## Discussion

Concepts– and theorems–in–action framework in this present study helped me produce a set of terminology closely related to mathematical terms (*Representational* Cartesian Products, *Representational* Sets, Irreducible Linear Quantities, Irreducible Areal Quantities, Combined Linear Quantities, Filling in the Puzzle Strategy, Term Wise Multiplication of the Irreducible Linear Quantities Strategy) to describe what my preservice teacher research participants were doing. These notions, as a mathematics teacher educator, helped me make sense of what my preservice teacher research participants were doing and delve further into their understanding of the mathematical situations.

Distinguishing how quantities interact with one another (e.g., additive vs. multiplicative) is an important element of algebraic reasoning. In that regard, *concepts–in–action* and *theorems–in–action* formalisms are powerful instruments to illustrate and explain the continuing progress of students' mathematical proficiency in a certain conceptual field (e.g., multiplicative structures, relational structures, mapping structures, quantitative structures). They also present a way to analyze, compare, and transform students' knowledge intrinsic in their mathematical performance (e.g., hand gestures, actions, operations, verbal descriptions) into the actual known and written algebraic identities and mathematical theorems. In that sense, these tools help teachers and researchers get a better sense of how students make sense of, reconcile, and shift among physical observables at different cognitive levels (e.g., algebraic expressions, their various representations, etc.). Using concepts– and theorems–in–action, teachers and researchers can come up with better strategies to diagnose what students do or fail to understand, to reveal the source of their misconceptions and conceptual flaws, and to help them see the internal and external connections. In this way, students are provided with a set of more interesting, better-prepared activities, and mathematically fruitful situations, which help them strengthen their knowledge, and increase their mathematical proficiency.

# PRESERVICE TEACHERS' CONCEPTUALIZATION OF FRACTION MULTIPLICATION

Jennifer M. Tobias
University of Central Florida
jtobias@mail.ucf.edu

*A classroom teaching experiment, focusing on number and operations, was conducted in a semester-long mathematics content course for preservice elementary teachers. The focus of the study was on preservice teachers' understanding of mathematics related to their development of the mathematical knowledge needed for teaching. This paper presents the results from preservice teachers' development of fraction multiplication. The results indicate that preservice teachers' knowledge develops in three phases.*

## Background

Teachers are entering the profession without a profound understanding of the mathematics they are to teach (Ma, 1999). Mathematics content courses for preservice teachers that provide nothing more than a reiteration of the traditional algorithms do not aid in preservice teachers' development of pedagogical content knowledge any more than what was provided in their K–12 education. Studies show that teachers with a deep understanding of mathematics positively impact student achievement (Kaplan & Owings, 2000); however, little research documents how classroom teachers develop the knowledge base they need to be effective. The knowledge base of effective teachers, which includes using students' knowledge to inform instructional decisions, is beyond the experiences typically received in preservice teacher mathematics education classes (NCTM, 2000). In order for teachers to assess students' knowledge accurately, they themselves need a deep understanding of the content. This is especially important for elementary teachers, as they typically do not have a substantive mathematics background.

The knowledge base that elementary and middle school teachers bring to the classroom is procedurally based and largely misunderstood (Ball, 1990a, 1990b; Ma, 1999; Tirosh, 2000; Tzur & Timmerman, 1997). This is particularly true with teachers' understanding of fraction operations. Several studies have documented the difficulties that preservice and inservice teachers have in conceptualizing fraction operation situations; however, research has lacked in describing the ways in which preservice teachers develop a conceptual understanding of these topics.

Previous studies have documented that teachers need similar experiences to what children need before they can conceptually understand the algorithms used in fraction operation situations (Tzur & Timmerman, 1997). Rather than being presented with an algorithm first and then asked to solve several problems using that algorithm, teachers first need the opportunity to use models and pictures to solve the problems. From there, teachers can develop their own algorithms for solving problems involving fraction operations.

## Methodology

This study was conducted at a large metropolitan university in the southeastern part of the United States during a semester-long undergraduate course focusing on mathematics for teaching elementary school. There were 33 participants in this study. Participants were all female undergraduate students majoring in either elementary or exceptional education. They were all at least in their sophomore year of college. The research team consisted of 2 professors and 6 doctoral students all in mathematics education. One of the mathematics education faculty members was the instructor for the course. The other members of the research team observed every class session.

This study was conducted during a spring semester. The course met twice a week for one hour and fifty minutes each day. Students in the course were situated at tables of at least four and no more than six. The classroom was equipped with a document camera as well.

Data were collected from 10 class sessions, which focused on a rational number unit. The rational number unit was part of a larger study which also included a unit focusing on place value and whole number operations in base 8 (Roy, 2008). The rational number unit constituted the second unit in the course, thus students were already accustomed to being videotaped and observed in every class. The data collected included video and audio recordings, student work, pre and post-test scores, and research team notes.

Three video cameras were used to capture varying aspects of the classroom. Facing the front of the room, one camera was situated at the back right of the classroom and focused on the whole class and individual students. The second camera was placed at the back of the classroom and focused on the work done at the board and the work presented on the document camera by both the instructor and students. The third camera focused on the instructor and individual students from the front left of the classroom.

Audio recordings documented small group interactions during class work activities. Three small groups were chosen to have audio recorders placed at their tables. Each of these groups consisted of at least one person who was interviewed individually, which is how the group was chosen to have the audio recorders placed at their table.

Students were given a pre and post-test before and after the rational number unit. The test used was the Content Knowledge for Teaching Mathematics (CKT-M) instrument developed at the University of Michigan (Hill, Rowan, & Ball, 2005). Scores from the test were used to document the changes in students' rational number understanding.

Five students were interviewed individually before and after the rational number unit. Each interview was videotaped and lasted approximately 40 minutes. During the interview students were asked to solve several rational number problems. Students' work from each interview was collected. These students also participated in a focus group session halfway through the rational number unit were the focus was on students' overall feelings of the classroom structure, their mathematical activities, and thoughts of the rational number unit thus far. Students were selected for interviews based off of their pre-test scores, their normative ways of working mathematically (i.e. some students preferred to solve problems algorithmically whereas others relied on alternative methods), and students whose mathematical beliefs and values were diverse.

Other data collected from students included class work, homework, and exams. The data collected from the research team included field notes and reflective journals from class observations. The research team met after every class session to discuss if the learning goals for the day were met and to plan the next class session. Each of these team meetings were audio taped.

## Theoretical Framework

The emergent perspective was used as the foundation for which the classroom structure was designed so that social and sociomathematical norms were established and sustained throughout the course (Cobb & Yackel, 1996). The social norms established as part of this course included student's explaining and justifying solutions and solution strategies, making sense of others, and questioning others when misunderstandings occurred (Roy, 2008). Sociomathematical norms included understanding what constitutes a different and acceptable solution and solution strategy (Roy, 2008).

The instructional unit used in this study was designed around the theory of Realistic Mathematics Education (Gravemeijer, 2004). The preservice teachers were first presented with problems situated within a context. They were then asked to solve the problem using their own methods. Finally, selected problems were discussed within a whole-class setting. Throughout the course, preservice teachers were encouraged to develop their own methods of solving problems through pictures. Tasks were designed so that the preservice teachers could reconstruct the mathematics for themselves.

## Results

The results indicate that preservice teachers' development of a conceptual understanding progresses through three phases. Within the first phase, preservice teachers revert to a procedure to solve a given problem. The second phase includes developing ways to explain and justify solutions and solution strategies. Within the third phase, new concepts are developed.

For illustration purposes, the results described will pertain specifically to preservice teachers' development of fraction multiplication. Fraction multiplication occurred over a day and half of instruction. When this topic was introduced, preservice teachers were given a set of contextualized situations and asked to solve them without any prompt from the instructor.

*Revert To Procedures*

The following is a contextualized problem that was presented:

Sue ate some pizza. 2/3 of a pizza is left over. Jim ate 3/4 of the left over pizza. How much of a whole pizza did Jim eat?

When presented with this problem, students knew that the problem represented a fraction operations situation, however were not instructed or given any information to indicate that the situation was multiplication. When initially solving this problem, many students reverted to using a known procedure to solve the problem as indicated by the following students' work (Figure 1).

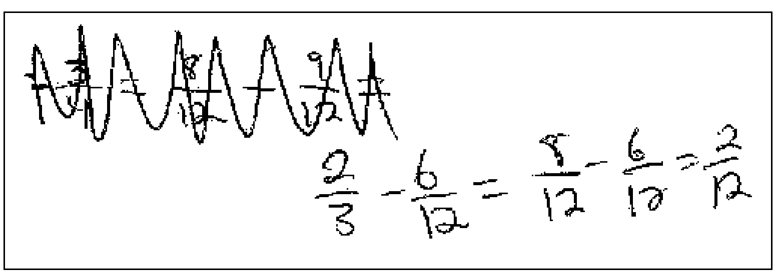

*Figure 1.* Student 15 uses subtraction procedure for multiplication.

$\frac{3}{4} \times \frac{2}{3} = \frac{6}{12} = \frac{1}{2}$

Since there was 2/3 pizza left, & Jim ate 3/4 of that; I multiplied the two numbers to find out how much total pizza

*Figure 2*. Student 2 uses multiplication procedures.

Both students' answers represented a typical solution presented by most students. As seen, both students reverted to using procedures to solve the problem. Though the first student was incorrect in her thinking that the problem represented a subtraction situation, she still used a procedure to solve the problem. The second student was correct in that the problem was multiplication; however, could only solve and explain the problem in terms of the algorithm used to multiply fractions (Figure 2). The class went on to discuss this problem as a whole group in which they established the notation of multiplication representing a 'groups of' meaning and also went on to solve the problem using a model.

*Develop Explaining and Justifying*

The class then moved from contextualized problems to problems situated without a context. To further discuss multiplication, the following problem was presented:

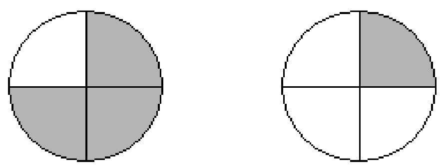
$$1\frac{1}{3} \times \frac{3}{4}$$

The class as a whole was asked to develop a model to solve the problem. When students were having difficulties representing the problem, the instructor further encouraged their understanding development by having them think of the problem in terms of a "groups of" situation.

Instructor: What if we thought about this as groups of objects? 1 1/3 groups of 3/4. How might we approach it that way? 1 1/3 groups of 3/4.
Claire: You draw 3/4, 1 1/3 times.
Instructor: Draw 3/4, 1 1/3 times. Okay.
Caroline: Wait.
Jackie: To figure out 1 1/3 times what do you mean?
Instructor: Well there's one time of 3/4. Are we okay with that?
Class: Yeah.
Instructor: What's a third time of 3/4?
Olympia: Don't you have to break it into pieces? Split the slices.
Instructor: Do I?
Olympia: Yeah because you have to get three wait.
Instructor: What is 1/3 of this?
Caroline: A fourth.
Instructor: A fourth?
Caroline: Yeah out of the 3/4.

Instructor: She didn't split anything up.
Claudia: My answer's 1.
Instructor: I don't really care. That's true but I didn't mean it that way. I don't care about the answer I want to know why.
Claudia: No I know because I don't know I'm thinking of it as if 1/3 is 1/4 so then
Instructor: Is 1/3, 1/4?
Students: No.
Caroline: What?
Claudia: Forget it.
Instructor: No keep going.
Olympia: I understand what you're saying.
Instructor: What is she saying?
Edith: Well because you showed the 3/4 out of 1 and so a third of the 3/4 would be 1/4.
Instructor: Claudia is that what you said?
Claudia: Yeah.

Throughout this discussion, the following picture was drawn on the board.



The first circle represents the one group of 3/4 and the second is the 1/3 group of 3/4. Throughout this discussion, students had to develop ways of explaining so that concepts such as 1/3 being 1/4 could be understood. As seen from this discussion, several students contributed to each others' development of explaining and justifying how to represent this situation. The same problem was then the first problem revisited during the next class session in which the class went on to discuss and develop the answer of one, and how the model represents that solution.

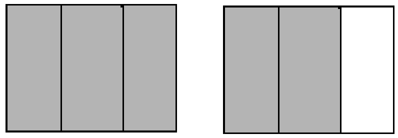
*Develop New Concepts*

After the previous problem was discussed on the second day of fraction multiplication, the class was then presented with the following problem, again out of context:

$$1\frac{1}{5}\times 1\frac{2}{3}$$

When the class was discussing how to solve this situation, one student asked to come to the board to explain 1 1/5 groups of 1 2/3.

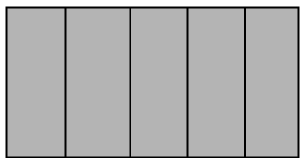
Claudia: So if we start off with two of these and divide them into thirds and then we find 1 2/3. Right? So then it would be this one, this one, this one, that's one. And then 2/3 would be this much.



So let’s like draw because now 1 2/3 is our new whole because we’re trying to find 1 1/5 of it. So if we just draw it altogether and make that our new whole. That’s right, right? Yeah. So then we look at this and we know

Instructor: How did she know that was right? What did she just check? You guys following her so far?

Claudia: So I’m just combining these into here to make that our whole.



Everybody follows?

Class: Yeah.

Claudia: Okay. So now this is our whole and now this is our whole and it’s divided already into five. So then this is one and then one more would be 1/5, right? Because this would be 1/5 since this is our whole and then this is one piece of that.

Suzy: I thought it had thirds, is that not a third?

Claudia: Yeah this is a third of one thing. But then

Suzy: Each of those thirds right?

Claudia: But then of this new whole which is 1 2/3, this is 1/5 of that

Suzy: Alright.

Claudia: because it’s divided into five. Does anybody not follow that?

Alex: I’m not following it. Sorry.

Suzy: Say it again. It took me a second, but that made sense.

Claudia: This is what 1 2/3 are right? Right here what I shaded.

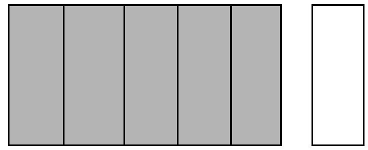
Suzy: Because we’re finding 1 1/5 times

Claudia: And 1 2/3 is going to be our new whole though because we’re trying to find 1 1/5 of that. So I just drew that as a new whole. Everybody okay up to there?

Class: Yeah.

Student: So you have that and then 1/5?

Claudia: Yeah so then one more of these would be 1 1/5 because this is 1/5, right of this 1 2/3? And then one more would be that and it would be two.



From this diagram the classroom conversation then continued with the class taking time to understand where the answer of 2 comes from. Within this discussion, new concepts started being developed. The concept of a new whole is presented within the context of fraction multiplication, which was the first time students started discussing the idea that the whole changes throughout the problem.

## Discussion

Fraction multiplication was used to illustrate the ways in which preservice teachers' develop an understanding of elementary mathematics. The results indicate that preservice teachers' conceptualization of elementary mathematics occurs in three phases. The first phase involves reverting to procedures to solve a given problem. Though these procedures are not always correct, many of the participants in this study initially used known procedures to solve the problem. The second phase involves learning to explain, justify, and conceptualize the mathematics within the problem. As illustrated within the class discussion of the problem 1 1/3 x 3/4, the class as a whole worked together to develop an understanding of taking 1 1/3 groups of 3/4. Finally, the last phase of conceptualization involves the development of new concepts. As seen with the discussion on the second day of multiplication, the idea of a new whole in multiplication was developed out of the idea of taking a group of something. These phases are summarized in Table 1.

Table 1
*Phases of Developing an Understanding of Mathematics*

| Phase | Indicator |
|---|---|
| 1 | Reverts to Procedures to Solve Problems |
| 2 | Developing Ways in Which to Explain, Justify, and Conceptualize Mathematics |
| 3 | Develop New Concepts |

These phases are not meant to be stringent in that if a problem is presented where a procedure is not readily known, students could start at the second phase instead of the first. However, being aware of the progression of preservice teachers' knowledge development could provide a better indicator of the types of instruction they need to receive in college teacher education programs.

# HOW DO PRESERVICE TEACHERS IN SPAIN AND USA PERCEIVE EFFECTIVE TEACHING OF MATHEMATICS

Hea-Jin Lee
Ohio State University-Lima
lee.1129@osu.edu

M. Begoña Alfageme-González
Universidad de Murcia
alfageme@um.es

*This study investigates how different educational contexts influence student perspectives and how those perspectives are applied to effective teaching of mathematics. Data shows that four criteria—desirable personal characteristics, student-oriented teaching, the use of various instructional strategies, and professionalism—were used to evaluate teacher effectiveness by participants. Preservice teachers in Spain and U.S. tend to identify nonexemplary teaching practice with a teacher's personal characteristics rather than their teaching approach. Results also show differences between two groups. Unlike U.S. students, Spanish students did not distinguish teacher characteristics from their instructional approaches. In conclusion, teaching is complex and multidimensional, and it is important to discuss teaching from multiple perspectives.*

## Introduction

Many mathematics teachers and mathematicians are concerned about students' inability to demonstrate mathematical understanding and convey any interest in the subject. Mathematics educators also have great concern when mathematics teachers are confused or have an unclear understanding regarding effective teaching of mathematics or their own perception of an effective teacher.

## Theoretical Framework

A large body of research suggests that a preservice teacher's entering beliefs greatly influence their development as a teacher (Minor et al., 2002; Tabachnick & Zeichner, 1984; Weinstein, 1989). In addition, "the combinations of characteristics and methods that teachers use to achieve those results may seem endless" (Polk, 2006, p. 23). Other studies also support that the quality of instruction influences student learning and its outcomes (Brown et al., 2006; Darling-Hammond, 2000a & 2000b; Darling-Hammond & Sykes, 2003; Rice, 2003).

Polk (2006) identified ten basic characteristics of effective teachers: good prior academic performance, communication skills, creativity, professionalism, pedagogical knowledge, thorough and appropriate student evaluation and assessment, self-development or lifelong learning, personality, talent or content area knowledge, and the ability to model concepts in their content area. A similar list of effective instruction characteristics is given by Brown et al (2006): instructional techniques, personal qualities, use of the instructional technology, social skills, consistency, and classroom organization. Studies on student beliefs about poor teaching listed the most disliked teacher qualities: inability to communicate and deliver the subject; boring and monotonous; lack of knowledge, uninformed in subject; disorganized; insensitive to students and their needs; aloofness, arrogance; no sense of humor and unenthusiastic; and unprepared (Kardash & Wallace, 2001).

Walls and his colleagues (2002) investigated beliefs about the characteristics of effective and ineffective teachers and characterized teacher behaviors in five categories: emotional environment, teacher skill, teacher motivation, student participation, and rules and grades. Some studies compared perceptions of effective teachers and instruction between prospective teachers and experienced teachers. Prospective teachers are far more concerned with teacher enthusiasm, the student-teacher relationship, and teacher stimulation of interest in the subject or the course, while an experienced educator's emphasis is on teaching technique, the teacher's ability to provide intellectual challenge and to stimulate students' intellectual curiosity.

According to Barns (1992), student beliefs on education are already formed by the time students begin the university. Teacher's beliefs can be challenged or nurtured throughout the teacher preparation program. The need to challenge preservice teachers' existing knowledge, beliefs, and attitudes is strongly addressed by many teacher educators (Doyle, 1997; Driel et al, 2001; Sunal et al, 2001). Thus, "it seems imperative that teacher education programs assess their effectiveness, at least in part, on how well they nurture beliefs that are consistent with the program's philosophy of learning and teaching" (Hart, 2002, p. 4). In order to identify appropriate experiences, discussion on effective teachers and teaching is a common activity in a teacher preparation program. Minor et al. (2002) suggest to have students examine textbook definitions of effective teachers, exemplify characteristics of effective teachers in their experience, think about past teachers, or list characteristics they believe reflect effectiveness.

The purpose of this study is to provide preservice teachers with an opportunity to reflect on their knowledge and beliefs about teaching mathematics. We hope to better understand how preservice teachers apply their understanding of effective teaching in evaluating teachers in practice. Data from Spain and the US were collected in order to see how different educational contexts and programs influence student perspectives and how those perspectives are applied to effective teaching of mathematics.

## Data Collection and Analysis

In Spain, we conducted a survey study with 245 Spanish undergraduate students, enrolled in their first course of an education program. Fifty percent of the participants intended to become elementary school teacher; the other fifty percent were students of physical education. Participant age ranged from 18 to the 40s, but almost all were in their early 20s.

In the United States, thirty-five preservice teachers, enrolled in a 5th year initial teacher preparation program at a Midwest state university, participated in the study: twenty-three early childhood education (ECE) and twelve middle childhood education (MCE) graduate students. Students in the early childhood education program will be licensed to teach pre-K – 3, while the middle childhood preservice teachers desired to teach Grades 4–9. Participant age ranged from the early 20s to the mid 40s.

During the first week of class, participants were asked to describe the characteristics of the best, respectively, worst, mathematics teachers they ever had. Students were also asked to identify their perspectives on effective teaching of mathematics, and what teachers need to know in order to be an effective mathematics teacher.

A multistage qualitative-quantitative analysis was used to analyze the data. The data were analyzed sequentially. The first stage consisted of a phenomenological mode of inquiry (inductive, generative, and constructive) to examine student perceptions of their best, respectively, worst, teachers (as well as the characteristics of effective teaching and an effective teacher). These data were rephrased in simpler terms. We categorized units that appeared similar in content. Each one of the categories represented a distinct theme. Several themes were revealed during this process. Next, we used descriptive statistics to quantify the themes. The data were coded by giving a number to represent each theme, and frequencies of these codes were calculated. From these frequencies, we computed percentages to determine the rates of each theme.

## Results

*An Effective Teacher*

Figure 1 depicts participant perceptions about an effective teacher. Spanish students' views on effective teacher characteristics were more divergent than those of U.S. students. Preservice teachers in the U.S. valued teacher characteristics in the following order: communication skills, caring nature, higher order thinking, motivation skills, flexibility, and classroom management skills. On the other hands, Spanish students value knowledgeable teachers the most, secondly motivation skills and enjoying teaching, flexibility, and caring nature. Interestingly, no Spanish students considered communication skills as a necessary characteristic to be an effective teacher. Spanish students also believe that an effective teacher should enjoy teaching, believe in lifelong learning, interact with students, and see teaching as a mutual learning experience. No American students mentioned these characteristics to define an effective teacher.

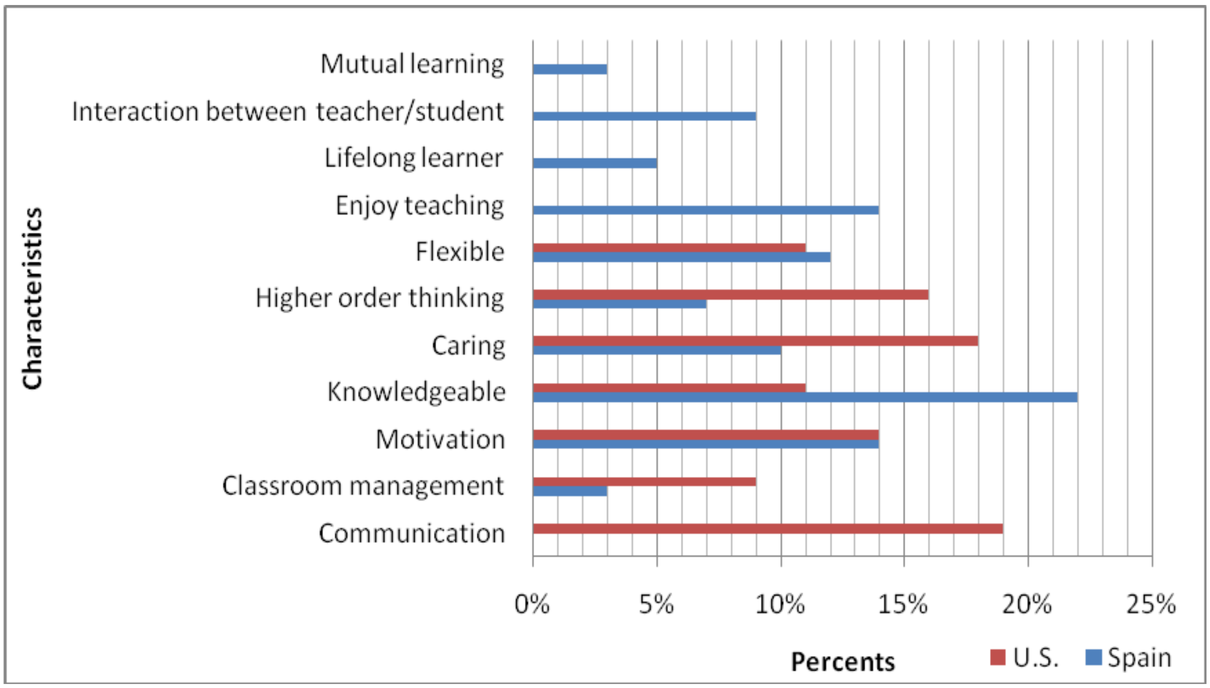

*Figure 1.* Characteristics of an effective teacher.

*The Best Teacher, the Worst Teacher, and Their Teaching Approaches – Spain*

Spanish students used an average of 5 items to describe the best/worst teachers and their teaching styles: a total of 1225 items for best and worst teachers, 1162 items for best teaching styles, and 1175 items for worst teaching styles (see Tables 1 & 2). As can be seen in Table 1, fifteen categories for best teachers and 16 for their teaching styles are identified. Twelve categories are found in both areas, and students emphasized the following areas: Innovative, creative, and uses various instructional strategies (17.6% for best teachers and 21.3% for their teaching styles); Close, pleasant, and amiable relationship with students (16.7 % for best teachers and 15.8% for their teaching styles); and Explains with clarity (9.8% for best teachers and 8.5% for their teaching styles).

Table 1
*Characteristics of the Best Teacher and Their Teaching Style – Spain*

| Characteristics of best teacher | % | Best teacher's teaching style | % |
|---|---|---|---|
| **Caring: understand and aid students** | **16.7** | **Close relationship with students, caring, pleasant, amusing** | **15.8** |
| Patient and tolerant | 7.0 | Patient and tolerant | 5.0 |
| Good communicator | 4.7 | Good communicator | 4.9 |
| Encourage students to be confident and motivate them | 7.9 | Motivate students, concern about student learning | 7.4 |
| **Innovator: creative, active, uses various teaching methods** | **17.6** | **Uses several instructional methods and activities. Active and innovative classes** | **21.3** |
| **Explains well** | **9.8** | **Explains with clarity** | **8.5** |
| Respects students | 7.0 | Respects students and has confidence in them | 7.7 |
| Desire to teach, enjoys teaching | 6.5 | Desire to teach, has a passion for their profession | 7.0 |
| Organized deliberation in teaching content | 3.6 | Orderly: well organized, and well prepared explanations | 6.2 |
| Impose authority, earn respect | 2.8 | Know to prevail when it is necessary, put order and respect | 3.4 |
| Demanding | 2.8 | Demanding: encourages students to challenge | 2.3 |
| Flexible: Allow various solutions | 1.4 | Corrects solutions | 2.5 |
| Uses games and activities in group work | 6.1 | Teaches in a practical way and use real life examples | 2.7 |
| Encourages students to reason and not to memorize | 1.4 | Creates pleasant class atmosphere | 1.2 |
| Holds strong professionalism | 4.7 | Competent in subject matter knowledge | 3.2 |
| | | Uses positive reinforcements, awards student work | 0.9 |

As shown in Table 2, 11 categories for worst teachers and 16 for their teaching styles are identified, which indicate a similarity up to the 11th category in both areas. In the area of worst teachers the order of the categories are: No desire to teach (21.4%), Authoritarian, unpleasant, strict, demanding, edgy (20.0%), and Boring (14.4%). In the order of teaching styles of worst teachers are Unpleasant, disagreeable, poorly educated, authoritarian, severe, strict, and demanding (20%), Not interested in teaching (18.7%), and Lack of respect for students, and favoritism (10%).

Table 2

*Characteristics of the Worst Teachers and Their Teaching Style – Spain*

| Characteristics of worst teacher | % | Worst teacher's teaching style | % |
|---|---|---|---|
| **Authoritarian, edgy, unpleasant, strict, demanding** | **20.0** | **Unpleasant, disagreeable, poorly educated, authoritarian, severe, strict, demanding** | **20.0** |
| **Boring** | **14.4** | Boring | 7.5 |
| Distant, lack of communication with students | 4.7 | Keeps a distance from pupils | 5.4 |
| **Favoritism, discrimination, lack of respect to students** | **12.1** | **Lack of respect to students, favoritism** | **10.0** |
| **No desire to teach** | **21.4** | **Not interested in teaching** | **18.7** |
| Imposes fear and tension in class (threatening, aggressive). | 5.1 | Abuses the norms (threatening, aggressive) | 3.7 |
| Explains poorly | 9.8 | Does not know how to explain/answer questions | 7.5 |

*The Best Teacher, the Worst Teacher, and Their Teaching Approaches – USA*

Tables 3 and 4 include characteristics of the best and worst teachers and their teaching approaches, as identified by U.S. students. A difference from the Spanish data occurs in the number of items used in student descriptions: an average of 4 items (total 128) to describe best teachers, 2 items (total 86) for the worst teachers, and 3 items for instructional strategies used by best and worst teachers (total 94 and 93).

As can be seen in Table 3, ten categories for best teachers and 14 categories for their instructional styles were identified. Only three categories are found in both areas. Students listed teachers who are: Caring (28.6%), Helpful/motivating/encouraging (18.4%), and Make learning fun/interesting (15.1%) as best teachers. With regard to best teachers' instructional styles, students described their best teachers as using: Various teaching methods (14.3%), Scaffolding/guided instruction (13.5%), and Higher order thinking (11.9%).

Table 3
*Characteristics of Best Teacher and Their Teaching Style – USA*

| Characteristics of best teacher | % | Best teacher's teaching style | % |
|---|---|---|---|
| Classroom management | 7.3 | Classroom management | 11.2 |
| Knowledgeable | 6.1 | Knowledgeable | 3.7 |
| Higher order thinking | 5.0 | **Higher order thinking** | **11.9** |
| **Caring** | **28.6** | Review and support | 6.0 |
| **Made learning fun/interesting** | **15.1** | **Variable teaching methods** | **14.3** |
| Good listener | 2.2 | Concise/good communicator | 11.2 |
| Sense of self | 6.7 | Individual projects | 2.2 |
| Likes teaching | 5.6 | Integrates subject areas | 6.7 |
| **Helpful/motivating/encouraging** | **18.4** | **Scaffolding/guided instruction** | **13.5** |
| Has high expectations | 5.0 | Direct instruction | 3.7 |
| | | Group work/discussion | 5.2 |
| | | Hands-on | 2.2 |
| | | Student centered | 6.0 |
| | | Explores real world | 2.2 |

There are 9 categories in the description of worst teachers and 11 categories in their instructional strategies; three categories are common to both. The most frequently listed worst teacher characteristic is Uncaring (51.0%) followed by Closed-minded (11.3%) and Disliked teaching (10.5%). Students said that instructional strategies used by worst teachers are: Poor teaching skills (29.7%), Only reading (16.4%), and Not helpful (14.8%).

Table 4
*Characteristics of Worst Teacher and Their Teaching Style – USA*

| Characteristics of worst teacher | % | Worst teacher's teaching style | % |
|---|---|---|---|
| **Uncaring/mean** | **51.0** | Uncaring/mean | 5.5 |
| Poor communication | 4.5 | Poor communication | 7.0 |
| Poor classroom management | 5.3 | Poor classroom management | 12.5 |
| **Dislikes teaching** | **10.5** | **Poor teaching skills** | **29.7** |
| Student fear or didn't want to be there | 3.8 | **Not helpful** | **14.8** |
| Boring | 3.8 | **Only lecture** | **16.4** |
| Unknowledgeable of subject | 6.0 | Teacher centered | 3.1 |
| Favoritism | 3.8 | Rote memorization | 1.6 |
| **Closed-minded** | **11.3** | Worksheets | 1.6 |
| | | Too much homework | 5.5 |
| | | No hands-on/exploration | 2.3 |

*Cross Comparisons*

Student responses are grouped in broader categories in Table 5, which compares the characteristics and instructional strategies of the best and worst teachers. Student responses may be grouped among four themes: Desirable/Undesirable personal characteristics; Teaching with/without consideration for students; Uses/Does not use various instructional strategies; and Professional or not. Table 5 also compares Spanish and U.S. student perspectives in each category.

*Table 5*
Comparative Analysis

| **Categories** | **Best teacher** | **Instructional strategies of best teacher** | **Country** | **Worst teacher** | **Instruction-al strategies of worst teacher** | **Categories** |
|---|---|---|---|---|---|---|
| **Desirable personal characteristics** | 28.4% | 25.7% | Spain | 33% | 33.9% | **Undesirable personal characteristics** |
| | 37.5% | 11.2% | USA | 62.3% | 20.3% | |
| **Teaching with consideration for students** | 17.7% | 18.3% | Spain | 17.2% | 13.7% | **Teaching without consideration for students** |
| | 33.5% | 6.0% | USA | 12.1% | 10.1% | |
| **Uses various teaching strategies** | 39.9% | 45.6% | Spain | 28.4% | 33.7% | **Does not use various teaching strategies** |
| | 11.1% | 71.6% | USA | 15.1% | 69.6% | |
| **Professional** | 14% | 10.4% | Spain | 21.4% | 18.7% | **Not professional** |
| | 17.9% | 11.2% | USA | 10.5% | 0% | |

Table 5 indicates that Spanish students did not distinguish characteristics of teachers from instructional approaches. On the other hand, students in the U.S. described their best and worst teachers in terns of their personal characteristics, while their teaching styles were discussed in terms of the instructional strategies implemented in class. Students in both countries described their worst teachers in terms of their personal characteristics rather than evaluating their teaching strategies.

## Implication

The results support other studies that effective teaching requires more than technique (Schaeffer et al., 2003; Shannon, 1998; Walls et al., 2002). As can be seen in Figure 1 and Tables 1–5, the characteristics of effective teaching and an effective teacher are complex and multidimensional constructs that are unpredictable, ambiguous, and contextual. Therefore, it is important to view the teaching enterprise from multiple perspectives. Research has explored variables that impact teaching, characteristics of teachers, students, and contexts in which teaching and learning occur (Shannon, 1998). For that reason, it becomes necessary to extend the different studies of educational contexts and countries so that new data may be gathered.

Recognizing and discussing specific effective teaching behaviors is one piece of the puzzle. "The commitment to use what has been found to be effective is one of the avenues that could help raise the teaching profession above the level it currently occupies…. If such qualities are not modeled we are far less likely to adopt the presented idea in classroom practices" (Sheeran & Vermette, 1995, p. 26).

