematics teacher educators and teachers use to engage in tasks, the discourse in this episode is embedded in the teachers' classroom experiences as teachers within a community of teachers. The mathematics teacher educator orchestrated discourse that modeled the public reflection aspect of the collective inquiry process.

*Environment*

The environment represents the setting or context in which the tasks and discourse are embedded for learning. When the teachers are engaged as learners of mathematics, the setting is a mathematics classroom community. However, when the teachers are engaged as professionals, the setting shifts to a community of mathematics teachers. As the teachers engage in this professional learning community the mathematics teacher educator models the interplay of intellectual and social characteristics of the members of the community that shape the evolving knowledge base of the community.

*Analysis*

Analysis in the NCTM professional teaching standards refers to the ongoing monitoring of classroom life-how well the tasks, discourse, and environment foster the development of every student's mathematical literacy and power. In terms of the collective inquiry process the mathematics teacher educator works to foster development of every teachers' enculturation in a professional learning community of mathematics teachers. One way a mathematics teacher educator fosters this enculturation is exemplified in the above episode as she listened in on the conversations of the groups. Through this process, mathematics teacher educator examines the group members' participation in the collective work of teachers. The teacher educator modeled the analysis of student thinking as a means of thinking about where to go next. She also modeled, we argue, by listening in on groups and selectively sharing what she was thinking about their learning from the perspective of analysis.

Table 2 characterizes the mathematics teacher educators' instructional acts as they model the collective inquiry process.

### Concluding Response

Collins, Brown and Newman (1989) and Lave and Wenger (1991) hypothesize that through observation, learners develop a conceptual model that provides them with an advanced organizer and interpretive structure for reflecting on a given practice. It can be argued that understanding how to participate in the collective inquiry process of a professional learning community of mathematics teachers is important because it provides insights into the nature of the professionalism of teaching advocated by the NCTM. In mathematics teacher education, teachers have the opportunity not only to deepen their mathematics content and pedagogy skill, but also the opportunity to engage in the collective inquiry process of mathematics teachers. The hope is that this research informs the body of knowledge about teaching the practice of teaching mathematics.

# BEGINNING TEACHERS AND NON ROUTINE PROBLEMS: MATHEMATICS LESSON STUDY GROUP IN AN URBAN CONTEXT

Hanna Haydar
Brooklyn College- CUNY
Haydar@brooklyn.cuny.edu

Betina Zolkower
Brooklyn College- CUNY
BetinaZ@brooklyn.cuny.edu

*This paper reports on a professional development and research initiative that engages a group of beginning middle school teachers in studying non-routine mathematics problems and investigates the effects of this intervention. Participants in this group engaged in the guided study of: a) non-routine mathematics problems, b) samples of students' written work on NRP, c) sample mathematics assessments that include NRPs, d) case studies of NRP-centered mathematics instruction, and e) 'vertical' analysis of various curricula. The study group improved teachers' lesson planning but varied in the authenticity of using the NRPs among individual participants. An instructional design framework was developed linking the NRPs, the lesson and the unit of instruction.*

## Background

This study draws on data from a larger professional development and research initiative that engages beginning middle school mathematics teachers in a lesson study group and studies the effect of their participation in this in-service initiative on the quality of their mathematics lessons. Lesson study participants are teachers in their first years of service who work in 'hard-to-staff", high poverty, urban schools. Our long term research goal is to explore the impact of participating in this study group on teachers' practice and their retention in the high need schools were they work.

In this report we describe how beginning middle school teachers interacted with lesson study activities centered on the solving, teaching, and learning of non-routine problems (NRP). Participants in this group engaged in the guided study of: a) non-routine mathematics problems, b) samples of students' written work on NRP, c) sample mathematics assessments that include NRPs, d) case studies of NRP-centered mathematics instruction, and e) 'vertical' analysis of various curricula.

## Theoretical Perspectives

Influenced by the seminal work of Polya (1945), Schoenfeld (1985) and the NCTM focus on problem solving (1989, 2000), mathematics education researchers highlight the need for instruction to engage students in solving rich, challenging, high level, and open-ended tasks. Researchers might vary in how they refer to these problems based on their wide range of frameworks ranging from cognitive science to social constructivism and activity theory. The literature refers to these tasks as high level tasks (Stein et al., 1996), model-eliciting tasks (Lesh & Harel, 2003), realistic modeling problems (Verschaffel & de Corte, 1997), spiral tasks (Fried & Amit, 2005), and multiple-solution connecting tasks (Leikin & Levav-Waynberg, 2007). What is common among all the above types of problems, which we refer to as non-routine problems (NRP), is their valuable role in eliciting thinking and reasoning, communication, critical attitude, interpretation, reflection, creativity, and generalization, all of which are central to the activity of mathematizing (Freudenthal, 1991).

Yet there is increasing concern that in many classrooms, especially in those attended by minority and low SES students, instruction focuses almost exclusively on mechanical ways of applying algorithms and formulas to the solution of stereotypical word or ‘story’ problems (Oakes, 2005; Boaler, 2002). The poor quality of mathematics instruction in schools attended by low SES and minority students is seen as a critical contributor to social inequality (Moses & Cobb, 2001) in that these groups of students are denied access to high level mathematical thinking as well as important pathways to economic and other enfranchisement (National Action Committee for Minorities in Engineering 1997; National Science Foundation 2000).

It is well documented that teachers rarely make non-routine problem solving an integral part of their instruction (Henningsen & Stein, 1997; Silver, 2005; Leikin & Levav-Waynberg, 2007). Therefore, it is hardly surprising that students have difficulties with these kinds of problems (Verschaffel & de Corte, 1997; Cooper & Harris, 2002). A modality of mathematics instruction that focuses only on routine problems is seen as very unlikely to prepare students to successfully tackle and solve novel problems in and out of school settings. While this poverty of mathematics instruction could be blamed to a great extent to mandated curricula and standardized testing (Haydar, 2009), it is also a result of limitations in teachers’ appreciation of the educative value of those kinds of problems, their own level of comfort in solving such problems, and their ability to handle the pedagogical demands that this type of problem solving activity entails, in particular in orchestrating whole-class discussions about multiple strategies for solving a given problem (Silver et al., 2005; Shreyar et al., 2009).

Mathematics teacher educators advocate the use of lesson study as a model of teacher-initiated and mentor-facilitated professional development (Stigler & Hiebert, 1999). Issues of adaptation of the lesson study model to the US context have been the subject of many recent studies (Fernandez & Yoshida, 2004; Lewis, 2002). However, we know little about how lesson study activities centered on non-routine problems affect beginning teachers’ planning and assessment skills, especially when in urban school contexts. This study is an attempt to fill some of these gaps.

## Research Questions

In this research we aimed to explore to what extent and how does NRP-centered lesson study group increase participants’ ability to effectively incorporate non-routine problem solving into their classroom practice. In addition, our goal was also to use this Lesson Study group as a laboratory and draw insights on the design, try out and documentation, revision and dissemination of a sequence of NRP-based activities and materials for the professional development of middle school mathematics teachers.

## Methodology

The participants in the Lesson Study Group (n=10) were either recent graduates or in their final year in a middle school mathematics master’s program. They were within their first 5 years of teaching in ‘hard-to-staff”, high poverty, urban schools. They teach seventh to ninth grade mathematics in urban school settings attended by a predominantly African-American, Latino, Asian, and/or recent immigrant school population. All of them expressed in writing, as a response to the invitation letter from the researchers, their interest in, understanding of, and commitment to the proposed project.

In line with what is typical to the Lesson Study modality of professional development in mathematics (Stigler & Hiebert, 1999; Fernandez & Yoshida, 2004), a central focus of the sessions was the design, try out, documentation, revision, and write up of mathematics middle school lessons. More specifically participants were engaged in the following activities:

- Solving and studying NRP
- Selecting and sequencing from a list of NRP
- Designing NRP-based lessons
- Trying out, documenting, discussing NRP-based lessons
- Analyzing curricula in search for NRP
- Analyzing assessments in search of NRP
- Inventing, finding, adapting NRP
- Transforming a routine problem into a NRP
- Analyzing student work samples on NRP

Parallel to the three face-to-face sessions, the pilot lesson study group project engaged participants in three a-synchronous on-line discussion boards via Blackboard.

All Lesson Study sessions were audio and video-taped and a record was kept of all the asynchronous online discussion board contributions. Portions of these sessions were analyzed in search for evidence of an increase in participant teachers' ability to: appreciate the value of NRP; solve and discuss alternative solution strategies for NRP; recognize NRPs in textbooks and assessments (as well as the lack thereof); design NRP-centered lessons, and organize NRP into a unit; and incorporate non-routine problem solving into their classroom practice.

In order to be able to assess the effect of participating in the LSG for each individual teacher, we collected pre- and post data from each participant regarding: a) solving and explaining in detailed write ups their solution to NRP, b) selecting NRP from a given list of 'scrambled' problems and sequencing those problems into a unit, c) transforming a routine problem into a non-routine problem, and d) designing a NRP-centered lesson for students in one of their classes for a given unit/topic.

We also conducted a follow up, open-ended survey four months after the last Lesson Study session. Survey questions focused on their recollection of the most memorable moments of the lesson study, their narratives of what NRP-related elements they incorporated or planning to incorporate in their mathematics lessons and their interest in future engagement in similar professional development activities.

In analyzing the above data, we looked for indicators of improved skills in studying, solving, and describing the solutions to NRPs as well as evidence of an enhanced ability on the teacher participants' part to search for, design, adapt, and sequence NRPs. We developed a coding scheme based on the PISA cross-disciplinary problem-solving framework and Competency Clusters (OECD, 2003).

To analyze the manner in which participant teachers incorporate non-routine problem solving into lesson planning we developed a lesson template based on the Japanese lesson study and its various adaptations (Fernandez & Yoshida, 2004).

## Snapshots from Lesson Study Sessions

To illustrate how teacher participants typically engaged in NRPs during the lesson study group activities we present below snapshots from one of the sessions. These snapshots are paradigmatic of the kinds of conversations that occurred during the sessions. Participants worked on the cross-to-square problem (fig.1). We selected this problem as a rich context that includes all the following features which we view as highly relevant to the classroom practice of middle school teachers:

- Conveyed through a diagram (invites diagrammatic thinking)
- A geometric dissection
- A constant area problem
- As a puzzle, it generates puzzling, puzzlement
- Linked to rotated or 'tilted' squares (transformational geometry: from a square to a tilted square)
- Connection to Pythagoras theorem
- Lends itself to other related problems (other square dissection puzzles)

<u>Cross-to-Square Puzzle</u>

Divide the shape below into four parts that can fit back together to form a square

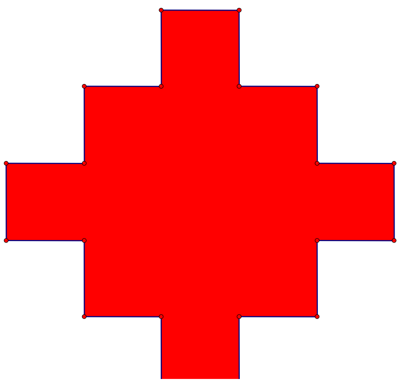

Figure 1.

The problem was introduced during a brief whole-group exchange following a "thinking aloud together" modality (Zolkower & Shreyar, 2007).

*Framing the NRP*

BZ: Can we dissect this rectangle in three pieces so the pieces may be re-arranged into a square? (*Draws a 2 by 8 rectangle on chart paper)*

*A few minutes later*

Ms. E: I got it! It will give you a tilted square with an area of 8.

*BZ draws the tilted square and shows with arrows how it results from dissecting the rectangle.*

BZ: Easy, right? Now the real problem consists of dissecting this cross-like figure… (*Draws diagram).*… in four pieces so that the pieces may be re-arranged to make a square.

Ms. S: How can this work?!

BZ: What do you mean?

Ms. S: I mean, if there are 13 squares. 13 is not...

Mr. H: Can we split the squares?
BZ: Split them how?
Mr. H: Cut them diagonally in some way
*BZ Draws a small square and splits it in half diagonally*.
BZ: What do you all think?
Mr. Z: It won't work unless we cut the squares.
*Shifting the Context: From the LSG to the Classroom*
After the solution was found.
Ms R: I have a question… How do we help our students solve these kinds of problems?
*BZ writes R's question on the board, crosses out 'help,' and substitutes it with 'teach.'*
BZ: I'd like to rephrase R's question: How do we TEACH students to solve these kinds of problems? What kinds of problems would they need to work on before tackling this one?
Ms. G: Unless they're familiar with the idea that a square can be tilted.... *Makes a hand gesture to indicate 'tilted'*
Ms. S: Also… as soon as they see 13, they may think, like I did, it's impossible to do it!
BZ: Those two issues seem quite related, right? So it may beneficial to first engage students in activities that involve sketching and finding the area of tilted squares… on graph paper, of course.
*From NRP to Pre-Requisite, Sub-Problem*

The above shift in perspective, from solving the math NRP problem to raising the question of how a problem such as this one could be introduced in a middle school classroom, led us to introduce a likely candidate for a pre-requisite (or sub-) problem (fig. 2).

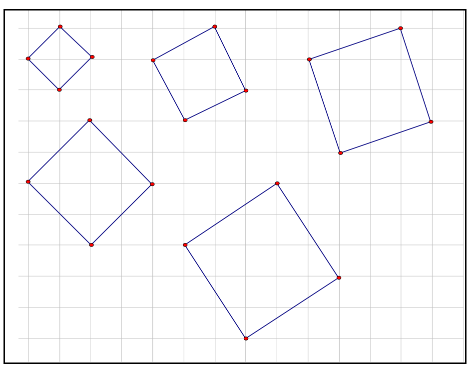

Figure 2.

*From Problems to Units*

And, in turn this was followed by an activity whereby participants were given a set of nine 'scrambled' problems and asked to solve each of them, identify the mathematics in each of the problems then select three to five problems to make an instructional unit with them. They were also asked to justify their choice of problems for the unit as well as its sequencing.

**Results**

The lesson study activities centered on NRPs proved to be a rich context for teachers' engagement with mathematics, learning, and teaching. Our analysis of the data revealed the following

- Mirroring the classroom: By asking teachers to try out and report on both their own problem solving and their incorporating of NRPs in their classrooms, teachers developed a better understanding of what their students go through when they solve mathematical problems and led them to realize the importance of providing a challenging and, at the same time, supportive classroom environment. As one participant put it: *"The engagement in solving non routine problems so resembled what happens in my classroom. Students demonstrate different approaches as did we as teachers. The environment needs to be safe so that all feel comfortable to share. I also rediscovered my own strengths and weaknesses as a problem solver."*
- The laboratory context: the participation in the lesson study encouraged teachers to experiment with incorporating non-routine problems in their classrooms and being able to experience gradual successes *"I have started incorporating NRPs occasionally in my class. I noticed that all my students are becoming more actively engaged and are asking if we are going to continue to do problems of that nature."*
- Lesson planning improvement: As noted before, teachers showed improvement in planning sequences of related lessons: *"I am planning to continue the use of proper sequencing of lessons and use more NRP's.*"
- Analytical pedagogical tools: Working on NRP and analyzing curricular and assessment materials with respect to non-routine problem solving gave teacher participants tools for examining their classroom practices. For example one teacher noticed: *"Comparing and contrasting the different assessment forms and questions from around the world was most memorable to me. I found it very interesting and insightful to critique the NYS math curriculum in comparison to other countries"*
- Community of practice: Teacher participants found in the group a learning community and enjoyed "*the experience of being able to work with teachers who have a different method or strategy of presenting a lesson different from what [they] will usually do in [their] classroom."* One teacher noticed how the group provided a structured time for collaboration and how other teachers became a resource: "*Not only did I have structured time to create a higher-level multi-topic activity to complete with my class, but now I can take the other activities created by the other teachers back to my school and use them with my students in the future.*
- School Leadership: One teachers played a leading role in replicating some of the lesson study activities at their schools. This participant wrote in a journal entry*: "Our professional development sessions at school are currently planned around solving non-routine problems as we wish to enhance teachers own skills (at their request)."*

The analysis of the lessons planned by individual participants both at the beginning of the study and at the end of the sessions showed that participants: (1) moved from the brief isolated lesson formats to more complex ones that place the lesson in the context of broader unit of instruction; (2) made more effort after the sessions to include mathematical problems in their lessons; (3) The success in incorporating non-routine problems into classroom practice on a routine basis varied by individual participants. Also only two teachers introduced the non-routine problems systematically as authentic contexts for mathematizing while others often contrived some of the mandated curriculum standards to the problems.

## Discussion

Given that NRPs are challenging for students and given their rich mathematical content create the need for teachers to act as curriculum and instructional designers and locate a given NRP (Pn) with another that should precede (Pn-1) and/or follow after (Pn+1) , this vertical analysis constitutes the backbone for designing a unit of instruction based on NRPs. Also NRPs are analyzed and compared horizontally to problems from other mathematical strands. NRPs are by their very nature amenable to a variety of approaches. The chart in Fig.3 describes our framework on the relationship between NRP, other NRPs, Problem-based lesson and problem-based unit. NRP-based Lesson study should guide teachers in relating and moving back and forth between these different instructional design dimensions.

Other than the curricular side, NRP-based teacher education activities were also found to help teachers improve their ability to conduct classroom interaction.

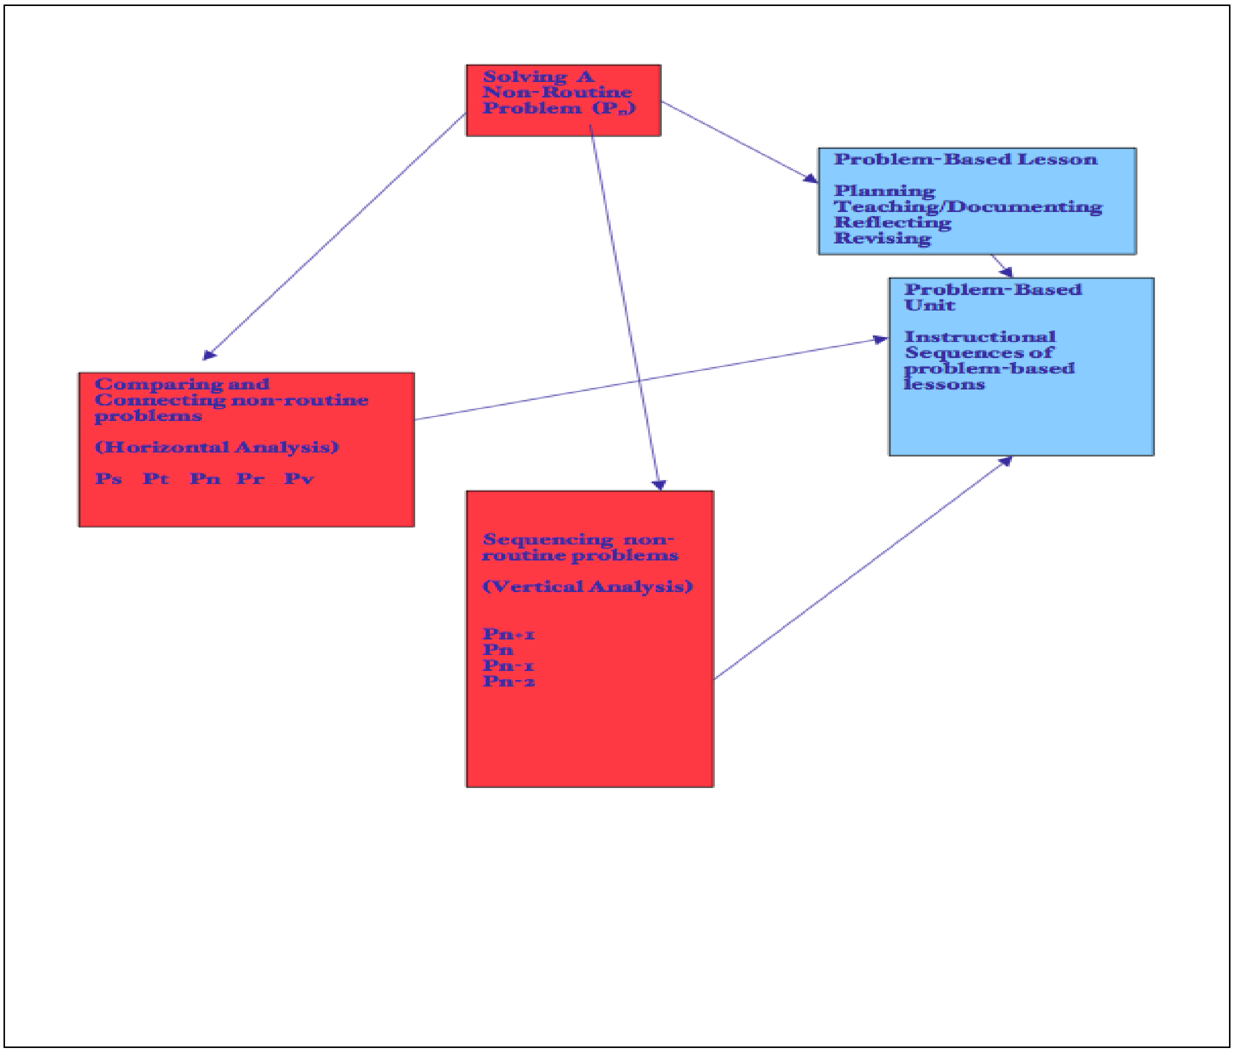

Figure 3.

Non Routine Problems require from teachers a connected understanding of mathematics where the isomorphic connections between the different mathematical strands and structures are developed and used to solve the problem. The uneven results found in this study in how individual participants incorporated NRPS in their lessons are due in part to the level of comfort with NRP mathematical content and linked to participants' disposition to try these in their classroom. Engaging teachers in NRP-based LSG proved to be a safe professional development modality strengthening teachers' own mathematical and problem solving content knowledge and guiding that shift from thinking about incorporating non-routine problem as potential tasks that beginning teacher will only do after they become expert teachers to that belief that this is essential part of being a better reform mathematics teacher.

# PROMPTING MATHEMATICS COACH DEVELOPMENT OF MATHEMATICAL KNOWLEDGE FOR TEACHING

Andrea Knapp
The University of Georgia
akknapp@uga.edu

*This teacher development experiment examined the development of mathematical knowledge for teaching (MKT) of three coaches of mathematics teachers (Hill, Rowan, & Ball, 2005). Coaches were graduate students in the field of mathematics who had an interest in teaching. Coaches developed knowledge of content and teaching as they reflected and collaborated with classroom teachers to implement inquiry-oriented lessons. Coach knowledge of content and students developed through observing and interacting with students. Finally, coaches developed specialized content knowledge as they discussed perturbations from lessons with teachers.*

## Background

The field of professional development coaching currently enjoys steady growth in mathematics education as schools search for effective ways to support the learning of in-service teachers. Although coaching is gaining popularity as a means of professional development, its forms and effectiveness of implementation vary from context to context (Olson & Barrett, 2004). For example, due to the difficulty in recruiting highly qualified coaches from the field of mathematics education, some school districts have looked to hiring their best mathematics teachers as coaches. As a result, districts rob students of qualified teachers and position the newly hired coaches to find their own way in supporting teachers. Thus, finding qualified, cost-effective coaches remains a difficulty for schools.

One alternative model of coaching matches graduate students in the fields of science, technology, engineering, and mathematics (STEM) as content specialist coaches with K-12 classroom teachers. The National Science Foundation (NSF) has established the Graduate Fellows in K-12 Education (GK-12) program that provided the context for this study. The GK-12 program places Graduate Fellows into K-12 classrooms as *collaborative coaches* (Olson & Barrett, 2004). The partnership is designed as a mutual professional development opportunity for both the coaches and the classroom teachers. Teachers develop content knowledge related to the subject matter they teach. (See Knapp, Barrett, & Kaufmann (2007) for teachers' development of mathematical knowledge for teaching through this model.) The teachers voluntarily participate in the partnership. The mathematics graduate coaches may or may not have prior teaching experience, but they have had summer and bi-weekly training on topics such as the National Council of Teachers of Mathematics (NCTM) Standards (2000) and social constructivism. Graduate coaches collaborate with practicing teachers and other graduate coaches on planning and delivering standards-based lessons. Coaches generally model lessons for teachers with the teachers' own students. On some occasions, however, the teacher leads the lesson with the coach's assistance. Most often, teachers and graduate coaches work in pairs, although at times teachers request the assistance of multiple coaches. NSF expects that graduate coaches will develop useful teaching abilities through the program that will prepare them for faculty positions that involve teaching. In order to examine the viability of the partnership, this study examines the impact of the coaching relationship on the teaching abilities of the *coaches*. More specifically, I investigate coaches' development of mathematical knowledge for teaching, which is the mathematical knowledge and habits of mind needed for *teaching* mathematics (Hill et al., 2005). In addition, I seek to ascertain aspects of the coach-teacher relationship that might lead to coach development. Thus I ask, "In what ways do graduate coaches develop mathematical knowledge for teaching as they engage in collaborative coaching with classroom teachers?" For the remainder of this paper, I refer to graduate coaches as *Coaches*, K-12 classroom teachers as *Teachers*, and K-12 students as *students*.

## Theoretical Framework

The construct of *mathematical knowledge for teaching* (MKT) has been linked to student achievement, and thus provided a framework for analysing the Coaches' development in this study (Hill et al., 2005). MKT includes these six elements: common content knowledge; specialized content knowledge (SCK) needed specifically for the mathematics classroom; knowledge of content and students (KCS) which is knowledge of how students learn mathematics; knowledge of content and teaching (KCT) which includes knowing the best representations for teaching mathematics; knowledge of curriculum; and knowledge at the mathematical horizon. This study focused on KCT, KCS, and SCK (See Table 1) (Hill et al.).

Table 1. *Components of Mathematical Knowledge for Teaching*

| Subject Matter Knowledge | Pedagogical Content Knowledge |
|---|---|
| Common Content Knowledge (CCK) | Knowledge of Content and Students (KCS) |
| Specialized Content Knowledge (SCK) | Knowledge of Content and Teaching (KCT) |
| Knowledge at the Mathematical Horizon | Knowledge of Curriculum |

For a theoretical framework, the emergent perspective appeared suited to this study because mathematical knowledge for teaching (MKT) is related to the construct of classroom social norms as outlined in the emergent perspective (Ball, 2003; Cobb & Yackel, 2004). The emergent perspective takes the social aspects of learning and the individual psychological aspects to be reflexively related. In this study, I investigated the individual and social construction of MKT of Coaches as they collaborated with teachers.

## Methodology

I chose to employ qualitative, multi-tiered teacher development experiment (TDE) methodology because the goal of a TDE is to generate models for teachers' mathematical and pedagogical development, closely matching our research aims for the collaborative coaches (Lesh & Kelly, 2000; Presmeg & Barrett, 2003).The methods for this qualitative teacher development experiment involved year-long case studies of three mathematics coaches: Melvin, Dave, and Marsha. I also conducted case studies on four Teachers, but I do not report on the Teacher development in this paper. Melvin had four years of teaching experience at the secondary level before pursuing his graduate degree in mathematics. Dave had two years of teaching experience, and Marsha had no former teaching experience or preparation.

Data sources for Melvin's development of MKT included 87 written pre/post lesson reflections, transcripts of two audiotaped interviews, 4 video-taped lessons, and transcripts of 9 audiotaped pre and post planning sessions done in collaboration with a 6-8$^{th}$ grade mathematics teacher, Mrs. Gerber. Data sources for Dave included 74 written pre/post reflections, transcripts of two interviews, 9 video-taped lessons, and transcripts of 7 audiotaped planning sessions with Teachers. Data sources for Marsha included 87 written pre/post reflections, transcripts of two interviews, 12 video-taped lessons, and transcripts of 11 audiotaped planning sessions with Teachers. Pre lesson reflections asked Coaches to describe the lessons that they would teach and to explain how students would be expected to invent knowledge and think through the content. Coaches were also asked to predict areas that would be difficult for students to understand. Post lesson reflections required Coaches to describe how the lesson went and whether students understood the content. These data sources were analysed for development in mathematical knowledge for teaching with regard to SCK, KCS, and KCT.

In order to analyse the data, SCK, KCS, and KCT were broken down into 17 codes relating to different aspects of each construct. A question accompanied each code in order to highlight ways that MKT development might occur. Questions came from the elements of the work of teaching elaborated by Hill et al. (2005) and from salient aspects of the pilot study. For examples of the codes and accompanying questions, see Table 2. Three transcripts were analysed by both the researcher and Melvin, Dave, and Marsha respectively until an interrater reliability of 80% was reached. After this, the researcher coded the rest of the transcripts. Each time a portion of transcript was coded as SCK, KCS, or KCT, the accompanying question was answered based on the data. Ways in which these elements developed were then categorized and tabulated.

Table 2. *Analysis Codes and Questions*

| Category | Analysis Question (Code) |
|---|---|
| KCT | How did the lesson study environment affect the Teachers'/Coaches' instructional choices and use of curriculum? (KCT1) |
| KCT | How did the Teacher/Coach encourage student construction of knowledge? (KCT4) |
| KCT | How did the Teacher/Coach provide explanations, examples, or counterexamples? (KCT7) |
| KCT | Did the Teacher/Coach ask students to justify their reasoning? (KCT6) |
| KCS | How does the Teacher/Coach notice students' knowledge/reasoning/thinking as they engaged in lesson study? (KCS12) |
| KCS | How does lesson study help Teachers/Coaches question their students [not as an instructional tool but to learn about students' thinking]? (KCS13) |
| KCS | How does lesson study help Teachers/Coaches see/hear student misconceptions? (KCS14) |
| SCK | How did mathematical discourse between Teachers and Coaches foster reasoning? (SCK17) |

## Results and Discussion

I coded Coach reflections for knowledge of content and students (KCS), knowledge of content and teaching (KCT), and specialized content knowledge (SCK). This meant that I coded quotes which I felt indicated that the Coach developed or had an opportunity to develop these elements of teaching. For example, if a Coach noted changes he would make to a lesson after teaching it, I coded an opportunity to develop KCT. I avoided counting quotes which showed teaching knowledge that the Coach possessed prior to the lesson. In addition to reporting results from reflections in this section, I also report codes from transcripts of audio taped reflections with teachers, videotapes of lessons, and interviews. The final tallies revealed 91 expressions of developing KCT, 41 expressions of developing KCS, and 14 instances of developing SCK. In addition, Coaches reported learning general pedagogy.

After coding the data, I looked back at each code, and identified *how* that type of knowledge developed. To focus on the primary ways in which Coaches developed, I eliminated all ways that were expressed less than ten times. Some ways I collapsed together into a single category. The compression phase of data analysis revealed five primary ways that mathematical knowledge for teaching developed for the Coaches. I list the five primary ways in Table 3, and I provide evidence for the ways in the sections following the table.

Table 3. *Primary Ways in which Coaches Developed Mathematical Knowledge for Teaching*

| Frequency | Way |
|---|---|
| KCT (46) | |
| 17 | **Reflecting** about changes and things to keep from a lesson taught |
| 11 | Having students construct their own knowledge and make discoveries and conclusions; **Teaching for conceptual understanding** |
| 18 | Reflecting on lesson with teacher; Considering perturbations or misconceptions prompting revision; **Collaborating with Teacher** in planning, with both sets of expertise working together; Repeating lesson or teaching strategy |
| KCS (32) | |
| 32 | **Observing**, listening, and interacting with students during lesson; seeing what's hard for them and misconceptions; seeing level of material students could handle, construct, or conjecture (raised expectations) |
| SCK (10) | |
| 10 | Finding an application to model the content; **Discussing perturbations** with Teachers or other Coaches; Testing a student conjecture |

*Coach Development of Knowledge of Content and Teaching*

The primary ways in which Coach mathematical knowledge for teaching developed focused on knowledge of content and teaching (KCT) and knowledge of content and students (KCS). The first primary way Coaches developed KCT was in reflecting about lessons they had taught and deciding to either retain or change elements of the lessons. For example, Marsha stated the following in a reflection:

> The kids really had a lot of fun with this game, and it really was simple in terms of materials and set up. They practiced a lot of multiplication problems and were really checking each others work since they wanted to win the cards that round. It also helped them to think about strategies of what is going to give you a big number when you multiply, which I think helps them to develop their estimating and telling if an answer is reasonable.

She learned a classroom activity to support students' estimating strategies (KCT). This finding substantiates Mumba et al. (2003) who found Coaches to have Technocratic-oriented reflections. In other words, they sought solutions to improve their teaching. Furthermore, like Mumba et al., the nature of the Coach reflections were descriptive, dialogical, and critical. Dialogical referred to reflecting with teachers during and after lessons as well as reflecting with other Coaches before and after lessons. Critical referred to expressing dissatisfaction with lessons and suggesting alternatives. The second way Coaches developed KCT followed from the first, in that Coaches often chose to change lessons towards inquiry. In other words, they valued to a greater degree students making their own discoveries and conclusions, individual construction of knowledge, and teaching for conceptual understanding. The third way KCT developed was similar to the first and second, but allowed for collaboration with Teachers. Coaches collaborated with Teachers on planning lessons, in which both sets of expertise went into the lesson design. The teacher contributed knowledge of her individual class and pedagogy. The Coach contributed content knowledge and knowledge about inquiry-based instruction. After lessons, Coaches and Teachers as collaborative partners discussed perturbations relating to student misconceptions, pedagogy, or technology. The Coaches and Teachers would then revise and sometimes repeat lessons based on their discussion of the issues. Finally, Coaches would at times repeat the cycle of revision, perhaps with another Teacher or another Coach.

*Coach Development of Knowledge of Content and Students*

Knowledge of content and students (KCS) primarily developed during lessons as Coaches observed, listened to, and interacted with students. Coaches learned what concepts were difficult for students to understand as well as misconceptions that students possessed. For example, all three Coaches independently encountered trapezoid as a challenging concept in middle grades classrooms. Dave and Marsha, independently in different lessons and different schools, found that students' conceptions of 'trapezoid' are often of an isosceles trapezoid where both legs are the same length. The Coaches then challenged this misconception by presenting them with right trapezoids, and discussing with them the properties of a trapezoid. Marsha used geoboards as a teaching tool and Dave used Geometer's Sketchpad to address the misconceptions. Melvin addressed the misconception during a class discussion. In a post lesson reflection he wrote,

> The best discussion I felt like came from discussing the trapezoids, as the students felt there was only one possible trapezoid, the picture we frequently see in books of an isosceles trapezoid. After determining the definition of a trapezoid to be one set of parallel sides, the students debated me as to whether or not a right trapezoid was really a trapezoid. This discussion really brought out the misconceptions created by always using the same figure to describe a family of figures and was a good chance to discuss what properties are necessary to classify a quadrilateral.

Thus, the Coach learned that students hold limited concept images of figures, developing knowledge of content and students (Vinner & Hershkowitz, 1980).

In addition to learning about student misconceptions, Coaches learned about the level of material the students could handle. Moreover, Coaches learned how students created conjectures and constructed knowledge. At times, Coaches' expectations were raised by observing students' productions in an open-ended environment. For example, in an open-ended lesson in which students were to conjecture about quadrilateral properties using Geometer's Sketchpad as a tool, the Coach, Melvin, expected students to come up with perhaps four or five conjectures. He and the teacher were amazed when the students produced twenty conjectures, some of which can be seen in the following portion of transcript:

Student: 2 sets of parallel lines.

Melvin: 2 sets of parallel lines. What do we think?

Students: Yeah, No [chorus of no's]

Melvin: Who says no? OK right there, you say no? Alright, so far she's the winner. She says that's not the case, but let's go back and let's look at this, OK. On your screen you might have parallel sides, but remember what a property is. A property is something that's true for every quadrilateral. So let's look over here. Do these have parallel sides? [motioning to a student screen and dragging] Are they parallel now?

Melvin: Look at mine up here [referring to the projected Sketchpad screen]. What I'm going to do is I'm going to start dragging this thing around, right? I can drag this around. Are those parallel? [chorus of no's] So it doesn't. Even though I can take these and I can make them parallel, and according to that observation right there, they are parallel. So I would agree with the young lady. However, we need to be true for all of the quadrilaterals, and so that isn't going to be one for all of them.

Student: All have four letters.

Student: Four segment lines.

Melvin pointed out that "segment lines" was contradictory and wrote, "Four segments." The transcript continues.

Student: They're all enclosed areas, I mean, inside it's all enclosed.

Melvin: OK, I'm going to tie all that up with one word – polygon, OK. Enclosed.

In the audiotaped post reflection between the Coach and the teacher, the Coach said,

> Yeah, I felt, I was very happy with their creativity, and their coming up with the properties. They all were involved. One thing we talked about might happen is that they'll just stare at me, and look at me. That didn't happen at ALL. So, so by that I was taken a little bit aback and was kind of enthused by it. Um, was maybe a little bit overwhelmed..."

Melvin learned that students are curious and eager to conjecture, and he also learned that student conjectures could appear very different from properties listed in a textbook. Thus, at times, the results of inquiry-based lessons took Coaches by surprise; knowledge of content and teaching had spawned knowledge of content and students.

*Coach Development of Specialized Content Knowledge*

The last area of Coach development related to specialized content knowledge. Although this type of development occurred less frequently than KCT and KCS, it surfaced through rich discussion as can be seen in the following example. Melvin, like Dave and Marsha, encountered trapezoids when he and a teacher developed a quadrilateral taxonomy in which a trapezoid was defined as having exactly one pair of parallel sides (Battista, 1998). During a debriefing session, the following discussion ensued between Melvin and the 7th grade Teacher, Mrs. Gerber.

Melvin: But see now the tricky thing, actually, I'm learning a lot, Mrs. Gerber, because having done this kite, now I see the relationship a kite… rhombus,

Mrs. Gerber: OK

Melvin: Every rhombus is a kite, by my, by our definition, and see this is the thing. Um, I'm finding out that that definitions vary from book to book. (That's true.) Do you guys have, do you guys talk about kite in your book?

Mrs. Gerber: No, we don't talk about it. No, we don't.

Melvin: I'm finding a lot of differences in the definition of trapezoid, a lot of differences in the definition of kite.

Mrs. Gerber: What are you finding in the differences in trapezoid?

Melvin: Some books just say that it's got um at least two [one] pairs of opposite sides [parallel], so that would mean a parallelogram is a trapezoid as well.

Mrs. Gerber: OK

Melvin: But it doesn't have to have all, it doesn't have to have all, it doesn't have to have two pairs of opposite sides parallel. It just has to have at least two opposite sides that are parallel, so that gives it a little bit of more flavor, so every parallelogram is a trapezoid, and every trapezoid is a quadrilateral, it would fit in that flow.

Mrs. Gerber: Oh, OK, now I've never seen that either.

Melvin: Yeah, actually, I like that better, if we're going to make a note on how things are going to be done next year, I would suggest doing that.

Mrs. Gerber: Well, you know, that that make the trapezoid not such an odd guy out.

In his final interview, Melvin stated,

> I will be honest with you, I was growing in my understanding as well, right with her [Mrs. Gerber]. I mean, because I, we had presented trapezoids as only one pair of opposite parallel sides as opposed to at least [one pair of parallel sides]. And that change makes quite a difference…

Thus, Melvin developed specialized content knowledge (SCK) about definitions of a trapezoid as he delved into the topic of quadrilateral relationships with the teacher. In another planning session, Melvin and the Teacher wrestled with adding arrows to their taxonomy to denote generality (Battista, 1998). For example, they showed that a square is always a rectangle with a down arrow, but that a rectangle is sometimes a square with an up arrow (See Knapp et al., 2007). They decided to give the same task to students. The collaboration between Melvin and Mrs. Gerber inspired a didactic problem situation, and thereby provided for the development of knowledge of content and teaching (KCT).

*Coaches' Path to Mathematical Knowledge for Teaching*

In reflecting about the ways in which Coaches developed mathematical knowledge for teaching, I summarize the development with the following cycle. In the *Coaches' Path to Mathematical Knowledge for Teaching*, Coaches develop specialized content knowledge (SCK) as they research the topic for a lesson. As they search for curriculum and collaboratively plan for instruction with Teachers and other Coaches, they develop specialized content knowledge (SCK) and knowledge of content and teaching (KCT). During the lesson, Coaches develop knowledge of content and students (KCS) through observation of and discourse with students. Finally, in the reflection/debriefing phase, Coaches develop KCT, KCS, and SCK as they consider perturbations from the lesson with the Teacher or another Coach and reflect on the lesson (Hart, Najee-Ullah, & Schultz, 2004). Finally, the lesson may be repeated at another school with another teacher, and the cycle continues. The debriefing phase is perhaps the most valuable aspect of the cycle because both mathematical and pedagogical issues get discussed and intertwined. For example, the definition of a trapezoid discussion between Melvin and Mrs. Gerber occurred during a debriefing meeting. Also during the debriefing sessions, the lessons are fine-tuned based on the knowledge of content and students gained from the teaching phase. It is important to note that not all Coaches follow this path for all lessons. Rather, it is when and to what degree Coaches follow this path or elements of it that they appear to develop mathematical knowledge for teaching.

In conclusion, Graduate Coaches developed MKT through collaborative coaching with teachers. In particular, development occurred during collaborative planning and subsequent debriefing with Teachers. This aspect of the Coaching relationship is critical and should not be shortchanged. This research implies that the coaching relationship can serve as a form of professional development for both Teachers and Coaches (Knapp, et al., 2007). Thus, I recommend that universities involved in the preparation and professional development of STEM professors or K-12 teachers consider offering coursework, student teaching assignments, or assistantships which involve coaching of K-12 teachers.

*This paper reports on how beginning mathematics teachers who are participating in the New York City Teaching Fellows program view and respond to their students' mathematical errors. It describes the error analysis-coding model used when identifying and analyzing the error-handling situations. The study focuses on (a) elicitation of the identified errors, (b) type of errors (c) teachers' immediate reactions, (d) teachers' follow-ups and (e) the correction and post-correction processes. The other focus of the study is teachers' views of error attribution, and their own role in responding to students' errors in urban context as expressed in end-of-year interviews. Results show the importance of considering influences of school contexts on individual teachers' error-handling role.*

## Theoretical Perspectives

Most mathematics education professional organizations and reform voices call for mathematics classroom environments where students participate actively in trying to understand what they are asked to learn. Effective learners in such environments recognize the importance of reflecting on their thinking and learning from their errors. As Lannin et al. (2006) emphasized "creating an environment where students can learn from their errors is paramount for supporting their mathematical learning" (p.186).

The NCTM standards (2000) elaborate that, in such environments, mathematical errors are seen not as "dead ends but rather as potential avenues for learning." This view considers the fact that "students feel comfortable making and correcting mistakes" as a basic and main reform characteristic. Teachers have a crucial role in building such environments, where students understand that it is acceptable to struggle with ideas, to make mistakes, and to be unsure (NCTM, 2000). However, there are fewer studies on error-handling activities of teachers in mathematics lessons (Heinze, 2005).

The research design and methods for this study are informed by a framework that articulates theoretical standpoints deriving from teacher education, learning theories and comparative education. First, we adopt the view of errors as resources for promoting learning rather than simply as diagnostic tools or stumbling points, we look developmentally at the immersion of beginning teachers in the teaching profession and realize the importance of the first years in shaping their teaching practices. We believe in the importance of supporting beginning teachers and considering their professional needs within the growing alternative certification context, we finally derive from the cross-cultural lens of comparative educational studies their emphasis on the importance of contextual nature of the teaching practices.

Researchers in mathematics education have long realized and studied the role of errors in learning (Baruk, 1985). Most of the earlier research held a diagnostic approach and tried to study the nature of students' errors and suggest remediation strategies (e.g., Radatz, 1979). Calls for teachers to capitalize on students' errors are also abundant in the literature (Borasi, 1994; Ashlock, 2005; Lannin et al., 2007; Smith et al. 1993). For example, Borasi (1994) proposed "using errors as springboards for inquiry" as a strategy to use students' errors in stimulating and supporting mathematics inquiry instruction while Lannin (2007) stated that " when students seek to understand the general nature of the errors, they engage in a critical boundary-defining process that can lead toward a normative view of the application of a particular concept [and] when students engage in considering the applicability of a particular concept, they define the boundary for when to and when not to apply a particular idea." (p.57). Martinez (1998) looked at errors as unavoidable part of the process of problem solving. He called for both teachers and learners to be more tolerant of them, arguing that "if no mistakes are made, then almost certainly no problem solving is taking place." In this view errors are not seen as signs of failure or weakness as other learning theories might suggest. Expanding on how different learning theories view errors, Santagata (2005) noted that different learning theories assign to mathematical errors rather fundamental roles: either as obstacles as in the case of behaviourists or as tools for learning with constructivists); however, "the extent to which they inform teachers' practices is a question yet to be investigated" (Santagata, 2005, p.492).

Comparative education studies showed differences in how teachers in different cultures and countries vary in their approaches to students' mathematical errors: for example Osborn and Planel (1999) reported on how teachers in England made more effort to protect students' self-esteem and avoid negative feedback while teachers in France were observed responding directly to students' wrong answers and sometimes yelling at students. Stevenson and Stigler (1992) reported that Japanese teachers viewed mathematical errors as having a positive function. Students in Japanese mathematics lessons are called to the front of the classroom to share their own problem solutions with their classmates even when they are wrong. These wrong solutions are regarded as sources of useful discussions. Japanese teachers also plan their lessons taking into account common mistakes made by their students. To the contrary, they found that US teachers avoided discussions of students' mathematical errors and showed more concern about students' self-esteem.

## Research Questions

This study aims to investigate whether and how beginning teachers, like the NYC Teaching Fellows, are aware, develop or practice their error-handling role. In particular, it aims to answer the following questions: (1) How beginning mathematics teachers respond to their students' mathematical errors in their classroom settings and (2) How do they view students' mathematical errors and look at their own role in responding to these errors.

## Methodology

This study draws on data from a larger research project facilitated by MetroMath (The Center for Mathematics in America's Cities at the Graduate Center- CUNY in NYC) that explores the nature of teaching and learning in "high-needs," urban schools having a large proportion of alternative-routes teachers. More specifically, the MetroMath study examines the impact that the NYCTF program, an alternative teacher certification program, is having on mathematics education in the NY City classrooms.

The NYCTF program is examined both from a macro study – using large scale surveys of the 2006 and 2007 cohorts, as well as a micro study. In the micro study, we draw on data from case studies of eight teachers whose mathematical classrooms we observe about once a month using field notes, video taping, written reflections and post-observation interviews to understand teachers' experiences in the classroom.

For this particular paper we focus on the video- -tapes and field notes that show occurrences of students' mathematical errors and analyse how the eight case study teachers responded to and handled these situations. A second set of data we used was end of year interviews that we conducted with the eight NYC fellows in order to better understand their views about errors and their perception of their own practices when they recognize mathematical errors.

## The Error Profile and Coding Scheme

In this study, a mathematical error was defined as a student's wrong answer to a teacher's question or mathematical task. To analyse teachers' responses to the error we developed an error profile form adopted from Haydar (2002) and Santagata (2005). For every identified error, the error profile included teacher name, date and time, instructional task, narrative of the teacher-student interaction followed by a table that organized the analysis of each error according to: elicitation activity; nature of talk; type of error; immediate reaction; teacher interaction; error correction and post-correction behaviour.

A coding scheme was developed to look at each of the aspects listed above. After we identified that the teacher had recognized a student error, we would fill out the identifying information for the first part of the error profile. We then analysed the elicitation activity (in what part of the lesson did the error occur? ) then the nature of talk: was it public (whole class)? private? (one-to-one)? or semi-private? (small groups). We then coded the type of error (conceptual, procedural, drawing, computational, distraction, notation). As for the teacher's immediate reaction we looked whether the teacher gave a negative verbal reaction or asked a question related or not to the content. We then analysed the intervention that followed (Did the teacher give another task?; Interviewed the student?; Repeated the same question?; Used picture or other teaching aids?; Explained?). The focus that followed was to locate who gave the correct answer at the end (Was it the teacher him/herself?; Another student? ; The same student?; Or was no correct answer given at all?). Finally, we looked at what happened right after the correction was done (Did the teacher use the error as a learning moment?; Did he/she use it as a warning for students?; Or did the teacher delay the response?; Or just moved to another task?). Following are two examples that illustrate the error profile, the identifying information were taken off for space and anonymity considerations, clarifications were added in italic.

Example 1: Private error profile.
Task or question: Simplify the following algebraic expression: 3) $3x^3 + x^3 - x + 2x^2 + x$

Narrative:
A.N. (seventh grade student) has written the following answer:
$3x^3 + x^2 + 36$

T (teacher) pointing to the $x^2$
"you forgot the 2 here" she adds the two then asks him:
"why did you put 36 here?"

*Figure 1*: Example of a partial private error profile.

Example 2: Public error profile.
Task or question: Simplify the expression: (n + 2) + (n + 4)

Narrative
T (teacher) moves to the front of the room and asked S1 (8th grade student) to answer #3: (n + 2) + (n + 4)
S1 immediately says **$n^2 + 6n + 8$.**
T moves to the back and asks if the answer was correct.
S2 (Another student) says no, and gives the answer 2n + 6.
T looks at S1 and explains that it is very important to see the difference between # 3 and # 4 in these two questions. He says that one has the plus sign in between parenthesis and the other has the imply multiplication and that these problems must be solved by different methods.
T looking at the whole class says: "We need to be careful not to use the FOIL method because we have the plus sign" and assures S1 that he did not ask this to trick him, but to show that we need to be alert.

## The Interview

In order to better understand how teachers looked at their students' mathematical errors and how did they view their roles in responding to students' errors, we included four related questions as part of an end-of-year interview conducted within the larger research methodology mentioned at the beginning of the methods section. The questions were: (i) When a student makes mistakes or errors in math, does it mean he/she is a weak student? Explain. (ii) When a student in your class makes math mistakes or errors, how do you react? That is, describe the different ways you typically respond to student errors. (iii) Some educators think that allowing students to present and explain wrong answers to their classmates, puts students at risk of acquiring wrong information or skills. What do you think? and (iv) How much can you do to improve the understanding of a student who always makes mathematical errors? Do you have such students? Explain.

When analysing teachers' answers, we focused on teachers' error attribution (why do they think student make errors?); their views of their own interventions; their views of the role of errors in learning; and their own sense of efficacy in dealing with students errors.

## Results and Discussion

Our findings show beginning teachers moving over time toward more private talk about errors situations with students in their classrooms. This fact may be a reflection of the workshop model being taught to the teachers in NYC in middle and high school math instruction. The workshop model was originally designed to promote interactive pedagogy and creative student learning and has been adopted in NYC public schools since 2003 (Traub, 2003).

Our analysis of the data is also showing variations in how individual teachers develop the way in which they respond to students' mathematical errors. This is due in part to the contextual differences in the culture of the schools where they each teach. The main influence themes that we detected:

Influence of the emphasis on successful test preparation strategy at the school. The focus on the State test preparation led two of our case study teachers to minimize any interactions around mathematical errors. This resonates with other studies that show how high stake tests are narrowing the mathematics curriculum and how teachers filter the policy messages according to their priorities and experiences (Haydar, 2009).

Influence of the workshop model at the school resulted in a shift from teacher ownership to including more students in the correction process. The participatory nature and structure of the workshop model helped some of the teachers especially in the schools where the model was systemically emphasized to delegate some of the correction role to students.

Influence of limitations in content knowledge. Teachers who showed limitations in their content knowledge tended to have more negative immediate reactions, less interviewing during the intervention and more of teacher correction.

Influence of discipline issues. In classrooms where teachers were still struggling with discipline issues, we found a narrowing in the correcting agent to the teacher or the student who made the error especially within public talk. This is in line with what other researchers described as beginning teachers facing challenges in "survival skills" (Kirby et al., 2006). Kagan (1992) affirmed that until beginning teachers have established standard routines and resolved their images of self as teachers, they will continue to be obsessed with discipline and class control.

The analysis of the teachers' interviews permits to draw the following observations:

Error attribution: six of the eight teachers interviewed distinguished between making errors and being weak in mathematics but for different reasons. For some, making mistakes is at least a sign of on-task work : “if they’re making mistakes, they’re doing something, which is half the battle.” For other teachers errors may result from simple confusion or wrong assumption: “I would say that a student who makes a mistake is either confusing something or is making an assumption that he or she shouldn’t make”.
Teachers self-scripted role: half of the teachers explained that they would seek the help of students’ peers: “ I would just tell the student who made the mistake to check with so and so and if you got a different answer try and figure out who’s right”. Others mentioned that, especially in public situation they would start by highlighting any positive aspects in the method that led to the wrong answer and then move to some questioning regarding the error itself: “I always tell them what they did correctly first.”
Errors and learning: six teachers thought that displaying individual students’ errors in front of the whole class can be beneficial. Some saw in that an opportunity to learn from common errors: “They’re going to make mistakes in math all the time anyways, so we might as well learn from the most common mistakes that the students are making.” Others thought that other students in the class are always critical to each other and hence playing the correcting agents “I think it’s very uncommon that a kid leaves the classroom thinking that that was the right answer because of just what the other kids do. They don’t let them get away with that”. Two teachers out of the eight saw some risks in the error public displays, one of them thought “it needs to be made explicit by the teacher and the student that what students presenting at this time is wrong answer”. The other teacher emphasized students’ short attention span as source for a risk of getting stuck on the error without paying attention to the correction: “ so all of the sudden now they think what the person presented was correct because they didn’t pay attention to the rest of the presentation.”
Self-efficacy: teachers sense of efficacy in going about helping students who make continuous mathematical errors varied between admitting a role and ability to help by “ keep working with them”;“ working one-on-one” ; “ try to identify their way of thinking”; “giving them individualized homework”. However, teachers were concerned with time constraints “You can’t sit with them every day either because you’ve got, you know; 29 other kids to worry about.” and students’ lack of cooperation “Some students just don’t even try”. These two factors were the most reported by teachers as hindering their role in helping students who always make mathematical errors.

This paper presented an inside view of how beginning teachers in the NYTF program think and behave when facing their students’ mathematical errors. The influences at the school and policy levels shown in this study along with teachers views of their error handling role and their content and pedagogical knowledge need to be considered seriously in any teacher education effort whether pre- or in-service aiming to help novice teachers reach a comfortable zone whereas they can create challenging yet safe environment where students feel comfortable making and learning from their errors.

# APPLICATION OF THE NECESSITY PRINCIPLE IN INQUIRY BASED MATHEMATICS LESSON DESIGN

Lance Burger
California State University, Fresno
lburger@csufresno.edu

Recently there has been increasing emphasis on constructivist-oriented teaching practices within professional development mathematics communities (Loucks-Horsley et al. 1996). Aimed at promoting inquiry based learning, this poster illustrates an example of curricular innovation inspired by Piaget's notion of *cognitive disequilibrium*, which maintains that "knowledge develops as a solution to a problem" (Piaget, 1997). Harel (2000) reformulated Piaget's ideas as a fundamental principle for teaching and learning in the *Necessity Principle*, which states that:

> For students to learn, they must see an (intellectual, as opposed to social or economic) need for what they are intended to be taught.

A widely pervasive mathematical relationship related to the development of perhaps all biological systems finds expression in the surface area to volume ratio. This poster describes lesson concepts, procedures, sample discussions, and activities coordinated using the Necessity Principle to allow student opportunities for genuine cognitive disequilibrium based on their familiar knowledge of dogs, combined with intellectual and mathematical justifications for topics and methods used. This poster illustrates how subjects were seen to:

1. Create cube models of small dogs and dimensionally doubled large dogs, while mathematically studying comparative surface area to volume ratios in an applied context.

2. Discover mathematical justifications and necessities for using concepts such as proportion, surface area, volume, and unifix cube manipulatives in addressing the 'cooling problem.'

This example of application of the Necessity Principle to lesson design represents preliminary pilot research in a study investigating the effectiveness of intellectual necessity for the transfer of familiar problem solving knowledge to less familiar, non-isomorphic problem settings.

# RESPONDING TO JOURNAL WRITING IN THE MIDDLE GRADES MATHEMATICS CLASSROOM

Kathleen Lynch-Davis
Appalachian State University
lynchrk@appstate.edu

In *Principles and Standards for School Mathematics* (2000), the National Council of Teachers of Mathematics (NCTM) asserts that written and oral communications are vital processes for the learning of mathematics. In fact, there exists a plethora of literature asserting the importance of writing in the mathematics classroom. However, the literature lacks analysis of the difficulties mathematics teachers may have in implementing writing in the classroom, beginning with the creation of writing prompts and proceeding through to responding to students' writing. Therefore, efforts to document the process of using writing in mathematics classrooms could prove invaluable to mathematics teachers and mathematics teacher educator.

The purpose of this poster is to report results from a research study where the aim was to develop a picture of how middle school teachers respond to student journal writing in mathematics. This poster focuses on how the teachers responded to student journal writing and the implications that has for the use of written communication in their mathematics classes.

Looking at the very nature of the teachers' responses allowed me to understand how teachers "listen" to their students thinking, and in turn make statements about what the teachers valued in the student writing. A lens for looking at this work is Davis's (1996) framework for listening. Davis defines three types of listening, evaluative, interpretive, and hermeneutic.

Teacher responses were disappointing. Teachers' responses much like the student responses were short and unelaborated. Most teacher comments on students' papers focused on assessing the quality of student responses, listening evaluatively, something that has been reported in the literature to lack benefit. In fact, almost all teachers' responses were evaluative although the literature reports that to achieve positive results from journal writing teachers should focus on nonevaluative comments (Borasi & Rose, 1989). Evaluative responses denote teachers' listening to students to determine correctness. Consequently, because of this practice teachers were unable to elicit better responses from their students, due to comments, which focused on correcting student thinking rather than trying to interpret student thinking (interpretive listening).

Another factor that caused difficulty in this study was the teachers' inability to respond to student writing in a timely manner. Often times, teachers would become bogged down in responding to student writing and this caused them to have to respond to a lot of writing at one time, in turn affecting the quality of the teacher response. Borrowing ideas from Language education, there exist alternative ways to respond to student writing that can help teachers manage time factors and the amount of writing assigned. Instead of commenting on each individual student response, teachers could engage students in peer sharing and responding, individual conferences, or respond to each student once per week.

As outlined by NCTM (2000), being able to communicate mathematically is a vital process to learning mathematics. A teacher's ability to encourage written communication is important. Therefore, responding to student journal writing is a crucial step. Teachers need to understand that with journal writing the point is not to necessarily critique the student work but is to push students' thinking, not imposing necessarily their own views on the student but to have the student think more deeply about mathematics (Borasi & Rose, 1989).

# THE IMPACT OF A MATHEMATICS IMMERSION EXPERIENCE ON MATHEMATICS EDUCATION FACULTY

Todd Abel
University of New Hampshire
tal9@unh.edu

Karen Graham
University of New Hampshire
kjgraham@unh.edu

Sarah Sword
Education Development Center
ssword@edc.org

This poster will report on the Education Development Center's (EDC) NSF-funded one-week summer institute for mathematics education faculty. The institute was guided by the principle that mathematics education professionals need first-hand experience with coming to understand mathematics and was inspired by a course for graduate students developed at the University of Maryland. It was designed to immerse the twenty-four participants (17 faculty members, 6 graduate students, and 1 retired faculty member) in mathematics, exploring problems posed by the organizers and investigating personally relevant questions posed by individuals or small groups. The group considered how such an experience could guide the development of mathematics courses for graduate students in mathematics education at their own institutions. The third author was the Principal Investigator for this project, and the other two authors conducted the project evaluation. The poster provides a general overview of the program and will focus on two questions that guided the evaluation component of the project: 1) How well does the institute serve the participants' mathematical needs?, and 2) How do participants' courses for pre-service teachers and graduate students change as a result of participating in the institute?

To address the first question we will describe the participants' responses to the mathematical experience. Data sources include participant journals (time was allotted twice daily during the institute for journaling), a follow-up survey, and observation and interaction with the participants. A thorough review of this data highlights several general themes among the participants' reactions to the mathematical immersion experience. For instance, several felt invigorated by engaging in and exploring mathematics in ways that were new, unfamiliar, or uncommon in their professional lives. Many participants related their own experiences to those of their students, and the social and community aspects of the work were impactful. There was some rejection of a perceived insinuation that mathematics educators in general lacked such experiences and would benefit from collaboration with mathematicians, but others anticipated a need for such collaborations in their own contexts. Overall, a general excitement about open-ended, low-stakes mathematical explorations for their own sake developed in the group, and many participants projected their own fulfilling experiences as valuable for graduate students.

To address the second question we will describe the various implementation strategies and professional reflections that occurred following institute participation. At least two participants developed collaborations with faculty members in other departments and taught graduate courses modeled after the institute at their institution. One participant reported moving from a Department of Education to the Department of Mathematics and Statistics as a result of an "awakened desire . . . to teach and 'do' mathematics".

# ANALYZING TEACHERS' MATHEMATICAL ACTIVITY IN AN ONLINE ENVIRONMENT

Ellen Clay
Drexel University
elc37@drexel.edu

Katherine L. Ernst
Drexel University
kle38@drexel.edu

David J. Fischer
Drexel University
djf49@drexel.edu

Jason Silverman
Drexel University
silverman@drexel.edu

Troy P. Regis
Drexel University
regis@mathforum.org

We will discuss our efforts to create an online environment that supports teachers engaging with the practices of "doing mathematics." We feel it is important to differentiate this from U.S. students' (and therefore U.S. teachers) common experience of mathematics as "doing procedure after procedure." In our work, we seek to engage teachers with practices common to professional mathematicians: asking mathematical questions, making conjectures, testing conjectures, proof, and generalization. Hiebert (1999) argued that teachers need opportunities to experience mathematics in the way they are expected to teach; teachers have few opportunities to do so. We believe this could be one reason for the inconsistent adoption of instructional processes recommended by the NCTM process standards (NCTM, 2000), as well as the methods of implementation of reform curricula by teachers (Senk & Thompson, 2003).

The model we use for our interactions is Online Asynchronous Collaboration (OAC) in Mathematics Education (Clay & Silverman, 2009), which was developed primarily to scaffold participants' engagement in legitimate mathematical practices online. OAC involves cycles of individual, small group, and whole class interaction and collaboration. In this poster, we will discuss our recent implementation of OAC in a professional development setting. We will include analysis of teachers' "regularities of practice" – the way they "do mathematics" personally and with their students – and the ways in which the structure and scaffolding provided by (a) the OAC environment, (b) the professional development (PD) facilitator(s), and (c) their colleagues supported the emergence of these mathematical practices. While we feel that professional development of this sort is invaluable for teachers, we also note that it is significant that we are having measurable success doing PD online, which opens up significant opportunities for scaling and for serving traditionally underserved communities.

# DISTRICT-WIDE IMPLEMENTATION OF STANDARDS-BASED MATHEMATICS INSTRUCTION

Drew Polly
University of North Carolina Charlotte
drewpolly@gmail.com

Standards-based curriculum embodies an approach to teaching mathematics that differs substantially from traditional, didactic approaches (Smith & Smith, 2006). Standards-based instruction employs rich mathematical tasks that allow students to explore mathematical concepts, determine their approach to finding a solution, and connect their answer to mathematical concepts by discussing mathematics and their strategies with their colleagues. Research on the use of standards-based curriculum indicates three things: 1) when implemented with a high level of fidelity students using standards-based curriculum significantly outperform their peers who use traditional curriculum on measures of problem solving (Smith & Smith, 2006; Stein, Remillard, & Smith, 2007); 2) teachers require sufficient amounts of support in the form of workshops and in-class assistance while beginning to implement standards-based curriculum (Cohen, 2006, Henningsen & Stein, 1997; Tarr, Reys, Reys, Chavez, Shih, & Osterlind, 2008) and 3) professional development that is content specific and develops teachers' content knowledge in conjunction with teachers' skills related to teaching with standards-based curriculum can positively influence teachers' instruction (Cohen, 2005; Fennema, Carpenter, Franke, Levi, Jacobs, & Empson, 1996; Makros, 2003).

This study employed survey data from over 200 teachers in 18 schools. Each teacher was involved in the piloting of a standards-based mathematics curriculum in a large urban district. Preliminary analysis of descriptive statistics revealed that a great deal of variance exists across schools regarding implementation. Further, teachers employed varying practices to assess students' understanding and supplement the material with other curricular resources. The poster will provide more elaborate details of the findings.

# STRIVING TO MEET THE CHALLENGE OF READING MATH

Barba Patton
University of Houston-Victoria
PATTONB@uhv.edu

Reading math is not like reading a basal reader or novel. Illustrations accompanying situational problems require students to begin at different points to correctly retrieve information. During mathematical testing today's students are expected to read lengthy real life situations and determine logical answers to questions. They are no longer expected to only calculate or manipulate the numbers Reading mathematic texts has put additional processing demands on the math readers that contradict with how readers process narrative and expository texts. The math reader may need to read 1) right to left as well as left to right. i.e. reading a number line, 2) from top to bottom or bottom to top. i.e. reading mathematical tables or 3) diagonally. i.e. reading mathematical graphs.

In addition, the math reader may have very little prior knowledge about lengthy mathematical word problems and a paucity of text material to activate prior knowledge (Patton, 2007). Brennan and Dunlap (1985), Culyer (1988), Thomas (1994) and Thomas (1988) stated in their research that mathematics texts contain more concepts per word, per sentence and per paragraph than any other type of textual material. Young math readers have difficulties visualizing mathematical concepts as the concepts have been addressed previously by memorization or in a very abstract format.

This study's purpose was to determine if teacher candidates were knowledgeable of the various approaches needed to interrupt (read) illustrations accompanying math problems. Subjects were 35 females enrolled in required EC-4 math/science methodology. The seven question instrument was researcher -designed and modeled very closely to the state released 4th grade test. A panel of experts was utilized to equate the proper procedure/s to solve each problem

Since the problems were modeled closely to a state achievement test released items, the success rate of participants (teacher candidates) was expected to be near 100% correct. Participants were successful on most problems. However, only 26% stated that they approached one of the problems in the best manner according to the panel of experts. It is enlightening, and alarming, that eighty-one percent of the participants stated they approached the problem in an inappropriate manner (Patton). More than one approach, therefore it is possible to have the sum of the answers selected greater than 100%.

To effectively teach elementary mathematics, teacher candidates must abandon misconceptions about mathematics teaching. Misconceptions may arise from the teaching practices of the past decades when the students were expected to memorize the facts with little emphasis placed on higher level thinking skills Teacher candidates' views and perceptions of mathematics must be broadened to encompass how teacher candidates more effectively facilitate and interpret the nature of children's thinking. It is time for teachers of elementary mathematics to stop memorizing facts and start developing the metacognitive awareness they need to select appropriate mathematics strategies for learner success (Patton, Klages & Fry 2008). ) Metacognition allows learners to make adjustments to different problem-solving tasks (Montague, 1998). Reading situational math problems with corresponding illustrations are considered to be different problem-solving tasks. Results conclude teacher candidates need more math instruction if they are to be truly successful with their students in the quest of learning.

# AFFORDANCES OF VISUAL REPRESENTATIONS: THE CASE OF FRACTION MULTIPLICATION

Beste Güçler
Michigan State University
guclerbe@msu.edu

Jungeun Park
Michigan State University
parkju20@msu.edu

Raven McCrory
Michigan State University
mccrory@msu.edu

*This study focuses on two instructors who taught a mathematics course designed for prospective elementary teachers and explores which interpretations of fractions they addressed and how they used visual representations when discussing fraction multiplication. Our findings indicate that the distinct interpretations of rational numbers can turn out to be quite intertwined during actual practice. As a result, it might be challenging to extract meaning from the visual representations, especially when the problems are not situated in a context, unless instructors explicitly attend to the interpretations underlying those representations.*

## Introduction

It is challenging to blend research on fractions with classroom teaching for several reasons. First, the development of fractions in the classroom is complex and non-linear. Second, "teachers are not prepared to teach content other than part-whole fractions" (Lamon, 2007, p. 632) and thus we may not see in reality the ideas and constructs that research suggests in theory. Third, teachers may not explain details supporting their choices of problems and representations, making them invisible to research. In this study, we explore some of the complexities of multiplication of fractions in the context of preservice teacher education.

There is evidence that part-whole has been the most dominant realization of fractions for students as well as preservice and inservice teachers (Domoney, 2002; Sowder, Philipp, Armstrong, & Schappelle, 1998; Tirosh, Fischbein, Graeber, & Wilson, 1999). Besides part-whole, Kieren (1980) proposed four other subconstructs or interpretations for fractions: measure, operator, quotient and ratio. Each of these interpretations may be illustrated with multiple representations, including numbers, and various discrete, linear, and area models and more. In her longitudinal study of six classes from grades 3 to 6, Lamon (2007) noted that the students who were exposed to these five subconstructs developed deeper understanding of rational numbers and proportional reasoning compared to students in the control group who received traditional instruction that did not explicitly attempt to use multiple interpretations of rational numbers. (Note that, in this paper we use "fraction" and "rational number" interchangeably, acknowledging that there are important and contested mathematical differences between the two.) As a result, she considers being able to "move flexibly between interpretations and representations" as one of the key elements of understanding fractions (Lamon, 2007, p. 636). Therefore, understanding of fractions entails experience with multiple interpretations (Kieren, 1980) as well as experience with multiple representations of fractions.

According to Izsák (2008), research on teachers' knowledge of fraction multiplication is not as extensive as the research on fraction division and decimal multiplication. There is a body of research indicating that teachers find it difficult to construct appropriate representations for fraction multiplication (Armstrong & Bezuk, 1995; Sowder et al., 1998; Tirosh et al., 1999). In this paper, we look at two instructors who teach mathematics content for undergraduate prospective elementary school teachers. The study addresses the following question: Which interpretations of fractions do instructors teaching elementary mathematics content to undergraduate preservice teachers concentrate on as they teach fraction multiplication, and how do they represent these ideas to students?

## Theoretical Framework

The *part-whole* realization of rational numbers entails "the partitioning of a continuous quantity or a set of discrete objects into equal-sized parts…" (Sowder et al., 1998, p. 8). Therefore, this subconstruct requires understanding of the whole and the ways in which it may be partitioned. The realization of a rational number as a *measure* "occurs when we want to measure something but the unit of measure does not fit some whole number of times in the quantity to be measured" and so "demands that the rational number be understood as a number, as a quantity, as how *much* of something" (Sowder et al., 1998, pp. 9-10, italics in original). A rational number acts as an *operator* when it is interpreted as:

> a function that can operate on a continuous region as a stretcher or shrinker or on a set as a multiplier or divider, in either case serving as a function machine that operates on one value to form an output of another value. (Sowder et al., 1998, p. 11)

A rational number can also be realized as a *quotient*. "A fraction $a/b$ can also represent the quotient $a \div b$ ; that is, $a$ and $b$ are integers satisfying the equation $a=bx$" (Sowder et al., 1998, p. 11). Finally, when we realize a rational number $a/b$ by means of the comparative relationship between $a$ and $b$, we are thinking of the rational number as a *ratio*.

Among the five subconstructs of rational numbers, the operator subconstruct seems to be the most effective for fraction multiplication (Behr, Harel, Post, & Lesh, 1993; Izsák, 2008; Sowder et al., 1998). Lamon's (2007) findings also suggest using the measure subconstruct for fraction multiplication since it might enable the extension of the operator subconstruct. She exemplifies the measure and the operator subconstructs and their meaning for the fraction $3/4$ as follows:

| **Interpretations of 3/4** | **Meaning** |
|---|---|
| Measure "$3(\frac{1}{4}$-units)" | $\frac{3}{4}$ means a distance of $3(\frac{1}{4}$-units) from 0 on the number line or $3(\frac{1}{4}$-units) of a given area. |
| Operator "$\frac{3}{4}$ of something" | $\frac{3}{4}$ is a rule that tells how to operate on a unit (or on the result of a previous operation): multiply by 3 and divide the result by 4 or divide by 4 and multiply the result by 3. This results in multiple meanings for $\frac{3}{4}$: $3(\frac{1}{4}$-units), $1(\frac{3}{4}$-unit), and $\frac{1}{4}$ (3-unit). |

Figure 10. *Portion of the table Lamon (2007, p. 654) uses when she addresses alternative instruction strategies to the part-whole interpretation of fractions.*

In this paper, we investigate how instructors of preservice elementary teachers utilize these interpretations as they represent fraction multiplication.

## Methods

Data for this study comes from a larger project that explores the mathematics content taught to undergraduate prospective elementary teachers. This paper uses data from two instructors, collected through observations of their classes when they taught fractions. Particular attention was given to the visual representations instructors used when addressing fraction multiplication. Fraction lessons were videotaped and portions of the tapes where the instructors discussed fraction multiplication were transcribed. Field notes taken during instruction supplemented the data.

We report on two instructors for whom we will use the pseudonyms Eliot and Sam. These instructors form contrasting cases with respect to the number of visual representations they used when discussing fraction multiplication. Eliot primarily relied on a single visual representation across the problems she solved whereas Sam used multiple representations for each of the problems she worked on. Given this, we investigated the possible impact of this difference on the interpretations of fractions the instructors facilitated in their classrooms. We used snapshots from the classroom videotapes for Eliot's representations to keep the authenticity of her representations on the whiteboard in her classroom. Sam's video snapshots were not clearly visible since she used a blackboard so we used field notes to reproduce her drawings. The researchers checked the fidelity of the field notes with Sam's actual representations in the video clips. We initially analyzed the data with respect to the subconstructs underlying the visual representations the instructors used for each problem individually and then compared our results until we reached consensus. In this respect, we used a form of competitive argumentation (VanLehn & Brown, 1982) during our data analysis.

## Results

### *Eliot's Representations of Fraction Multiplication*

Eliot based her initial discussion of fraction multiplication on whole number multiplication. Although her initial introduction encouraged students to think about fraction multiplication in terms of repeated addition, Eliot also mentioned that multiplication does not necessarily lead to a larger number in the case of fractions. After these, she explicitly pointed out the word *of* means *to multiply* and started modeling fraction multiplication problems using diagrams. Throughout her discussion of multiplication of fractions, Eliot consistently used a visual diagram in which two hexagons were considered as one whole. At the very beginning of her fraction lessons, Eliot introduced these hexagons and their subunits consisting of triangles, rhombi (Eliot used the word rhombuses instead of rhombi so we will stick with her word use), and trapezoids using pattern blocks. Afterwards, she kept on using the same idea by drawing the hexagons on the board. Below is the relationship among the units and the subunits:

2 hexagons (the whole) = 12 triangles = 6 rhombuses = 4 trapezoids
1 rhombus = 2 triangles
1 trapezoid = 3 triangles

Eliot assumed her students knew how to compute fraction multiplication and briefly mentioned the rule. She focused only on modeling during her discussion of multiplication of fractions. For all the problems she worked on, except for one, she used the diagram in which two hexagons referred to one whole. For example, she modeled $\frac{2}{3} \times \frac{1}{2}$ as follows:

| | |
|---|---|
|  | Eliot first modeled $\frac{2}{3} \times \frac{1}{2}$ by considering it as $\frac{2}{3}$ of $\frac{1}{2}$. She shaded one hexagon noting that it was the half of her whole, which was two hexagons. |
|  | Eliot: "What is two thirds of my half? I need to split my half into three pieces and shade two again" (The class was familiar with representing thirds by rhombuses). Therefore, Eliot split the hexagon into three rhombuses and shaded two of them one by one. She then asked what the double shaded region was in terms of the whole. Two rhombuses made up a third of the whole, so Eliot wrote $\frac{1}{3}$ as the answer. |

Figure 11. *Eliot's representation of $\frac{2}{3}$ of $\frac{1}{2}$*

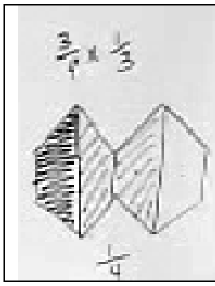
Eliot's wording while shading $\frac{2}{3}$ of one hexagon might be considered as recursive partitioning when she split the hexagon into three equal pieces and shaded two of them. Given this, she might be using the idea of finding part of a part by applying the notion of part-whole recursively. On the other hand, it is also possible that Eliot operated on the hexagon that represented $\frac{1}{2}$ as she split it into three parts (divide by 3) and then shaded two of them (multiply by 2). In this respect, given the description in Figure 1, she might have also used the operator subconstruct. Therefore, for this problem, it is not explicit which subconstruct she is particularly attending to. Eliot then modeled $\frac{2}{3} \times \frac{1}{2}$ again, this time considering it as $\frac{1}{2}$ of $\frac{2}{3}$:

| | |
|---|---|
|  | Eliot noted that in order to take the half of $\frac{2}{3}$, we first needed to know what two thirds of the whole was. She asked, "two-thirds is how many rhombuses? Four" (Eliot used the equivalent fraction $\frac{4}{6}$ for $\frac{2}{3}$ to be able to represent it with rhombuses. The students were familiar with this use). She then divided the hexagons into six rhombuses and shaded four of them. |
|  | Eliot: "What is half of my four rhombuses? Two rhombuses. How much of my whole is shaded twice?" (Note that she used the names of the geometric shapes rather than saying 'what is a half of two thirds'?)<br>She then shaded two rhombuses out of the four rhombuses she already shaded and wrote $\frac{1}{3}$ as the answer. |

Figure 12. *Eliot's representation of $\frac{1}{2}$ of $\frac{2}{3}$*

When finding the half of four rhombuses, Eliot considered four rhombuses as another whole. It is likely that she used part-whole interpretation with recursive partitioning here since she made the number $\frac{2}{3}$ concrete by naming it "four rhombuses". Then half of four rhombuses would be equal to two rhombuses. On the other hand, she often emphasized in her previous classes on fractions that students needed to think about this model in terms of area. For example, when modeling addition of fractions with these hexagons, she said, “we are merging the areas together to find out how much of our same whole the new area takes up”. Similarly, when she explained why $\frac{3}{4}$ of two hexagons would be equal to three trapezoids, she mentioned, “because we can cover three fourths of the area of our whole using three trapezoids”. Given this, she might also be attending to the measure subconstruct (See Figure 1) as she modeled $\frac{1}{2}$ of $\frac{2}{3}$.

Eliot modeled $\frac{3}{4} \times \frac{1}{3}$ by considering it as $\frac{1}{3}$ of $\frac{3}{4}$:



Eliot mentioned that three fourths of the whole would be three trapezoids and shaded them in her drawing. She then asked, “what is a third of three trapezoids? One trapezoid. *Because when you have three of anything, a third of it is one of them*”. She then shaded one trapezoid out of the already shaded three trapezoids and asked how much of the whole was shaded twice. Students answered by saying a fourth. Eliot wrote $\frac{1}{4}$ as the answer.

Figure 4. *Eliot’s representation of* $\frac{1}{3}$ *of* $\frac{3}{4}$

Note that Eliot talked about one third of $\frac{3}{4}$ as one third of three things (trapezoids), which would be the recursive application of the part-whole subconstruct. Here, it seems relatively clear that Eliot used recursive partitioning for finding the part of a part rather than attending to the operator subconstruct. However, when the numerator of the operator is equal to 1, it might also be difficult to identify from the visual representation whether the operator subconstruct or the part-whole interpretation is used.

Eliot might have used the operator subconstruct when she modeled $1\frac{1}{4} \times \frac{2}{3}$ considering it as $\frac{2}{3}$ of $1\frac{1}{4}$. The following is the picture she drew:

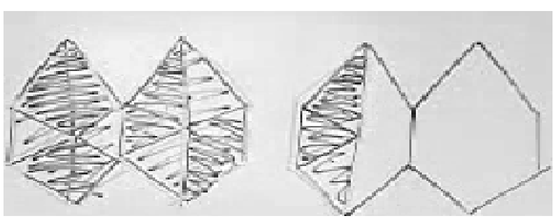


Figure 5. *Elliot’s representation of* $\frac{2}{3}$ *of* $1\frac{1}{4}$.

Eliot noted that $1\frac{1}{4}$ would be equal to a whole plus an additional fourth. Since a pair of hexagons corresponded to one whole, she drew two pairs of hexagons. She shaded all of the first pair and a trapezoid in the second pair that corresponded to the additional fourth. She then said, “You want to ask yourself what is two thirds of the shaded portion? I need to think of a way to cut that into three equal portions…I guess I am going to cut everything into triangles”. After this, she split the shaded portion, which is $1\frac{1}{4}$, into triangular portions. She then noted she was going to shade “two out of every three”. Given Eliot’s previous examples and arguments, one can again assume that she used part-whole interpretation with recursive partitioning. On the other hand, it is relatively clear in this example that she operated on the fourths in $1\frac{1}{4}$ since she split every fourth in $1 + \frac{1}{4}$ into three equal portions (divide by 3) and then took “two out of every three” *fourths* (multiply by 2), which would suggest she was attending to the operator subconstruct. Eliot’s consideration of $1\frac{1}{4}$

as $1+\frac{1}{4}$ when splitting each fourth into its thirds and taking two out of three fourths also signaled an implicit use of the distributive property.

*Representations of Fraction Multiplication in Sam's Class*

Sam also started her discussion of fraction multiplication with whole number multiplication. She structured her class around the three cases: a whole number multiplied by a fraction, a fraction multiplied by a whole number, and a fraction multiplied by another fraction. Similar to Eliot, Sam also mentioned the relationship between the word *of* and multiplication. Sam did not discuss mixed number or improper fraction multiplication. Unlike Eliot who used a single visual representation for each problem, Sam used a variety of visual representations (some of which were initiated by her students) for the problems she worked on. Her representations consisted of pie diagrams, rectangular area models and also the number line. For example, while modeling $\frac{1}{2}\times\frac{1}{3}$, Sam considered it as $\frac{1}{2}$ of $\frac{1}{3}$ and used the following visuals:

| | |
|---|---|
|  | Sam drew this model mentioning, "we draw a whole and then have one third. We then think about what one half of that third is". She split the third she shaded into two parts horizontally following a student's suggestion. She then labeled the portion that corresponded to $\frac{1}{2}$ of $\frac{1}{3}$. |
|  | Sam then asked students if she could split the shaded third into two parts vertically by saying "I will split this to halves." She drew dotted lines and shaded one strip as shown . The students agreed that she could do this vertically. |
|  | Sam: "How about trying other models? How about a pie?" After saying this, she drew a pie diagram and divided it as shown with solid lines. She then added the dotted lines and said "because of that, we have to cut the other parts, so this one half of one third will be what?" A student answered "one sixth of the whole". Sam confirmed this was the correct answer. |

Figure 6. *Sam's representations of* $\frac{1}{2}$ *of* $\frac{1}{3}$

Sam seemed to be using the part-whole subconstruct with recursive partitioning for these representations. However, it is also possible that she might be using the operator subconstruct when she the split the third into two parts and shaded one part. On the other hand, Sam went on and split the other thirds into halves after this step for each of the visuals. In this respect, it is more plausible that she used the part-whole subconstruct with recursive partitioning rather than the operator. In general, it is difficult to distinguish the operator subconstruct from the part-whole subconstruct in situations where the numerator (of the operator) is 1 or when the denominator is equal to the numerator of the operand. The latter is shown when Sam elicited the following representations for $\frac{2}{3}\times\frac{3}{4}$:

| | |
|---|---|
|  | A student drew this representation first by drawing the rectangular region as the whole, then cross-partitioning it and shading three fourths. The student then said, "I will take two thirds of this three fourths" and shaded the two parts as shown on the right. Sam did not add any other explanation for this picture and asked what other models the students could use. |

| | |
|---|---|
|  | Another student drew this picture. In Sam's class, this model is referred to as the bar diagram and is mostly used for situations involving measurement. The student first split the bar into four parts and then labeled three fourths of the whole. She then shaded two parts one part at a time. Again, Sam did not have any additional comments about the picture and asked the class if they could model the same problem using the number line. |
|  | Sam drew this model herself. She first put the numbers 0 and 1 on the line and then divided the interval into four parts. She marked three fourths. She then labeled other points in terms of fourths and asked, "what will be the two thirds of three fourths of this line |
| | (pointing to the region between 0 and 1)? Two fourths (pointing to the region between 0 and $\frac{2}{4}$)". She then labeled the portion of the number line from 0 to $\frac{2}{4}$ as $\frac{1}{2}$ and concluded, "so we can use different models to show the idea of multiplication of fractions". |

Figure 7. *Representations of $\frac{2}{3}$ of $\frac{3}{4}$ in Sam's class*

Sam's primary goal seemed to be providing a variety of representations for this. The student might have drawn the first model using part-whole (recursive partitioning) or operator (split the region into three s and shade two) interpretation. Yet, because the student did not explain her thinking process fully and Sam did not follow up , it is hard to identify which interpretation was in use. Similarly, for the second drawing, although Sam often used a bar diagram for measurement situations, the student might have used the part-whole interpretation with recursive partitioning if she thought about the problem as part of a part. That the part already consisted of thirds blurs whether the student attended to the operator subconstruct when finding two thirds of three fourths. The last drawing seems to clearly use the measurement subconstruct given Lamon's (2007) definition of the notion (See Figure 1). However, Sam did not refer to the numbers in terms of their distances or measures from 0 since she asked what two-thirds of three-fourths would be pointing to the line segment between 0 and 1. If she considered this portion of the line segment as the whole that was partitioned, she might be attending to the part-whole interpretation with recursive partitioning.

In summary, both Eliot and Sam used visual representations to illustrate solutions to fraction multiplication problems. While doing so, Eliot relied on a single representation across problems whereas Sam used multiple representations for each problem. It remains unclear whether their use of visual representations also facilitated understanding of the different mathematical interpretations underlying fraction multiplication.

## Discussion

Identifying the relationships between visual representations and mathematical interpretations was challenging in our study possibly because: (a) different interpretations of fraction multiplication could result in the same representation, and (b) instructors did not explicitly address which interpretations they were attending to as they represented fraction multiplication. For example, in using a subdivided area as both instructors did, whether they interpret fractions as part-whole or operator depends on the language they use to explain the representation and, in some cases, the order in which they subdivide the object. Making the steps clear could tie the fraction more closely to the interpretation or subconstruct. Another possibility is that using real contexts for fraction problems could lend meaning to the fractions that is absent in the abstract representations both of these instructors used.

One difficulty we encountered in analyzing these cases is that *representing a fraction* and *representing an operation with fractions* create different requirements for the teacher. Representing a single fraction using one of the subconstructs is relatively straightforward. Representing an operation, though, is not so easy. A subdivided area, as in Sam's pie diagram, can represent a part-whole fraction. But dividing each piece in half can be seen as creating smaller pieces (part-whole) or as operating on a single piece (operator). The language surrounding the representation as well as the choice of numbers in the multiplication problem is important for what idea the picture evokes for the student.

Does it matter? About this we have little evidence in this study, but previous work by Lamon (2007) suggests that it does matter. If K-8 students end up with a better understanding of and greater fluency with fractions by specifically learning about different interpretations of fractions, then it makes sense that teachers should themselves recognize these interpretations. We see in this case study, however, that the subconstructs of fractions can be intertwined during actual classroom practice. Our findings also indicate that it might be difficult to extract meaning from visual representations unless instructors clearly attend to the interpretations underlying those representations.

This study suggests several important areas for further research. In our view, it is especially interesting and important to understand more fully how explicit instructors of future teachers need to be about fraction interpretations and representations to equip their students – the future teachers of K-8 children – to teach fractions effectively.

## Acknowledgements

This research is funded by the National Science Foundation (Grant No. 0447611). The authors wish to thank the two instructors who generously participated in this project and the other team members – Rachel Ayieko, Changhui Zhang, Andrea Francis, Rae-Young Kim, Jessica Liu, Jane-Jane Lo, Helen Siedel, and Sarah Young – who collected data and participated in discussions that made our analysis possible.

*Prospective elementary teachers must understand fraction division deeply to be able to teach this topic to their future students. This paper explores how two university instructors help prospective elementary school teachers develop such understanding. In particular, we examine how instructors teach the meaning of division, the concepts of unit, and the connections between multiplication and division.*

## Purpose of the Study

The National Mathematics Advisory Panel has identified "proficiency with fractions" as a major goal for k-8 mathematics education because "such proficiency is foundational for algebra and, at the present time, seems to be severely underdeveloped" (p. xvii). However, as acknowledged by the authors of *The Mathematical Education of Teachers* (Conference Board of the Mathematical Sciences (CBMS), 2001) and supported by prior research studies, many prospective and practicing teachers possess shallow understanding of fractions (e.g., Ball, 1990; Ma, 1999; Simon, 1993; Tirosh & Graeber, 1989), and some are convinced that "mathematics is a succession of disparate facts, definitions, and computational procedures to be memorized piecemeal" (p. 17, CBMS, 2001). This characterization stands in stark contrast to the depiction of mathematical knowledge needed for teaching that has arisen from research on the mathematical knowledge that teachers draw upon in the context of teaching. This research (cf., Ball, Thames & Phelps, 2008) suggests that prospective teachers need mathematical knowledge and skills beyond basic competency with the topics they intend to teach. They need, for example, to be able to give or evaluate mathematical explanations, and to connect representations to underlying mathematical ideas and other representations.

How can college mathematics courses help prospective elementary teachers develop the deep understanding of mathematics that they will need for their future teaching? In this paper, we analyze two sets of fraction division lessons for prospective elementary teachers to highlight both the content and nature of two different approaches to achieving this goal. We chose to focus on fraction division because of the well-known and well-documented struggles of U.S. prospective and practicing teachers with fraction division. For example, In Ma's study (1999), 20 of the 21 U.S. teachers were unable to come up with correct story problems for the given fraction division sentence 1 ¾ ÷ ½. The findings of this study provide paradigm cases to highlight the challenges of designing mathematics courses for prospective elementary teachers.

## Theoretical Framework and Prior Study

Based on interviews with U.S. and Chinese elementary teachers, Ma (1999) proposed a 'knowledge package for understanding the meaning of division by fractions" that teachers should have as illustrated in the diagram below (from Ma, p. 77). In this paper, we focus on three specific aspects of this knowledge package, as suggested by the bolded objects in the diagram: the meaning of division for both whole numbers and fractions, the concepts of unit, and the properties and relationships among four basic operations.

Fishbein et al. (1985) identified two primitive models for division: a partitive model and a measurement model. For measurement division, one tries to determine how many times a given quantity is contained in a larger quantity. For partitive division, an object (or collection of objects) is divided into a given number of equal parts (or sub-collections), and the goal is to determine the quantity in (or size of) each part (or sub-collection). The "primitive" version of partitive division restricts the number of equal parts to a whole number, thus precluding division by a fraction, and reinforcing the idea that division makes smaller. Tirosh and Graeber (1989) found that partitive division was the dominating model held by U.S. prospective teachers, which led many of them to believe that in a division problem, the quotient must be less than the dividend, even though they could apply procedures to solve problems with divisor less than one correctly. This finding has prompted increasing attention to fraction division in the measurement context as well as calls for a modified interpretation of partitive division by capturing the idea of division as an inverse operation of multiplication. For example, Parker and Baldridge (2003) suggested thinking about 12 ÷ 2/3 as "12 is 2/3 of what?"

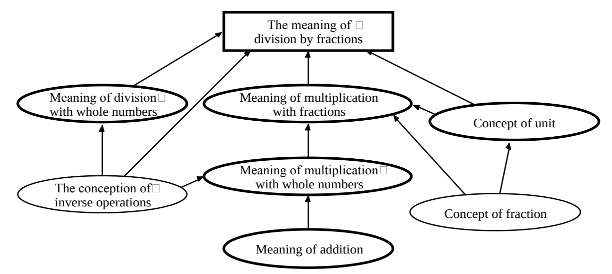

Fig. 3.2. A knowledge package for understanding the meaning of division by fractions
From Ma, 1999, p. 77.

The concept of unit in definitions and in operations is a key part of developing a deeper understanding for fraction division. For example, solving a measurement division problem such as "How many 2/3's are in 2?" requires the students to conceptualize "2/3" as a reference unit and interpret the "2" in terms of chunks of that particular unit: a process called "unitizing" by Lamon (1996). In the context of partitive division, such as when Parker and Baldridge (2003) suggest that students think of 12 ÷ 2/3 as "12 is 2/3 of what?" the unitizing process is more complex. In partitive division an object –the initial unit – is divided into a given number of equal parts, in this case 2/3 of a part. The goal is to determine the size of each part, a new unit, in this case 18. To solve a partitive division problem, a student must conceptualize the "unknown" quantity as both a unit itself and a fraction of a different unit.

Finally, the properties and relationships among operations (addition, subtraction, multiplication, and division) are needed when developing alternative algorithms (e.g. solving division word problems through repeated subtraction) or when explaining why the "flip and multiply" algorithm works.

## Methods

This paper reports findings from the case study component of a large-scale research project that investigates mathematics content courses taken by prospective elementary teachers during their undergraduate education. We focus here on two of seven case studies in the larger study, the cases of Pat and Eliot. During the units on fractions, we videotaped, wrote observation notes, and collected artifacts from students and from the instructor. We interviewed the instructors to probe their ideas about teaching the course, and both instructors completed an extensive written survey about their teaching. As part of the larger project, students in theses courses took pre- and post-tests assessing their mathematical knowledge. Results of these tests suggest that both of these instructors were successful at teaching their students mathematics, producing among the highest gain scores of all 42 instructors in the larger study. (For additional information about the larger project and the pre-post-test results, see McCrory, 2009.)

Both Pat and Eliot taught at universities that prepare large numbers of future teachers in their respective states. They provided the greatest theoretical contrasts in their professional backgrounds and instructional approaches to fraction division among the seven participating instructors. Eliot was a new instructor who had received her Ph.D. in mathematics the previous year. This was the second time she taught this course and her instructional approach was a combination of lecture and individual seatwork. Pat was an experienced math instructor with a Ph.D. in mathematics education and several years' experience teaching high school math. He had taught this mathematics course for future teachers over 20 times. The majority of his class time was spent on a combination of small group work and students explaining and justifying their solutions in front of the class, interspersed with his comments, questions, clarifications, or explanations. He occasionally gave a prepared short (15 minute) lecture. Finally, the course taught by Eliot was a 3-credit math content course that met for 50 minutes three times a week, while the course taught by Pat was a 4-credit integrated content and methods course taught for 80 minutes twice a week.

Data from multiple sources for each instructor was compiled. Tabular materials chronicled the major goals and instructional events of each lesson as well as narratives containing initial memos about the research questions were generated to form the case study database for each participating instructor. The research team went through the videotaped lessons to identify the opportunities prospective elementary teachers had to develop deeper understanding of fraction division. Episodes that illustrated the development of a particular aspect of the knowledge package of fraction division were selected and transcribed for further comparative analysis.

## Results

Our analysis on the fraction division lessons taught by the seven participating instructors uncovered a wide variety of approaches and emphases. The discussion of Eliot's and Pat's lessons helps illustrate such diversity. In the following we will first provide a summary of the main activities for each instructor's instruction of fraction division. Then we will discuss the main differences between these two different instructors using specific episodes from their lessons.

As noted in the introduction the three key features of a deeper understanding of fraction division include: the meanings of division for both whole numbers and fractions, the concepts of unit, and the properties and relationships among four basic operations. In terms of the key fraction division concepts, Eliot's lessons were based exclusively on the measurement interpretation of division. Pat's students had opportunities to make sense of both measurement division and partitive divisions, and also spent considerable time to contrasting the two. In the context of measurement division, both instructors emphasized the process of unitizing, conceptualizing the divisor as the "unit" to represent the given quantity (dividend). ). Eliot explained why the division algorithm worked by utilizing various properties of operations, while Pat facilitated his students' own discovery of the logic and reason behind this algorithm. Next we describe in detail episodes from each of the instructors.

*Eliot' Lessons*

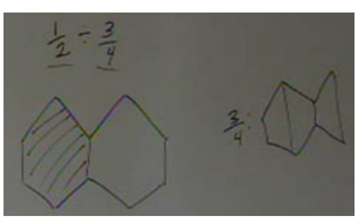

*Figure 1*. Eliot's board drawing for 1/2 ÷ 3/4.

In Eliot's lessons, students were familiar with the "2-hexagon as the whole" model when using it to model operations with fractions. She expected that her students could move flexibly among representations and interpretations such as "1/2 ÷3/4", "How many ¾ in ½?" and "How many 3-trapezoids in one hexagon?" and the drawings associated with them. This was an approach that required developing an understanding of the model itself, as well as an understanding of the operation for division applied to fractions. Eliot modeled such processes for her students as shown in the following episode (see Figure 1 for Eliot's board drawing).

Eliot: Let's illustrate a half which we decided is one hexagon [Draws on board], and just to refresh our memory, three-fourths, we decided was three trapezoids. [Draws on board]. Now do I have an entire set of three trapezoids in my half? No. How much

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

of three trapezoids do I have in my hexagon? [Some students responded two, others responded two-thirds.]

Eliot: Two-thirds. That's exactly it. I have two-thirds of three-fourths in one-half. So I have two-thirds of three trapezoids in two trapezoids. So I have two out of the three I was looking for in my shaded region. Two-thirds. (Transcript, 2/29/08)

In terms of the explanation of why the invert and multiply algorithm works, Eliot used 2/3 ÷ 5/7 as an example. As she wrote on the whiteboard, (Figure 2) she explained each step:

> What you are really doing when you flip and multiply is multiplying by one…. If I were to multiply by something over itself, I would be multiplying by the number one... So I want to multiply by seven-fifths over seven-fifths Have I changed a thing? No. …What is something multiplied by its reciprocal? One. So now all I have is two-thirds times seven-fifths divided by one. Well one is also the division identity. So guess what I have here? Two-thirds times seven-fifths. So what have I done effectively? Flipped it and multiplied. …This is why you can do that, because all you are really doing is multiply by the multiplicative identity. (Transcript, 2/29/08)

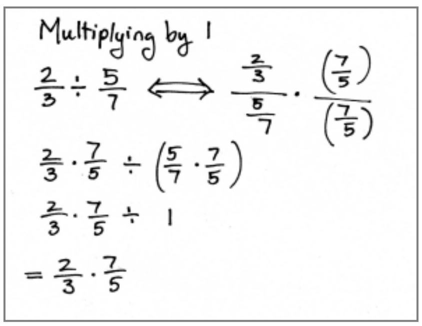

*Figure 2.* Eliot's explanation of "flip and multiply".

During all of her lessons on fraction division, Eliot designed her lessons around modeling with pattern blocks. She provided her students with clear, step-by-step explanations of the process and ample opportunities for them to practice on similar problems both in class where they could get additional support from her and as homework. She provided them with actual pattern blocks during class so that they could physically manipulate them. She acknowledged the struggle some of her students were having and re-visited this topic two more times, once after the quiz and once before the final exam, to address some of the common mistakes her students made. Eliot also modeled for her students how to use reasoning and logic to determine the reasonableness of their answers. She wanted her students know why the division algorithm works.

*Pat's Lessons*

Pat used the following word problem to discuss fraction division in the measurement context. *A batch of waffles requires ¾ of a cup of milk. You have two cups of milk. Exactly how many batches of waffles could you make?*He gave students time to work on the problems in small groups (a mode of work that they were used to), and after about 30 minutes, asked the class what answers they got. Individual students gave answers – 2, 2 ¼ (later changed to 2 ½ after discovering a computation error), 2 2/3, 2 3/8. After some discussion the class agreed that there was enough milk to make 2 batches, and the computation 8/4-6/4=2/4=1/2 was carried out to get the answer 2 ½. One student who thought the answer was 2 2/3 batches was asked to explain his reasoning. He first wrote down 2/4 and ¾ and explained that 2/4 is 2/3 of ¾. He then drew the following diagram (Figure 3) while explaining his reasoning:

Student 1: This is two cups of milk [draws the two rectangles and then sub-divides each into four equal parts]. This is going to be batch number one right here [shades three parts of the rectangles, angle to the right]. And then batch two would be this [shades another three parts, angle to the left]. You got two boxes left. So there would be two boxes left. You need three boxes for a batch, so we have two boxes, we need three for a batch so we are only going to fill in two of these boxes [draws the three circles and shades two of them], 'cause this is one batch right

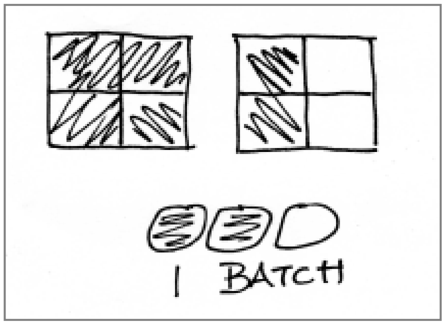

*Figure 3.* Student 1 waffle problem drawing.

here [points to the three circles and writes "1 BATCH" underneath them]. It's every three boxes. We have two left, which means there is two thirds of the last batch. So we have one batch right here [points to first three rectangle parts shaded], two batches [points to the next three], and two thirds of the last batch. ...the number two is two-thirds of three. ... I changed the wholes or whatever…. two-quarters is two-thirds of three-quarters. (Transcript 4/10/08)

Pat re-iterated the entire explanation and emphasized the point of "2 is 2/3 of 3, so you have 2/3 of a batch" which he wrote on the board. He also wrote "2/3 of a batch" and "½ of a cup" on the board for the shaded two of the three circles. He then asked the class what the student meant by changing the whole.

Student 2: Every time you make a batch of waffles, your whole or what is left over changes.

Student 3: You are changing from the whole as being the cup to the whole as being one batch of waffles.

Pat: So a cup is a whole and a batch is a whole… rather than writing 2 ½, you have 2 batches and ½ a cup of milk left over…. These two boxes [pointing to the bottom of the students' drawing] have double meaning. (Transcript, 4/10/08)

Instead of providing his students with a representation like the 2-hexgon, Pat asked them to generate their own drawings. He continued to push his students on being explicit about their explanation. In the process, he provided ample opportunities for his students to make connections among multiple representations: the story context, the drawings, the words, and the number sentences. His students were comfortable with being pushed and they also started to push each other for clear explanations or other their own elaboration without being prompted.

Pat introduced the question of why "flip and multiply" works after discussion of the waffle problem. Many students settled on the number sentence "2 x 4/3" for the waffle problem, but Pat pointed out that 4/3 was not a number in the problem (a requirement for an acceptable number sentence). One student offered an explanation using algebra, $\frac{3}{4} \cdot x = 2$ so $x = 2 \cdot 4/3$. Pat asked for another justification that would work in their teaching, pointing out that an algebraic equation was beyond the comprehension of elementary students. Another student proposed thinking of 4/3 as the number of batches that could be made with one cup of milk. Pat delayed the rest of the discussion until the next class, during which the class worked on an additional contextualized division-by-fractions problem, this one a partitive problem:

*You have 2 cups of flour to make some cookies. This is ¾ of what you need for one full recipe. How many cups of flour are needed for a full recipe?*

Pat again asked students to work on the problem in groups, then to share and explain their solutions at the board. At the end of the second class, he asked students to use the pictorial representations of the two problems to figure out why the invert and multiply algorithm makes sense as a homework problem.

Following the principles of Cognitive Guided Instruction (Carpenter, et. al, 1999), Pat's lessons on fraction division were built upon story problems embedded in daily contexts. His students were encouraged to develop their own solution methods and models to explain their reasoning. Not apparent in the short episode discussed earlier were attempts both Pat and his students made to compare and contrast different models based on different solution methods of the same given problem.

## Discussion

In this paper, we described the opportunities to develop deeper understanding of fraction division offered by two mathematics instructors in their courses. In terms of content, Eliot's lessons addressed topics that were not discussed in Pat's class, while Pat's lessons went deeper in connecting the meanings of whole numbers, fractions, multiplication and divisions through contextualized problems. Furthermore, Pat insisted on developing language and representations accessible to elementary students, while Eliot used concepts and terminology that would not be familiar to elementary school students.

Some of these differences are surely the result of the difference in course purposes: Eliot's a mathematics content course; Pat's an integrated content & methods course. They may also be a result of the difference in instructor backgrounds: Eliot a mathematician and Pat a mathematics educator and former high school math teacher. The effectiveness of these different curriculum models, math first then methods vs. integrated math and methods, is beyond the scope of the current study, as is the effectiveness of their very different approaches to teaching these ideas. We can observe, however, some differences in the mathematics of the lessons and provide conjectures about what these differences might mean for future teachers.