# UNDERSTANDING BASE-TEN NUMBERS: WHY DON'T YOU JUST TELL THEM IT IS TEN?

Eva Thanheiser
Portland State University
thanheisere@gmail.com

*Six preservice teachers (PSTs) participated in a 1-week teaching experiment designed to assist them in developing more sophisticated conceptions of numbers using tasks based on a framework for PSTs' conception of multidigit numbers developed in previous work. All 6 PSTs developed more sophisticated conceptions; however 3 PSTs did not develop a conception that enabled them to relate adjacent digits multiplicatively. In this study I describe and analyze the first of 5 teaching sessions. I trace the development of the PSTs' conceptions and show that (a) exposure to correct conceptions is insufficient to help PSTs develop more sophisticated conceptions and (b) conceptual change is slow. These facts counter the commonly held notion that if one simply tells PSTs the value of the digit, they will understand base-10.*

Number is the central theme in the elementary mathematics curriculum. "Proficiency with numbers and numerical operations is an important foundation for further education in mathematics and in fields that use mathematics"(Kilpatrick, Swafford, & Findell, 2001, p. 1). However, although most PSTs and teachers can execute algorithms, many struggle when asked to explain them conceptually (Ball, 1988/1989; Ma, 1999; Thanheiser, 2005). Consider, for example, one PST's explanation for the regrouping in 527 – 135 (see Figure 1): "You put a 1 over next to the number and that gives you 10. … I don't get how the 1 can become a 10. One and 10 are two different numbers. How can you subtract 1 from here and then add 10 over here? Where did the other 9 come from?"

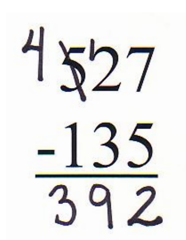

*Figure 1.* Standard subtraction algorithm for 527 – 135.

**For students to come to understand the underlying concepts, teachers (and thus PSTs) must have "solid understanding of mathematics so that they can teach it as a coherent, reasoned activity and communicate its elegance and power" (Conference Board of Mathematical Sciences, 2001, p. xi). The PST described above would be unable to help a child make sense of the regrouping.**

## Theoretical Framework

My research grows out of a rich cognitive-science paradigm focused upon children's prior knowledge in learning situations, a consideration that is equally important in work with adults (Bransford, Brown, & Cocking, 1999). To help PSTs develop a solid understanding of mathematics, we mathematics educators need to build upon their initial conceptions, which both determine what they understand when looking at a number and serve as a basis for building more sophisticated conceptual structures.

In previous work (Thanheiser, 2005), I categorized PSTs' conceptions of multidigit whole numbers into four major groups: thinking in terms of (1) *reference units*, (2) *groups of ones*, (3) *concatenated-digits plus*, and (4) *concatenated-digits only*. The distribution of the conceptions of the 15 participants in that previous study can be seen in Table 1. Because 10 of the 15 PSTs held an incorrect conception of number and only 3 explained all aspects of regrouping in detail, I considered how to assist PSTs in developing more sophisticated conceptions, keeping in mind that adults cannot simply forget the algorithms they know and value to invent new ones.[iv]

Table 1
*Distribution of Conceptions in the Context of the Standard Algorithm for the 15 PSTs in the Study*

| Conception held | # (%) of PSTs |
|---|---|
| *Reference units.* PSTs with this conception reliably conceive of the reference units for each digit and relate reference units to one another, seeing the 3 in 389 as 3 *hundreds* or 30 *tens* or 300 ones, the 8 as 8 *tens* or 80 *ones*, and the 9 as 9 *ones*. They can reconceive of 1 *hundred* as 10 *tens*, and so on. | 3 (20%) |
| *Groups of ones*. PSTs with this conception reliably[a] conceive of all digits in terms of groups of ones (389 as 300 *ones*, 80 *ones*, and 9 *ones*) but not in terms of reference units; they do not relate reference units (e.g., 10 *tens* to 1 *hundred*). | 2 (13.3%) |
| *Concatenated-digits plus.* PSTs with this conception conceive of *at least one* digit as an incorrect unit type at least sometimes. They struggle when relating values of the digits to one another (e.g., in 389, 3 is 300 ones but the 8 is only 8 ones). | 7 (46.6%) |
| *Concatenated-digits only*. PSTs holding this conception conceive of *all* digits in terms of *ones* (e.g., 548 as 5 *ones*, 4 *ones*, and 8 *ones*). | 3 (20%) |

[a]*Reliably* in these definitions means that after the PSTs were first able to draw on a conception in their explanations in a context, they continued to do so in that context.

## Method

The data analyzed are drawn from the first of five 150-minute teaching sessions and pre and post interviews with each of 6 PSTs at a large, urban, comprehensive state university. All participants were volunteer preservice teachers who participated in a 1-week summer teaching session. Two PSTs had completed their methods course and were about to begin student teaching. The other four PSTs had not yet taken their mathematics methods course.

The pre and post interviews, each 60–90 minutes in duration, were conducted immediately before and after the sequence of teaching sessions. Questions for the interviews were designed to elicit the PSTs' conceptions. The tasks for the teaching sessions were designed to build on the

PSTs' initial conceptions and to enable them to develop more sophisticated conceptions. Tasks for Day 1 were designed on the basis of the preinterviews and those for the succeeding days were based on PSTs' changing conceptions. Tasks for the teaching sessions included addition and subtraction of 3-digit numbers using various manipulatives; discussion of artifacts of children's mathematical thinking, such as video clips of children solving problems; discussion of various manipulatives; and exploration of Mayan numbers (a base-twenty system). All teaching sessions and interviews were video taped. The interviews and critical moments of the teaching episodes were transcribed. The analysis focused on the PSTs' developing content knowledge throughout the teaching sessions using the framework introduced above. In this paper, I analyze the first day of the teaching experiment.

## Results and Discussion

Results indicate that carefully chosen mathematics tasks in conjunction with artifacts of children's mathematical thinking addressing the PSTs' preexisting conceptions enable PSTs to re-examine their conceptions and develop more sophisticated conceptions. Five of the 6 participants developed more sophisticated conceptions (the sixth already held the most sophisticated conception; see Table 2), however, only 3 of the 6 PSTs held the most sophisticated conception in the post interview. In this paper I trace 2 PSTs' conceptions to illustrate the difficulties PSTs encounter when asked to make sense of multidigit whole numbers and operations on such numbers.

Table 2
*Conceptions in the Context of the Standard Algorithm for the 6 PSTs in a Teaching Experiment Before and After the Study*

| Pseudonym | Preinterview | Post interview |
|---|---|---|
| Silvia | Reference Units | Reference Units |
| Holly | Groups of Ones | Reference Units |
| Saskia | Concatenated-digits plus | Groups of ones |
| Jason | Concatenated-digits plus | Groups of ones |
| Beatrice | Concatenated-digits only | Groups of ones |
| Isabelle | Concatenated-digits only | Reference Units |

Because most PSTs enter our classrooms (and the teaching experiment) with one of the concatenated-digits conceptions, the tasks for this teaching session were developed to address those conceptions. For example, students were presented with digit cards (see Figure 1a) and asked to build numbers (see Figure 1b).

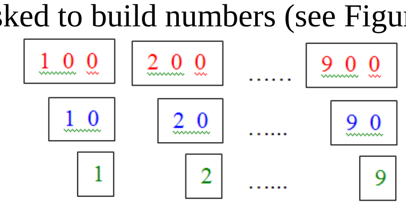

*Figure 1a*. Digit cards representing the place value of each digit 0–9 (increments of 1, in green), 10–90 (increments of 10, in blue), and 100–900(increments of 100, in red).

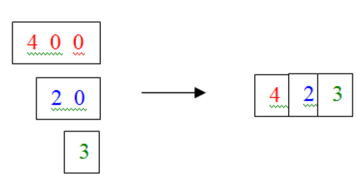

*Figure 1b*. Representing 423 with digit cards.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

This task was designed to help PSTs connect the symbol to its value. Beatrice and Isabelle both held a concatenated-digits conception at the beginning of the teaching sessions; however their approaches to this task differed. Isabel, on the one hand, used the cards in a concatenated way. She stated, “You can really make so many numbers by putting them together to make them bigger. Putting tens together can give you thousands, and so on” (see Figure 2a). Beatrice, on the other hand, overlaid the digit cards to build a three-digit number: “For me, I actually just stayed with like 3-digit numbers. … I didn’t do the thousands, and, you know, like this was 400 and then I put the 80 and then the 6 to make 486” (see Figure 2b).

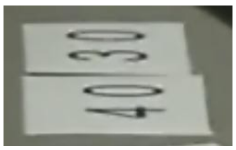

*Figure 2a.* Isabel put 40 next to 30 to make the number 4,030.

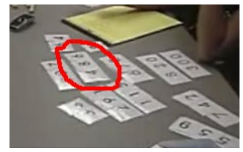

*Figure 2b.* Beatrice overlaid 400, 80, and 6 to build 486.

Thus, whereas the cards enabled Beatrice to connect symbols and values, they did not help Isabel do so. During the class discussion of the usefulness of the cards, Silvia (who held a reference-units conception at the outset) explained, “And the first thing I realized was that this would be a very good way to get students to realize that each number … represents more—like if it … it was 211, that the 2 is not just 2, but 200.” Even though Silvia explicitly stated the relationship between the digit and its value, Isabel did not make that connection for herself. She realized that her way differed from the others’ way but did not evaluate one way as better than the other. When asked how she was thinking about the 40 in her 4,030, she said, “As just a 40.” After they had built numbers with the digit cards, students were asked to solve 389 + 475 in as many ways as they could, using digit cards, base-ten blocks, paper and pencil, and so on. The students were also asked to make notes on their methods in a way that would be understandable to a third grader. Saskia, who held a concatenated-digits-plus conception in the preinterview, developed a horizontal addition strategy using the digit cards (see Figures 3, 3a, and 3b). She explained:

> I split them all up, like into parts, like 300, 80, and 9; 400, and 70, and 5. So I added across: 9 + 5 = 14, so that is a 10 and a 4, so the 10 moves up in the ten’s column and the 4 would stay in the one’s column. Then 80 and 70 equals 150, so that’s 100 and 50 and the 10 from last time. So then the 100 moves up to the next column, and then 50 + 10 would just be 60, and then 700 + 100 is just 800. And then you just combine it all, so it is 864.

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Hundreds: | 300 | 400 | ⟶ | 700 | | ⟶ | 700 + 100 = 800 |
| Tens: | 80 | 70 | ⟶ | 100 | 50 | ⟶ | 50 + 10 = 60 |
| Ones: | 9 | 5 | ⟶ | 10 | 4 | ⟶ | 4 = 4 |

*Figure 3*. One PST’s invented addition strategy to add 389 + 475.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

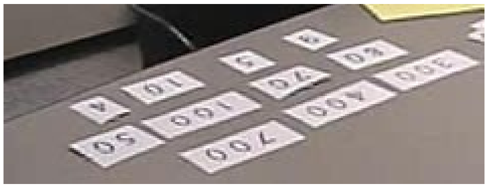

*Figure 3a*. Saskia's strategy to add 389 + 475 before regrouping.

*Figure 3b*. Saskia's strategy to add 389 + 475 after regrouping.

Saskia shared a second strategy for adding the numbers (see Figure 4a) by decomposing the number into their reference units and relating those to one another. She explained, "Fourteen ones is just 1 ten and 4 ones, and16 tens is actually 1 hundred and 6 tens." Thus, through working with cards and blocks to invent strategies to add two 3-digit numbers, Saskia developed more sophisticated ways of conceptualizing numbers. Through inventing these strategies, she was able to draw on more sophisticated conceptions than she had before.

Beatrice, who held a concatenated-digits-only conception in the preinterview, also developed a horizontal addition strategy using the digit cards (see Figure 4b) and translated that into a written strategy (see Figure 4c), seeming to draw on a groups-of-ones conception. However, when working with base-ten blocks, she represented each digit in terms of ones (see Figure 4d) and added those ones, reverting to a concatenated-digits conception. Beatrice showed that providing evidence of holding a correct conception in one instance does not establish that a student holds that conception across multiple contexts.

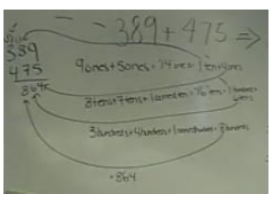

*Figure 4a*. Saskia's second strategy to add 389 + 475 before regrouping.

*Figure 4b*. Beatrice's strategy to add 389 + 475 with cards.

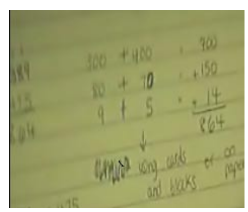

*Figure 4c*. Beatrice's written strategy to add 389 + 475.

*Figure 4d*. Beatrice's strategy to add 389 + 475 with blocks.

Isabel, even after being confronted with various students' conceptions and having access to the digit cards as well as base-ten blocks, still drew on a concatenated-digits conception. She used the cards to explain:

> I did the 389 and then 475, and I was just going by colors. … The pencil and paper way, like that [one's column] would be 14; I took away my 1 [not 10]—and then carry over the 1. ... Like it [using cards] will just help them [children] to see like the 4 goes here; then you add over the 1, and then this lines up.

In her use of the cards (see Figure 5), Isabel clearly showed that she saw the regrouped digit in terms of ones (1 one) rather than in terms of a ten or a group of 10 ones. Thus exposure to more sophisticated, correct conceptions may be insufficient to assist a PST in developing a correct conception herself.

*Figure 5*. Isabel's strategy to add 389 + 475 with the digit cards.

After using various manipulatives to add numbers, the group watched a video clip of a child attempting to add 638 + 476 using the partial-sums algorithm, which is similar to the horizontal addition strategy invented by the participants of this study. In this algorithm, one adds the hundreds first, then the tens, then the ones, and then adds these partial sums (see Figure 6a). The child added the single digits rather than the partial sums, providing evidence of viewing the numbers in a concatenated way.

| | |
|---|---|
| 638<br>476<br>1000<br>100<br>14<br>1114 | 638<br>476<br>10<br>10<br>14<br>34 |
| *Figure 6a*. Partial-sums algorithm for adding 638 + 476. | *Figure 6b.* Child's attempt to use partial-sums algorithm. |

When commenting on the video clip, Beatrice stated, "I think she doesn't see the 600; she is just thinking about single digits. … Instead of doing 600 and 400, she does 6 + 4, and that is why she is getting the wrong answer." Thus, Beatrice again drew on a groups-of-ones conception. In commenting on this video clip, Isabel, for the first time, acknowledged that her conception of numbers (concatenated digits) is insufficient to explain various situations:

> She [the child] is just adding them as single digits, like 6 + 4, and then that's one problem, and then 3 + 7 is another problem, and then taking those numbers and making it a third problem or a fourth problem … instead of looking at it [the numbers] as one whole.

Although this statement does not suffice to establish that Isabel drew on a more sophisticated conception, it does demonstrate that she recognizes the deficiency of her conception.

## Conclusions

The tasks discussed in this paper were developed to address the concatenated-digits conceptions of multidigit numbers and to help students connect the symbols to their values. Although the tasks served to help some (like Beatrice) connect symbols and values fairly quickly, others (like Isabel) maintained their concatenated-digits conceptions throughout most of the activities. Thus, simply exposing students to correct conceptions (telling them the meanings of the digits) does not help them develop such conceptions. Even for students who seem to make those connections, their newly established conceptions may be unstable. Whereas most students were able to use a groups-of-ones conception to explain addition and talk about the video clip by the end of the first teaching session, multiple sessions with additional experiences were needed to solidify the PSTs' understanding. I am often asked whether telling students the meanings of the digits would suffice: "Can't you just tell them it is 10?" This study clearly shows the inadequacy of such an approach. Although all 6 PSTs held a correct conception at the end of the study, developing these conceptions is a complex task, requiring multiple sessions. Mere exposure to correct conceptions is neither enough to enable all students to recognize that their conceptions are incorrect nor to allow them to develop more sophisticated ones. Even after engaging in carefully designed tasks and in-depth discussions, only half the PSTs developed the most sophisticated, reference-units, conception. Thus, the fact that many teachers leave their teacher education programs without a deep understanding of number is unsurprising (Ma, 1999).

## Endnotes

[1]This has, however, been successfully done with children (Ambrose, 1998; Hiebert & Wearne, 1996; Kamii, 1994; Kamii, Lewis, & Livingston, 1993; Sowder & Schappelle, 1994).

*This study reports on teacher educators' learning on-the-job. In this study, two novice teacher educators worked with an experienced teacher educator reflecting on the process of supporting elementary pre-service teachers in developing adult-level understandings of foundational mathematical ideas. Using reflective teaching-learning cycles and incorporating ideas from lesson study we reflected on our experiences teaching a mathematics content course for pre-service elementary teachers via problem solving. A dominant theme from our preliminary data analysis indicates that the mathematics knowledge for teaching needed by teacher educators is even more complex when teaching via problem solving than in more traditional instructional approaches.*

Researchers have argued that it is vital that pre-service elementary teachers develop deep and connected understandings of important mathematical ideas (Ball & Bass, 2000, Ma, 1999). The Conference Board of the Mathematics Sciences (CBMS) (2001) has called for engaging pre-service elementary teachers in doing mathematics and supporting them in developing adult-level understandings of foundational mathematical ideas that are taught in grades K-8. It is argued that teachers' mathematical knowledge significantly influences how and what teachers teach and how and what their students learn (Ball & Bass 2000, Borko et al., 1992; Hill & Ball, 2004; Hill, Rowan, & Ball, 2005). Ball and Bass (2000) argue that teachers' mathematical knowledge needs to be strong in order to allow them to deal flexibly with the complexity of teaching mathematics to diverse student populations. They further claim that "not providing teachers with this [mathematical knowledge] undermines and makes hollow efforts to prepare high-quality teachers who can teach all students, teach in multi-cultural settings, and work in environments that make teaching and learning difficult" (Ball & Bass, 2000, p. 94). This need to adequately prepare new teachers has been highlighted in the reform movement in mathematics education and has necessitated not only calls for different approaches to teaching mathematics, but also the reinvention of teacher education (Simon, 2000). An immediate consequence of this is the need to adequately prepare educators of prospective teachers for the job of preparing and supporting the development of teachers.

We propose that one way to foster deep mathematical knowledge development in pre-service elementary school teachers (PSTs) is to engage them in learning mathematics via problem solving (Masingila, Lester & Raymond, 2006; Schroeder & Lester, 1989). In an analogous manner, it is important that teacher educators learn to support PSTs' development through learning via problem solving. We claim that learning to support PSTs' mathematical development via problem solving is also a problem-solving activity for teacher educators. Thus, they are also learning via problem solving, and their learning is about supporting PSTs' mathematical development. Further, in ways that are similar to how in-service teachers grow through interactions with teacher educators and peers in professional development work, we propose that teacher educators learn through working with mentors and peers in reflective ways.

In this study, two novice teacher educators (the first two authors, PK and DO) worked with an experienced teacher educator (the third author, JM) in a supportive professional community, and reflected together on the process of supporting pre-service teachers in developing adult-level understandings of foundational mathematical ideas that are taught in grades K-8. This was achieved through interconnecting theory, participation in a community of practice, and being reflective about our experiences in teaching a mathematics course for pre-service elementary teachers via problem solving. We took a position of *inquiry as stance*—within an inquiry community "to generate local knowledge, envision and theorize" our "practice, and interpret and interrogate the theory and research of others" (Cochran-Smith & Lytle, 1999, p. 289)—throughout this research study.

## Perspectives and Guiding Frameworks

Our theoretical framework is grounded in two bodies of research. The first involves research regarding mathematics teacher educator learning. In recent years, there has been an emergence of literature about how mathematics teacher educators learn (García, Sánchez & Escudero, 2006; Zaslavsky & Leikin, 2004). These researchers draw some parallels between ways in which mathematics teacher educators learn on the job and the ways mathematics teachers learn on the job (Jaworski, 1994). Reflection-on-action and reflection-in-action (Schön, 1983) are the notions underlying the interpretive processes through which these two communities of practice learn. The former refers to ways in which members of a community of practice (in our case, mathematics teacher educators) reflect on past experiences with the intention of refining their work to achieve their instructional goals, while the latter refers to "thinking on your feet" (Schön, 1983, p. 54).

One way in which teachers have operationalized Schön's reflective practice is through lesson study (Lewis & Tsuchida, 1998; Lewis, Perry & Murata, 2006; Stigler & Hiebert, 1999). When lesson study was introduced in the United States, it was initially looked at as a way for American teachers to learn from each other by forming communities of practice. Some researchers have tried to extend this idea to university professors with the view of providing them with professional development opportunities (Cerbin & Kopp, 2006).

Another approach that mathematics teacher educators have used to generate a framework or scheme for thinking about their evolving knowledge about preparing pre-service teachers is the *Teacher Development Experiment* (TDE) (Simon et al., 2000). The TDE provides researchers/teacher-educators opportunities to study the complex interactions that occur in a teaching-learning cycle. Knowledge is developed through "multiple iterations of a reflection-interaction cycle" (Simon, 2000, p. 339) (see Figure 1). A TDE methodology uses both retroactive and ongoing analysis of data to track the development of the students and the researcher/teacher-educator.

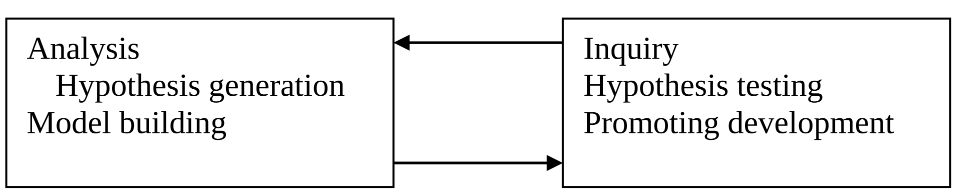

*Figure 1.* Knowledge development (Simon, 2000, p. 339).

The second body of literature involves research regarding the use of problem solving to teach mathematics. This approach to teaching mathematics hinges on the use of a constructivist theory of learning. Researchers argue that students acquire new knowledge by actively participating in the learning process (Grouws, 1992; *Journal for Research in Mathematics Education*, 1994) and not through passive absorption of what their teacher models (Masingila, Lester & Raymond, 2006). In a problem-solving approach, the role of the teacher changes from that of a disseminator of knowledge to that of a facilitator. Masingila and her colleagues (2006) argue that the teacher's responsibility is to "establish a mathematical community in the classroom where everyone's thinking is respected and in which reasoning and discussing mathematical ideas and meanings is the norm" (p. xxi). This means that in the case of learning via problem solving, both the students and the teacher take on roles that are potentially different from what they are used to. In their review of research on problem solving, Stein, Boaler, and Silver (2003) document many advantages of using this approach to teach mathematics — equal or better student performance on standardized tests, more positive and broader student attitudes about mathematics, and more equitable student performance with no achievement differences along social class or gender lines. However, the authors also point out the difficulty of teaching mathematics via problem solving, and state that "much remains to be learned about how to teach mathematics through problem solving in ways that enhance the learning of all students" (p. 254). We hope through this research project to contribute to this knowledge base.

## Research Goal and Methods

Situated in research on how mathematics teacher educators learn, and research on teaching via problem solving, our goal in this study was to reflect critically on the process of learning to teach via problem solving and to support PSTs in learning mathematics via problem solving. In Fall 2007, each of the authors was the instructor for a section of a mathematics content course for pre-service elementary teachers that was taught via problem solving. The content of the course included the concepts of numeration, operations, number theory, probability and statistics, and functions. The course met two days a week for 80 minutes each day; the third author taught the first section of the course, and the first and second authors taught their sections on the same day after they had observed the third author teach the first section. In Spring 2008, each of the authors was the instructor for a section of the other course in a two-course sequence. The content of the second course included the concepts of rational numbers, geometry, and measurement. The emphasis in both of these courses is on learning mathematical concepts through solving problems in a cooperative learning situation. The courses were developed using five principles as a guiding framework: (a) solving many problems is an essential ingredient in becoming a good problem solver, (b) problem solving involves a very complex set of processes, (c) the instructor's role in fostering productive problem-solving performance is vitally important, (d) cooperative, small-group work is encouraged, and (e) assessment practices should be closely connected to instructional emphases.

It is within the context of teaching these mathematics content courses via problem solving that we carried out this research study. We modeled our critical reflection process on the TDE's (Simon, 2000), "reflection-interaction cycles," and also on Schön's (1983) ideas of reflection-in-action and reflection-on-action. While we incorporated ideas from lesson study, since we taught each lesson only once during the semester, it was not practical to model our research directly on lesson study itself; however, the reflection-interaction cycles constituted a type of modified lesson study.

In our version of the reflection-interaction cycle, all three of the authors filled the role of teacher-researcher, and we reflected upon our own teaching while interacting with each other, as well as with our students. We had a number of data sources. The first two authors both observed the third author's lesson each class period. The rationale for this was that she has the most experience teaching in general, and has experience in supporting pre-service teachers in learning mathematics via problem solving. As mentioned previously, following the observations, the first two authors each taught the same lesson in their own sections of the course. As teachers and professionals, we incorporated reflection-in-action (Schön, 1983) while we were teaching. After each class/observation period, each of the authors wrote a memo of the day's lessons. These memos were part of our reflection-on-action. We reflected on the day's teaching and observing, noting things that we wanted to discuss with the group of teacher-researchers. On the day following the second classes of the week, we met for approximately one hour to discuss our observations, how the class was going, particular struggles that we noticed either students having or that we were having. We also used these meetings to plan our future lessons based on our reflections.

We audiotaped these meetings and transcribed portions that we found significant for our results. Thus, our meetings and memos cover the first part of Simon's (2000) model—hypothesis generation, model-building, and analysis—and our teaching and class observations correspond to the second part of the model—inquiry, hypothesis testing, and promoting development. We continued this reflection-interaction cycle throughout the semester. The data sources for this project are our collective memos, the transcribed notes from our meetings, and our experiences teaching in the classroom itself.

Following the methodology of the Teacher Development Experiment, we used both ongoing and retrospective analyses of the data. The ongoing analysis, which occurred during the teacher development experiment, was the basis for continued reflection on our teaching and learning about our teaching, the testing of emerging hypotheses, and the strategies for promoting further development of the pre-service teachers' mathematical understandings. During the retrospective analysis of the data, which is continuing, we are examining the larger corpus of data through a carefully structured review of all relevant data of the teacher development experiment.

We began coding our data at the end of the first course. We started by each looking at the data (memos and meeting transcripts) from the first two weeks of the semester and identifying themes that emerged. After looking at the data individually, we met and compiled a list of the themes that we had identified. Using this list, we then individually looked at five weeks' worth of data to see if these codes matched our data. We met together again, and as a group refined our list. During this meeting, we compiled a list of code definitions and examples, so that we were using the codes consistently.

We continued to code the data individually, focusing on one month's worth of data at a time. Each of the three researchers coded all of the memo data individually. At our weekly meetings we spent time discussing our coding in an effort to triangulate the coding. We discussed any areas where we were uncertain of the coding, and came to agreement. Following our group discussions, we coded our data electronically using a coding software package and ran reports to analyze the data within and across codes.

## Results

While the retrospective analysis continues, a dominant theme that emerged from the data is that the mathematics knowledge for teaching needed by mathematics teacher educators is even more complex when attempting to teach via problem solving than in more traditional instructional approaches. Our goal as instructors was to support these PSTs' growth both as learners and doers of mathematics, and also as problem solvers. Parallel to this, our main goals as researchers were to understand the processes of learning to teach mathematics via problem solving and learning to support PSTs in learning mathematics via problem solving.

In analyzing our data, we found that we supported PSTs' growth through (a) understanding and deciding on the mathematical goals of individual lessons and the two-course sequence as a whole, (b) choosing and facilitating tasks, (c) using questions and modeling to scaffold PSTs' learning, (d) assessing PSTs' understandings, and (e) monitoring PSTs' dispositions. We discuss the first two of these results in this paper. Since we taught these mathematics content courses via problem solving, our efforts to support PSTs' growth in mathematics and in problem solving were intertwined, as we found ourselves consciously and continually working to support PSTs in deepening their mathematical understandings and become more proficient problem solvers.

*Deciding on Mathematical Goals*

We see mathematics as an active venture in which students are encouraged to explore, make and debate conjectures, build connections among concepts, solve problems growing out of their explorations, and construct meaning from all of these experiences. Perhaps the most important goal of these mathematics content courses for PSTs is to support them in developing adult-level perspectives and insight into the nature of foundational mathematics. Another goal is to expose PSTs to key, recurring themes, processes, and tactics in mathematics and support them in making connections among mathematical ideas through these themes, processes, and tactics. We want PSTs to realize that elementary mathematics is foundational mathematics, and is not "elementary" (Ma, 1999).

Teaching mathematics via problem solving requires the instructor to understand the mathematical ideas involved in a problem in a deep and connected way, and further requires the instructor to anticipate the different approaches that students may use in solving the problem. Our data revealed that we first made sense of the mathematical goals of activities, of units, and of the course, then facilitated student engagement of activities so that these mathematical goals were accomplished, and then reflected upon this process.

Making sense of the mathematical goals sometimes involved thinking about how manipulative materials support or fail to support student understanding. For example, when using base ten blocks to model operations with whole numbers, there are limits to using this representation: "You can think about having three flats, four times, and it makes sense [3 + 3 + 3 + 3]. However, as we found, it doesn't make sense to think about three flats times four flats, at least pictorially" (DO, Memo 9/12/07). We found that as instructors it was important for us to think through carefully the relationship between the materials and the mathematical activities in which we want to engage the PSTs.

Making sense of the mathematical goals engaged us as instructors in thinking critically about what concepts and processes we wanted our students to engage with, and how to facilitate this happening. For example, each of us found the chapter on probability and statistics to be problematic in the sequencing of activities and the inclusion or exclusion of particular ideas. We decided that we did not want the probability activities to become an exercise in which the PSTs tried to determine whether to use the command on their calculator for permutations or combinations, but rather we wanted to engage them with methods of counting and have them reason through the solutions.

> I decided to talk about combinations without really calling them combinations. This worked out all right in class when I was thinking about making the slots and then dividing by the possible number of orders because order doesn't matter. However, when trying to answer the homework questions, this proved to be much more challenging. The question that [student] asked was, if you flip eight coins, how many outcomes have exactly three heads. In my head, I knew the answer was just eight choose three. You have eight coins and you want to choose three of them to be heads. This makes total sense to me and I usually teach it that way. However, since I am not doing "choose," I had a lot of trouble explaining it. In fact, I had so much trouble, that I told her I would figure it out and tell them on Wednesday. Grrr. I really wanted this to be a good way. I finally worked it out that we would need three slots for the three heads. We have eight choices for the first head (coins 1-8), seven choices for the second head, and six choices for the third head. Then, since order doesn't matter (coins 1, 3 and 4 being heads is the same as coins 4, 1 and 3), we have to divide by the number of ways of arranging three things. (DO, Memo 11/5/07)

A challenging aspect of teaching mathematics via problem solving is that in the same way that we want to support PSTs in developing deep and connected mathematical understandings, we as instructors need to have even deeper and more connected understandings ourselves.

Deciding on mathematical goals involves focusing on some things instead of others. As with all instruction, teaching via problem solving engages the instructor in balancing depth of exploration versus quantity of concepts.

> I hesitated with trying to decide whether to get into a deeper discussion of what larger than single-digit multiplication is when discussing multiplying two-digit numbers in bases other than ten. In the end, I did go into the meaning of multiplication using partial products. I think this did prompt the students to think more deeply about multiplication and their talk showed this, but is also slowed them down and was more difficult. Trade offs! (JM, Memo 9/12/07)

We found that deciding upon, implementing and reflecting on mathematical goals are critical aspects of the process of teaching mathematics via problem solving and learning to teach via problem solving.

*Choosing and Facilitating Tasks*

Given that the mathematics courses we taught had an activity-based textbook (Masingila, Lester & Raymond, 2006), most of the mathematical tasks were already chosen for us. We found that our focus was not in picking tasks (although for one lesson we designed alternate tasks), but in sequencing tasks, modifying them and deciding how to have the PSTs engaged with the tasks. One of the biggest challenges, we found, was to scaffold and support students' problem-solving efforts without taking the problem solving out of the work, and to facilitate so that powerful mathematical ideas emerged. Our data reflect our process of making sense of the tasks, facilitating their implementation, and reflecting upon the PSTs' engagement with and our facilitation of the tasks.

As discussed previously, we found the chapter on probability and statistics in need of revision and so we did some revising in the midst of teaching the chapter: "I prepared an alternate activity reinforcing the ideas of mean, median and mode, and then engaged students in working with and representing paired data. Again, we used graphing calculators to input data into lists and plot them as scatter plots" (JM, Memo 11/7/07).

While choosing activities and deciding how to use them is important, an equally important part is facilitating their use. Reflecting on the alternate activity, PK discussed how he facilitated the PSTs' engagement with the activity:

> Contrary to other questions that asked the students to find a five-number summary for a set of data, the first question in this alternate activity asked the students to generate a data set that would have a specified five-number summary. I had the six groups put up their data sets on the chalkboard and led a whole class discussion on the data generated. While all the groups had data sets that worked, it was interesting to see that all the groups came up with data sets that utilized only natural numbers. I asked the students if this was necessary. They decided that other values could be used also and we as a group came up with one such set. (PK, Memo 11/7/07)

A third aspect of the instructor's role related to tasks is reflecting on the tasks used, their facilitation, and the PSTs' interaction with them. One set of activities engaged PSTs in exploring and understanding algorithms, including ones that are different from ones that are traditionally used in school. In our memos, we reflected on these algorithms and their relevance to our PSTs: "I think that the Cashier's Algorithm may be a bit outdated. Nowadays, cash registers just tell you what change to give back, and so many people use credit cards, that the students are not really able to relate giving back change with subtraction. There may be some value in just calling it "adding up," and changing the activity" (DO, Memo 9/24/07). We found that choosing, facilitating and reflecting on tasks are critical aspects of the process of teaching mathematics via problem solving and learning to teach via problem solving.

## Discussion

In the same way that "prospective teachers need mathematics courses that develop a deep understanding of the mathematics they will teach" (CBMS, 2001, p. 7), novice mathematics teacher educators need experiences that will develop a deep understanding of the mathematics that they will teach to pre-service elementary teachers and support these PSTs in understanding deeply. The importance of the mathematical knowledge for teaching for mathematics educators cannot be overemphasized. We found that using a teacher development experiment and modified lesson study framework allowed us to think critically about many aspects of teaching mathematics via problem solving and supporting PSTs in learning mathematics via problem solving.