One big difference is the representations and how they were used. Eliot relied on pattern blocks and modeled reasoning with pattern blocks for her students. Pat encouraged his students to generate their own diagrams and expected them to use the context of the story problems to support their explanations. Both approaches get at the meaning of fractions and require moving flexibly across representations, which Lamon (2007) noted as a key part of fraction division understanding.

We also noticed a difference in the level of abstraction different representations demanded. For example, in Eliot's case, students need to be able to relate the actual physical blocks with the fraction quantities each block represents. Although the manipulatives are "real", the association of the block with the fraction is abstract and requires learning to connect the two. In Pat's case, the students need to create diagrams that connect with fraction quantities and the corresponding unit. In this case, the connections have meaning outside of the realm of mathematics, and may not be experienced as abstract. They also needed to attach each number and picture to something in the context of the word problem. The uses of both manipulatives (e.g. pattern blocks, fraction bars) and student-generated diagrams have been the primary focus of prior research investigations, and the findings have highlighted the complexity of making such contexts meaningful in elementary classrooms (e.g. Olive, 2000). The question, "How might these different uses of representations affect the development of deeper understanding of fraction division among prospective elementary teachers?" is worth pursuing.

The goals of mathematics courses specifically designed for prospective teachers should go beyond K-12 mathematics in order to distinguish themselves from mathematics courses for non-teachers. Both instructors did this. Eliot takes the students to mathematical explanations of the underlying mathematics that would not be appropriate for elementary students (e.g., the "flip and multiply" explanation) but, if successful, serves to provide the future teachers with deeper understanding of why the algorithm works. Pat's use of story problems requires students to understand why the problem is division and write number sentences for the problems they are learning. They give public explanations for their reasoning, thus teaching each other.

In this paper, we analyzed two sets of fraction division lessons for prospective elementary teachers and highlighted how two different representational contexts were used to achieve this goal. Even though mathematics courses for prospective elementary teachers are just a small component of the professional development continuum, these courses provide a common context to reach a large number of prospective elementary teachers. Thus it is important that we continue to explore how such classes are taught and how instructors choose and use representations to help future teachers learn mathematics.

## Acknowledgements

*Research has painted a dreary picture of preservice elementary teachers' preparation to teach school mathematics. A response to this problem has been to focus on the mathematical knowledge that is needed for teaching. However, another response remains largely uninvestigated—the learning to enact mathematics teaching. In this paper we report on our ongoing investigation of elementary preservice teachers' learning of mathematics teaching practices. Here we focus more narrowly on one of our focal practices and report our progress defining and unpacking the ways prospective elementary teachers at different stages in their teacher preparation program perform interpretations of students' mathematical work. We report on the conceptual and empirical work we have done to define the practice of interpreting with greater precision and with the goal of broadening what might be considered competent performance, especially for those just beginning their studies of mathematics teaching.*

## Introduction

The practice of listening to and making sense of students' mathematical ideas comprises much of the work of mathematics teaching. Either on the fly or when grading papers, teachers are constantly reading and interpreting what students say, write, and do. Such interpretations inform teachers' instructional decisions and actions—which in turn affect students' access to, and opportunities to learn, mathematics. It is therefore no coincidence that there is so much emphasis in reform documents and rhetoric on the need for teachers to develop new and better ways of seeing, interpreting, and handling students' mathematical ideas.

Noteworthy here is that although we can all recognize that the practice of interpreting students' mathematical work is essential to teaching, this practice is not named anywhere as an explicit object of study in teacher preparation. The study of teaching is focused on the knowledge, skills, and dispositions that support teaching practice, and not on the practices themselves. Yet increasingly we find preservice and inservice teachers working on instructional activities that prompt them to interpret students' work and to sometimes construct a teacher response. While there is an increasing collection of such materials for teacher learning, much less work has been done to understand the practices of mathematics teaching that those instructional activities aim to develop, especially at the early stages of teacher preparation.

In this study we are concerned with unpacking the practice of *interpreting* students' mathematical work by characterizing the performances of elementary preservice teachers who are at different stages in their teacher preparation. By examining closely the differences and similarities among these prospective teachers' interpretations we seek to generate more detailed descriptions of how the practice of interpreting students' mathematical work is performed by those who are just beginning their formal studies of mathematics teaching.

## Theoretical Framing

We draw on the research literature in mathematics education to broadly define the practice of interpreting as the work teachers do to figure out students' mathematical ideas expressed in oral or written form. In theory, this is a practice that teachers get better at as they gain more experience with students' ways of thinking and doing mathematics. It is also reasonable to assume that as teacher preparation students move through their program, they accumulate exposure to the work of mathematics teaching, and hence to the practice of interpreting students' mathematical work. As we considered how one might differentiate between an uninitiated and an experienced student of mathematics teaching, in terms of how they might interpret students' mathematical work, we found that such distinctions have been theorized more so than empirically established and mainly with a focus on practicing teachers.

Davis (1996) theorized three orientations to listening in mathematics classrooms (evaluative, interpretive, and hermeneutic) and suggested that a hermeneutic orientation (one in which the teacher and students co-construct and negotiate meaning) is rare and mainly performed by accomplished teachers of mathematics. An evaluative orientation, on the other hand, is quite prevalent and indicative of mathematics teaching of poor quality. In fact, Crespo (2000) found that elementary preservice teachers, as Davis suggested, had difficulties interpreting students' work and an overall tendency to promptly evaluate without carefully analyzing it. Additionally, Sherin's (1997) notion of teachers' professional vision—which she defines as the ability to notice and interpret significant features of classroom interactions—is also an attempt to describe teaching practice. She argues that teachers, as all professionals, develop particular ways for looking and making sense of what happens in classrooms. They develop selective attention to classroom events (focusing and narrowing the landscape of what needs to be made sense of) and then use various strategies to make sense of what is noticed.

Drawing on Davis' (1996) descriptions of teachers' *orientations to listening* and Sherin's (1997) construct of *professional vision* we conceptualized the practice of interpreting students' mathematical work as embodying aspects of 'noticing' (what is selected as the focus of analysis) and also strategies and orientations to the analysis of students' mathematical work (how the analysis is performed). In order to interpret students' mathematical work, teachers then need to purposefully select what is important and use some analysis strategies to unpack that work.

We used the distinctions and descriptions provided by Davis (1996) and Sherin (1997) as starting points but it became evident that we needed more conceptual tools to help us make distinctions among preservice teachers of elementary school mathematics that were at the very beginning of their professional preparation. As Hiebert and colleagues (2007) suggest, we needed to define a more reasonable and a wider set of performances for those beginning their formal study of mathematics teaching than the expert teaching practices that are more readily available and discussed in the research literature. We have therefore adopted three conceptual tools to help us make distinctions across a range of performances and allow for a broader sense of what we might consider competent practice for a beginner. We are conceptualizing mathematics teaching as a set of practices for which teachers build a *repertoire*, as practices that can be bound to, or flexibly used across, *teaching genres*, and as practices that have both *imagined* and *implemented* performances.

In using the concept of *repertoire* we are borrowing from music education, where it typically means a collection of well-practiced pieces (routines) that are ready to be performed publicly. Our hypothesis is that experienced teachers would have a broader collection than inexperienced teachers, and that they would be able to de-compose and re-compose their collection (set of routines) much easier than novices.

By using the concept of *teaching genre* we are hoping to be able to look at a wide range of teaching practices rather than draw a line between teaching that is usually seen as reform or traditional– and think about the ways that those learning to teach execute the practices of posing, interpreting, and responding within and across these genres. By drawing on the notion of genre, we could think about differences between beginning and experienced teachers in the way they did something like assign and correct practice problems as well as differences in more complex genres of teaching like facilitating a mathematical discussion. We expect that some genres might be easier to learn than others.

Finally, because teacher preparation students do not have a fully developed practice, we have adopted the terms *implemented and imagined* enactments of practice to describe a distinction and relation we see between these two forms of teaching practice. To us these two forms are equally important in the construction and development of a repertoire of mathematics teaching. For example, it would be difficult to consistently and thoughtfully enact teaching moves that one has not imagined as possibilities and rehearsed in some imaginary, vicarious, or simulated situation.

## Methods

The practice of interpreting students' work is not performed in a vacuum but rather happens in conjunction with other instructional practices. Hence, we study the practice of interpreting in relation to two other practices not discussed here (that of posing mathematical tasks to students, and of responding to their mathematical ideas). We conceptualize these three practices as interrelated. Even within the simplest of math lesson structures—introduce task, monitor students' work on that task; and then close the lesson—teachers find themselves enacting the practices of posing, interpreting, and responding. Previously (at this conference) we presented about this project's goals, design, and initial insights from pilot data (see Crespo et. al, 2007). In this paper we report on the cross-sectional phase of the study with a focus on the practice of interpreting to look more specifically at how preservice teachers who are at the beginning, middle, and end of their program conduct interpretations of a given students' mathematical work.

### *Studying Teaching Practice with Written Tasks*

As in many other research projects, we use paper-pencil teaching scenario tasks to collect data about the participants' enactments of mathematics teaching practice. While it might seem odd to study teaching practice anywhere but inside classrooms, researchers have used proxies to real classrooms for a long time. In our case and because teacher education students construct performances of mathematics teaching long before they have the opportunity to try them out in an actual classroom, we began our explorations of preservice teachers' performances of teaching practice by using written scenario tasks.

The conceptual tools of repertoire, genre, and imagined/implemented practice played key roles in the design of the paper-pencil instruments used in this project. First, we consider all responses to our paper instruments to be *imagined* performances of teaching practice. Only practice that we observe in an actual classroom is considered as *implemented*. Furthermore, in designing the project's written tasks we paid close attention to the implied *genre* of mathematics teaching that particular scenarios suggested. We have explicitly designed teaching scenario tasks that are not clearly identifiable as belonging to a particular genre of mathematics teaching. We have also included tasks that can be identified as portraying a particular genre, in particular those explicitly promoted in the teacher preparation program where this study is located.

Following on our assumption that the teaching repertoire of experienced and beginning teachers are quite different we also designed tasks that would allow us to peer into the range and depth of the participants' repertoire of posing, interpreting, and responding practices. While it is impossible to get a complete picture of anyone's entire teaching repertoire, we designed tasks to prompt participants to share multiple ways they could imagine performing the target practice. For instance, one particular task prompts participants to "share at least three different ways you can imagine setting up this task in a classroom."

Because we are studying three practices (posing, interpreting, and responding) that are intricately connected and that for the most part happen altogether within a single lesson, we designed our instrument so that each task places the respondent at the start of a math lesson and prompts them to perform the practices of posing, interpreting, and responding within a lesson. All of our tasks' math content was focused on the strand of Number and Operations. We designed and used 6 such tasks but in this paper we only focus on only one (shown below). Task 1(a) shown in Figure 1 focuses on the practice of posing a mathematical task, and 1(b) focuses on the practice of interpreting students' mathematical work.

1. (a) Imagine you are going to ask your class to solve the following addition. What can you imagine saying and doing to get them ready to work on this task?

$$\begin{array}{r} \mathbf{258} \\ \underline{\mathbf{+389}} \end{array}$$

**Teaching Scenario Continued**

1. (b) Imagine that a student shows on the board the following strategy for adding.
   i.) What would you want to make sure your class notices in this student's work?
   ii.) What are three different questions you can imagine asking to the class about this student's strategy, and say a bit about how these three questions are different?

$$\begin{array}{r} \mathbf{258} \\ \underline{\mathbf{+389}} \\ \mathbf{17} \\ \mathbf{130} \\ \underline{\mathbf{500}} \\ \mathbf{647} \end{array}$$

*Figure 1:* Sample P-I-R project task*.

* This task was adapted from a mathematics-for-teaching task used by another project at the authors' institution. Original task was developed by the IMAP (Integrating Mathematics and Pedagogy) project.

*Data Collection and Participants*

The project's instrument was administered in the Spring 2008 to elementary preservice teachers who were at three different stages of teacher preparation (Junior, Senior, and Internship). Roughly speaking the junior year of this program focuses on children as learners. During the Senior year, they study teaching methods in each of four subject areas (mathematics, literacy, science and social studies). During the Internship, they spend a year working with a mentor teacher (and supported by a field instructor) as they take increasing responsibility for teaching in each of the subject areas while also taking four graduate level courses of teaching methods throughout the year.

All preservice teachers enrolled in the program were invited to participate in the study. The tasks were administered during class (when instructors were able to fit us into their class schedule, typically at the end of class so that students could choose to participate or leave the room) and also outside of class (during lunch hour). Participants were given 30-40 minutes to complete either form A, B, or C; with each form including 2 of the teaching scenario tasks. Participants were invited to complete more than one form. A total of 126 Juniors, 152 Seniors, 69 Interns participated in the cross-sectional study. Task 1 was included in Form A and was completed by 46 Juniors, 42 Seniors, and 56 Interns.

## Some Results

Our work in this project has reminded us that even though there seems to be an over abundance of descriptions of mathematics teaching practice, the field lacks clear language to characterize with more precision those practices. This becomes very apparent when attempting to distinguish among a set of questions, which could have been generated by experienced teachers. Figure 2 offers a few sample responses to task 1b (ii) that were constructed by pilot participants who were and were not teachers. Figuring out (and explaining reasons for) which of these questions one might think were made by which group of participants is not that simple.

- Can someone explain why Susie has 130 in the second line and not 13?
- Does someone have a different way to solve this problem?
- Why did this student put zeros in their work?
- Why didn’t this student carry the numbers?
- Will this work for any 3 digit + problems? For any + problem? For any problem?
- Can you see how this student was able to get to the answer?
- Why did they add 17, 130, and 500?
- How do you know that this answer is correct?

*Figure 2*. Sample responses to task 1b(ii) “three different questions you can imagine asking …”

Would we be surprised if we learn that all of these questions have been generated by non-teachers; by experienced teachers? What would we consider ‘typical’ and ‘not typical’? Which of these would we agree should be in all teachers’ repertoire of mathematics teaching (and why)? In order to be able to address these sorts of questions, this project aims to generate more precise language and descriptions of three focal practices of mathematics teaching. We are also proposing that these practices need to be explicit objects of study. But most importantly, as Hiebert and colleagues (2006) suggest, we aim to not just map expert performances of these practices, but to construct descriptions of beginners’ enactments of these practices.

### *Developing Analytical Rubrics*

While designing analytical rubrics to code the participants’ responses to the project’s tasks we have had to continually revise and rework our definitions. Initially we broadly defined interpreting as the practice of figuring out students’ mathematical ideas expressed in oral or written form. Later we had to make our definition more precise and applicable to the project tasks. For the practice of interpreting our current working definition is that it involves the process of selecting (and discarding) and then analyzing and drawing conclusions from data (in this case students' work). It involves narrowing the data (what Sherin calls 'selective attention') and making low and high inference observations—such as describing, explaining, comparing, evaluating—about that data.

Because task 1b includes a student's work that features non-traditional arithmetic algorithms our rubric is also consistent with criteria articulated by Campbell, Rowan, and Suarez (1998)—validity, generalizability, and efficiency—that teachers should consider to support student-invented strategies in teaching situations. Ball, Bass, and Hill (2004) also suggest these criteria when stating that there is some relevant work teachers must do in order to be able to respond to students' strategies they haven't seen before—what, if it exists, is the method and will it work for all cases? What these (as well as many other) mathematics educators suggest is that teachers, upon encountering a non-standard piece of mathematics (especially if proposed by students), would carry out some analysis about the validity of the method, not only whether it produces the correct answer, but how and why it works. They would explore if the method works for other examples and perhaps contrast or connect with other methods. They might also explore if and when it makes sense to use (or not) this method.

Our rubric for Task 1(b), therefore, attempts to capture these aspects of the practice of interpreting students' work. It includes codes for parts (i) *what is important to notice in the student's work* and (ii) *questions one might ask about the student's work*. For both parts (i) and (ii) the response is first coded in terms of where the focus of attention is (A. the answer, B. the method, C. Big ideas) allowing for the possibility that attention can be spread across all three foci (to be consistent with our notion of repertoire). In fact, mathematics educators have often alluded to teachers needing to develop multiple lenses and peripheral vision in the classroom (i.e., Lampert, 2001). Then each category is coded in more detail to characterize more precisely the analysis work that is done on the answer, the method, and/or big idea.

A. Focus on Answer – (A1: Answer is correct; A2: incorrect; A3: other evaluation of answer)
B. Focus on Method – (B1: description; B2: explanation; B3: comparison; B4 evaluation)
C. Focus on Big Ideas – (C1: Mathematical; C2: Pedagogical)
E. Explanations are or not provided for generated questions in (ii) – (E0 and E1)

<u>*Sample statements for task 1b(i):*</u>

(A1): "to notice that the student was able to come up with the correct answer."
(A2): "this is wrong for adding but perfect for multiplication."
(A3): "this is set up as a multiplication problem not an addition problem"
(B1): "that they added each column and put the whole answer down."
(B2): "adding the 2 and 3 in the 100's column does not give you 5, it gives you 500."
(B3): "instead of carrying the 1 the student placed it beneath and worked downward instead of from right to left."
(B4): "this is a different but not incorrect method of finding the sum."
(C1): "that this strategy relies on place value to work."
(C2): "I would also want to see what other students were thinking about this problem."

<u>*Two sample responses to task 1(b)*</u>

(i) I want to make sure that the class notices that there is more than one way to solve math problems. They are free to use whatever strategy they choose to arrive at the correct answer. I want the class to pay close attention to place value (ii.) Can you tell me how you started this problem? Will this strategy work for all addition problems? Can you think of a time when this strategy would not be the most effective? (Student A)

*(i) I would want my class to notice how the student used the different numerical places in order to help him/her solve the problem. (ii) Is this a sufficient strategy to use when adding? Why or why not? Why did the student start from the ones place? Would it have made a difference if he/she began from the hundredths place? Is this the correct answer? How do you know? * These three questions are different because the first one deals with the efficiency of the problem (is it the fastest way to get to the answer), while the second questions deals with the place values. The third question focus on the answer, and whether it is correct and why. (Student B)*

Student A's response was coded as follows. Part (i) was judged as exhibiting attention to the answer and a mathematical big idea—place value. More specifically the response was characterized as C1, A1. The three questions generated in response to (ii) of the prompt were judged as exhibiting attention to the answer and the computational method. It was assigned the following codes: B1, A3, B4. In turn, student B's response was coded as follows. Part (i) was judged as exhibiting attention to a mathematical big idea – "numerical places." More specifically the response was characterized as C1. The three questions generated in part (ii) were judged as exhibiting attention to the method and the answer and the response was characterized with the codes B4, B2, A1. We chose these two students as examples not because they were the 'best' or because they stood out from the rest, but rather because these statements were common across all the cohorts of participants. What is noteworthy also about these and other similar comments is the breadth of what these two students were able to notice about the given student's work. If task1b had only used prompt (i) or (ii), we would have missed the range of what these students are considering (answer, method, big idea) when asked to interpret a student's mathematical work.

*Contrasting Cross-Sectional Interpretations*

Our initial observations from the pilot data were that as a group the non-teachers had a narrower repertoire (in both what they noticed and in the types of questions they generated about the students' work) than the experienced-teachers group. We also noticed that the experienced teachers made noticing statements and generated questions that were not at all made by the non-teachers group. However, we also found that there were also unexpected overlaps between the two groups. We were therefore curious about what we might learn by examining the performances of those who were at the very beginning, right in the middle, and at the very end of their formal study of elementary mathematics teaching.

Simple frequencies (see Table 1) of the coded performances in tasks 1b (i) and (ii) using the developed rubric showed that when interpreting the given student's mathematical work the main focus of attention for all the cohorts (including students who were enrolled in a pre-requisite course but not yet applied to the teacher preparation program – Pre-TP) was mainly on the computational method (B). Additionally, the most frequent type of analysis was that of description (B1), regardless of how far along the participants are in the program.

*Table 1*
Distribution (in percents) of Participant Statements across Rubric's Criteria

| TE Stage | No. Participants | Task | A1 | A2 | A3 | B1 | B2 | B3 | B4 | C1 | C2 | E0** | E1 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Pre-TP | 32 | 1b(i) | 16 | 22 | 0 | 50 | 22 | 16 | 16 | 34 | 9 | N/A | N/A |
| Juniors | 46 | 1b(i) | 4 | 2 | 22 | 65 | 35 | 22 | 17 | 33 | 15 | N/A | N/A |
| Seniors | 42 | 1b(i) | 12 | 5 | 7 | 57 | 26 | 26 | 14 | 88 | 12 | N/A | N/A |
| Interns | 56 | 1b(i) | 9 | 2 | 20 | 70 | 52 | 14 | 16 | 70 | 16 | N/A | N/A |
| Pre-TP | 32 (91 Q*) | 1b(ii) | 25 | 22 | 6 | 59 | 16 | 19 | 38 | 25 | 25 | 53 | 28 |
| Juniors | 46 (123 Q) | 1b(ii) | 20 | 0 | 37 | 48 | 26 | 24 | 37 | 30 | 2 | 46 | 54 |
| Seniors | 42 (113 Q) | 1b(ii) | 14 | 2 | 12 | 69 | 26 | 26 | 36 | 79 | 5 | 55 | 45 |
| Interns | 56 (172 Q) | 1b(ii) | 29 | 0 | 46 | 63 | 48 | 29 | 38 | 34 | 4 | 11 | 89 |

*Note.* * (# Q) means total number of questions generated by the participants
** E0 means – no explanation; and E1 means explanations were written

In terms of differences, the interpretations made by those who were farther along in the teacher preparation program (Interns) had, in addition to the focus on the description of the method (B1), a prominent focus on the explanation of the method (B2) more than the other three groups. They also provided the highest percent of explanations for the questions they generated about the student's mathematical work. The Interns and those in the middle of the program (Seniors) also had a strong focus on the mathematical big idea(s) that were involved in the solution method of the student. It is hard to tell whether this could be a product of being in the classroom more or having completed more coursework. While we have not yet delved into making finer categories about the quality of their noticing and questions, one thing that is remarkable, however, is that although the practice of interpreting is not explicitly taught at this institution's teacher preparation program, the preservice teachers who are farther along in the program do pick up and learn to enact some aspects of this practice on their own. We wonder what more they might learn should this practice become an explicit and systematic focus of instruction in teacher preparation.

## What Next?

Coding and analyzing the cross-sectional responses to task 1(b) showed us some important differences and similarities in the ways prospective elementary teachers at different stages in their teacher preparation program perform interpretations of students' mathematical work. Our rubric has helped us to identify salient responses for each cohort of participants and to also identify aspects in the practice of interpreting students' work that seem productive to build on and aspects that appear to be challenging for those at the very early stages of teacher preparation.

Because we are looking at the collective rather than individual performance of preservice teachers and because we are using the conceptual lens of repertoire, we have been able to elicit and see a wider range of performances from preservice teachers than we expected. Our analysis so far suggests that preservice teachers may have a much broader collection of interpretive moves than the research literature has reported in the past. There is however much work still to be done to further unpack these participants' interpretations of students' mathematical work. In terms of what comes next, we are currently in the process of exploring clusters and combinations of interpreting moves performed by participants. We are also continuing the work of developing more detailed descriptions and finer distinctions among the cohorts as to what might be considered reasonable performances at different stages of teacher preparation.

*Prospective elementary mathematics teachers should be able to understand how their future students understand number concepts. A difficult concept is that of rational numbers. Rational numbers often have complicated means of representation, signifiers and signifieds, making them difficult for students to understand and teach. In this paper, we describe how one teacher integrates a theory of semiotics when instructing prospective elementary school teachers about rational numbers. We propose that by teaching prospective teachers about semiotics, connections between signs and units are made explicit and prospective teachers will be more equipped to approach the instruction of rational numbers to future students*.

## Background on Obstacles to Understanding Rational Numbers

Lamon (2007) suggests that fractions are a subset of rational numbers, in that fractions are notational and are "non-negative rational numbers" (p. 635). We are interested in how to instruct preservice elementary school teachers to move beyond simply the use of symbols (notational systems in which there are two integers written with a bar between them) to a conceptual and transferable understanding of what those symbols represent.

Preservice elementary teachers often have trouble understanding and ultimately teaching future students about rational numbers (Graeber, Tirosh, & Glover, 1989; Harel et al., 1994; Simon & Blume, 1994). One key issue that prospective teachers face when they are trying to understand and work with rational numbers is whether a fraction is related to division, is a type of multiplication, or is a ratio of some sort (Ni, 2001). For example, Behr and his colleagues (Behr et al., 1993, 1994) demonstrated that transformation involved in solving problems with rational numbers use compositions and recompositions of units. The part–whole construct for 2/3 suggests two interpretations: two-third as parts of a whole are two one-third units, i.e., 2(1/3-unit), or two-thirds as a composite part of a whole is one two thirds unit, i.e., 1(2/3-unit). In the number sentence $2 \div 3 = 2/3$, fractions are related to the idea of division. However, in another sense, in order to get 2/3 you must first define 1/3 and then multiply it by the number of 1/3rds that you have. Further, if the numerator and denominator are meant to express a ratio—like there are two dogs for every three cats, then 2/3 cannot be thought of in either of the above ways. You cannot have 2/3 of a dog.

## Purpose of this Study

In this paper we consider how semiotics instruction can be used to help preservice elementary school teachers learn about rational numbers. While there may be many reasons why rational numbers are hard for students to understand, from a lack of prerequisite knowledge to a lack of working memory to hold multiple numbers in mind at one time, we are going to focus on how different meanings denoted by a single representation of a fraction in different relevant contexts may lead to an inability to fully understand rational numbers. We describe how one professor used a dyadic, or two part, semiotic framework developed by Ferdinand de Saussure (1957) to help instruct preservice elementary school teachers about rational numbers. Furthermore, by using this framework, the teacher was able both to decompose the problems themselves and to give the preservice teachers a way to understand how their future students will view the problems.

## Theoretical Framework: Why the Study of Rational Numbers is a Semiotic issue

Semiotics, broadly conceived, "is concerned with everything that can be taken as a sign" (Eco, 1976, p. 7), including "images, gestures, musical sounds, objects…these constitute, if not *languages*, at least systems of signification" (Barthes, 1967, p. 9). Ferdinand de Saussure (1957) described a linguistic sign as a two-sided entity made up of a signifier and signified. A signifier is the material aspect of the sign whereas the signified is the mental concept associated with the material symbol. For example, the English word "tree" is made up of the material sounds /t/, /r/, and /e/ (the signifier) as well as the mental concept we each hold of what it means to be a "tree" (the signified).

In addition to the simple model of a signifier and signified, one must also bear in mind the community in which this relationship takes place. Saussure (1957) reminds us that regardless of the signifier a linguistic system uses "to designate the concept 'tree,' it is clear that only the associations sanctioned by that language appear to us to conform to reality" (p. 66-67). Thus, there are many different signifiers that can represent the same signified. In the field of semiotics, "langue" refers to the collection of signs, the overall system of signification, that permit individual speech utterances. Put another way, "langue" is "language minus speech," the structure that permits individual utterances (Barthes, 1967, p. 14). Depending on how the words are combined in a phrase or what words are chosen in a particular phrase, the concept of the signified may change. In other words, the meaning of a sign is not contained within the signifier or signified alone, but develops within a phrase and within a community as well. To make sense of the sign, not only do the signifier and signified need to be taken into account, but the context that contains that sign must also be considered. One type of sign may be signified by a written symbol. Therefore, it follows that one way to study and begin to understand rational numbers is by using semiotics.

Taking the idea of rational numbers as signs, we can see how it can be difficult for students to make sense of them. A single signifier of a rational number, like two whole numbers with a bar in between them (ex – ½), can take on multiple meanings. Consider the following uses of rational numbers taken from a popular book used to teacher prospective elementary teachers mathematics (Billstein, Libeskind, Lott, 2007, p. 299) (Table 1):

*Table 1*
Uses of Rational Numbers

| Use | Example |
|---|---|
| Division problem or solution to a multiplication problem | The solution to 2x = 3 is 3/2. |
| Partition, or part, of a whole | Joe received ½ of Mary's salary each month for alimony. |
| Ratio | The ratio of Republicans to Democrats in the Senate is three to five. |
| Probability | When you toss a fair coin, the probability of getting heads is ½. |

In the example, a rational number could be used as division, to partition something, as a ratio, or even as a probability. Similarly, Kieren's semantic analysis of rational number identifies five "subconstructs" of rational numbers. They are part–whole, ratio, quotient, operator, and measure (Behr et al., 1992; Kieren, 1976). Depending on the context, the meaning of the rational number—even if it is represented by the same numbers—changes.

Consider the following question out of context. What does 2/3 mean? This signifier, 2/3, could mean any of the following (the list is certainly not exhaustive):

- 2 candy bars shared equally by 3 people, each person gets 2/3
- 2 dogs for every 3 people
- 2 ÷ 3 = 2/3
- 1 ÷ 3 = 1/3 (partitioning), there are 2 1/3rds = 2/3 (iterating)
- 2 parts, with 3 equal parts to make a whole
- 2/3 = 4/6 = 6/9, etc.
- It could be 2/3 of a number greater than one, like 6, which is equal to 4
- It could be 2/3 of a number less than one, like 1/6, which is equal to 1/9

We posit that one difficulty students have when trying to first understand and then later teach rational numbers is that they must navigate across multiple meanings, or signifieds, for the same symbol, or signifier, a relatively common task in spoken and written language, but not necessarily common in the understanding of numbers. We use the phrase 'semiotic dissonance' to describe the difficulty or inability for a person to meaningfully construct a sign from a signified (meaning) and its associated signifier (symbol). Further, when a teacher develops the ability to navigate across meanings, he or she must be able to step back and understand how future students must then navigate across meanings. This understanding is the basic semiotic framework that we will refer to for the rest of this paper.

## Mode of Inquiry: A Case of One Teacher Using a Semiotic Framework to Teach Rational Numbers to Prospective Elementary Teachers

As part of a larger study that explores the mathematics content taught to undergraduate prospective elementary teachers, this paper focuses on one of seven instructors who were video-taped while they taught fraction lessons. The video data was supplemented by the field notes taken during instruction and of an interview of the instructor. For more information about the project, including student test data and teacher surveys, see McCrory (2008). Since in this paper we are concerned with overcoming the difficulties students face when trying to work with rational numbers, we looked at one college professor in more detail. For this project, over 15 hours of video data was gathered for this instructor. The analysis of the video tapes used an Iterative Refinement Cycle (Lesh & Lehrer, 2000) model in which multiple interpretive cycles were used on the data. The first interpretive cycle was used to identify those issues that pertained to general pedagogy and classroom culture. The second cycle was used to identify those issues that reflected the semiotic framework that framed this research investigation. The third cycle was used to establish explicit connections between the instructor's pedagogical decisions in order to make clear to the students the semiotic issues in their problem solving process. Finally, throughout the entire iterative viewing and interpretive process, the analysis of the other data source, including field notes and the exit interview with the instructor, was used to help inform the context and nature of the classroom discourse.

Below we provide excerpts of the interpretive narrative and discuss how Pat (a pseudonym), a professor of prospective elementary school teachers, used semiotics to instruct his students about rational numbers. The following episodes from Pat's class show how an understanding of semiotics can help preservice elementary teachers understand rational numbers and ultimately how to understand how to navigate these teachers' future students' misconceptions of rational numbers.

## Results

Before delving into the difficult concept of rational numbers, Pat did a short presentation introducing the students to semiotics. In the presentation, Pat first defined a linguistic sign as a "…two sided entity, a dyad, between the signifier (symbol) and the signified (meaning)." He then gave the following visual example of linguistic sign using the concept of 'dog':

**sign → <u>Spoken word "Dog"</u>**
**Concept of Dog**

Pat would refer back to this simplified semiotic framework when semiotic dissonance arose in problems that had the same numbers, but different units, to explicitly show students how the semiotic framework provided insight into their confusion. Pat specifically chose the waffle and cookie problems below to include two meanings of division: partitive/sharing (how many/much per group?) and quotative/measurement (how many groups?).

- The Waffle Problem: *A batch of waffles requires ¾ of a cup of milk. You have two cups of milk. Exactly how many batches of waffles could you make?*
- The Cookie Problem: "*You have 2 cups of flour to makes some cookies. This is ¾ of what you need for one full recipe. How many cups of flour are needed for a full recipe?* (Class handout, 4/10/08)

In his class, Pat began by having students work in six groups of four students to solve the above problems. When Pat asked for solutions to the first problem, four of the six small groups each gave a different answer (2, 2 ¼, 2 2/3, 2 3/8), only one of which was actually correct. Clearly this question posed a series of problems for this class. Pat proceeded to have the group that had 2 ¼ go to the board and write how they solved the problem for the class. One student said, "I knew that 1 cup of milk was four fourths," and then wrote out on the white board 4/4 + 4/4 = 8/8 to represent the 2 cups of milk. He continued saying, "I know ¾ a cup is batch so I took away 6/8 for two batches," while writing 4/4 + 4/4 = 8/8 – 6/8 = 2/8. The student concluded by saying that he had 2 batches so far, represented by the 6/8, and a ¼ leftover, simplified from the 2/8, giving a final answer of 2 ¼ batches. Another student quickly pointed out that 4/4 plus 4/4 was actually 8/4, not 8/8. Using that fact, Pat reworked the problem on the white board writing 4/4 + 4/4 = 8/4, and 8/4 – 6/4 (for the two batches of waffles) = 2/4 = ½. The class then began to discuss the meaning of the ½, whether it meant ½ a batch or ½ a cup. After some class discussion on how to interpret the ½, a third student pointed out that the ½ left over was not ½ a BATCH, but rather was ½ a CUP and that ½ cup was the same as 2/3 of a batch. To illustrate his point, the student drew a pictorial representation of the problem (figure 1) trying to show how ½ cups of milk was equivalent to 2/3 batch of waffles.

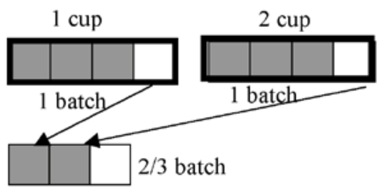

*Figure 1*. Pictorial solution to the waffle problem.

After the students explained why they got their answers, Pat brought the class back and explained how both a cup and a batch could be a whole. Pat stressed that the students needed to attend to the context, and said, "technically the ½ is not wrong until you put a name to it. You say ½ a batch. That's not true, because it's half a cup" (from video on 4/10/08 and 4/15/08).

This is clearly a semiotic problem, where the signifier, or visual mark "1/2," had taken on two different meanings, depending on the signified, or concept, with which the students associated the signifier to construct their sign. One student incorrectly associated the ½ to 'batches' while another student correctly associated the ½ to 'cups,' which was equivalent to 2/3 of a batch. In this case, the single signifier, ½, could only be meaningfully associated with one meaning, cup. We describe this phenomenon with the phrase 'semiotic mismatch,' in which a signifier is incorrectly associated with a particular signified as determined by the context. As illustrated in this excerpt, by explicitly showing students how signs can mean different things depending on the context, the students gained insight in how to determine what the accurate signified, or intended meaning, was in the problem.

When Pat moved to a discussion of the cookie problem, he encouraged the students to use a semiotic framework not only when approaching their own understanding, but also in future instruction of rational numbers to elementary school students as well. As with the waffle problem, Pat first had the class work in small groups to come up with a way to model their solution. Pat had two groups put up two solutions. The first solution, which was an algebraic solution, looked like this:

2 cups = 8/4 cups
2 divided by ¾
8/4 divided by ¾
8/4 x 4/3 = 8/3
2 2/3 cups

The second solution (figure 2), copied in the notes as replicating the board drawing, was a pictorial strategy.

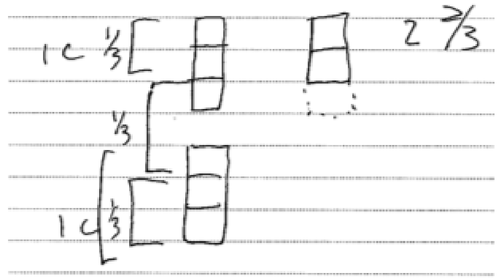

*Figure 2*. Pictorial solution to the cookie problem.

At this point, Pat gave the students some time to think about how they would explain each of the above answers to their future students. Pat discussed how this was a content pedagogy course, so he wanted them to understand the content, but then, as future teachers to be able to explain the mathematics with clarity. While no one seemed eager to attempt to explain the first solution strategy, one student did label and explain the second strategy. First, she labeled the model (figure 3) and noted that she thought it was important to label cups on one side and ¼ batch on the other side so students would not get confused. Here the student had moved from having semiotic dissonance to realizing the importance of being consistent with the use of symbols when there are multiple signifieds, quantities of cups and recipes, as a result of the context.

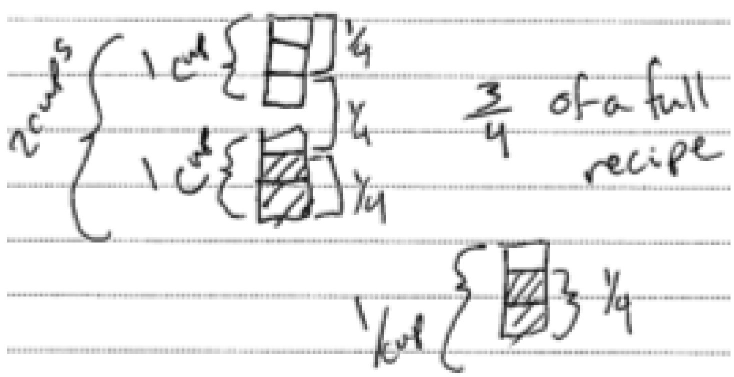

Figure 3. Pictorial solution to the cookie problem with student explanation.

Pat waited for the students to comment as the model was explained. He then pointed out that the two shaded boxes in the drawing, 1/3 of 2 cups and ¼ of a recipe were also both equal to 2/3 cups. In this case, the signifier represented by the two shaded boxes, could be associated with three different meanings, the signified, depending on context.

After students shared solutions of the cookie problem, Pat asked the groups to think about what mathematics was necessary for kids to solve the problem using the different strategies presented. The class decided that to solve the problem using strategy 1, the algebraic solution, the child would need to know improper fractions, the division of fractions, fraction algorithms, and whole number operation facts. On the other hand, for strategies 2 and 3, the pictorial strategy, the child would need to know how to partition pictures, split quantities up, and recognize the concept of a changing whole. One of the students specifically pointed out that in strategy 1, number facts were necessary while in strategies 2 and 3 a conceptual understanding of division was needed. Furthermore, looking back over the three representations, one could see that while the first strategy was mathematically correct, a student would not necessarily need a conceptual understanding to solve the problem. There were no units labeled, and thus semiotic confusion could arise in children. In the second solution, the diagram was not labeled adequately, which could also lead to semiotic confusion. The third solution had taken into account much of the semiotic framework that had been taught, including labeled pieces so that a child could more easily figure out what is signified by the images and numbers.

By analyzing the three representations of the cookie problem and determining what langue, or semiotic context, was needed to solve the problem using the two strategies, Pat enabled his students to begin to think about how they could instruct future students about rational numbers. He emphasized the importance of labeling the units and how the changing whole could be tricky for their future students to understanding and learn. He presented them with a semiotic framework to be able to create meaningful signs by connecting the appropriate signifiers with the appropriate signifieds, depending on the knowledge available to his students as well as his students' future school aged students.

After discussing the waffle and cookie problems individually, Pat asked the groups to determine the difference between the two problems. While both problems used the same numbers (2 and ¾), the same operation (division), and had the same answers (2 2/3), the contextual difference led to different solution strategies and conceptions of the fractional quantities. Again, Pat wanted the students to understand that the langue of the problem affects the ultimate meaning of the signifieds (amount) and of the signifiers (visual or auditory number itself). By now, the students had decomposed both problems and quickly answered that: 1) In the problems they are asking two different questions; 2) In the first you have everything you need. In the second problem you need to figure out what extra represents. You don't have everything you need. 3) In the first problem, ¾ makes a whole, in the second it is ¾ of what is a whole; and 4) In the first problem, the measurement is division, where you know the amount of groups and want to know what the whole is and the second is partitive division, in which you know how many groups/parts are in the whole. By analyzing the problems and giving students a semiotic framework to allow them to determine the meanings of the symbols being used, the students were able not only to understand the rational numbers themselves, but were also able to conceptualize what kinds of mathematical knowledge their future students would need to understand such problems.

## Discussion

As noted in the introduction, preservice elementary teachers often have trouble understanding how to conceptualize and use rational numbers. Without adequate conceptual understanding, this lack of content knowledge will be perpetuated when these students go to teach their future elementary school students about rational numbers. This paper has shown how one teacher has used a framework of semiotics to help students understand, use, and ultimately instruct each other about rational numbers. Whether this knowledge transfers to the elementary classroom is an area that needs further study. Nonetheless, the preservice teachers in this case study clearly showed growth in their understanding of rational numbers through the use of a semiotic framework. The study of semiotics helps students to interrogate "how" things mean, not just what they mean, that a secondary system underpins the superficial representations of concepts with which they have become so familiar. Further, breaking down the problems using semiotics makes explicit what we often think we are doing implicitly. Finally, this explicit decomposing of problems allows students to begin to see where their future students may encounter difficulties when trying to understand rational numbers.

*This paper reports on a study of the development of knowledge of geometry and measurement of more than 450 pre-service elementary teachers (in two cohorts) that were taking a required mathematics course focused on these topics. They completed pre- and post- tests consisting of multiple choice and open response items. Pre-service teachers' mean percent correct doubled between the pre- and the post- test. Such large increase was also evident in some individual items; however, this improvement in mean scores was not at all uniform. This suggests that after a semester of study on these topics preservice teachers made significant progress but there were still concepts they continued to find difficult. Implications of these and other results are discussed.*

## Introduction

Mathematicians and teacher educators have been studying what mathematics is needed for teaching at elementary grades for decades. These studies have been summarized in the recommendations of the Conference Board of the Mathematical Sciences (2001) and include individual studies conducted by scholars such as Ball (1990), Borko et al. (1992), and Ma (1999), and the reviews by Begle (1979), Ball, Lubienski, and Mewborn (2001), and Hill, Sleep, Lewis and Ball (2007). The book by Even and Ball (2009), a study of the International Commission on Mathematical Instruction (ICMI) about the education of mathematics teachers, indicates that the concern about mathematical knowledge for teaching is worldwide. Most of the studies of mathematical knowledge of prospective or practicing elementary teachers have tended to focus on knowledge of number and operations. In particular—except for a few studies about pre-service teachers' van Hiele levels, e.g., Mayberry (1983)—little is known about prospective teachers' knowledge of geometry, measurement, or spatial reasoning. Yet, after number and operations, the topics of geometry and measurement are the most frequently taught content strands in elementary grades (Rowan, Harrison & Hayes, 2004).

In this paper we report on a study that addresses this gap in the literature on mathematical knowledge for teaching. A mathematics research group originally set up by the Teachers for a New Era Project [TNE] at Michigan State University has been conducting self-studies of what prospective teachers in the elementary teacher certification program learn about knowledge for teaching mathematics from the required courses in mathematics and mathematics education. In this paper we report on one part of our work: an investigation of the knowledge of geometry and measurement acquired during a required undergraduate mathematics course about geometry and measurement designed for students in the elementary teacher education program. In particular, the study reported here addresses the following research questions:

1. What knowledge of geometry and measurement do pre-service teachers have at the beginning of a mathematics course addressing those topics?
2. To what extent and in what ways does the pre-service teachers' knowledge of geometry and measurement change by the end of the course?

## Participants

The population of concern is the set of students enrolled in the 5-year elementary teacher preparation program at the authors' University. Students in this program are required to take two mathematics courses designed especially for future teachers of Grades K–8 (The State's elementary certification is for Grades K–8 and secondary is for Grades 7–12). In the first course, called MATH 1 here, students study whole numbers, rational numbers, number theory, ratio and proportion, and elementary ideas in algebra. In the second course, called MATH 2, students study topics in geometry and measurement, including spatial visualization, and properties of 2-D and 3-D figures, such as congruence, similarity, transformations, perimeter, area and volume. This choice of content was influenced by the recommendations and research mentioned earlier, as well as by national and state standards for students in Grades K–8. To develop what Ma (1999) calls "profound understanding of fundamental mathematics," both MATH 1 and MATH 2 emphasize developing multiple representations for mathematics concepts, writing and solving word/story problems, and explaining why mathematical statements are true or why procedures "work."

MATH 1 is required for admission to the elementary teacher preparation program; so most students taking it are freshmen or sophomores. MATH 2 may be taken at any time prior to the 5th year internship; so students are a mix of freshmen, sophomores, juniors and seniors. Both MATH 1 and MATH 2 are taught in sections of 25–35 students. Typically, one section each semester is taught by a professor, and other sections are taught by teaching assistants, most of whom are doctoral students in mathematics or mathematics education. In order to investigate the stability of results, this study was conducted in two consecutive years in MATH 2. Students enrolled in MATH 2 in Spring 2007 used the first edition of Beckmann's text (2004), and in Spring 2008 they used the second edition of the same book (2007). A different faculty member was course supervisor each semester. Students in Spring 2008 spent more time on volume and less time on properties of quadrilaterals than the students in Spring 2007. Other aspects of curriculum and instruction were the same.

## Methods

Each semester students were given a pre-test on the second day of class. As part of the consent process students were informed that their pre-test score would not count towards the course grade. They were also informed that these questions were about material that would be studied and examined later in the course and that the results would help instructors evaluate the effectiveness of their instruction. Most questions on the pre-test were also embedded in the final exam (post-test) for the course.

*Instruments*

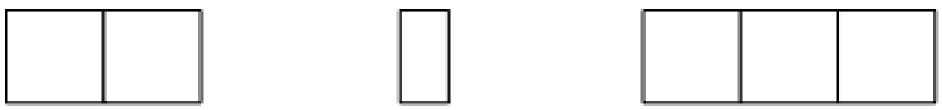
Topics on the pre-test included properties of polygons and polyhedra, the meaning of measurement units, perimeter, area and volume. Items addressed various strands of mathematical proficiency, including conceptual understanding, adaptive reasoning, and strategic competence (National Research Council, 2001). Several items were taken from previous research involving school children (e.g., Battista, 2007), or teachers (e.g., Ma, 1999). In this paper we report on a total of eight items—three multiple choice and five open-ended. Several of the free response items have multiple parts, and some items can be solved in more than one way.

Figures 1 and 2 show two items dealing with concepts of area. Figure 1 shows a multiple choice item assessing conceptual understanding of the effect of changing the unit of measure on the area of a figure. Understanding such transformations is essential for most real world applications of geometry. In addition, a successful response to this item would indicate the ability to integrate what Battista (2007) calls measurement and non-measurement reasoning.

Figure 2 shows a free response item asking students to identify and explain the relation between the areas of two triangles. As Beckmann (2002) notes:

> *prospective teachers should learn to explain mathematics not only because they will explain mathematics to their future students, but also because explaining mathematics enhances their own understanding of mathematics and their own mathematical reasoning abilities.* (p. 2)

Juan, Kim, and Angelo each measured the area of the same shape using the area units shown below.



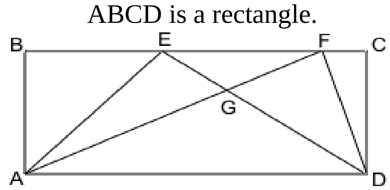
Juan's unit    Kim's unit    Angelo's unit

Which of the following could be a correct set of area measurements for the shape?

(a) Juan: 60 units Kim: 15 units Angelo: 90 units
(b) Juan: 60 units Kim: 240 units Angelo: 40 units
(c) Juan: 120 units Kim: 30 units Angelo: 80 units
(d) Juan: 120 units Kim: 480 units Angelo: 180 units

*Figure 1.* Item G4 – a multiple choice question about units of area.

ABCD is a rectangle.



a. How do the areas of triangles AED and AFD compare? (Mark one.)
   (a) The area of triangle AED is equal to the area of triangle AFD.
   (b) The area of triangle AED is greater than the area of triangle AFD.
   (c) The area of triangle AED is less than the area of triangle AFD.
   (d) There is not enough information to determine how the areas of triangles AED and AFD are related.

b. Justify your answer.

*Figure 2.* Item G6 – assessing reasoning about areas of triangles.

*Scoring Items*

Each correct multiple choice item was given one score point. For each free response item the research team developed a scoring rubric, with 4 points maximum allotted for each free response item. This results in a maximum total score of 29 points.

Influenced by the work of Malone et al. (1980) and Thompson and Senk (1998), rubrics typically assigned 4 points to a model solution, 3 points to a solution that is conceptually correct but has a minor computational error, 2 points to an item that indicates a chain of reasoning but contains either a conceptual error or gets only about halfway to a solution, 1 point to a solution that does not contain a valid chain of reasoning, but has at least one correct relevant statement, and 0 points to a completely incorrect solution.

Rubrics were developed iteratively, generally over a period of several weeks for any given items. Typically, a team of two or three researchers would select sample solutions that they thought illustrated the general scoring guidelines described above, and present them for discussion and potential revision to the full 7-person research team. Once agreement on the language of the rubric was reached, anchor papers were identified, and the full team practiced scoring a small set of other papers. Once acceptable levels of reliability were reached, the team that proposed the rubric scored all remaining papers. Figure 3 shows the rubric developed for Item G6 (b). Once rubrics had been developed for all items, other researchers who had not been involved in the original scoring, rescored a random 15% of the samples. For Item G6 (b), the rescoring resulted in 98% agreement.

| | |
|---|---|
| 4 points | (a) Complete, correct argument based on Cavalieri's principle (must include a statement that side BC is parallel to side AD because figure ABCD is a rectangle, or other equivalent statement). (b) Responses that use the formula Area=(base)*(height)/2 and justify why the bases and heights of the two triangles are the same [must include the statement that the distance between the opposite sides of a rectangle are equidistant because they are parallel]. (c) Responses that correctly show some combination of categories (a) and (b) or other method. |
| 3 points | (a) Same criteria as 4(a) but minor errors/omissions (e.g., student fails to mention that rectangles have parallel sides). (b) Same criteria as 4(b) but minor errors/omissions. (e.g., failing to mention opposite sides of a rectangles are parallel, parallel lines are equidistant) (c) Same criteria as 4(c) but minor errors/omissions. |
| 2 points | (a) Explanation that mentions Cavalieri's Principle and/or shearing process (or other related term). (b) Explanation that uses the formula Area=(base)*(height)/2 but does not show how the bases and heights of the two triangles are equal. (c) Combination of (a) and (b) or other methods that shows a chain of reasoning but either has major conceptual errors, or half way done. |
| 1 point | There is at least one correct and relevant fact in the response. |
| 0 point | Incorrect, irrelevant, or blank statements |

*Figure 3.* Rubric for Item G6 (b).

## Results

The mean and standard deviation of the overall score earned on the pre- and post-tests for the two samples is given in Figure 4. Also given are the Test Difficulty, defined as the ratio of the mean score to the maximum possible score (29), and the distributions of scores. Performance on the pre-tests was quite stable across semesters, with a mean score about 9 of 29 points possible in each semester. Mean scores rose to almost 20 points on the post-test in 2007 and 18 points in Spring 2008. In each semester the growth from pre- to post-test was more than two standard deviations. Table 1 reports descriptive statistics for the items shown in Figures 1 and 2, including the mean, standard deviation, and item difficulty (defined to be the ratio of the mean score to the total number of points possible on the item).

| *Administration of Test* | *N* | *M* | *SD* | *Test difficulty* |
|---|---|---|---|---|

| | Spring 2008 Pre | 232 | 0.25 | 0.65 | 0.06 |
| | Spring 2008 Post | 232 | 1.54 | 1.08 | 0.39 |

Both Items G4 and G6 were difficult for the students in this study. The correct answer to Item G4 is choice (b) and on the post-test this was the most commonly chosen answer, but only 55% in 2007 and 43% in 2008 chose the correct answer. Each semester, the most commonly chosen wrong answer on the post-test was distractor (a) with about 30% choosing it in 2007 and about 55% in 2008.

For Item G6, although only about a third of the students recognized on the pre-test that the areas of the two triangles are equal; by the end of the semester about 80% in 2007 and about 73% in 2008 recognized that the two areas are equal. However, justifying this conclusion was more difficult for students even at the end of the course. In 2007 and 2008 combined only 1% of students on the pretest and 24% on the post-test scored 3 or 4 on part (b) of Item G6. That is, by the end of the semester less than one student in four was successful at justifying why the areas are equal. Figure 5 shows two valid arguments illustrating the two most commonly used solutions for this item.

| Student A | Student B |
|---|---|
| We know through Cavaleri's principle that we can shear an object along a parallel line and preserve it's area. We know through def of a rectangle (w/ 4 right angles) that opposite sides must be parallel. If we sheared $\Delta AED$ on the parallel line $\overline{BC}$ to point F, we would have $\Delta AFD$. Since we can shear this, we know the area's of both triangles are the same. | $\square ABCD$ is a rectangle, so it's also a parallelogram and $\overleftrightarrow{BC} \parallel \overleftrightarrow{AD}$. Therefore, the distance btwn. these lines is constant and the heights of $\Delta AED$ and $\Delta AFD$ are equal. They share base AD, so their areas $= \frac{1}{2}bh$ are also equal. |

*Figure 5.* Sample solutions to Item G6(b) shown in Figure 2.

Student A used Cavalieri's principle to compare the area of triangles AED and AFD. Whereas there were no students who used this particular principle on the pre-tests in 2007 or 2008, on the post-tests there were 45 students altogether who used this principle to justify successfully their response that the area of the two triangles must be equal. This type of response is interesting because Cavalieri's principle is not typically taught in high school geometry, and it is clear that these students did not know this principle at the start of MATH 2; but by the end of the course about 10% of the samples were able to use a newly-learned abstract principle in a problem context and to construct a well-argued explanation for their responses.

Student B used the formula A=b*h/2 for the area of a triangle to argue that if the bases and heights of two triangles are equal, then the two areas must be equal. Whereas on the pre-tests there were only 5 students who invoked this particular argument with some success (all scored 3 points), on the post-tests there were 67 students altogether who used this argument to justify successfully (scored 3 or 4) their response. Students typically enter MATH 2 familiar with the area formula for triangles. Responses like Student B's are interesting because they show that what students seem to have learned in the course is not new content but rather how to apply what they already knew to a new problem situation involving the construction of an explanation or justification. In both cases, these students seemed to understand that areas can be compared without calculations or measurement—one can use properties of shapes and general principles to determine areas. More generally, solutions such as those of Students A and B show how pre-service elementary teachers can use formulas and general principles to understand relationships, contrast shapes and even make arguments about relationships among mathematical objects.

## Discussion

This study investigated the knowledge of geometry and measurement that pre-service teachers displayed at the beginning of a mathematics course addressing those topics, and to what extent and in what ways did pre-service teachers' knowledge of geometry and measurement change by the end of the course. The overall scores on the TNE Geometry Test show that consistent with results reported by Mayberry (1983) the pre-service teachers in this study began their course with weak knowledge of geometry, with mean scores of about 9 of 29 points on a pretest about properties of polygons and polyhedra, the meaning of measurement units, perimeter, area and volume. These results were stable across two semesters. The post-test scores show that they learned quite a bit about geometry and measurement in MATH 2 with average scores on the same items on the post-test increasing to about 18 - 20 points. However, when examining specific items we see that some topics explicitly taught in the course were learned successfully, but that there were other concepts that many students continued to find difficult.

Item G4 about the size of the unit and the resulting measure of area addresses a fundamental concept of area that shows up in many elementary curricula. This item was quite difficult even at the end of the semester with slightly more than half the sample getting it correct in 2007 and slightly less than half successful in 2008. It is not clear how much the complexity of the item, involving three different measurement units, contributed to its difficulty. But this item taps a concept that is fundamental to understanding area. It is therefore important for researchers and teacher educators to figure out why this concept is so difficult and how to help pre-service teachers understand it.

Item G6 assesses reasoning about areas of triangles that is typical of mathematics included in some state standards for Grades 7 or 8. Results show that during this study, the percent of students who were successful on this item increased between the pre-test to post-test from about 30% to 75% on part (a) and from about 1% to 24% on part (b). Thus, after completing a whole semester of a geometry course that places considerable emphasis on explaining your thinking, the majority of preservice teachers made excellent progress on recognizing that two areas were equal, but continued to have difficulties explaining and justifying their responses. Most had no trouble recalling the area formula for triangles, but applying the formula and properties of quadrilaterals to construct an argument about the equivalence of the area of the two triangles was difficult for many students. However, it is heartening to see that other students, about 15% of the sample, not only were able to learn a new mathematical principle, Cavalieri's Principle, but they were also able to apply it to write an argument about areas of triangles. Thus, Beckmann's (2002) proposition that explaining mathematics will help future teachers to enhance their own understanding of mathematics and their own reasoning abilities is somewhat supported by our research. However, for the majority of students in our sample, the development of strong reasoning abilities is still an elusive goal.

This study was undertaken with the joint goals of contributing to the research on knowledge for teaching mathematics and of investigating what prospective teachers in the elementary teacher certification program at our university learn about mathematics for teaching from the required courses in mathematics and mathematics education. To the former, we have contributed items about geometry and measurement that are lacking in the literature, and rubrics for scoring those items that can be used reliably by other scholars. Starting with the current semester, Spring 2009, we have begun to share the results of this work, with faculty and teaching assistants who are currently teaching MATH 2, with the belief that knowing about pre-service teachers' performance in previous years will engage instructors in conversations about ways to improve teaching and learning.

## Acknowledgments

This work was partially supported by the Teachers for a New Era grant from the Carnegie Foundation to Authors' Institution, (Robert Floden, PI). We gratefully acknowledge the contributions of Mike Battista in designing this study and developing items for it, and the assistance of Aaron Brakoniecki, Aaron Mosier, Ji-Won Son, and Violeta Yurita in developing rubrics for items and scoring them.

# FROM "THESE" CHILDREN TO "MY" CHILDREN: SHIFTS IN DISCOURSE ABOUT THE NEEDS OF CHILDREN FROM POOR COMMUNITIES

Azita Manouchehri
Manouchehri.1@osu.edu

*In this work we examined the impact of a 10 weeks long experience of one-on-one work with children from disadvantaged communities at a learning center on a cohort of thirty middle school mathematics teacher candidates' views about children's learning and teaching matters. Data collected through reflective journals indicated that personal and sustained experience of working with children allowed the teacher candidates to shift their focus from identifying what they perceived to be children's academic and social "deficiencies" to importance of making mathematics meaningful to children. The teachers however, continued to overestimate their ability to influence children's academic and social growth.*

## Introduction

The importance of designing educational experiences that prepare teachers to work productively with children from economically disadvantaged communities has been voiced and recognized by teacher educators in various areas for quite some time (Mason, 1997). In mathematics education, the NCTM's call for making mathematics accessible to *all* children, including those in poor communities, has generated concerns about how teacher candidates might be assisted to develop necessary skills and dispositions to so. There is certainly legitimate ground for such concern since research findings continue to suggest that teachers maintain negative attitudes towards low income, culturally under-represented student groups, assuming them incapable of academic success (Garcia, 2004). Though not widely explored in mathematics education, research on teacher candidates' beliefs confirm that they have lower expectations for economically disadvantaged students' academic performance and undermine the role of ability in explaining their academic success when they occur (Tiezzi & Corss, 1997). Challenging such views is a must if the goal of empowering all children to achieve mathematics is to be accomplished.

The overarching goal of the study we report here was to investigate the impact of a 10 weeks long field experience which required teacher candidates to work, in an after-school program, with individual and small groups of children from urban schools on teachers' conceptions about the academic needs and intellectual capacity of children from disadvantaged economical backgrounds. Of particular interest to us was documenting what teacher candidates viewed as important for children to know, ways in which they examined children's mathematical thinking skills, as well as orientations they adopted in their interactions with children. More specifically, we aimed to document and analyze how the experience of sustained one-on-one work with children from poor communities impacted their conceptualization of the children's needs and their mathematical knowledge.

## Literature Review and Conceptual Framework

In recent years one of the foci of attention of research in mathematics education has been on understanding the nature of professional knowledge base and beliefs of future teachers. As some researchers have studied the substance of knowledge of mathematics teacher candidates as it relates to specific pieces of content, others have explored their beliefs and perceptions of teaching and the subject matter (Phillip, 2008). The body of research suggests that teacher candidates enter teacher education programs with well-established teacher role identities (Bush, 1986) and strong convictions about teaching and intentions on how to teach (Phillip, 2008). Their beliefs about effective teaching and learning can be strongly held and appear to be resistant to change (Pajares, 1992). These beliefs strongly influence the extent of teacher candidates' willingness and ability to learn while in teacher education programs. In studying the source of teacher candidates' beliefs about mathematics teaching and learning, researchers have noted that those beliefs, for the most part, are formed in contexts dating back to teachers' own schooling years (Phillips, 2008). Families and social communities provide additional contexts in which teachers form their beliefs and perceptions about not only teaching but also about the impact of race, culture and socio-economic status on academic success and ability (Ladson-Billings, 1997). Bush (1986) labeled the combined impact of these forces as "enculturation." Several researchers have documented that pre-service teachers about to begin student teaching expected teaching tasks to be less problematic for themselves than for others (Weinstein, 1988). These scholars have suggested that pre-service teachers may have an unrealistic optimism about their future teaching performance, and that this optimism may be associated with a lack of motivation to become seriously engaged in critical examination of their own knowledge base for and beliefs about teaching. Assuming beliefs to be context-bound *raises concerns about preparing teachers to teach in contexts drastically different from their own culture, race, ethnic background and social class background* (Tiezzi & Cross 1997, p.113-114). Teaching force in the US consists primarily of white, middle class females whose goal is to pursue teaching appointments in settings similar to where they were raised (Gutierrez, 1999). Combined with knowledge that teachers' stereotypes about children are sufficient to impact student performance (Oaks, 1990) and that many teachers have negative attitudes about individuals from cultures different from their own (Irvine & York, 1993 cited in Gutierrez) heightens the need to design experiences that raise teacher candidates' awareness of the intellectual strengths and capabilities of children from poor communities and to challenge their perceptions about what this student population is capable to accomplish. In mathematics education this need is paramount since national and international data on student achievement in mathematics continue to indicate that children from low socio-economic backgrounds perform at significantly lower levels compared to their white, middle class peers (NCTM, 2008). While it is naïve to ignore the non-instructional factors that both implicitly and explicitly impact student performance, the significant role of the teachers on advancing student learning even in the presence of non-instructional elements cannot be contested (Ladson-Billings, 1997) and one which is of concern in teacher preparation. Our study aimed to explore potential for creating change in teacher thinking about mathematical ability of children from disadvantaged communities. We conjectured that an intensely supervised experience in which teachers worked with individual and small groups of children would allow them to focus on instructional factors that could assist in advancing children's mathematical thinking.

Our design of the experience was informed by three perspectives guiding current thinking on teacher preparation. These include: The use of concrete contexts for learning about the profession (Brown et al, 1989), the value of sustained reflective practice on development of professional knowledge (Schon, 1987), focus on children's cognition as a means to advance teacher thinking (Fuson et al, 1999).

The notion of "contextual learning" accompanied with reflection proposes that teachers' engagement in intentional efforts to think about their experiences potentially create cognitive change in both their beliefs and practices (Schon, 1987; Tobin, 1990). Additionally, as Thompson and Thompson (1996) proposed we espouse the teachers gain knowledge about teaching and mathematics through sustained and reflective work with students and mathematical ideas, analyzing students' work, their own teaching, and reflecting on what they intended as well as what they achieved.

## Setting

The goal of our research was to collect data on mathematics teacher candidates' perceptions about teaching children from poor communities as they worked with individual and small groups of children in an after-school program for a period of 10 weeks. During this experience teacher candidates worked with approximately 40 children ranging in age from 6 to 16 years. All children were of African American heritage and from low socioeconomic background. The after-school program was housed in the learning center on the university campus and provided free tutorial and assistance to community members. The children were transported directly from their schools to the learning center. Each child was assisted approximately three hours a week on two different days (1.5 hours each day). Each child worked with the same teacher candidate for the entire 10 weeks. Hence, the number of hours of contact with each child by each teacher candidate was approximately 30 hours. With the exception of three, each teacher candidate was assigned two specific children, based on schedule and grade level.

*Participants*

The participants were 30 teacher candidates pursuing an undergraduate degree in middle level mathematics teaching. Nine of the participants were male and 21 were females. All participants were Caucasian and had completed at least one field experience in the previous quarters. They had also completed a minimum of 25 credit hours of mathematics coursework. Lastly, they all had completed 12 credit hours of coursework in general education. One of the education courses completed by students focused on global multicultural issues.

At the time of data collection, the participants were enrolled in a course titled, "Field Experiences in Mathematics Teaching." Traditionally, this course required the teacher candidates to observe teachers of their own choice once a week for 8 weeks. An examination of past data indicated that a majority of the teacher candidates enrolled in the course had opted to complete the required field experience in their own hometown, frequently observing a former teacher of their own. The quarter during which the study took place was the first attempt at modifying the field experience requirement so to assure teacher candidates gained a different learning experience, moving away from their own comfort zone, focusing their attention on children's cognition.

In addition to the 3 hours of work at the learning center, the participants attended course sessions on campus. During these sessions, the instructor of the course granted teachers the time to talk about their experiences, ask questions about teaching techniques or resources they could use with children, and discuss course readings which linked closely to teaching specific content pieces at different grade levels. The articles were selected from professional journals published by the National Council of Teachers of Mathematics. Additionally, during the campus sessions the course instructor used samples of children's work on specific problems the teacher candidates had used in the after school program to comment on the mathematical ideas that children seemed to be grasping, problem solving strategies they had used and reasons that could have contributed to their choice of representations and/or solutions to tasks. These discussions were framed to capitalize on approaches that could help or hinder children's progress.

*Data Collection and Analysis*

The teachers' weekly reflective journals served as primarily data sources for the study. While these journals were augmented with field notes on on-campus course session discussions, and observational data completed on site (learning center), in discussing the impact of the experience we are relaying solely on the written documents submitted by teacher candidates. Data was collected with the intent to trace a trajectory of the impact of the experience on participants' to cognitive needs of children and ways in which their socio-economic background influenced these views. Since no previous reports on such an experience in mathematics teacher preparation were published our research was of exploratory nature. Indeed, in coding the data the following categories guided our analysis: (a) experiences influential in candidates' thinking when assessing children's work and ability; (b) challenges and tensions that the candidates were experiencing in their work with children; and (c) frames that teacher candidates used when analyzing and interpreting children's work.

## Results

Throughout the 10 weeks long field experience each of the teacher candidates submitted 8 reflective journals on their work at the center (n=240), 3 progress reports on each of the children with whom they worked and one final report on their experience working with children and what they extracted about teaching and learning through their work. In their reflective journals teacher candidates documented their impressions of the children's needs, procedures they had used in detecting these needs, issues they struggled with in their work with children, as well as areas in which they felt children and they themselves were making progress. Additionally, they were asked to comment on teaching approaches and problem types they were using and whether they found children responsive to these tasks. Children's progress reports had a specific structure. In each report the teacher candidates identified specific mathematical areas they had worked with children each week, level of progress in those areas as well as plans for their subsequent work in the follow up sessions. Lastly, the final report was structured so to provide the teacher candidates with an opportunity to assess not only the experience of working with children but also their overall assessment of their own growth and development as teachers. In analyzing the data, we divided the reflective journals into two groups reflecting teachers' ideas during the first three weeks of experience (Phase I) and the last three weeks of experience (phase II). Constructing such a phase analysis was essential to study the impact of two particular interventions: (1) Modeled teaching by the field experience supervisor, (2) implementation of specific problem solving tasks to be used as a means to assess children's mathematical thinking.

*Assessment of Learners and Teaching*

Tables I and II summarize a typology of teacher candidates' comments as well as the frequency of each comment type that they made about teaching and children as reflected in their first three journals (Phase I) and last three reflective journals (Phase II). During the first phase, despite the instance of the course instructor that the candidates must rely on multiple sources to determine learners' facility with different mathematical concepts they relied primarily on on-line diagnostic tests which measured (in a narrow way) children's mastery of basic skills. These instruments failed to capture the abilities of children in a meaningful way and in problem solving contexts. Hence, the candidates' perception of children's needs was shaped by these results. In places where children offered correct solutions to questions using non-traditional strategies the merit of these approaches were dismissed. The children's authentic approaches were labeled as "inefficient" or "inadequate" to help them launch answers on tests "quickly." This assessment was universal among the candidates even in places where children were enrolled in advanced or honors courses (middle level and high school children).

In addressing these perceived procedural gaps, the candidates eagerly relied on using various games and puzzles to engage children in learning however, they failed to connect the content of these games and puzzles to mathematical competencies they had hoped to address. Therefore, due to the disconnect between what they were asked to do during their time with candidates, children became less and less engaged in tasks, less responsive to teacher candidates' expectations and "demands," and at time refused to do what they were assigned. These results directly confronted teacher candidates' initial optimism towards their ability to teach. However, rather than a retrospective analysis of children's behaviors, they "blamed" their home cultures and backgrounds to their lack of interest. Reflective journals submitted during this phase were indicative of the candidates' resistance to examine their own actions. Rather than exploring the impact of instructional choices they had made on children's behaviors they assumed children's own lack of motivation to learn as primary issue they struggled with. Indeed, on several occasions when teacher candidates felt they had made progress with a child at the end of a session (the child had successfully imitated the process the teacher had modeled through the use of several examples) they were disappointed that during the subsequent session the child had exhibited difficulty performing the procedures again. In explaining this phenomenon the teacher candidates referenced lack of support and/or reinforcement at as the primary reason for children's "failure." The following statements are typical of the type of comments teacher candidates made in the reflective journals during this phase.

> *When she left last week I knew she understood borrowing, she showed me she could subtract two digit numbers from three digit numbers. She came and we were back on the same step as we were last week. I think that had she practiced more at home this would not have happened. I think as teachers we need to be able to rely on families to get kids to their work. I know these kids are not getting that at home. (S1)*
>
> *I feel so sad for these kids, they come here and we help them but then they go home and I am guessing there is no one there to help them. (S2)*

These results, while disheartening, were not unexpected. Previous studies had documented similar findings during the initial exposure to children of similar backgrounds among teacher candidates (Haberman, 1996).

Table 1. *Teacher candidates' comments about children (Numbers reflect the total number of times statements had occurred on the first three journal entries. Numbers larger than 90 indicate that in the same journal a remake may have been repeated more than once by the teacher candidate)*

| Comments about Children | | | | | | | |
|---|---|---|---|---|---|---|---|
| | It is sad what these kids can't do | Not sure if they get support at home | It is sad how little they know | They are capable but problems are boring | They are not getting the support they need at home | They don't want to do their homework, they probably are not getting reinforcement at home | They don't sit still long enough to do the worksheets |
| Phase I (First four journals) | 120 | 56 | 84 | 12 | 75 | 65 | 62 |
| | | | | | | | |

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Phase II (Last for journals) | 34 | 42 | 32 | 48 | 29 | 28 | 10 |

During the first phase the candidates primarily commented on what learners were unable to do, referencing them as "these children," using a passive voice in identifying the impact that their own actions or choices could have had on children's learning. A prominent portion of the reflective journals concerned their perceived notions of children's home life, assuming their families to be less supportive of academic pursuit. Indeed, in nearly 28 of the 30 cases children's lack of mastery of basic skills was attributed to lack of support at home and their families low expectations for success. These assumptions were not supported with data and mirrored the teachers' pre-conceived notions of what children experienced at home and value attached to education by their guardians and parents. Additionally, the candidates were unable to understand the children's lack of interest in completing drill and practice exercises that were either assigned at school or asked to do at the center by them. Almost each of the teacher candidates made comments reflecting greater concerns for children's social behaviors and habits of children than their mathematical thinking. They seemed unwilling or unable to go beyond what they perceived as "inappropriate behavior" (walking, not sitting down while working on problems, or not completing work as they were told by the teacher candidates) and to analyze differences due to cultural practices (Ladson-Billings, 1997).

Table 2. *Teacher candidates' comments about teaching and their expectations ((Numbers reflect the total number of times statements had occurred on the first three journal entries. Numbers larger than 90 indicate that in the same journal a remake may have been repeated more than once by the teacher candidate)*

| Comments about Teaching and expectations for children | | | | | | | |
|---|---|---|---|---|---|---|---|
| | My job is to make sure they feel good while they are with me | I don't want to push them too much | Teaching **these** kids is hard | Teaching is harder than I thought | I need to learn more about how to teach (CONCEPT) | If I could find a way to connect their estimation skills to algorithms | I am surprised at their problem solving skills |
| Phase I (First four journals) | 76 | 65 | 45 | 3 | 7 | 0 | 12 |
| Phase II (Last for journals) | 23 | 12 | 12 | 44 | 46 | 43 | 47 |

*From "**These**" Children to "**My**" Children*

During the second phase however, frequency of comments that indicated some awareness of the need to learn alternate ways to effectively work with children increased significantly. Having developed a personal knowledge of each child due to extended weekly interactions with them, allowed for the development a personal bond that motivated greater investment in children's success on their part. This personal bond appeared to have also made them conscious of the impact of their own choices on what children did or gained from their time at the center. Although the teacher candidates continued to make unsupported claims about what they perceived to be the conditions of children' home lives, the frequency of their comments decreased significantly. Additionally, while they seemed to overestimate their own influence on children. This is consistent with the findings of Tiezzi and Cross (1997) as they reported that in their reflections over the experience of observing teaching in an Urban setting the teacher candidates offered idealized notion of teaching children in such settings, believing they could "help." Unlike their findings though, it seemed that the desire to be helpful (on an affective way) facilitated the development a disposition to focus on children's thinking and cognition as a means to achieve this goal. The following comments were typical of statements teacher candidates made in their journals during this phase.

> *I know my kids are doing better, I know they can do just as well as others. I feel I have made a lot of progress with them. They are happier when they are with me here and I know I am more at east working with them. (S1)*

Indeed, an examination of progress reports written for children also indicated a shift in quality of teacher candidates' assessment of children's work over time. Whereas in the first 3 progress reports a majority of teachers' comments concerned what children were unable to do; highlighting their lack of proficiency in some basic procedural domains; the last two reports manifested a deeper appreciation for children's problem solving skills and their resourcefulness in solving problems in authentic ways on their parts.

*An Analysis of Major Influences*

While the depth of analysis of teacher candidates remained relatively native, the shifts in their foci are particularly important and promising. These shifts were due to two major interventions implemented starting the fourth week of experience: (1) on site modeling by the supervisor, (2) assignment of specific problem solving tasks on which teacher candidates were asked to implement at the center.

The field experience supervisor attended the learning center three times a week for approximately 3 hours each for 5 weeks. During the time at the center, she held small group problem solving sessions with children while teacher candidates observed her interact with kids and her teaching. In organizing the sessions, she deliberately chose to work with those children whose tutors had diagnosed as having learning problems due to their lack of responsiveness during the sessions. During these sessions the supervisor presented both the children and the teacher candidates with the same mathematical problem as they sat at the same table using identical resources and concrete materials. As children worked on the task, the supervisor asked them to explain their thinking and repeatedly inquired whether the teacher candidates understood what concepts they were using. On several occasions, teacher candidates were puzzled by the fact that the children could solve problems in ways that they themselves were unable to grasp. Indeed to assure continuity in challenging the teacher candidates' views about children's ability, the supervisor assigned specific problems to be administered to children. Many of these tasks involved algebraic reasoning, guessing and estimation skills. Classroom discussions then focused on analysis of methods children had used and ways in which these methods could be connected to different topics in school curriculum.

## Epilogue

Teacher education programs have traditionally utilized an urban field experience prior to student teaching in teacher preparation Mason (1997) assuming that such an enculturation allows for development of positive professional insight and heighted awareness about children in urban schools. Results of research on the impact of this approach on teacher candidates' beliefs however have been inconclusive. In fact, several scholars have questioned the effectiveness of such experiences suggesting that these exposures can reinforce, rather than challenge, negative attitudes towards students from low Socio-economic backgrounds (Haberman, 1996). After an extensive review of literature, Mason (1997) concluded that the *overall research fails to provide evidence supporting the value of field experiences on teacher candidates' conceptions about teaching and learning in poor communities of the abilities of children in achieving success in such settings* (p. 120). He punctuated the need for identifying elements of supervised experiences that are necessary to provide positive learning opportunities for teacher candidates.

In the current study, rather than placing teacher candidates in urban schools as observers of teaching, we organized a quarter long supervised tutorial experience during which they worked one on one with children from disadvantaged communities. Our goal was to determine whether such an experience would assist the future teachers in learning about the potential of children for learning and their capacity for problem solving. This experience, supported with extensive supervision and teacher modeling proved to be a useful vehicle for engaging teacher candidates in learning to focus attention to children's strengths as opposed to their shortcomings in procedural domains. Such a content focused supervision impacted teachers candidates' professes assessment of their own professional needs as reflected in their journals.

While it would be naïve to make claims to long term impact of this experience on teacher candidates' beliefs and views about teaching and learning in poor communities, results of our exploratory research provide some evidence that such an experience can be valuable when carefully supervised by a content specific specialist who can help them make sense of mathematical merit of children work and introduce them to techniques and tasks they could immediately test and verify. This approach is consistent with current recommendations for using children's cognition as a springboard for advancing teacher development. Providing teachers opportunities to establish personal relationships with children of different culture and socio-economic background might serve as a good starting place for advancing their professional growth.

# RELATIONSHIPS BETWEEN CONTENT KNOWLEDGE, AUTHORITY, TEACHING PRACTICE, AND REFLECTION

Denise S. Mewborn
University of Georgia
dmewborn@uga.edu

*This paper presents a description of the ways that elementary teachers' mathematical content knowledge and locus of authority are related to their instructional practices and their reflections on their teaching. The cases of four teachers are used to illustrate the four possible combinations of content knowledge (high/low) and authority (internal/external). Although four cases are presented as exemplars, teachers' practices were not consistent across time and setting, and the changes were not necessarily reflective of "growth" toward more reform-oriented teaching. Data were drawn from a 5-year study in which two cohorts of elementary school teachers were followed from their junior year in college through their first two years of teaching.*

## Background

In my previous research, I identified connections between the locus of authority (internal or external) from the viewpoint of preservice teachers and their propensity to think reflectively about pedagogical dilemmas (Mewborn, 1999). I proposed that when preservice teachers see themselves as having the authority to raise and solve pedagogical dilemmas, they are more likely to think reflectively. In contrast, when preservice teaches see authority as external to them (residing in a teacher educator, an experienced classroom teacher, or in a textbook), they are inclined not to think reflectively about pedagogical dilemmas. In the study reported here, I have extended this connection to include the way that authority and mathematical content knowledge are interconnected in shaping teaching practice and reflection on that practice. In particular, I describe four possible interactions between authority (internal/external) and mathematical content knowledge (high/low) and associate each with a particular approach to teaching mathematics and reflecting on that teaching.

## Theoretical Perspective

This project is situated within the interpretive paradigm for teacher socialization (Zeichner & Gore, 1990). This interpretive approach involves an attempt to understand the nature of a social setting at the level of subjective experience. The purpose of this approach is to gain an understanding of the situation from the perspective of the participants and within their levels of consciousness and subjectivity. The goal is to "capture and share the understanding that participants in an educational encounter have of what they are teaching and learning" (Kilpatrick, 1988, p. 98). Eisenhart (1988) noted that the purpose of the research questions posed by researchers using the interpretive paradigm is to first describe what is "going on" and second to uncover the "intersubjective meanings" (p. 103) that undergird what is going on in order to make them reasonable.

## Methods

The data reported in this manuscript were collected as part of a 5-year research project entitled Learning to Teach Elementary Mathematics[8] in which two cohorts of preservice teachers were studied for two years of their preservice program and their first two years of teaching. The overall goal of the project was to develop conceptual frameworks for understanding teaching and learning in elementary mathematics teacher education by studying how novice teachers craft their teaching practices across time as a result of their personal theories, teaching experiences, and teacher-education programs.

The participants for the project were selected from two cohort groups who began the four-semester teacher education program in the fall of 2000 (Group A) and 2001 (Group B) and remained together as a cohort for the four semesters. Some data were collected on all students from each cohort, but the majority of data collection focused on two target subsets—6 students from Group A and 9 students from Group B. The target students were selected by purposeful sampling (Bogdan & Biklen, 1992) to represent a range of personal theories about mathematics. And to the extent possible, the target students were reflective of the diversity of students enrolled in each cohort. The 15 target students consisted of 13 White women, 1 White man, and 1 African American man. Although the racial and gender composition of the targeted students was fairly homogeneous, there was considerable diversity in their experiences with mathematics and their personal theories about the teaching and learning of mathematics.

The data set includes a mathematics beliefs survey (Ambrose, Phillip, Chauvot, & Clement, 2003), a content knowledge assessment (Hill & Ball, 2004), and all written work produced by the students during their two mathematics methods courses. In addition, the target students were observed four times teaching a mathematics lesson and individually interviewed on four occasions during their preservice years. The observations occurred during field experiences in the second and third semesters of the program (one observation each) and during their student teaching experience (two observations). The four interviews were semi-structured and took place at the end of every semester of the teacher education program. The first interview was conducted near the end of the first mathematics methods course and focused on eliciting autobiographical data from the participants regarding their views of mathematics and their prior experiences as a mathematics learner. They were also asked to reflect on their experiences working one-on-one with a student in mathematics during the methods class. The second and third interviews occurred at the end of the second and third semesters of the teacher education program and asked participants to reflect on their practicum field experiences and how these experiences differed (or not) from their one-on-one teaching experience and from what they had learned in their mathematics methods course. The fourth interview, conducted at the conclusion of student teaching, focused on their reflections about their various teaching experiences during their teacher education program and the changes (if any) in their conceptions about mathematics and mathematics teaching and learning from the beginning to the end of their teacher education program. Most of the target students (those teaching within reasonable driving distance) were observed teaching mathematics monthly and interviewed twice per year during their first 2 years of teaching.

---

[8] This study was funded by the Spencer Foundation under grant number 200000266. I am grateful to Patricia Johnson, David W. Stinson, and Lu Pien Cheng for their contributions to data collection and analysis throughout the project.

All data were transcribed and organized for coding purposes, and the research team defined an initial set of 25 codes. Line-by-line coding of data took place chronologically for all 15 target participants with different researchers coding data for different participants and then writing summaries, called "data stories." These chronological and parallel data stories facilitated comparison and contrast among the participants. Finally, the data stories and original data were recoded across participants.

## Results

Figure 1 depicts the hypothesized relationship between content knowledge and view of authority and the resulting nature of both lessons and post-lesson reflections. Following Figure 1 I describe a teacher who typifies each cell and give an example of a lesson she taught that depicts the type of teaching and reflecting that is suggested by the category.

| | | Content Knowledge | |
|---|---|---|---|
| | | High | Low |
| Authority | Internal | Lessons are student-centered, mathematically rich, developmentally appropriate, and teacher is reflective about self, students, and content after the lesson. | Lessons focus on fun activities with some mathematical substance, but they sometimes fail due to the preservice teachers' lack of mathematical foresight or inability to "think on the fly." Teacher is reflective after the lesson, but reflections center mostly on self and teaching actions. |
| | External | Lessons consist of attempts to provide clear and concise procedural explanations. Preservice teachers assume that this is how children learn mathematics best and that improving their teaching is merely a matter of giving better/clearer explanations. Little reflection after the lesson. | Preservice teachers try to provide lessons that make math fun and easy in order to spare students the agony of learning. The content of the lesson is often unclear and sometimes mathematically inaccurate or unimportant. There is little reflection on the lesson beyond whether or not the students enjoyed it. |

*Figure 1.* Relationship between content knowledge, authority, teaching practice, and reflection.

*Jayne*

Jayne provides an example of a teacher with high mathematics content knowledge and an internal locus of authority. She described herself as favoring language arts and mathematics, with a particular affinity for algebra. She also described herself academically as "creative," "original," "independent," "wanting to stand out from the crowd," and "not afraid to ask for help." Her scores on the Learning to Teach Mathematics instrument placed her in the top 10% of all students participating in the study. Jayne had an internal locus of authority and wanted to help her students develop a similar sense of independence. Even as a preservice teacher, her view of textbooks provided a good example of her internal locus of authority: "I feel that [the textbook] gives a lot of good suggestions and activities for teachers to pick and choose from. Some activities just need a little adjusting." When asked how she planned her lessons, she noted, "I went through them [the curriculum materials] and saw what I thought. I went through and picked what I like and what I didn't like and some stuff I thought was a good idea and just kind of

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

modified it to what I thought my classes need." As a classroom teacher Jayne challenged her principal's decision to ability-group students across classes for a portion of mathematics instruction every day to help students with weak procedural knowledge prepare for criterion-referenced testing. Jayne participated as required but continued to state her case, and, after test results came back and Jayne's students had the highest scores in the building, her principal relented and allowed her to manage mathematics instruction for her students for the full period.

A lesson that typifies Jayne's teaching style and that of teachers fitting in the first cell of Figure 1 involved introducing first-graders to addition sentences. Jayne made the lesson engaging by using a song about frogs sitting on a log being joined by others. She allowed the students to pick numbers and to act out the problems, and then she introduced the corresponding notation. At one point a student proposed to act out a story that corresponded to 10 – 0. Jayne asked him to state his story as a number sentence, which he did correctly, and then asked him if it was an addition sentence. The child acknowledged that it was not. Jayne then asked him to recast his story so that it would correspond to an addition sentence, which the child did successfully. Throughout the lesson, Jayne asked questions such as "What are we going to do with the numbers?" "How does the addition work?" "What can you tell me about adding two numbers?" "What is the number sentence? Why?" "Does it make sense?"

In a post-observation conference following this lesson, Jayne was able to reflect on her teaching, students' learning, and the content of the lesson. She articulated the purpose of her lesson this way:

I wanted to see if the students could understand the concept of numbers sentences in a context, almost like a story problem. Because I have notice that my kids have problem with story problems, you know, trying to deicide if they need to add or subtract—knowing what to do with the story—where to start. I wanted them to have some basic comprehension of mathematical sentences and understand to go back and check their work, and to determine if their number sentence made sense—all the basics.

She also reflected on the seatwork portion of the lesson, noting that the individualized nature of the task allowed children to self-differentiate by selecting numbers with which they were comfortable. She also noted that she challenged particular children by asking them to choose larger numbers.

*Cynthia*

Cynthia also possessed strong content knowledge in mathematics (and in other subjects, graduating from college with perfect 4.0 grade point average). Cynthia considered herself to be "fairly good" at mathematics and attributed her success to teachers' clear explanations rather than her ability. She was often one of the first people to catch on to new material in her high school math classes and her college math class for elementary teachers, and her peers often came to her for help. If she did not understand something right away, she made a point of going to the teacher for help immediately.

However, Cynthia was a "teacher pleaser" who had an external locus of authority both as a student and as a teacher. As a college student, Cynthia would often read ahead in the syllabus and ask detailed questions about expectations for future assignments. She frequently turned in drafts of assignments early and asked if she had done it "right." During interviews for this research study, Cynthia would ask, "Am I telling you what you want to know?" "Am I giving you what you need?" Cynthia's lessons, both as a preservice and inservice teacher, were characterized by following the textbook and presenting clear, logical, well-organized explanations to students. Students did engage in activities, including hands-on activities, but these were always tightly structured and almost always procedural in nature. Cynthia's interactions with students were generally quite directive. As a preservice teacher, Cynthia offered the following response to a written case: "To break this habit of writing the problems incorrectly, I would show them many times how to write the problem and have them do many practice problems themselves because practice makes perfect!" In providing suggestions for a peer who was having difficulty teaching a child the standard addition algorithm, Cynthia wrote, "First, the child needs to learn to start every addition problem in the right-hand column, or she will never remember to add the one. Model for her the correct way to do two-digit addition problems while you are teaching her how to actually do them." These suggestions typified her teaching during her field experiences and her first two years of teaching.

During one observation Cynthia was circulating around the classroom as students worked independently. One student was confused, and she looked at his paper and said, "Write 3. Just write the number 3." Two more students had questions, and Cynthia told them what to write on the worksheet. Similarly, in a lesson on graphing in a second grade classroom, Cynthia was working with a small group of children who had just finished collecting data from their peers. She asked the group what color most people chose as their favorite. One student noted that he had a tie–the same number of people selected two colors as their favorite. Rather than asking the student what he meant by a "tie" or engaging the children in a discussion about what they should put on the worksheet if two colors were tied, she simply told the student to write the names of both colors in the blank. Later in the lesson, the worksheet contained the question, "How many people liked horses or dogs the best?" The children were not sure how to interpret the "or" part of the question. Cynthia quickly told them to count how many people picked dogs and how many people picked horses and write the total in the blank.

Cynthia's reflections on her lessons were generally confined to assessments of student behavior and her organization in preparing for and implementing the lesson. For example, after one lesson she noted that students were engaged because "I made my word problems contain aspects of the Halloween season, such as trick-or-treating, candy, and toys, because those things were what [they were] interested in at the time."

*Shelly*

Shelly provides an example of a teacher with low content knowledge and an internal locus of authority. Shelly struggled with mathematics, taking the Praxis I basic skills test several times before passing the mathematics portion. She admitted to feeling a great deal of anxiety and to having a lack of self-confidence regarding mathematics teaching and learning.

Shelly demonstrated that she had an internal locus of authority by making modifications to textbook lessons even as a preservice teacher. During a field experience where she was in a school that had adopted the Saxon curriculum, she felt comfortable going outside the scripted lesson to add her own touches. In particular, she often incorporated children's literature and hands-on activities in her lessons. She also demonstrated her internal locus of authority in her reflections on her teaching. At the conclusion of an 8-week one-on-one teaching experience she noted, "I have made some improvement through trail and error….I stopped worrying so much about planning things that were on her grade level but rather planning things based on her success during a lesson."

Although Shelly planned lessons that engaged students, her lack of mathematical knowledge often caused her lessons to collapse. She frequently started lessons with children's literature books that were only tangentially related to the topic at hand. For example, one day during her second year of teaching she had planned a lesson on graphing in late October. The lesson involved children making glyphs based on their favorite things about Halloween. Shelly began the lesson by reading a book about Halloween, but it had no connection to the mathematics of the lesson, so 15 minutes of the lesson were spent discussing ghosts, witches, and other Halloween creatures.

A more illustrative example of how Shelly's weak mathematical knowledge interfered with her lesson planning came from a lesson on even and odd numbers that she taught in her first-grade classroom during her second year of teaching. After an introduction, Shelly handed each child a piece of paper and told them to write their first name on it. She then placed a pile of cubes at each table and told the children to count out enough cubes to equal the number of letters in their first name and snap them together. Shelly then told the children to "see if you can divide your cubes into 2 groups evenly." She chose a student's cube train and said "This is what I'd do." She modeled snapping off one cube at a time and alternating placing them in one pile or another. She then asked if the result was fair, if the piles were the same (her informal definition of "even"). After giving the children time to work independently, she called the class back together and asked one child at a time to say how many letters were in their name, to show their cubes and tell whether they could put them into 2 equal groups, to declare whether their name (not the *number of letters* in their name) was odd or even, and to come to the front of the room to attach their name to a poster under "odd" or "even." She had one child snap his cubes off one at a time and place them in her hands, alternating between left and right. Then she had him count 6 in one hand and 5 in the other and asked him whether it was fair or even. The child said "yes," so, she ended up telling him it was odd when he said the amounts were not equal. After the lesson I examined a child's textbook and discovered that the book taught odd/even by having children use cubes to represent a quantity and then snap the cubes off in 2s (pairs) rather than putting them in two groups (measurement division rather than partitive). When I asked Shelly if she had already taught even and odd numbers this way she seemed completely unaware of this approach and said that she would try it because it might be easier. This is an illustration of Shelly feeling comfortable to go beyond the textbook to design her own lesson but not having the mathematical foresight to realize that she was creating problems with students' understanding by introducing a method that was contrary to the method the students had to use to do their homework. In our post-observation conference Shelly indicated that she planned to delay the test on this chapter because she did not think the students had a firm grasp on even and odd numbers.

*Tracey*

Tracey was not confident in her mathematical ability, claiming that "math has always been my least favorite subject throughout school, and I've always called it my worst subject." She said she was not good at quick computations and memorizing algorithms, and this had worked to her disadvantage in school. She hoped not to have to take any math in college but said she enjoyed her math for elementary teachers course "once I figured out what I was supposed to be doing."

I claim that Tracey had an external locus of authority for herself as a future teacher and that she saw herself as that external authority for her students. As a preservice teacher she noted that time would be a constraining factor in the classroom and that it would not be possible to hear ideas from many children. She stated that moving through the curriculum at a predetermined pace and adhering to school system requirements was a higher priority than listening to children. She also noted that sometimes what a child says is "off the wall and would only confuse mattes more or lead the topic off on a tangent."

In Tracey's first field experience, I saw evidence that she viewed herself as an authority for her students. Her lesson was very directive, and she was spoon-feeding the children to enhance their short-term success. In helping second-graders complete a two-digit subtraction problem, she asked questions such as, “Where do I start?” “What problem do I do first?” “What is 8 minus 5?” “Where do I put it?” “Am I done with this part?” “Where do I go next?” Her lesson was a string of such bite-sized questions with no “why” questions at all. For much of the lesson she was helping students create a bar graph about circus animals in order to answer word problems. She directed students to “put your finger on the yellow box. Find the line that says ‘elephants.’ Point to the number of elephants. Who can tell me how many elephants there are?” Then she told a student to come to the board and put the prescribed number of elements on the graph she had created.

Tracey’s overriding concern as a teacher seemed to be to “protect” children from the pain of doing mathematics by either breaking it down into tiny steps and asking structured question that they could answer without much thought or by doing “fun” activities with them. An example of a fun activity occurred during a lesson when she was teaching kindergarten. The goal of the lesson was for children to tell time to the hour. She began the lesson by reading a children’s literature book (*The Grouchy Ladybug* by Eric Carle) and then had the children make their own clocks in the shape of ladybugs using paper plates, construction paper, brads, and pipe cleaners. The bulk of the one-hour lesson was spent on the craft activity of the children constructing the ladybugs. After they had spent 40 or more minutes on their creations, Tracey directed the children to fill in the numbers on the clock face. She did not anticipate that this would be difficult for kindergarteners (cognitively and in terms of fine motor skills), but most of the students ended up with inaccurate representations of clock faces (starting with 1 where the 12 should be, numbers unevenly spaced, numbers going past 12, etc.). Her plan had been to have the children bring their clocks back to the reading rug while she read the book again and have them show each hour on their own clocks. As the time allotted to the lesson began to wind down, she realized that the clocks were not functional because the clock faces were not accurate and because the crafts contained too much wet glue to withstand handling, she omitted the final part of the lesson. In reflecting on the lesson later in the day, Tracey was disappointed in the lesson, but she mainly focused on the effort she had put into cutting out the ladybug wings and spots and bending construction paper to make ladybug legs and her frustration that the clocks did not turn out to be functional because of the glue issue. She did not mention the fact that the clock faces were not accurate or that the lesson involved virtually no mathematics. A similar but slightly less dramatic example comes from Tracey’s second year of teaching second grade in a lesson on “grater than” and “less than.” In an effort to make a lesson “fun,” she gave each student three colored index cards–a pink one with a less than sign on it, a green one with a greater than sign on it, and a blue one with an equal to sign on it. She put two numbers on the white board and asked the students to hold up the correct card (with the sign facing her). In planning this lesson she failed to take into account that the greater than and less than signs are really only one sign and that when the students held up the cards to face her, they would be facing the opposite of the way the children saw them at their desks. After about 10 minutes, she called a halt to the lesson because she could not tell whether the children understood greater than and less than. In reflecting on the lesson, she noted that she had tried to make the lesson more fun and interactive than a worksheet but that a worksheet was probably a better way to assess this content.

## Discussion

Although I have presented examples of four teachers who seem to fit neatly into the cells of Figure 1, the reality is that teachers fit in one cell for some lessons and in another cell for other lessons. Teachers' practices are not consistent across time and setting, and the changes are not necessarily reflective of "growth" toward more reform-oriented teaching or the upper left cell of Figure 1. For example, some teachers were very comfortable asking open-ended questions and building instruction from children's mathematical thinking in their first mathematics methods class field experience in which they worked with one child. In subsequent whole-class field experiences, however, they became more tied to the textbook and focused on correct answers. In most cases, the teachers were aware of the contrast in their instructional style across settings. The teachers attribute these differences to a variety of factors: curriculum constraints, the difficulty of orchestrating discourse in a large group, the challenge of managing children on so many different levels, and the pressure to "cover" the curriculum prior to testing. These findings support Tabachnick and Zeichner's (1984) portrayal of the socialization of teachers as a negotiated and interactive process rather than as one that is predetermined. Our challenge is to refine this claim by explicating the factors that influence this negotiation and in what ways. If we can better understand the ways in which individual teachers integrate the messages they receive from various sources to shape their teaching practice, we can develop ideas about how teacher education programs, induction year support programs, and professional development programs can best assist teachers in developing a practice that leads to rich mathematical activity in the classroom.

*While it has been found that teacher knowledge affects mathematics student achievement, to date, little research has explored how professors affect preservice elementary teacher's mathematical knowledge. This study explores future teachers' learning in undergraduate mathematics classes. Our data includes pre and post tests from over 1000 students in classes of 41 instructors at 17 institutions in four states as well as teacher survey data from those 41 instructors. In our multilevel models, we identify three key variables that influence gain: students' prior knowledge, use of specifically designed textbooks, and the methods the professor uses to teach the course.*

## Introduction

Improving the mathematical knowledge of elementary teachers is key to improving children's mathematical knowledge (e.g., Conference Board of the Mathematical Sciences, 2001; Hill, Rowan, & Ball, 2005; Monk, 1994; Rowan, Correnti & Miller, 2002). Mathematics classes required for certification provide a unique opportunity to influence teachers' mathematical knowledge, yet there has been little research about either what is offered or what students learn in these undergraduate mathematics classes. In this study, we begin to address these questions. On average, undergraduate programs require teachers to take 2.7 mathematics courses for elementary certification and in states where there is a separate endorsement or certificate, 5.6 classes for middle school certification, up from 2.4 and 3 respectively in 2000 (Lutzer, Rodi, Kirkman, & Maxwell, 2007). Although the number of mathematics classes required of these future teachers has been increasing over the last decade, we know almost nothing about the content of these courses, who teaches them, or what their impact is on future teachers' mathematical knowledge. The goal of our research is to understand what these future teachers learn and what accounts for differences in learning across instructors at various institutions. Specifically, we ask what characteristics of students, courses, instructors, and institutions explain variation in achievement across mathematics classes for future teachers that are focused on number and operation?

This work is important because these undergraduate classes are a unique sustained opportunity to influence teachers' mathematical knowledge. If we could learn more about how to make these classes better – to have a greater impact on teachers' knowledge – through changing the content, the textbook, the way classes are taught, or other variables, our findings could have an enormous impact on the preparation of elementary teachers for teaching mathematics

## Background

To investigate this question, we designed a multilevel study at undergraduate institutions in 4 states. We collected data from future teachers (students in undergraduate mathematics classes), instructors, and mathematics department chairs. We developed hypotheses about what variables might predict student learning and tested these hypotheses using multilevel analyses. The complete study is described in detail in other documents including McCrory (2009).

*Literature Review*

The National Math Panel (NMP) report, (see p. 5-1) which summarizes research on teacher knowledge, suggests that the effect of teacher quality on student achievement is large. In one study, 12-14% of the variation in student achievement was attributed to differences in teachers. In another study, the difference in outcomes for students of the worst and best teachers was 10 percentile points on a mathematics assessment. Yet, the NMP report points out that understanding the individual differences that constitute teacher quality remains elusive. One likely candidate is teacher knowledge of mathematics, but there, the research is inconclusive.

Studies of teacher knowledge have typically relied on proxy data (number of math classes, certification status, years of experience, test scores such as SAT or ACT) to investigate the question of what mathematics teachers bring to their teaching. One exception is the work of Ball and colleagues at the University of Michigan (e.g., Hill, Rowan, & Ball, 2005; Hill Schilling & Ball, 2004). In their project, Learning Mathematics for Teaching (LMT), they developed measures of elementary teachers' mathematical knowledge and went on to show that the knowledge measured by their instrument was a significant predictor of K-8 student achievement in mathematics. That is, teachers who scored higher on the LMT measures had students who scored higher on standardized mathematics achievement tests. Their work shows that there is specific mathematical knowledge that contributes to or is an indicator of teacher quality.

What we do not know is whether or how prospective teachers might learn this content. It seems unlikely that they learn it from their high school mathematics classes or from conventional college mathematics courses. If that were the case, the problem of elementary teachers' mathematical knowledge would be nonexistent or at least easy to address. Although some have argued that more required mathematics classes would improve teacher quality, research suggests otherwise: taking more mathematics courses does not necessarily result in teachers who teach mathematics more effectively. Wilson, Floden and Ferrini-Mundy (2002) point out in their report on teacher preparation that studies about subject matter preparation "undermine the certainty often expressed about the strong link between college study of a subject matter and teacher quality" (p. 191). What is missing is a better understanding of the content that matters and how best to offer it to future teachers.

*Purpose of this Study*

This study begins to address what affects prospective teachers' mathematical content knowledge in their mathematics courses. In particular we investigated a number of factors that we hypothesized might influence their mathematical achievement, measured with the LMT items that we know correlate with teacher quality. Factors include the textbook used, the instructor's attitude toward the class and experience teaching the class; and how the textbook was used; and methods of teaching. Other factors, related to the students themselves, are prior knowledge, socio-economic status, and attitude toward mathematics.

## Method

*Population*

Data for this study were collected at institutions in 4 states, chosen to reflect variation in state policy and K-8 mathematics outcomes. The analysis here includes data from 41 instructors and 1706 students at 17 institutions. The data reported in this paper were collected between September 2006 and December 2008.

*Instruments and Data Collection*

Students completed pre- and post-tests using items from the LMT project. The pre and post-tests were different, equated through Item Response Theory (IRT) methods to make results comparable. We used two forms and 6 additional common items. Each student took one of the forms plus the 6 common items for the pretest and the other form for the posttest, making the pretest somewhat longer than the posttest. Thus, every student completed every item, but had completely different pre- and post-tests. The student tests also included attitudes and beliefs items and demographic questions as explained below. The pretest was administered in the first two weeks of class; the posttest in the last two weeks. LMT items are not generally available for public release, but a set of released items is available on the LMT Web site, http://sitemaker.umich.edu/lmt/measures.

Instructors completed an extensive survey developed for this project. It includes questions about content coverage, teaching methods, contextual issues, personal demographics, and more. The complete instrument is available at our Web site, http://meet.edu.msu.edu. The instructor survey was administered at the end of the semester during which student pre/post tests were administered.

*Data Analysis and Results*

The first analyses were on the test scores themselves. We used IRT parameters from the University of Michigan project to calculate pre- and posttest scores for all students. IRT scoring takes into account the difficulty of items and thus makes it possible to compare pre- and posttest scores on the same scale. The scores, however, do not correspond to percent correct and are more like z-scores. For reporting purposes, we set the average pretest IRT score to 50 with a standard deviation of 10. The range of scores is theoretically infinite, but practically, scores fall within 3 standard deviations of the average. Posttest scores are calculated using the same parameters and are placed on the same scale as the pretest. In these data, the pretest mean is 50.00, with a posttest mean of 59.16.