This framework, along with our position of inquiry as stance, also facilitated us developing a community of practice among the three of us as the course instructors. Within this community of practice, we were able to establish trust where any of us could make observations about the course materials, the questions we asked, the decisions we were pondering, etc. and these observations were received by the other instructors as valid and were considered within the context as we made instructional decisions. The establishment of trust also mediated the balance of power within our community of practice. JM, as the experienced teacher educator, a faculty member and one of the co-authors of the textbook we used, came with more power, by default, into the relationship. However, because we worked diligently and purposefully to form a community of practice with full participation by all three of us, the power relationship was held in check.

In reflecting on the processes of learning to teach via problem solving and supporting PSTs in learning via problem solving, we recognize the importance and are working toward developing a principled way of making pedagogical decisions. These include deciding when to have PSTs continue working on an activity and when to move on, what level of justification is sufficient, when should mathematical ideas be introduced by the instructor and when should they arise from the PSTs' activity.

There is much more analysis to do on this rich set of data. We anticipate coming to better understand how and what we, as mathematics teacher educators, learn about the processes of teaching mathematics via problem solving and supporting pre-service teachers in learning mathematics via problem solving.

*This study examined 96 elementary pre-service teachers' active-learning experiences in the first of a sequence of three mathematics content courses intended to provide them with opportunities to experience as learners Standards-based mathematics teaching. Participants indicated that they had many opportunities to engage in active learning that they had not experienced in their previous mathematics content courses. Participants also described how active learning influenced their level of confidence in their ability to do and discuss mathematics.*

## Purpose of the Study

In recent years teacher preparation programs have been criticized for failing to adequately prepare K-12 teachers to teach mathematics according to the standards set forth by the National Council of Teachers of Mathematics in *Principles and Standards for School Mathematics* (NCTM, 2000). For example, the National Research Council (2001) notes that elementary teachers "possess a limited knowledge of mathematics, including the mathematics they teach. The mathematical education they received, both as K-12 students and in teacher preparation, has not provided them with appropriate or sufficient opportunities to learn mathematics" (p. 372). Similar concerns have been raised by the National Mathematics Advisory Panel (2008), which argues that "the preparation of elementary teachers must be strengthened by providing teachers with ample opportunities to learn mathematics for teaching" (p. 38).

One way of helping elementary pre-service teachers (hereafter referred to as PSTs) develop and strengthen their mathematics knowledge for teaching (Ball, Bass, Delaney, Hill, Phelps, Lewis, Thames, & Zopf, 2005) is to provide them with consistent opportunities to engage in active-learning activities in their mathematics content courses (Conference Board of the Mathematical Sciences, 2001; Mathematics Association of America, 1998). In such activities, PSTs have opportunities to collaborate with peers, make meaningful mathematical connections through discussion, engage in higher-order thinking, and develop new mental structures (Bonwell & Eison, 1991; Meyers & Jones, 1993). Proponents of this paradigm shift towards active-learning argue that new ideas are formed and discoveries are made not by individual competition but through collaboration with others. Furthermore, they claim that the notion of learners constructing their own understandings of mathematics concepts is central to the nature of the subjects (Atwater, 1994; Becker, 1995). Rogers (1992) states:

A pedagogy that emphasizes product deprives [learners] of experiencing the process by which ideas in mathematics come to be and perpetuates a dualistic view of mathematics in which right answers are known by authorities and are the property of experts. Such a pedagogy strips mathematics of the context in which it was created and is based on misconceptions about its very nature. (p. 42)

The shift from studying mathematics as a *product* of human activity to studying it as a *process* of human activity places greater emphasis on the development of mathematical ideas and encourages K-12 teachers to develop their *mathematical power* – that is, a positive disposition toward, curiosity about, and self-confidence in mathematics; the ability to logically reason about

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

and analyze mathematics; a deeper and more connected understanding of mathematics across strands of mathematical content (e.g., algebra and geometry) and to disciplines outside of mathematics; and the ability to communicate mathematical ideas (Baroody & Coslick, 1998; NCTM, 1989; Orrill, & French, 2002). The notion of mathematical power aligns closely with NCTM's (2000) five *process standards* (problem solving, reasoning and proof, communication, connections, and representation). Therefore, if teachers are to provide their students with opportunities to engage in these process standards, they too need opportunities to participate in learning experiences that emphasize the process standards and develop their mathematical power.

The work described in this paper is part of a larger project that seeks to understand elementary PSTs' learning in a sequence of three mathematics content courses specifically designed for this population and to identify the sources of their learning. The focus of this paper is on one source of this learning, namely, the active-learning opportunities PSTs had during the first of a sequence of three mathematics content courses that are intended to provide them with opportunities to engage in active-learning as a way of making sense of mathematics. In this paper, we seek to explore the following research questions:

1. To what extent do elementary PSTs engage in active learning in a mathematics content course?
2. In what ways does active learning influence PSTs' learning and mathematical power?

Thus, the current study considers the opportunities PSTs have to learn mathematics and how engaging in those experiences influences their learning and mathematical power.

## Theoretical Framework

This study was guided by Astin's (1996) theory of student involvement which defines involvement as "the amount of physical and psychological energy that the student devotes to the academic experience" (p. 518) in formal and informal contexts both in and outside the undergraduate classroom. This theory is particularly relevant to studies of the relationship between active learning and academic outcomes because active learning inherently requires undergraduates to invest physical and psychological energy in the learning process. Reform efforts that incorporate active-learning opportunities in undergraduate mathematics education seek to change the focus from faculty members' intentions for the undergraduate experience to students' lived experiences. Similarly, the theory of student involvement shifts the emphasis away from faculty content knowledge, university resources, and individualized instructional approaches to focus on what students actually do by examining how students invest their time and energy and understanding the effect that this has on important learning outcomes. Astin asserts that of the three forms of involvement that have the greatest influence on cognitive and affective outcomes – academic involvement, involvement with faculty, and involvement with peers – involvement with peers has the most powerful influence on undergraduate students' academic and personal development (Astin, 1996).

## Method

### *Setting and Participants*

The study was conducted at a four-year public university in the Southeastern United States. The 96 participants (93 female; 3 male) in this study were elementary PSTs who were enrolled during either the spring 2008 semester (72 participants) or fall 2008 semester (24 participants) in the first of a sequence of three mathematics content courses, each of which had a particular mathematical focus (Course 1 focused on whole numbers and whole-number operations, Course 2 focused on rational number, and Course 3 focused on geometry and measurement). The spring 2008 participants were enrolled in one of five sections of Course 1 taught by two different faculty members, and the fall 2008 participants were enrolled in one of two sections of Course 1 taught by one faculty member. These three faculty members used the national and state standards for elementary mathematics as a backdrop for the course and created opportunities for PSTs to be actively engaged in the learning process. For example, PSTs had opportunities to solve mathematical tasks in multiple ways, share and discuss their thinking with their peers, use manipulatives such as base-10 blocks, and analyze children's mathematical thinking in the form of written work and video.

*Data Collection and Analysis*

The study employed a mixed methods approach that involved both quantitative and qualitative data collection and analysis. First, the *Developing Mathematical Power Learning Experiences Survey* (hereafter referred to as the DMP Survey) was administered to PSTs in electronic or paper form to participants at the beginning and end of the course. The DMP Survey used Likert-scale items to assess PSTs' perspectives of their opportunities to engage in active-learning. For each of the 13 items (shown in Table 1) that addressed in-class experiences, PSTs were asked to indicate the frequency in which they engaged in particular active-learning activities during the course by selecting "Not at All," "About Once or Twice a Month," "About Once Every Week," or "Almost Every Lesson." The DMP Survey also assessed PSTs' perspectives on their mathematical power with the four items shown in Table 2. In these items, PSTs indicated their level of agreement relative to their experiences prior to taking the course by selecting "Strongly Disagree," "Somewhat Disagree," "Somewhat Agree," or "Strongly Agree."

A small subset, six PSTs, participated in semi-structured interviews conducted at the end of the course in which they described their learning and their experiences in the course. A final data source was a writing assignment in which PSTs were asked to consider what mathematical power is, and how they think their mathematical power had changed during the course. This assignment was used by one faculty member, for a total of 18 PSTs enrolled in the course during Spring 2008 completing this assignment.

The DMP Survey data were analyzed using descriptive statistics and correlation analyses to explore the context and frequency PSTs' participation in active learning of mathematics during the course and to examine relationships between and among reported levels of active-learning experiences in previous mathematics content courses, during the current mathematics content course, and participants' mathematical power after taking the course. The interview data were analyzed using the constant comparison method (Strauss, 1987). Patterns and themes were identified, merged, discarded, and revised as the researchers compared and contrasted the interview transcripts. The data from the writing assignments were also analyzed in this way. Quotations selected from the interviews and writing assignment on mathematical power are illustrative of the experiences of the majority of the PSTs and are similar in context and meaning to other PSTs' responses and descriptions.

## Results

In this section, we compare the experiences of PSTs who had previous experience with active learning in mathematics to those who did not. Of the 96 PSTs who completed the DMP Survey at the beginning of the course, only 36 (37.5%) indicated that they had regular opportunities to actively engage in the learning of mathematics prior to taking this mathematics course. 77 PSTs completed the DMP Survey at the end of the course, of those, 70 (90.1%) indicated that they had high-levels of active-learning experiences during this mathematics course. This number includes 41 PSTs who indicated low-levels of active-learning experiences in mathematics prior to taking the course. There were 11 (out of 13) active-learning opportunities in particular for which a majority of PSTs indicated that they agreed or strongly agreed to having had engaged in during the course, as shown in Table 1.

Table 1. *End-of-Course Reported High Levels of In-Class Active-Learning Experiences*

| | Freq (n=77) | Percent |
|---|---|---|
| "I listened to and evaluated other students' ideas, solutions, or points of view." | 74 | 96.1 |
| "I was challenged to defend, extend, clarify, or explain how I derived my answers or ideas." | 68 | 88.3 |
| "I was expected to 'investigate' or 'discover' mathematical principles and ideas." | 74 | 96.1 |
| "I worked with other students to explore new ideas/concepts through problem examples." | 69 | 89.6 |
| "I shared strategies with other students for approaching or solving a problem." | 69 | 89.6 |
| "I justified my reasoning in a problem or steps in a proof." | 58 | 75.3 |
| "I discussed connections between mathematical ideas/concepts with other students." | 66 | 85.7 |
| "I worked with other students to evaluate or construct proofs or make conjectures/propositions." | 54 | 70.1 |
| "When students were working together, we were encouraged to admit confusion and ask questions." | 66 | 85.7 |
| "I taught a particular mathematical idea to the class." | 9 | 11.6 |
| "I directed questions to other students about mathematical ideas/concepts." | 43 | 55.8 |
| "I put individual or group work on the board for classmates to examine or comment on." | 28 | 36.4 |
| "I worked in groups with other students on projects to be turned in for a grade or extra credit" | 39 | 50.6 |

These results indicated that PSTs engaged in a variety of active-learning experiences during the course. It is also important to note that although this data was collected from PSTs who took the course from one of three different faculty members, correlation analyses indicated that the active-learning opportunities were not statistically different across the courses. Moreover, many of these experiences emphasized the process involved in the study of mathematics rather than the product of mathematical activity. These findings were supported by the data from interviews and writing assignment as well. During the interviews, PSTs consistently spoke of their professors' expectations to explain their ideas, solve problems collaboratively with their peers, and share their ideas publicly and in writing. Some PSTs in interviews and on the writing assignment noted how these expectations were different from their experiences in previous mathematics classrooms.

PSTs indicated on the DMP Survey administered at the end of the course that some aspects of their mathematical power increased during the current mathematics content course. As shown in Table 2, a majority of teachers agreed or strongly agreed with the four statements used to assess their mathematical power relative to their experiences prior to the course.

Table 2. *End-of-Course Responses to Mathematical Power Items*

| | Freq (n=77) | Percent |
|---|---|---|
| "I feel more comfortable with elementary mathematics content." | 66 | 85.7 |
| "I am more knowledgeable about pedagogical issues related to teaching elementary mathematics content." | 62 | 80.5 |
| "I feel more comfortable discussing mathematics with others." | 66 | 85.7 |
| "I feel more confident in my ability to do mathematics. | 65 | 84.4 |

In addition to finding that PSTs' perceived mathematical power increased during the course, correlation analyses revealed that all of the mathematical power items were highly correlated with statistical significance at the alpha = 0.01 level. This data indicates that PSTs developed their sense of their ability to understand, do, and communicate mathematics in tandem.

Common themes from the writing assignment were consistent with the quantitative analyses and interview data and suggested that PSTs mathematical power may have been influenced by the types of active-learning experiences in which they engaged. For example, Margorie described how considering different strategies influenced her confidence to participate in discussions about mathematics:

> All the way up through high school my worst subject was math. I would always fear having to speak out in class or answer a problem on the board. I would do what I had to do to get by. It was not until college that this changed. I began to have teachers that would challenge me, but at the same time help me to understand different way of thinking and going about solving math problems. I began to feel more confident in my mathematical abilities and I am now able to speak out in class… I love being able to discuss a problem with other students and get their point of views on how to go about solving a problem. I feel that I learn so much more through interaction rather than just lecture and taking notes.

The data collected from the interviews also indicated that PSTs recognized that the opportunities to talk with their peers and listen to others' solutions played an important role in the development of their mathematical power. For example, Teaghan suggested that her experiences even influenced her confidence in other classes:

> ... because at first, I mean nobody wanted to say anything. We were all like, 'Oh my gosh, I hope [the professor] doesn't call on me.' And now, you're expecting it. I mean, you still may not like it. But at least, I know now, that I can say whatever, and, I might say it one way, or might get kind of stuck on a word, and then the girl in the front will chime in, and then they take over and stuff like that, so it's definitely helped my confidence in this, and I mean, other classes.

## Discussion

The results reported in this paper offer some promising support for on-going efforts by mathematics teacher educators in the United States to enrich the mathematics content courses for prospective elementary school teachers. In particular, the results of the current study show that PSTs who are actively engaged in learning tasks in these courses do feel that their mathematical power has increased. Although our results are based on PSTs' self-reporting, we believe it is essential that prospective teachers perceive the usefulness of the active-learning experiences if we want them to incorporate opportunities for such experiences in their own classrooms. If it is indeed the case that teachers teach the way they were taught, then, an important role of mathematics content courses for prospective elementary school teachers is to help them experience the type of teaching we want them to practice in their future classrooms.

This notion of "modeling" the type of instruction that prospective teachers are expected to implement in their classroom practice becomes even more critical when we realize that in many elementary teacher preparation programs, prospective teachers take more mathematics content courses than mathematics methods courses. It is very difficult, if not impossible, for a single mathematics methods course to develop a new vision of mathematics teaching and help prospective teachers learn to implement this new vision. Therefore, mathematics content courses might be promising sites for not only developing PSTs' content knowledge, but also begin to help them confront their own beliefs regarding what it means to teach, by providing them firsthand experience in being students in mathematics courses that likely look very different from their K-12 mathematics experiences.

The study reported in this paper also suggests some specific features of active-learning experiences that may be useful in mathematics content courses. Those experiences include opportunities for PSTs to talk with each other about their mathematical thinking, justify and explain their ideas to their peers and to their instructors, and explore and discover new mathematical relationships through problem solving.

Opportunities for PSTs to talk with each other may be particularly important given that this particular population is predominantly female. Existing literature suggests that female students are often excluded from classroom discourse about mathematics (Fullerton, 1995; Linn & Kessel, 1996; Moreno & Muller, 1999; Seymour & Hewitt, 1997). Drawing upon Belenky, Clinchy, Goldberger, and Tarule’s (1986) work, Becker (1995) argues that traditional lecture teaching methods support separate knowing and devalue connected knowing and create little opportunity for women to develop the participatory competence that would enable them to be self assertive in mathematics. She describes connected knowing and separate knowing as being analogous to inductive and deductive reasoning in mathematics, respectively, and claims that women are more often connected knowers and men are more likely to be separate knowers. Moreover, these practices disempower women and discourage them from developing their own voice (Mau & Leitze, 2001; Rogers, 1992). Mau and Letize (2001) assert that empowering curricula would place women in a position where they not only *could* participate but *would* participate in the articulation of meaningful mathematical understandings without fear of ridicule.

The current study is limited in a number of ways. However, its limitations and some of the findings suggest some potentially important and fruitful future studies. Philipp, Ambrose, Lamb, Sowder, Schappelle, Sowder, Thanheiser, & Chauvot, (2007) reported the usefulness of incorporating opportunities to examine children's thinking in mathematics content courses for prospective teachers. In this study, a number of participants indicated how their experiences with children influenced their perception of the course work. Some of them noted how much better they were able to help children, whether their own or tutees, with mathematics after their course experiences. For example, when asked how the course has influenced her level of confidence in her ability to communicate mathematics, Teaghan commented:

> …last year when I worked at an after school program, I was helping kids do math. And I was telling them the answers cause I just didn't know how to teach it to them…But this year I've noticed that I'm able to help the kids a lot more…Like one of the kids at [the after-school program], it was just a simple worksheet, 20 minus 8 or something like that, but he just couldn't do it. And I just got out little cubes and we did it that way. And he put 20 together and took 8 [away] and I mean, he got it when he could use things. But he couldn't just look at it and say, 'Ok, 20 minus 8.' And I definitely didn't know how to do that last year…So I mean, I just thought back to when I was in class, how did [the instructor] teach it to us, and just kind of remembering all the different things we did… yeah, it's easier to help the kids at [the after-school program] than it was last year.

Others PSTs indicated how viewing brief video clips of children doing mathematics influenced the way they approach these courses. However, what is not clear is how these experiences influenced their learning of mathematics. In some cases, the role these experiences plays is limited to motivational. In other cases, these opportunities may be directly related to PSTs' learning of mathematics content. A further investigation into relationships between examining children's thinking and PSTs mathematics learning is needed.

Another potentially important future study involves the role of manipulatives in these courses. A number of teachers indicated that the "hands-on" nature of the courses influenced their learning. However, several of the interviewees noted that they found it more difficult to solve mathematics problems using manipulatives. One of them even admitted that she solved the problem first and then matched her use of manipulatives to that solution. Yet, all of the interviewees indicated how manipulatives would be useful in their future classrooms. It is not quite clear why they felt the use of manipulatives to be positive when they themselves did not experience the benefits of manipulative use. A further investigation on prospective teachers' experiences with manipulatives and their beliefs of the roles of manipulatives in their own classroom may be necessary if we want teachers to use manipulatives meaningfully.

Finally, probably the most significant limitation of the current study as reported is the lack of objective measures of prospective elementary school teachers' learning of mathematics content knowledge. We did administer the *Mathematical Knowledge for Teaching* (MKT) measures (Learning Mathematics for Teaching Project, 2006) to some participants, and there were general upward trends. However, due to a small sample size, we are unable to report any conclusive finding. It is hoped that we will be able to incorporate the MKT measures in our future studies.

# TEACHER TRAINING IN VIRTUAL ENVIRONMENTS

Janet B. Andreasen
University of Central Florida
jandreas@mail.ucf.edu

Erhan S. Haciomeroglu
University of Central Florida
erhansh@mail.ucf.edu

*This study sought to examine the merits of TeachME – an innovative virtual teaching environment for teacher training – in teacher education programs. TeachME, Teaching in Mixed-Reality Environments, provides an environment in which the students are virtual and the teaching is real. In a semester-long methods course, prospective secondary mathematics teachers developed and taught lessons in this virtual environment. In this collaborative training environment, the prospective teachers focused primarily on delivery of a lesson to accommodate the diversity of students and how to manage the classroom. Our results suggest the use of virtual environment can be beneficial to teacher training.*

## Introduction

Traditional teacher training programs focus primarily on developing prospective teachers' content and pedagogical knowledge – what to teach and how to teach it in ideal environments. Environments for teacher training often include field experiences, microteaching experiences, and internships. These are widely used and accepted methods for training prospective teachers for the classroom, yet teachers in their first years of teaching often face difficulties related to classroom management. Without adequate management of student behavior the content knowledge of the teacher becomes irrelevant. This begs the question as to whether there may be an additional method for teacher training which could assist beginning teachers, particularly in classroom management. This study reported here sought to examine the merits of TeachME – an innovative mixed-reality teaching environment for teacher training.

## Development of TeachME

Given high teacher attrition and turnover in public school settings due to difficulty managing classroom behavior (Swan, 2006; Veenman, 1984; Hollingsworth, 1988), a discussion began amongst the education faculty at a large university in central Florida. The question became, "How can we prepare teachers to manage the classroom and student behavior without putting teachers and students at risk?" The answer was a mixed-reality teaching environment for teachers to practice their skills prior to entering the classroom (Hughes, Stapleton, Hughes, & Smith, 2005).

The mixed-reality environment is called TeachMe (Teaching in Mixed-Reality Environments) and is housed at the University of Central Florida (UCF). TeachMe is the result of a unique collaboration rarely seen in education to develop the educational technology for teachers of the future. The outcome of this collaboration between education, computer sciences, and simulation technology provides a path to address the problem of teacher attrition by creating a working, mixed-reality environment to train beginning teachers (Dieker, Hynes, Hughes, & Smith, 2008).

The initial prototype focused on behavior and classroom management, an area of concern for most beginning professionals (Goodell, 2006; Van Zoest, 1995). One goal of the mixed-reality environment is to create an interactive, simulated environment to train beginning teachers in mathematics, science and special education before they enter the teaching force. The methodology for developing the virtual environment was built on strong, scientifically based-research related to the training of people in the military and corporate America, made possible through UCF's long-standing record as a leader in simulation technology (Dieker, Hynes, Hughes, & Smith, 2008). In order to have a successful virtual environment, students in the virtual classroom must be representative of real middle school students. The characters were developed using the American Academy of Child and Adolescent Psychiatry's description of adolescent development, William Long's classification of adolescent behavior, Rudolf Driekurs' theory of understanding adolescents maladaptive behavior, and the work of other early theorists in human development such as Piaget, Freud, Kohlberg, Erikson and Maslow (Dieker, Hynes, Huges, & Smith, 2008). The result is five students who have distinct and specific personalities designed using the conceptual framework for adolescent development of William Long.

One interactor is the human avatar for all five students. The interactor can escalate or de-escalate the level of behavioral responses depending on teacher interaction. Furthermore, the interactor can create behavior issues between students if the specific needs of students are not addressed, creating a simulated classroom with real student-to-student interaction. The teacher faces a large screen that displays all of the students. By stepping towards the screen and leaning towards the child, the teacher can interact individually with each student, or stand in the front of the room to address the group.

In the mixed-reality environment, the teacher feels a sense of realism in trying to get the students to stay on task and complete a lesson, yet also has the ability to go back and try again as the virtual students can be reset, unlike a real classroom environment. This puts a safety net under the novice teacher and protects actual children from any harm. Teaching in a simulated classroom environment allows for teachers to deliver instruction, self-analyze the teaching experience, make changes in the lesson based upon the teaching results, and re-teach the lesson to increase mastery of teaching and learning concepts in a way that does not put children at risk.

## Theoretical Framework

According to Prensky (2001), our education system fails to teach today's students, growing up with new technologies, and the biggest problem facing education is educators, who are Digital Immigrant educators, who speak an outdated language to today's students, who are Digital Natives, native speakers of new technologies. New technologies are integral parts of our students' lives, and we as educators must use emerging technologies in our teacher education programs to prepare prospective teachers for diverse classrooms. In integrating the new technologies into our mathematics teacher preparation program, we sought a theoretical framework that takes into account the dynamic nature of the virtual environment and at the same time addresses the complexity of designing learning experiences for prospective teachers in a virtual environment. We find the instructional design framework of Model Facilitated Learning (Milrad, Spector, & Davidsen, 2003) particularly useful to achieve such goals. As a theoretically grounded framework, Model Facilitated Learning (MFL) draws on well-established learning theories and methods of system dynamics to manage complexity in technology-enhanced learning environments in order to achieve meaningful learning and deep understanding. The MFL framework allows learners to build models and/or experiment with existing ones as part of their effort to understand the structure and the dynamics of a complex phenomenon, in this case teaching mathematics to diverse learners. Following the MFL framework, we designed learning experiences for prospective secondary teachers. The MFL is guided by four principles: 1) Situate the learning experience: The prospective teachers worked in groups of three, and we asked the groups to plan and write a detailed lesson plan for the same algebra problem, an algebraic reasoning problem involving generalizing a non-linear pattern; 2) present problems and challenges of increasing complexity: We presented the prospective teachers with correct, incorrect, and incomplete student work samples to the algebra problem for which they wrote lessons, and asked them to discuss these work samples; 3) involve learners in responding to a set of increasingly complex inquiries about the problem situation: After each teaching session, each group member wrote a reflection based on his/her role in the teaching (i.e., teacher or observer), then watched their own videos and revised their lesson plans in preparation for the next cycle of teaching; 4) challenge learners to develop decision–making rules and guidelines for a variety of unanticipated situations: In an attempt to help the prospective teachers develop appropriate solutions and strategies for challenging student behaviors in a virtual environment, we challenged the prospective teachers by escalating or de–escalating the level of behavioral responses.

## Design of the Study

We sought to examine the merits of TeachME in teacher education programs through a mixed study with fifteen prospective secondary mathematics teachers. Data were collected in a semester-long methods course for prospective mathematics teachers through videos of the teaching episodes and classroom discussions, interviews, classroom observations, students' lesson plans and reflections. Analysis and data collection were an ongoing process throughout the study, and the research team held weekly meetings during the study.

All teaching episodes were video-taped and student reflections and lesson plans were collected for each teaching cycle. Additionally, members of the research team observed the teaching episodes. Student conversations during class time in which the groups were discussing their teaching episodes were audio-taped. Video and audio tapes were transcribed by members of the research team.

The prospective teachers were randomly divided into 5 groups. All groups wrote lesson plans for the same problem, an algebraic reasoning problem involving generalizing a non-linear pattern, which they had previously solved in class. The groups followed a three-stage cycle of teaching in which one member taught the lesson and the other two members observed. The member responsible for teaching changed with each teaching cycle. An interactor behind the scenes acted for the virtual students and provided realistic interactions as might occur in an urban middle school classroom.

In order to deepen the prospective teachers' thinking about various solutions to the problem, eleven correct, incorrect, and incomplete student work samples for the problem were created by the research team and were then assigned to the virtual students in TeachME (See Figure 1). All groups received the same work samples in each teaching cycle, and the prospective teachers were asked to discuss these work samples during their 15-20 minute TeachME sessions. The work samples were changed for each teaching cycle.

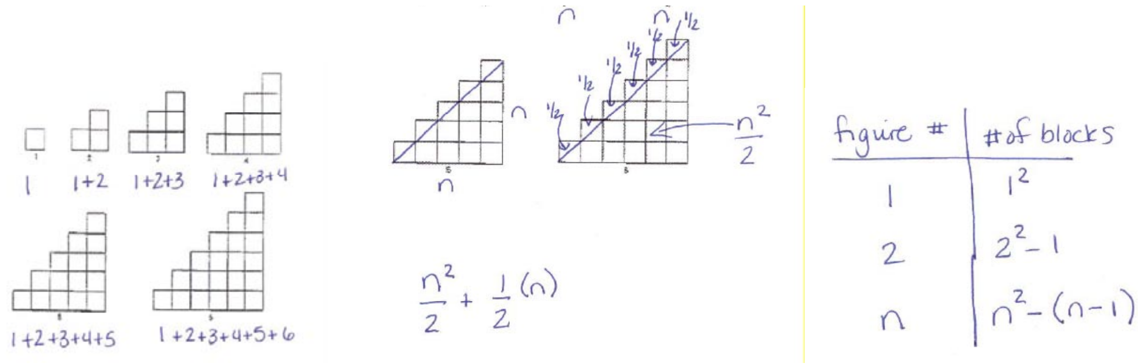

*Figure 1:* Examples of incomplete, correct, and incorrect solutions.

All sessions were videotaped. After each teaching session, each group member wrote a reflection based on their role in the teaching cycle (i.e., teacher or observer). During the next class session, the groups watched their own videos and revised their lesson plans in preparation for the next cycle of teaching.

## Data Analysis

The prospective teachers developed and taught lessons in TeachME environments. From these fifteen teaching episodes, two virtual teaching episodes will be presented which illustrate various challenging student behaviors the prospective teachers encountered in the mixed-reality environment, TeachME. In the first, we examine the teacher, Mr. Jeffrey, interacting with the five virtual students, whom we will call Monica, Michael, Victor, Michelle, and Freddy. Following this, we examine the teacher, Ms. Jennifer, interacting with the same five virtual students.

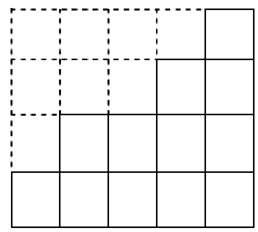
*Episode One*

In this episode, the teacher, Mr. Jeffrey, interacted with the five virtual students during the first teaching cycle. Each student had a different solution and Mr. Jeffrey was asked to teach the classroom discussion portion of the lesson. At one point in the episode, Mr. Jeffrey had to interact with Michael's incorrect solution a shown in Figure 2.

| Figure #1 | # of Blocks |
|---|---|
| 1 | $1^2$ |
| 2 | $2^2 – 1$ |
| N | $N^2 – (N-1)$ |

*Figure 2.* Michael's solution.

Mr. Jeffrey asked Michael what would happen if he used his formula to find the number of blocks in figure 3 of the problem. Despite Mr. Jeffrey's encouragement that Michael had done good work, Michael's response was concern and frustration that his work was wrong. Mr. Jeffrey dealt with Michael's attitude and continued to encourage Michael to find a generalization that would work for all the figures. As the teaching episode continued, Mr. Jeffrey then interacted with Monica related to her solution. Monica had a correct solution as shown in Figure 3.



$$\frac{n(n+1)}{2}$$

*Figure 3.* Monica's Solution.

Monica is a high achieving student, but she does not like to participate in class discussions. As Mr. Jeffrey worked to elicit her thinking, Monica was uncooperative said "I learned this in 6th grade". In an attempt to further explore Monica's thinking with the rest of the class, Mr. Jeffrey asked Monica to explain her solution in a whole group discussion. She was resistant, saying "I just told you." When asked to tell the whole class, she explained her work in an extremely concise way and only provided discussion when directly asked.

As the episode continued, Mr. Jeffrey continued to have to deal with the management of the classroom, particularly in leading a whole class discussion. As he worked with Victor and Michelle, Mr. Jeffrey's goal was to get Victor and Michelle to understand Monica's method for generalizing the formula. Victor and Michelle interpreted the discussion as their solutions being wrong and Monica's being correct, even though their solutions were correct.

Mr. Jeffrey: Michelle, can you tell us about the solution you got?

Michelle: Um, yeah, my solution, I got the same answer I just did a lot more adding and Monica did multiplication and division and adding and I just did straight adding, but I got the same answer.

Mr. Jeffrey: Very good. Did you understand the way Monica did it?

Michelle: Does that mean I am wrong because I didn't do it the way Monica did it?

A similar interchange occurred between Mr. Jeffrey and Victor, with similar thoughts stated by Victor when he said "So I should have done it like Monica?". Both Victor and Michelle knew that Monica usually had a correct answer and interpreted the efforts of Mr. Jeffrey to get the students in the class to make sense of Monica's solution as their solutions were unvalued or incorrect. Mr. Jeffrey tried to manage this situation and to encourage the students that their solutions were as equally valued as Monica's solution.

In leading a whole class discussion, Mr. Jeffrey had to deal with the emotional aspects of teaching children in dealing with Victor's and Michelle's reactions to his asking them to make sense of Monica's work. These interactions provided for a realistic picture of classroom dynamics.

*Episode Two*

In a second teaching episode, Ms. Jennifer was teaching in TeachME during the second teaching cycle. Ms. Jennifer began teaching and was immediately encountered with a confrontation with Michael who had been throwing virtual spit balls at Michelle. Michael admitted to throwing the spit balls and a confrontation ensued as to who was in charge of the classroom.

Ms. Jennifer: Are you throwing spit balls at Michelle?
Michael: Yeah.
Ms. Jennifer: Why?
Michael: Because this is my classroom and that's what I felt like doing.
Ms. Jennifer: Oh, I thought this was my classroom.
Michael: Well you thought wrong, now didn't you.
Ms. Jennifer: Oh, really? Well, we are going to work on our staircase problems and, this is my classroom, and that is what we are going to do.
Michael: Ha. Your classroom! Did you hear that Victor? She said this is her classroom.

This interaction began the lesson which proved to be difficult for Ms. Jennifer. As Ms. Jennifer continued to interact with the other students in the class, the confrontation which began with Michael contaminated the entire classroom, as it often does in reality. Ms. Jennifer's difficulty managing the behavior and responding appropriately to Michael's claim that it was his classroom undermined Ms. Jennifer's authority and affected her interactions with all the other students in the class. The students became hostile and Ms. Jennifer tended to be hostile as well. As Ms. Jennifer interacted with Monica, for example, Monica's response was not only unmotivated as in the episode with Mr. Jeffrey, but was also disrespectful.

Ms. Jennifer: How's it going with the staircase problem? Do you have an answer?
Monica: Yep.
Ms. Jennifer: Can I see it?
Monica: Yep.
Ms. Jennifer: Can you explain to me what you did?
Monica: Used the formula that we learned in sixth grade.
Ms. Jennifer: And how did you get that formula?
Monica: We learned it in sixth grade.
Ms. Jennifer: Okay, so then you can tell me what this means.
Monica: You plug the numbers into the formula and you get the right answers depending on what number you want.
Ms. Jennifer: No. What does the formula mean? What does n squared over 2 plus ½ times n mean?
Monica: You don't know? I thought you were the teacher.

Not only did Ms. Jennifer have to deal with Monica's behavior, she also had to deal with the impact of her inability to manage Michael's behavior and its impact on Monica who challenged Ms. Jennifer's authority in the classroom. The focus of the lesson became managing behavior and the content was left to the wayside. Without the ability to manage the behavior of the students, the content involved in the lesson became irrelevant.

## Conclusions

In the virtual teaching environment, TeachME, the students were real, sometimes disrespectful, unmotivated, and unenthusiastic. The teachers could not rely on anyone but themselves for delivery of content and the added component of behavior management, even on a small scale as in Mr. Jeffrey's case, provided for an enhanced and realistic environment for learning to teach, particularly with aspects of management of behavior.

We conclude that there are potentialities in TeachME for not only deepening content knowledge through discussion of correct, incorrect, and incomplete student work samples, but also for developing behavior management strategies. The virtual teaching environment sharply differs from other teacher training environments (e.g. microteach). Rather than a focus on teaching content, the virtual environment allows for a focus more on managing student behavior in order for delivery of content to occur. This is by no means to say that other training environments, such as microteaching and internships, are not useful in teacher training, but rather that we as teacher educators must see the weaknesses and strengths of these teaching experiences and find ways to enrich the student teaching experience. Moreover, we argue that the realistic aspects of the virtual environment can, in fact, enhance prospective teachers' preparation for classrooms, particularly in urban schools. The incorporation of the virtual in complement to other environments provides for multiple experiences which can focus on both mastery of content and its delivery as well as behavior management strategies which can be effective in schools.