Table 1. *Student (Future Teacher) Descriptive Data*

| Variables | Coding and Range | Mean | SD |
|---|---|---|---|
| Pretest Score | 17 – 79 | 50.00 | 10.00 |
| Prior Knowledge (CACT = SAT or ACT on a common scale) | 12 – 36 | 23.17 | 4.38 |
| I like Math | 0 = Strongly disagree, disagree, undecided<br>1= Strongly agree or agree (Used in model)<br>On 5 point scale (used in correlations) | 0.46<br>3.03 | 0.50<br>1.26 |
| College Math Coursework | 0 = none<br>1 = 1 | 2.47 | 1.12 |

| | | | |
|---|---|---|---|
| | 2 = 2<br>3 = 3<br>4 = 4 or more | | |
| SES (Mother's Education) | 0 = no higher ed, 1 = some higher ed | 0.46 | 0.50 |

Descriptive data for students and instructors are shown in Tables 1, 2 & 3. We developed a measure of prior knowledge for students using self-reported ACT or SAT scores. We put these on a common scale (1-36) using conversions published by ETS and named that variable CACT. We used a single question from the student survey to measure their attitude toward mathematics. They ranked from 1 (Strongly disagree) to 5(Strongly agree) the statement "I like mathematics". We converted their responses to a two-point scale: 0 for a response of 1, 2 or 3; 1 for a response of 4 or 5.

Table 2. *Correlations of Student (Future Teacher) Descriptive Data*

| | 1 | 2 | 3 | 4 | 5 | Variable Explanation |
|---|---|---|---|---|---|---|
| 1 | 1.00 | **0.49 | **0.48 | -0.02 | **0.20 | Pretest Score |
| 2 | | 1.00 | **0.41 | -0.33 | **0.21 | Post test Score |
| 3 | | | 1.00 | -0.01 | **0.31 | Prior Knowledge (C_ACT) |
| 4 | | | | 1.00 | **0.13 | College Math Coursework |
| 5 | | | | | 1.00 | "I like math" (5 point scale) |

*Correlation significant at the .01 level, two- tailed.

For instructors, we asked them what textbook they used for the course. Based on their response and on the list of 13 textbooks in print written specifically for such a course (list available on the Web site http://meet.educ.msu.edu), we created a variable that had the value 1 if they use one of the textbooks on the list as their primary textbook, 0 if they use some other textbook or do not use a textbook at all. We also asked them about their interest in teaching the course before the current semester, and their interest in teaching the course again. Results of these questions are shown in Table 3, along with information about class size, and experience.

Table 3. *Instructor Descriptive Data*

| Variables | Coding and Range | Mean | SD |
|---|---|---|---|
| Primary Textbook from choice of 13 | 1 = a primary textbook on our list<br>0 = not a textbook on our list | 0.65 | |
| Class Size | 4 – 102 | 26 | 13 |
| CACT (mean SAT or ACT on a common scale) | 20 – 27 | 23 | 1.6 |
| Years College Teaching Experience | 0 – 41 | 16 | 11 |

| | | | |
|---|---|---|---|
| Interest in teaching this course | 0=no interest at all<br>1=limited interest<br>2=some interest<br>3=a great deal of interest | 1.26 | 0.59 |
| Interest in teaching this course again | 0=no interest at all<br>1=limited interest<br>2=some interest<br>3=a great deal of interest | 1.22 | 0.55 |
| Teaching Methods (Mean of 11 items) | 1.45 – 4.00 | 2.74 | 0.58 |

Another variable we developed was a measure of teaching methods. For this variable we asked instructors: “In your mathematics course, how often do your students engage in each of the following activities? Please check the box that best describes what happens in your course.” The scale was from 1 to 4: 1. Never or almost never; 2. Some lessons; 3. Most lessons; 4. Every lesson. The 11 items instructors ranked included (complete list available in McCrory, 2009):

- Explain the reasoning behind an idea
- Work on problems for which there is no immediate method of solution
- Listen to you explain terms, definitions, or mathematical ideas (Reversed)
- Listen to you explain computational procedures or methods (Reversed)

Since these are questions about what the instructor expects *students* to do, the last two on the list were reverse coded to create a scale that indicates student’s personal engagement with the mathematics as compared to listening to the instructor. At one extreme (4), students would be doing mathematics at all times. At the other extreme (1), students would be listening to the instructor at all times. As table 3 shows, the mean score on this variable was 1.81 suggesting that these instructors use a mixture of methods, leaning slightly toward student engagement. Although the dataset includes many more variables than described here, we include only those used in the models developed thus far.

To put the student and instructor data together and investigate our hypotheses, we developed a growth model using HLM (Raudenbush & Bryk, 2002). Although growth models are most often used with more than two data points to measure growth, we chose this model because it allowed us to interpret the data more completely than a two level model with either gain or posttest score as outcome, and it allowed us to use level 1 data from students who took only the pre or post test. Because we are using scores from an Item Response Theory (IRT) model, it is possible to estimate the growth model with only two data points. In this model, we define three levels. Level 1 is the growth level with time set to 0 for the pretest, 1 for the posttest. Level 2 is the student level. Level 3 is the instructor level. We do not have adequate data for an institutional level, and have not developed a state-level model (which would include only 2 states because of the sparse data in the other 2 states).

*Figure 1.* Unconditional model for allocating variance.

Level 1- Growth:

$$Y = P0 + P1*(TIME) + E$$

(TIME is 0 or 1)

Level 2 - Student:

$$P0 = B00 + R0$$

$$P1 = B10 + R1$$

Level 3 - Instructor:

$$B00 = G000 + U00$$

$$B10 = G100 + U10$$

(E, R, and U are random error)

The unconditional model is used to allocate

*Figure 2.* Model 2 with preditors at student and instructor levels.

Level 1: Growth Model
    Y = P0 + P1*(TIME) + E
    (Time is 0 or 1)
Level-2: Student Level with CACT
    P0 = B00 + R0
    P1 = B10 + B11*(CACT) + R1
Level-3: Instructor Level with Textbook and Methods
    B00 = G000 + U00
    B10 = G100 + G101(TEXTBOOK) + G102(METHODS) + U10
    B11 = G110

variance. There are no predictors in the model and what we learn from it is how much of the variance is within instructor and how much between instructors. Although we are interested generally in explaining achievement, the primary purpose of this analysis is to explain variation between instructors. This model is shown in Figure 1.

From this model we get the following data:

Mean Pretest score (B00): 50.56
Average gain (B10): 7.73
Gain Score student level variance: 3.72
Gain Score Instructor level variance: 7.80

Note that the mean score of 50.56 differs from the set mean of 50 because even in this simple model, Bayesian estimation techniques are used and error is in play. For our models, we assume that there is measurement error, and we use expected a posteriori (EAP) procedure for calculation of parameters. Variance is a pure number without units, and this tells us that if we assume there is measurement error, we have a lot of variation between instructors relative to the variance within classes.

We built a number of models to test hypotheses and found no significance for student SES, instructor experience, instructor attitude toward the class, or class size. Significant predictors include student CACT, student attitude toward mathematics, textbook used, and method of instruction. We found that CACT and student attitude were correlated, so that if both are in the model, one loses significance. We chose to use CACT rather than student attitude in our models because of the measure's greater reliability. Although we have not completely tested all hypotheses, the model that best predicts student outcomes so far is shown in Figure 2.

Results of Model 2, shown in Table 4, are:

Mean Pretest: 51.48
Average Gain, no primary textbook, average methods: 4.79
Average Gain, Add primary textbook 4.58
Average Gain, Change in methods by one point: 2.92
Average Gain, Change in CACT by one point: 0.52

Again, the mean pretest is different from 50 and also different from the unconditional model because the estimation method is recursively using the data to come up with the most likely "true" value of the mean pretest. In this model, we predict that an instructor with average methods score of 2.73 (see Table 3) who did not use one of the 13 textbooks on our list would have an average posttest score in his/her class of 51.48 + 4.79 = 56.27. If the instructor used one of the textbooks, the predicted posttest score would increase by 4.58 points; and if the instructor scored a point higher on the methods measure, the predicted score would increase by 2.92.

There are numerous issues with these models and with the results, not least of which are the set of decisions about the role of error; which parameters are fixed and which are allowed to vary by instructor (e.g., in Model 2, we did not let CACT vary by instructor, indicating an assumption that instructors are equitable with respect to prior knowledge); and which IRT parameters to use. We have tried the models with different assumptions, and although the absolute numbers are different, we consistently see that the use of one of the textbooks and the use of different teaching methods are significant – statistically and practically – at the instructor level; and the CACT score (a measure of prior knowledge) is significant at the student level. The more prepared students are for this class (as measured by SAT or ACT), the better they do on the tests. That is no surprise, but it may be a surprise that the CACT and attitude toward mathematics are equally good predictors (raising a chicken and egg question that cannot be answered with our data). We also checked the assumption that instructors are equitable with respect to CACT and found it to be correct.

Table 4. *Model 2 Results*

| | Coefficient | Error | T-Ratio | d.f. | P-Value |
|---|---|---|---|---|---|
| For INTRCPT1, P0 (pretest score) | | | | | |
| For INTRCPT2, B00 | | | | | |
| INTRCPT3, G00 | 51.48 | 0.60 | 85.82 | 37 | 0.000 |
| For POST slope, P1 (Gain score) | | | | | |
| For INTRCPT2, B10 | | | | | |
| INTRCPT3, G100 | 4.79 | 1.08 | 4.42 | 35 | 0.000 |
| TEXTBOOK, G101 | 4.58 | 1.35 | 3.40 | 35 | 0.002 |
| METHODS, G102 | 2.92 | 1.10 | 2.70 | 35 | 0.011 |
| For CACT, B11 | | | | | |
| INTRCPT3, G110 | 0.53 | 0.07 | 7.73 | 952 | 0.000 |

## Discussion

Several results stand out in this analysis. First, students' attitudes toward mathematics are very important. In particular, whether they like math or see themselves as capable of doing mathematics are both significant predictors of their achievement. This is no surprise given the history of research on attitudes toward mathematics, but it signals a possible leverage point for improving teacher knowledge. If we could make inroads into improving future teachers' confidence in their mathematical ability or their attitude about mathematics, we might be able to teach them more effectively. An alternative hypothesis is that they dislike mathematics because they are bad at it and that their self-assessment is accurate. This depressing view is not borne out by research that suggests that students' mathematical abilities are not fixed, but depend on their effort and engagement.

Second, students' prior knowledge is important. If students enter the class with a weak background, these classes generally do not make up for these deficits, although some instructors are more successful here than others. On the encouraging side, even students with weak prior knowledge are, on average, learning from these classes.

Third, students are learning a lot from these classes. A gain of 9 points is almost a full standard deviation. This is a big gain by any standards, and since we have reason (from LMT) to believe that what they are learning matters in their future teaching, this is an important finding. Fourth, students in classes of instructors who use one of the textbooks designed for a mathematics class for future elementary teachers are more successful than those in classes that do not use such a book. This may be because the books tend to treat the mathematics more coherently or appropriately than self-developed materials or other mathematics textbooks not intended for such classes. Alternatively, it may be that the textbook signifies something else about the class that matters. For example, it could be that instructors who use one of these textbooks teach in a more consistent manner across the semester, or that the department syllabus based on the textbook is better developed. There are many other possibilities that could explain this result. Without more data from different textbooks, there is little we can say to explain this further.

Finally, and perhaps most surprisingly, the teaching method matters. Teachers who report more student engagement with mathematics and less lecturing tend to have greater student achievement. This may be related to the first point in this discussion: students do better when they have a more positive attitude toward mathematics. A class in which they have an opportunity to work directly on mathematics rather than only listen to mathematics may be instrumental in developing a more positive attitude. One could argue that agreeing to participate in the ME.ET project signals a different set of beliefs or commitments to mathematics education, making the method result an artifact of the particular instructors involved in this study. But we did have considerable variation on this measure, suggesting that even if these instructors are different than nonresponders, they are also different from one another.

We are still analyzing these data, and will have a more complete report on model development. We will also develop structural equation models to try to tease out more complex relationships among variables (e.g., that the teaching methods may result in more positive attitudes that then impacts learning). In the meantime, our results suggest that there are leverage points in the courses that could be used to improve the mathematical knowledge of future elementary teachers.

## Acknowledgements

This research is funded by the National Science Foundation (Grant No. 0447611). The authors wish to thank the instructor who generously participated in this project and the other team members – Ga Young Ahn, Rachel Ayieko, Marisa Cannata, Beste Güçler, Rae-Young Kim, Young-Yee Kim, Jane-Jane Lo, Jessica Liu, Jungeun Park, and Helen Siedel – who collected data and participated in discussions that made our analysis possible.

# INSIGHTS FROM MATHEMATICS TEACHERS IN URBAN/SUBURBAN CLASSROOMS: FIRST YEAR AFTER TEACHER PREPARATION

Pier A. Junor Clarke
Georgia State University
pjunor@gsu.edu

*This study examines alternatively prepared secondary school mathematics (SSM) teachers' thinking and what they actually do to facilitate teaching and learning in their classrooms. After teacher preparation, these SSM teachers complete their first year in an urban or suburban school. A phenomenological approach captures and unfolds the SSM teachers' perspectives. Deep caring and other authentic strategies were their pro-activities that led to success among their students and provided further insights and new directions to the preparation of future alternatively prepared secondary school mathematics teachers.*

## Objectives and Purposes of the Study

The impact of teachers on the education of students in urban schools has continued to be of concern at both local and national levels (Junor Clarke, 2008; Ingersoll, 2001). In particular, a high percentage of these teachers who were going into the urban classrooms were alternatively prepared (Wilson, Floden & Ferrini-Mundy, 2001). As a faculty member in an alternative teacher preparation program at an urban institution in the southeastern United States, I continue to inquire about the experiences of our teachers as they commit themselves to teach in urban or suburban classrooms. Four out of the five schools to which a cohort of our graduates returned would be considered moderate- to high-diversity schools because they have greater than 10% ethnic minority student population (Freeman, Brookhart, & Loadman, 1999). In such environments, understanding the way these teachers think and facilitate teaching and learning becomes necessary. The objective of this inquiry is to gain insights and to think further or rethink how these teachers are being prepared for the urban classrooms.

In this study, I examine five alternatively prepared secondary school mathematics (SSM) teachers who have completed their first year in an urban or suburban school after teacher preparation at an urban research university in the southeastern United States. To understand the teachers' thinking and what they actually do to facilitate teaching and learning in their classrooms, I ask the following research question: *What are alternatively prepared secondary school mathematics teachers' perspectives of the reality in their urban/suburban classrooms?* For the purpose of this proposal, I report on two alternatively prepared SSM teachers.

## Conceptual Framework and Context of the Study

A phenomenological approach provided the framework to capture and unfold the teachers' perspectives as they continued to teach students in urban and suburban schools. Phenomenology research design allowed me to study the deep human experiences of the secondary mathematics teachers in their own classrooms and provided the flexibility to take every word that accurately depicts the rich descriptions of the teachers' experiences (Blodgett-McDeavitt, 1997; Husserl, 1970; Junor Clarke, & Thomas, 2009; Moustakas, 1994; Schwandt, 2001). This level of engagement enabled me to see data from new and naïve perspectives such that fuller, richer, and authentic descriptions can be rendered (Junor Clarke, & Thomas, 2009; Blodgett-McDeavitt, 1997) and that I make meaning based on the SSM teachers' human experiences (Patton, 2002).

*Context for the Study*

The participants of the study are secondary school mathematics teachers, who were prepared at an alternative teacher preparation program in an urban institution in the southeastern United States. They were teaching with a provisional licensure and pursuing certification and a master's degree in the program. The duration of the program was for four semesters. Upon graduation, the SSM teachers continued to teach in their urban/suburban schools.

## Methodology

The participants of this report are two women out of the study's five SSM teachers—three female and two male. The two women were assigned pseudonyms, Anna and Laura. Anna was chosen because she was the only one at a suburban school, and Laura was randomly selected from the remaining four participants who were in urban schools. While in the preparation program, they taught during the day and came to classes in the evenings. These teachers were already teaching on a provisional licensure and were in the program to gain their full certification and a master's degree. After graduation, the participants remained teaching in their schools. Class descriptions (Table 1) and the demographics (Table 2) of Anna and Laura's schools are provided below:

Table 1. *The Secondary School Mathematics (SSM) Teachers' Teaching Experience, Ethnicity, Content Taught, Grades Taught, and Class Size*

| Teacher | Experience | Ethnicity | Content Taught | Grade(s) | Average Class Size |
|---|---|---|---|---|---|
| Anna | 3 yrs | Latina | Algebra, Calculus | 10-12 | 10 |
| Laura | 4 yrs | Hispanic | Algebra | 9 | 18 |

Table 2. *The Demographics of the Secondary School Mathematics (SSM) Teachers' Schools*

| | | Demographics of Students | | | | | |
|---|---|---|---|---|---|---|---|
| Teacher | School Type | Black | White | Hispanic | Black & Latino | Latino | Asian and/or White |
| Anna | Suburban | n/a | 95% | n/a | 5% | n/a | n/a |
| Laura | Urban | 40% | n/a | 20% | n/a | n/a | 40% |

*Procedures*

A graduate research assistant (GRA) conducted the 1.5 hour-interviews using a storytelling approach to capture the SSM teachers' stories that depicted their experiences (Creswell, 1998, p. 54). Stories are defined as socially constructed accounts of past events that are important to members of an organization (Junor Clarke, & Thomas, 2009; Hansen & Kahnweiler, 1993). These accounts are seldom factual; however, they reflect what people believe should be true. They differ from gossip because they have a moral. Stories permit researchers to examine perceptions that are often filtered, denied, or not in participants' consciousness during traditional interviews. "Stories happen naturally as a way of telling one's perceptions of past events, problems, or people . . . They are easy to follow, generally entertaining and are more likely to be remembered than other forms of written or oral communications" (Hansen & Kahnweiler, 1993).

This approach allowed the SSM teachers to convey their thinking and understanding of the reality in their urban/suburban classrooms (Eisner, 1998; Mertens, 1998). The follow-up questions in the interviews explored the meaning of each teacher's lived experience (Creswell, 1998). Through the interviews, data for this study was collected. Use of storytelling allows a unique aspect of analysis with respect to story components. Stories can have main characters, motivating difficulties, heroes, villains, turning points, and morals. After the teachers told their stories, the following questions were asked: (1) Who is the main character in your story? (2) What is the motivating difficulty? (3) Who or what is the hero(s) in your story? (4) Who or what is the villain in your story? (5) What is the turning point in your story? (6) What is the story's moral? (7) Is there anything else you would like to add? In the interview, the following additional questions were asked before bringing the interview to a close: (1) What effect did your preparation have on your practice? (2) What were your experiences in the teacher preparation program that prepare you for your profession?

*Data Collection and Analyses*

The GRA informed the SSM teachers about the goals of this study and asked them to tell a story about mathematics teaching and learning. They were encouraged to include in their stories their perspectives on the impact made on their students. Their stories could be about any event that occurred within the past 6 months, or they could simply relate an incident that was of particular interest. The story should have a hero, a villain, a turning point, a moral, and anything else the SSM teachers may want to add.

The GRA transcribed the teachers' stories and I coded the data. Using the codes, I was able to dissect the stories in searching for essential structures. Data were extracted from each SSM teacher's story about the reality in their urban/suburban classrooms. The additional questions in the interview provided supplemental data for the analysis. In the data analysis, I exercised the research process, known as epoche (Holstein & Gubrium as cited in Denzin & Lincoln, 1994) in which I set aside my taken-for-granted orientation about the phenomenon. The SSM teachers' experiences that highlighted the content and pedagogy were the themes used to demonstrate the reality in their urban/suburban classrooms.

## Findings and Analyses

The SSM teachers' stories reflected on common themes that were evident in their classrooms and that had drawn their interest as being important to them at the time, such as (1) classroom culture, (2) management of students, (3) teaching content, (4) cognitive aspects of student learning, and (5) affective aspects of student learning.

*Anna*

Anna's story was based on her lived experience in a calculus class, where she changed her students' work ethics and development during one year. Her story describes how one student became upset with her after receiving the results of his test, recognizing that problems on the test were not the same like the ones Anna gave them in class. Anna was persistent with her approach, maintained the standards set, remained in charge, and helped her students. Subsequently, she was able to build a learning community where her students realized success and developed great attitudes that other teachers recognized. She established a positive reputation from her efforts not only in her classrooms but also in the school.

*Culture of the classroom.* The main character of her story was the student who helped her to make all the other students understand what she was expecting from them. The students were expecting a different teacher, not one who was tough and demanded much from them. They found that lots of work and "hard" tests became the norm in the class. Anna had high expectations for her students to do well at any cost and she was willing to pay the price. One student said to her after receiving his test, “This is not exactly what we have been doing, this is something new.” Anna responded, “Yes, it is something new! But there is some supplemental material you are supposed to get for yourself after what we have studied in class; this is part of your expectations.” She further expressed to her students that their expectations of her giving them examples of questions on the test would not happen and her expectation is that they must be able to work on problems they have not seen before. Anna began a new classroom culture where students do not have to like her but trust her. She admits that trust is important.

*Classroom management.* Anna’s class was always pre-occupied with work so there was no opportunity for negative classroom management, except for the time when the one student challenged her. There was a back and forth response on which she did not give in to the student but tried to let him understand her expectations. This confrontation was not helping her because she was trying to establish positive relationships with the students. However, Anna maintained her position on the expectations and worked on building relationships with the students all year. She sets the tone for the class through maintaining a class that is well managed and organized and has procedures and high expectations for her students.

*Content focus.* The student who challenged Anna was actually very bright, but he was apprehensive based on his previous experience of getting what he wanted, that is, samples of problems on the test. Because Anna did not accept his unwarranted needs, he responded: “Well, I think you need to start giving us examples of the questions you are going to put on the tests.” Anna made it clear to the student that, “Well, if that is your expectation then that is not going to happen. I expect you to work on problems you have not seen before on a test.” She continued to give her students problems where they could be successful but at the same time allowing them to explore and solve problems they did not see before. She insisted that students had to overcome their preconceptions about mathematics and how they learn mathematics. She maintained her support and fostered commitment of her students to mathematics all year.

*Cognitive aspect of learning.* The one student who had complained earlier in the class did a wonderful job. Other students of her calculus class would attend after school sessions to work with students from different classes. However, one day her students’ previous teacher came to Anna and said, “I want just [for] you to know that I am so amazed of what you have done with this group of students this year because they were all in the after school [session] working and even though you were not even there, they had a great attitude and even though it was a tough problem and they did not know what to do, they were discussing the math[ematics], they were arguing.”

*Affective aspect of learning.* Though the challenges from her students and her persistence for them to be accountable in the learning process, Anna recognized that over the year she and her students were able to build a learning community at the school, which she thought was a very positive and encouraging experience for their learning. She believed that she was responsible for establishing the relationship and helping students to achieve success.

*Connection to her teacher preparation.* Anna’s confidence in teaching was credited to her preparation in the teacher preparation program. One of the NCTM standards is to maintain high expectations and Anna surely made her point and followed it through to the end with her students in the suburban classrooms. She also felt that she was successful in establishing a true learning community that she experienced with her colleagues during her teacher preparation program. Her definition of a high quality teacher depicts what she did with her students.

*Laura*

Laura's story is about the development of a notebook in one of her algebra classes. This was similar to an idea from one of her colleagues in a teacher preparation class where they worked in groups. While her colleague used the idea of a toolbox, she used the idea of the notebook as a "BRAIN." When Laura tried to implement this idea at first it was "really a disaster" because she claimed that the students were overwhelmed and the idea just went for naught. "Trying to implement new ideas in the classroom and how to be successful" was the motivating difficulty in Laura's story. However, she decided to be a little more organized and more committed on her next trial in the next semester. She gave the students time during the semester like on Fridays every two weeks she gave the students 30-45 minutes for the activity. As a teacher she invested a lot of time and resources to ensure students had their work organized. Laura struggled with the students' lack of skills and the time constraints to implement the idea on a regular basis.

*Culture of the classroom.* The main character and hero of Laura's story was Ashley, whose work had impressed her. The activity had created a new culture in the classroom where Laura felt "students were talking about math," and they were sharing and using the mathematical language in asking each other: "Do you have this one about solving equations [correct]? – No, I don't have that one." Laura realized that her students were really beginning to use that math language related to mathematical concepts that they never use. She also recognized that they had to be attentive to the vocabulary and be more detailed oriented for them to create notes for the notebooks. This was different from what they would do, as Laura said, "If you send them home and tell them okay this is due at the end of the month they could care less, but if you put time in the classroom, then they see more value"

*Classroom management.* However, on her two efforts to implement the notebook "BRAIN" idea, she realized that she needed to give the students class time, for example, every two weeks on a Friday she provided 30-45 minutes to the students during the semester to work on this activity. Intermittingly, she found that she fell behind in the curriculum because of the students' lack of skills and the time constraints. The villain of Laura's story was her struggle to manage the lack of skills and the time constraints to do so effectively.

*Content focus.* Laura's students were extremely weak in the mathematics skills. The activity that Laura gave to her students was to reinforce the mathematics concepts they have learned and learning in class. The final product of the activity at the end of the semester was anticipated to be an organized notebook called the "BRAIN" with the important concepts and skills learned in the class. Her intention was that students would have a product "that they feel proud of and that was related to the material they were learning."

*Cognitive aspect of learning.* Laura had a plan for her students. She wanted them to see the value in the work of the notebooks. But she realized that she had to communicate what she wanted to the students and to give them time in class to process that way of thinking. Laura stated, "that is what made them [the notebooks] valuable to them [the students]." Though her first attempt was a "disaster," she realized that in her next effort she would do it much better because "I knew it was something of academic importance for my students."

*Affective aspect of learning.* The hero of Laura's story was one of the exemplar in the class. As Laura expressed,

> The second semester was much, much better. Most of my students participated during the semester. What I really liked about it was a girl who put her heart [the drawing of a heart] in the notebook. That showed me the talent and the potential,

> this girl had. She really put all her heart into it [the assignment]. It [the notebook] had everything I had asked for. She was very proud and I was also very proud of her because she really dedicated her time to it. There were other stories a little bit similar, students who showed their personality, it was a good experience because I got to know the students a little bit better.

*Connection to her teacher preparation.* Laura aluded in her story to her process in teacher preparation ending positively saying:

> It was positive because students like Ashley turned in really good work. It was like going through a process, sometimes when you go through college, the kind of work that you do in college, you have to make sure that everything is in there. Sometimes it is hard, but you have to go through the process and finish it and I think I gave that opportunity to the students. It was good because at the end of the semester most of the students made sure it was finished and they were talking about their content, in what order and I think it was a good experience.

Laura's persistence in retrying her notebook activity came directly from her experience in the teacher preparation program with one of her colleagues who tried a similar activity several times and convinced Laura that it will work. Therefore, Laura was confident that with a few trials, she would be successful, too. She revealed, "So although the first time it was not successful, I knew I could try again and do it much better. I knew it was something of academic importance for my students."

## Discussion and Insights

The stories were actually small testimonies of their teaching that provided multiple meanings and interpretations (Newkirk, 1992). The two SSM teachers' data indicated that they were proactively reflecting and using the experiences they had in the teacher preparation program. Through their lens, deep caring and the authentic strategies they explored with their students brought them successes that were much needed in their urban/suburban classrooms (Blodgett-McDeavitt, 1997; Junor Clarke, & Thomas, 2009; Moustakas, 1994; Schwandt, 2001). The meanings that I perceived from their voices (Patton, 2002) are described in the following sections:

### *Prior Experiences from Teacher Preparation*

In the methods courses, the SSM teachers and I developed a learning community built on sharing, trusting, and caring. In this nurturing environment, they were expected to pull from the experiences of each other. Therefore, it was not surprising but fulfilling to realize that the graduates were actually drawing upon the expertise of each other. Specifically, Laura enacted an activity that Anna had shared in our learning community. I believe the graduates had a sense of community which began in the preparation program.

### *Reflecting on Practices*

The theme of our teacher preparation program was *"Teacher as Reflective Practitioner."* The SSM teachers were consistently reflecting as part of their preparation. I realized that this practice became routine in the program and even in their K-12 classrooms. Teachers who reflect on their practices are expected to improve, but when they do so in learning communities, the results are powerful (Wenger, 1999).

*Insights and New Directions*

Unlike other mid-career changers, the SSM teachers in this study have at least 3 years' experience in the mathematics classrooms. These teachers have the ability and commitment to remain in their schools and community. Their impetus to work with children was paramount. Their stories were actual experiences in their classrooms and interestingly they provided the challenges they face in implementing some of the ideas they learned within our program. Although this may be limited evidence on which to make judgments about the shared views of their classrooms and the discourse, some inferences could be made. The SSM teachers provided authentic experiences, which were growth statements depicting the changes brought to their classroom to assist students to achieve. However, for the episodes they focus more on classroom management, specifically the attitudes of the students and developing their confidence in engaging the students during implementation of the ideas. I felt a sense of silence in the collective stories (Newkirk, 1992)—no one particularly talked about their own mathematics knowledge for teaching students and how that knowledge was perceived by their students. This is the second cohort of students that I worked with in collecting similar data. From this experience, I believe that the nature of the methods was limiting in providing more holistic perspectives of what happened in their classrooms. To gain more insights would definitely demand different methods of data collection.

I am encouraged to enhance the emphases on mathematics knowledge for teaching and the benefits/challenges of technology integration in their mathematics classrooms in such a way that it also becomes a continuing conversation for our graduates.

## Endnotes

I acknowledge the graduate research assistant, Hender Jimenez-Saavez, who interviewed the secondary school mathematics teachers and worked in accommodating their busy schedules. Appreciation is also extended to the secondary school mathematics teachers who volunteered to share their time and experiences with us.

*This study compared mathematics beliefs and content knowledge for teaching of two groups of preservice teachers in a changing elementary teacher preparation program: (a) those who completed a program with three mathematics content and two mathematics methods courses, and (b) those who completed a program with four mathematics content and one mathematics methods courses. Results show both of these programs increased personal teaching efficacy, teaching outcome expectancy, and cognitively-oriented pedagogical beliefs. Exchanging a methods course for a content course had no significant effect on content knowledge for teaching; further, greater content knowledge for teaching correlated with more cognitively-oriented pedagogical beliefs.*

## Objective

A teacher preparation program at a large, urban university in the southeastern United States recently responded to a mandate from its university system by increasing the number of mathematics courses for elementary preservice teachers. This change resulted in the exchanging of a second mathematics methods course for a fourth mathematics content course. That is, the Old Program included three courses in mathematics content for elementary teachers and two courses in mathematics teaching methods; the New Program now includes four mathematics content courses and a single mathematics teaching methods course. To examine the longitudinal impact of these programmatic changes, we created a research effort we call the Mathematics Education Research Project (MERP). This specific study compares longitudinal changes during the Old and New Programs.

## Theoretical Perspectives

Relationships between teachers' beliefs and teaching are well-established. Beliefs influence teacher behavior and decision-making (Thompson, 1992), and change in beliefs is a crucial precursor to real change in teaching. Beliefs develop over time (Richardson, 1996), are well-established by the time a student enters college (Pajares, 1992), and develop during what Lortie (1975) terms the *apprenticeship of observation* while a student. Teacher preparation programs have a limited amount of time to effect any changes.

Many studies on changing mathematics pedagogical beliefs have focused on aligning these beliefs with a reform perspective. These studies often looked at change during only one course or semester; although some reported achieving desired effects, others did not. Similarly, most studies of preservice mathematics teaching efficacy beliefs have examined a single methods course. However, these studies more uniformly reported significant increases in mathematics teaching efficacy. While these studies contribute to our understanding of these beliefs, it is also

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

important to examine programmatic effects on these beliefs over a longer period. Longitudinal effects of the Old Program on these beliefs are documented in Swars, Smith, Smith, and Hart (2007; 2009/2008 online) and Swars, Hart, Smith, Smith, and Tolar (2007).

## Research Question

What effects has this programmatic change (one more mathematics content course and one fewer methods course) had on longitudinal changes in preservice teachers' efficacy beliefs, pedagogical beliefs, and content knowledge for teaching?

## Methods

In the elementary teacher preparation program studied, groups of teacher candidates completed the 4-semester professional program together in cohorts. The first three semesters each included on-campus courses and 2-day-a-week field placements, followed by a semester of full-time student teaching. Field placements prior to student teaching (and coursework, when applicable) followed a developmental model, with the grade level focus starting in pre-kindergarten and finishing in fifth grade.

The Old Program included three courses in mathematics content for elementary teachers (in addition to university general education mathematics requirements). This sequence of courses, taught by faculty and adjunct instructors in the Mathematics Department, was started before admission to the professional program to ensure the sequence was completed before student teaching. The Old Program also included two mathematics methods courses, occurring during the second and third semesters of the teacher preparation program. The first methods course focused on grades PreK-2, and the second methods course focused on grades 3-5. The methods courses were taught by faculty in the elementary education department, who shared a common philosophical orientation toward the teaching and learning of mathematics. Important goals of the courses included: (a) developing beliefs consistent with the perspective of the *Principles and Standards* (NCTM, 2000), (b) understanding children's thinking about important mathematics concepts, (c) creating problem-solving learning environments to facilitate discourse and understanding, and (d) building confidence as a lifelong learner and doer of mathematics.

The New Program exchanged the second methods course for a fourth mathematics content course. Although the focus of the remaining methods course was changed to P-5, the field experiences during the second semester continued to focus on grades 1-3.

This study includes data from two 5-point Likert-scale surveys, the Mathematics Beliefs Instrument (MBI) and the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI) (Enochs, Smith, & Huinker, 2000). The data also includes scores from a multiple-choice content knowledge for teaching assessment, the Learning Mathematics for Teaching Instrument (LMT) (Hill, Schilling, & Ball, 2004).

The MBI assesses beliefs about the teaching and learning of mathematics and the degree to which these beliefs are cognitively-aligned (Peterson, Fennema, Carpenter, & Loef, 1989, as modified by the Cognitively Guided Instruction Project). The three MBI subscales include: (a) relationship between skills and understanding (Curriculum), (b) role of the learner (Learner), and (c) role of the teacher (Teacher).

The MTEBI consists of the Personal Mathematics Teaching Efficacy (PMTE) subscale and the Mathematics Teaching Outcome Expectancy (MTOE) subscale. The PMTE subscale addresses teachers' personal beliefs in their capabilities to teach mathematics effectively; the

MTOE subscale addresses teachers' beliefs that effective teaching of mathematics can bring about student learning regardless of external factors.

The LMT is designed to identify specific knowledge and reasoning that are important for teaching mathematics from a reform perspective, including such understandings as how to generate representations, interpret student work, and analyze student mistakes. Items are identified in one of three content strands: Number and Operations; Geometry; and Patterns, Functions, and Algebra. However, only aggregate LMT scores were used for this study.

Data from six groups of students are used in this study (three Old Program groups and three New Program groups). MBI and MTEBI data were collected at five points in the program, including the beginning of the 2-year program and the end of each of the four program semesters. The LMT was administered once at the end of the program (following student teaching), using Form E04-A. Sample sizes in the data are 1236 (630 Old, 722 New) for the PMTE and MTOE, 1215 (611 Old, 714 New) for the MBI Curriculum subscale, and 1218 (614 Old, 714 New) for the MBI Learner and MBI Teacher subscales.

## Analysis and Results

The data in this study involve a 3-level nested structure that warrants the use of hierarchical linear growth modeling (HLM) for analysis. Individual measurements over time (L1) are nested within persons (L2) that are in turn nested in groups experiencing Old and New Programs (L3). In addition, there are some variances in the number of measurements per group as well as per person. Both issues are compensated for when using HLM (Singer & Willett, 2003).

Prior research suggests that content knowledge for teaching is correlated with more cognitively-oriented pedagogical beliefs and higher teaching efficacy beliefs (Swars, Smith, Smith, & Hart, 2009). Thus, the results of the LMT were included at the teacher candidate level (L2) of the conditional model. Teacher candidates in both programs completed one mathematics methods course (M1) during the second semester of the program. Only the Old Program teacher candidates completed a second mathematics methods course (M2) during the third semester of the program. The full model equation reduces to the following predictor equation (final model):

$$\hat{Y}_{ij} = \gamma_{000} + \gamma_{010}(\mathrm{LMT}) + \gamma_{100}(\mathrm{TIME}) + \gamma_{110}(\mathrm{LMT})(\mathrm{TIME}) + \gamma_{200}(\mathrm{M1}) + \gamma_{301}(\mathrm{Program})(\mathrm{M2})$$

This model was used to analyze five outcome variables: personal teaching efficacy, teaching outcome expectancy, and pedagogical beliefs about curriculum, the learner, and the teacher. Coefficients from this analysis are given in terms of values on the 5-point Likert scale used in the instruments. Coefficients of influencing factors indicate the changes in the linear model attributable to each significant factor. For each of the five variables analyzed, significant variances remain unexplained.

The difference in mean LMT score (as a percentage correct based on raw score) for teacher candidates from the Old and New Programs was not statistically significant (p = .065), indicating that exchanging a second mathematics methods course for an additional mathematics content course did not have a significant impact (either favorably or unfavorably) on content knowledge for teaching as measured by the LMT. However, the LMT score was found to be a statistically significant factor in accounting for change in most of the other outcome variables, indicating again that teacher candidates with greater content knowledge for teaching also have more cognitively-oriented beliefs and greater personal teaching efficacy.

Table 1 shows the results for personal teaching efficacy beliefs (PMTE), which were positively impacted by LMT score, time, and the second mathematics methods course.

Table 1. *PMTE Significant Results**

| Fixed Effects (final model) | Coefficient | S.E. | t-value | p-value |
|---|---|---|---|---|
| Mean PMTE Score at t = 0 | 3.048 | | | |
| Influence of LMT | 0.685 | 0.250 | 2.734 | .041 |
| Change per semester (TIME) | 0.179 | 0.066 | 2.713 | .042 |
| Influence of 2nd Methods Course (M2) | 0.207 | 0.054 | 3.867 | .017 |

* In this and all other results tables, only statistically significant results are reported.

Table 2 shows the results for teaching outcome expectancy beliefs (MTOE), which were positively impacted only by the second mathematics methods course. This variable is not correlated with the LMT score.

Table 2. *MTOE Significant Results*

| Fixed Effects (final model) | Coefficient | S.E. | t-value | p-value |
|---|---|---|---|---|
| Mean MTOE Score at t = 0 | 3.54 | | | |
| Influence of 2nd Methods Course (M2) | 0.191 | 0.005 | 3.853 | .017 |

Table 3 shows the results for pedagogical beliefs about the curriculum (MBI Curriculum), which were positively impacted by the LMT score and the first mathematics methods course.

Table 3. *MBI Curriculum Significant Results*

| Fixed Effects (final model) | Coefficient | S.E. | t-value | p-value |
|---|---|---|---|---|
| Mean MBI Curriculum Score at t = 0 | 2.719 | | | |
| Influence of LMT | 0.693 | 0.196 | 3.532 | .022 |
| Influence of 1st Methods Course (M1) | 0.460 | 0.062 | 7.394 | <.001 |

Table 4 shows the results for pedagogical beliefs about the learner (MBI Learner), which were positively impacted by the interaction of time and LMT score and by the second mathematics methods course.

Table 4. *MBI Learner Significant Results*

| Fixed Effects (final model) | Coefficient | S.E. | t-value | p-value |
|---|---|---|---|---|
| Mean MBI Learner at t = 0 | 2.850 | | | |
| Influence of (TIME)(LMT) | 0.179 | 0.050 | 3.560 | .022 |
| Influence of 2nd Methods Course (M2) | 0.145 | 0.039 | 3.756 | .019 |

Table 5 shows the results for pedagogical beliefs about the teacher (MBI Teacher), which were positively impacted only by the LMT score, indicating that teacher candidates with greater content knowledge for teaching also held more cognitively-oriented beliefs about the role of the teacher.

Table 5. *MBI Teacher Significant Results*

| Fixed Effects (final model) | Coefficient | S.E. | t-value | p-value |
|---|---|---|---|---|
| Mean MBI Teacher Score at t = 0 | 3.036 | | | |
| Influence of LMT | 0.495 | 0.146 | 3.386 | .025 |

## Discussion and Conclusions

Previous studies have shown that preservice teachers enter teacher preparation programs with relatively well-entrenched beliefs about mathematics teaching and learning (Pajares, 1992). However, our results indicate that this cohort-based, developmental teacher preparation program had significant impacts on many of those beliefs.

The findings reveal that during both the Old and New Programs teacher candidates' pedagogical beliefs became more cognitively oriented, thus more consistent with a reform perspective. In general, those with greater content knowledge for teaching had more cognitively-oriented pedagogical beliefs. In the case of cognitively-oriented beliefs about learners, greater content knowledge for teaching correlated with larger increases in these beliefs as indicated by a greater slope in the linear model for this variable for those with higher LMT scores (i.e., the TIME-LMT interaction).

Teacher candidates' beliefs about the elementary curriculum were significantly impacted by the first methods course in both the Old and New Programs. This course emphasizes problem solving and other mathematical processes fundamental to a standards-based curriculum, as well as student construction of both conceptual understanding and procedural knowledge.

The second methods course in the Old Program significantly impacted teacher candidates' personal teaching efficacy, teaching outcome expectancy, and pedagogical beliefs toward learners. The New Program did not significantly influence teacher candidates' teaching outcome expectancy. Pedagogical beliefs related to the teacher were not effected significantly by either the first or second mathematics methods course.

Both the Old and New Programs were effective at increasing teacher candidates' personal teaching efficacy and pedagogical beliefs during the three semesters of coursework and field experiences prior to student teaching. During student teaching, as expected, personal teaching efficacy continued to increase, while teaching outcome expectancy and pedagogical beliefs remained relatively stable.

Interestingly, the exchange of a second methods course for a fourth mathematics content course affected these program outcome variables in both expected and unexpected ways. Previously reported increases in personal teaching efficacy and teaching outcome expectancy attributed to the second methods course are, as expected, not present in the data for the New Program. Changes in MBI Curriculum beliefs during the first methods course continue to be significant in the New Program. Changes in MBI Learner beliefs are still influenced significantly by time in the program, even though the significant effect of the second methods course is no longer available. While greater content knowledge for teaching mathematics (as represented by LMT scores) continues to be correlated with higher scores on most of these belief variables, it is interesting that the additional content course did not result in a significant increase in LMT scores. Also, MBI Teacher beliefs continue to show an influence from LMT scores and continue to be more cognitively oriented at the end of the program. Unexpectedly, this increase is not attributable to time in the program or a specific methods course and remains unexplained by this analysis.

Limitations of this study include significant unexplained variances that warrant further exploration. We expect some of these variances may be explained by post-hoc analyses of differences due to methods course instructor or field experience location. In considering other research directions, we also hope to acquire data for these same teacher candidates from the ECE mathematics content subscale of the Georgia Assessments for Certification of Educators (GACE) as an additional indicator of mathematics content knowledge.

# PRE-SERVICE ELEMENTARY TEACHERS' UNDERSTANDING OF AN EQUIPARTITIONING LEARNING TRAJECTORY

Gemma Mojica
North Carolina State University
gmmojica@ncsu.edu

Jere Confrey
North Carolina State University
jere_confrey@ncsu.edu

*In this design study, we investigated 56 pre-service elementary teachers' understanding of equipartitioning. Teachers' understanding was assessed before and after an eight-week long teaching experiment that used a learning trajectories approach. Findings from this study indicate that after using a learning trajectories approach in instruction, teachers' knowledge of equipartitioning and their knowledge for teaching equipartitioning increased significantly.*

## Introduction

In the last couple of decades, research on learning has focused on understanding how students reason and how this thinking changes and evolves over time. Some researchers have verified consistent findings relating to these constructs, which they have articulated in the form of learning trajectories. While this has contributed greatly to the knowledge base of how students learn, the field has just begun to explore the extent to which learning trajectories can be integrated into the practice of teaching or in the preparation of pre-service teachers (PSTs).

## Theoretical Perspective

Different terminology and definitions have been used to describe learning trajectories in the literature. Simon (1995) indicates that a *hypothetical learning trajectory*, a teacher's anticipation of the progression of the learning path, provides a rationale for designing instruction, taking into account the learning goal that defines the direction, learning activities, and the teacher's prediction of the potential reasoning and learning of students. Clements, Wilson, and Samara (2004) indicate a learning trajectory is comprised of a mathematical goal, domain-specific developmental progressions that children advance through, and activities corresponding with distinct levels of progression. Catley, Lehrer, and Reiser (2005) suggest learning should be viewed as the process of developing key conceptual structures (Case & Griffin, 1990), or *big ideas*, which coordinate and integrate isolated conceptual components, indicating instruction can be viewed as an orientation towards core ideas that direct teaching and assessment around foundational concepts. They suggest teaching should trace a prospective *developmental corridor* (Brown & Campione, 1996), or *conceptual corridor* (Confrey, 2006), spanning grades and ages, with central concepts introduced early in the school experience and are progressively refined, elaborated, and extended (Catley et al., 2005).

A common theme among the various terminologies is that knowledge progresses from less sophisticated to more sophisticated levels of understanding in a relatively predictable way. Building on the work of others, Confrey, Maloney, Nguyen, Wilson, and Mojica (2008) define a *learning trajectory*, as:

> a researcher-conjectured, empirically-supported description of the ordered network of experiences a student encounters through instruction (i.e., activities, tasks, tools, forms of interaction and methods of evaluation), in order to move from informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time.

We view a learning trajectory as a tool that can be utilized by PSTs to inform key instructional activities, such as planning, teaching, and assessing. While student understanding cannot be observed directly, learning trajectories seek to identify and describe key items, constructs, and behaviors, which can be observed.

Confrey (2008) defines equipartitioning as the "cognitive behaviors that have the goal of producing equal sized groups (from collections) or pieces (from continuous wholes) as 'fair shares' for each of a set of individuals." Confrey makes a distinction between creating unequal sized parts, which she refers to as "breaking," "fracturing," "fragmenting," or "segmenting," and creating equal parts of a group or whole (i.e., equipartitioning). Confrey et al. (2008) conducted a synthesis of the literature on equipartitioning and other areas of rational number reasoning, where they articulate a learning trajectory for rational number reasoning concepts and organize children's reasoning of equipartitioning into four cases: (A) sharing a discrete collection, (B) sharing a continuous object, and sharing multiple continuous objects between (C) more people than objects and (D) more objects than people. Confrey et al. (2008) has built a progress variable for equipartitioning (see Table 1), describing the behaviors and verbalizations of different levels of understanding of equipartitioning. Within each level (i.e., 1.1, 1.2, etc.), Confrey at al. (2008) describes another level of the progression of knowledge: methods, multiple methods, justification, naming, reversibility, and properties.

Table 1. *Equipartitioning Progress Variable in Relation to Cases A, B, C, and D*

| Case | Equipartitioning Progress Variable |
|---|---|
| D | 1.8 $m$ objects shared among $p$ people, $m > p$ |
| C | 1.7 $m$ objects shared among $p$ people, $p > m$ |
| B | 1.6 Splitting a continuous whole object into odd # of parts ($n > 3$) |
| B | 1.5 Splitting a continuous whole object among $2n$ people, $n > 2$, & $2n \neq 2^i$ |
| B | 1.4 Splitting continuous whole objects into three parts |
| B | 1.3 Splitting continuous whole objects into $2^n$ shares, with $n > 1$ |
| A | 1.2 Dealing discrete items among $p = 3 - 5$ people, with no remainder; $mn$ objects, $n = 3, 4, 5$ |
| A, B | 1.1 Partitioning using 2-split (continuous and discrete quantities) |

## Methods

This paper reports findings from a larger on-going design study that took place during eight weeks of a semester long mathematics methods course within the elementary education department of a large southeastern university in the U.S. The study occurred during part of the course that focused on the teaching and learning of equipartitioning. Participants included 56 PSTs who were enrolled in two sections of the course, which met for 75 minutes twice a week. The first author was the instructor of both sections of the course.

One goal of a design study is to create instructional activities or tasks for classroom use (Cobb, 2000) and to systematically investigate "those forms of learning with the context defined by the means of supporting them" (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003, p.9). Thus, a series of instructional activities, or interventions, were designed and implemented to investigate PSTs knowledge of an equipartitioning learning trajectory. These interventions included the following:

- engagement with equipartitioning tasks to develop PST content knowledge;
- an introduction to the articulation of an equipartitioning learning trajectory;
- instruction in the conduct of clinical interviews with different types equipartitioning tasks; and,
- instruction in the analysis of video and student work with respect to the equipartitioning learning trajectory.

During the course, PSTs were first introduced to the construct of a learning trajectory. Next, they were introduced to the equipartitioning learning trajectory for rational number reasoning (Confrey et al., 2008) that situates equipartitioning within this realm of rational number reasoning, in order to help PSTs recognize the foundations of equipartitioning in developing a more robust understanding of a rational number than is currently enacted in U.S. classrooms (Confrey et al., 2008). Over the eight-week period, PSTs were exposed to parts of the equipartitioning learning trajectory and progress variable one case at a time.

As each case was introduced, interventions initially focused on equipartitioning tasks to assess and support the development of PSTs' content knowledge of equipartitioning. The equipartitioning/splitting construct (Confrey, 2008) was new to all PSTs. After PSTs engaged in equipartitioning tasks and discussed their own solutions, as well as the underlying mathematical structures of the tasks, they were introduced to the components of the learning trajectory and progress variable. When these components were introduced, video exemplars of K-5 students, engaged in working with equipartitioning tasks, were presented. Next, instructional activities focused on analyzing other video exemplars of K-5 students. The video exemplars illustrated a range of students' verbalizations and activity as they participated in clinical interviews on the same equipartitioning tasks with which PSTs had previously engaged. Class discussion focused on analyzing student thinking with respect to the equipartitioning learning trajectory. Lastly, PSTs implemented equipartitioning tasks with students in K-2 classrooms.

Data for this study includes pre- and post-tests developed by the research team to assess PSTs content and pedagogical content knowledge of equipartitioning. Many items came from or were modified from our synthesis work on equipartitioning or rational number reasoning (Empson & Turnner, 2006; Lamon, 1996; Pothier, 1981; Pothier & Sawada, 1989). Rubrics were created to score the assessments so that responses could be categorized into four distinct levels per item. Instruments were piloted with teachers who were either teaching elementary school at the time or who had previously taught elementary school. The pre-test was administered prior to the interventions and the post-test was administered on the last day of the study. Both assessments were administered during regular 75-minute class meetings under the same conditions. For the pre-test, half of the PSTs were randomly assigned to form A and the other half were assigned to form B; alternate forms of the assessment were assigned for the post-test.

## Results

Pre-test scores ranged from 16 to 41 on a 54-point scale. Post-test scores ranged from 22 to 48 on a 54-point scale. Pre- and post-test data were paired by PSTs and analyzed for differences using the Wilcoxon signed rank test. The median of the gain scores was 6 points, which was significantly greater than zero ($S = 70.5$, $p < 0.0001$). Four items have been selected to illustrate the ways in which PSTs did and did not show changes in their knowledge. Tasks were selected to provide an example of items used to assess pedagogical content knowledge (i.e., Tasks 1 and 2) and content knowledge of equipartitioning (i.e., Tasks 3 and 4). Each item and scoring rubric will be described, followed by a report on the frequencies of responses and illustrations.

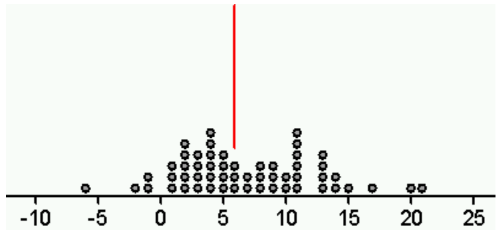

*Figure 1*. Distribution of gain scores.

Equipartitioning a continuous object (i.e., Case B) involves coordinating three components: i) using the entire whole; ii) creating equal sized parts of the whole; and, iii) creating the appropriate number of equal sized parts of the whole (Confrey, 2008). Tasks 1 and 2 required PSTs to generate imagined student responses for students who pay attention to only one of these three components (Task 1: component iii; Task 2: component ii), requiring them to consider how the other two components could be varied to produce an incorrect or incomplete result. Task 1 (form A) and Task 2 (form B) are stated below, and the scoring rubrics can be found in Table 2:

- Draw a picture of how a student might respond to the following task given the indicated understanding. Provide an explanation: Sharing a round cookie among 3 people if the *focus is on the number of pieces*.
- Draw a picture of how a student might respond to the following task given the indicated understanding. Provide an explanation: Sharing a (rectangular) pan of brownies among 5 people if the *focus is on the size of the pieces*.

Table 2. *Rubric for Scoring Tasks 1 and 2*

| Level | Response Characteristics for Task 1 | Response Characteristics for Task 2 |
|---|---|---|
| 3 | Correct number of pieces (with either unequal sized pieces, or not filling the whole) with full explanation | Equal sized pieces (with either the incorrect number of pieces, or not filling the whole) with full explanation |
| 2 | Same as above with incomplete/poor explanation or no explanation | Same as above with incomplete/poor explanation or no explanation |
| 1 | Same as Level 3 with incorrect explanation, or correct number of equal sized pieces that uses whole with full explanation | Same as Level 3 with incorrect explanation, or correct number of equal sized pieces that uses whole with full explanation |
| 0 | Incorrect response or no attempt | Incorrect response or no attempt |

As the results presented in this paper are part of a larger on-going study, we are considering the appropriateness of coding correct predicted responses (i.e., correct number of equal sized pieces that use the whole) on Tasks 1 and 2 of the pretest as Level 1. While these responses meet the criteria for the tasks, they over define it. While coding these responses as a Level 1 on the pre-test may be too strict, it is appropriate for the post-test, since the language used in the items was made clear in the context of instruction. These items will be modified in the future to clarify that PSTs should *only focus on the number of pieces* or *size of the pieces*.

The percent of PST responses in each of the four levels is located in Table 3. On the post-test, more PSTs provided Level 3 and 2 responses, 43% in comparison to 13% on the pre-test. Fewer PSTs provided Level 0 responses on the post-test (25%) than on the pre-test (46%).

Table 3. *PSTs' Pre- and Post-test Responses to Tasks 1 and 2*

| Level | Pre-test | Post-test |
|---|---|---|
| 3 | 9% | 34% |
| 2 | 4% | 9% |
| 1 | 41% | 32% |
| 0 | 46% | 25% |

Examples of PSTs' representative responses to Tasks 1 and 2 can be found in Tables 3 and 4, respectively. The responses are PSTs' prediction of student strategies for that task, not their own strategy. The most common Level 3 response can be characterized in the following way: PSTs indicated that students might create 2 parallel cuts that result in 3 unequal sized pieces of the cookie. These PSTs explained that students using this strategy would create the appropriate number of pieces, but the pieces would not be the same size. Another Level 3 response by PSTs suggested students might split the cookie in half, and then half one of the halves, using the same explanation as above. PSTs providing a Level 2 response indicated that a student would use repeated halving to create four equal sized groups, and then throw away one of the pieces; however, the explanation in Table 3 does not explicitly state the child intended to create the appropriate number of pieces. The most common Level 1 response suggested a student might use the entire cookie by creating 3 radial cuts, coordinating equal sized pieces, appropriate number of pieces, and using the entire cookie. Even though Task 1 asks PSTs to provide a strategy for students who *focus on the number of appropriate pieces*, these PSTs presumably assumed the student would focus on creating equal sized pieces, as well. The Level 0 response provided in Table 3 does not show a student strategy that would result in creating the appropriate number of pieces; the PST broke the cookie into 32 pieces, which is not divisible by 3 without a remainder.

Table 3. *PST Responses to Task 1 (Form A)*

| Level | Strategy | Explanation |
|---|---|---|
| 3 |  | |

With respect to Level 3 on Task 2, PSTs suggested that students might create both the appropriate number of pieces, as well as equal sized pieces of brownies, by creating a composition, explaining that extra pieces would not be used or would be saved as leftovers. This was the most common Level 3 strategy and explanation provided by the PSTs. Another Level 3 response was that students might create *n* cuts, instead of *n* –1 cuts, explaining that students who focused on the size of the pieces would create 6 equal sized pieces, not 5. PSTs indicated Level 2 responses included the strategies from Level 3, but these responses by PSTs did not provide explanations. Almost a third of the PSTs (32%) responded with a student strategy that coordinated size, appropriate number of pieces, and use of the entire cake by creating *n* – 1 cuts. Even though the task asks PSTs to provide a strategy for students who *focus on the size of the pieces*, these PSTs presumably assume that students might focus on the number of appropriate pieces, as well. The Level 0 response provided in Table 4 shows a student strategy that focuses on the appropriate number of pieces, but these pieces are not the same size.

Table 4. *PST Responses to Task 2 (Form B)*

| Level | Strategy | Explanation |
|---|---|---|
| 3 |  | |

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

methods, whereas Level 1 responses listed one or two methods for folding the paper. Level 0 responses included one of the following: a) the method of creating $n$ - 1 (i.e., 11 or 17) parallel folds, b) an incorrect method, or c) no attempt. Distinct methods for solving Task 3 include some permutation of folding the paper in the following ways: i) half, half, third; ii) fourth, third; iii) half, sixth; and, iv) 11 parallel folds or a permutation involving a 12$^{th}$. Methods for solving Task 4 include some permutation of folding the paper in the following ways: i) half, third, third; ii) sixth, third; iii) half, ninth; and, iv) 17 parallel folds or a permutation involving an 18$^{th}$.

Table 6. *PSTs' Pre- and Post-test Responses to Tasks 3 and 4*

| Level | Pre-test | Post-test |
|---|---|---|
| 3 | 2% | 4% |
| 2 | 2% | 9% |
| 1 | 20% | 59% |
| 0 | 76% | 29% |

On the pre- and post-tests, the majority of PSTs were unable to describe more than one method for folding the paper to obtain the correct number of equal sized regions. The most typical response for Task 3 was some permutation of folding into a half, a half, and a third; the most common response for Task 4 was some permutation of folding into a half, a third, and a third. On both the pre- and post-tests, PSTs who did not provide the above strategies, often responded with an unproductive strategy that involved folding in half or repeated folding in halves. Others did not attempt to respond. Very few PSTs utilized the strategy of creating $n$ - 1 (i.e., 11 or 17) parallel folds; however, more PSTs used this strategy on the post-test than the pre-test, sometimes in conjunction with other methods. Although very few PSTs were able to list three or more distinct strategies for folding a piece of paper to create a given number of equal sized partitions, PSTs showed a better understanding on the post-test. More than half of the PSTs (59%) were able to describe one or two strategies on the post-test, while more than three-fourths (76%) of the PSTs could not elucidate one strategy for folding a piece of paper to create a given number of equal sized partitions on the pre-test. Of all the items from the pre- and post-tests, PSTs performed the poorest on Tasks 3 and 4. Responses to these items were scored significantly lower than any other item.

## Discussion

PSTs knowledge of partitioning and knowledge for teaching equipartitioning increased significantly after their participation in instruction that used a learning trajectories approach. There is also evidence to suggest that PSTs used components of the equipartitioning learning trajectory (Confrey et al., 2008) in their responses relating to students' understanding. For example, consider Task 3. Current work by the DELTA research team and earlier work by Confrey (2008), have identified distinct behaviors of students who cannot coordinate creating both equal sized parts and the appropriate number of parts when splitting a circle into three parts. In this specific case, students often create 2 parallel cuts or might split the circle in half, and then half one of the halves. Almost half of the PSTs (43%) showed evidence of anticipating and adequately interpreting such a student response on the post-test. To be prepared for the complexity and range of diversity in student knowledge that they will encounter as they enter the profession, drawing such distinctions is key.

Although PSTs' gain scores significantly increased after the intervention, most PSTs scored very low on Tasks 3 and 4 in comparison to the other items. In a study examining children's multiplicative reasoning, Empson and Turner (2006) investigated the role of repeated halving in relation to first, third, and fifth graders' multiplicative thinking as they engaged in paper folding tasks. They found that children initially connected the action of folding and the outcome in *non-recursive* ways. Other children used an *emergent recursive strategy*, such as recursive doubling, understanding that creating a half fold could double the number of partitions. Few children used a *recursive* strategy to connect the fold and subsequent number of partitions. On the pre-test, 76% of PSTs used non-recursive strategies that were nonproductive. On the post-test, only 29% of PSTs utilized non-recursive strategies in the paper folding tasks. Like the children in the Empson and Turner study, very few PSTs used recursive strategies. Even on the post-test, the majority of the PSTs needed a concrete material for the paper folding task and only provided one or two methods. The first author observed the majority of the PSTs folding paper as they worked on both assessments. This is further evidence that few PSTs were using recursive strategies. Further on-going item analysis needs to be completed before definitive conclusions can be made about PSTs multiplicative reasoning.

Further analysis is underway to gauge the impact of a learning trajectories approach on PSTs. A complete analysis will include examining how their participation in the course tasks generated changes in their knowledge of both student thinking and equipartitioning. In addition, a detailed analysis of their subsequent interactions with children will begin to permit us to evaluate the degree to which a learning trajectories approach can be a productive strategy in pre-service teacher education.

# THE NATURE OF MATHEMATICS IN MATHEMATICS TEXTS FOR PRESERVICE ELEMENTARY TEACHERS: A CRITICAL LINGUISTICS ANALYSIS

Leah N. Shilling
University of Pittsburgh
les31@pitt.edu

*In this study, I use the tools of critical linguistics analysis to explore how preservice elementary school teachers' beliefs about the nature of mathematics may be influenced within a primary source of mathematical activity in classrooms: textbooks. The language within these textbooks implicitly promotes particular views about mathematics, which we analyze here. I discuss how the textbook authors' choices related to Halliday's (1973) ideational function of language—which includes the actors within the text as well as the processes present—can promote three particular views about the nature of mathematics:* the Platonist view, the instrumentalist view, *and* the problem-solving view.

## Introduction

Though it has been well-established that textbooks play a substantial role in teachers' decisions about what is taught in K–12 classrooms (Stein, Remillard, & Smith, 2007), less is known about the nature of preservice teacher mathematical beliefs and textbook interaction before entering those classrooms, particularly within their teacher preparation programs. Just as textbooks influence what is taught and learned in elementary through high school mathematics classrooms, they "exert a major influence on the content and approach of courses for prospective elementary teachers" (McCrory, Siedel, & Stylianides, 2007, p. 5), reaching over 80,000 students in teacher preparation programs each year. Textbooks work from an underlying philosophy about the nature of mathematics as a discipline, as well as the assumed knowledge that students bring with them to the classroom. These ideas "combine to create a distinct view of mathematics and mathematics learning that permeates each textbook" (McCrory et al., 2007, p. 13), one that has the potential to influence the development of the beliefs of their readers. While this study does not provide a complete picture of that development, it aims to provide a good starting point by using the tools of systemic functional grammar (Halliday, 1975) to address my research question: what views about the nature of mathematics are being promoted in textbooks for preservice elementary school teachers?

## Conceptual Framework

The critical discursive framework developed for this analysis is shown below (see Figure 1). Its foundation is in the work of Morgan (1996), whose ideas about critical discourse analysis closely reflect those used by linguist Norman Fairclough (1993) and are grounded in his assumption that every text somehow contributes to an individual's identity within their culture. Both claim to have their ideas rooted in the multifunctional linguistic theories represented in Halliday's (1985) functional systemic linguistics.

| | | ***Relational*** *(denote relationships)* | | | | | | | | | ☆ | ☆ | | ☆ |

*Figure 1. Conceptual Framework.*

The framework has two dimensions, the first comprised of the components of linguistic analysis and the second being the different views about the nature of mathematics. I adopt the three distinct views Ernest (1988) detailed in his review of empirical studies focusing on teachers, namely the *problem-solving view*, the *Platonist view,* and the *instrumentalist view*. While others have suggested different characterizations about the nature of mathematics, my choice to use these three is supported by Thompson's (1984) findings that these views parallel those most frequently observed in mathematics teaching.

This framework proposes ways in which the linguistic components of *actors* and *processes* can be connected to these different views about the nature of mathematics by indicating the probable actors present as well as the types of processes in which they would likely participate within each view, with these intersections indicated by the stars. For example, according to the star placement in the framework, the Platonist view supports the intersection of non-human actors participating in material processes. Next, I elaborate further on the different dimensions of the framework and how they intersect.

*The Platonist View*

So named due to its roots in ideas of Plato, the Platonist view portrays mathematics as a static body of knowledge, "bound together by filaments of logic and meaning" (Ernest, 1988, p.10), waiting to be discovered as opposed to being created. A textbook working from the Platonist view would indicate the presence of the reader as an actor in the discourse by using the personal pronoun *you*, with phrases such as *you see* controlling the ways in which the mathematics is seen and understood. Mathematics is not created but is depicted as an entity that exists independent of the student. In addition to human actors, this view would support the frequent use of *nominalization* within the text, where mathematical objects themselves are positioned as actors in control of the understandings and the human actors positioned as passive recipients of the knowledge. Given that both human and nonhuman actors are present, use of both the active and passive voice is possible, obscuring the agency of the reader as well as any other human participant. Morgan (1996) suggests that having a large portion of "mental processes (e.g., seeing, thinking) may suggest that mathematics is a pre-existing entity that is discovered" (p. 4), in agreement with the followers of Plato. These processes involve the inner experience of the participant, representing their perceptions, desires, and emotions such as *think*, *observe*, and *recall*.

*The Instrumentalist View*

Textbooks working from an instrumentalist view see the discipline as a collection of "unrelated but utilitarian" (Ernest, 1988, p.10) facts and procedures used by those trained with the tools to accomplish a particular end. Emphasis on procedures here necessitates the presence of human actors to carry out those procedures, yet with a very restricted role in the creation of the knowledge. Though the use of an active voice would be expected, the reader's actions would stress the importance of systematic, rote exercises in order to promote precision and mastery of tools. Of all the views, it is the instrumentalist view that is most likely to use the pronoun *you* with expressions of the form *you* + (a verb), such as in *you calculate*, often accompanied by temporality sequences that consequently restrict the reader's activity. Such a focus on procedures indicates a large proportion of material processes, which "may be interpreted as suggesting a mathematics that is constructed by doing" (Morgan, 1996, p.3), procedures taking precedence over conjectures. These processes deal with the actors participating in some kind of activity outside of themselves in the physical world involving some other actor within the situation, using verbs such as *write*, *draw*, and *calculate*.

*The Problem-Solving View*

Textbooks grounded in the dynamic problem-solving view suggest that new mathematics is constantly being invented through a process of inquiry that is open to revision. Given the emphasis placed on the student's role as an active participant in the creation of knowledge, a textbook promoting this view would not only suggest the presence of human actors within the activities, but that the reader is actively included as a decision maker within those activities. Pronouns such as *I* and *we* may point to the acknowledged presence of the reader, and the high level of interaction on the part of the student required by this conception suggests the use of the active voice promoting the actors present performing the action. Since "a high proportion of material processes may be interpreted as suggesting a mathematics that is constructed by doing" (Morgan, 1996, p. 4), that is the mathematics promoted within the problem-solving view. Relational processes are those that identify and associate one experience with other experiences, using verbs such as *is*, *connects*, and *relates*.

## Methodology

*Textbook Selection*

The textbooks included in this analysis were chosen based on the work done by McCrory et al. (2007), which explored and compared the content of 14 textbooks used in mathematics courses for prospective elementary school teachers. One of many dimensions discussed there, the *mathematical stance* of a textbook was described as "addressing the conception of mathematics that the book presents: What is important? What is the nature of mathematics? How does mathematics work as a discipline?" (p. 13). Given that my goal was to analyze the nature of mathematics being presented in these textbooks, I concentrated my exploration on three of the four textbooks described as possessing *explicit* mathematical stance in the McCrory et al. (2007). These textbooks were found to be consistently *explicit* in describing the general function and importance of mathematical ideas. However, this earlier analysis was not able to illustrate what the authors' proposed as *being* the general function and importance of mathematical ideas, indicators of the view about the nature of mathematics being promoted. Therefore, these explicit textbooks offered the greatest opportunity to capture a text's promoted view using my analytic tools. Written by Darken (2003), Parker & Baldridge (2004), and Wu (in preparation), the texts will be referred to by their authors' names from this point forward. I could not obtain a copy of the fourth book classified as *explicit* in time to include it in this analysis.

*Focus on Number Theory and Definitions*

Here, we restrict our discussion to only definitions found within the chapter in each book related to number theory topics. The fact that number theory is a customary topic covered in most mathematics courses for preservice elementary school teachers serves as the rationale for its selection. At the author's request, Wu supplied an electronic copy of his number theory chapter for my analysis, as the complete textbook is still being revised for publication.

The choice to focus my analysis on definitions in textbooks was not arbitrary. In addition to playing an important role in mathematical activity, the presentation of definitions in textbooks can capture how the textbook promotes different mathematical views. For example, one text may simply provide the reader with a single definition and present it as being the only definition possible, while another may engage the reader in the creation of a definition that is open to modification. These two textbooks would be promoting vastly different views about the nature of mathematics, the first Platonist and the second problem-solving.

*Coding*

Though one of the three textbooks did not contain a chapter explicitly titled "Number Theory", the chapter chosen had the greatest intersection of topics with the other two textbooks' number theory chapters. The analyses that follow focus only on the following concepts: factors, divisors, divisibility, even and odd numbers, prime numbers, LCM, and GCD. I determined the section to be analyzed to include the introduction, statement, and discussion of each definition. This did not include examples or related theorems or lemmas. Each sentence in these sections was coded according to the actors present and the type of process used. Human actors were coded according to personal pronouns used (*you*, *we*), while third-person participants (e.g. *the student*, *someone*) and non-human actors (e.g. mathematical objects) were simply coded as belonging to one of the two groups. A list of all verbs used in within the sections of interest were generated and classified as representing either a mental, material, or relational process and then shared with two other mathematics education doctoral students. These classifications were discussed and modified until all three parties reached agreement, and each sentence was given the appropriate process code. Since there were several sentences in each section, it was possible for concepts to have multiple codes. In addition to the quantitative code frequency measures, I also share sample qualitative analyses of the findings.

## Results and Discussion

*General Findings*

Table 1 shows the results of my analysis, with the values representing the percentage of codes falling into each intersection of the different actors and processes. By summing the columns or rows, this table also provides the frequencies of each individual actor or process, respectively, for each analyzed text.

Considering the high proportion of both human and non-human actors participating in material processes (62% overall), Parker and Baldridge (2004) appears to strongly support an instrumentalist view of mathematics. The very first sentence of the chapter supports this categorization and sets the tone for all of the activities that follow: "Mathematics is built on precise definitions and proceeds using clear reasoning" (p. 109). As described in the case of prime numbers and to some degree common to all three texts, the majority of the discussions surrounding the various terms defined in the chapter acknowledged the presence of human actors (the student), yet those actors had a very restricted role in the creation of the knowledge being developed. While the use of *we* may imply that the author is establishing solidarity with the reader and placing them at equal positions of power within the text, there are several instances within discussions that indicate this *we* is more *exclusive* than *inclusive*. For example, in the section dealing with divisibility tests, the authors precede the definition of divisible with the following statement: “In the remainder of this chapter, *we* will often use letters A, B, …, k, l, … and a, b, … to represent whole numbers. At any time, *you* may assign them specific values (like A=20, k=5) to aid *your* understanding” (p. 113, italics added). Therefore, while the students are certainly present, the processes in which they are to engage are purely material, constructing a mathematics which is about practical activity that is carried out in a procedural way. I also found a large proportion of the codes (20%) showed non-human actors participating in relational processes, which my framework suggests would be promoting a problem-solving view of mathematics by focusing on connections between mathematical ideas. Non-human actors engaged in material processes points towards a more Platonist view.

*Table 1*
(Rounded) Percentages of Actors and Process Found in the Textbooks

| | | **Frequencies (in percentages)** | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | ***Darken (2003)*** | | | | ***Parker and Baldridge (2004)*** | | | | ***Wu (in preparation)*** | | | |
| | **Actors** | We | You | 3rd person | Non-human | We | You | 3rd person | Non-human | We | You | 3rd person | Non-human |
| **Processes** | ***Material*** | 13 | 21 | 8 | 11 | 14 | 12 | 16 | 20 | 33 | 2 | 4 | 9 |
| | ***Mental*** | 5 | 5 | 2 | 0 | 3 | 6 | 6 | 1 | 15 | 12 | 2 | 1 |
| | ***Relational*** | 0 | 5 | 0 | 30 | 0 | 0 | 2 | 20 | 1 | 1 | 0 | 20 |

The picture of mathematics presented by Wu (in preparation) has some similarities to Parker and Baldridge (2004). Though I found *we* to be the most prevalent actor in the text (accounting for almost half of the codes), which suggests human agency in the discussion, there is strong evidence that the reader is not assumed to be actively participating in the knowledge being introduced. When describing “our enduring interest in the primes” (p. 10), Wu places himself in the authoritative role, considering that prime numbers had only been defined in the previous sentence and the reader has not yet had a chance to fully understand what prime numbers are, let alone develop such a powerful interest in them. The mathematics is introduced in a very matter-of-fact manner, with each new idea logically derived from the former in a linear fashion. Like Parker and Baldridge, the presence of non-human actors involved in material processes is evidence of what linguists call *nominalization,* which “describes language structure that obscures human agency” (Herbel-Eisenmann & Wagner, 2005, p.123), where inanimate objects (in this case, mathematical objects) perform activity usually related to humans. Almost every definition described in the chapter, and more generally the entire book, is followed by a collection of theorems using those definitions. In this area, it is common to find a phrase such as “the theorem tells us”, or “the theorem says”, which “depicts an absolutist image of mathematics, portraying mathematical activity as something that can occur on its own, without humans" (Herbel-Eisenmann & Wagner, 2005, p.123). Indeed, the reader has little to do with the creation of definitions or related mathematical knowledge, asked to serve as a mere spectator of the activities, and to accept that which has been "clearly" outlined. Though material processes such as "check", "remove", and "define" were most commonly found throughout the chapter, at 30% Wu contained the largest proportion of mental processes of the analyzed text, processes that Morgan (1996) claims "may suggest a mathematics that is a pre-existing entity that is discovered by mathematicians" (p. 2). These things considered, I suggest that Wu's text works from and portrays a more absolutist view of mathematics, having instrumentalist tendencies but more Platonist considering the overwhelming restriction of reader activity (the exclusive *we*) and the 12% of codes describing mental processes in relation specifically to the reader (*you*), which was the was the highest frequency any processes.

Though being the least common human actor present (at 18% of the total), Darken's (2003) *we* not only suggests an awareness of human agency, but the ways in which it is used also includes the reader as a participant of mathematical activity. Most of the 21% of *you* actors participating in material activities were in the form of imperatives, commands which were seen as *inclusive*, welcoming into the community as an active participant first given the chance to construct their own knowledge with the formal definition coming later. This is in sharp contrast to the similar activity described in Parker and Baldridge (2004), where the definition was given with little reader contribution, after which the student is lead temporally through a procedure. Whereas Parker and Baldridge employed a narrow to broad pathway (meaning they began with the definitions and then used a variety of problems to discuss the term), Darken's approach started broad, narrowed, and then broadened once again, starting the conversation with a reader-driven activity that better prepared them for a more formal discussion of prime numbers. Despite a clear emphasis on certain procedures, there is evidence to characterize this text as promoting a problem-solving view of mathematics, with some instrumentalist tendencies. At 35%, the book contained the largest proportion of relational processes found in any of the analyzed texts, with most of the 52% material processes related to human actors (excluding the 11% with non-human actors) being classified as inclusive imperatives. More importantly, these processes are combined with a picture of the reader/student that often appears to be invited to share in the mathematical activity of defining, as well as to be engaged in considering the evidence supporting the developed argument.

Now that I have provided an overview of the general findings of my discourse analysis, I next focus on the particular definition of prime numbers. In describing the actors and processes used in the different text in relation to this common concept, I attempt to illustrate the different views about mathematics that may be promoted by each textbook.

*Prime Numbers: An Illustration*

Though each textbook acknowledges that the student has a role within the discussion of prime numbers, the authors' choice of processes in which the students are involved seem to promote different ideas about what that role entails. In addition to using *we* as a means to construct the student as an active member in the mathematics, Darken (2003) encourages the student to initially share in the responsibility of creating their knowledge about primes. With prime numbers in particular, Darken asks the student to initially share in the responsibility of creating new knowledge instead of simply stating the definition for the reader to accept unquestioningly. The chapter opens with an activity meant to fuel the students' investigations into possible emergent patterns that moves them toward the notion of prime numbers.

Instructions are given about how to use the chart, but the authority is quickly given to the reader, where the author makes comments about "*your* work" and "*your* patterns" at the heart of the activity. By participating in the relational processes of investigating and observing patterns, the students are presented with "a picture of mathematics as a system of relationships between objects or between objects and their properties" (Morgan, 1995, p. 3), in this case natural numbers, their factors, and the property of being prime.

In contrast, Parker and Baldridge (2004) and Wu (in preparation) restrict the student's role as an active participant in the mathematics. While Darken (2003) asks the student to explore the mathematical terrain of prime numbers and to share in decision-making activity, a student using Parker and Baldridge is directed to carry out material tasks related to a described procedure to follow, using imperative instructions. While the former suggests a view of mathematics that is dynamic and creative, the focus of material processes in the latter "may be interpreted as suggesting a mathematics that is constructed by doing" (Morgan, 1995, p. 3), procedures taking precedence over conjectures. Though not immediately clear, the use of imperatives in both texts is related to their seemingly more exclusive use of *we*. Instead of interpreting imperative commands like *find*, *list*, and *explain* as mathematical convention, the reader may interpret their role in relation to mathematics as only that of a follower of rules in a procedure-centered discipline. As in earlier discussions, I use Rotman's (1988) dichotomy of imperatives as being either *inclusive* or *exclusive*, with the first constructing a reader whose actions are *included* in a community of people doing mathematics, whereas the other constructs one whose actions can be *excluded* from such a community. I illustrate the difference between these imperatives as used in two of the texts, and discuss the corresponding consequences.

Parker and Baldridge (2004) and Darken's (2003) main activities within the discussion of prime numbers appear at first glance to be superficially similar. While both seem to acknowledge the student as an active participant, their efforts to demonstrate the relationship between the factors of a number and the attribute of being prime, the differences and the processes that are entailed highlight contrasting views about where the authority in that knowledge lies. Before any mention or definition of the term *prime*, Darken opens the chapter with a mostly blank chart that is meant to fuel the students' investigations into possible emergent patterns. Instructions are given about how to use the chart, but the authority is quickly given to the reader, where the author makes comments about "*your* work" and "*your* patterns" at the heart of the activity. The commands are *inclusive*, welcoming the reader into the community as an active participant. Parker and Baldridge on the other hand, acknowledge this relationship between factors and the condition of being prime, but instead of promoting exploration the students are guided through a process driven by *exclusive* imperatives such as "proceed, circle, cross out", not giving them a choice to act otherwise or question the command. Though both are grounded in the same mathematical ideas, the different processes engaged in by the reader (mental vs. material) in discussing prime numbers have the potential to present two very different views about mathematical activity, the first situating them as creators and the second as followers.

## Conclusions and Implications

This analysis explored how linguistic choices made by textbook authors can promote different views about the nature of mathematics. I observed distinct contrasts in the ways the authors of the three textbooks examined have chosen to create, discuss, and use definitions, affecting the ways in which those views are being promoted. Are pronouns such as *you* and the inclusive *we* present with imperative verbs, inviting the reader to play an active role as a problem solver in the discussion? Does the author place actions in the hands of inanimate mathematical objects, Platonistic and existing independent of human activity? Does the student feel present in the mathematical conversations, but only as an individual meant to accept given material and procedures to follow as unquestionable?

In conjunction with the work done by Morgan (2005), the sample analyses of this study can provide textbook authors, curriculum developers, and teacher educators charged with selecting textbooks with linguistic tools that can help them "anticipate the meanings, both substantive and positional" (Morgan, 2005, p. 9) relating to views about mathematics that is being supported by textbooks for elementary school teachers. Also, it may help those authors realize the views about mathematics being promoted in their texts about which they may have not even been conscious. These tools can serve as a guide to develop textbooks that construct the roles and authority, the relationships between the reader, author, and mathematics, and the overall vision about the nature of mathematics more purposefully in alignment with the view of mathematics desired by the author. In attempts to investigate consistencies in linguistic choices, an interesting direction for future research would be to examine other content areas in addition to number theory and compare the results with those found here. While textbooks are certainly not the only potential source that influences preservice elementary teachers' beliefs about the nature of mathematics, they are certainly a prevalent feature in the majority of classrooms in this country, from the elementary to the university level. Therefore, whether intentional or not, the language choices made by textbook authors promote particular views about the nature of mathematics that may influence the reader's view of the nature of mathematics and their position with respect to the discipline, and so those choices should be made carefully and consciously.

# EXPLORING PRESERVICE TEACHERS' CONCEPTIONS OF NUMBERS VIA THE MAYAN NUMBER SYSTEM

Eva Thanheiser
Portland State University
thanheisere@gmail.com

Kathryn E. Rhoads
Rutgers, the State University of New Jersey
kerhoads@eden.rutgers.edu

*Preservice elementary school teachers (PSTs) struggle to understand numbers in our base-10 number system, but uncovering their base-10 conceptions is difficult because the underlying mathematical structure is masked by language and prior experience operating on numbers in base-10. PSTs' conceptions of numbers were explored through work on identifying numerals in the Mayan number system (base twenty) during which PSTs drew on their base-10 conceptions. Of 24 participants only 6 could identify a 3-digit and a 7-digit Mayan numeral correctly. Both those numerals were the digit equivalent to 1 with 2 and 6 zeros, respectively, attached. The PSTs' answers are categorized and explained. Implications for mathematics education are discussed.*

## Background and Theoretical Framework

Place value is an essential part of the elementary school mathematics curriculum. However, PSTs as well as teachers often struggle explaining numbers beyond procedural applications (Ball, 1988; Ma, 1999; Ross, 2001; Thanheiser, 2005). Previous work (Thanheiser, 2005) has shown that only 3 of 15 PSTs were able to draw on the underlying structure of our number system to interpret the values of the digits in a number and relate them to one another. Because of this underlying structure of the base-ten power sequence, the relationship among adjacent digits is a multiplicative relationship with a factor of 10. Each place represents a value 10 times as large as the next lower place. Thus, if one moves a digit one place to the left, its value is 10 times as great as previously. One difficult aspect of understanding the underlying structure on which our numbers are built is that it is implicit, not explicit. Many PSTs use a *tens and ones language;* that is, they use phrases such as "I borrowed a ten." However, that *tens and ones language* is often only procedural (Ball, 1988; Thanheiser, 2005). For many prospective teachers, facility using base-ten language masks lack of understanding (Ball, 1988). Even though PSTs read 367 as "three hundred sixty-seven," they may not think of the individual digits as representing 3 groups of 100, 6 groups of 10, and 7 groups of 1 or that a hundred is 10 tens and a ten is 10 ones— both important aspects of understanding numbers in our base-ten number system. To avoid the use of this tens-and-ones language and other masking aspects of our base-ten language, we explored a different number system (the Mayan base-twenty system[1]) and related it to the base-ten system. We conjectured that considering mathematics through the lens of a different numeral system would help teachers recognize the complexities of the base-ten system.

Our research grows out of a rich cognitive-science paradigm focused upon children's prior knowledge in learning situations, a consideration that is equally important in work with adults (Bransford, Brown, & Cocking, 1999). To help PSTs develop a solid understanding of mathematics, we need to build upon their initial conceptions, which both determine what they understand when looking at a number and serve as a basis for building more sophisticated conceptual structures. Our goal in this study was to further understand how PSTs think about numbers in our number system and how we could use those conceptions to design instruction.

## Method

The data analyzed are drawn from four 160-minute teaching sessions and a preinterview, and a pre- and post-assessment with each with 24 preservice teachers at a large, urban, comprehensive state university. All participants were enrolled in a preservice teacher elementary mathematics methods course and were about to begin student teaching. The teaching sessions were part of the regular methods course.

In the pre- and post-assessments, we asked the PSTs to explain regrouped digits in addition and subtraction problems (e.g., see Figure 1).

```
  1 1
  389
+ 475
-----
  864
```

1. Please explain what the “1” above the 8 represents.
2. Please explain what the “1” above the 3 represents.

*Figure 1.* Sample task from pre- and post-assessment.

During the teaching sessions, the PSTs explored Mayan numerals, a base-twenty place-value system that uses three symbols. A dot represents one unit, a bar represents five units, and a shell represents zero units. These symbols are grouped to create digits from 0 to 19. Five dots are grouped into a bar. Thus, the number 13 would be represented by two bars and three dots. Four bars are regrouped as one dot on the next higher level. Place values increase from bottom to top. That is, symbols on the lowest level represent groups of ones, and thus have values 1–19, whereas symbols on the second level represent groups of 20 and thus have values 20–380, and so forth. Participants began by exploring Mayan numerals in a homework assignment in which they converted between Mayan numerals and standard (base-ten) notation and performed simple addition problems with Mayan numerals. The assignment was taken from *Teaching Mathematics in the Middle School* (Overbay & Brod, 2007). Included in the homework was a reference table that listed the Mayan numerals equivalent to 1–29 in base-ten notation (for some sample references and problems, see Figure 2).

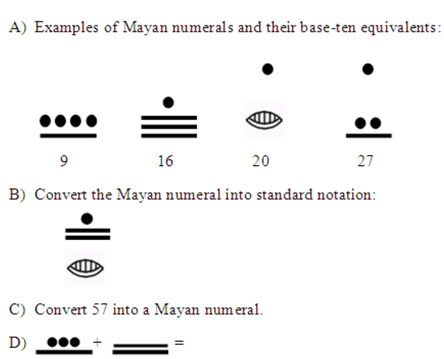

*Figure 2*. Examples of references and questions on homework assignment.

During the class period following the Mayan homework assignment, PSTs worked in groups to answer the questions in Figure 3. The homework assignments and in-class writing assignments were collected and analyzed using open coding (Strauss & Corbin, 1990). The analyses of the answers to the questions in Figure 1 are reported in this paper.

Please answer the following questions

1. How would you represent 20 in Mayan Numerals, why?
    - How would you know that it represents 20 and not another number like 1?
2. What value does the number below have in our base-ten system?

Mayan Symbol

Please explain why you think your answer is correct:

3. What value does the number below have in our base-ten system?

Mayan Symbol

Please explain why you think your answer is correct:

*Figure 3.* In-class task for preservice teachers.

## Results and Discussion

Only 7 of 25 PSTs in the class correctly explained the regrouped 1s in a three-digit addition problem (see Figure 1) at the beginning of the class. Nine PSTs said that both 1s represented 10, and 8 PSTs said that both 1s represented 1.

Table 1. *PSTs' Explanations for the Regrouped 1s in Three-Digit Addition on Pretest*

| Values attributed to the 1s in<br>1 1<br>389<br>+ 475<br>864 | 1—10 regrouped from the one's place<br>1—100 regrouped from the ten's place | 1—10 (from the 14)<br>1—10 (from the 16) | 1—1 (from the 14)<br>1—1 (from the 16) |
|---|---|---|---|
| Number of PST responses | 7 | 9 | 8 |

Developing an understanding of the values of the digits in a number is nontrivial (Thanheiser, 2008). The Mayan-numbers task was designed to illuminate the PSTs' conceptions of how numbers are built on the underlying structure of the number system.

All PSTs correctly represented 20 as *dot, shell* for Question 1. This result is not surprising inasmuch as PSTs used the Mayan numeral for 20 in their homework assignment. The correct answer for Question 2 is 400 in the base-twenty system in which the value of *dot* in the third place is $20^2$, $20 \times 20$, or 400. Only 11 PSTs correctly answered this question (see Table 1), and

13 PSTs incorrectly answered 200 on the basis of (a) interpreting the *dot, shell* as 20 and the *shell* as a zero that is appended, (b) interpreting the *dot, shell* as 20 and appending another place value, or (c) using the fact that the number had three symbols to assign the highest place value as hundreds. J, for example, explained, “Dot, shell = 20, and shell = 0. [The] shell symbol represents the 0 place holder, so the 0 will be added [meaning *appended*[2]] to the 20 making the number 200.” E stated, “There is a symbol for 20 with one more for the place value.” And T explained, “Because dot, shell represent 20 and another shell underneath represent another place value, hundreds.” These answers reflect the rules of our base-ten system in which a symbol with 1 zero has a value in the tens and a symbol with 2 zeros has a value in the hundreds (e.g., a 3 with 1 zero is 30, and a 3 with 2 zeros is 300). PSTs are able to read such numbers without thinking of the underlying structure of our base-ten system. This structure relates adjacent place values by a multiplicative factor of 10 (i.e., in 33333, the second 3 from the right is 10 times the value of the first 3 on the right, etc.). This multiplicative relationship between number places is not obvious to PSTs (Ross, 2001; Thanheiser, 2005). The rule of appending a zero for each place value when we move to the left combined with the fact that most adults are fluent readers of numbers masks the fact that the value of each digit in a number is 10 times the value of the digit to its right. More than half of the PSTs in this class did not utilize this multiplicative relationship to determine the value of *dot, shell, shell*.

All 13 PSTs who incorrectly interpreted *dot, shell, shell* as 200 incorrectly answered Question 3. Twelve interpreted a dot with 6 shells as 2,000,000, and one interpreted it as 20,000,000. Justifications were consistent with those used for 200 in that most students discussed appending zeros to a number each time they saw a shell. For example, W explained, “As the above problem, we used 20 because it’s a base-twenty system and then added the zeros after.” W explicated her understanding of a base-twenty system as a 20 with zeros added for increasing place values. Instead of viewing the succeeding values of the symbols in a base-twenty system as 20 times as great as the preceding, W saw the values of the symbols as increasing according to appended zeros. Other PSTs’ ideas were similar to W’s. J explained, “Dot, shell represents 20 plus 5 shell so add 5 zeros to 20, which equals 2,000,000.” C explained, “Dot, shell is our 20, and the remaining shells stand as place holders.”

As noted, all 13 PSTs who incorrectly answered Questions 2 and 3 had correctly said that *dot, shell* represents 20. Their Question 1 explanations often lacked the specificity needed to determine how they thought about the number. H, for example, explained, “The dot above stands for *20,* and the shell is zero. So 20 + 0 = 20.” If not probed further, this answer could represent multiplicative thinking; her explanation for *dot, shell, shell* as 200, however, revealed that she was thinking of the shells in terms of place holders to the right of a *2*: “Two shells are place holders.” Similarly C explained *dot, shell* as “top is one group of 20; shell means zero.” Again this response could be indicative of multiplicative thinking, but her explanation for *dot, shell, shell* as 200 revealed that it was not: “Dot zero is 20 so if you add a zero (shell),” it is 200. Thus, because the PSTs knew that *dot, shell* represented 20, some gave explanations that sounded multiplicative but that when probed we saw were not.

Table 2. *The PSTs' Interpretation of Mayan Numerals*

| Task | | Dot shell shell and dot with 6 shells | |
|---|---|---|---|
| Responses | 200 and 2,000,000 / 20,000,000 | 400 and other incorrect second response | 400 and 64,000,000 |
| Nature of response | Both incorrect | First correct second incorrect | Both correct |
| Number of PSTs giving the response | 13 | 5 | 6 |

Of the 11 PSTs who correctly answered Question 2 as 400, 5 gave incorrect answers for Question 3. Four of these 5 PSTs explained the 400 for Question 2 similarly[3]: Because of the 20 in the second place value, the value is 20 × 20 with a zero in the first place value, yielding 400 + 0. Three of these 4 gave 40,000 as their answer to Question 3.[4] K, for example, explained, "Dot shell is in the raised spot and is multiplied by 20 which equals 400, then the shell is equivalent to 0, so 400 + 0 = 400." For Question 3 she explained, "The top = 400 then the next two reps. a place value of 0 in the 1000's + 10,000's spot." D used a similar explanation for *dot, shell, shell:* "It is 20 groups of 20 (shown by the top) and zero on the bottom—20 × 20 = 400." For Question 3 she explained, "Mayans may have written numbers from top to bottom rather than left to right like we do." D and K seemed to see the *dot shell* as one numeral (20) on the second level worth 20 *twenties* rather than *dot* as a 1 on the third level worth 1 *four-hundred*. This is equivalent to seeing 500 in the base-ten system as 50 tens and 0 ones. This is a correct interpretation of the number, but interpreting the *dot, shell* as one symbol masks the nature of the place-value structure as iterations of multiplication by 20. D's interpretation does not show that she understands 20 *twentie*s as equivalent to 1 *four-hundred*. This connection between 20 twenties and 1 four-hundred is an important connection for understanding these numbers. In our base-ten system it translates to being able to see 100, for example, as 1 *hundred* as well as 10 *tens*. This connection has been shown to be nontrivial for PSTs (Thanheiser, 2005). In addition 100 is connected to 100 *ones,* as is inherent in the place-value language in the base-ten number system. This connection becomes important, however, when we move beyond interpreting the symbol for hundreds to interpreting symbols for larger numbers and operating on numbers. G explained the answer 40,000: "Mayans might've written numbers top to bottom & two symbols (top & bottom) make a number set & just write it out in order. Shell, shell = 0 (because 0 × 20 + 0 = 0) and the second set of shell, shell is also zero, so place it next to 400." Thus G seemed to interpret Mayan numerals in double-digit sets. She seemed to think two shells together were equivalent to appending a zero as a placeholder in the base-ten notation of the number. She seemed to interpret the dot followed by six shells in three parts: *dot, shell, shell* on the top is 400, *shell, shell* is a zero placeholder; and the following *shell, shell* is another zero placeholder, which gives 40,000.

The interpretations of *dot shell* as 20 and thus *dot, shell, shell* as 200 or of *dot, shell, shell* as 400 and thus a dot with 6 shells below it as 40,000 may be rooted in the notion that in base ten we merely append zeros to a number. In base ten, this practice of appending zeros is equivalent to multiplying by 10, but in different base appending zeros is equivalent to multiplying by that base (i.e. in base 4 the number 12 multiplied by 4 is 120). One reason to work with PSTs in a different base is to explicate some of these underlying structures of our base-ten system. PSTs often operate on numbers without understanding the reasons underlying those operations (Ball, 1988; Ma, 1999), and because the language facilitates the connections between numbers and values, these underlying structures are often difficult to explicate in base ten.

All 6 PSTs who correctly answered Question 2 (400) and Question 3 (64,000,000) indicated the use of iterative multiplication by 20 as their source for their answers to Question 3. Z, for example, justified his answer that dot followed by six shells was 64,000,000 as follows: “Each level is 20 of the previous level. $1 \times 20 \times 20 \times 20 \times 20 \times 20 \times 20 = 64{,}000{,}000$.” Similarly, A explained the same answer: “There is a pattern where each dot on each level is 20 times more than [*sic*] the dot on the previous level,” indicating that she understood the nature of a base-20 number system in which the value of each place is 20 times the value of the place to the right. However, not all 6 of these PSTs used this reasoning to answer Question 2. Three PSTs argued that one must regroup to the next higher level once there are “too many” in the second place. M, for example, stated, “Because the dot is the 3rd level, and once you are at 4 bars, you go up another level for a dot. Each bar in the second level equals 5 dots, and thus $5 \times 20$ or 100. Thus four bars equal 400 and would need to be regrouped into a dot at the next level.” This is a valid argument, but impractical for explaining large numbers. Two PSTs used the argument that they had a 20 in the second place value; thus $20 \times 20 = 400$. One PST gave no explanation.

## Conclusion

The Mayan-numeral activities described were designed to assess PSTs’ understanding of the underlying structure of numbers in our place-value system. Although the PSTs had worked with 2-place Mayan numerals for homework, more than half of the participants were unable to correctly interpret 3-place Mayan numerals. Most PSTs did not attend to the underlying structure of base twenty. They either interpreted the *dot* as a 2 and appended 2 zeros for the two shells or interpreted the *dot, shell* as 20 and appended 1 zero. Appending a zero to a digit is equivalent to multiplication by 10 in our base-ten number system, but doing so in the Mayan (base-twenty) system is equivalent to multiplication by 20. Although the PSTs were able to read a *dot shell* in the Mayan system as 20, most were unable to assign the correct value ($1 \times 20 \times 20$) to *dot, shell, shell*. The underlying structure of numbers in our base-ten system remains implicit when PSTs work with numbers in base ten. PSTs become accustomed to reading base-ten numbers, in which each digit is 10 times the value of that to the right of it. In doing so, they may miss the number meaning in the base-ten number system. Making the structure of the base-ten system explicit while working within base ten is difficult because the labels we use for the places (ones, tens, hundreds) are the same as their quantities; thus, whether PSTs are using labels or quantities is unclear. In coming to understand a different base, PSTs must explicate the underlying base structure and relate it to our base-ten system. A thorough understanding of number and place value is essential for teachers, especially elementary school teachers. With follow-up discussion and practice, the activities used in this study may be effective for helping PSTs recognize the complexities of all number systems, including our base-ten system. By working with a number system with which they are less comfortable, PSTs can explore the meaning of a place-value system. We close with two PSTs’ reflections:

- The most important thing that I learned about my own understanding of the base-ten system I realized through discovering the Mayan number system. … Just as the Mayans multiplied each new level by 20 since it was a base 20 system, our system is really just multiplying each place by ten more then the line [place] below. For example in the number 326, this can be seen as 6 + (2*10) + (3*10*10) since each level up is another times ten.
- We know base-ten means that each place value is multiplied by 10, and that we group and regroup when a certain place value exceeds 10. … What really broke it down for me was when we got into working with the Mayan system. It allowed me to compare and contrast the difference between their system and ours. Theirs is a base-twenty system and follows the same concept as us, except they would regroup after 20 in a place value (level) and each level is multiplied by 20 instead. I first struggled with any number beyond the second level in the Mayan system, but as we discussed more in class and I did some self-discovery at home, I came to see how similar our systems are.

## Endnotes

[1] In our class we considered the Mayan numbers as base-twenty numbers. In the literature the Mayan numeral *dot shell shell* can be found as representing 18 × 20 rather than 20 × 20 as we would expect in a base-twenty system. We disregarded this aspect in this lesson (Bennett & Nelson, 2007).

[2] Students often use the *adding* zeros when they mean *appending*.

[3] The other PST gave a generic explanation: "In order to get *400*, … the top number must be multiplied."

[4] The other PST gave 64,000 as her answer; her explanation, however, was insufficient for us to interpret.

# INFLUENCES TO WANT TO TEACH MATHEMATICS IN AN URBAN SETTING: A PRE-SERVICE TEACHER'S STORY

Desha L. Williams
Kennesaw State University
dwill178@kennesaw.edu

*What influences a pre-service teacher to decide to teach in an urban school? Despite challenges associated with teaching in urban schools, there are per-service teachers making this decision. This study takes a phenomenological look at a secondary mathematics pre-service teacher's, who has made the conscious decision to teach urban learners, journey through student teaching. It details factors that influenced her decision to teach in urban schools and how student teaching further effected her decision.*

## Introduction

There has been a plethora of literature on the shortage of teachers in urban environments and an ample amount of research dedicated to acknowledging the need for increased teachers of mathematics (Bracey, 2002; Cavallo, Ferreira, & Roberts, 2005; Follo, Hoerr, & Vorheis-Sargent, 2002; Howard, 2003; Ingersoll & Smith, 2003; Ng, 2003). According to a study by Villegas and Clewell (1998, as cited in Valli & Rennert-Ariev, 2000), 13% of 3000 teachers state they do not want to teach in an urban setting. The participant for this study, however, has made the conscious decision to teach in an urban school. Thus, this research will provide a glimpse into possible influences that encourage or hinder a teacher candidate from continuing a career as a teacher of urban learners after completing student teaching in an urban school. Understanding possible influences may also provide insight into the retention of new teachers in urban schools.

## Philosophical Framework

The tenets of phenomenology provided the philosophical framework for this study. "Phenomenology is oriented…toward describing the experiences of everyday life as it is internalized in the subjective consciousness of individuals" (Schwandt, 2001, p. 191). Therefore, the crux of phenomenology is to understand the experiences of an individual from his or her own unique perspective. Schutz (1967) combined the tenets of Husserl's descriptive phenomenology with Max Weber's sociology. In his version of phenomenology, as one reflects on an experience, the reflection is not purely based on the individual but is influenced by social interactions with others. Conversations, other experiences, and subconscious and conscious thoughts influence how one reflects on an experience. These reflections provide a foundation for the construction of knowledge (Wagner, 1970). Schutz acknowledged the importance of interpreting phenomenon in context and he also valued the social influences that impede upon the perceptions of the experiencer (Schutz, 1967; Wagner, 1970). Schutz's standpoint on phenomenology encompasses both the internal processes involved in knowledge construction and the social aspects that influence that development. The influences of the interactions between Tanjala (the pre-service teacher of this study) and her cooperating teacher, her students, other teachers, and parents factor into how Tanjala interpreted her experiences and thus influences her decisions regarding maintaining a career in an urban environment.

There are two attitudes that are presented in the philosophy of phenomenology. They are the natural attitude and the phenomenological attitude.

> The *natural attitude* is the focus we have when we are involved in our original, world-directed stance, when we intend things, situations, facts, and any other kind of objects. The natural attitude is, we might say, the default perspective, the one we start off from, the one we are in originally. We do not move in to it from anywhere more basic. The *phenomenological attitude*, on the other hand, is the focus we have when we reflect upon the natural attitude and all the intentionalities that occur within it. (Sokolowski, 2000, p. 42)

The natural attitude and the phenomenological attitude offer viewpoints of how the Tanjala experiences student teaching as she develops her views on teaching in urban contexts. The natural attitude illustrates her naïve thoughts on teaching in urban schools. The phenomenological attitude then validates or contradicts Tanjala's initial thoughts as she reflects upon her experience. Both positions are depicted through her journey.

## The Participant and Research Methodology

A phenomenological approach was taken to gain insight into the phenomenon from the participant's perspective. The participant, Tanjala, is a 40-ish African American woman, who was enrolled in an alternative teacher preparation program. The program in which she attended admits individuals who have a degree in mathematics or a related field. Through an intensive four semester program the students earn a Masters of Arts of Teaching degree along with their initial certification. This program, located at a large metropolitan university in the southeastern region of the United States of America, has obtained funding to financially support students who wish to focus on teaching urban learners. Tanjala was awarded $10,000 to support her as she matriculated through the program.

Data was collected in several phases. Tanjala participated in an interview prior to any field experience. She shared stories of her years as a student of mathematics, how she came to want to be a teacher, more specially a mathematics teacher of urban learners, how she defined urban, and what she expected to gain from her student teaching experience which would be in an urban setting. As Tanjala completed her student teaching experience, she maintained journals detailing her successes and challenges. After student teaching was completed, she shared her reflections of the experience during a phenomenological interview.

## Data Analysis

The three data sources were used to construct a textual description of Tanjala's experience. The textual description is a rich and detailed account of the participant's experiences prior to student teaching, during and after. The textual description provides Tanjala's naïve and phenomenological attitudes (Colaizzi, 1978; Moustakas, 1994; Polkinghorne, 1989).

Tanjala was provided an opportunity to read her textual description and provide approval or suggest revisions. Tanjala's has approved her textual description as it appears as accurate and acceptable (Colaizzi, 1978). From the textual descriptions, the meaning of the phenomenon is drawn, providing structural descriptions. To form the structural description, I began the analysis by reading the data to gain an in-depth awareness. Next, I separated phrases that pertained to the phenomenon from non-revelatory material. Once only relevant material remained, the statements were clustered, themes emerged, and then were phenomenological reduced into eight themes. These eight themes are (a) evidence of mentoring versus lack of mentoring; (b) individual versus collective behaviors; (c) relating to the characteristics of an urban teacher; (d) to stay or not to stay (in urban schools); (e) influencing factors; (f) anxieties; (g) classroom management; and

(h) pedagogical style. A zigzag approach between these themes and the participant's narratives was utilized to establish the structural descriptions of the phenomenon (Colaizzi, 1978).

### Tanjala's Textual Description

I open Tanjala's textual description with a story that she shared with me that affected why she wanted to be a teacher.