# PRESERVICE PREPARATION OF MATHEMATICS CANDIDATES IN THE LARGEST ALTERNATIVE CERTIFICATION PROGRAM IN THE U. S.

Beverly Smith, City College of New York
Andrew Brantlinger, University of Maryland
Laurel Cooley, Brooklyn College

*In this empirical study we examine the preservice training the New York City Teaching Fellows (NYCTF) program provides its middle school and secondary mathematics teacher candidates. Drawing on in-depth survey and journal data we present findings about the preservice programs at the four NYC-area universities that partner with NYCTF program to train mathematics fellows. We describe the scope and sequence of the four programs, compare and contrast them, and document the experiences and perspectives of first-year mathematics teaching fellows in these programs.*

## Background

The New York City Teaching Fellows (NYCTF) is the largest alternative certification program in the U. S. and currently places some 300-400 new mathematics teachers in high needs NYC schools every year. Established in 2000, the NYCTF program prepares teachers for in-demand and high turnover disciplines like mathematics, science, bilingual education, and special education. It is a collaborate effort between the New York State Education Department (NYSED), the New York City Department of Education (NYCDoE), The New Teacher Project (TNTP), and a number of colleges/universities. The program, which combines full-time teaching in a New York City public schools with part-time academic coursework, leads to a Master's degree and New York State initial certification in the teaching field (Boyd, Grossman, Lankford, Loeb, Michelli & Wykoff, 2006).

The first cohort of 250 teachers in 2000 was relatively small, but the NYCTF program has grown rapidly over its brief existence. According to the NYCTF website, there were 16,700 applicants for approximately 2500 positions in 2004 including 317 positions for middle and high school mathematics teachers. Since that time, 60% or more of all new mathematics teachers entering NYC schools were participants in NYCTF (Bernstein, 2006). Due to this growth, it is expected that the influence on the entire New York City mathematics teaching force of those teachers prepared through NYCTF has increased substantially.

## Theoretical Framework

We situate this empirical research in studies of alternative certification and alternative route programs (Darling-Hammond & Youngs, 2002; Feistreizter & Chester, 2003; Hawley, 1990). We note that, to our knowledge, none of the extant research literature examines the preparation of alternatively certified mathematics teachers. Additionally, while not focused on mathematics teachers, we find that there are five studies that report results on the NYCTF program and its teachers, including three qualitative studies (Costigan, 2004; Goodnough, 2004; Stein, 2002) and two statistical analyses of student achievement (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006; Kane, Rockoff, & Staiger, 2006).

In an early small-scale survey study of the NYCTF program, Stein (2002) found that approximately 90% of the 31 fellows she surveyed were already considering leaving the high needs schools in which they initially were placed, after they fulfilled a two-year commitment.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

Despite this, Stein concluded that the NYCTF program is an “unqualified success,” citing the fact that it includes a mentoring component and that recruits have strong academic credentials.

Nevertheless, the qualitative and quantitative evidence indicates the fellows may not teach that differently than both uncertified and traditional route (college certified or recommended) teachers in similar NYC schools. Two qualitative studies indicate that novice teaching fellows are similar to other novice teachers in many regards (Costigan, 2004; Goodnough, 2004). In particular, the novice teaching fellows in these studies articulate similar high-minded ideals as traditionally prepared novices (e.g., about “molding students”). However, the fellows switch into “survival mode” once they become teachers of record – a mode characterized by a narrow focus on management concerns and teacher-centered instruction.

It is not clear what teacher preparation programs – alternative or traditional – can do to help novice teachers maintain and realize the student-centered ideals that many aspire to (Flores, 2006). Those who have studied the NYCTF program raise concerns about the program design, particularly, the preservice component that is less than two months in duration. Costigan (2004) writes that the NYCTF “immersion model may not, through a 2 year reduced credit program with full time teaching, adequately prepare self-identified ‘urban pioneers’ … to teach in the increasingly complex and intensified educational situation today, particularly in poor urban neighborhoods” (132). Goodnough (2004) expressed similar concerns, referring to the NYCTF preservice program as a “boot camp” and pointing out that many uncertified teachers had more formal preparation than first-year fellows. To be clear, neither Costigan or Goodnough focused on the NYCTF preservice training of teaching fellows in their research.

The question is what effect, if any, might a shorter “boot camp” style preservice training for mathematics teachers have on student learning? Two quantitative studies of NYC schools address this question, though only one was peer-reviewed. In their peer-reviewed study, Boyd, et al. (2006) find that there are statistically significant, if modest, differences in student mathematics achievement ($4^{th}$ to $8^{th}$ grade tests) between alternative and traditional route teachers; the students of the NYCTF teachers scored about 3.5% of a standard deviation lower respectively on standardized state mathematics exams than that of comparable traditional route (i.e., “college recommended”) teachers. There was some evidence, though not statistically significant, that the fellows catch up to the college recommended teachers if they stay in the classroom for three or more years. This might make sense given that, by their third year, the NYCTF’s have completed a comparable amount of educational coursework to traditional route teachers in NYC (though not necessarily in mathematics). At the same time, Boyd, et al. (2006) include data showing that the fellows have significantly lower rates of retention than traditional route teachers who teach at similar urban schools.

## Research Questions

1. How are alternatively certified middle school and secondary school mathematics teachers prepared to teach during their preservice training?
2. What are alternatively certified teachers’ experiences and perspectives during the preservice component of their training?

## Methods

This large-scale qualitative study of the NYCTF program and its mathematics teachers involves a team of more than a dozen researchers and an extensive amount of data (e.g., videotaped lessons, administrator interviews, in-depth surveys). The study of the NYCTF program for mathematics was designed to compliment aforementioned quantitative research on the NYC teachers from various pathways already under way (Boyd et al., 2006). In this paper we focus on survey and teacher journal data collected about the preservice programs at the four NYCTF partnering universities for mathematics. These preservice programs have three major components: (1) university coursework, (2) fieldwork in NYC summer schools, and (3) “Fellows Advisory.” Fellows Advisory is a highly structured program primarily delivered by former teaching fellows (i.e., those with regular certification and still in the classroom) and is designed to provide pragmatic information about teaching in NYC schools and navigating the NYC public school system.

*Survey Data*

We collected 269 in-depth surveys from first-year mathematics teaching fellows (MTFs) at the four university partners during their last week of their summer preservice programs. This was more than 90% of the MTF population who entered in the summer of 2007. The survey included closed (Likert-scale) items and open-ended items. About 25% of the survey questions concerned aspects of the preservice programs. Another 10% of questions were indirectly relevant and asked questions related to the MTFs personal views of themselves as urban mathematics teachers.

*Journal Data*

In early June of 2007, we met with officials at the four partnering universities and explained our study to them. After getting their consent, we next met with 9 newly recruited MTFs who agreed to collect information on their preservice programs – 3 of the MTFs attended the largest program and the other six were split evenly between the 3 other university partners. The participating MTFs varied in terms of being prepared for middle or high school mathematics teaching. They were each paid $75 a week to: (1) collect handouts (e.g., syllabi, assignments, articles) from university coursework and other NYCTF professional development sessions held off-campus; (2) keep a written daily overview – one or two pages – organized by the lesson, session, or activity, and that provided information about what they and their instructors were doing during that time (i.e., taking notes, math problem solving, role playing); and (3) reflect daily about a particular activity or the day as a whole and, once summer school began, their experiences in fieldwork classrooms and the interplay between their university coursework, NYCTF profession development, and fieldwork experiences. They kept both written accounts and also audio reflections and notes in digital recorders supplied to each of them. The written data and transcriptions of the audio data were then organized to create week-by-week folders for each of the nine fellows.

*Survey Analysis*

Responses to the survey were analyzed using a mixed method approach, including classic statistics, exploratory data analysis, and coding of expository responses, as appropriate. The closed, Likert-scale items were entered into a spreadsheet, electronically counted and compiled into a distribution table. For the open-ended survey items, we used open coding schemes (Emerson, Fretz, & Shaw, 1995). In order to understand how the four partnering university preparation compared, we disaggregated both closed and coded open item responses by the partnering universities.

*Journal Analysis*

The three authors read and reviewed the data folders of the 9 fellowss. We then created one-page overviews that summarized the content that each program covered and activities the individual fellows engaged in on a week-by-week basis. From this we were able to successfully hone the content that each university program generally covered and, to a lesser extent, how this content was organized and presented. Within and across program comparisons of these overviews allowed us to examine both (potential) within program variation and to compare the four programs. These overviews were then analyzed in the context of five survey items that reported on the content and instruction of the four university programs.

**Results**

The MTFs at the four university partners report reviewing similar content in the preservice programs – approximately 1/3 of their time on general education issues (e.g., classroom management, lesson planning), 1/5 on mathematics content, 1/5 on mathematics teaching methods, 1/8 on multicultural education, and 1/10 on educational psychology. Special education received minimal coverage.

In spite of these commonalities, there were also significant variations in the preservice curricula at the four partnering universities, which we refer to as University A, B, C or D in order to organize the results. In particular, fellows at university A reported spending over half their time on general education issues. In their journals, the two MTFs at this university reported viewing a series of videos on classroom management and completing repeated assignments on lesson planning. University A MTFs reported spending less time learning about mathematics-specific teaching methods and mathematics content than MTFs at other university partners. They overwhelmingly evaluated their coursework favorably on the surveys. MTFs at University B spent more time on mathematics content, multicultural education, and mathematics specific teaching methods than the other three partners. Fellows at this program generally evaluated this preservice program negatively on the surveys. To be clear, these negative evaluations have been a result of many factors other than the content of the courses, such as university setting or quality of instructors. As a group MTFs at University B felt less prepared to handle classroom management issues than MTFs at University A – though they may be better prepared to teach mathematics.

In the survey data, the MTFs also reported significant variation in fieldwork experiences. To clarify, there was far more variation in fieldwork within programs than between program. While some MTFs report being in their summer school site for 75 or more hours, another group report completing less than 35 hours. They also appear to have had different opportunities depending on their fieldwork placement. A small number report teaching their classes more than 75% of their time instructing the whole class, while others report spending most of their time working with individual students or observing their mentor. (Still others were not placed in mathematics classrooms at all.)

Initial results from a follow up survey with those math Fellows who remained in teaching after one year provided additional insights about NYCTF summer preservice training. In particular, while most of these experienced MTFs were able to point to strengths of the program – fieldwork was the most oft cited strength – many MTFs reported that the summer program was too short, too accelerated, or too theoretical. That said, the majority of the “experienced survivors” felt prepared – though generally “not well prepared” – to teach their assigned courses. They were about equally split between those who felt prepared and those who felt poorly prepared to handle a range of management/disciplinary concerns and teach using a variety of instructional methods. That said, most did not feel prepared to teach mathematics to ELL students and those with learning difficulties.

## Discussion

The NYCTF program has had a profound effect on high needs NYC schools – replacing uncertified teachers in such areas in mathematics, science, and special education. The NYCTF program has also had a national impact; since its inception in 2000, a number of Teaching Fellows programs, modeled after the NYCTF program, have emerged in a number of high needs districts across the U. S.. While the extant research on alternative certification programs, including the studies of the NYCTF program, suggest that novice alternative route teachers are underprepared in comparison to novice traditional route teachers (who may also be under-prepared in some respects), we know little about the nature of alternative route teacher preparation – both in general and in mathematics in particular. That is, while the research literature points to significant variability in teacher effectiveness and retention, it says little about what type of preparation helps to produce effective teachers and how it might be a factor in keeping them in the classroom. This study begins to address this shortcoming in the existing literature on alternative route programs, in particular, those for urban mathematics teachers.

# AN EXPLORATION OF PRESERVICE TEACHERS' CREATION AND ANALYSIS OF FRACTION MULTIPLICATION WORD PROBLEMS

Tracy Goodson-Espy
Appalachian State University
goodsonespyt@appstate.edu

*This article reports on activities within a mathematics methods course designed to deepen PSTs' understanding of the multiplication of fractions. PSTs examined students' work concerning fraction multiplication from the National Assessment of Educational Progress. The PSTs then posed and investigated a set of multiplication problems in groups. These problems and the PST explanations of the solutions of these problems were analyzed. Results revealed features of PSTs' conceptions of fraction multiplication.*

## Background

Often, the arithmetic of whole and rational numbers, which forms the bulk of elementary school curriculum, is taught to PSTs in a maximum of 2 courses. A question we should consider is, *When preservice teachers emerge from an elementary mathematics methods class, what understandings do they possess regarding the multiplication of fractions (including improper fractions) and how will they approach instruction?* This paper describes an investigation of PSTs' responses to questions regarding multiplication of fractions. An instructional approach is described, as are findings concerning PSTs' responses before and after class investigations. These results are explored for implications concerning how best to develop and sequence tasks to help PSTs achieve a more profound understanding of fraction and mixed number multiplication. First, the relevant research literature is examined to provide a conceptual framework.

## Conceptual Framework

Ma (1999) contends that elementary teachers must understand elementary mathematics at a "profound level" (p. X) in order to be able to understand and apply knowledge of appropriate pedagogy. This is consistent with Sowder, Philipp, Armstrong and Schappele's (1998) observations that as teachers' gain in content and pedagogical knowledge, they view students as more capable and are willing to use student-centered teaching approaches. Thus, appropriate experiences in mathematics teacher education have a potential to affect instruction.

Researchers have explored several areas of fraction knowledge development in children and teachers. The development of the fraction concept in children has been explored (Keiren, 1993; Behr, et. al 1993, 1997; Steffe, 2004), as has the development of children's understanding of the multiplication of fractions (Fischbein, Deri, Nello, & Marino,1985), and preservice and inservice teachers' understanding of this concept (Harel & Behr, 1995; Post, Harel, Behr, & Lesh, 1991; Cluff, 2005; Iszak, 2006). Kieren (1976) postulated that fraction concepts were difficult for children to learn because they consisted of many subconcepts that must be constructed first, including partitioning (1993). Behr and colleagues (1993, 1997) expanded these notions in the *Rational Number Project* developing a theoretical model of fraction understanding based on the notions of part-whole, quotient, ratio number, operator, and measure. Recently, Charalambous & Pitta-Pantanzui (2007) used structural equation modeling techniques to study the understanding of fractions among 5$^{th}$ and 6$^{th}$- grade students in Cyprus using the Behr subconstructs as their theoretical frame. The findings confirmed theorized associations between the subconstructs. They also noted that, “a profound understanding of the different interpretations of fractions can uplift student’s performance on tasks related to the operations of fractions and to fraction equivalence” (p. 311).

However, other researchers contend that the Behr model considers fraction understanding from a “top-down” view of an instructional expert, rather than from a learner’s perspective. Hence, in a series of teaching experiments Steffe (2001, 2003, 2004), Steffe and Olive (2001) and Iszak (2006) pursued a separate line of investigation of the development of fraction concepts based on children’s thinking. Steffe’s model is based on the notion of conceptual units and nested levels of units, i.e. the standard part-whole approach to fractions illustrates two levels of units.

In early research concerning children’s understanding of multiplication, Fischbein, Deri, Nello, & Marino (1985) posited that the <u>intuitive</u> model for multiplication is repeated addition. The inherent issues associated with the repeated addition model is that it leads one to assume that the multiplier needs to be a whole number which leads to a further assumption that multiplication always yields a larger quantity. These results were confirmed in several studies that examined elementary school teachers’ knowledge (Graeber, Tirosh, & Glover, 1989; Harel & Behr, 1995; Post, Harel, Behr, & Lesh 1991) and demonstrated that they experienced difficulties in solving word problems where the multiplier was less than one.

More recently, Cluff (2005) defined three case studies of elementary PSTs that described their growth in knowledge concerning fractions, fraction multiplication, and fraction division during a mathematics methods course. Cluff’s study demonstrated that PSTs can exhibit an expansion of their conceptual understanding of fractions and fraction operations based on interactions with multiple representations. Another example of recent work is Iszak’s (2006) study of inservice teachers’ understandings of fraction multiplication which is described below.

Iszak (2006) examined the knowledge applied by two sixth-grade teachers (Ms. Reese and Ms. Archer) in the context of teaching fraction multiplication. The fraction concepts were situated in problems that use lengths and rectangular areas as fraction representations. Iszak’s case studies emphasized that the unit structures produced by these teachers fundamentally shaped the ways in which they used drawn representations and the extent to which they could adapt these representations. This study highlighted disconnections between teachers’ conceptual foundations of fractional multiplication, their inability to use various representations pedagogically, and the expectations of current curriculum in regard to teacher expertise.

## Purpose and Research Design

The purpose of the study is to assess PSTs’ understandings of fraction and mixed number multiplication in the context of an elementary mathematics methods course. The study employed an action research model as defined by del Mas, Garfield, & Chance (1999).

1. *What is the teaching/learning problem?* In addition to the literature cited, the paper describes PST’s responses to two situations intended to provoke discussion of their initial understanding of the concept of fraction multiplication. Fraction multiplication is initially explored by 1) examining a set of problems and student performance data from the National Assessment of Educational Progress (NAEP); and 2) placing PSTs in small groups and asking them to create word problems that can be solved by fraction multiplication and asking them to explain why and how the algorithm works. Examining

NAEP student performance data motivates PSTs and helps them focus their attention on developing sound problems in their small groups. I chose to have them develop fraction multiplication problems in groups based on the strategy employed by Ma (1999) in gathering information about teachers' understanding of fraction division by asking them to create a representative problem.

2. *What techniques can be used to address the learning problem?* Using prior research concerning PSTs' understanding of fraction division as a guide, and Crespo & Nicol's (2006) approach to developing a series of pedagogical tasks for PSTs in the context of division by zero, I designed a series of instructional tasks to assess PSTs' initial understandings of the multiplication of fractions followed by content and pedagogical instruction on the concept.
3. *What type of evidence can be gathered to show whether the implementation is effective?* Following a series of instructional activities, the PSTs answered extensive take-home test questions to assess their understanding of the concept following instruction.
4. *What should be done next, based on what was learned?* Based on results of PSTs' responses to questions about fraction multiplication before and after instructional interventions, I make recommendations for further study.

The research questions for the design and conduct of the study were:

1. How do prospective elementary teachers approach the multiplication of fractions, including mixed numbers, before, during and after instruction regarding the topic? What types of explanations do they use to justify their answers?
2. How do prospective elementary teachers respond to questions about the multiplication of fractions, including mixed numbers following an instructional sequence? Can they use arguments from the instructional sequence to help them solve and explain problems?
3. What do the results for Questions 1 and 2 suggest regarding instructional methods and the amount of instructional time required for PSTs to learn the multiplication of rational numbers (including mixed numbers) to the profound depth required for sound elementary instruction?

In order to assess the readiness of PSTs to provide conceptually-based explanations of algorithms (Ma, 1999) to their students, it is necessary to assess their ability to move beyond rule-based explanations of concepts and construct well-reasoned arguments themselves (Weston, 2000). Well-reasoned arguments explain a concept by: 1) providing examples or counterexamples that confirm or contradict given premises; 2) using deductive logic to test premises; and/or 3) providing an alternative representation that illustrates the concept in a new manner (Crespo & Nicole, 2006). It is also informative to examine the locus of control that appears to underpin PSTs' explanations. Specifically, is this locus of control internal or external?

## Participants and Setting

In the elementary teacher education program at Appalachian State University, PSTs are required to take 9 hours of mathematics and mathematics methods courses beyond general education. The subjects for this study were enrolled in Curriculum & Instruction (CI)-3030 – *Investigating Mathematics and Learning*, a methods course focused on the number and operation strand of the NCTM *Standards*. There were 71 participants in this study enrolled in four sections of CI 3030, two during fall 2006 and two during spring 2007—all four taught by the author. CI 3030 is a 3 hour class, meeting twice a week for 2 hours over 12 weeks, followed by an 8-day practicum in the elementary schools. The demographics of the participants were: 95% below the age of 25; 96% Caucasian; 2% African-American; 2% Hispanic; 94% female; and 6% male.

The paper describes only a portion of the first stage of the study— PST's responses to two situations intended to provoke discussion of their initial understanding of the concept of fraction multiplication. Fraction multiplication is initially explored by 1) examining a set of problems and student performance data from NAEP; and 2) placing PSTs in small groups and asking them to create word problems that can be solved by fraction multiplication, explaining why and how the algorithm works. The results of the after-intervention will appear in a separate paper.

## Data Collection and Analysis

The data included individual subjects' written responses to in-class tasks, individual reflection papers, and tests. The data included sheets of poster paper where groups recorded their responses to in-class tasks, and the instructor's observation field notes kept during two semesters and four sections of the course. The researcher categorized subjects' responses to pre-instruction tasks, in-class group activities, and after-instruction tasks looking for evidence of well-reasoned arguments. Groups were given task sheets on which to record the groups' main points.

The analysis of the PSTs' preliminary notions about fraction multiplication began by classifying their responses to the NAEP problems. Next, I classified the types of fraction multiplication problems they created in their small groups. Their initial responses to the question, *Why does the fraction multiplication algorithm solve your problem?* were grouped and coded by determining their correctness, their locus of authority, and their use of mathematical language and representations. The PSTs' responses to test questions are also described.

## Results: PSTs NAEP Problem and Analysis of Student Performance Results

The classes were given a set of 20 NAEP questions involving fractions to solve individually. (Four of these problems involved fraction multiplication and division and are discussed here. While the paper focuses on fraction multiplication, PSTs were asked to examine and think about fraction division within these problems, in order to help them compare and contrast these concepts.) Then, they were placed in small groups and assigned specific problems to discuss in more depth within the groups. The groups were given a page of questions to guide their discussion and were asked to record their answers. For each NAEP question that the group was asked to discuss, they were asked to respond to the following questions:

> *1) NAEP Problem Number; 2) Complete the question; 3) What math concept is being tested? 4) How is this concept being approached? 5) Does it relate to anything we have talked about in class, thus far? 6) How would you explain how to do this problem to students? 7) What percent of students would you expect to complete this question correctly? 8) What kinds of mistakes would you expect students to make on this problem? 10) How did the actual test results for the problem and the student work you examined compare to your predictions? Were you at all surprised by the results? Why or why not?*

The PSTs solved the problems, predicted erroneous student reasoning, and predicted students' performance results. They then discussed their predictions within small groups. After completing these activities, the PSTs were shown actual NAEP results, including examples of student work for the constructed response problem. PSTs were largely successful in solving these problems.

However, while many could solve the problems computationally, they were unable to provide an explanation of why they chose to use a particular algorithm, and were unable to explain how and why the algorithms work.

## Development of Fraction Multiplication Word Problems by Groups

As the class began the study of multiplication of fractions, I encouraged them to think about what they knew about the topic beyond the algorithms. The PSTs were asked to form groups and to write a word problem that would require students to multiply fractions. They were also asked to show the completed solution for their problem. The PSTs were asked to think about and record any materials, manipulatives, or diagrams that could be used to help explain their problem. They were not given any directions concerning whether they should use proper or improper fractions, or whether whole numbers or mixed numbers could be used. The following shows the list of problems created by the groups of PSTs.

## Fraction Multiplication Problems Created by Preservice Teacher Groups (in Class) During One Method Course

*Problem 1. Ms. Smith's class is going on a field trip. For their lunch* $^1/_2$ *of the students want a peanut butter and jelly sandwich. Of the* $^1/_2$ *who want peanut butter and jelly,* $^3/_4$ *of them want the sandwich with grape jelly? [sic]*
$^1/_2 \times {}^3/_4 = {}^3/_8$
*Models and Representations:* PSTs suggested actually modeling making the sandwiches. PSTs were confused when asked to model the problem in another way.
*Why does the fraction multiplication algorithm solve your problem?* "Well, you know you need to multiply because, 1) you see the word "of", and 2) you know only $^3/_4$ of the group wants jelly."
*Researcher's comments:* This group seemed unaware that their problem did not clearly state an actual question until this fact was pointed out by classmates. When asked if there were other ways of modeling the problem other than actually making sandwiches, the group seemed puzzled, as were several other students in the class. When asked, *What does* $^3/_8$ *represent?* The group explained that you get $^3/_8$ by "multiplying the numerators and putting that answer over where you multiplied the denominators together. $^3/_8$ shows how many students want jelly." Then I asked them, "OK, so if you are going to make the sandwiches with the class, how many sandwiches will you need to make?" There were some audible "Ohs!" as some students grasped the point of my question. During the subsequent discussion, we specified that the problem was really indicating that, regardless of the number of people in the class, and therefore the total number of sandwiches to be made, only $^1/_2$ of the entire class wanted peanut butter and jelly, and only $^3/_4$ of that $^1/_2$ wanted grape jelly on their sandwich. One preservice teacher then made the comment, "OK, so we're taking part of a part!"
*Locus of authority:* External
*Problem 2. There are 6 students in class, each student received and ate* $^1/_2$ *an apple. How many apples did they eat altogether?*
*6 x* $^1/_2$ *= 3*
*Models and Representations:* PSTs recommended modeling the problem with apples and showed a picture of six students, each with ½ of an apple.
*Why does the fraction multiplication algorithm solve your problem?* "You can see that if each of the 6 students gets $^1/_2$ an apple, then you can add $^1/_2$ six times and get 3. That's the same as saying 6 x $^1/_2$ = 3
*Researcher comments:* This problem was interesting because it showed the use of a whole number being multiplied by a fraction. It also provided an example of preservice teachers visualizing fraction

multiplication as repeated addition. The group's solution was also noteworthy in that it was written as 6 x $^1/_2$ rather than $^1/_2$ x 6 or "$^1/_2$ of 6".
*Locus of authority:* Internal. The locus of authority was judged to be internal with this group because they were focused on reasoning within the problem context rather than on the computational process.
*Problem 3. Margaret wants to make her Super-Puppy a cape. Her fabric is $^1/_3$ ft. long by $^1/_4$ ft. wide. How big is the cape?*
*$^1/_3$ x $^1/_4$ = $^1/_{12}$ ft.*
*Models and Representations:* PSTs provided a rectangular diagram to accompany their problem.
*Why does the fraction multiplication algorithm solve your problem?* "It makes sense to use an area representation here. So, we showed it was $^1/_3$ foot on one side and $^1/_4$ foot on the other side, and then we multiplied to get the answer."
*Researcher comments:* As the group read and explained their problem, they encountered some objections from their classmates, notably from one who sewed. "$^1/_{12}$ foot doesn't make sense." I asked the class what $^1/_{12}$ of a foot was and a student replied, "1 inch." Others in the class quickly agreed that $^1/_{12}$ of a foot couldn't be right. I then encouraged the class to think about how they could go about making Super-Puppy's cape. The seamstress pointed out that $^1/_3$ foot would be the same as 4 inches and that $^1/_4$ foot would be 3 inches and so the cape would be 12 *square* inches. Another student then pointed out that this was the same as $^1/_{12}$ of a square foot. At this point, several students stated that they did not think elementary students would understand this problem well because of the measurement complications.
*Locus of authority:* Both internal and external. I ranked this group's work as showing both internal and external authority because, while they attempted to make a diagram to support their computations, the diagram and subsequent discussion revealed that they did not understand completely what the diagram and computation represented.
*Problem 4. Maggie the mechanic had $^5/_6$ of a quart of oil. She only wanted to use $^1/_3$ of that quart. How much oil did she use? $^5/_6$ x $^1/_3$ = $^5/_{18}$*
*Models and Representations:* PSTs made a drawing of a jar with showing $^5/_6$ full and then drew another jar pouring out $^1/_3$. Then a third jar was drawn showing a lesser amount than $^5/_6$ labeled $^5/_{18}$. The PSTs also suggested using beakers and water to model the problem.
*Why does the fraction multiplication algorithm solve your problem?* "Maggie started out with $^5/_6$ of a quart of oil, then she used some oil, $^1/_3$ of a quart. So, we're showing how much is left in the bottle. If you multiply the numerators together and the denominators together, then you get that amount."
*Researcher comments:* The group explained their problem, its diagram, and the solution process to the satisfaction of their classmates. I then asked them why they drew a second jar, labeled with $^1/_3$. "Is this a separate container of oil?" I asked. The group replied, "No, it's really being poured out of the first one, but that's kinda hard to draw." I replied, "OK, can you show me where the 18ths come into play here?" Some of the group members pointed to the algorithm and explained, "It comes from multiplying 6 times 3." To which I replied, "OK, I see, but how can you show the 18ths in your diagram?" At this point, most of the class was puzzled, but a couple of students asked, "Could we use paper-folding here, instead?" (I account for this by some of the students having completed the assigned readings in the van de Walle text prior to class.) I encouraged them to try this approach, and following the creation of their successful model, we ended the discussion of this problem by discussing how the answer represented $^5/_{18}$ or nearly $^1/_2$ of one quart and we also discussed why this physical representation illustrated the solution better than the original drawings.
*Locus of authority:* Both internal and external. I ranked this group's work as showing both internal and external authority because, while they attempted to make a diagram to support their computations, the diagram and subsequent discussion revealed that they did not understand completely what the diagram

and computation represented. The locus of authority for some of the students changed to internal, however, as they decided to use the paper-folding model and could explain its significance.

*Problem 5. Izzy was making cookies. The recipe called for* $^1/_3$ *cup of flour. If Izzy wanted to make* $^1/_2$ *of the recipe, how much flour did she need to use?* $^1/_3 \times {}^1/_2 = {}^1/_6$

*Models and Representations:* PSTs recommended modeling with cups and flour and also made a drawing of a series of cups, showing $^1/_3$ of a cup with half of the contents marked out, and then a second cup showing $^1/_6$ cup of flour.

*Why does the fraction multiplication algorithm solve your problem?* "Well, the original recipe calls for $^1/_3$ cup of flour but since you're only making $^1/_2$ of the recipe, you only need $^1/_2$ that much. So, multiplying by $^1/_2$ is like dividing the recipe in half here."

*Researcher's comments:* The group commented that their problem was, "Sort of like one of the NAEP problems." They explained the problem situation and their application of the multiplication algorithm to solve it. The group was able to explain to their peers that the solution represented $^1/_6$ of one cup. When I asked them if they could show a different diagram, they were initially bothered until one student exclaimed, "We could use paper-folding here, too!"

*Locus of authority:* Both internal and external. I ranked this group's work as showing both internal and external authority because, while they created a diagram and could explain the context of the problem and its solution, they experienced difficulty in applying more than one representation to the problem. It is not clear that if they had not seen paper-folding used in the previous problem, whether they would have thought of using it here.

These problems and their solutions were recorded on large sheets of poster board with markers and posted in the classroom during our subsequent discussions. For the sake of brevity, only one set of word problems developed by the methods classes is explored. However, this class was extremely representative of the problems developed in the other sections. The author asked the PSTs to solve their problems and followed with a class discussion concerning why the fraction multiplication algorithm provided a correct answer to the problems they constructed. The PSTs, were asked to respond to the questions, *So what does this mean? Why does the algorithm solve your problem?* They were asked to respond to these questions within their small groups and record their answers on posters.

## Summary Analysis of the PST Created Problems

Analysis of the problems created by the groups reveals several interesting features. First, most of the groups wrote problems that used only proper fractions. Only one group chose to use a whole number in a problem and none of the groups chose to use a mixed number or an improper fraction. Second, at least one group in each methods class experienced some difficulty in writing a question that made complete sense either in terms of grammar, punctuation, or in phrasing an answerable question. Third, in choosing the numbers for their questions, most groups chose familiar fractions, such as $^1/_2$, $^1/_3$, or $^3/_4$. In our class discussion, I asked each group to explain how they chose the numbers for their problem. They commented that they chose what they thought were "easy numbers" and did not think ahead about whether the numbers they chose would be easy for them (or their students) to model or diagram. Fourth, until the groups developed their own problems, they did not appreciate the intricacies associated with choosing appropriate pedagogical models to illustrate fraction multiplication. For example, at the close of our discussion of Problem 1-The Sandwich Problem, I asked them what models we could use to illustrate the problem in place of making sandwiches. They did not appreciate the differences in using a set model versus an area model until we attempted to illustrate the solution in both ways.

After the problems were posted in the class, and prior to our discussions of each problem, we discussed as a group which problem they ranked as most difficult (Problem 1) and which they thought would be easiest for students (Problem 3). The PSTs thought Problem 1 would be the most difficult for students because of how it was worded and because three numbers appear in the problem. They chose Problem 3 as the easiest problem because they found the group's diagram easy to understand. At the close of the class, I asked them to re-rank the group problems. This time, they ranked Problem 2 as the easiest and Problem 3 as the most difficult. The responses reported in the preceding section are consistent with the types of responses I have encountered in several semesters of using such tasks in the methods class.

# PRESERVICE TEACHERS' REFLECTIONS ON THEIR INSTRUCTIONAL PRACTICES

Guney Haciomeroglu
Canakkale Onsekiz Mart University
guneyh@gmail.com

*Purpose of this study was to examine the nature of preservice secondary teachers' instructional strategies and views about teaching and learning mathematics as they planned and taught algebra lessons. The study also looked at how the preservice secondary teachers' views influenced their instructional practices as a result of their participation in reflection activities. The results of this study revealed that reflection activities helped the preservice secondary teachers identify strengths and weaknesses in their lessons and teaching. They also began to think about issues associated with planning, teaching, and assessment as a result of self-reflection and analysis their own thinking.*

## Introduction

Reflection is defined as looking at one's experiences, making connections with his/her thoughts and feelings, then utilizing in actions. Reflection-in-action is described as one's thinking about the teaching/learning process or when he/she is engaged in teaching. Effective reflection-in-action appears when one changes his/her teaching approach and recognize that his/her way of teaching is not working. Reflection leads to building new understandings to describe one's actions for teaching (Schön, 1983).

Reflection is viewed as a key element in an on-going learning process since teachers continue to learn about teaching and about themselves through reflection (Llinares & Krainer, 2006). In addition, learning to teach is a complex process that different factors (e.g., teacher's content knowledge, pedagogical content knowledge, organization of content for teaching) affect the nature of teachers' decisions before, during, and after teaching. In this process, reflection and development of reflection activities may enrich teacher's learning experiences and teaching practices as they become more effective teachers of mathematics (Kaminski, 2003). Davis (2006) suggests that tasks, allowing teachers to integrate different aspects of teaching such as learning, teaching and instruction, be used to promote productive reflections. To answer the question of what makes a reflective teacher, we need to focus on what types of experiences and tasks preservice teachers would need in order to become effective teachers of mathematics.