> I was born into a family of nine children. I am number seven of nine. My father was an alcoholic and he was really abusive to my mother. We would see him give her black eyes, split her arm, do this, do that, and on and on. When I was 7, my father and mother had an argument. My father went into another room and got a gun. I think at this time they had been married 15 years. She was really tired and she let him know. She said I know it is loaded so go ahead and shoot. She told us to get ready to go over to her sister's house. My brother ran out to call the police. When the doorbell rang, my father said, "If it is the police I'm going to shoot you." In the meantime, they were arguing about something, and she was pressing my hair. I remember being on the floor by the stove while she was pressing my hair. My father went to the door and of course it was the police. So he came back and he shot her. We actually saw her die. The next day we went to live with my auntie. My auntie, God bless her soul, was such a strong lady. She took 8 of us. She lived in a project in a large metropolitan city. This happened in 1971. The projects were bad, but they weren't horrid, like they are now, but there was still a lot of crime. There were a million people that were kind of unmanaged living in these conditions. At my auntie's house I learned to love school. School is where I could found safety, where I could find consistency. So I just kept running to school. When I became a teenage, that place [of safety] became church. Church is where I found love and consistency. So I kept running to there. That whole experience happened over two decades or even longer of my life. This is how I developed a love for education and for helping people. My brothers would say if you want to get out of the projects you needed to go to school. So school was no problem. No question for me. I loved it anyway, so I am going. All of my brothers and some of my sisters had a love for education. So that is basically the foundation of why I am here. I really love school and I want to help women who sometimes feel like they are trapped. I think my mom may have felt trapped. It was the 70s. She didn't work. My father worked. He actually had three businesses: a moving business, a furniture business, and a trucking business. So he was doing really well, but I think she felt trapped in that abusive situation 'cause she didn't work and she had 9 kids. So I want to help women or help people, specifically women, who are in situation no matter why or whatever the cause, to know that they have options and education always brings options. It is not the only option, but it helps to open you up to a lot of different options that weren't available before.

Prior to making the decision to become a teacher, Tanjala worked as a data analyst but found no personal rewards in this work. Therefore she took a sabbatical and worked as an urban missionary. Tanjala found this work extremely fulfilling and thought, "I would make an even better impact as a professional teacher." So at the age of 42, Tanjala enrolled in an alternative preparation program to become a secondary mathematics teacher of urban learners.

Through her childhood experiences, Tanjala had a connection with the urban community, which she defined as "a metropolitan area, inside the city limits...a ghetto…ghetto meaning lower economic status." She believed that her connections would aid her in reaching urban youth. Connecting the content to the students' life would assist her in teaching mathematics and her cultural connections with the students would support positive relationships and interactions. Tanjala also believed that creating a safe environment, where the students can ask questions without being ridiculed, provided further benefits to an effective learning environment.

In preparing to teach urban learners, Tanjala wanted to learn how to put information she learned from books into action. She wanted a mentor who would be open to sharing his or her experiences as well as communicate openly. A perfect mentor for Tanjala was "somebody who is more experienced, walking besides [her] through an experience, to guide [her] or just be there as a sounding board and possibly to be a model."

Throughout Tanjala's student teaching experience, she was constantly seeking guidance for improvement in her performance as a teacher. She used resources, such as books, peers, other teachers, her college supervisor, and her cooperating teacher, Ms. Stanley. These resources provided a source for Tanjala to improve upon her pedagogical skills. Below are some excerpts to substantiate this claim:

> My cooperating teacher has modeled a lot of constructivist activities for me and I feel comfortable using them in my lesson plans. However, I am still lost as to how to make Algebra more appealing. I will talk with my peers and supervising teacher for help.
>
> Started using the foldables a few weeks ago and they were a lifesaver. I found that the students are more engaged when using the foldables and they produce "neater" work, namely graphs. I am glad that my mentor teacher introduced me to this tool.
> I observed another seasoned teacher today. The objectives were clearly written along with the agenda. The teacher was VERY effective in leading a class discussion on finding the roots of polynomial equations. When one student inquired about the definition of a root, she asked the entire class if they knew the definition. When no one was able to explain, she said that I will draw a picture and you tell me what you notice. She drew x-y axis, an up-open parabola and from the x-axis began to draw flowers, trees, daisies, etc. The students began guessing and eventually stated that a root is where the parabola crosses the x-axis. This discourse was amazing. The students were actively engaged the entire session. I was so encouraged by seeing her example.
>
> Spoke with my peer about the review and I was given some good tips on conducting review sessions. One method suggested was to give the review on a day prior to the scheduled quiz/exam/test, and provide sample problems so that the students can practice/study for the exam. On the day of the exam, ask students if there are any questions about the problems. Do not work the problems, instead have the students articulate the concept, process or step that presented their problem and briefly discuss that issue.

The advice Tanjala received helped her to form reflective practices as well as be observant of her students' behaviors that may affect their opportunities to learn. Even though Tanjala was audacious enough to seek guidance, she had anxieties about being effective in an urban classroom:

> I am feeling so overwhelmed. Why am I doing this again???? Oh, I love the city and want to serve in the city. Lord, I could really use a lift today. I could use some event or something that would make it easier for me to choose to be positive.
>
> Today, I assessed the students on the four methods used to solve quadratic equations. The assessment was planned to be in the form of a game. Before the assessment, I conducted a review of the key issues. The review took a very long time. I feel as if I had to re-teach the lesson. The students apparently did not "get" it the first 3 times I taught it. I feel frustrated because I am running out of ideas to actively engage the students in learning.
>
> I am so tired and I am not quite sure why, the work of preparing lessons daily or the emotional work of keeping a good attitude in this atmosphere. I know that I am called/purposed/destined to be in education—so I will press on. I sure can use a break.

In spite of these anxieties, Tanjala commanded respect and took a position of authority in the classroom by not allowing students to interrupt the learning environment or break school or classroom rules:

> I told one pair of students, who I caught kissing when I exited the restroom that they had to clear the halls. The male student was very upset that I stood there until they began to walk towards the exit.
>
> During my discourse, I just fell silent, looked straight ahead and said that I will not be able to continue until there is silence. The silence lasted for almost thirty seconds and then there were distractions from two members of the classroom. I asked to speak with one young man, who by co-incidence was White, outside. During our conference, I asked if everything was all right with him and if I could help him in any way. He said that everything was fine; he just did not like me. I began to laugh on the inside and told him that his "liking me" was not a requirement for the class, but his respecting the class guidelines and me was a requirement. I asked him if he was ready to respect the rules of the school and the classroom. He said "no." I told him that he would not be able to return until he was ready to do so. He did not return until after the bell rang to collect his belongings. This challenge of my authority was intense and I felt a little threatened by his influence on the class' behavior.

After student teaching was completed Tanjala responded that she was glad it was over. Tanjala realized that even though she had dealt with challenging situations during student teaching; she had anxieties about her personal safety and the support she would receive from school administration. Once she completes her scholarship requirements, she stated she would like to teach at the college level.

Tanjala saw herself as a compassionate teacher with a passion for teaching mathematics. She viewed herself as someone who strived to help others accomplish their goals. Her confidence in the classroom was correlated to her pre-lesson preparation. If she rehearsed the lesson several times prior to teaching it, she felt more confident in her abilities. Through her experience she viewed teaching as an activity where "I do it, we do it, you do it." However, she planned to incorporate the hands-on method of "foldables" introduced to her by her cooperating teacher. Tanjala attributed the construction of her identity to her faith in God, diligent search of the literature, and the events of her childhood:

> The compassion I believe really came from my faith. It is attributed to God because I really had to learn how to love people when they come to you and say I just can't stand you. Okay let it bounce off kind of thing. That was just something in my personal life that I had to learn. As far as being an effective teacher in other areas, I just kept searching. I was like I know there is somebody out there who has an answer for me on how to do this successfully and that is why I read a lot. I just kept looking and looking and looking. One day the light came on. (Williams, 2007, pp. 50 - 55)

## Conclusions

It has been reported that most pre-service teachers prefer to teach in schools similar to the schools they attended, thus teaching students who are similar to them (Quality Counts, 2000). According to Zeichner (1996) economically disadvantaged students of color traditionally do not excel with teachers from different cultural backgrounds then their own. Therefore, one would presume that Tanjala, who grew up in a poverty-stricken urban environment, would thrive in such an environment. In fact, she mentioned in her textual description that she felt that personal history would help her connect with her students. However, classroom management challenges led her to have reservations about teaching teenagers:

> I had a student. I think I talked about him the journal. He appeared to be a White student and his mom was . . . he was mixed with something. But anyway, from the first day that I started teaching, his class was a geometry class. He [would] just sit in the back of the room and I could feel him like staring at me that did not bother me. So I would just keep teaching and on and on, but like a week or two later he would start really acting out while I was teaching, like I could be in the middle of saying something about a circle or inscribed triangle or whatever and he would just bust out HA or whatever. He would say something disruptive and the first time I did call him on it and I said is there a problem? Is there something I can help you with? No, Huh and he would be sort of a little disruptive. He had two friends that he was always sitting with and they were never disrespectful to me, the two friends. They could get disruptive in the class, but they were never disrespectful to me, but I always felt like he was attacking me. So one day I asked him . . . one day after he was going through his normal "ha . . . I don't want to do this" and his grades was really low and if I looked at his handwriting. He writes like a 3rd grader. I mean it is probably not even a 3rd grader, but a second grader. It is never straight on the line. None of his letters are even, even if he is writing on lined paper. It is always up and down and up and down and his letters are not always complete. The "A" and it would not be in the middle, but one day I asked him to step out into the hall so we could talk for a minute while everyone else was working and I said what is the problem? Are you doing well today or are you having a good day? Yeah and he would never look at me and he would be like Yeah. I would say okay. Is there a problem with your work or do you need some extra help with it? Can I help you do it or something? "No." So why aren't you doing it? "I don't want to" So I said is there a problem with me? I forgot what else I said, but I jumped to the quick of it...is there a problem with me? "No, I just don't like you". So I look at him. At first I was like ouch and then I said okay and I laughed and said you don't have to like me that is not going to affect…that is not what I am grading you on, but you have to respect the rules of the classroom and while I am talking there can be no other talking unless

> I am asking you a question. There can't be any disruptive talking or something I said and he said HUH and I said well are you ready to respect the classroom rules and he said NO. I said well I don't think you should enter classroom the again until you are ready to respect the rules and he was like well and I was like okay then you can stand right here until you are ready, let me know when you are ready and he did not come back until the end of the class. Then I let him in to get his stuff and went on. He was a little challenged (Williams, 2007, pp. 101-103).

Despite the challenges of classroom management, Tanjala remained encourage to be successful at teaching urban learners. After Tanjala narrated this story, I asked her how she felt now about handling challenging situations. She replied:

> He gave me a lot of experience. Now I am . . . I mean really that was good experience and now I can go back I just need to know I am the teacher. That is the fact. I am the teacher and he does not have to like me, but it is my responsibility and role to make sure that the class climate is safe for other people to learn (Williams, 2007, pp. 104-106).

## Discussions

Various factors may influence pre-service teachers to make the decision to establish careers in urban schools. For Tanjala, is was the connection with the urban life and desire to want to help young women know they have options through education. However, student teaching in an urban environment may increase pre-service teachers' ability to teach urban learners, it may also reduce their desire and commitment to establishing a career within urban schools (Wiggins & Follo, 1999). This reduction may be due to the factors often connected with urban schools including, but not limited to, issues of classroom management, lack of resources, lack of teacher support, and lack of student interest in their own education (Bracey, 2002; Brown, 2002; Gormley, Hammer, McDermott, & Rothenerg, 1993; Ingersoll & Smith, 2003; Matus, 1999). Despite these challenges there are teachers, like Tanjala, who want to make a difference in the lives of urban learners. It is the responsibility of teacher educators and the larger community to nurture these teachers into what Haberman (1995) refers to as "star teachers": teachers with persistence, resilience, resourcefulness, a connection with students, and a board perspective on factors that contribute to student failure.

*This study investigated the extent to which seven professional and sociomathematical norms intentionally fostered in a mathematics methods course through the use of a video case professional development curriculum re-emerged in a later course with a different cohort. All seven norms were evident, to varying extents, in the written analysis and group discussion of 11 prospective teachers who engaged in a video case analysis similar to those they had participated in during their first methods course one to four semesters earlier. This paper discusses the norms, evidence, and counterevidence for their re-emergence, and implications for teacher preparation.*

## Objectives

A key intended outcome of our mathematics teacher education program is for prospective teachers to experience *self-sustaining generative change*, defined by Franke, Carpenter, Fennema, Ansell, and Behrend (1998) to involve "teachers changing in ways that provide a basis for continued growth and problem solving" (p. 67). This paper analyzes the durability of one component of our efforts to achieve this outcome—the development of professional and sociomathematical norms embedded in the Learning and Teaching Linear Functions (LTLF) video case professional development curriculum (Seago, Mumme, & Branca, 2004). Specifically, we address the extent to which professional and sociomathematical norms intentionally fostered in a mathematics methods course re-emerge in a similar context later in the program with a different cohort of prospective teachers.

## Perspectives

Since the identification of sociomathematical norms as critical contributors to school mathematics learning (Yackel & Cobb, 1996), a growing body of research has investigated the subtle power of these norms to support the development of mathematical learners (e.g. Kazemi & Stipek, 2001; McClain & Cobb, 2001). More recently, researchers have turned their attention to the role of such norms in supporting teachers' learning during professional development (e.g. Elliott et al., in preparation; Grant, Lo, & Flowers, 2007).

Recognizing that sociomathematical norms have the potential to support teachers' learning, Seago, Mumme, and Branca (2004) incorporated the development of such norms, as well as a set of professional norms, into the LTLF materials that we adapted for use in our mathematics methods course. These professional and sociomathematical norms are listed in Column 1 of Table 1 and form the basis of our study. We see these norms as important to preparing teachers in three ways: (1) supporting the development of their own mathematical understanding;

(2) learning to view and analyze classroom practice in productive ways; and (3) thinking about what norms should be developed in mathematics classrooms with students.

One of the challenges of investigating norms is the difficulty of determining normative behavior from a snapshot of practice. For example, in one class session, there may not be time for each participant to present a solution to a mathematical task, but if most who do include a mathematical argument, a reasonable inference is that mathematical argumentation is a norm for that class. On the other hand, if few include a mathematical argument, it is safe to conclude that it is not a norm. Another way to infer the presence of a norm is when the norm is not exhibited and this is recognized and corrected by other members of the group.

We approach both the development of the program and our research from a situated perspective (e.g. Borko et al., 2000). That is, we generate learning situations that are similar to those in which we intend prospective teachers to use the learning in their future teaching, and we study the way in which they interact in these situations. We also follow Cobb, Stephan, McClain, and Gravemeijer (2001) in our interest in coordinating the social and psychological perspectives. For the study reported here, this means that we have concerned ourselves with evidence of professional and sociomathematical norms in both group interactions (social perspective) and in the prospective teachers' individual written work (psychological perspective).

## Modes of Inquiry

The participants in the study were 11 prospective mathematics teachers (PTs) enrolled in their final mathematics methods course who had used the LTLF video case curriculum in their first mathematics methods course one to four semesters earlier. During one 80-minute class session, these PTs were engaged in a video case discussion similar to those they had participated in during their first methods course. Prior to the session, the PTs solved the mathematics problem (see Figure 1) individually (Data Source 1) and predicted possible student correct (DS 2) and incorrect (DS 3) thinking. The session began with a group discussion about the mathematics. Next, the PTs watched a video of middle school students discussing their thinking about the same problem and responded in writing to questions about what they noticed (DS 4), student thinking (DS 5 and DS 6), and teacher actions (DS 7) in the video, and then engaged in a group discussion about these ideas. At the end of the session, the PTs reflected in writing about what they learned from the discussion (DS 8). In addition to these written data sources, the group discussions of the mathematics and the video were videotaped and transcribed (T).

Study the sequence of cube buildings below. Assuming the sequence continues in the same way, how many cubes will there be in the 4th building? The 17th building? The nth building?

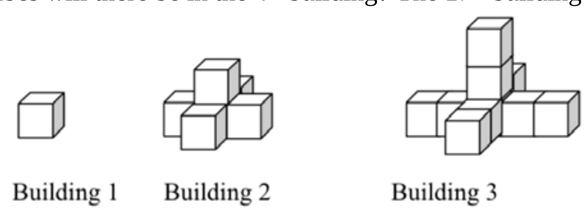

*Figure 1.* Counting Cubes problem solved by the PTs and the students in the video. The problem and the video are from the *Turning to the Evidence* project (see Seago & Goldsmith, 2005).

The first two authors facilitated the session. Both had taught the first methods course, but half the participants had taken it from other instructors. The facilitators made a point of not introducing professional or sociomathematical norms in order to see if any of the norms established in the first methods course would spontaneously re-emerge.

In order to analyze the data for evidence of the seven professional and sociomathematical norms (see Column 1, Table 1), transcripts of the mathematics and video discussion and all written work were coded independently by at least two researchers for examples and counterexamples of each norm. Any differences were resolved through refining the code definitions. The analysis was completed using multiple charts that cross-referenced evidence and counterevidence of each norm by PT. These charts were then collapsed into the summary chart shown in Table 1.

## Results and Discussion

*Overview*

Table 1 summarizes the professional and sociomathematical norms exhibited by each PT, as well as the identifier of the data source in which each norm was exhibited [1-8, T]. “C” indicates that a counterexample of the norm was identified. For example, Abby’s “TC” for *talking with respect yet engaging in critical analysis* indicates that she was critical, but not respectful of the teacher in the video in at least one instance in the class discussion.

The bottom two rows list the number and percent of speaking turns during the discussion. It is worth noting that Hana spoke only during the mathematics portion of the discussion when she presented a possible way that students might think about the problem, Abby spoke at the end of the video discussion after being encouraged to do so by the facilitator, and Ruth did not speak at all, despite a direct invitation.

Table 1.
*Professional and Sociomathematical Norms Exhibited by Prospective Teachers*

| | Norm | Abby | Evan | Hana | Iris | Jim | Ken | Leah | Lily | Lew | Roxy | Ruth |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Professional Norms | Listening to and making sense of or building on others’ ideas | 4, 6 | T, 6, 8 | 7 | 8 | T, 8 | T, 1, 4, 5, 8 | T, 4, 8 | 4 | T, 8 | T, 4 | |
| | Adopting a tentative stance toward practice – wondering vs. certainty | 8 | | | T | 8 | T | T, TC | | T, 8 | T, TC | |
| | Backing up claims with evidence and providing reasoning | T, 7 | T | | T | T, 7 | T | T | 7 | T, 4, 6, 8 | T, 4, 6 | |
| | Talking with respect yet engaging in critical analysis of teachers and students portrayed on the video | TC | T | | T | T, TC, 7, 8 | T | T, 4 | T, 6 | T | T | |
| Sociomathematical Norms | Naming, labeling, distinguishing, and comparing mathematical ideas | 4, 5, 8 | T, 4, 5, 6, 7 | 4, 5, 7 | T, 4, 5 | T, 4, 5, 8 | T | T, 4 | T, 4, 5 | T, 4, 8 | T, 6, 7, 8 | 4, 7 |
| | Using mathematical explanations that consist of a mathematical argument, not simply a procedural description or summary | T, 1, 4, 6 | T, TC, 1 | 1 | T, 1, 5 | T, TC, 1, 6 | T, 1, 6 | T, 1, 6 | T, 1, 4, 6 | T, 1, 5 | T, 1 | 1 |
| | Raising questions that are related to the mathematics and push on understanding of one another’s mathematical reasoning | 7, 8 | 4 | | 7, 8 | T, 7 | T, 4, 7, 8 | T | | 4 | T, 7 | 8 |
| | Total Speaking Turns | 3 | 21 | 9 | 12 | 22 | 18 | 15 | 6 | 17 | 19 | 0 |
| | % Participant Speaking Turns | 2% | 15% | 6% | 8% | 15% | 13% | 11% | 4% | 12% | 13% | 0% |

*Note.* Professional and sociomathematical norms are from Seago, Mumme, and Branca (2004).

As can be seen in Table 1, 3 of the 11 PTs (Iris, Ken, and Lew) exhibited each of the seven norms in the discussion and/or their written work with no counterexamples. An additional 2 PTs (Jim and Leah) exhibited each of the seven norms, but Leah also had a counterexample for the norm of *adopting a tentative stance toward practice*, while Jim had counterexamples of both *talking with respect, yet engaging in critical analysis* and *using a mathematical argument*. Three of the remaining PTs exhibited six norms overall (Abby, Evan, and Roxy), 1 exhibited five norms (Lily), and 2 PTs exhibited three (Hana and Ruth).

In the whole-group discussion, 7 of the 11 PTs (Evan, Iris, Jim, Ken, Leah, Lew, and Roxy) exhibited at least five of the norms. The other 4 PTs exhibited zero (Hana and Ruth), two (Abby), and three (Lily) of the norms, but they all participated in the discussion in a very limited way. As might be expected, there appears to be a general correspondence between the percent of speaking turns during the discussion and the number of norms exhibited, with the largest number of norms exhibited by those PTs who participated the most. Iris is an exception to this, however, as she had only 8% of the speaking turns, yet exhibited five of the seven norms.

To better understand evidence and counterevidence of the norms during the discussion, consider an exchange that occurred at the end of the session and contained Abby's entire contribution to the video component of the discussion:

F2: There's a few people that we haven't heard from yet. Wondering if any of you who've not talked a lot have something that you want to add to [previous comment]. Like Abby.

Abby: I didn't like the teacher. I didn't like that he didn't ask about the picture. I felt like he was feeding them the answers. I hated line 85. So I have nothing good to say about the teacher, which,

F2: Can you say a little bit more about what it was that—

Abby: I feel like he should have tried to make more connections about the picture, because, like we were talking about, group 2 didn't really know what the minus 4 was; it just worked for the numbers, and I think he could have tried to pull more out of them. Same with what Iris was saying about group 3. We know nothing about their method. He just kind of let them put that up there, and then used it to make the, the number connection about the expressions, the algebraic stuff. Like he could have made more connections with the visual, uh, aspect of it. And then I just didn't feel, like he just talked [brief pause] at the end, in line 85, like he could have let them explain that more.

F2: Okay. You were storing up a lot. [laughter] So there's several things to respond to there.

Jim: I felt the same way, because in line, 26, he, you know, "How many cubes would be in a [seventh] building?" And Cassie says "31," and how, you know, he asked how they got that. They've already made it apparent that they know how to substitute, because, before that, Cassie says that they first thought it was $5n + 1$, but they found out that it didn't work for the first one. And so, he just asks a redundant question, and, by asking them what the seventh one was, all they have to do is plug it in. But he never asks *why* it's $5n – 4$. He just, they give him the answer, he asks what the seventh one is, they give the right answer and it's over. But never why, where did the minus 4 come from? Again, never relates it to the picture.

Iris: I guess it kind of depends on what his teacher goal was for the day. [laughter] [T539-564]

Both Abby and Jim were coded as exhibiting a counterexample (TC) for the *critical yet respectful* norm because they did not talk about the teacher's practice in a respectful way during this exchange. Iris, on the other hand, shifted the conversation back toward showing respect towards the teacher by raising the question of whether his actions might have been appropriate for his goals for the day. Although it is difficult to see emotions in a transcript, the points at which the laughter occurred support the facilitators' sense that Abby's and Jim's comments made the group uncomfortable, and thus were not normative. It seems that the laughter served the role of diffusing tension caused by a violation of a group norm and the action taken by Iris to re-establish it. Also interesting to note is that both Abby and Jim used evidence to back up their claims, demonstrated that they had been listening to the prior conversation, and, in fact, raised valid concerns about the teacher's actions. Thus, even though they were not respectful, they were critical in a potentially productive way. In our experience, however, the respectful component is important to developing an atmosphere where teachers feel comfortable talking about their teaching and, in so doing, are able to identify and act on specific opportunities to improve their practice. If the group had not self-corrected, the facilitator would have used this exchange to point out the importance of being critical in a respectful way and to remind the PTs that their analysis should focus on the instance of teaching practice, not the teacher himself.

In the written work, all 11 PTs exhibited at least three norms, with 5 exhibiting five or more of the seven norms. The PTs demonstrated the norms in two ways: by participating in the norms themselves and by making a statement that indicated they recognized that the norm was important in the classroom. For example, Lew exhibited the norm of *using a mathematical argument* both ways. First, he made a mathematical argument to justify a mathematical expression: "A better more visual formula would be $5(n-1) + 1$, since I have five 'arms' that are $(n-1)$ long and one single 'central' block" [DS 1]. Second, he recognized the importance of the norm in the classroom when he reflected that the students in the video "were very thorough and were very aware of what everything stood for in their solution" [DS 5]. Each PT demonstrated between two and five norms in their own analyses and reflections, and made statements indicating they recognized the importance of between one and five norms. Looked at in another way, over half of the PTs made statements alluding to the importance of the norms that could be considered most relevant to their future classrooms: *listening to and making sense of others' ideas; backing up claims with evidence; naming, labeling, distinguishing, and comparing mathematical ideas; using mathematical arguments;* and *raising questions that push on others' understanding.* This is important as these future teachers will not likely work to establish these norms in their own classrooms unless they are explicitly aware of the norms and recognize them as important to developing mathematical understanding.

In sum, all seven norms fostered in the first mathematics methods course through the use of the LTLF materials were evident during a video case written analysis and group discussion that occurred at the end of the program with a different cohort. This is significant in that the PTs had not explicitly discussed the importance of these norms, nor were they reminded of the norms prior to the session. In addition, the PTs had participated in the prior video case discussions with at most three others, and thus had not constituted the norms as a group. Rather, the norms had been developed in four separate classrooms, yet appeared to re-emerge naturally during a similar discussion focused on analyzing teaching and learning.

To give the reader a further sense of what it means to exhibit the professional and sociomathematical norms examined in this study, we now turn our attention to a more detailed analysis of three norms that are particularly relevant to developing students' mathematical understanding and to teachers' continued professional development. We will first discuss results related to the professional norm of *backing up claims with evidence*—a norm that is critical to becoming a reflective practitioner. We then focus on the sociomathematical norms of *naming,* *labeling, distinguishing, and comparing mathematical ideas*, and *using mathematical arguments*, both which are critical to supporting students' understanding of mathematics.

*Providing Evidence*

All seven of the PTs who participated substantially in the video discussion, as well as one who did not, made at least one claim during the discussion that they backed with evidence and/or reasoning, referring either to specific line numbers in the video transcript or directly referencing the transcript in another way (e.g., "on page 1 it says …"). Of the 13 instances where PTs referenced the video transcript, 10 (77%) occurred without any prompting, three were prompted by the facilitator and one by another PT. Notably, all four PTs who were prompted to use evidence also had instances where they used evidence without prompting.

The following exchange illustrates how the practice of providing evidence to back claims was normative in the group:

> Ken: Well, Arden's [expression] works if you have his variable.
>
> Jim: Exactly. So it works for all of them, if you use his variable, which he specified in the very beginning. But apparently the girls weren't listening to what he said.
>
> Ken: Where did he explain that? Because I—
>
> Jim: Line 7. The equation was that 5*n* + 1 equals the volume, and *n* equals the length of one individual arm. So he told people, but everyone was just so caught up on the building number. [T326–332]

Here, one PT, Ken, actually prompts another to refer back to the transcript to back up his claim that a student had clearly defined his variable.

Yet another source of evidence of this norm is the use of line numbers in the PTs' written work, which was completed before the group discussion, and thus before any prompting was provided. In this case, four of the PTs cited specific line numbers in their reflections, while another provided more indirect evidence. It is important to note that using evidence does not come naturally to PTs and, in fact, takes some time to develop in the first methods course.

*Comparing Mathematical Ideas*

All 11 of the PTs *named, labeled, distinguished, and compared mathematical ideas* either in the video discussion or their written reflections, providing strong evidence that doing so was normative in the group. Ten participated in the norm by directly comparing students' thinking, and six, including the one who did not directly compare, made statements that indicated they thought comparing solutions was important.

In the video discussions, all eight of the participants who substantially contributed to the conversation exhibited this norm in at least one of three ways: (1) comparing their mathematical thinking to that of other PTs ("I was just going to say that I came up with the same formula, 5(*n*–1), but I saw it in a different way" [Lily, T65–66]); (2) comparing their thinking to the students' in the videos ("They were adding 1 for that middle cube. They were kind of looking at it the same way I did." [Evan, T338–340]); or (3) comparing the students' thinking in the video to each other's and/or recognizing that it was important that the teacher did so. The following, which immediately preceded the exchange with Abby and Jim cited above, illustrates this recognizing:

> Well, a lot of it seemed to me like [the teacher]'s checking them for their own understanding. … asking them to like compare and contrast is showing like if they understand their own method enough to talk about how it's different from the way someone else did it, and how, how they're the same. [Lew, T533–538]

In the written work, all but two of the PTs responded to at least one reflective prompt by discussing the different ways students in the video were defining their variable, which indicates that they were comparing students' solutions as part of their individual analyses. Evidence of this norm was also shown in a variety of other ways in the written work, including recognizing that the teacher pushed students to compare their solution methods, directly discussing and comparing student solution methods, and discussing whether students really understood each other's solutions. In addition, five PTs noted that comparing and contrasting solutions was important in their end-of-day reflection. For example, Roxy reflected that "It is important to tie everything together and see how or if different solutions are related to each other" [DS 8].

*Mathematical Arguments*

All of the PTs attempted to use mathematical explanations that consisted of a mathematical argument—not simply a procedural description or summary—in their own solutions to the problem [DS 1] and all but two either did so again or noted the importance of doing so when analyzing the student thinking or teacher moves in the video [DS 4–8, T]. In justifying their own solutions the PTs were successful in using a mathematical argument to varying degrees. To illustrate, consider Leah's justification for her expression, $4(n - 1) + n$: "The solution supports the picture since you have four branches that are the size of the previous building ($n - 1$), and one branch that is the size of the current building ($n$)" [DS 1]. Here, Leah justifies each part of her expression in relation to the diagram provided with the problem, though it would have been clearer if she had said "building number" instead of just "building." In contrast, to justify her expression, $5n - 4$, Hana says, "My solution accommodates my visualization of 5 blocks adding every [time] to the original cube: one cube spreading out at its arms" [DS 1]. While Hana adequately justified the coefficient in her expression, she did not make any attempt to justify the – 4, rendering her argument incomplete.

Further evidence that the behavior is normative can be seen in the fact that seven of the PTs made statements in their written reflections on the teacher and students in the video indicating that they recognized the importance of using mathematical argument. In the following reflection, for instance, Abby demonstrated the norm by noticing a lack of argumentation:

> One thing that stood out was that the teacher never asked Cassie to explain where the minus 4 came from. During her explanation, at the end she would just say, "and then you subtract 4." There was no connection to the picture or explanation of where that came from. [DS 4]

In the end-of-day reflection that prompted for insights/connections related to teaching that the discussion generated for them, Iris wrote, "Teachers should ask questions that prompt connections between pictures and expressions/equations" [DS 8].

Similar statements related to this norm were made throughout the video discussion. In total, 24 instances of this norm were coded, involving nine different PTs. In one telling utterance, Roxy discusses how the students in the video were able to justify a part of a mathematical expression that the PTs could not in their own mathematical discussion:

> Yeah, because that's what I had trouble seeing. I couldn't figure out like how to describe where you take away the 4. 'Cause I did it like Leah did it, with the 4—well, I did it in a table, but then I also saw the $4(n - 1) + n$. I was like, oh, well, that's how you get your minus 4. But I like how [the solution looking at the minus 4 as subtracting the overlap when the middle is included in each "leg"] actually shows this is how you take away the 4. [T215–219]

Thus, Roxy recognizes the students' mathematical argument, while at the same time indicating its importance by noting her own inability to fully justify a mathematical expression.

## Conclusions

Professional and sociomathematical norms developed early in a teacher preparation program seem to be durable in the sense that they re-emerged in a similar situation at the end of the program. This is encouraging because these norms support a richness of discussion about the teaching and learning of mathematics that is not prevalent in descriptions of practicing teachers in research on teacher learning. In particular, the PTs in this study focused on student thinking and the implications of the teacher's actions for supporting student thinking in a way that is not commonly seen. The fact that we were able to foster these professional and sociomathematical norms through use of a practice-based video case curriculum in a methods course (Stockero, 2008), combined with the findings from this study regarding the durability of the norms, suggests the value of making the development of such norms a key part of curricula used in university methods courses. Not only will moving PTs further along the teacher development trajectory during their university education give them a solid start, experiencing *self-sustaining generative change* will position them to accelerate their movement along the teacher professional development trajectory as they become more experienced teachers.

# JUXTAPOSITIONAL PEDAGOGY: DESIGNING CONTRASTS TO ENABLE AGENCY IN METHODS COURSES

Thomas Ricks
Louisiana State University
tomricks@lsu.edu

*Powerful forces resist the preparation of teachers, especially the 'apprenticeship of observation' and critical professional colleagues. This paper describes a pedagogy of juxtaposition for mathematics methods courses, namely: (a) critically examining polarized videos of teachers' practice, (b) considering contrasting opinions about mathematics education, (c) participating in modified lesson study, (d) co-teaching the method curriculum to peers, (e) public school teaching during two separate field experience blocks, (f) solving dual part problems, and (g) reflecting on previous personal reflection. Student data is presented that confirms the cognitive dissonance such a juxtapositional approach creates, and positive results for independent student thought.*

## Statement of the Problem

Elementary education preservice teachers hold deeply held beliefs (Ball, 1990), beliefs so entrenched by long years in the "apprenticeship of observation" (Lortie, 1975), that receptiveness to alternative teaching possibilities is unfortunately curtailed. Worse yet, new teachers embracing university methods often encounter conflicting messages from veteran teachers (Skempp, Sparkes, & Templin, 1993) skeptical that university theory is just that—theory unconnected to classroom realities where discipline issues, testing pressures (Webb & Coxford, 1993), and lack of time (Stanley, 1998; Wildman & Niles, 1987) demand a more pragmatic (indeed, straightforward) approach to instruction. And not just new teachers face this hardship; Mr. Murano, an eighth-year middle school teacher selected to participate in a research project because of his dynamic whole-class discussions, admitted feeling considerable pressure, and even animosity, from more traditional colleagues over his unique teaching approaches (Ricks, 2007). Another teacher of 15 years experience, Ms. Auburn, had even considered transferring to another school and hand-picking teachers herself, so as to alleviate adverse colleague pressures. Ms. Auburn was also aware of other pressures new teachers face besides disagreeable peers; she had served as the district's mathematics specialist when the district's adoption of an NSF-approved curriculum resulted in a tidal-wave parent backlash that forced the district to drop the mandatory curriculum implementation (Ricks, 2007).

In the context of these difficulties, I have tried an atypical approach to influence preservice teachers' beliefs about the nature of teaching during the few short weeks they are under my tutelage. Rather than plunging them as rapidly and as deeply as possible in a vat of reform ideas, hoping a pressurized, 16-week saturation will infuse into them enough concentrated reform antidote to overcome the previous poisonings and outlast the upcoming epidemics, I have opted for a milder approach of careful comparison of teaching possibilities through an appeal to *juxtaposition*, which allows preservice teachers the opportunity to develop and defend their own conceptions of effective teaching practices as they experience contrasting situations.

The purpose of this paper is to describe this juxtapositional stance that guides my actions during preservice teacher methods courses at Louisiana State University. This paper draws on ideas being tried during the longitudinal Teaching in Mathematics Education (TIME) study, an ongoing 5-year study at Louisiana State University investigating practical, implementable

strategies to significantly improve preservice teacher preparation by participation in a reflective curriculum of juxtaposition. As the project is only in its initial stages, this paper is designed to be a descriptive account of the course, a medium known to contribute to furthering avenues of possible research (Bush, 1986).

## Juxtapositional Pedagogy

I consider a *juxtapositional pedagogy* to be a pedagogy respecting the preservice teachers' inherent, inalienable right to choose and pursue for themselves their own pedagogical paths, which in mathematics education involves navigating terrain often overly-stereotyped as an either-or, traditional-reform quagmire. This juxtapositional pedagogy comprises sufficiently-contrasting experiences, coupled with the adequate time and social support, to augment preservice teachers' evaluative cognitive capacities.

In particular, I view teaching as a constant form of judgment-in-action; teachers are relentlessly making decisions, whether privately as they ponder and reflect on past teaching and future plans, or publicly as they think on their feet during dynamic whole class discussions (Yackel, Cobb, & Wood, 1999). Teachers must make instantaneous decisions with limited access to information and time to consider the results of their actions. Good teachers are able to choose among many possible paths of action to further propel learners in productive directions.

The underlying theoretical premise of the course envisions teachers—ultimately—as rational, reasoned, decision-making agents (Bush, 1986; Dewey, 1981/1933). The course attempts to augment teachers' decision-making powers. Believing that social interactions play a pivotal role in forming new understandings (Cobb, Wood, & Yackel, 1990; Vygotsky, 1978), I attempt to present carefully constructed juxtapositional experiences to form the catalysts for intellectual conversations between class members. When presented with polarized viewpoints, preservice teachers can begin to critically reflect on their own beliefs. This reflection becomes especially potent when their own thinking is juxtaposed with others' differing viewpoints in social contexts (Feldt, 1993). The following juxtapositional features are described in this paper: (a) critically examining polarized videos of teachers' practice, (b) exposure to contrasting opinions about mathematics education, (c) the collaborative environment of modified lesson study, (d) co-teaching the method curriculum to peers, (e) two separate field experience blocks in a local public school, (f) dual problem parts, and (g) reflecting on previous personal reflection.

### *Critically Examining Polarized Videos of Teachers' Practice*

Drawing from a variety of video sources such as TIMSS (NCES, 2003), professional development mediums, and a growing, personally-videotaped collection (Ricks, 2007), I show short segments of contrasting teachers' practice. These episodes are strategically chosen to bring a pedagogical issue to the forefront, or to highlight certain principles arising in our own class discussions. By using video mediums, portions of the videos can be re-watched and revisited, aiding class reflection; additionally, encapsuled experience in video form, although not equal to the ideal (observations of student thinking in actual classrooms), do provide a manageable nexus for coherent whole class discussion as the camera is only pointing in one direction, a redundant component helpful in whole-class discussions (Davis & Simmt, 2003).

Watching videos has the added benefit of showing alternative strategies for reform instruction. Using the words of Stigler and Hebert (1999), videos provide "a penetrating and unparalleled look into classrooms" (p. 9). Most of my students have never experienced a mathematics class taught in a reform manner; preservice teachers struggle to conceive of what the NCTM, for example, is describing in their vision of school mathematics (NCTM, 2000), having no concrete mental models. The nebulous terminology of *constructivism* (Kilpatrick, 1986), *community* (Grossman, Wineburg & Woolworth, 2001), and *discovery learning* (Davis, 1994) takes on new meanings with these solidly accessible images of practice. It also is convincing proof that such instruction can be done, and done well; a video of Deborah Ball teaching 3rd grade is one of my personal favorites in assisting the preservice teachers' paradigm shift that students *can* think powerfully about mathematics in unexpected ways even in the early grades, and grapple with issues they themselves as adults have never considered.

*Exposure to Contrasting Opinions about Mathematics Education*

Another fundamental part of the pedagogy of juxtaposition involves preservice teachers reading articles by individuals with sharply contrasting beliefs about mathematics education; the preservice teachers begin to understand the arguments of anti-reformers and the rhetoric of reformers. They recognize that this country is deeply and passionately divided over instructional methods for their children (Jackson, 1997), and that they need not only to better situate themselves on the battleground of the math wars (Ball, Ferrini-Mundy, Kilpatrick, Milgram, Schmid, & Schaar, 2005; Schaar, 2005), but should be able to justify their position as well. Stigler and Hiebert's (1999) *The Teaching Gap* is a particularly good reading that inherently emphasizes juxtaposition within the text itself through international comparisons of Japanese, German, and American classrooms.

*Modified Lesson Study*

I engage my preservice teachers in four-person lesson study groups modeled after the common form of Japanese lesson study discussed in Stigler and Hiebert (1999). Typically, American teachers work in isolation (Hart, Schultz, Najee-ullah, & Nash, 1992; Shulman, 1987; Stepanek, 2000; Valli, 1997); lesson study forces the preservice teachers to work together to plan a lesson (Lewis & Tsuchida, 1998). This can be for them a frustrating form of juxtaposition because how their peers think about mathematics often differs in substantial ways from their own conceptions, providing a rich social environment for discussion, negotiation, and cooperation (Davis & Simmt, 2003; Feldt, 1993). Ideally, the research lesson is eventually taught in a local public school classroom, revised, and taught again to a different elementary class a few weeks later, which forms another opportunity to juxtapose experiences through personal reflection on the two lessons' effectiveness.

*Co-teaching the Method Curriculum to Peers*

I also have pairs of preservice teachers teach portions of the class curriculum to their peers. Having videotaped their teaching, I then provide them with a reflection assignment—they report this experience is one of the most eye-opening experiences in their entire teaching program (especially as for many, this is their first time watching a videotaping of their own teaching). In a way, watching oneself teach is the ultimate form of teacher juxtaposition, because the imagined self usually appears very different from how reality (or at least a video rendering of reality) really is. Co-teaching becomes another opportunity besides lesson study to juxtapose one's ideas against that of another teacher.

*Public-school Teaching: Two Separate Field-experience Blocks*

A fifth form of juxtaposition is teaching two blocks in a local elementary school. This achieves juxtaposition in a variety of ways. First, the exposure to their cooperating in-service teachers' mathematics instruction is eye-opening, especially in light of their developing opinions on good teaching practice formed in the weeks before—the preservice teachers are beginning to see with new eyes and return two weeks later after this first block transformed. Then, for three weeks we engage in energized discussion as the preservice teachers are now recognizing the national generalizations Stigler and Hiebert discussed (1999) about American teachers all teaching the same. The preservice teachers are dismayed, discouraged, and yet determined. Dismayed by what they saw—the lack of high-quality math instruction; discouraged because they themselves tried to teach in a more engaging way, by posing challenging mathematical tasks, but found it exceedingly difficult; and determined because they know it can be done—they have seen videos of Japanese and selected American teachers succeed in engaging students in meaningful, exciting mathematics lessons. As Goethe wrote: "Every new object, clearly seen, opens up a new organ of perception in us" (von Goethe, 1988, p. 39).

Additionally, the first lesson study lesson is taught by each group during the first block. The three-week interim also gives time for lesson study groups to analyze the effectiveness of their first lesson attempt, and re-plan for a better second attempt in a different class later in the second block.

It is during this three-week hiatus between field experience blocks that I detect a palpable shift in the preservice teachers' desires regarding the course—something I can best describe as a new hunger. They now recognize that they lack something needed to teach mathematics at a level they know is possible. I change the thrust of the course during this crucial time. Whereas the first part of the semester focused on recognizing, modifying, or developing challenging mathematical tasks, I shift the course's focus to emphasize the implementation (Stein, Smith, Henningsen, Silver, 2000) of these well-designed tasks. The first half focused on *what* teachers might do effectively, and the second half now focuses on *how* to actually do it successfully. The second round of field-experiences allows the preservice teachers to better practice what they tried in the first go-around.

*Strategically-designed, Dual-part Problem-posing*

These juxtapositional activities, which permeate the course, are designed to illustrate a particular learning issue by dividing an instructional task into two parts to allow the preservice teachers the opportunity to compare and contrast their own experiences in the task solution. For example, to illustrate the difference between doing mathematical computations through rote memorized procedures (which many unfortunately believe is 'mathematical activity') and understanding the underlying conceptual principles, I choose a simple fraction division problem, such as: 1 ¾ ÷ ½ (Ma, 1999). Students can easily solve this problem through an appeal to the invert-and-multiply maxim, but struggle writing a real-life story that would be applicable to this computation.

A second dual-part problem I find effective is 198 divided by 12. Again, the preservice teachers are able to implement the long division algorithm and arrive at the correct answer, but struggle explaining the second part of the problem which asks to detail what mathematical reasoning is encapsulated by each step of the algorithm. This is not at all trivial. Even though many preservice teachers recognize the repeated-subtraction conceptual structure of the algorithm, the most difficult step is understanding the place value placement of the quotient's numerals. Their natural inclination is to think "How many times does 12 go into 1? No times. How many times does 12 go into 19? One time." But 12 is neither being divided into 1 or 19 in the algorithm. Further class discussion reveals asking "How many times does 12 go into 100 (or, similarly, 190)?" The mathematical concepts embodied in this algorithm are deep, fascinating, and accessible to even young children, but the preservice teachers have never thought about the mathematics in this way. It is left to the reader to ponder why in this particular algorithm (knowing there a multitude of different long division algorithms, each with their own conceptual base) students do not write an 8 over the dividend's 1 place, as 12 goes into 100 eight times (hint: asking "How many times does 12 go into…?" is an incorrect understanding of what the algorithm is doing mathematically, although it is often erroneously taught that way, even by mathematics educators). These dual-part problems help preservice teachers ponder the differences between, for example, procedural and conceptual understandings, and how certain tasks may reveal little about one or the other type of learning.

*Reflecting on Previous Personal Reflections*

A final form of juxtaposition utilized in this course is the course's purposeful repetitive nature, designed to allow preservice teachers the chance to reconsider previous ideas from a new perspective, resume work on difficult, unresolved issues, or to allow them to consider how their views are changing during the course. For example, students re-respond to certain notebook prompts later in the semester, such as: *What is mathematics?*, *How is it best taught or learned?*, and *What is the purpose of a methods course?*. These can be contrasted to their previous answers kept in their notebooks. Many of the above mentioned videos are re-watched and re-discussed for a second time. Because of the intervening experiences, the re-watching and resulting discussion is always different than before, revealing substantial changes in perception about teaching mathematics. As the Greek philosopher Heraclitus claimed, one can never step into the same river twice.

We also re-watch a promotional video at the end of the semester which touts the virtues of a traditional drill-and-kill approach, and it is remarkable the change in student disposition by the end of the course toward this regimented approach. In particular, preservice teachers discern the pithy, superficial phraseology saturating the video, as well as the lack of mathematical thinking expressed by the elementary students in the video.

## Discussion and Conclusions

I attempt to design components of my class to be matching compliments of one another to stimulate my preservice teachers' judgmental awarenesses using contradicting and/or paradoxical circumstances for personal introspection. In particular, this juxtapositional approach tries to respond to factors which are known to erode preservice teacher education, namely: (a) the apprenticeships of observation (Lortie, 1975) and (b) corrosive collegial atmospheres undermining university theory supposing it is unconnected to the realities of classroom practice (Schempp, Sparkes, & Templin, 1993).

Although still in its early stages, the TIME project at Louisiana State University is demonstrating through circumstantial evidences and initial indicators the positive effect a curriculum of juxtaposition has had on preservice teachers' fundamental perspectives of mathematical pedagogy. The following excerpts are anonymous student comments from end-of-semester university evaluations that reflect this positive aspect of juxtapositional instruction. A student wrote: "The beginning of the semester was a shock and I thought this class was going to be terrible, but I ended [up] learning so much and [I] became open to a new style of teaching." One student said:

> This was quite an interesting course. At the beginning I was unsure as to where this class would go. However, [the approach] challenged us, our minds, in ways that had never been challenged before. The end result was quite phenomenal.… I believe that I will go into the classroom as a more powerful teacher.

Another student wrote:

> It was a very different form of instruction but it was very interesting to learn. It opened my eyes to a different type of teaching and student learning. Even though this

was a tough course it allowed me to learn lots of new ideas.

Admittedly, the beginning of the course was unusually stressful; the preservice teachers were purposefully placed in overwhelmingly uncomfortable positions of ambiguity (Stigler & Hiebert, 1999). Another student bluntly confirmed this in the end-of-course evaluation: “The course started out rough.” Such tenor is echoed by this student’s comment: “The beginning of the semester was rocky because [the approach was] unconventional… but…. I learned so much about education and myself.” Where they expected a typical methods course’s rigidly determined calendar (i.e., *this* reading to be done by *this* date), concise grading rubrics (i.e., so many points for this aspect of the assignment—checklist-like), and traditional memorize-regurgitate exams, I offered a litany of tasks and activities that had little immediate closure and unusually difficult cognitive demand, forcing them into the position of decider—or common judge—for themselves: “I will admit that there were times I was extremely frustrated but I know that a lot is learned through frustration. I think [the approach to be] very innovative…. [The course] turned out to be really good!”, said another student.

Hopefully, these quotes capture the flavor of the initial shock that gave way to the ennobling freedoms offered by the juxtapositional approach. I believe such action provides for significant learning experiences—issues remain open for weeks, problems unsolved, opinions shared but with no teacher judgment passed (e.g. Carpenter, et al., 1989). They are thinking about this class *outside of class*, chewing things over, letting their subconscious go to work. This approach also mimics typical inservice-practice: no authority to turn to for quick, immediate answers or approval in one’s own classroom. One student expressed in their evaluation:

> Class started somewhat slow and with a disoriented feel…but by fall break things picked up…. By the second half of the semester things were going really well and I enjoyed the class. I feel that I have really learned a lot about how to teach. Real stuff, not busy work, but real applicable knowledge and practice.

I consider that these comments hold some degree of credibility as they were comments turned in anonymously to the university as part of the university’s evaluation procedures—also, not all comments were optimistic. One student grumbled: “He never answered questions.” But such is the way of juxtapositional pedagogies—the answers (or ‘learning’) students seek is not doled out by the professor, but is generated through cognitive consideration of the contrasting curriculum components.

My ultimate strategy with using a juxtaposition strategy in my courses is for the preservice teachers to consider knowledge as problematic, uncertain, fallible, socially determined, and revisable (Boaler, 1999; Ernest, 1990; Richards, 1991; Romberg, 1994; Schwartz & Hershkowitz, 1999; Thom, 1973; von Glasersfeld, 1985; Woods, 1992; Yackel, 2000). They then formulate (construct?) their own understandings and positions on issues. In other words, they must make decisions themselves about what is considered ‘good’ teaching practices, grounded through reflective analysis (Dewey, 1981/1933)—I will not make the decisions for them. Hopefully, self-formed preservice teacher reasonings will better withstand school enculturation buffetings that are known to minimize university teaching.

And I think they may well do just that. Many of the students’ comments hint at a deep, underlying paradigm shift about the way teaching and learning is construed:

> I wish I had been exposed to [these] methods much earlier in my college career. I believe [it] could have a great impact on [the university’s] college of education if allowed to continue.

I ended up loving the class. In the beginning I wanted to drop, but ended up learning

> so much from this class. There should be more [approaches like this] in the college of education.
>
> [The approach] did an excellent job in opening my mind about mathematics. I learned a lot about math concepts through discussion. A lot about math concepts were de-mystified. I feel like I am ready to go into the schools and effectively teach math.

Such is the potential of a juxtapositional pedagogy. In particular, as these comments express, preservice teachers regularly demonstrated the expected cognitive dissonance needed to effectuate an inward-motivated, long-lasting paradigm shift from traditional pedagogical thrusts to more meaningful forms of mathematics education (Carpenter, Fennema, Peterson, Chiang, & Loef, 989; Stigler & Hiebert, 1999). And their lessons reflected such a shift by the end of the semester. The fact that the science educator (who teaches science methods in the same semester as the elementary math methods block) noticed that their *science* lessons were incorporating the core structural features of their math methods lessons adds credence to the belief that the preservice teachers' apparent belief changes were not a mere superficial surface adjustment to my course expectations, but were a deeper paradigm shift about what teachers *do*, a shift that was now spilling over into other aspects of their teaching. I believe the juxtapositional approach helps the preservice teachers to become reasoned, purposeful practioners because it instills in them a reflective attitude toward their actions:

> [Reflective thinking] emancipates us from merely impulsive and merely routine activity…. it enables us to act in deliberate and intentional fashion to attain future objects or to come into command of what is now distant and lacking. By putting the consequences of different ways and lines of action before the mind, it enables us to *know what we are about* when we act. *It converts action that is merely appetitive, blind, and impulsive into intelligent action*. (Dewey, 1981/1933, p. 125, emphasis in original)

A curriculum of juxtaposition may provide a suitable environment for developing reflective habits of mind because the nature of contrasting points of view causes the open-minded to reconsider in the face of seemingly-contradictory yet equally-plausible data their own reasons and justifications for supporting their own actions and beliefs. By placing opposing ideas, each which appears to have legitimate support from other intelligent individuals, next to their own cherished beliefs, the way is open for resisting the urge to dismiss the opposition (Rodgers, 2001), and to begin forming habits of accepting or rejecting positions based on appeals to data (Dewey, 1981/1933). The purpose of juxtaposition strengthens future teachers' decision-making and respects their agency, even if they are not accustomed to this mode of university instruction at the outset of the course. In particular, juxtaposition allows preservice teachers to simultaneously consider various viewpoints and to make judgments themselves about which attributes from the differing positions they really value, enhancing their teaching potentials by grounding their actions in "*wide-awake, careful, thorough habits of thinking*" (Dewey, 1981/1933, p. 177, emphasis in original).