Curriculum reform for mathematics teacher education has been considered as a crucial aspect in education. With assistance from the World Bank, Development of Ministry of Education Project–Higher Education Council restructured Turkish teacher education programs to increase quality in all primary and secondary education programs in education colleges (Higher Education Council [HEC], 2007) and proposed two teacher education programs. One of these programs, offered under the guidance of education colleges, required high school students to take the nationwide university exam to enroll in this program. The other teacher education program, housed within education colleges, is designed for college graduates with a Bachelor's degree in mathematics. The latter is called Masters of Science degree without thesis (4+1), and in this program, preservice teachers are required to enroll in courses in two major areas: pedagogy courses and mathematics teaching methods courses.

I present data from a semester–long study conducted enrolled in methods courses. In an attempt to investigate how preservice teachers' views about teaching and learning of mathematics influenced their instructional practices, they were encouraged to plan and teach lessons collaboratively and participate in reflection activities. I describe the results of the study and discuss pedagogical implications of these results in a final section.

## Background

Research studies emphasized teachers' experiences as they develop and teach lessons as a focus for reflection (e.g., Jaworski, 1998). Over the past two decades, researchers (e.g., Artzt & Armour–Thomas, 1999; Artzt & Armour–Thomas, 2002; Shulman, 1986) have investigated the relationships between teachers' views and their instructional practices. In an attempt to answer the question of what makes a reflective teacher and explore the relationship between teaching practice and reflection, research studies (e.g., Fendler, 2003; Marcos & Tillema, 2006) have been conducted. Researchers (e.g., Jaworski, 1998) emphasized the importance of enabling teachers to reflect on their practice as a means for the improvement of mathematics teaching. However, these studies have been challenged to explain what has been learned (Darling-Hammond & Youngs, 2002).

On the one hand, Nicole and Crespo (2003, cited in Llinares & Krainer, 2006) suggested that introducing analysis and reflection through teaching practice provide preservice teachers with better opportunities to integrate theory and practice. On the other hand, research studies, conducted with preservice teachers in Turkey, revealed that preservice teachers were limited to discussions and reflections on teaching practices in their teacher education courses (e.g., Çakıroğlu & Çakıroğlu, 2003; Sahin–Taskin, 2006). Moreover, many teacher education programs in Turkey have provided preservice teachers with inadequate opportunities to engage them actively in developing and teaching lessons and to help them connect research and practice as well as develop research–based teaching strategies. I agree with Alp and Şahin–Taşkın that an increased attention should be given on research studies examining preservice teachers' reflections and practices in Turkish teacher education program.

## Theoretical Framework

This study is framed by the research of Artzt and Armour–Thomas (1999). Artzt and her associate posited a model with reflection activities (i.e., pre–lesson, post–lesson reflections, and self assessment) to facilitate preservice teachers' analyses of their views and instructional practices before, during, and after teaching. The model was influential in my descriptions of preservice secondary teachers' reflection activities and was also used as a guide as preservice teachers reflected on their instructional practices. For instance, the preservice teachers were asked to describe how they would teach their lessons by writing reflections on the following components suggested by Artzt and Armour–Thomas: (1) goals for students, (2) knowledge for students, (3) knowledge of content, (4) knowledge of pedagogy, (5) the teacher's role in the lesson, (6) the students' role in the lesson, (7) anticipated difficulties and (8) resources used to get ideas and criteria for selection. These items of the pre–lesson reflections were aimed at helping preservice teachers consider goals of the lessons for their future students. The four components (1–4) were used to encourage preservice teachers to utilize their content knowledge and pedagogical strategies to design their lesson. The three items on the list (5–7) were expected to assist preservice teachers to envision the engagement and interaction between the teacher and their future students, and to be aware and plan for possible difficulties that might occur during their teaching. The last item (8) was designed to encourage preservice teachers to utilize different resources to improve their knowledge and to consider alternatives to design their lesson.

## Methods

This study sought to examine the nature of the preservice secondary teachers' instructional strategies and views about teaching and learning mathematics as they planned and taught algebra lessons. Thirty–eight preservice teachers who were enrolled in secondary teacher education program at a university in the north eastern Turkey (i.e., Masters of Science degree without thesis) participated in the study. Data were collected through the preservice teachers' written reflections, activities, class discussions, and observations in a semester–long study. The preservice teachers were placed in groups of 2 or 3, and each group was asked to choose a topic in algebra. Although members of each group would be teaching the same topic, each preservice teacher was asked to plan and teach individual lessons with two components: 1) Teaching strategies (e.g., student–centered, teacher–centered, problem solving) and 2) Use of various teaching technologies. Since the preservice teachers had a lack of experience in designing a lesson plan, they were asked to use a lesson plan from Ministry of Education as a guideline. Having determined mathematical topics for their lessons and written reflections on the eight components suggested by Artzt and Armour–Thomas (1999), each preservice teacher taught his/her lesson in 25 minutes to their classmates acting as students. In post–lesson reflection, they were asked to reflect on the entire experience considering factors that influence their teaching and ideas to improve their lessons if they were to teach it again. These reflections provided perspectives about what factors influenced preservice teachers' planning and teaching as well as whether or not their views about teaching and learning of mathematics changed as a result of their participation in this study.

## Results

### *Pre–Lesson Reflection*

In the pre–lesson reflection, the preservice teachers discussed the resources such as materials, textbooks, and teaching strategies that they considered utilizing for their lesson planning and teaching. Twenty–seven preservice teachers emphasized that teacher-centered approach would be appropriate for their teaching. Eleven preservice teachers considered student-centered teaching strategy as an effective way to teach their lessons. Seven of these eleven preservice teachers considered using hands-on material for their lesson. Consider the following excerpts from their reflections:

*S1:* I think the most effective way to teach this topic is teacher-centered approach. I would first introduce the key concepts related to this topic. Then, I would solve examples to have students grasp the concept. At the same time, students would be asked to solve problems. Students should listen carefully and participate actively in class activities. I plan to teach my lesson using overhead, I think I would not have any difficult getting students' attention.

*S2:* In my lesson, role of a teacher is to introduce key concepts and then guide students to help them to learn by themselves. With this pre-knowledge, students could be active in the learning process and develop their skills. At the beginning of the lesson, I plan to use real life examples to attract students' attention to the lesson. I will include hands-on material to teach my lesson, but I am going to utilize discovery learning. I am going to ask them questions to have them involve in the lesson. My only concern about the lesson is interaction between me as a teacher and students. That is why I am thinking of using simple language to teach my lesson.

*S3:* I will be guiding the students in my lesson. I am going to help them to reach the goal by asking them questions. My only concern about this lesson is related to the examples. Students might have difficulty in solving examples and comparing their results. Since I will not use teacher-centered approach, it won't be difficult to get students' attention. In addition, student-centered approach would be extraordinary and enjoyable for them. I will give the key concepts and write notes on the board. After that I will start asking questions to students.

In his reflections, S1, a preservice teacher, thought that the most appropriate way to teach his lesson was to use teacher-centered strategy. He also wanted his students to be active in problem solving during his lesson. Therefore, he planned to use an overhead as a teaching technology to attract students' attention during his teaching. S2 considered student-centered teaching strategy with using discovery approach for her lesson. She said the use of simple language (e.g., describing concepts in her own words) in her lesson would help her increase interactions among her students. S3 wanted to utilize a student-centered teaching strategy for her lesson. She said it would be easy to engage her students in the lesson by using a question-and-answer technique in a student-centered approach.

All three preservice teachers were asked to consider the possible difficulties that might arise during their teaching. S1 thought that teaching the lesson with an overhead projector may not motivate his students to participate in the lesson. Both S2 and S3 were concerned about interaction between the teacher and the students. To prevent lack of communications among students and attract their attention for the class activities, the preservice teachers, S2 and S3 said they would create a student-centered learning environment.

Pre-lesson reflections were informative for the preservice teachers. The preservice teachers were given an opportunity to verbalize their ideas and concerns as they envisioned interactions among their students. Descriptions of pre-lesson reflections also provided opportunities for them to understand their envisioned practices and decision making processes.

*Post-Lesson Reflections and Self Assessment*

Most of preservice teachers were concerned about finding ways to make introduction of mathematics concepts interesting or strategies to interact with their students. Although the preservice teachers emphasized that the lessons could be taught using different teaching strategies, most of them claimed that their teaching strategies were more appropriate for their lessons. Twenty–seven preservice teachers described teachers as dispensers of knowledge and chose a teacher–centered approach for their lessons. The remaining eleven preservice teachers preferred a student–centered approach to guide student learning.

Regarding the weakness of their teaching, eighteen preservice teachers found rather difficult to implement the teaching strategies. Thirteen of them thought that they went over the key concepts quickly. Eleven of them were concerned about lack of communication between themselves as a teacher and their students. Seven preservice teachers had difficulty selecting appropriate examples. Following excerpts illustrate the preservice teachers' post-reflections on their teaching:

*S4:* I had a problem with my material. I wanted to put on the board but I had a problem with magnets. Somehow magnets did not hold the material on the board. I ended up spending too much time with material.

*S5:* I knew what I needed to teach, but I could not help myself going over to content quickly.

*S6:* I lectured the students. They were not active during the teaching because I did not ask any question.

*S7:* Number of examples I presented was not enough. I could not relate to real life. I should have solved more examples.

In reflecting on their teaching, the preservice teachers identified appropriate teaching strategies, introduction of the concepts, and communications with students as factors influencing their instruction.

Regarding the strengths of their teaching, one third of the preservice teachers said that that they had a good introduction and selected appropriate examples for their lessons. Some of the preservice teachers, who implemented student–centered teaching, were satisfied with the questions to engage students in the lesson. Few pointed out class management, interactions with students, and the use of technology as the strengths of their teaching. Consider the following excerpts:

*S8:* I did not have any problem introducing key concepts, but it would have been easier for students to understand if I had given examples that started from basic to more complex.

*S9:* I wanted to get the students attention at the beginning of the lesson but I could not say something to attract their attention. Overall, I was able to choose appropriate examples. I selected questions from easy to more complex questions. I believe they were good examples introducing the math content in a logical order.

*S10:* The best part of my teaching was students were active in the learning. That is why I chose student-centered teaching method. If I could teach this topic again, I would also include slides in my teaching.

*S11:* I thought material that I used was simple and fun. I thought I was able to have student involve and participate in their own learning.

The preservice teachers reconsidered several components of their teaching when asked what they would change if they had an opportunity to teach this lesson again. Eleven preservice teachers said that they would use different teaching materials (e.g., worksheets, transparencies) for their lessons. Six preservice teachers wanted to change their examples and pay more attention to interactions with students in their teaching. Due to their difficulties in communicating with students and engaging the class in the lesson, five of them said they would change their teaching strategies (see Table 1).

Table 1. *Preservice Teachers' Suggestions about Their Lesson*

| Changes on teaching | Frequency of responses |
|---|---|
| Pay attention to communication with students | 6 |
| Spend more time on contend | 7 |
| Changing teaching strategies | 5 |
| Selecting appropriate examples | 6 |
| Using different teaching material | 11 |
| Utilizing time efficiently | 3 |

Although the preservice teachers were given an opportunity to teach this lesson once, they expressed various components in their lessons and teaching that they wanted to change. Consider the excerpts from their written reflections:

*S12:* This was my first time for teaching. I could not manage the class well. I don't think I paid enough attention to my students. Overall students were listening. After my teaching I realized that it was very important to plan the lesson ahead of time. I lectured in my teaching but if I could teach it again I would use an activity to teach Cartesian coordinate system.

*S13:* I prepared various math problems, but I was not successful at engaging students in solving the problems. I should have practiced and utilized different questioning techniques.

*S14:* Presenting the concepts with manipulatives was beneficial but I did not spend enough time on introducing the key concepts related to my lesson topic. If I could teach again, I would have introduced the concepts slowly.

In their reflections, it appears that the preservice teachers observed the outcomes of their instructional decisions and actions in their teaching. As a result, they began to think about how mathematical concepts could be represented to teach effectively and consider utilizing teaching techniques, instructional materials, and activities to actively engage students in learning mathematics.

## Discussion

In Turkish teacher education programs, preservice teachers take internship, called School Experience, to be prepared for teaching and exposed to various aspects of the profession under the guidance of both supervisor and cooperating teacher. Preservice teachers are expected to observe mathematics classes and write reports about the entire experience at their internship schools. Preservice teachers do not receive much benefit from classroom observations. Having stated that preservice teachers' internship experiences involving only class observations do not prepare them for teaching and preservice teachers must actively participate in classes by assisting teachers and students, we as educators can create a rich learning environment in which preservice teachers are encouraged to develop lessons collaboratively and teach to their students. In methods courses, preservice teachers should be challenged with issues associated with planning, teaching, and assessment that emphasize self-reflection focusing on the analysis of the teacher's own thinking and dealing with students in a way to plan their education (Ticha & Hospesova, 2006).

In this study, prior to their internship in schools, the preservice teachers gained experience in planning and teaching lessons as they worked with their classmates collaboratively. By reflecting on their teaching and observing different teaching strategies, they identified their weaknesses and strengths in their lessons, and analyzed issues in teaching. It was observed that with the reflection activities, the preservice teachers had opportunities to work together to refine and revise their lessons and improve their teaching.

The model of Artz and Armour–Thomas (2002) provides an insightful framework to describe preservice teachers' analyses of their views and instructional practices before, during, and after teaching as well as assessment of their thoughts and decisions in a structured way. Under the supervision of their professors or supervising teachers, this model could be an excellent tool for professional growth, and preservice teachers utilize this model to assess and reflect on their teaching in a structured way. If preservice teachers get used to thinking about their lesson in such a structured way, it could become a natural part of their reflective practices.

# PRESERVICE TEACHERS' DEVELOPMENT OF WHOLE NUMBER CONCEPTS

George J. Roy
University of South Florida-St. Petersburg
georgeroy@earthlink.net

As learning unfolded in an elementary education mathematics classroom, a classroom teaching experiment was conducted to document preservice teachers'(PST) development of whole number concepts (Cobb, 2000). The development of PSTs' understanding of whole number concepts was emphasized in this study for two reasons. First, whole number concepts are a core component of elementary school mathematics; therefore, the importance of whole number concepts is inherent on future mathematics learning (National Council of Teachers of Mathematics, 2000). Second, PSTs entering the profession need a depth of knowledge necessary to support children's unique understandings of whole number concepts (National Mathematics Panel, 2008, National Research Council, 2001).

As stated by Hopkins and Cady (2007), familiarity with base-10 can prevent adults from fully comprehending various whole number concepts, as such, this study had PST's participate in an instructional sequence where learning tasks were situated in base-8. By having the PSTs reason solely in base-8, it provided them a similar mathematical experience to children learning the same concepts in base-10. In addition, the results of this study found that many of the PSTs reasoned in base-8 in similar ways that children reason in base-10, such as making mathematical connections between place value, number sense, properties of operations, and conservation of number (Huinker, Freckman, & Steinmeyer, 2003; Kamii, Lewis, & Livingston, 1993). Most importantly, PSTs were able to reconceptualize their understanding of whole number concepts, and as a result, strengthen their conceptual understanding of children's unique ways of thinking.

# PEN-PAL PARTNERSHIPS IN THE PREPARATION OF PRE-SERVICE TEACHERS

Angie Conn
Virginia Tech
aconn@vt.edu

Research on posing mathematical tasks has focused on student-independent task analysis (e.g. Silver, 1996). In contrast, this study used student-dependent analysis by studying responses to mathematical tasks. Continuing the work of Norton and Rutledge (2007) and Crespo (2003), this research examines NCTM process standards (NCTM, 2000) and levels of cognitive demand (Stein et al., 2000), elicited by tasks designed by preservice teachers (PSTs).

PSTs enrolled in a mathematics course were partnered with precalculus high school students and exchanged 6 biweekly letters. In the letters the PSTs posed discrete mathematics tasks seeking to elicit NCTM processes and high levels of cognitive demand, the highest of which is 'doing mathematics' (Stein et al., 2000). The PSTs attempted to predict the NCTM processes and levels of cognitive demand in which their student partners would engage. They later assessed students' actual responses. This arrangement provided PSTs with an authentic experience in designing individualized tasks and analyzing student thinking.

In this 3rd iteration of the study, PSTs engaged in weekly letter-writing workshops in which they shared student responses and worked together to make inferences about the students' mathematical thinking. At the conclusion of the project PSTs completed surveys on their experiences. Our research team is using this data to answer the following questions:

- Did the project help PSTs pose tasks that elicited more processes and higher levels of cognitive demand?
- What factors led to elicitation of processes and high levels of cognitive demand?
- Did the PSTs' predictions of responses improve?

Preliminary results from analysis of PST feedback show a positive response to the project; they found it valuable in learning to pose mathematical tasks and investigate student thinking. Ongoing data analysis will compare processes and levels of cognitive demand elicited from week to week, as well as identifying important factors in PSTs' growth.

# THE ROLE OF TEACHER IDENTITY IN LEARNING TO ATTEND TO STUDENT THINKING IN MATHEMATICS TEACHER EDUCATION

Jill Neumayer DePiper
University of Maryland
jmndp@umd.edu

Ann R. Edwards
University of Maryland
aedwards@umd.edu

Classroom teachers and researchers suggest that understanding student identity, including beliefs, dispositions and self-understandings, may allow classroom teachers to better meet the needs of students as learners. Similarly, teacher educators also need to understand their students—teacher candidates (TCs)—as learners to better prepare them to teach. Research has shown that teacher identity influences a teacher's instructional decisions and shapes whether and how teachers construct and take up professional learning opportunities (Collopy, 2003). Comparing case studies of TCs in two elementary Masters-credential programs, we investigate how their *identity as narrative activity* (Sfard & Prusak, 2005) shapes their participation in practices constituting *attention to student thinking* (Kazemi & Franke, 2004) in math methods courses. Sfard and Prusak (2005) frame the activity of identifying as fundamentally discursive, and define identity as "collections of stories about persons… narratives that are *reifying*, *endorsable* and *significant*" (p. 16, italics in original). This narrative-defined identity can be useful, even as people define their identity differently to different people, because it is "the activity of identifying rather than its end product that is of interest to the researcher" (p. 17).

The two programs in the study attract TCs with different personal and professional backgrounds and structure their field experiences differently. The math methods courses in both programs have the same instructor, goals, activities and assessments. Data consist of video recordings of all course sessions, TCs' course assignments, observations of TCs' teaching, and interviews with selected TCs. Analysis utilized methods of narrative and story analysis to characterize how the TCs see themselves as teachers and learners, grounded theory to develop categories for TCs' participation in the practices of the methods courses, and comparison across case studies to reveal key relationships between aspects of identity and participation.

The poster will highlight how identity as narrative mediates how TCs are able to learn to attend to student thinking and how they integrate experiences with student thinking into their narrative identities. Our analysis reveals three trends: (1) TCs who see themselves as teachers and their work as teaching, rather than someone who is "learning to teach," situate their analyses of mathematical thinking in their broader experience with students; (2) TCs whose vision of mathematics teaching is centered around promoting student engagement tend to approach attention to student thinking as an assessment of the effectiveness of an activity; (3) For TCs who describe their own mathematics learning experiences as personally damaging, engaging in mathematics through student work supported the redefining of their relationship to mathematics.

# HOW PRE-SERVICE TEACHERS NOTICE PROPERTIES AND WHAT WE CAN LEARN FROM IT

William A. McGalliard
University of North Carolina - Greensboro
wamcgall@uncg.edu

Sarah Berenson
University of North Carolina - Greensboro
sarah_berenson@uncg.edu

Kerri Richardson
University of North Carolina - Greensboro
kerri_richardson@uncg.edu

Early algebra is a topic that is of great interest in the mathematics education community. Pattern finding is an aspect of early algebra that is particularly important in the elementary school. Property noticing is the fourth level of the Pirie and Kieren (1994) theory [PK] of growth of mathematical understanding following image having. When students notice properties it is usually closely associated with the image that they have constructed from the previous levels. They are now about to take that image and begin to identify special phenomena or properties that might be attributable to it. An example would be when a student is able to take an image of ½ and ¼, noticing that ½ > ¼ and that adding these two quantities requires a sum greater than either one. These are properties of fractional addition of unlike denominators that a student may notice. The focus of this case study is to determine what properties a pre-service teacher [PT] notices in a teaching experiment that focused on algebraic reasoning. In this case, algebraic reasoning refers to the ability of the PT to generalize and justify rules that describe patterns. In this analysis the sources of data are Edy's transcripts and written class work from a three-week teaching experiment. Elementary pre-service teacher Edy, a pseudonym, was a 21 year-old Caucasian female in her first semester and had not student taught. Edy was selected for study because her algebraic reasoning was strong even at the beginning of the teaching experiment and she was able to quickly and efficiently generalize and justify rules of the patterns involved. The transcripts were examined and coded for instances of property noticing, with a second coder brought in to assure inter-rater reliability. Then the coded items were examined for common themes. To begin with her property noticing took the form of recognizing properties in the model that she was constructing.

> Edy: Because each time one [block] goes together, you lose two sides. Because here's a side and here's a side and put them together and you lose two sides.

Over time the properties that Edy noticed became increasingly mathematical.

> Edy: Yeah. So, the pentagon's going to be 3n plus two. Because there is a pattern. 1N plus two, 2N plus two, 3N plus two.

Edy noticed properties in a variety of ways that include but are not limited to: recognizing a property of the model, recognizing a pattern in the model, simplifying a pattern in the model, noticing a similarity between two models, or noticing an error in the model.

Property noticing as a level within Pirie and Kieren's growth of mathematical understanding is an important element in educational theory that could inform our practice. If there are certain properties of a task that the PT recognizes, then there could be ways for the PT to encourage learners to find them. This could have bearing upon the way in which we construct our teacher preparation curriculum. Applications can be made to the way that the content is presented and to the way that we question and encourage our pre-service teachers.

# PRESERVICE TEACHERS' PERSPECTIVES ON A CULTURAL DIVERSITY MATHEMATICS ASSIGNMENT

Dorothy Y. White
University of Georgia
dywhite@uga.edu

Tonya Brooks
University of Georgia
tcw2b6@uga.edu

Nicholas Cluster
University of Georgia
ncluster@uga.edu

Kanita DuCloux
University of Georgia
kducloux@uga.edu

This study examined preservice teachers' perspectives on an assignment designed to prepare them to teach in culturally diverse mathematics classrooms. Three cohorts (n=76) of elementary and middle school preservice teachers were asked to research the available literature for an article that specifically addresses the teaching of mathematics to students who are culturally different than themselves. Data were collected from the written reports that specifically asked students to answer the following questions: why did you choose the article, what are the cultural differences between you and the culture(s) discussed in the article, and what is the value of using the strategies discussed in their article. Data was analyzed, coded, and categorized using analytic induction.

*Why this article?* Most preservice teachers chose an article for their *professional preparation* because they felt it would help them become better teachers. Preservice teachers that wanted to learn about a different culture were placed in the *personal gain* category. Lastly, as the title suggest, some preservice teachers chose an article for *both professional preparation and personal gain*. An example of this type of response is, "Latinos are [a] different culture than my own. I do not know very much about Latino education and home life. With the trends in [this state], more Hispanic children will be in schools. This article will give me an idea of how to relate to this different culture." Three students did not answer this question.

*How is the Culture Different*? Eight categories were mentioned as cultural differences between the preservice teacher and the culture they chose to study. Schooling issues such as instructional strategies, curriculum, resources, tracking, class size, and teacher expectations was cited the most (19%). Racial differences (17%), geographic location (16%), language (14%) and Socio-economic status (13%) were next among the most commonly mentioned cultural differences. Differences in family (size, parenting, structure) and customs (birthdays, traditions) were both mentioned by thirteen percent of the preservice teachers. Comments related to differential societal views about cultures (labeling, racism, prejudices) were mentioned by 3% of the preservice teachers.

*What is the Value*? Most preservice teachers found the teaching strategies as having *student value* (i.e., making mathematics more enjoyable and increasing student self-confidence). Thirty-eight percent discussed the *professional value* of the strategies, such as a better understanding the students. About 27% of preservice teachers assigned *conditional value* to the teaching strategies, discussing how the strategies helped certain groups such as English Language Learners. Finally, 5% of preservice teachers discussed the *personal value* of the teaching strategies.

The finding from this study are encouraging and suggest that preservice teachers want to learn ways to reach all of their students. Although their reasons may vary, preservice teachers want opportunities to explore multicultural activities in their mathematics methods courses.

# SUPPORTING TEACHERS' DEVELOPMENT OF COHERENCE THROUGH A FOCUS ON MATHEMATICAL STRUCTURE

Jason Silverman
Drexel University
silverman@drexel.edu

Ellen Clay
Drexel University
elc37@drexel.edu

*We present our emerging model for supporting the development of coherence in teachers' mathematical understandings. Key to this model is the notion that coherence involves coming to see a variety of mathematical ideas as conceptually and structurally related and that while teachers are aware of particular examples that employ a particular mathematical structure, they are unaware of the benefits of connecting the examples. We report on our efforts to support teachers in making these connections in an online content course for teachers.*

## Objectives and Purpose of the Study

The importance of teachers' mathematical knowledge has been well documented in the literature (Ball, 1993; Bransford, Brown, & Cocking, 2000; Ma, 1999; Shulman, 1986) and increasing teachers' mathematical knowledge continues to be a major focus in both education research and policy (Greenberg & Walsh, 2008; National Mathematics Advisory Panel, 2008). Despite the fact that there is widespread agreement as to the importance of teachers' mathematics knowledge, there is little consensus as to the particular content and structure of that knowledge. In this paper, we will discuss a perspective on the question of the mathematical knowledge that is needed for teaching mathematics in which teachers learn mathematics as a coherent and interconnected system of ideas. We focus on a segment of teacher professional development that was designed to support teachers' developing deeper and more sophisticated mathematical understandings that will position the teachers to make connections between a variety of mathematical ideas regularly taught in middle and high school mathematics courses. In particular, the focus of this paper will be how an explicit focus on the mathematical structures of sets, operations, and equivalence relations can serve as a catalyst for conversations that support coherence in teachers' mathematical understandings.

## Theoretical Framework

Ball and her colleagues (Ball, 1993, 2007; Ball, Hill, & Bass, 2005; Ball & McDiarmid, 1990) have focused on understanding the special ways one must know mathematical procedures and representations to interact productively with students in the context of teaching. Their pioneering work has succeeded in identifying a statistical relationship between this *mathematical knowledge for teaching* (MKT) and student achievement (Ball, et al., 2005; Hill, Rowan, & Ball, 2005). We extend this work by focusing not only on particular mathematical understandings but also the conceptual structures within which those particular understandings lie. Our reason for this focus is pragmatic:

> If a teacher's conceptual structures comprise disconnected facts and procedures, their instruction is likely to focus on disconnected facts and procedures. In contrast, if a teacher's conceptual structures comprise a web of mathematical ideas and compatible ways of thinking, it will at least be possible that she attempts to develop these same conceptual structures in her students (Thompson, Carlson, & Silverman, 2007)

Rather than focusing on identifying the mathematical reasoning, insight, understanding and skill needed in teaching mathematics, we focus on the mathematical understandings "that carry through an instructional sequence, that are foundational for learning other ideas, and that play into a network of ideas that does significant work in students' reasoning" (Thompson, 2008). We refer to these understandings as *coherent* understandings: powerful, generative "big ideas" from which an understanding of a body of mathematical ideas and its relation to other bodies can emerge.

It is important to note that coherence is not a characteristic of one's understanding of a particular mathematical idea, for coherence in curricula or students' understandings depends on the way in which they fit together (Thompson, 2008). This notion of coherence problematizes traditional mathematics teacher education efforts that seek to support teachers in "gain[ing] the ability to do the mathematics…and understand[ing] the underlying concepts so they will be able to assist their students, in turn, to gain a deep understanding of mathematics" (Musser, Burger, & Peterson, 2008). When a focus is on coherence, the emphasis is not just on doing and learning "the mathematics," but rather on developing a scheme of understanding within which a variety of mathematical ideas are connected and that can serve as a conceptual anchor for mathematics curricula and instruction.

In this article, we discuss our emerging model for supporting pre- and in-service teachers as they deepen and extend their mathematical understandings and develop schemas within which a variety of mathematical ideas are conceptually connected. First, we begin by exploring mathematical ideas that the teachers teach regularly and ostensibly know well. We then seek to problematize their current mathematical understandings by presenting the abstract mathematical structure that lies behind the math they teach and orchestrating conversations about examples from different mathematical contexts that have similar mathematical structure. We feel the shift to a higher level of abstraction is essential for two reasons. First, it is at this level that the mathematical ideas fit together—on the surface there is little similar about two numbers being equal and two polygons being congruent. It is only when one explicitly focuses on the mathematical structure that the similarities between examples or contexts can "do work" for teachers. It is our goal that teachers come to see the hundreds of concepts that make up the school mathematics curriculum as entailing a small number of big ideas that they can then orient their instruction around. Further, as they learn to engage with these big ideas and mathematical abstractions, they are developing a mode of discourse that they can use as they engage with particular examples of the big idea that can support students coming to see the connections. Second, following Blanton (2002) it is often the case that teachers need to legitimately engage and grapple with mathematical ideas to actually *think mathematically* and that is hard to do in contexts that the teachers (believe they) know well.

## Setting and Participants

In this article, we will discuss the first two weeks of 10-week course titled *Geometry and Geometric Reasoning*. This online graduate course is a content-based course required for the master's degree program in mathematics education at a university in the Northeastern United States. The course was developed and taught by the authors. Tasks and activities were taken from the *Re-Conceptualizing Mathematics* program (Sowder, Sowder, & Nickerson, 2008) and the authors' personal repertoire developed over a combined 25 years of work in mathematics teaching and teacher development. The data for this paper comes from one iteration of our

Online Asynchronous Collaboration model (Clay & Silverman, 2008a, 2008b) and includes private solutions, revisions, and commentary as well as discussions focused both on individual problems and emergent issues (Clay & Silverman, 2009).

The first two weeks of the geometric reasoning course focused on polygons and transformations. We began with the assumption that the teachers were familiar with, and teach or have taught, the ideas of congruence and transformation of polygons. We also assumed that, consistent with typical texts, instruction and state standards, teachers' understandings of congruence was grounded in the idea that congruent polygons have "the same size and the same shape." In addition, almost all teachers were familiar with the rigid transformations of reflection, translation, and rotation.

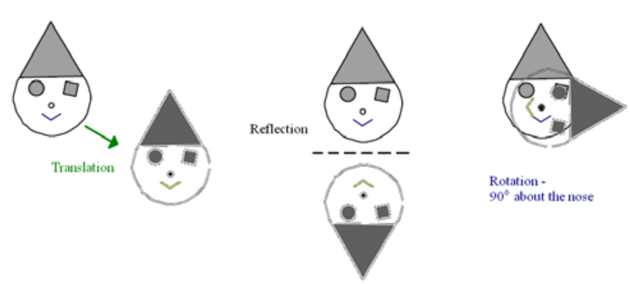
We began the unit by providing opportunities to explore mathematical ideas that the teachers currently teach and were ostensibly familiar with. For example, we initially focused on "standard" problems of the type: "given a polygon and a transformation find the resulting polygon." We then pushed on teachers' current understandings through focusing on the other half of the bi-relational relationship: "given two congruent polygons, you can find the transformation that transforms one to the other." Our goal was then to support teachers in relating their work and developing understandings of transformation to more abstract mathematical ideas like operations on transformations, composition of transformations, and properties of "the set of transformations" such as the set being closed (A set $S$ is closed under the operation $\circ$ if for all $a,b \in S,\ a \circ b \in S$ . Finally, students were asked to re-examine their understanding of congruence by redefining it from "same size, same shape" to "there exists a rigid transformation" from one polygon to another and explore the implications of this new understanding.

## Analysis and Results

*Engaging with the Mathematics*

Teachers were familiar with the notion of transformation and each was able to translate, reflect, and rotate figures in the plane. On a task that asked the participants to translate, rotate, and reflect a given figure, most provided diagrams consisting of the original image and the transformed image and few provided descriptions or explanations of what they did. A paradigmatic example of such a solution is provided below (all names are psuedonuyms).

Quinn: Working with Mr. Conehead here, I've performed the three transformations:
He was translated along the green vector.
He was reflected about the black center line.
And then he was rotated about his nose.



When engaging with the mathematics they teach, participants' posts were mater-of-fact descriptions of what they did. When the class discussed the posts, there was little conversation about the mathematics – conversations were either affective ("I really liked your diagrams") or focused on the technology used to generate the transformations (grid paper, Geometer's Sketchpad, Adobe Photoshop). Examples included:

Carla: I love that you named him! Anywhoo... I was wondering what you used to make your pictures. They are very nice.

Adam: Yours look like perfect replicas....where you able to copy them or did you draw them? If you were able to copy them, how did you do so? The only thing missing for your rotation is the point that its rotated about

Una: I enjoy looking at your work because it is easy to understand. I never thought of using Adobe Photoshop.

Opall: Did Photoshop do everything? If so, would you allow your students to use it or make them follow the directions in the book and produce accurate hand drawn transformations?

It has proven tremendously difficult to orchestrate generative mathematical conversations around mathematical content that teachers' believe they know well. This result is consistent with Blanton (2002), who noted the importance of "legitimate mathematical situations" in supporting teachers' mathematical and pedagogical development. While initial engagement with mathematical tasks that teachers are comfortable with has proven not to be a site propitious for the development of more coherent understandings, it has proven to be a good jumping-off point for discussions that focus explicitly on coherence in mathematical understandings.

*Mathematical Abstraction #1: The Set of Transformations and Operations on that Set*

While participants were familiar with transformations, the idea of transformations as a set that we could define an operation on was unfamiliar territory for the majority of the students. The following three excerpts demonstrate the 'newness' of the idea along with connections the teachers are able to make to something that they do 'know' and teach.

Carla: I also never heard the terminology "composition" of two motions. I remember in high school doing multiple transformations to an object, but the word "composition" never came up. To me in school it would be doing multiple translations, not doing a single translation with multiple steps as this suggests. I found that interesting, and created a shift in thought for me.

Wendy: I have taught reflections, rotations, and translations, but I had never heard of compositions either. I had always treated them as separate motions. But when I think about it, asking the student to use compositions forces them to see the big picture as the sum of the parts. I think both viewpoints are important to get a true understanding of what is happening. The student needs to see the whole as well as its parts.

Therin: Carla, I also don't remember learning about composition of rigid motions before. I am more familiar with composition of functions from teaching Algebra 2. I have a hard time thinking about the composition of rigid motions as a single rigid motions...

Carla admits that she's never heard of "composition" of two motions, although she has literally done the steps of composition. Wendy follows by saying she's taught translations but never heard of compositions. Again, she has done and taught the steps of the composition, just never heard of or used the mathematical terminology. She uses what we believe to be informal, everyday language to describe composition as the "sum of the parts." We believe it to be informal rather than making the connection here that 'summing' is also an operation. Finally Therin makes the connection to composition of functions from teaching Algebra II and is trying to come to terms with this new idea.

In the above excerpts, we see teachers engaging in mathematical discourse and thinking about mathematical abstractions in the context of transformations that they ostensibly already know. We believe that it is significant that these conversations do not take place in the context of school mathematics, but require moving beyond school mathematics and problematizing teachers' mathematical understandings (Cobb & Bauersfeld, 1995). Although we are only claiming at this point that we have problematized the participants understanding, the teachers each claim new understandings of some kind—Carla a shift in thinking, Wendy an impact on her teaching, and Therin connections between algebra and geometry.

*Abstraction #2: Equivalence Relations*

Another example in which students had knowledge but not coherence was in the study of congruence. Teachers are almost universally familiar with the informal notion of congruence of polygons as polygons that have "same size, same shape," and while this notion works for most of school geometry, it is not generative and does not easily generalize beyond the particular case of school geometry. It is possible to define congruence more formally using transformations: two polygons are congruent if there exists a rigid transformation that maps one onto the other. Intuitively this definition of congruence makes sense to the participants, but when asked to explore congruence more abstractly through the equivalence properties—reflexive, symmetric, and transitive—participants are challenged to reconcile their prior understandings with this new notion of congruence. As an example, consider the following posts in response to the task:

Use the meaning of congruence from the transformation point of view to decide:

a) If Shape 1 is congruent to Shape 2, is Shape 2 congruent to Shape 1?
b) If every shape congruent to itself?
c) If Shape 1 is congruent to Shape 2 and Shape 2 is congruent to Shape 3, is Shape 1 congruent to Shape 3?

*Figure 1*. Congruence Task

Adam: The definition of congruent: Two shapes are said to be congruent if one can be transformed into the other through isometry. Since, the definition clearly states two shapes, a single shape cannot be congruent to itself. …Yes, a = a, and 7 =7 and pi=pi, but those are values...not shapes. To say that a shape is equal to itself, seems silly to me. A shape is inherently discrete...from my perspective. So, to say it is equal to itself just seems improper.

Carla: Congruence, by definition, is similar but not the same. When explaining to my students the difference between "equal" and "congruent" I tell them that two congruent objects are so because their properties are the same, same lengths, angles, measurements, etc, but they are not equal because the two objects are still two different objects. They go by different names and in the real world two objects are different because they both occupy their own space. Comparing an object to itself is, what I would think, crossing over from congruence to equivalence.

Pearl: Carla – [C]ongruence and equality…are not the same, but they are related. I know when I have done them with my classes, we use the two kind of interchangeably. Shapes or parts of shapes would be congruent, and the measures are equal. So for example, two angles are congruent if they have the same measure and conversely, if two angles have the same measure, then they are congruent. For my geometry classes, that has been an important part of proving different statements.

Carla: I agree with you completely. I am just not convinced that a shape is congruent to itself. …[The] history that I found also said that the words "equals" and "congruent" throughout the last 4 centuries has been interchangable in translations of Elements. This has basically reinforced that they really are the same. In all this searching I didn't find anything that conclusively stated why we have the separate terms, but I would like to believe that there was at one time a reason. Why, if we specify different terms for equivalence in Geometry verses Algebra, don't we have different terms for addition? Or other operations?

In these posts we see evidence of the teachers' struggling to make sense of the mathematics at hand and reconcile it with their current understandings. We see Adam relying on the definition of congruence "from a transformation point of view" and concluding that this definition implies that a shape cannot be congruent to itself, apparently neglecting the identity transformation (which he was familiar with in other contexts such as the real numbers under addition or multiplication). Interestingly, his post also makes clear the most problematic issue that participants have with this task: "a = a, and 7 =7 and pi=pi, but those are values...not shapes. To say that a shape is equal to itself, seems silly to me."

Looking beyond Carla's informal and unfortunately mathematically incorrect use of the term *similar*, Carla expresses a similar sentiment as Adam, noting that the congruence has to do with the space the objects occupy. She is falling back on her intuitive knowledge rather than the mathematical definition of equivalence. As with many students the intuition comes from her first experience with equivalence, equality. Pearl shifts the conversation to how equality and congruence are really saying similar things, but apply to different kinds of things: "Shapes or parts of shapes would be congruent, and the measures are equal." We believe that Pearl is using the term "measure" to indicate particular values a measureable quantities can take on—in other words, real numbers. She is however not demonstrating clarity as she states, "we use the two interchangeably." We then see Carla still struggling with the different "kinds of equivalence" and posing a potentially significant question: "Why, if we specify different terms for equivalence in Geometry verses Algebra, don't we have different terms for addition? Or other operations?" We do not have data to claim that Carla understands the significance of the question she is asking, but she is asking about what else she might know that is only an example of something bigger and seeking coherence through that bigger idea. Finally, Nora seems to have come to terms with the definition of congruence but is wondering how and when one would decide to use it.

In these excerpts, we see teachers' impoverished understandings of equivalence and the beginnings of a discussion that holds the potential for supporting teachers in moving towards more generative understandings. Their subjective, qualitative notion of equality and congruence as "some kind of sameness" works for particular cases/examples. However, understanding congruence as an equivalence relation supports teachers in helping their students connect aspects of geometry, algebra, functions, etc.

## Discussion

Above, we argued the importance of teachers' coherent mathematical understandings. We have seen teachers willing and able to engage with the broad topics (transformations and congruence) at a limited level: given a particular transformation, they were able to perform that transformation. This activity was not problematic and they were willing and able to relate it to mathematics they already 'know' and teach. It is also clear that as the participants began to engage with transformations and equivalence at a higher, more connected level, they began to become less sure of their understandings. It is important to note that their confusion did not lie in the particular school mathematics ideas; rather it was in the mathematical connections between the school mathematics topics that the confusion became evident: *What do you mean you can compose transformations? Equality and congruence are the same thing?*

At its most basic level, transformations and congruence are mathematical ideas to be taught, but we argue that the significance of these topics for teachers does not lie simply in teaching transformations or congruence. Both are examples of larger mathematical ideas—an abstraction—that it is evident the teachers were not consciously aware of. Transformations *are* functions that map $\mathbb{R}^2 \to \mathbb{R}^2$. Congruence *is* an equivalence relation. While teachers are likely to have experience with transformations and congruence and *may* have some level of familiarity and experience with functions and equivalence relations, they are less likely to be aware of the various different ideas and contexts from which they are abstracted, how they are related, or the value of seeing the relatedness. It is this aspect of understanding—understandings of the ways in which a variety of ideas and contexts fit together—that makes one's understandings coherent (Thompson, 2008).

It is important to acknowledge that we cannot make claims that these experiences have supported our participants increasing their coherence in understandings of transformations, functions, congruence and equivalence—we do not have access to data that would allow us to make that claim (though we are currently involved in a study designed for that purpose). What we can say is that we have created an online system consisting of tasks and an interactional space within which mathematical abstractions of school mathematics ideas problematize teachers' mathematical understandings and support legitimate mathematical engagement. Further, engagement in conversations about the mathematical abstractions of day-to-day school mathematics was able to focus on how the specific examples of the abstractions are related and, thus, holds the potential for participants to develop coherence among previously unconnected mathematical ideas the teachers are currently teaching.

# MATHEMATICAL KNOWLEDGE FOR TEACHING EXHIBITED BY PRESERVICE TEACHERS RESPONDING TO MATHEMATICAL AND PEDAGOGICAL CONTEXTS

Aaron Brakoniecki
Michigan State University
brakoni1@msu.edu

*Two independent research projects at a large Midwestern university used paper and pencil items to obtain information on different aspects of preservice teachers' Mathematical Knowledge for Teaching. Through happenstance occurrence, several preservice teachers participated in both studies. This paper examines the responses of this subgroup to items from both projects and shows that a richer picture of students' Mathematical Knowledge for Teaching is obtained when looking at students' Mathematical Content Knowledge and Pedagogical Content Knowledge in tandem.*

This work has been made possible by the support of the Teachers for New Era (TNE) project funded by the Carnegie Corporation of New York (Dr. Robert Floden, PI) and the National Science Foundation's PIR-Project (award no. 0546164, Dr. Sandra Crespo, PI).

One of the persistent issues in mathematics education is the preparation of qualified mathematics educators. A current trend in mathematics education has been one that attempts to describe and quantify types of knowledge required for mathematics teachers. Part of one framework was first proposed by Shulman (Shulman, 1986, 1987) and his colleagues (Wilson, Shulman, & Richert, 1987) which differentiated between content knowledge, pedagogical content knowledge, and curriculum. This framework has since been further defined for mathematics by Ball and others with their Mathematical Knowledge for Teaching framework (Ball, et al., 2005; Hill, Rowan, & Ball, 2005). A recent publication by Ball and others continues to refine and describe in greater detail these categories (Ball, Thames, & Phelps, 2008).

Several research studies have used these frameworks to examine and quantify the mathematical knowledge exhibited by preservice teachers. While most of these projects attempt to describe one aspect of the complete framework for a certain population of preservice teachers, there has yet to be a study that attempts to describe multiple aspects of Mathematical Knowledge for Teaching for a set of preservice teachers within a population. Through a happenstance occurrence, two independent research projects at Michigan State University did just that by collecting responses from preservice teachers who participated in both studies. This paper examines what information can be gained about their Mathematical Knowledge for Teaching when their responses to these two different assessments are examined in tandem.

## Literature Review/Framework

In Shulman's original article (1986), he outlines a shift in state teacher preparation requirements from one that was almost entirely content driven (with very little pedagogy) in the late 19th century, to one that focused heavily on knowledge of pedagogical issues (with little emphasis on knowledge subject matter content). Shulman calls for preparation of teachers that emphasize content knowledge, pedagogical content knowledge, and curricular knowledge. *Content Knowledge* is described in this article as more than just the knowledge of facts or content of a subject, it is also the knowledge of the underlying structure beneath those facts and content. *Pedagogical Content Knowledge* is described as almost a subset of content knowledge, a specialized part of content knowledge. Here, pedagogical content knowledge is made up of not just the content, but knowledge of effective and different ways with which to teach that content. The last of Shulman's categories is *Curricular Knowledge*. This type of knowledge is described as knowledge of the various resources available to teach the content, and knowledge of where the current content fits into the scope of the students' educational program.

Ball and colleagues have described a framework that refines and expands upon these original ideas (and subsequent works) proposed by Shulman and his contemporaries into something more descriptive of the subject of mathematics. Described as a framework that identifies the various aspects of Mathematical Knowledge for Teaching, this "egg" framework (see Figure 1) is split into two main categories of knowledge which are then further refined: subject matter knowledge, and pedagogical content knowledge. The subject matter knowledge category is split into Common Content Knowledge (CCK), Specialized Content Knowledge (SCK), and Horizon Content Knowledge. *Common Content Knowledge* (CCK) is described as "knowledge that is used in the work of

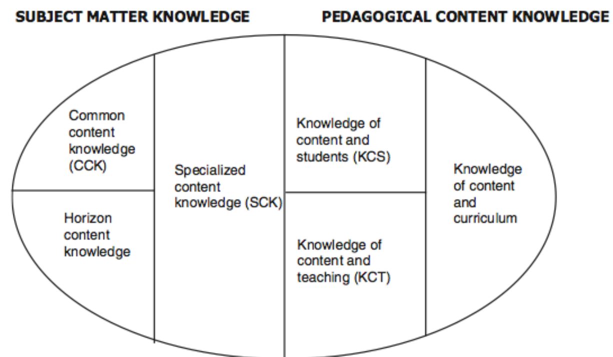

***Figure 16.* Mathematics Knowledge for teaching from Ball, Hill, and Bass (2005).**

teaching in ways in common with how it is used in many other professions or occupations that also use mathematics" (Hill, Ball, & Schilling, 2008, p. 377). In describing *Specialized Content Knowledge* (SCK) they refer to an earlier work by Ball which described SCK as "the mathematical knowledge that allows teachers to engage in particular teaching tasks, including how to accurately represent mathematical ideas, provide mathematical explanations for common rules and procedures, and examine and understand solution methods to problems (Ball, et al., 2005)" (Hill, et al., 2008, pp. 377-378). Horizon Content Knowledge is described as knowledge of the mathematics as it relates to future classroom subjects. Here it is by knowing the mathematics that is forthcoming on the horizon, teachers can appropriately lay the groundwork with the subjects they are teaching now. It is noted that CCK, SCK and Horizon Content Knowledge require only the knowledge of mathematics, and no knowledge of students or teaching is required to have sufficient knowledge in these categories. The authors elaborate that the categories they have under Subject Matter Knowledge are most closely associated with Schulman's original framework of Content Knowledge (though they argue that CCK is more directly related to Content Knowledge, than SCK). The pedagogical content knowledge category is split into Knowledge of Content and Students, Knowledge of Content and Teaching, and Knowledge of Curriculum. *Knowledge of Content and Students* (KCS) is described as "content knowledge intertwined with knowledge of how students think about, know, think about, or learn this particular content" (Hill, et al., 2008, p. 375). *Knowledge of Content and Teaching* (KCT) is described as knowledge of mathematics as used in the design of instruction. This can include sequencing of tasks for greater effect, or knowledge of what ideas to elaborate on, what to hold for later, and when to pause for clarification. The descriptions used by Ball and colleagues for Knowledge of Content Curriculum and by Shulman for Curricular Knowledge are similar.

The two research projects described below had different goals with the administration of their test items. Although not designed to map directly onto the Shulman, or Ball et al. frameworks, these frameworks do provide a lens with which to look at the tasks and the preservice teacher responses. As will be shown, it could be argued that the TNE test items attempt to capture more information on the subject matter knowledge of preservice teachers, whereas the PIR test items attempt to capture more information on the pedagogical content knowledge of preservice teachers. By examining the responses obtained in two research projects, we attempt to answer what Mathematical Knowledge for Teaching is exhibited by three preservice teachers in both studies.

## Methods

At Michigan State University, two separate research projects are looking at preservice elementary school teachers and their mathematics teaching by using paper and pencil item administrations. These two projects have items that share some of the same question stems, though the focus of the questions is different for the projects. These research projects administered their test items over several years and as such, there are some students who participated in both research projects. This paper looks at some of these students, and the mathematical content that they used in answering these “common” questions.

*Project Overviews*

MSU is one of the universities participating in the multiple-institution project Teachers for a New Era (TNE) funded by the Carnegie Corporation of New York. As part of the work going on at MSU in this project, the mathematics education faculty is performing a self-study of the mathematics in their elementary education program. The purpose of this study is to analyze what mathematical content knowledge preservice teachers learn as part of their content classes, and what is retained through the duration of the program. For this paper, we will use responses from the administration of the TNE items that occurred at the end of the preservice teachers’ math content class that focused on number and operation. At this point, the preservice teachers had not yet taken their math methods course as they were generally at the beginning of their program (freshman and sophomores). This data set was collected in 2005 and 2006.

The PIR project is a NSF funded project looking at the enacted practice of mathematics teaching for preservice and in-service teachers of the MSU elementary education program. The larger research question involves the study of the practices of posing, interpreting, and responding (P-I-R) of current students and alumni of the MSU elementary education program. For this paper, we will use responses from the administration of the PIR items that occurred the semester before students enrolled in their mathematics methods classes (but several years after their math content courses). Preservice teachers in these administrations were generally near the end of their program (juniors and seniors). This data set was collected in 2008.

*Comparing Tasks*

Many items of the TNE tasks and PIR tasks shared the same stem or set-up, but asked students different questions from this common starting point. Here we describe the general nature of the questions used in this paper.

All of the TNE tasks listed ask preservice teachers to assess the validity of students’ alternative methods (is the solution method correct, is the method generalizable, will it work for other numbers, etc.) or to come up with word problems that accurately described a given mathematical situation. Here, the items tend to be asking about the Mathematical Content Knowledge part of MKT. These questions attempt to have the preservice teachers understand student solutions (described as SCK). This paper uses item W1 from the TNE test administration (see Figure 2). An alternate subtraction algorithm is presented to the preservice teacher and two questions are asked. The first question asks if this method is generalizable. The second question asks the preservice teacher how this hypothetical student would use this method on a new problem. Here we can see this question is trying to assess the preservice teachers' SCK regarding subtraction (do they understand the alternative algorithm well enough to use it to solve another problem).

Within the PIR tasks, these questions have a general theme of the posing, interpreting, and responding that preservice teachers imagine themselves doing when presented with these situations. This paper uses items 2(a) and 2(b) from the PIR administration (see Figure 3). The first question asks preservice teachers what they imagine saying and doing with their class when receiving puzzling looks after they pose a task. This question allows for a multitude of different responses from preservice teachers as they are left to determine exactly why students may be puzzled. This confusion could stem from students lack of content knowledge on subtraction, to not knowing where to begin with different ways. The responses here could vary from MCK type responses (CCK or SCK) to more PCK responses to deal with the student confusion (KCS or KCT). The second part of the question states that a student has come up with a new strategy and asks the preservice teacher to describe what they imagine saying and doing. Here again the responses can take on many different forms, from validating or invalidating the method, offering congratulations for unique thinking, or even using the method to connect to the standard algorithm. Here again we can see that these responses could map onto the MKT framework in a variety of different ways.

***W1***

Imagine that one of your students shows you the following strategy for subtracting whole numbers.

$$\begin{array}{r} 37 \\ \underline{-19} \\ -2 \\ \underline{20} \\ 18 \end{array}$$

a. Does this strategy work for any two whole numbers? (Circle your answer.)

Yes

No

I don't know

b. How do you think the student would use this strategy in the problem below?

$$\begin{array}{r} 423 \\ \underline{-167} \end{array}$$

Adapted from: Ball & Hill (2002). *Cultivating knowledge for teaching mathematics: Early fall survey.* Cultivating Teachers' Knowledge for Teaching Mathematics Study. Ann Arbor, University of Michigan.

***Figuee 2.*** **TNE item W1.**

2. (a) Imagine you just asked your class to explore different ways to solve the following subtraction. The students look puzzled. What do you imagine <u>saying</u> and <u>doing</u> next?

$$\begin{array}{r} \mathbf{37} \\ \underline{\mathbf{-19}} \end{array}$$

<New Page>

2. (b) After giving students some time to work on the task you call on their attention and ask for volunteers to share their strategies. Imagine that one of the students shows the following strategy. What can you imagine <u>saying</u> and <u>doing</u> to the student and to the class? Say a bit about what you would want to accomplish by saying and doing so.

$$\begin{array}{r} \mathbf{37} \\ \underline{\mathbf{-19}} \\ \mathbf{-2} \\ \underline{\mathbf{20}} \\ \mathbf{18} \end{array}$$

***Figure 3.*** **PIR items 2(a) & 2(b).**

The responses of three preservice teachers (Dean, Becky, and Lisa – all pseudonyms) who had completed both TNE and PIR items were chosen for analysis. These preservice teachers were chosen in particular because they all gave identical responses to the TNE item and very different responses to the PIR item. Below is a table of the responses of the preservice teachers (see Table 1).

| Preservice Teacher | Response to TNE Item W1 | Response to PIR Item 2(a) | Response to PIR Item 2(b) |
|---|---|---|---|
| Dean | (a) Yes<br><br>(b)<br>423<br>-167<br>-4<br>-40<br>300<br>256 | 1) Ask the students if they can make the problem into two problems<br>37 27<br>-10 -9<br>27 18<br><br>2) Ask the students, what plus 19 equals 37?<br>19 + 18 = 37<br><br>3) Use chips to show the two methods | • I would ask the student to re-write the problem and show each step they took to get to their answer.<br><br>• I would want the students to learn the importance of showing their work and how they can use it to retrace their steps in a problem |
| Becky | (a) Yes<br><br>(b)<br>423<br>-167<br>-4<br>-40<br>300<br>256 | 1: Draw a picture (visual is the best way)<br><br>2: Cannot take nine from seven –<br>3: Take 10 → Pull over to ones<br>And take 9 from 17.<br><br>Or $^{2}\cancel{3}\ \ ^{1}7$<br>$-1\ \ 9$<br>$1\ \ 8$<br>• Slip into two different columns | • I do not like this way – Math for higher on is going to be a lot harder if they learn this now. |
| Lisa | (a) Yes<br><br>(b)<br>423<br>-167<br>-4<br>-40<br>300<br>256 | I would ask the students where we start, in the ones column. We can't take 9 away from 7 so we need to borrow from the tens column. Cross of the 3 and make it a 2 since we borrowed one for the 7. Put a 1 in front of the 7 to make it 17. 17-9=8. Then we do the tens column. 2-1=1 so our answer is 18. | This strategy can work. The student knows that we start in the ones column. 7-9= -2. The tens column is also correct, as 30-10=20. Now what the student did was combine -2 and 20, to get 18. We got the same answer. I would want to let the class know that there is more than one way to solve a problem, and it is important to remember that subtraction of multiple digit numbers involves multiple subtractions, depending on how many places are in the number. |

Table 1. *Student Responses*

## Results

*TNE Item W1*

When responding to this TNE item Dean, Becky, and Lisa all replied with identical answers. Despite the limited amount of response material due to this item not having a written response section, several pieces of information about these preservice teachers can be extrapolated. All three preservice teachers examined the work shown by the hypothetical student, and were able to uncover enough of the student's method to solve an additional problem with the same method. In addition to this, all three preservice teachers circled the response that our hypothetical students' method would work for any two whole numbers. This may have been due to guessing, but based on the preservice teachers correctly applying this method to a new problem, there is reason to believe that Dean, Becky and Lisa were each able to figure out that this method is indeed generalizeable to all whole numbers. Here, there is some evidence that these three preservice teachers have some Specialized Content Knowledge (SCK). It seems reasonable to say that based on the responses to the TNE items, Dean, Lisa and Becky have in their repertoire an ability to analyze this method of subtraction to determine its generalizability, and an ability to take this non-standard subtraction method and apply it to a new problem. Given this, it seems reasonable to assume that these skills could emerge when the preservice teachers were asked to respond to the same subtraction method in a teaching scenario. However, not only do these skills not emerge in their responses to the teaching scenario, three very different responses emerge.

*Dean*

Dean's response to the two PIR items offer some insight into the Pedagogical Content Knowledge he brings to these related items. When asked to describe what he imagined saying and doing after his students looked puzzled when he told them to explore different ways of solving 37-19, Dean suggests three things he might do with his class: breaking the problem into smaller steps, making the subtraction problem into an addition problem, and using manipulatives. All three of these proposed actions display some Knowledge of Content and Students (KCS). Dean appears to be addressing the student confusion by suggesting alternate ways to present the problem that would make sense to students, or be similar to how students would think about a problem. In the second half of this task, the main theme of Dean's response to this question is to emphasize that students need to show their work. What Dean's answer does not contain here is how he might use this student's work productively in a classroom. From Dean's response to the TNE item, we know that at one point in time, Dean was able to circle the response that this method was generalizable and he showed that he was able to understand the method enough to apply it to a new problem. However, in talking about the same solution method to students, Dean only reminds students to show their work. This may be an example of further KCS as Dean believes that students need to show their work in order to be able to retrace their steps, which will lead to more opportunities to learn.

*Becky*

Becky's response to the first question also contains three items. The three things that Becky imagines saying and doing include drawing a visual representation of the tens and ones of the subtraction problem, mentioning that you cannot take nine away from seven, splitting the subtraction problem into two columns, and performing the traditional subtraction algorithm on the problem. What is interesting is that Becky notes that her first item is actually the best as "visual is the best way". This response was given at the end of her math content class and before she was enrolled in any math methods classes for her program so it is not apparent where Becky has come to know this claim. Regardless of where this claim originated, Becky has incorporated it into her KCS as she believes that visual ways of representing content will be the ways that students can best engage with. Additional pedagogical knowledge appears again in Becky's response to the second half of the PIR task. When asked how she would respond to the student and her classroom when someone presented the non-standard method, Becky writes, "I do not like this way – Math for higher on is going to be a lot harder if they learn this now." This claim appears to fall under Knowledge of Content and Curriculum in saying that future mathematics learning will be hampered by learning this method now. Regardless of whether one agrees with the assessments Becky has made, it is clear that Becky is displaying some of her thoughts about Pedagogical Content Knowledge in her responses to these items.

*Lisa*

In responding to the confused looks of her students as described in the first PIR task, Lisa responds by walking the students through the traditional subtraction algorithm. The prompt in the question called for the teacher to ask her students to explore different ways of solving subtraction. It is not clear if Lisa is reforming the question to be about finding one way of solving a subtraction problem, or if her step by step description of this method is supposed to serve as a launching point for her students to then explore other methods. Regardless, it appears that walking the students through the traditional subtraction algorithm is important for Lisa for it will serve either as instruction of the traditional subtraction algorithm or as a review of the algorithm that will serve as a launching point into further explorations and understanding of subtracting. There appears to be some KCS in that Lisa believes this explanation will end the student confusion and they will come to understand subtraction, as no other moves are mentioned. In the next part of the PIR items, Lisa states that she would walk the students through the method used to solve this problem, remind students that there are many ways to solve a problem, and remind students that sometimes a single subtraction problem actually requires several subtractions. Here what we notice is that in both PIR responses, Lisa walks students through the steps of two different methods for her class. This may be due to thinking this is how math instruction is performed, or it may be due to thinking that this is the most effective way that students learn mathematics (possibly evidence of KCS). This is a pedagogical choice that Lisa is making and is yet another way that the MKT of one preservice teacher can be examined through the moves they make in a classroom.

## Discussion

Mathematical Knowledge for Teaching is a way of describing the knowledge that teachers should have in order to be effective teachers of mathematics. This framework is divided into two parts: one part dealing with Mathematical Content Knowledge, and the other part dealing with Pedagogical Content Knowledge. In this study, we looked at a sample of responses from three preservice teachers in an elementary education program. These preservice teachers participated in two research projects that had items that used the same stems. One research project had items that more closely mapped onto the MCK part of MKT while the other research project had items that seemed to map onto PCK. It was by looking at these items in tandem that we were able to obtain a better understanding of the Mathematical Knowledge for Teaching that each of these students possessed. This study looked at only one item that these two research projects shared. Even more information could be obtained about these students if additional items were analyzed.

In going forward, we recognize that this method of using both MCK and PCK items provides a much broader and deeper picture about students MKT than either can do alone. Furthermore, by trying to differentiate, distinguish and study the individual categories of MKT, we loose important information on how these categories interact with each other. This is where much information of MKT is located. While this ad hoc study found itself in a unique position of being able to study not only similar test items, but similar students, it provides a unique insight into what information can be gained if tests and surveys are intentionally designed to capture multiple categories at once. Here we state again, the preservice teacher responses used in this paper were obtained after their math content classes, but before their math methods classes. We expect that a different, yet just as rich, picture would be obtained if preservice teachers were surveyed after their math methods courses. Furthermore, by obtaining this information about preservice teachers both before and after their methods courses, a survey such as the one used in this study could provide institutions with a rich body of information as to how their methods courses are affecting their students' mathematics knowledge for teaching.

There has been much research into the different categories of MKT that Ball and others have described. And while there continues to be opportunities for further explorations into these individual categories, there is also a need to fortify the connections between these categories. The method used in this research is one way that we can start putting the pieces of this MKT egg back together so that we can construct a clearer picture of the knowledge that teachers of mathematics are equipped with and how they can use it in their classroom.

# MIDDLE GRADE TEACHERS' REORGANIZATION OF MEASUREMENT FRACTION DIVISION CONCEPTS

Soo-Jin Lee
University of Georgia

Chandra Hawley Orrill
University of Georgia
corrill@uga.edu

*Twelve middle grades mathematics teachers were given division problems in a professional development program designed to help teachers understand rational numbers. This paper analyzes how teachers reorganized their measurement interpretation of fraction division by operating on conceptual units. Past studies have documented that many teachers are not able to reason about fraction division in terms of quantities. The present study extends these past studies by examining teachers' capacities to reason in a sequence of fraction division situations in which the mathematical relationship between the dividend and divisor became increasingly complex.*

## Background

The National Council of Teachers of Mathematics' standards for teaching and learning (NCTM, 2000) require teachers to have a richer understanding of mathematics than traditionally required. One topic that is particularly difficult for teachers is division of fractions. For instance, Ball (1990) asked U.S elementary and secondary prospective teachers to contextualize the problem $1\frac{3}{4} \div \frac{1}{2}$. Her results revealed that teachers could not generate appropriate word problems or situations even though most of them could calculate a solution using the 'invert and multiply' method. She found that teachers were likely to confound division by a half with division by 2 or multiplication by a half when they tried to contextualize the problem. Simon (1993) adapted the problem from Ball's study and asked prospective elementary teachers to write a story problem for $\frac{3}{4} \div \frac{1}{4}$. Twenty-three out of 33 teachers could not create an appropriate problem. Twelve of those 23 teachers used 'invert and multiply' and represented the problem as multiplication thereby creating a problem situation for multiplication rather than maintaining the fraction division. Borko et al. (1992) also examined prospective teachers' knowledge as exhibited during their student teaching and reported the case study of a middle school teacher, Ms. Daniels. When asked by a child to explain why the invert-and-multiply algorithm worked, Ms. Daniels could not clearly explain fraction division and instead showed fraction multiplication, despite having completed a fair number of mathematics courses in her undergraduate program and being able to compute accurate answers with the invert and multiply method. In her study of 23 U.S. teachers and 72 Chinese teachers, Ma (1999) introduced the term *knowledge package*, which refers to pieces of knowledge consisting of numerous subtopics that are related to one another that support more advanced learning. For fraction division, she suggested that teachers' knowledge packages should include whole number multiplication, the concept of division, the concept of division as inverse of multiplication, the meaning of multiplication with fractions, and the concept of unit. Ma's study revealed that pieces of the ideal teacher knowledge package are relatively weak for U.S teachers.

Although previous studies (e.g., Ball, 1990; Borko, 1992; Simon, 1993; Ma, 1999) have stressed errors and constraints on teachers' knowledge of fraction division, they have not considered teachers' capacities to reason in a sequence of fraction division situations. Further, even though studies have revealed teachers' knowledge in detail, they have not examined teachers' reasoning about fractional quantities in terms of conceptual units, although several research programs have investigated children's reasoning with conceptual units in the context of fractions. In this paper, we focus on one approach for supporting teachers' development of mathematical knowledge for teaching fraction division by emphasizing the relationship between the units and operations associated with the measurement conception of fraction division. Conceptual analysis of teachers' knowledge at this grain size allows us to develop a stronger understanding of teachers' capacities to reason about fraction division in detail.

## Theoretical Perspectives

The theoretical framework used for our analysis of twelve teachers' reasoning with drawn quantities in solving fraction division problems draws from the literature on children's development of conceptual understanding of fractions. We draw from these ideas because we noted that the ideas and operations documented with students appeared in our teachers' reasoning. In the literature, the ideas of *iterating* and *partitioning* have been determined to be fundamental for fraction knowledge development (e.g., Piaget, Inhelder, & Szeminska, 1957; Olive, 1999; Olive & Steffe, 2002; Steffe, 2002, 2004; Tzur, 1999, 2000, 2004). This is the notion that a unit whole can be divided into any number of pieces (partitioning) and that any one of these pieces may be iterated to reconstruct the unit. Another critical operation we considered was the *unit-segmenting scheme* for division in a whole number context (Steffe, 1992). This entails the operation of segmenting the dividend by the divisor. In his teaching experiment, Steffe (1992) observed that a child needed to reason with at least two composite units in the unit segmenting scheme: one composite unit to be segmented and the other composite unit to be used in segmenting. For example, consider how many times a child would count if dividing a pile of fifteen books by three. That child would use three as a segmenting unit to divide composite unit fifteen. It is likely that even in cases where the child was using the unit-segmenting scheme in this content, that child may have to reorganize his/her unit-segmenting operations to approach more complex problems.

Olive (2000) defined *common partitioning fractional scheme* to refer to the child's ability to coordinate and compare his two number sequences for two composite units until a common number was found. He also stated that the child who had common partitioning fractional schemes could keep track of how many of each composite he had used to get to the common multiple of both composite units. In other words, it requires units-coordination at three levels that is a coordination of two iterable composite units. To illustrate, when the child was asked to partition a bar that would allow him to pull out both one-third and one-fifth of the same bar, his procedure was to count by 3s and 5s until he found a common number in the two sequences. The common partitioning fractional scheme was a building block for the children's construction of *measurement fractional scheme*. With fractions as *measurement units,* division of fractions becomes meaningful in that children can now answer questions like "How many thirds are in two-ninths?" when children have constructed fractions as measurement units, they could then find a *co-measurement unit* for the two fractions by constructing any fraction from any other.

A co-measurement unit is defined as a measurement unit for commensurable segments, that is segments that can be divided by a common unit without remainder. For example, one child could make one-ninth of a unit stick using one-twelfth of the stick by finding one-thirty sixth as a co-measurement unit for both one-ninth and one-twelfth. In addition to the common partitioning operation children used to find the common partition for two fractions, cross-partitioning using area model also emerged in Olive's teaching experiment. For instance, the children used the *cross-partitioning* operation to solve $\frac{1}{3}\times\frac{1}{5}$ by partitioning a bar vertically into three parts and horizontally into five parts and get 15 of one-fifteenth automatically. In his observations of Nathan, Olive (2000) found the use of cross-partitioning operations in a fraction multiplication context differed from the common partitioning operation in that the former provides for a simultaneous repartitioning of each part of an existing partition without having to insert a partition into each of the individual parts, and it is a fundamental operation to produce *fraction composition scheme* (Steffe, 2004) which is multiplying scheme for fractions. While the Fractions Project's (Olive, 1999; Olive & Steffe, 2002; Steffe, 2002, 2004; Tzur, 1999, 2000, 2004) research on the conceptual analysis of children's construction of fractional schemes made important contributions to the field of knowledge of fractions, the studies were limited in that they did not follow the students beyond the development of fraction multiplication schemes.

In the fraction division, reasoning with conceptual units became increasingly complex as mathematical relationship between the dividend and divisor changes. In this paper, we begin the work of identifying the fraction schemes teachers used to reason about fraction division from a measurement (quotative) perspective. We first considered a simple division problem in which the dividend was evenly divisible by the divisor. In this situation, teachers simply used a *measurement unit* and segmented the dividend into the groups of divisors. In the second case, the dividend did not clearly segment by the divisor, leaving a remainder to be considered. This required teachers to bring forth the conception of the *referent unit* in that it was plausible to quantify the remaining part in terms of one by conflating the referent unit. We say that teachers can attend to the referent unit when they can keep track of the referent whole. The third case involved a divisor larger than the dividend. In this case, teachers reorganized their understandings to move toward conceptualizing the multiplicative relationship between the divisor and the dividend.