# WHO TEACHES MATH FOR TEACHERS?

Susan Oesterle
Simon Fraser University
smo2@sfu.ca

Peter Liljedahl
Simon Fraser University
liljedahl@sfu.ca

*Math for Teachers courses are specialised mathematics content courses whose nominal aim is to build conceptual mathematics understanding in prospective elementary school teachers. But who teaches these courses? This paper offers some insights into this question, exploring the views of two particular instructors whose interview responses reveal very different perspectives on their goals for this course with respect to knowledge-for-teaching, beliefs about mathematics, and the attitudes/emotions of their students.*

## Background

Prospective elementary school teachers are often expected to exhibit proficiency in mathematics by completing a university level mathematics content course before entering their accreditation programs. In an effort to provide this group of students with a course that is potentially more appropriate to their needs than a calculus or statistics course, mathematics departments at many colleges and universities have developed specialised "Math for Teachers" courses. Though they differ from institution to institution, these courses typically cover elementary school arithmetic and geometry topics, with an aim to help prospective teachers develop a strong conceptual understanding of the mathematics they will one day teach.

Relatively little research has been done to explore the role that these specialised content courses play in the development of teachers. As part of this larger project this qualitative study focuses on the instructors of these courses. Despite the surface similarities between Math for Teachers courses offered within and between institutions, given the autonomy that most post-secondary educators enjoy, the course-as-delivered has the potential to be significantly influenced by the individuals who teach the course. This study seeks to shed light on who the instructors of the Math for Teachers course are and how they attempt to contribute to the development of future teachers.

## Theoretical Perspectives

Our inquiry is both informed by and informs a number of theoretical perspectives including classic and contemporary views on knowledge-for-teaching and sociomathematical norms.

Initial review of curriculum descriptions for Math for Teachers courses suggested that Shulman's (1986) framework for classifying knowledge for teaching might be helpful in understanding the types of knowledge that instructors of these courses hope to transmit to their students. Shulman identifies three major categories of knowledge: subject content, pedagogical content and curricular content. Given that the Math for Teachers course is intended to be a content course, we anticipated that in interviews instructors would address subject content knowledge, but not curricular content in their descriptions of their goals for this course. However, we were interested to see the extent to which pedagogical content issues would be addressed. Under this type of teacher knowledge Shulman includes: *the most useful forms of representation of those [mathematical] ideas, the most powerful analogies, illustrations, examples, explanations, and demonstrations—in a word, the ways of representing and formulating the subject that make it comprehensible to others. (Shulman, 1986, p. 9)*He goes on to add: *an understanding of what makes the learning of specific topics easy or difficult: the conceptions and preconceptions that students of different ages and backgrounds bring with them to the learning of those most frequently taught topics and lessons.* (Shulman, 1986, p. 9)

The work of Ball and Bass (2003) also contributes to our perspective on the scope of pedagogical content knowledge. They identify an ability to unpack (or break-down) mathematical ideas, to understand the connectedness of mathematics concepts both at a particular level and across levels, and how students conceptions of mathematical concepts will evolve over time, as examples of mathematical knowledge required for teaching. Furthermore, they include knowledge of conventional mathematical practices, such as the role of definitions, and what constitutes an adequate explanation.

Though theories of knowledge-for-teaching influenced our initial interview questions, recurrent themes led us to broader and deeper considerations. Early interviews revealed that students' beliefs and attitudes are also of particular concern for instructors of this course. They can affect the students' ability to acquire knowledge content (Ball, 1990), and contribute to the development of the attitudes, beliefs and values that they will carry forward with them into their teaching careers. It also became apparent that any analysis of these affective issues would need to consider not only the aspects of their students' attitudes and beliefs which the instructors hope to influence, but also the instructors' beliefs and attitudes about mathematics and the teaching of mathematics that ultimately influence their own practice (Ernest, 1989).

Cobb and Yackel's (1996) notion of sociomathematical norms offers a lens through which to view this complex interplay between the beliefs and attitudes of the instructors and their students. Sociomathematical norms are normative understandings, negotiated through the interaction of teacher and students, which relate specifically to mathematical activity. Research supports the view that the development of these norms is closely integrated with the mathematics beliefs and attitudes of the teacher and students:

*With regard to sociomathematical norms, what becomes mathematically normative in a classroom is constrained by the current goals, beliefs, suppositions, and assumptions of the classroom participants. At the same time these goals and largely implicit understandings are themselves influenced by what is legitimized as acceptable mathematical activity.* (Cobb & Yackel, 1996, p. 460)

Though the negotiation of norms involves participation of the students as well as the teacher, the teachers' various roles (as initiator, facilitator and validator) underscore the relevance of examining the beliefs and attitudes that the instructors bring to this negotiation. Integral to Cobb and Yackel's (1996) emergent perspective is the view that these social constructs are reflexively related to the individual's mathematical beliefs and values. From this perspective, references to beliefs about the nature or activity of mathematics can suggest the sociomathematical norms the instructors hope to establish in Math for Teachers courses, and vice versa.

## Methodology

Interviews were conducted with instructors of Math for Teachers courses at post-secondary institutions in a metropolitan region. The Math for Teachers courses offered at these institutions are locally developed but are sufficiently similar that students can transfer credit for this course from one school to another.

The interviews, which lasted approximately one hour, began with a standard set of questions about the backgrounds of the instructors, their education, number of years of teaching, and number of years of teaching Math for Teachers. These questions were followed with questions about their initial orientation (preparation) for teaching the course, about what they do differently with this group of students compared to their other mathematics students, about their goals in teaching the course, and the outcomes they believe they achieve. As each interview was completed it was transcribed and coded for emergent themes through a process of constant comparative analysis (Cresswell, 2008; Corbin & Strauss, 2008). As part of this reflexive process the interviews were only semi-structured. This allowed the interviewer to incorporate additional and/or deeper questions to respond to new themes as they arose. To compensate for any bias that our own personal experience as occasional instructors of this course may introduce, the interview coding was corroborated by a more neutral colleague. Furthermore, narrative descriptions of the interview subjects were read and verified by the subjects themselves.

Through the analysis of the transcripts nine themes emerged: two related to teacher knowledge (subject content and pedagogical content), five related to sociomathematical norms (beliefs about mathematics, emotions/attitudes, aesthetics, communication, and community) and two others (teaching methods and tensions). Due to space limitations, in this report we will restrict our discussion to the two themes related to teacher knowledge, as well as two of the themes related to sociomathematical norms: beliefs about mathematics and emotions/attitudes. To facilitate readability, we will further limit ourselves to quotations from only two of our interview subjects, Harriet and Bob. Elaboration on these cases will permit us to illustrate two of the very different approaches that were revealed through our study.

We will begin our discussion of results with brief narrative descriptions of Harriet and Bob, and follow this with analysis of the selected themes.

## Narrative Descriptions

*Harriet*

Harriet is an experienced Mathematics instructor who has been teaching for 22 years. She is relatively new to teaching Math for Teachers, but has taught the course six times over the last three years. She has neither taken any Mathematics Education courses, nor does she have a formal teaching designation. She has a Masters Degree in Mathematics, and has a special interest in the history of mathematics. Harriet was initiated into the teaching of this course by a colleague who has a Masters Degree in Mathematics Education, has taught Math for Teachers for many years, and has a particular passion for the course. This colleague provided information about course materials and the nature of the students and their difficulties. She also provided teaching resources, including suggestions for activities.

Harriet feels strongly about the need for good teachers of mathematics in the elementary schools, and has put a great deal of thought into what can be done in a Math for Teachers course. Her priority when teaching the course is to change students' attitudes towards mathematics and their own mathematical abilities. She hopes students will come to see mathematics as enjoyable, even when it is challenging, and will develop confidence, based on a solid conceptual understanding of elementary mathematics.

*Bob*

Bob has been teaching mathematics for 13 years and has taught the Math for Teachers course nine times over the last nine years. He has a Masters Degree in Mathematics, has not taken any Mathematics Education courses, and has not had any formal teacher training. Bob's first forays into teaching the course were guided by the established curriculum, the textbook that had been selected by colleagues who had taught the course before, and through informal discussions with those colleagues.

Bob is passionate about mathematics. He enjoys its logic, its structure, and the challenges presented by a good problem. He cares about producing students who will be successful elementary teachers in the future, and to that end he hopes to equip them with a solid understanding of fundamental mathematics concepts, good communications skills, and a capacity to enjoy mathematics.

## Analysis of Interviews

*Knowledge for Teaching: Subject Content and Pedagogical Content*

Harriet and Bob's interviews are illustrative of two quite different conceptions of the role of the Math for Teachers course in developing prospective teachers' knowledge-for-teaching.

Harriet's description of her goals and strategies for teaching the Math for Teachers course are permeated with comments coded under "pedagogical content knowledge". When describing the content of her course she mentions varieties of algorithms for arithmetic operations, along with models for their representation. Although these topics are part of the prescribed curriculum, her comments indicate that she goes beyond merely delivering this as subject content. She explicitly considers its relevance for teaching mathematics, noting: "*We spend some time on the basic algorithms and different approaches to them, and how those can lead into different understandings of what you're doing when you're multiplying, or adding…*"

This notion of developing multiple understandings arises again when she is asked if there is anything that she teaches her Math for Teachers students about fractions that she wouldn't teach someone who just wanted to learn how to use fractions. She states: "*The fact that there are different models, there are different ways of picturing what's going on, and that they are appropriate for...what may work well for some situation, or for some student, may not work for some other one*". For Harriet, access to a variety of representations and approaches is mathematics content that is particularly relevant for her students as prospective teachers.

Connections between mathematical ideas also play a central role in Harriet's conception of the knowledge content of the course. She explains: *"…what you can do with a grade three student, and what you can do with a grade six student are quite different and I want them to see that it's all interconnected…*" Her evident appreciation for these connections echoes Ball and Bass's (2003) description of knowledge-for-teaching, addressing both the connections within and across grade levels. In her words:

> *I emphasize it [connections between topics] all the way through. I don't try to plan the course to start from the beginning and go through to the end with an obvious thread, because mathematics is way too big for that. […] But at all times I connect it, as far as I can, to what goes on at different levels. What you might do with a grade 1 class, how that connects to what they're going to see in, you know grade 4 or 5 or something like that, how that connects to what they might do in high school and how that connects to what I'm doing in Calculus. Because they've got to see how it's connected, and how we build bigger and bigger, you know, understandings of sets of numbers, or calculations, or whatever.*

Harriet does not just pay lip-service to these ideas. She describes assignments and activities for her classes that provide them with opportunities to exercise their pedagogical content knowledge: her students engage in analyses of pupil errors, as well as activities that allow them to compare alternative methods for solving math problems. While Harriet is concerned to ensure that her students build proficiency in mathematics subject content, her interview stands out from the others in that she constantly returns to comments related to how the content would be used by her students in their future roles as teachers.

In contrast, Bob's interview stands out for its lack of statements that can be coded as pedagogical content knowledge. His emphasis is instead on the notions of developing both a strong understanding of fundamental mathematics and communication skills in his students. When comparing the Math for Teachers course with his other mathematics courses he notes *"...this one focuses on their ability to communicate and convey the ideas that they should, hopefully, be already familiar with and capable of doing."* Bob describes teaching various algorithms and models as part of the course content, but does not specifically address any comments to consideration of how this information can be used differently at different grade levels.

Bob needed to be pressed by the interviewer to consider what aspects of the course content might be particularly relevant to prospective teachers as opposed to general learners of mathematics. Initially his comments revolve around his methodology, the use of group work and manipulatives (both coded under "teaching methods"), but he makes no reference to any special mathematics knowledge for teaching. Eventually an association between the mathematics that he teaches and the students' future role as teachers appears when he describes challenging his students to think about the kinds of questions that they will encounter as teachers:

> *…what kinds of questions will you encounter? And why is it important that you to be able to communicate your ideas effectively, […], why should you understand this material to the most, [...], fundamental and basic level, and understand all of the structure?*

Even then, this response seems to be a justification for developing strong subject matter content knowledge and communication skills. There appears to be a strong connection for Bob between knowing the mathematics subject content and being able to teach it. He goes on to note:

> *...when you get some of these obtuse questions, that are seemingly [...] obtuse, you have to be able to appreciate it and be able to differentiate whether that's something that can lead you into a teachable moment...*

His focus on subject content knowledge is echoed in his description of what his students leave the Math for Teachers course with:

> *…I think that they […] leave having had some sense of the structure of mathematics, because there's a sufficient amount of that in the course, and I think that they also leave the course feeling that they can solve problems, on their own. […] probably it's the technical skills that they have [...] solidified the most.*

Bob's views on the readiness for teaching of those who complete his course shed further light on this. Though he admits that they are not ready, he describes his students as still lacking maturity, confidence and communication skills. But in regard to their mathematics skills he relates:

> *...[for] my A's and high B students I wouldn't have any problem giving a recommendation in terms of how they're outfitted to [...] go into a classroom, and [...] I think other aspects of their [...] education career, will help fill out all of their [...] professional skills, in terms of knowing what's in the better interests of kids...*

It appears that for Bob, mastery of the subject content along with general pedagogical skills are sufficient for the teaching of mathematics—a traditional and not unfamiliar point of view (Hill et al, 2007).

*Beliefs about Mathematics*

Interview subjects commonly commented on the beliefs about mathematics the prospective teachers brought with them into the course, and about their efforts to influence those beliefs, though both the specific beliefs they addressed and their approaches differed.

Bob describes his students as believing that mathematics is arbitrary and incomprehensible: "*So many things seem magical to them.*" He affirms that "*it's not your standard sort of math group, it's one that has encountered some challenges along the way, and it hasn't always left them with a positive impression of mathematics.*" More than once in his interview he describes the Math for Teachers course as a second start for these students, an opportunity to reshape their beliefs about mathematics and their own mathematical ability.

For Bob, this reshaping is attempted by providing his students with opportunities to see the logical structure of mathematics, which in turn will improve their ability and their conceptions of their ability to do and understand mathematics. In his words, the course "*focuses on a very sound fundamental ability to appreciate it [mathematics], in a theoretical way, why things work, as opposed to technical aspects of how do you do mathematics*". He tries to "*give them a sense that "yes, they can" but also ...force[s] them to dig a little bit deeper, so that they also know that they can understand this as well*". He also challenges their presumptions about the root of authority in mathematics, attempting "*to make sure that they know I'm not just saying this stuff because "It's the way it is" and Math isn't just something handed down by the gods, it's understandable*".

Harriet focuses on quite different aspects of her students' beliefs. Her comments indicate that her students believe that mathematics is rigid (allowing for only one right answer), that mathematics is arithmetic, and that at least some of it is irrelevant. She observes: "*It's never occurred to them that there's more than one way to do something.*" In response to this, she takes the time to reinforce the existence of multiple representations and methods of solution. This is clearly a belief about mathematics that she values highly, as later in the interview she reiterates "*if I get across to them that they have to be aware that there are different ways to think about things, and they are all correct, even if they don't remember the details, then they've learned something*". Harriet also makes an effort, through course content, activities and assignments, to expand her students' conception of what mathematics is, noting that by the end of the course "*they're more open to the idea that geometry is a big part of mathematics than they might have been before.*" She also tries to "*explain why it is that fractions are important*", challenging beliefs that a portion of the elementary school mathematics curriculum is dispensable.

Harriet's comments about beliefs seem directed not only towards students' beliefs about the nature of mathematics, but also to beliefs about the teaching of mathematics. A nice example of this is the following comment which she makes in her discussion of teaching about division of fractions:

> *The students know the algorithm so well, they don't remember learning it. They don't remember a thing about how they learned to do these things. They just remember the rules. And their idea of helping somebody find their mistakes is to say "Oh! You're supposed to cross that out, and carry the one." Which isn't going to help anyone understand anything.*

This quote brings out the students' frequent belief that mathematics is a set of static rules that need to be memorised (Szydlik, Szydlik and Benson, 2003), as well as Harriet's contrary beliefs that not only can mathematics be understood, but it is the responsibility of the teacher to foster that understanding. Harriet provides her students with activities that allow them to analyse and discuss pupil errors. Through their discussion of these errors, she seeks to counter the belief that teaching mathematics merely involves showing someone how to execute the correct procedure.

It is worth noting that although the instructors are conscious of their students' beliefs about mathematics, and comment on how the activities and methods hope to contribute to a renegotiation of those beliefs, the development of positive beliefs and attitudes towards mathematics is not normally listed in the official course curricula for Math for Teachers courses.

*Emotions/Attitudes*

We bring our description to a close with a few comments related to the theme of emotions/attitudes that arose in the interviews. Once again this was a common concern, with instructors categorically describing their students as suffering from mathematics anxiety and lack of confidence in their ability to do mathematics. There were however, considerable differences in instructors' approaches to these negative feelings. Bob and Harriet represent two of the views expressed.

Bob describes his students as suffering from confusion and anxiety, which is closely linked to poor performance:

> *in many cases, some of the very elementary arithmetic operations are in fact, confused in their minds and so when they hit upon things, in particular when you hit rational numbers, as an example, that's one place where students have a great deal of anxiety and they would demonstrate poor understanding of ideas.*

For Bob the source of their anxiety is their lack of skill. It is his belief that improved skills will lead directly to increased confidence, however he confesses that the realities of the course conspire against this. At the beginning of the interview he expresses a wish that the students in his course develop a love of math, but when asked about whether this goal is accomplished, he admits: "*...in terms of the other goal, for love of math? Unfortunately, the course is so packed, that in some ways, I think they do get a little bit beaten by the end, and they're just tired.*" This begins to touch on the theme of "tensions" (not discussed here) however it illustrates Bob's realisation that the volume of subject matter content that he needs to cover in the limited amount of time he has with his students is at odds with his objective of instilling a "love of math" through building subject competence.

Harriet is also very concerned about her students' math anxiety: "*they are very anxious around problem solving. They are just terrified, most of them, of a problem they haven't seen before.*" In contrast to Bob, her efforts to address this seem to be centred on changing their ideas of what the enterprise of mathematics is all about. She tries to convince them that "*we're supposed to have fun with this*" and tells her students that "*you may never have seen it; you might not get all the way through it. But what I'm looking for is how far did you get, and how well can you explain what it is that you got*", shifting the focus away from getting the right answer, towards less threatening goals. By the end of the course she hopes her students have grown in confidence and also "*they have more of a sense of play...I think they're more flexible. They think they're more flexible. They're not as scared if... that someone will ask them a question that they can't answer.*" It is not clear if Harriet needs to compromise on time spent on building mathematical proficiency in order to make time for students to approach the course in this way.

## Conclusion

In her 2002 plenary address to the PME-NA, Ball noted that "we have not put in the foreground the "who" of teacher learning as often as we might" (Ball, 2002). The partial results of our study presented here provide a glimpse into the "who" of instructors of the Math for Teachers course, a course that is often the final mathematics content course taken by prospective elementary school mathematics teachers. We have shown that despite the course's nominal focus on subject content knowledge, there is also potential for instructors to address pedagogical content, beliefs about mathematics and the teaching of mathematics, as well as attitudes.

The comments of the interview subjects reveal intentions for the course that go beyond the transmission of mathematical proficiency, providing examples of instructors' efforts to expand students' conceptions of mathematics and their relationship with it. However, we are aware that our methodology permits only a description of the instructors' espoused beliefs and intentions of practice, which may not be consistent with their actual practice (Liljedahl, 2008). Classroom observations, follow-up interviews, and examination of artefacts (such as assignments and tests) will be useful in providing validation for our conclusions. Furthermore it is our hope that the full report of this study will help inform future investigations into the contribution that mathematics content courses can and do make in the development of mathematics teachers.

*Use of multiple representations can positively influence students' mathematical learning and problem solving performance. In this study, we investigate how two preservice teachers utilized multiple representations in solving a pattern task. In characterizing their solution strategies and the difficulties they encountered, we make use of concept images and concept definitions. Our results suggest that translating between multiple representations can help students solve a problem that they have difficulties with in the given representation. Furthermore, once they find the solution they can revisit the initial representation they struggled with and make necessary corrections in their solution strategies.*

## Introduction

NCTM standards emphasize the importance of different representations as they enable multiple ways of thinking about mathematical objects (NCTM, 2000). Using different representations facilitates learning algebra meaningfully and effectively (Friedlander & Tabach, 2001). Students can explain their mathematical strategies in multiple ways such as verbally, numerically, algebraically and graphically to gain a deeper understanding of mathematical concepts. Janvier (1987) supports that all meanings of an object cannot be encompassed within a single representation, as a result students need to translate between different representations to gain a richer knowledge. In order to translate between multiple representations effectively, students should have correct and strong links between each representation (Dreyfus, 1991). This study examines how pre-service teachers utilized multiple representations and the difficulties they encountered as they solved an algebra task.

## Theoretical Framework

NCTM defines representation both as a process and product. It is a process because a representation is the *act* of capturing a mathematical concept or relationship in some form, and it is a product because it is the form itself (NCTM, 2000). The ability to use multiple representations is an important skill for solving mathematical problems, as it allows students to view problems from different perspectives. To use multiple representations effectively, students should know how to translate between different representations, and how to apply transformations within a single representation. Strengthening and remediating these abilities can positively influence students' mathematical learning and problem solving performance (Lesh, Post, & Behr, 1987).

A mathematical object can be defined formally which is called the *concept definition* of that object (Tall & Vinner, 1981). What students usually remember, however, is not the concept definition, but the *concept image* which is a set of all mental constructs and processes that are associated with that object (Vinner & Dreyfus, 1989). A concept image may be contained within a single representation (e.g. slope may be associated only with the coefficient of *x*), or it may encompass multiple representations (e.g. in addition to coefficient of *x*, a student may think of the coordinate system or a numerical pair of *x*-*y* values for slope). Additionally, one may have

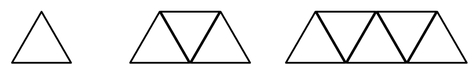

*Figure 1*. The beam task.

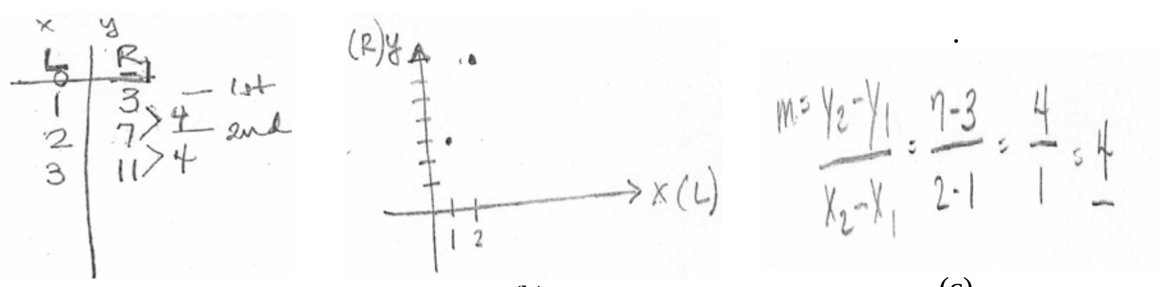

(a) (b) (c)

By translating the numerical representation to a graphical one, George was able to find the $x$ and $y$ values that can be used in the algebraic formula. This suggests that his algebraic concept image for slope was more accurate, and therefore he felt more comfortable in this representation. Once George found the slope using the algebraic formula, we asked if he can make sense of what 4 was in his table:

Interviewer: What does this difference of 4 tell you?

George: This 4 here with respect on $R$ [number of rods] is going to be the change. It is going to be the rate of $y$. Well yes of course it is going to be the rate of change because you are doing this [pointing to Figure 2c] to find the slope.

This dialogue shows that George was initially confused about interpreting his table, but once he noticed the correspondence between the algebraic result and his numerical solution, he realized that the difference between the successive entries in his table also gave the slope value. Thus, George was able to make sense of his table by referring to his algebraic solution.

He then continued to solve the problem by trying to find $b$ using the linear equation, $y = mx + b$. Although he described $b$ as the $y$-intercept, he had difficulty to use this representation:

George: For the $y$-intercept we already have the slope. Let's see $y$ equals to zero. No [erase what he wrote]. I can write this in standard form. $y$ equals the same formula $y = mx + b$ where $m$ is 4. I want to find the $y$-intercept [long pause].

This time George had difficulty to use the algebraic representation to find the $y$-intercept. Therefore, he was encouraged to solve the problem by using another representation. He then went back his numerical representation (i.e. table), and noticed that he needed to find the value of $x$ when it is equal to zero to find the $y$-intercept. He found that when $x$ is zero $y$ becomes -1 (see Figure 2a). The following excerpt shows how he used the numerical representation to find the $y$ intercept and the final result (Figure 3):

George: So if $x$ is 0 I have to subtract 4 from 3 which give me -1. So this one now became $y = 4x – 1$ [Then he changes the variables back to $R$ and $L$ to obtain, $R = 4L - 1$]

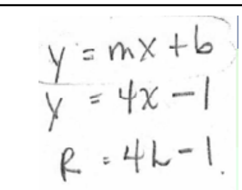

*Figure 3*. George's solution (continued from Figure 2).

George's solution suggest that he had difficulties when using only one representation, but his ability to translate between different representations helped him to find the correct answer. Furthermore, once he found the answer, he was able to revisit the representations that he had difficulties with, and could make better sense of them.

Linda also started to solve the problem by drawing a table. She first wrote the given information in the task into a table as shown in Figure 4. Then she tried the check-and-guess approach to find the general formula of pattern sequence:

Linda: Maybe $2n + 1$. That is not going to work for that one [shows the second value which is 7]. How about $3n + 1$? But this is not going to work for the first one.

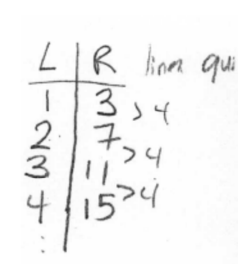

*Figure 4*. Linda's

After she tried several formulas, she found the difference between the numbers of rods ($R$) in successive table entries which was 4. Then she was asked to explain what the number 4 represents in her table. Linda stated that the number shows that it should be plus 4 in the general equation of the pattern task. The following excerpt show how she interpreted number 4 in her numerical representation:

Linda: So it should be plus 4 in the equation, because every time it goes up by 4; from one pattern to the other pattern.

Linda considered 4 as the *y*-intercept instead of the slope. This may suggest a mismatch between her concept image and the concept definition of slope when she is using the numerical representation. Since she had difficulty to find the answer using the numerical representation, she was encouraged to use another approach. Then she drew a graph and plotted the points in the table. After that she connected the points and found the slope geometrically by computing the ratio of vertical change versus horizontal change (Figure 5):

Linda: [Using data points in her table] One is three, two is seven. I can find the slope [Linda finds the slope as rise-over- run by using the graphical representation].

Interviewer: So what is the slope?

Linda: 4

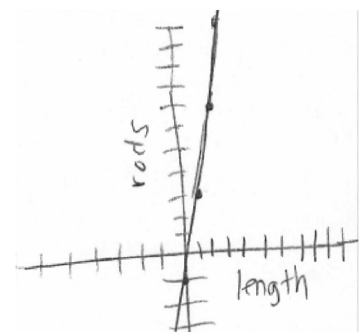

Figure 5. Linda's graph

Once Linda found the slope using the graphical representation, she revisited her table and realized that the difference 4 between the successive table entries corresponded to the slope rather than the *y*-intercept. She then revised her answer as "4*x* plus something" instead of "something plus 4". Thus, graphical representation helped her to translate from numerical representation to algebraic representation. Next Linda also found the *y*-intercept as -1 using the graph (Figure 5).

Linda's solution illustrates the case where the student has multiple concept images of the same object, but these images conflict with each other. As this example shows, in these cases it may be possible for the student to revisit the representation she struggled with and make the necessary corrections.

## Conclusion

In this study, we observed that students used their concept images when solving a mathematical problem. Furthermore, they had multiple concept images, and when their concept images were misaligned with the actual concept definition, they struggled to find the solution. However, students were able to translate between different representations, and as a result they could solve the problem in a representation where their concept images were accurate. This allowed them to revisit the representations they had difficulties with and discover the problems in their understanding.

To conclude our brief analysis, we believe that using multiple representations by having correct concept images of the mathematical objects involved and practicing those representations in different forms of the same task can positively influence mathematical learning and problem solving performance.

# CARTESIAN PRODUCT–IN-ACTION: VERGNAUD'S THEORY APPLIED TO PRESERVICE SECONDARY MATHEMATICS TEACHERS' INTERPRETATION OF POLYNOMIAL MULTIPLICATION MODELED WITH ALGEBRA TILES

Günhan Caglayan
The University of Georgia
sezen@uga.edu

*This study examines preservice secondary mathematics teachers' understanding and sense-making of polynomial multiplication modeled with algebra tiles. I base this research within a framework of concepts and theorems-in action (Vergnaud, 1983, 1988, 1994, 1997). My data consist of videotaped qualitative interviews. I generated a thematic analysis by undertaking a retrospective analysis, using constant comparison methodology. The main result of this study is that representational Cartesian products-in action at two different levels, indicators of multiplicative thinking, were available to two research participants only.*

## Background

The study of multiplicative structures has been conducted by mathematics education researchers since the 1980s. In his 1983 article, Vergnaud defines the notion *conceptual field* as a "set of problems and situations for the treatment of which concepts, procedures, and representations of different but narrowly interconnected types are necessary." (p. 128). In particular, he views the multiplicative structures, a conceptual field of multiplicative type, as a system of different but interrelated concepts, operations, and problems such as multiplication, division, fractions, ratios, similarity. Although multiplicative structures can to some extent be modeled by additive structures, they have their own characteristics inherent in their nature, which cannot be explained solely by referring to additive aspects. Behr, Harel, Post, and Lesh (1994) developed two representational systems – extremely generalized and abstract – in an attempt to transcribe students' additive and multiplicative structures in which the notion "units of a quantity" plays the main role. According to Steffe, "for a situation to be established as multiplicative, it is always necessary at least to coordinate two composite units in such a way that one of the composite units is distributed over the elements of the other composite unit." (1992, p. 264). Confrey provides splitting, "an action of creating simultaneously multiple versions of an original," (1994, p. 292) as an explanatory model for children's construction of multiplicative structures.

## Theoretical Perspectives

Vergnaud's conceptual field theory asserts that "one needs mathematics to characterize with minimum ambiguity the knowledge contained in ordinary mathematical competences. The fact that this knowledge is intuitive and widely implicit must not hide the fact that we need mathematical concepts and theorems to analyze it." (1994, p. 44). I base this present study within a framework of concepts- and theorems- in action (Vergnaud, 1983, 1988, 1994, 1997). According to Vergnaud, *theorems–in–action* are "mathematical relationships that are taken into account by students when they choose an operation or a sequence of operations to solve a problem" (1988, p. 144). He goes on to state "To study children's mathematical behavior it is necessary to express the theorems–in–action in mathematical terms." (p. 144). Concepts-in-action serve to categorize and select information whereas theorems-in-action serve to infer

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

appropriate goals and rules from the available and relevant information (Vergnaud, 1997, p. 229).

Vergnaud (1988) claims that "a single concept does not refer to only one type of situation, and a single situation cannot be analyzed with only one concept" (p. 141). He argues that teachers and researchers should study conceptual fields rather than isolated concepts. He then goes on to define a conceptual field as "a set of situations, the mastering of which requires mastery of several concepts of different natures" (p. 141). Grounded in this theory, I developed a series of terminology in an attempt to reveal my research participants' concepts-in-action arising from their verbal descriptions, actions, statements, hand gestures, and drawings in the context of polynomial multiplication problems modeled with algebra tiles.

## Research Questions

1. How do preservice secondary mathematics teachers make sense of polynomial multiplication problems modeled with algebra tiles?
2. What types of concepts- in action are available to these preservice teachers?

## Methodology

I conducted my study with (2 middle and 3 high school mathematics) preservice teachers enrolled in the Mathematics Education Program in a university in the southeastern United States. I interviewed 5 people individually twice during Spring 2007 semester. Duration of each interview was about 75 minutes and each session was videotaped using one camera.

The focus of this present study is on problems on identities of the form "product = sum" for products of polynomials modeled with algebra tiles. In this model, each little black square tile represents the number 1, purple bar represents the *x*, blue bar represents the *y*, purple square represents the $x^2$, blue square represents the $y^2$, and green rectangle represents the *xy*. The 1, the *x*, and the *y* are called Irreducible Linear (or Areal, depending on the context) Quantities (ILQ or IAQ); whereas the $x^2$, the $y^2$, and the *xy* are called Irreducible Areal Quantities (IAQ). Preservice teachers constructed rectangles with specified dimensions of the form $(ax + by + c)$, where *a*, *b*, and *c* were natural numbers. They were also asked to write their answers for the area of the polynomial rectangle as a product and as a sum.

After the end of data collection, I reviewed each interview data in order to generate possible themes for a more detailed analysis. I transcribed significant events of these interviews. A retrospective analysis, using constant comparison methodology, was then undertaken during which the interviews were revisited many times in order to generate a thematic analysis from which the following results emerged.

## Results

On the first polynomial multiplication task, my instruction was "Use the algebra tiles to multiply the polynomials $x + 1$ and $2x + 3$ on the multiplication mat." Ben first placed the dimension tiles (irreducible linear quantities) on the side and at the top. He then followed a "filling" process during which he tried to fit the areal tiles (irreducible areal quantities) in the polynomial rectangle outlined by the dimension tiles. Rather than a pair-wise multiplication, he relied on a *Filling in the Puzzle Strategy*, a concept-in-action, indicative of his additive thinking; despite the fact that he was asked to "multiply" these polynomials. Figure 1a depicts Ben's polynomial rectangle, which he obtained by the *filling in the puzzle* concept-in-action. Figure 1b depicts what he would have produced if reasoned multiplicatively. Figures 1c-d depict, another preservice teacher, Ron’s *Filling in the Puzzle Strategy*, while commenting “Any chance of fitting this [green tile] there [right next to the purple square]”?

Figure
13a

Figure
1b

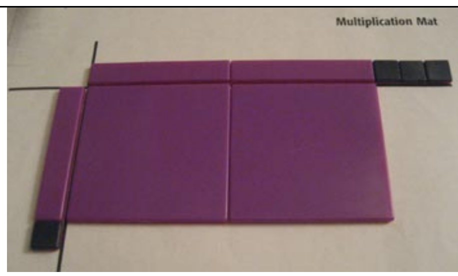

Figure
1c

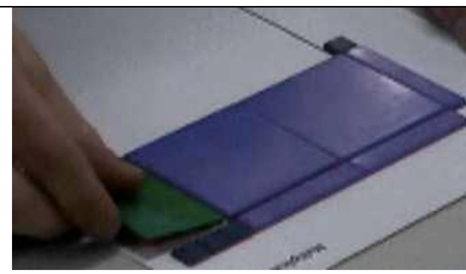

Figure
1d

John, when working on the second task on the $x + 1$ by $2y + 3$ polynomial rectangle, produced a polynomial rectangle with blue squares, blue bars, and black squares only (i.e., the polynomial rectangle was independent of $x$). *Filling in the Puzzle* strategy appeared in that John started with blue squares instead of green rectangles, which indicated that what he was doing was definitely not term wise multiplication (Figure 2a). Below the two blue squares, he placed 3 blue bars (Figure 2b). Right next to the two blue squares, he placed 6 blue bars (Figure 2c). Figure 2c stands as visual evidence that John was not using multiplication. In fact, John said “I am making the rectangle by parts.” Therefore, John's statement validates my previous hypothesis that the “Filling in the Puzzle” strategy seems to be related to an “area as a sum” strategy, namely calling for an additive nature. This contrasts with the “Term Wise Multiplication of Irreducible Linear Quantities” strategy, which naturally defines the irreducible areal quantities (IAQ) as products, namely of multiplicative nature. Finally, he placed 9 black squares right below the previous three blue bars hence completing his *puzzle* (Figure 2d).

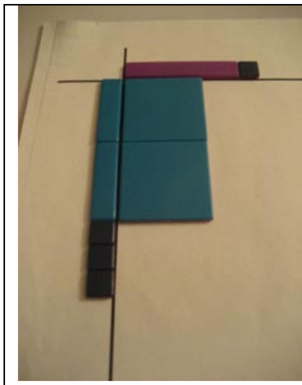

Figure 2a

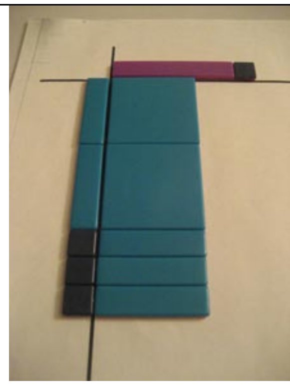

Figure 2b

Figure 2c

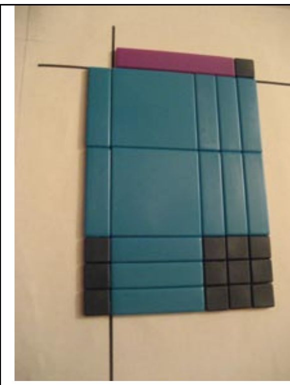

Figure 2d

Though he obtained a totally different polynomial rectangle for this second task, John's written answers and verbal descriptions were consistent in that he was always referring to his *y*–dependent–only polynomial rectangle. Because the initial instruction was to make a polynomial rectangle with length $x + 1$ and width $2y + 3$, at some point he had to write an identity in the last column of the activity sheet. In fact, he wrote the identity "$(x + 1)(2y + 3) = 2y^2 + 3y + 6y + 9$" as his answer. John's written answer warrants a disconnect as well, in that John was unable to write an *area as a product* expression (LHS) based on the *actual dimensions* of his rectangle. If he was able to refer the *actual dimensions* of his rectangle, the correct identity would then be "$(y + 1)(2y + 3) = 2y^2 + 3y + 6y + 9$" instead of "$(x + 1)(2y + 3) = 2y^2 + 3y + 6y + 9$." The following protocol takes this issue into account and reflects how John reconciled the equivalence of *x*– and *y*–dependent LHS with the *y*–dependent–only RHS:

Protocol 1: John establishes the LHS–RHS equivalence.

Interviewer: Are they equal? [about the LHS and the RHS of his identity "$(x + 1)(2y + 3) = 2y^2 + 3y + 6y + 9$"]

John: I mean... they're equal... they have to be equal...

Interviewer: Do you want to verify?

John: Do you want me to multiply that [the LHS] out? [I then ask him to do it on the board. Here is the first step of his verification. Figure 3a]

Interviewer: Is there something wrong?

John: No... It's just that... we don't know what *x* is... so... if you knew what *x* was you'd probably... *x* probably equals... [He looks at his figure] It looks like *x* equals *y* plus 2 [He then substitutes $x = y + 2$ and completes his verification. Figure 3b]

Interviewer: So it works with the condition that...

John: With the condition that *x* equals *y* plus 2.

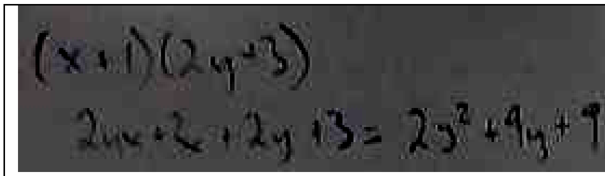

Figure 3a

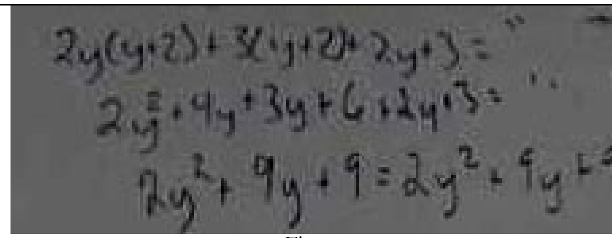

Figure 3b

At the beginning of the conversation, John was so certain about his equality that he did not feel the need to question it. Upon my request to verify his findings, he obtained “$2yx + 3x + 2y + 3 = 2y^2 + 9y + 9$” (Figure 3a). At this point, he realized that the RHS is *y*–dependent–only whereas the LHS has “*x*”s and “*y*”s, and deduced that he somehow had to get rid of the “*x*” on the LHS. He then referred to his figure made of tiles. He actually *measured* the *x* at the top of his figure using the “*y*” and the “1” tiles. In order to get rid of the “*x*” on the LHS, he substituted $x = y + 2$ (Figure 3b), based on his measurements. In other words, *John made sense of the dimension tiles for the first time*. For him, the dimension tiles do not stand as irreducible linear quantities (ILQ) whose term wise multiplication yields the corresponding irreducible areal quantity (IAQ), though. They rather stood as some sort of measurement tools helping John establish the LHS–RHS equivalence of his written identity.

On the third polynomial multiplication task, my instruction was “Use the algebra tiles to multiply the polynomials $2x + y$ and $x + 2y + 1$.” Both Nicole and Sarah, when placing the dimension tiles, followed the “*x* tile followed by the *y* tile followed by the 1 tile” ordering. As was the case with all the polynomial multiplication problems, both Nicole and Sarah actually did each term wise multiplication carefully by pointing to the corresponding irreducible linear quantities, and placed the resulting irreducible areal quantity accordingly (Figure 4).

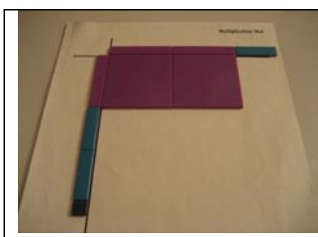

Figure 4a

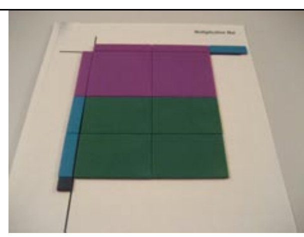

Figure 4b

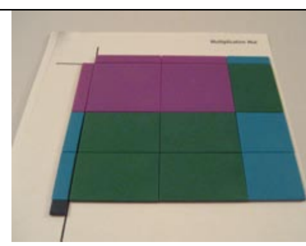

Figure 4c

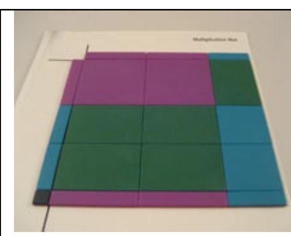

Figure 4d

Both Sarah and Nicole thought aloud and pointed to the irreducible linear tiles at the top and on the side for each multiplication. The “multiplicative nature” of the “irreducible areal quantities” seems to be warranted by Sarah’s statements in the following protocol:

Protocol 2: Sarah’s reference to a Representational Cartesian Product of Type I.

Sarah: This is [pointing to and placing the areal *x* squared tile] *x* [pointing to the linear *x* tile on the side] times *x* [pointing to the linear *x* tile at the top]. This one is also *x* times *x* [in a similar manner]. This one is $x$ times $y$ [pointing to and placing the green tile representing the areal unit $xy$]. And $x$ times $y$ [in a similar manner].

Interviewer: Where is the $x$ times $y$?

Sarah: $y$ [pointing to the linear $y$ tile at the top] and $x$ [pointing to the linear $x$ tile on the side]. And $x$ times $y$ [in a similar manner]. And $x$ times $y$ [in a similar manner]. And this is $x$ times $y$ [in a similar manner]. And then this is $y$ [pointing to the linear $y$ tile at the top] times $y$ [pointing to the linear $y$ tile on the side]. And $y$ times $y$ [in a similar manner]. This is $x$ [pointing to the linear $x$ tile on the side] times 1 [pointing to the linear 1 at the top]. And $x$ times 1 [in a similar manner]. And $y$ [pointing to the linear $y$ tile on the side] times 1 [pointing to the linear 1 at the top].

Sarah did not say "$x$ squared," nor "$y$ squared." She rather said "this is $x$ times $x$," "and then this is $y$ times $y$," i.e., multiplicative in nature. Her language "$y$ and $x$" is also indicative of an ordered pair ($y$, $x$) of linear quantities. In this vein, both Sarah and Nicole can be said to construct a *Representational Cartesian Product* of Type I defined on the *Representational Sets of Irreducible Linear Quantities* (RSILQ). With relational notation, Sarah and Nicole's verbal descriptions accompanied by their hand gestures can be modeled with the following (Representational) Cartesian Product-in-action of Type I:

- $RCP_1 = RSILQ_1 \times RSILQ_2 = \{x, x, y\} \times \{x, y, y, 1\} = \{(x, x), (x, y), (x, y), (x, 1), (x, x), (x, y), (x, y), (x, 1), (y, x), (y, y), (y, y), (y, 1)\}$.

When we discussed the "area of the boxes of the same color as a product" column on the activity sheet for the same polynomial multiplication problem $2x + y$ times $x + 2y + 1$, Nicole's answers, once again, were areas defined as the product of two quantities, i.e., multiplicative in nature. The following protocol illustrates Nicole's multiplicative thinking.

Protocol 3: Nicole's reference to a Representational Cartesian Product of Type II.

Interviewer: You are saying $2x$ times $x$ [About Nicole's expression $(2x) \cdot (x)$, which she wrote on the activity sheet]. And why not 2 times $x^2$?

Nicole: Because I just saw these as a pair together... [pointing to the linear $2x$] same things you can group them together. So it's just $A$ [pointing to the linear $2x$ at the top] times $B$ [pointing to the linear $x$ on the side]. Because when you look at this whole thing, this whole purple area [pointing to the $2x$ by $x$ "same–color–box"] as one area... so you look the length as one number, $2x$, instead of 2 times $x$.

Interviewer: So what is the difference between this and the other way [I am asking her to compare the expressions $(2x) \cdot (x)$ and $(2) \cdot (x^2)$] representationally?

Nicole: I did it [About her expression $(2x) \cdot (x)$, which she wrote on the activity sheet] in terms of the length times the width. Now it [About the expression $(2) \cdot (x^2)$ via which I am trying to challenge her] would be... talking about... how many of these [pointing to the purple squares] you have. In the other case, length times width gives the area of the whole thing [pointing to the $2x$ by $x$ "same–color–box"].

Interviewer: Please do the same for this one... [pointing to her expression $(2x) \cdot (2y)$, which she wrote on the activity sheet] why not 4 times $xy$?

Nicole: Again I did this [pointing to the $2x$ by $2y$ "same–color–box"] as one area. I did it as length times width. Now this [about the expression 4 times $xy$ I am trying to challenge her with] means I have 4 of them [meaning 4 green rectangles] and each one is an $xy$.

Nicole showed a mathematically fruitful performance in creating a *Representational Cartesian Product* of Type II, in her comparison of "$2x$ times $x$" vs. "2 times $x^2$." The "pair" in Nicole's statement “I just saw these as a pair together” refers to the pair of linear “$x$”s in “2$x$” and not to the ordered pair ($x$, 2$x$) of linear quantities. In other words, at the initial stage of defining a *Representational Cartesian Product* of Type II, she first identified the elements of the *Representational Sets of Combined Linear Quantities* $RSCLQ_1 = \{2x, y\}$ and $RSCLQ_2 = \{x, 2y, 1\}$. Her later usage “So it's just $A$ [pointing to the linear 2$x$ at the top] times $B$ [pointing to the linear $x$ on the side]” signaled the onset of a *Representational Cartesian Product* of Type II, another *concept–in–action*, an indicator of Nicole’s multiplicative reasoning. In this way, she established the existence of her concept–in–action: Nicole first picked an element, “$A$” from the set $RSCLQ_1 = \{2x, y\}$ and then picked another element, “$B$” from the other set $RSCLQ_2 = \{x, 2y, 1\}$. She then formed pairs ($A$, $B$) – another concept–in–action – of combined linear quantities (CLQ) by which she generated her RCP. In fact, what she referred to is an abstract definition of a Representational Cartesian Product RCP = $\{(A,B) \mid A \in RSCLQ_1, B \in RSCLQ_2\}$ where $RSCLQ_1 = \{2x, y\}$, $RSCLQ_2 = \{x, 2y, 1\}$ with the set builder notation. $A$ and $B$ can be anything as long as they are coming from the first set $RSCLQ_1$ and the second set $RSCLQ_2$, respectively. Nicole did not describe the expressions $(2)\cdot(x^2)$ and $(4)\cdot(xy)$ as representationally multiplicative, as opposed to Ben and Ron, who embraced the *Filling in The Puzzle Strategy*, which is an indication of their additive thinking. Although $(2)\cdot(x^2)$ and $(4)\cdot(xy)$ are representationally additive, as Nicole explains in Protocol 3 above, for Ben and Ron these expressions are *mis*interpreted as of multiplicative nature. The algebraic symbols $(2)\cdot(x^2)$ and $(4)\cdot(xy)$ can be deduced only within an additive context, according to Nicole, *representationally*.

In the same vein, I asked Sarah to outline the same-color-boxes on her $2x + y$ by $x + 2y + 1$ polynomial rectangle (Figure 4d). The multiplicative nature of the areas of these “same-color-boxes” was prevalent, as reflected in the protocol below:

Protocol 4: Sarah's reference to a Representational Cartesian Product of Type II.

Sarah: This one is 2$x$ [pointing to the linear 2$x$ on the side] times $x$ [pointing to the linear $x$ on the top]. This one is 2$y$ times 2$x$ [pointing to the corresponding linear tiles in a similar manner]. This one is 2$x$ times 1 [pointing to the corresponding linear tiles in a similar manner]. This one is $x$ times $y$ [pointing to the corresponding linear tiles in a similar manner]. This would be $y$ times 2$y$ [pointing to the corresponding linear tiles in a similar manner]. And this would be $y$ times 1 [in a similar manner].

Interviewer: So the product... each time you were doing the same thing... tell me more about that... I just want to make sure that I understand that...

Sarah: I was using the area as a length times width where... this is a length or... and this would be the width... and basing it of like that... otherwise I could have added the insides [pointing to the areal tiles]... the way I did it was length times width.

In other words, Sarah was aware that what she was doing was term wise multiplication of the combined linear quantities, and not addition. Her statement “otherwise I could have added the insides” combined with her gestures indicate that there are only two possibilities: The areas of the “same–color–boxes” could be modeled either via multiplication, or addition, *representationally*. But since she was asked about the areas of these boxes as products, the other option, namely additiveness is irrelevant as she responded “the way I did it was length times width.” This is in contrast to Ben and Ron's written answers and verbal descriptions of these “boxes” indicating an additive nature. Using set notation, Sarah's descriptions can be modeled via a *Representational Cartesian Product*–in-action of Type II defined as follows.

- $RCP_2 = RSCLQ_1 \times RSCLQ_2 = \{2x, y\} \times \{x, 2y, 1\} = \{(2x, x), (2x, 2y), (2x, 1), (y, x), (y, 2y), (y, 1)\}$.

## Preservice Teachers' Concepts-In-Action

In this research study, all five research participants worked on all three tasks. Due to the page limitation, I could not include fifteen different participant-task pieces. In this section, without loss of generality, I summarize the research participants' concepts-in-action pertaining to the 2nd polynomial multiplication task "Multiply $x + 1$ by $2y + 3$ using algebra tiles" for the sake of the constant comparison analysis methodology.

On the first level (Figure 5a); Ben, Ron, and John interpreted the ¨Irreducible Areal Quantities" as meaningless Areal-Singletons, which corroborates their *Filling in the Puzzle* concept-in-action, indicative of their additive thinking. Sarah and Nicole, on the other hand, interpreted these ¨Irreducible Areal Quantities" as Areal-Singletons *resulting from* the multiplication of the corresponding pair of irreducible linear quantities, which corroborates their *Term-Wise Multiplication of Irreducible Linear Quantities* concept-in-action.

On the second level (Figure 5b); Ben, Ron, and John interpreted the "Same-Color-Boxes" additively, whereas, Nicole and Sarah interpreted these areal quantities multiplicatively. Table 1 illustrates my research participants' additive/multiplicative interpretation of the *area of the same-color-boxes as a product* phrase for the $x + 1$ by $2y + 3$ polynomial rectangle.