## Research Questions

1. What were the primary operations and units that the teachers used when reasoning about the fraction division problems?
2. How did teachers modify or reorganize their measurement fraction conception when faced with increasingly complex problem situations?

## Method

The data reported here were collected as part of the larger NSF-funded *Does it Work?: Building Methods for Understanding Effects of Professional Development* (DiW) project. As part of the DiW research effort, a professional development course called *InterMath – Rational Numbers* (IM) was offered to middle grades teachers in a large, urban district. The course provided teachers with opportunities to develop their content knowledge of multiplication and division of fractions and decimals and to explore direct and inverse proportions by engaging them in solving technology-enhanced, open-ended investigations and by exploring a variety of drawn representations. To support the course goal of raising fluency in the use of visual representations, teachers used a variety of software packages including *Fraction Bars* (Orrill, undated). The course met three-hours per night, once per week for 14 weeks. All meetings were videotaped using two cameras – one to capture the participants' facial expressions, written work and hand gestures, and the other to capture the instructor's teaching. These two sources were then mixed to create a *restored view* of the event (Hall, 2000).

A single class meeting focused on measurement fraction division was considered for this analysis. The first round of analysis involved taking memos of the trends that emerged from the data in the ongoing observation of the lessons as they occurred. Then a retrospective second analysis was conducted after all IM data had been collected. The purpose of the retrospective analysis was to understand teachers' ways of operating mathematically. In qualitative research, notions of reliability, validity, or viability hinge on the quality of thinking and internal consistency of the witness-researcher, since a researcher doing qualitative research is the research instrument (cf. Peshkin, 1988; Richardson, 2000; Weis & Fine, 2000). However von Glasersfeld (1995) emphasized the role others play in developing one's own thoughts and characteristics. He suggested that intersubjective knowledge is the most reliable knowledge in experiential reality. Hence the researchers took advice and shared their thoughts with the teacher-researcher and another witness-researcher of the IM class.

## Results

We considered the teachers' measurement fraction division knowledge across three different types of division problems. The first involves a dividend that can be clearly measured out by the divisor, the second is when there is the remainder as a result of measuring out the dividend by the divisor, and finally when divisor is larger than dividend. By providing teachers with tasks and drawing representations that motivated them to reason with quantities rather than to rely on calculation, we could understand teachers' thinking in detail.

*When the Dividend Clearly Measures Out by the Divisor*

This is the case when there is no remainder in fraction division like $2 \div \frac{1}{4}$. The instructor provided teachers with the task that was comprised of various fraction division expressions such as $2 \div 3$, $2 \div \frac{1}{4}$, $2 \div \frac{3}{4}$, and $\frac{2}{3} \div \frac{3}{4}$. Teachers were asked to find the quotients for each of the expressions without using an algorithm. Moreover the instructor encouraged teachers to use various drawn representations such as area or number line model. When teachers were asked to solve $2 \div \frac{1}{4}$ using drawing representations, most teachers used one-fourth as a measurement unit and segmented the composite unit 2 into 8 parts of one-fourth, and successfully stated that the answer was 8 because 8 groups of one-fourth fit into 2. Even though most teachers derived the answer 8 using measurement division concepts, teachers' strategies were different in that some teachers repeatedly subtracted one-fourth from 2 to get 8 whereas others thought of the problem in terms of how many groups of one-fourth formed 2. Note that the latter method does not imply multiplicative reasoning because we are not clear that the teachers were aware of the multiplicative relationship between the two fractional quantities, a dividend and a divisor, rather than finding the numbers of divisors that fit into the dividend.

*When the Dividend Does Not Clearly Measure Out by the Divisor*

In a problem such as $2 \div \frac{3}{4}$ there is a remainder in the result of measuring out the divided by the divisor. Although our participants did not attend to the referent unit for the first type of fraction division problem, the referent unit concept played a key role here. For instance, one teacher drew two rectangles and divided each rectangle into fourths, then circled three of each of the fourths in each rectangle, and said $2\frac{1}{2}$ was the answer because there were $2\frac{1}{2}$ of the three-fourths fit into 2 wholes (see Figure 1).

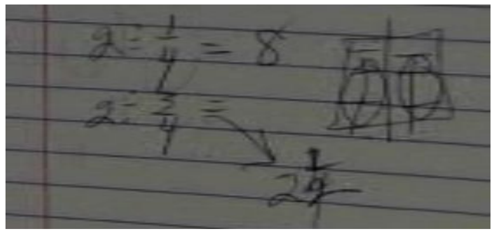

*Figure 1.* A teacher's representation of $2 \div \frac{3}{4}$ using area model and her initial answer $2\frac{1}{2}$.

She made this error at first because she was not attending to the referent unit of the remaining two-fourths that was left after she measured out three-fourths twice. However when the instructor asked her to talk through her reasoning, the teacher reflected upon that reasoning to determine that the remaining two fourths was two-thirds of three-fourths not two-fourths of one whole. So she changed her answer to $2\frac{2}{3}$, which was then correct. In other words, she determined the dividend 2 could be divided into $2\frac{2}{3}$ groups of three-fourths.

Similar issues arose in the whole group discussion as the teachers were considering how a number line could be used to solve this problem. In the whole class discussion, the teachers suggested $2\frac{1}{2}$ but did not recognize that their answer was incorrect until one teacher suggested using the referent unit concept. Teachers' attention to the referent unit was not clear until we observed teachers solving division problems in which the divisor cannot evenly divide the dividend. In the first type of problem, teachers did not have to attend to the referent unit because they could easily figure out the number of divisors that fit into the dividend if they just chose the divisor as the measurement unit. However when teachers were given a situation in which they had to reason with the remainder from fraction division, they needed more than the divisor as their measurement unit. They also needed to attend to the referent unit.

*When the Divisor is Larger than the Dividend*

For people who rely on measurement conceptions of division, problems in which the divisor is larger than the dividend are often problematic because the fractional quantity being measured is smaller than the dividend, leading to an awkward conceptualization. For example, in $\frac{2}{3} \div \frac{3}{4}$, the question being asked from a measurement perspective is how many three-fourths are in two-thirds. In IM, the instructor chose two teachers to explain how they used a number line model and an area model to represent $\frac{2}{3} \div \frac{3}{4}$. The teacher who used the number line model drew his model on a flipchart as he explained his approach. When he tried to use three-fourths as a measurement unit to find the solution, he faced a perturbation because the divisor was larger than the dividend. He was stated, "you can't quite get three-fourths into two-thirds." He continued,

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

“for fraction division, we ask ourselves question like how many three-fourths we can put into two-thirds.” We can infer from his statements that his initial conception about measurement division relied on finding the numbers of divisors in the dividend. In order to find how many three-fourths go into two-thirds, he first decided to find the least common denominator (his term) of three and four. He used one-twelfth as a co-measurement unit for two-thirds and three-fourths, and used $\frac{9}{12}$ as a commensurate fraction for $\frac{3}{4}$ and $\frac{8}{12}$ for $\frac{2}{3}$. He drew a number line and divided it into three parts, then subdivided each third into another thirds, using the common partitioning operation. Then, he denoted each $\frac{1}{12}$ segment from 0 to $\frac{9}{12}$ (See Figure 2). He said that $\frac{8}{12}$, which was a commensurate fraction of $\frac{2}{3}$, was $\frac{8}{9}$ of $\frac{9}{12}$, so $\frac{2}{3} \div \frac{3}{4}$ was $\frac{8}{9}$.

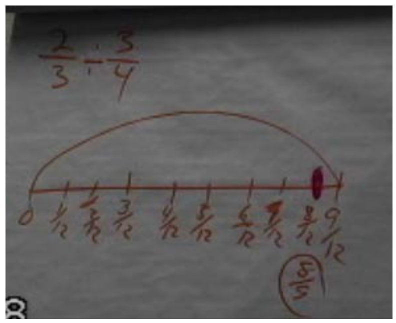

*Figure 2*. The teacher’s representation of $\frac{2}{3} \div \frac{3}{4}$ using a number line.

Even though he used the common partitioning operation and came up with two commensurate fractions, his perturbation was not resolved because he still could not measure out $\frac{8}{12}$ by $\frac{9}{12}$. He needed to use a different approach than the one with which he started. At least in this context, his initial conception of measurement division was modified into a more efficient one as he attended to the multiplicative relationship between the two quantities $\frac{8}{12}$ and $\frac{9}{12}$ instead of looking for the number of divisors that fit into the dividend. In other words, $\frac{8}{12}$ was now for him could be reinterpreted as $\frac{8}{9}$ of $\frac{9}{12}$, and generalizing his measurement division conception in such a way was powerful in that he was not confined by the quantities of dividend and divisor. His attention to the multiplicative relationship between two quantities was novel considering his initial conceptions about fraction division and the comment that he made “you can’t quite get three-fourths into eight-ninths.” The teacher’s clear attention to the referent unit nine-twelfths was another knowledge element that supported his reasoning with this problem.

In contrast to the teacher above who used common partitioning operation with a number line model, other teachers in the class relied on cross partitioning in an area model to reason about this problem. This led them to cut the whole into 12 pieces by partitioning it into thirds one way and fourths the other. Then, the teachers counted the number of rectangles that represented two-thirds of the whole and the number of rectangles that represented three-fourths of the whole to determine that the three-fourths was 8 blocks and two-thirds was 9 blocks (‘block’ was the teachers' to describe the smaller rectangles created by partitioning the area model). The teachers did not discuss the fact that those blocks were $\frac{2}{3}$ or $\frac{3}{4}$ of $\frac{12}{12}$, not $\frac{2}{3}$ or $\frac{3}{4}$ of 12. One teacher explicitly stated that they needed to find "how many 9 blocks fit into 8 blocks?" and "it's eight-ninths". The teachers began to use cross partitioning in the new situation to acquire a co-measurement unit for two-thirds and three-fourths where the denominators of two fractions were relatively prime to each other. We assert this was a reorganization of their conception of measurement fraction division. However, computing the quotient eight-ninths without attending to the referent unit of both the two-thirds and three-fourths is problematic in classroom settings because students may reinterpret the problem to be 8 ÷ 9. We worry that the teachers, in our case, had moved away from their consideration of the referent whole, which was 1 (12/12) at the time. While this was a shortcut for the teachers, such shifting may interfere children's learning.

In summary, we found that some teachers modified or reorganized their initial conception of measurement fraction division conception, which began as finding the number of pieces of the size of the divisor that fit into the dividend. They moved toward using more efficient strategies by incorporating more sophisticated operations and conceptual units. While we do not know whether such modifications or reorganizations were permanent, they were relatively new ways of thinking about measurement fraction division for these teachers as they considered the relationship between the divisor and the dividend in increasingly complex situations.

## Discussion

Although past studies have documented that teachers lack sufficient fraction knowledge, our results suggest that teachers can reorganize and generalize operations and concepts that they have when provided with a professional learning experience in which they can reason in terms of drawn quantities. We observed that teachers' operations and conceptual units necessary for reasoning with the situation where no remainder was left for fraction division did not necessarily transfer to fraction division with a remainder. Teachers needed to incorporate strong referent unit concept in addition to their use of the measurement unit in order to quantify the remainder in terms of the correct referent unit. Moreover, teachers relied on more operations and conceptual units such as common partitioning, cross-partitioning, co-measurement unit, commensurate fraction, and multiplicative reasoning when the divisor was larger than the dividend.

Most studies have not looked at teachers' knowledge any closer than simply saying that teachers' reasoning about fraction measurement division is insufficient. Hence, the idea of examining measurement division more closely using tasks of gradated difficulty as well as understanding where teachers are more and less competent at reasoning about fraction division, and why, in terms of close analysis of operating on conceptual units, is a contribution to the field of mathematics education. This study is only a beginning step toward that understanding.

Note that this study considers only twelve teachers and that we make no claims of the generalizability of the patterns of reasoning observed. We certainly believe that teachers may follow a variety of paths in learning to reason about these concepts. In this study, we considered only those ways of reasoning that emerged from the participants. By building on understanding of teachers' mathematical concepts and operations in the ways illustrated here, we propose that a rich understanding of teachers' understandings could be developed which could be used as the foundation for developing stronger professional learning opportunities for teachers.

*This study examined the application of a conceptual framework for learning new conceptions to the design and use of tasks/prompts that can lead students to construct multiplicative double counting (mDC) – a scheme underlying the development of multiplicative reasoning. Within the context of a teaching experiment with fourteen 4$^{th}$-5$^{th}$ graders, we analyze the teacher-researcher's work with one student, Megan, as she progressed from having no such conception to the participatory and then anticipatory stage of mDC. Our analysis demonstrates how tasks can (a) draw on available conceptions and (b) be designed to engender the intended learning via orientation of reflective processes.*

## Introduction

How might tasks that promote conceptual understanding of multiplicative operations be designed and implemented based on students' available conceptions? In this study we addressed this critical pedagogical problem, which is consistent with the growing interest of mathematics educators in the role tasks play in students' learning of mathematics (Watson & Mason, 1998, 2007; Watson & Sullivan, 2008; Zaslavsky, 2007). In particular, we examined the application of Tzur and Simon's (2004) stage distinction (see below) to the process of instructional task design. This application contributes to the recent focus on task use, because it is rooted in a framework that explicitly links learning of new (to the learner) conceptions with interventions that can promote such learning. Thus, we applied the stage distinction, reflexively, to both the analysis of students' available conceptions and the tasks used for transforming these conceptions into intended, more advanced mathematical ideas.

We chose the difficult-to-grasp domain of multiplicative reasoning because of the central role it plays in empowering students' mathematics (e.g., algebra preparedness, see Confrey & Harel, 1994). We believe that inadequate conceptualization in this domain is one key cause for the ever-growing gaps among students during the upper elementary, middle, and early high school years. Consequently, this study focused on the commencement of multiplicative double counting (mDC, see details below), a milestone mental operation that constitutes a child's transition from a unitary counting stage to a binary counting stage (Vergnaud, 1994). Our central thesis is that the stage distinction, and the reflection on activity-effect relationship (Simon, Tzur, Heinz, & Kinzel, 2004) framework in which it is rooted, provide useful tools for creating and adjusting tasks/prompts conducive for nurturing mDC at a level necessary for students to independently carry out cross-context problem solving processes proper to a situation at hand.

## Conceptual Framework

In this section, we first briefly describe the general and content-specific constructs that

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31$^{st}$ annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

guided this study, and then delineate how they were used to design a set of tasks/prompts for teaching mDC. The general constructs constitute the reflection on activity-effect relationship (*Ref*AER*) framework (Simon et al., 2004), itself an elaboration of Piaget's (1985) and von Glasersfeld's (1995) scheme-based theories. *Ref*AER* is the postulated mechanism by which the human mind forms novel conceptions. It commences with the learner's assimilation of a problem situation into her available conceptions, which set her goal and trigger the activities (usually an activity sequence) that the mind and body carry out to accomplish the goal. The learner's goal then regulates, from within the mental system, the progress of her activity sequence and her noticing of effects that this activity brings forth. Through two types of reflection, in the form of brain-based comparisons, the learner first relates the newly noticed effects with the activity and later with the situation in which she should anticipate such an activity-effect relationship (*AER*). *Type-I reflection* consists of comparison between the learner's goal and the actual effect of her activity sequence; *Type-II reflection* consists of comparison across records of experience in which the learner invariantly uses *AER* compounds for solving what then become similar problem situations for the learner. A novel anticipation of *AER* is formed via two stages (Tzur & Simon, 2004). In the first, *participatory* stage, the learner forms a provisional anticipation of *AER* that she cannot access directly from her available schemes. Rather, this anticipation can only be retrieved if the learner is somehow *prompted* for the activity, which generates the effect and hence the *AER* compound. In the second, *anticipatory* stage, the learner forms a robust *AER* that she can independently and spontaneously call up, use, and transfer to new situations. The anticipation encapsulated in the *AER* of both stages is the same; they differ in the learner's access to that anticipation.

The content-specific constructs are rooted in the work of Steffe et al. on children's construction of number schemes, particularly of numerical composite units (CU) through mental activities of iterating the unit of one (1's, see Steffe & Cobb, 1988; Steffe & von Glasersfeld, 1985). Steffe (1994; Steffe & Cobb, 1998) proposed that a child who has constructed CU can operate on such units not only additively (e.g., counting-on to solve a missing-addend problem), but also multiplicatively, via simultaneously applying her counting scheme to CU and to the 1's that constitute the CU (e.g., a child may find 3x4 by counting from 1 to 12 in 'triplets' as in '1-2-3, 4-5-6, 7-8-9, 10-11-12', while keeping track of those triplets on the other hand's fingers, '1, 2, 3, 4'). Most importantly, in using mDC, the child creates a scheme of correspondence, where one CU is distributed across the other. In our example, each CU of 3 is distributed into the composite unit items that make up '4'. Thus, mDC enables a child to quantify, in the absence of objects (i.e., in anticipation), the total number of 1's that are embedded in a given number of same-size CU without having to count each and every singleton. It is important to clarify here that mDC refers to the mental quantification of the units—not to the manner in which it is executed (e.g., using fingers, or making tally marks to monitor each CU, or mentally counting the CU).

To complement the *Ref*AER* with a pedagogical approach, Tzur (2008) elaborated on Simon's (1995) and Simon & Tzur's (2004) teaching approaches by proposing a 7-step cycle. It proceeds from specifying students' available conceptions and the intended mathematical ideas, through identifying an activity sequence they can carry out, designing and implementing tasks that may engage them in such a sequence, to monitoring students' progress and orienting their reflection via intentional introduction of follow-up tasks/prompts. In this study, the tasks were designed to trigger the learner's setting of a global goal of finding the total number of 1's (Unifix cubes) embedded within a given number of CU ('towers' of cubes). Once such situations are recognized, the teacher can hide the cubes to encourage the learner's creation of a fundamental sub-goal – namely, to keep track of how of the number of CU – and introduce the activity of mDC as a means to accomplish that sub-goal. Numbers for tasks were chosen to require more than two hands, hence a transformation in the child's available activity of counting all 1's as a single sequence of numbers (e.g., 1-2-3, 4-5-6, etc.). A child's inability to keep track could be resolved by introducing another set of items on which to keep track of CU accrual, and orient her attention to the stopping point of mDC when she accounted for all of the CU.

## Methodology

This study was part of a teaching experiment (Steffe, Thompson, & von Glasersfeld, 2000) with three 4th graders and eleven 5th graders, designed to develop multiplicative reasoning in elementary school students with (or at risk of) learning disabilities in mathematics[i]. Three teaching episodes with one student, Megan (a student at risk), were conducted over the course of 4 weeks by the sixth author. Megan was selected for this study because, prior to the work presented in this paper, she had constructed the anticipatory stage of using composite units numerically (e.g., for missing addend tasks).

The teaching episodes consisted of students playing a game called "Please Go Bring Me..." (PGBM). It involves one player sending another to a box containing individual Unifix cubes and instructing her to create a tower *m* cubes high. The 'bringer' returns the tower to the table and the process repeats until she brings *N* towers of *m* (henceforth notated $NT_m$). Three principal questions are then asked: (a) How many towers did you bring? (b) How many cubes are in each tower? And (c) How many cubes do you have in all? These questions prompt the child to identify, respectively, the number of composite units (CU), the unit rate (UR), and the total number of cubes (1's). A version of the game that we used frequently utilized "What if?" tasks, which require figuring out her answers in the absence of the cubes (e.g., by asking her to pretend she brought them, or by covering the towers).

Data from the episodes consist of field notes, videotapes, transcripts, and notes from ongoing analysis sessions. The research team initially analyzed episodes soon after conducting them, focusing on significant events and on necessary modifications to the plan for the next teaching session(s). A second round of analysis highlighted critical events in the transcripts of the sessions, where the team inferred Megan's thinking processes at the participatory or anticipatory stages via attending to her language and actions. Final, retrospective analysis involved a team discussion of the highlighted segments, which were integrated into a story line of her growth in multiplicative reasoning. The episodes included in the analysis begin after Megan had become familiar and comfortable with the basic form of PGBM (with cubes).

## Analysis

In session 1, the teacher asked Megan: "Pretend I send you to get towers of 4… and I asked you to bring 7 towers of 4. Can you figure it out, using any other way except bringing those and counting the cubes, how many cubes you would have now?" Megan simply could not answer the question. Even after the teacher offered paper and pencil, and later said she could use her fingers, she threw up her hands and exclaimed, "I can't do it." Her inability to attempt this initial task of $7T_4$ indicated that at this point she had no access to mDC. Below, we present excerpts of critical events from three consecutive teaching sessions and suggest how they promoted Megan's transition to an anticipatory stage of mDC.

### *Promoting Construction of the Participatory Stage*

In order to move Megan to the participatory level of mDC, the teacher suggested that Megan use her fingers to keep track of the number of towers while counting the number of cubes:

*Excerpt 1 (Session 1, Introduction to Double Counting)*

T: Let me suggest the following. I'll give you my fingers for every tower. Okay? Every time we have a tower that's (holds up one finger) one tower of four– how many do we now have? You can use your fingers for [counting] the four [cubes].

M: So 4.

T: What if I brought another tower (raises a 2nd finger)?

M: 8.

T: What if I brought another tower (raises a 3rd finger)?

M: 12? (Doesn't look confident.) No wait.

T: You can use your fingers to figure it out.

M: (Counts under her breath.) 16? No!

T: So we had 4 – now let's use your fingers (shows counting on from 4 on his other hand) 5-6-7-8. And then, 9-10-11-12.

M: Yeah.

T: So now we have 3 [towers], what if we added another one (raises a 4th finger)?

M: 16.

T: Ok another one.

M: (Counts on her fingers under the table) 17-18-19-20.

T: So with 5 we have 20. We still have to go [bring towers] two more times.

M: (Counts on her own fingers) 21-22-23-24; 28.

The exchange in Excerpt 1 enabled Megan to start developing an intentional method for keeping track of the number of towers and to anticipate when to stop counting cubes. The teacher's continual prompts of, "What if I brought another tower?" oriented Megan's Type-I reflections between the accruing effects of the double counting activity and the global goal of finding the total number of cubes. This was possible because she could assimilate indicating a CU by the teacher's finger into her available numerical composite unit scheme. Consequently, Excerpt 1 provides a window to two important facets of the work: Megan's early shift to the participatory stage of mDC and how the teacher used tasks/prompts to promote this shift. Following the prompts, Megan knew to operate on the proper unit (cubes) with her number sequence, including anticipating that 4 cubes comprised a single CU (tower). Thus, the task, which required her to retrieve only one tower at a time and to count after each new acquisition, seemed to promote Megan's *coordination* of the two number sequences as evidenced by her finishing of the last two towers without needing to actually go get them.

Megan's construction of the participatory stage for mDC became evident in the task that followed (Excerpt 2).

*Excerpt 2 (Session 1, Participatory Double Counting)*

T: So you have 6 towers of 3 over there, and you use your fingers or your brain or (jokingly) your hair, or your blinking, or whatever, figure out how many are there all together… Can you put your fingers [above the desk] so I can see what you did?

M: (attempts to skip-count, first by 3's , then by 6's) 3-6-12-19? No, wait. (double counts, nodding her head as though counting, e.g., 4, 5, 6, but only speaking the total after each tower out loud) 3-6-9-12-15-18?

T: So 18? That's very good … I saw you putting 3, almost immediately; then 6 almost immediately. Then you started and recounted… So, could it be you said in your head, 7-8-9, 10-11-12, 13-14-15, 16-17-18 (puts a finger for each triplet)?

M: (nods yes)

Excerpt 2 indicates that the work on the previous task and the availability of counting triplets enabled Megan to solve $6T_3$ while internalizing the differentiation of 1's (cubes) from CUs (towers), distributing her units across each of the re-presented units, and coordinating the addition of the cubes and the number sequence of the CUs (tower). Two interventions were key to the formation of this coordination. The teacher began the task by imposing a constraint on Megan: she was not allowed to use paper and pencil to draw the $6T_3$. This oriented her to move away from simply counting individual (drawn) cubes. The teacher's prompt, "Can you put your fingers so I can see what you did?" provoked a Type-I reflection as Megan revisited the use of mDC *for* finding the total, as evidenced in her immediate self-correction after the first attempt ("3, …, 19") toward using mDC *intentionally* in distributing the unit rate (3 cubes/tower) over the number of CU (towers).

Megan's work on those two tasks indicated that she was in the participatory stage of mDC. We did not expect she could yet spontaneously call up the activity sequence, but we did expect she would use mDC when prompted. To test our hypothesis, we began the next episode by testing if Megan was at the anticipatory stage of mDC by engaging her in a prompt-less situation.

*Excerpt 3 (Session 2, Test Anticipatory/Participatory Double Counting)*

T: Pretend you were going (to retrieve a tower of Unifix cubes), and I sent you to get a tower of 3; another tower of 3, and another (etc.). And you brought, think of $7T_3$. Can you figure out how many cubes are there?

M: (Thinks – uses her fingers to count 1-2-3, 4-5-6, (inaudible speech), gets up to the 6th finger and gets lost.) Ok. I just forgot.

T: Ok. Just take your time. If you need my fingers, you can use them.

M: 3, 6... (Starts using teacher's fingers, but then goes back to her own.) 3, 6... 21. I think.

T: How did you get 21?

M: I added three 7 times.

T: Did you do this? (Demonstrates double counting with one hand monitoring) You raised one finger and said 1-2-3. Then you raised another finger and said 4-5-6 [and so on]. Is that what you did?

M: Yeah.

T: Ok. Let's see if your answer is true.

M: (Builds 7 towers of 3 and counts cubes.) 3, 6, 9, 12; 13-14-15; 16-17-18; 19-20-21.

Excerpt 3 indicates that Megan was yet to construct the anticipatory stage of mDC, as she became lost prior to the teacher's prompt for using *his* fingers. Once prompted, however, she could immediately regenerate an anticipation of the *AER* for mDC. She momentarily used the teacher's fingers, but then internalized the activity as evidenced in her shift to her own fingers for successfully completing mDC to reach her global goal. It confirmed our hypothesis, and led to interventions for promoting transition to the anticipatory stage via tasks with larger numbers.

*Promoting Construction of the Anticipatory Stage*

*Excerpt 4 (Session 4, In transition to anticipatory stage of Double Counting)*

T: Pretend you have a tower of 6, another tower of 6, and another [etc.]. Seven towers of 6. [How many cubes] would you get?

M: Um, 6, 12, 24 (gets lost on her fingers) I don't know. That's hard.

T: You can use my fingers.

M: I can't. That's hard.

T: That's harder, because I gave you larger numbers. [See if you can use] my fingers for the number of towers and use yours to count how many in each. So you said the first one is going to be 6 (puts out one of his fingers), then you said 12. (Puts down another finger) Then you started struggling. Use your fingers to add from 12, 6 more.

M: (Counts-on with her fingers) 12; 13-14-15-16-17-18.

T: Ok that's another tower (puts out another finger). That's 3 towers.

M: (Counting-on with her fingers.) 19-20-21-22-23-24 (Pauses for teacher to put a finger); 25-26-27-28-29-30 (Pauses for teacher); 31-32-33-34-35-36; 37-38-39-40-41-42.

T: Should we stop now, or go on? I said 7 towers.

M: Yeah, that's it.

When finding the number of cubes in $7T_6$, Megan struggled with the size of the numbers because each CU was larger than 5 (her fingers). This brought about her Type-2 reflection, evidenced in her realization ("I can't. That's hard") that using mDC would be difficult for the current situation because, *unlike previous situations*, she would not be able to simultaneously hold the number of towers and count the number of cubes. This Type-2 reflection, however, enabled her to easily assimilate the teacher's suggestion to use his fingers to keep track of CU and she immediately completed the task. It was her spontaneous contribution, evidenced in the intentional pause until the teacher raised his next finger, which led us to conjecture Megan might solve a similar task in the next week's episode at an anticipatory level.

To test our conjecture, we introduced a problem situation at the beginning of the following week's episode that required Megan to use mDC in a different context, asking her to create a PGBM situation (cubes, towers) that would be equivalent to having 7 baskets with 8 chicks in each. Megan immediately built a tower with seven same-color cubes and one different color cube, counting under her breath, "1-2-3-4-5-6-7-8." She then continued building more $T_8$ of the same color pattern until she had $7T_8$, at which point the teacher asked if she could figure out the total number of cubes. Megan spontaneously asked, "Can I use your hands?" and proceeded to count individual cubes on her fingers while counting towers on his, successfully stopping at 56. That is, Megan no longer needed a prompt. Rather, she clearly anticipated and spontaneously carried out the entire mDC activity sequence. The way she built her towers to present chicks and baskets, and her initiative for using the teacher's fingers, indicated that she intentionally (a) distinguished between the CU (towers) and UR (cubes/tower) and (b) used mDC to determine the total. Megan assimilated the chicks and baskets task into her global goal of finding total cubes and independently called up the activity sequence needed for multiplicative coordination of CU: differentiate 1's (cubes) from CUs (towers), distribute her units of 8 across each of the re-presented seven CU, coordinate the addition of the cubes and the number sequence of the CUs (tower), and employ two sets of objects (fingers) to keep track of both counts.

## Discussion

This study demonstrated a fundamental transition to multiplicative thinking. At the beginning of our analysis, we saw that Megan, a student at risk in mathematics, had not constructed mDC, putting her at a disadvantage with her peers (2-3 years behind). Through a *Ref**AER* designed intervention, Megan learned to spontaneously call up mDC for reaching her goal in various multiplicative situations. Megan's intentional translation of and solution to the mDC task in the last episode, including her request to use another set of fingers, indicated the commencement of her anticipatory stage of a units-coordinating scheme to which Steffe (1994) refers as an implicit concept of multiplication. Most importantly, this study demonstrated how Tzur and Simon's (2004) stage distinction for determining a learner's available conceptions could guide selection of tasks and prompts for transforming these conceptions. Such guidance included the introduction of double counting on one's and another person's fingers upon shifting to 'for pretend' tasks as a means to the sub-goal of simultaneously keeping track of clearly differentiated CU and 1's, progressing from small to large numbers, and continually orienting the learner's reflection onto the critical questions of when to stop counting (e.g., when Megan paused for the teacher's next finger).

## Endnotes

i) This research was conducted as part of the activities of the *Nurturing Multiplicative Reasoning in Students with Learning Disabilities* project, which is supported by the National Science Foundation under grant DRL 0822296. The opinions expressed do not necessarily reflect the views of the Foundation.

*This study investigated fraction problem reasoning and solving processes of pre-service elementary teachers from the United States and Taiwan. Eight open-ended problems were given to eighty-three pre-service elementary teachers, forty-one from the U.S. and forty-two from Taiwan. The results show that U.S. pre-service teachers were outperformed by their Taiwanese counterparts and tended to use more intuitive and visual but less formal and symbolic reasoning and solving processes compared to their Taiwanese counterparts. U.S. pre-service teachers had greater difficulty in solving non-pictorial problems embedded in a linear measure or set model than in an area model.*

## Introduction

The purpose of this study is to compare pre-service elementary teachers' processes in reasoning and solving fraction problems across countries. A study attempting a comparison of mathematics education between different educational traditions has been believed helpful to recognize the perpetual challenge to improve the quality of mathematics education in detail, and those based on the West and East Asia appear particularly promising for a cross-national comparison (ICMI, 2000). From the most recent Trends in International Mathematics and Science Study (TIMSS) report, we can find a substantial gap in student mathematics achievement existed between the five East Asian countries including Taiwan, Republic of Korea, Singapore, Japan, and China (Hong Kong SAR) and the United States (Mullis, Martin, & Foy, 2008). Meanwhile, the Programme for International Student Assessment (PISA) conducted in 2006 indicates that Taiwanese students had the highest level of mathematics achievement among participating countries including the U.S. (OECD, 2007). This study chose the U.S. and Taiwan to be the two comparative countries to illuminate the current interests on cross-national research of mathematics education.

It has been revealed that the countries with better quality of mathematics knowledge produced higher mathematics achievement (Akiba, Letendre, & Scribner, 2007; Kulm, 2008). Researchers also indicated that U.S. teachers have a weak grasp of basic mathematics knowledge as compared with their East Asian counterparts (Ma, 1999). With the gap of student mathematics achievement between the U.S. and the East Asian countries, therefore, it would not be a surprise that contrasting performances of mathematics teacher knowledge between the U.S. and East Asian countries can be discovered. Yet, in-depth studies on the relative differences of teacher knowledge are very limited. Without recognizing the relative insights and patterns of their differences in knowledge, the efforts for improving the quality of mathematics teacher knowledge cannot gain a focus and may result in a "mile wide and an inch deep" – the characteristic of current mathematics curriculum in the U.S. (Mirra, 2008).

## Theoretical Perspectives

The theoretical framework for this study derives from Shuman's (1986) discussion of subject matter content knowledge. Mathematics content knowledge refers to knowing a variety of ways in which "the basic concepts and principles of the discipline are organized to incorporate its facts" and "truth or falsehood, validity or invalidity, are established" (Shulman, 1986, p. 9). Mathematics content knowledge is rooted in how the knowledge of mathematics facts is coordinated with deeper understanding and application (Kahan, Cooper, & Bethea, 2003). Our focused topic is fractions – the seeds of advanced mathematics. Difficulty with fractions is a major obstacle for further progression in mathematics, including algebra, as described by the National Mathematics Advisory Panel (2008). Research studies on U.S. pre-service teachers have shown that many possessed limited concepts and operations of non-whole numbers (Azim, 1995; Ball, 1990a, 1990b; Graeber, Tirosh, & Glover, 1989; Tirosh, 2000; Simon, 1993). They concentrated on remembering rules and mastering standard procedures, and they often lacked comprehensive understanding of mathematical ideas and procedures (Ball, 1990a).

As was the case with the international student achievement studies, a substantial gap of mathematics knowledge was found between the U.S. teachers and their East Asian counterparts (Zhou, Peverly, & Xin, 2006). Significant differences were also found on their predication and expectation about students' solutions (Cai, 2004, 2005; Cai & Wang, 2006). With the awareness of a cross-national gap in mathematics teacher quality, teacher education programs in the U.S. have been encouraged to enhance their mathematics courses offered to their pre-service teachers and to provide more professional development opportunities to school teachers (Kulm, 2008). In addition, the approach of having elementary school teachers as mathematics content specialists has been proposed (Li, 2008). Elementary teachers need to know various mathematical topics for teaching, but teacher education programs typically include more training in pedagogy methods than in content knowledge (Hill, Schilling, & Ball, 2004). By focusing the need for expertise on fewer teachers who are specialized in elementary mathematics teaching, there could be a more practical alternative than increasing all elementary teachers' content knowledge (National Mathematics Advisory Panel, 2008). Still, more high-quality research must be undertaken in order to create a sound basis and provide different approaches for the mathematics preparation within pre-service elementary teacher education (National Mathematics Advisory Panel, 2008). Through comparing the problem reasoning and solving processes across countries, this study seeks to find the insights needed for developing a deeper understanding of mathematics called for by Ma (1999) and the Conference Board of the Mathematical Sciences (CBMS, 2001).

## Research Questions

Two research questions guided this study: (a) How well are pre-service elementary teachers from the U.S. and Taiwan capable of coordinating mathematics facts to reason and solve fraction problems, and (b) what are the similarities and differences of problem solving and reasoning processes between two groups of pre-service teachers?

## Methodology

*Participants*

Participants include eight-three pre-service elementary teachers, forty-one from the U.S. and forty-two from Taiwan. The purposive sampling was adopted to determine the participants (Leedy & Ormrod, 2005). On the U.S. side, the participants were selected from a regional teaching institution. On the Taiwanese side, the participants were selected from a traditional teacher education university. The selection unit is a class instead of an individual, but the number of total participants from each country is almost the same. Since most pre-service elementary teachers in Taiwan have their own content concentration, this study excluded the mathematics and science education majors to avoid their content strength contributing to a potential difference.

*Data Collection*

The results were drawn from the participants' solutions for eight open-ended problems designed for supporting another cross-national study. The collected solutions would allow us to know how well pre-service elementary teachers from the U.S. and Taiwan were capable of using mathematics facts to solve problems. The results from their solutions would also provide a comparison of the similarities and differences of reasoning processes between two groups of pre-service teachers. Table 1 below provides a summary of the eight open-ended problems representing combinations of two basic fraction concepts (part-whole relationship and fair sharing) and three common contextual models (area, linear measure, and set). Several problems were also developed into pairs to make an appropriate comparison: Problems #2 and #6 were embedded in the same mathematical concepts and contextual models, but only problem #2 has a pictorial illustration as part of the problem statement. Both problems #1 and #7 involve the concept of part-whole relationship, but they are different in terms of contextual models. Both problems #3 and #5 involve the concepts of fair sharing, but they are rooted in different contextual models. To measure the influence of visual and concrete representations, problems #2 and #8 include a pictorial illustration.

Table 1. *The Problem Concepts and Models*

| Concepts | Models | Problem Numbers |
|---|---|---|
| Part-Whole Relationship | Area | #1 |
| | Linear Measure | #8, #4 |
| | Set | #2, #6, #7 |
| Fair Sharing | Area | #5 |
| | Linear Measure | #3 |

*Data Analysis*

The technique of content analysis was utilized to identify specific characteristics of collected data. Coding the collected data into categories relevant to the research objectives is an essential procedure of a content analysis (M. Gall et. al, 1996). All the mathematical solutions were treated as the data sources and were coded into five success levels: failing (0), poor (.25), weak (.50), fair (.75), and good (1). The success rate for a problem was calculated by averaging the sum of scores from all pre-service teachers in the same group. To gain insights of pre-service teachers' reasoning and solving processes, each data source was coded with respect to its mathematical representations as well as specific characteristics of the solution procedures.

## Results

To compare the problem reasoning and solving processes between U.S. and Taiwanese pre-service elementary teachers in reasoning and solving fraction problems, we list the success rates and calculate their differences for each problem. As shown in Table 2, U.S. pre-service teachers' ability of reasoning and solving fraction problems were much poorer than that of their Taiwanese counterparts. The contextual models appear to be associated with the success rate of U.S. pre-service teachers but not with that of their Taiwanese counterparts. Both problems #1 and #5, the two problems with smaller differences of success rates between groups, are contextualized in an area model. Within the same contextual model and complexity, U.S. pre-service teachers had a higher success rate on a pictorial problem than on a non-pictorial one.

Table 2. *Success Rates and Differences between Groups for Each Problem*

| | #1 | #2 | #3 | #4 | #5 | #6 | #7 | #8 |
|---|---|---|---|---|---|---|---|---|
| U.S. | 56.1% | 70.8% | 29.3% | 33.5% | 76.4% | 47.6% | 25.6% | 28.7% |
| Taiwan | 95.0% | 97.0% | 89.7% | 100% | 88.2% | 97.5% | 89.9% | 95.2% |
| Difference | 38.9% | 26.2% | 60.4% | 66.5% | 11.8% | 49.9% | 64.3% | 66.5% |

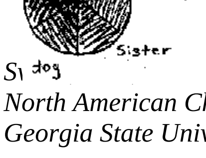
*Problems #1 and #7*

Both problems #1 and #7 are multiple-step problems, but contextualized in different models (see Table 3). It is more challenging for an individual to solve problem #1 than to solve problem #7. Only straightforward reasoning processes are needed to solve problem #1, but unnatural backward reasoning processes would be required to solve problem #7. The difference in the nature of the problem had a greater impact on U.S. pre-service teachers than on their Taiwanese counterparts. For the U.S. group, there was a wide difference between success rates for solving problems #1 and #7. The success rates of Taiwanese pre-service teachers were maintained at a relatively high level compared to their U.S. counterparts. Two groups of pre-service teachers used very different reasoning forms. For problem #1, particularly, most U.S. pre-service teachers used graphic drawing while the majority of their Taiwanese counterparts used symbolic equations to solve this problem. From the Figure 1 and Figure 2, we can see the contrasting reasoning processes between two groups. It is worth noticing that twenty-three Taiwanese pre-service teachers but only one U.S pre-service teacher used the algebraic symbol "*x*" to represent the unknown size of the whole. Figures 3 and Figure 4 are two examples illuminating the difference of problem reasoning and solving processes between two groups for problem #7.

Table 3. *Problem statements, Success Rates, and Reasoning Forms for Problems #1 and #7*

| Problem Statements | U.S. | | Taiwan | |
|---|---|---|---|---|
| #1. Mom baked a cake. Dad ate 1/6 of the cake. Brother ate 1/5 of what was left. Sister ate 1/4 of what was left after that. The dog ate 1/3 of what was left after that. Another kid ate 1/2 of what was left after that. How much of the original cake was left for Mom to eat? | Success | 56.1% | Success | 95.0% |
| | Symbolic | 9.8% | Symbolic | 100.0% |
| | Pictorial | 65.9% | Pictorial | 7.5% |
| #7. At the circus, the clown was busy counting all of the animals that performed. The clown figured that one half of the animals were horses, 1/4 of the remaining were big cats, and the rest were 9 monkeys. How many animals did the clown see altogether? | Success | 25.6% | Success | 89.9% |
| | Symbolic | 26.8% | Symbolic | 95.2% |
| | Pictorial | 36.6% | Pictorial | 21.4% |

*Figure 1.* A U.S. solution sample for problem #1



$\frac{1}{6}$ of the original cake was left for mom to eat after everyone was done. because eac time someone eats, you taking one piece aw from whats left.

*Figure 2.* A Taiwanese solution sample for problem #1

解: $[(1-\frac{1}{6})\times(1-\frac{1}{5})\times(1-\frac{1}{4})\times(1-\frac{1}{3})\times(1-\frac{1}{2})]$

$= [\frac{\cancel{5}}{6}\times\frac{\cancel{4}}{\cancel{5}}\times\frac{\cancel{3}}{\cancel{4}}\times\frac{\cancel{2}}{\cancel{3}}\times\frac{1}{\cancel{2}}]$

$= \frac{1}{6}$

*Problems #3 and #6*

As shown in Table 4, the U.S. group of pre-service teachers had much greater difficulty in solving problem #3, a linear measurement model, than in solving problem #5, an area model. Compared to U.S. pre-service teachers, Taiwanese pre-service teachers appeared to be much more adaptive to problems in different context models, and they were much more successful. Only minor difference existed between their success rates in solving both problems. Same as the finding for solutions for problem #1 and #7, it was found that the nature of reasoning processes demonstrated by the U.S. pre-service teachers is different from those demonstrated by their Taiwanese counterparts. U.S. pre-service teachers preferred to use pictorial processes to solve problems than using symbolic processes. In contrast, their Taiwanese counterparts had an inverse tendency.

Table 4. *Problem Statements, Success Rates, and Reasoning Forms for Problems #3 and #5*

| Problem Statements | U.S. | | Taiwan | |
|---|---|---|---|---|
| #3. A 2 meters long strip of paper was folded into three equal pieces. How long was each piece? | Success | 29.3% | Success | 89.7% |
| | Symbolic | 29.3% | Symbolic | 65.9% |
| | Pictorial | 63.4% | Pictorial | 34.1% |
| #5. Aunt Rachel had 2 cupcakes for the kids to share equally. There were three kids. How much did each kid get? | Success | 76.4% | Success | 88.2% |
| | Symbolic | 23.8% | Symbolic | 61.0% |
| | Pictorial | 73.8% | Pictorial | 39.0% |

Four Taiwanese pre-service teachers used advanced algebraic concepts to reason how to solve problem #5. As shown in Figure 3, a pre-service teacher from Taiwan addressed that each kid would obtain 2/3 of a cake for the situation of equal cakes and 1/3 $(x+y)$g cake for the situation of unequal cakes. None of U.S. pre-service teachers tried to apply the concepts of unknown algebraic symbols to solve this problem. We also found that seven U.S. pre-service teachers used decimals as their answers. A U.S. pre-service teacher used an intuitive reasoning to solve this problem by adding decimals repeatedly to make to make the quantity of 2 meters (see Figure 6). Similarly, seven Taiwanese pre-service teachers also used decimals as their answers. However, instead of using decimals to solve the problem, they directly transferred their fraction results from division computation into decimal answers.

*Figure 3.* A U.S. sample for problem #7

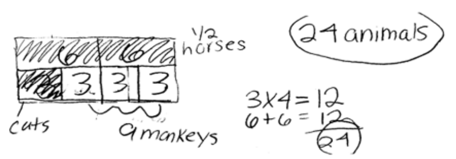


*Figure 4.* A Taiwanese sample for problem #7

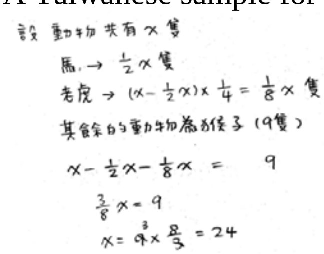


In addition, it was found that fourteen pre-service teachers, seven from each group, conducted a unit conversion. Nine of them tried to convert the given unit “meter” into the smaller scale unit “centimetre,” so the size of the number for representing the length of paper strip has to be expanded to 100 times. Their responses include $200\frac{2}{3}$ centimetres, 66.67 centimetres, and so on. The other five pre-service teachers were from the U.S. group. They tried to transfer the unit “meter” used in the metric system into “foot” or “inch” used in the English system, but did not make a successful unit transformation because of an insufficient knowledge of the metric system.

*Problem #2 and #6*

To examine the influence of the pictorial illustration further, we compared pre-service elementary teachers’ ability in solving the problems #2 and #6 (see Table 5). Notice that both problems involve the application of the same fraction concept and contextual model. From the problem-solving results for #2 and #6, we found that U.S. groups of pre-service teachers had much greater difficulty in solving the problem #6, which does not include a pictorial illustration than in solving the problem #2, which includes a pictorial illustration. It appeared that Taiwanese pre-service teachers were free from the influence of pictorial illustration, and their success rate maintained at relative high level compared to their U.S. counterparts.

Table 5. *Problem Statements, Success Rates, and Reasoning Forms for Problems #2 and #6*

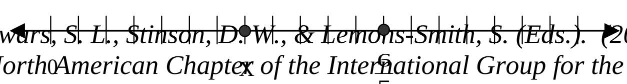
| Problem Statements | U.S. | | Taiwan | |
|---|---|---|---|---|
| #2. A basket contained 8 red apples, 2 bananas, and 4 green apples. What fraction of the apples is green?  | Success | 70.8% | Success | 97.0% |
| | Symbolic | 14.6% | Symbolic | 85.7% |
| | Pictorial | 19.5% | Pictorial | 0.0% |
| #6. Brandon has a box which contains 7 red marbles, 3 purple buttons, and 5 green marbles. What fraction of the marbles is green? | Success | 47.6% | Success | 94.5% |
| | Symbolic | 12.2% | Symbolic | 81.0% |
| | Pictorial | 53.7% | Pictorial | 4.8% |

*Problem #4 and #8*

As shown in Table 6, problem #4 is not a straightforward problem, but all of Taiwanese pre-service teachers provided correct solutions. Consistent with the findings for the other problems, Taiwanese pre-service teachers had a strong preference in adopting symbolic ways to reason and solve problems #4. Although U.S. pre-service teachers used more symbolic process than pictorial processes to reason and solve problem #4, the insights of their symbolic processes are different from those of Taiwanese pre-service teachers’ symbolic processes. U.S. pre-service teachers only engaged in the level of numerical symbols while their Taiwanese counterparts would involve the usage of algebraic symbols.

Table 6. *Problem Statements, Success Rates, and Reasoning Forms for Problems #4 and #8*

| Problem Statements | U.S. | | Taiwan | |
|---|---|---|---|---|
| #4. Jim jogged $1\frac{1}{2}$ miles yesterday. This is $\frac{3}{8}$ of his weekly goal? How many miles does he plan to run each week? Explain. | Success | 33.5% | Success | 100.0% |
| | Symbolic | 36.6% | Symbolic | 97.6% |
| | Pictorial | 22.0% | Pictorial | 14.3% |
| #8. What is the value of x? Explain. | Success | 28.7% | Success | 95.2% |



| | | | |
|---|---|---|---|
| Symbolic | 0.0% | Symbolic | 95.2% |
| Pictorial | 43.9% | Pictorial | 54.2% |

The reasoning processes of U.S. pre-service elementary teachers were more intuitive, informal, and pictorial than those of their Taiwanese counterparts while solving problem #4. Figure 7 and Figure 8 illuminate the difference of their reasoning processes. Problem #8 was one of most challenging problems for U.S. pre-service teachers, but an easy problem for Taiwanese pre-service teachers. Twenty out of forty-one of pre-service teachers from the U.S. omitted this problem. Most U.S. pre-service teachers approached this problem used a trial-and-error way to find the value for x reason while 95.2% of Taiwanese pre-service teachers incorporated symbolic and proportional reasoning processes to solve this problem.

Figure 7. A U.S. solution sample for problem #4

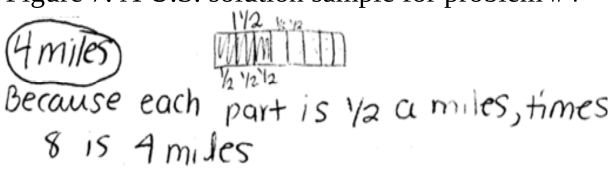


Figure 8. A Taiwanese solution sample for problem #4

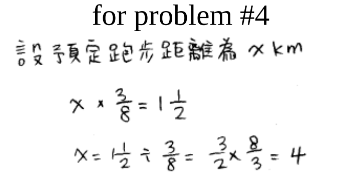

## Discussion and Conclusions

This study observed similar reasoning processes across groups. As addressed in the results, several pre-service elementary teachers from both groups converted the fraction for representing the magnitude of length into a decimal and/or converted the measure unit of length for a 2 meter strip into a smaller scale unit. Pre-service teachers might try to do the unit conversion to avoid the existence of fractions on the number line as described by Kerslake (1986). Additionally, they might perceive that the magnitudes of length should not be less than 1. Further investigation such as interviews should be conducted to explore their understanding about the magnitude of a quantity to provide appropriate treatments. For example, if their conceptual and procedural knowledge about fractions with magnitudes less than 1 is not consistent with fractions with magnitudes greater than 1, the background knowledge of fractions with magnitudes in each range needs to be taught directly (National Mathematics Advisory Panel, 2008).

Additionally, this study adds to our understanding of issues in the preparation of teachers' mathematical ability. Consistent with previous cross-national studies, this study did not find sufficient evidence to draw the conclusion that U.S. pre-service teachers have established a satisfactory ability of reasoning and solving fraction problems as their Taiwanese counterparts. U.S. pre-service teachers favored using intuitive, informal, and pictorial strategies more than their Taiwanese counterparts. We suspect that is what these pre-service elementary teachers learned when they were upper elementary or middle school students. Without any intervention, it is very likely that these U.S. teachers will adopt intuitive mathematic methods in their future classrooms without seeking to enter advanced mathematical reasoning and problem solving skills. We conclude then research on what U.S. upper elementary and middle school mathematics teachers should know and what they should expect their students to learn needs to be undertaken.

# MATHEMATICS-FOR-TEACHING: AN ETHNOPOETIC PERSPECTIVE

Joy A. Oslund
Alma College
oslund@alma.edu

*Ongoing research seeks to discover and describe the knowledge of mathematics-for-teaching teachers employ to facilitate students' understandings. Convinced by Davis and Simmt (2006) that much of this knowledge is implicit, this study seeks to show that teachers' unarticulated mathematics-for-teaching competencies can be studied through ethnopoetics (analysis of the form of teachers' talk). The findings broaden the range of competencies that may be called mathematics-for-teaching and suggest that mathematics-for-teaching is context-specific. Implications for teacher professional development and research are discussed.*

## Purpose of the Study

The mathematics needed for teaching is different than classical mathematical knowledge, but what counts as necessary mathematics-for-teaching is not yet fully known. Ball, Bass, and Hill (2004) have studied what teachers do (job analysis) to theorize mathematics-for-teaching and include practices such as interpreting students' mathematical work and unpacking the mathematical ideas in a problem. Davis and Simmt (2006) expand on those notions by observing what teachers say about teaching in interactions around mathematical content in a teacher study group. They argued that much of teachers' knowledge of mathematics-for-teaching is implicit. They said, "We believe that a key (and perhaps *the* key) competence of mathematics teachers is the ability to move among underlying images and metaphors—that is, to *translate* notions from one symbolic system to another." (p. 303).

These studies have reported on the *content* of teachers' talk about mathematics and mathematics teaching. However, if much of teachers' knowledge of mathematics-for-teaching is implicit, as Davis and Simmt (2006) claim, then looking beyond the content to the *form* of teachers talk is needed. *"How* something is said is a part of *what* is said" (Hymes, 1972, p. 59). How teachers' ways with words perform their understandings of mathematics-for-teaching requires further study.

I analyzed two teachers' narratives of a lesson about fractions on a number line to learn about their mathematics-for-teaching. To examine their tacit knowledge of mathematics-for-teaching, I focused on the *form* of their discourse. I unveiled tacit mathematics-for-teaching competencies in both teachers' stories. Whereas I had begun the analysis with an initial perception that one teacher was more mathematically sophisticated, the results challenged my initial perception.

## Theoretical Framework

### *Mathematics-for-Teaching as Discourse: The Centrality of Metaphor*

Davis and Simmt (2006) argued that the ability to move between metaphors is key to mathematics teaching. Metaphor is a discursive tool. In fact, mathematics may be conceptualized as a discourse. That is, mathematics may be theorized as communication (with oneself or others) about mathematical objects (which are constructed through discourse). Metaphor, or the mapping of language from one domain (for example, physical objects) onto another (such as abstract ideas), is central to creating and understanding mathematical ideas (Sfard, 2008). In the sections that follow, I report on teachers' talk about a lesson on fractions and number lines. Therefore, I will next explain some metaphors that are important to understanding those two concepts.

*Grounding metaphors.* Lakoff and Nuñez (2000) theorized four grounding metaphors that ground arithmetic to physical objects—the *metaphor of object collection*, the *metaphor of object construction*, the *measuring stick metaphor*, and the *metaphor of motion along a line*. Fractions are often understood using the *metaphor of object construction*, because they are constructed by dividing a whole into parts. In that case, a key metaphor is *numbers as objects*. In the *measuring stick metaphor*, arithmetic is conceptualized as the use of a measuring stick. Numbers are physical segments, with the basic physical segment being one. Longer segments are greater and shorter ones are less. Arithmetic is putting segments together and taking them apart.

*Linking metaphors.* Linking metaphors take us beyond the physicality of grounding metaphors to more sophisticated ideas. The metaphor of *numbers as points on a line* is an example. It builds on the measuring stick metaphor and the metaphor of arithmetic as motion along a path but maps these ideas onto the concept of a line (instead of a physical object). This requires understanding several other metaphors: a number $P^1$ as point $P^1$ on a line, zero as a point 0 on the line, one as a point 1 to the right of 0, etc. Sophisticated mathematical understandings and are built by layering metaphor upon metaphor, a process called *conceptual blending*. In contrast, teaching mathematics involves unpacking the layers of metaphor (in effect, unblending) and deftly moving between them to facilitate students' conceptual blending.

*Communicative mathematics-for-teaching competencies.* The teachers in this study had participated in a professional development course that focused (in part) on broadening notions of mathematics and mathematical competence. Teachers discuss competencies of students' that have not traditionally been considered mathematical and ways to help students mobilize them to solve mathematical problems. The goal is for the teachers to ask *how* a student is mathematically competent instead of *whether* they are, recognizing that perceptions of competence are culturally-laden. Likewise, in this paper I investigate the competencies teachers bring and how they mobilize them to teach mathematics. I am assuming that there are competencies required for mathematics teaching that have not yet been considered by the literature.

Viewing mathematics as a discourse, it makes sense to study teachers' mathematics-for-teaching competencies by analyzing their discourse. Survey-based work has increased understanding of mathematics-for-teaching and its importance for student learning (Ball, Bass, & Hill 2004). However, how teachers translate this knowledge into discourse is unknown. Such translation requires knowledge of mathematical content and pedagogy, but also communicative competencies, including effective use of metaphor. Additionally, discursive norms vary between contexts, so such work involves understanding culture. I use the phrase *mathematics-for-teaching competencies* to encompass all these ways of knowing.

*Ethnopoetics and Mathematical Discourse*

If much of teachers' mathematics-for-teaching is tacit, then researchers need new tools to access it. To do so, I employed methods from ethnopoetics, a premise of which is that speakers construct arguments through both the *content* and the *form* of speech (Hymes, 1972). Because mathematics is a discourse, mathematical knowledge and arguments are also constructed through both the *form* and *content* of the communication. Consider the following example from the literature. Staats (2008) highlighted the syntactic parallelism through which a child made a mathematical argument about passing out Cuisinaire rods to a group:

1 Yes

2 Cos every fifth one
3 from William
4 is going to be
5 a white,
6 and every fifth one
7 from the next person
8 is going to be
9 a red,
10 and every fifth one
11 from the next person
12 is going to be
13 a green
14 eh? (Staats, 2008, p. 26)

Staats argued that the parallel structure of this speech is the way this child makes his mathematical argument. That is, through a grammatical pattern, he is performing understanding of the arithmetic pattern and generalizing. She points out the importance of looking across sentences to discern arguments made implicitly by the form of discourse. (Staats, 2008).

However, the discourse of mathematics teachers has been primarily studied in terms of content. Little attention has been paid to the form of teachers' mathematical talk. Therefore, the field is missing some important knowledge about how teachers communicate mathematical ideas in their teaching practice. The research question that guides this study is:

- What can be learned about teachers' mathematics-for-teaching through an investigation of the *form* of teachers' discussions of mathematics and mathematics teaching?

## Method

*Context, Data Collection, and Participants*

This paper describes part of a larger study on experienced elementary teachers' narratives of practice as they implemented new mathematics pedagogies. The teachers had participated in a professional development (PD) course on strategies for teaching mathematics with cooperative groups. They were implementing strategies from the workshop during the eight months of data collection.

I conducted pre- and post-lesson individual interviews with teachers about lessons in which they used cooperative grouping strategies. I asked teachers to tell me the story of the lesson and prompted them to fill in details about students' mathematical ideas, their use of teaching strategies learned in the PD course, and their thoughts and feelings during the lesson.

The teachers and I also met together as a group for a total of six hours over several weeks to discuss their use of the strategies. They came prepared to share classroom stories. One teacher would tell a story about teaching, and the group would discuss it. After the group had finished discussing that teacher's story, the second teacher would tell a story of teaching, so on. I video- and/or audio-taped every interview.

The larger study includes four teachers. All had taken the PD course, chosen to be a part of the study, were interested in reflecting on and improving their mathematics teaching practice, and were attempting to implement the group work strategies learned in the PD. They were experienced teachers (with 10-30 years of experience). They varied in school context, grade-level, race, and gender, and in how they identified as mathematically competent (or not).

I report here on two focal teachers who seemed to speak about mathematics-for-teaching differently. Jonathan, a fifth-grade teacher who identified as "the math guy" in his school, was eager to talk about the mathematical understandings of his students, often spending several minutes talking about his students' mathematical ideas with little or no prompting. In contrast, Glynnis, who taught fourth grade, directly identified as "not a math person". When asked about the mathematics at stake in particular tasks she often responded with only a few words, and when asked about her students' understanding of mathematics, she often had less to say than Jonathan. A first impression might lead one to believe that Jonathan had more sophisticated knowledge of mathematics-for-teaching than Glynnis. However, this paper explores the ways with words Glynnis and Jonathan employed to make mathematical metaphors accessible to students.

Both teachers taught variations of the same mathematics task to their students. Students were given some numbers with decimals and asked to plot them on a number line. Both teachers told me their stories of the lesson afterward. In this paper, I will compare parts of the two stories.

*Data Analysis*

After repeatedly listening and watching the interviews and writing analytic memos about their content, I transcribed analytically salient segments of the data. For this paper, I compare two particular stories about the same mathematics task told by two different teachers. I chose to present in detail a small excerpt of each in which both teachers are trying to accomplish the same thing—helping children to conceptualize the number *one* and *fractions* on a number line. I examined the transcripts and audio for the teachers' use of theatrics (such as dialogue and asides) and poetics (including alliteration, cadence, etc.) After experimenting with several ways of arranging the transcripts, I settled on an arrangement that highlights parallel syntax and ideas, in order to illustrate teachers' use of parallelism for facilitating students' conceptual blending.

## Results

*Connecting Mathematically Important Ideas and Moving Between Metaphors*

*Glynnis.* In the following excerpt, Glynnis is describing an event in which she is talking to a student about placing numbers on a number line. I arranged the following transcript excerpt to highlight parallel ideas. In this case, the subject and action of the sentences are on the left, and the mathematical objects are aligned further left as well as highlighted with bold text. When certain actions were mentioned repetitiously, I tried to align those as well (drew and plotting in lines 38-41, for example). I also divided it into stanzas to highlight shifts between metaphors.

**Stanza 1**

| **Stanza 5** | | | | |
| 48 | I says so | | | |
| 49 | you're figuring out that between | | **here and here** | |
| 50 | represents | A | **whole,** | |
| 51 | | and the | **whole** | has to be |
| 52 | | | | divided into what. |

Glynnis brought different metaphors of number into relationship via parallelism as she told this story. In Stanzas 1 and 5, notice the alignment of the words "here to here", "one", and "whole". Glynnis drew on a metaphor these children understood--the metaphor of *number as object* (Lakoff & Nuñez, 2000)--to define the space between zero and one as the *object* on which children should act (divide) to construct fractions. However, in using the words "here to here", she made a *line segment* an object. Therefore, she drew a connection to Lakoff and Nuñez's second grounding metaphor of arithmetic—the measuring stick metaphor—which includes the linking metaphors *numbers as physical segments* and *one as the basic physical segment*. The effect of placing different words for different objects in the same syntactical place is that the audience hears them as synonymous.

In Stanza 4, Glynnis used parallelism to bring "number line", "landmark number", "one-and-three-tenths", "half", and "here" into relationship. This is a different metaphor of number, *numbers as points on a line*. The way Glynnis mapped the metaphors of numbers as objects, physical segments, and points on a line onto each other is in the *form* of her language. She did not explicitly state the different metaphors on which she is drawing. However, she brought the ideas into relationship through the form of her speech—by using the language of different metaphors but using the cohesion strategy of syntactic parallelism (all of these mathematical ideas are used as the objects of her sentences) to help the audience map them onto each other.

In Stanza 5 in lines 47-50, Glynnis returned to language of numbers as line segments. However, in line 50-51, when she said, " the whole has to be divided into what", her language was that of the *arithmetic as construction of objects* metaphor, which Lakoff and Nuñez claim is often the metaphor by which children first understand fractions (because fractions are constructed by cutting an object into equal pieces). Glynnis built on this metaphor, adding the new metaphor of numbers as points on a line, to facilitate a conceptual blend: fractional numbers as points on a number line. By moving back and forth between metaphors and substituting one idea for another across lines of speech, she facilitated students' development of sophisticated metaphorical blends.

*Jonathan*. In the following excerpt, Jonathan is telling the story of the number line lesson:

| | | | | | | |
|---|---|---|---|---|---|---|
| 1 | I | Had | | | | **meter** sticks |
| 2 | I | held up | | | the | **meter** stick. |
| 3 | I | said to them | | This is | a | **meter** stick. |
| 4 | | | | It 's | **one** | **meter.** |
| 5 | | | So | this is | the | **whole.** |
| … | | | | | | |

As Jonathan continued the story, he began to go through students' work and tell me about various groups of students during the lesson. One group had made a diagram like that in Figure 1.

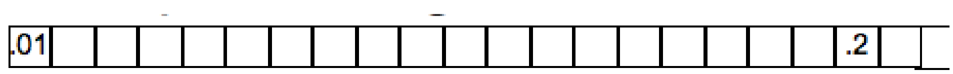

*Figure 1.*

Instead of drawing the kind of number line Jonathan had envisioned before the lesson, the students drew a row of one hundred boxes. They had placed the numbers they were supposed to put on the number line into boxes in the row. Then Jonathan continued with the story:

| | | | | |
|---|---|---|---|---|
| 260 | I guess | | | |
| 261 | I hadn't done enough with | | **number lines.** | |
| 262 | | About what a | **number line** | really means. |
| 263 | **It**'s not | | numbers in order | |
| 264 | **it**'s | | places on a line. | |
| … | | | | |
| 279 | Right so actually | | | |
| 280 | what they did is not said where the | | **spot** | is |
| 281 | but they said | | | |
| 282 | **this square** | Represents | **one (hundredth),** | |
| 283 | so they thought of it more as | | **a fraction** | |
| 284 | Right? | | | |
| 285 | | | **One out of a hundred.** | |

Jonathan also used parallelism to bring ideas together. In lines 1-5 he brought the ideas "meter", "one", and "whole" together. Like Glynnis, he drew on two of Lakoff and Nuñez's metaphors here: numbers as line segments (lines 1-4) and numbers as objects (line 5). Again, these are metaphors that were commonplace in the classroom, and he brought them into relationship by substituting one for another using syntactic parallelism.

In lines 260-264 he added the concepts "number line" and "places on a line" in the same way. However, he explicitly described a number line ("it's") as "places on a line" by placing "it's" in the subject of the sentence (in bold text above). In effect, he used multiple ways with words to build this sophisticated conceptual blend—explicit descriptions of metaphors to clarify concepts, and syntactic parallelism to build connections between them.

In lines 279-286 he used parallelism to bring the terms, "spot", "square", "one hundredth", "fraction", and "one out of a hundred" together with previous ideas. The word "square" (an object) draws on the metaphor of number as object, the words "one hundredth", "fraction", and

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

"one out of a hundred" draw on the metaphor of arithmetic as object construction, and the word "spot" (substituted for point) draws on the metaphor of numbers as points on a line. In lines 279-281 and 283-286 these ideas are grammatically parallel to one another. However, in line 282 Jonathan again placed the mathematical idea (square) in the subject of the sentence to explicate the metaphor his students had demonstrated. Again, he explicitly described a metaphor (resulting in clarity) then used grammatical syntax to facilitate conceptual blending.

*Differences between stories*. Glynnis and Jonathan both used similar poetics to bring concepts into relationship as they moved across metaphors. Why, then, was I initially under the impression that Glynnis's talk was less mathematically sophisticated than Jonathan's? Was it simply because Jonathan made metaphors explicit in his story? In Table 1 I place parts of these transcripts side by to highlight other differences in the form of their talk. Above, I described how Glynnis and Jonathan used parallelism in similar ways to make the moves between metaphors more cohesive. This is indicated in Table 1 as a box with a solid line. However, the rest of their speech is structured very differently. Jonathan's appears to be neat and tidy, only including phrases that line up nicely in parallel (indicated in shaded boxes). In contrast, Glynnis includes an aside (lines 5-13) in which she describes the numbers the students were using in the task. Before and after this aside Glynnis inserts two 3-line stanzas that are grammatically parallel. This brings a sense of cohesion and connection between lines 1-3 and lines 47-49. It seems that a major difference may be in the economy of syntax, as opposed to the level of sophistication of their conceptual blends.

Table 1. *Comparing Glynnis's and Jonathan's Stories*

| Glynnis | | | | Jonathan | | | | |
|---|---|---|---|---|---|---|---|---|
| 1 Actually | | | | 1 | I | had | | **meter** sticks. |
| 2 one of the women | | | | 2 | I | held up | | a **meter** stick. |
| 3 | recognizing that from | **here to here** | was the | 3 | I | said to them | **this** is | a **meter** stick. |
| 4 | | **one whole** | | 4 | | | **It** 's | **one meter** |
| 5 You know cuz I think | | | | 5 | | | So **this** is | the **whole** |
| 6 we were doing it yesterday | | | | | | | | |
| 7 and they were ordering | | **one** and | | | | | | |
| 8 | | **one** | | | | | | |
| 9 | it was all | **one** and | | | | | | |
| 10 | | **one** and | | | | | | |
| 11 | it was still | | | | | | | |
| 12 | hundredths and | | | | | | | |
| 13 | Stuff like that. | | | | | | | |
| … | | | | | | | | |
| 47 I says so. | | | | | | | | |
| 48 You're figuring out that between | | **here and here** | | | | | | |
| 49 | represents a | **whole**. | | | | | | |
| 50 | and the | **whole** | has to | | | | | |
| 51 | | | be divided into what. | | | | | |

## Discussion and Conclusions

Discourse and culture are related--language is spoken and interpreted differently in different contexts. Perhaps both teachers are performing knowledge of their particular students and schools in the form of their talk. Certainly, culture influenced my initial perception their talk.

Both teachers moved among important underlying metaphors, performing a key mathematics-for-teaching skill (Davis & Simmt, 2006). But does Jonathan's story perform a more sophisticated understanding of mathematics-for-teaching than Glynnis's? Maybe. Jonathan did sometimes make ideas explicit in a way that Glynnis did not. However, it is also possible that my initial perception was due to the comparative *elegance* of Jonathan's talk, an aesthetic evaluation of the storytelling that parallels something valued in the culture of mathematics. Einstein said of mathematical proofs, "We are completely satisfied only if we feel of each intermediate concept that it has to do with the proposition to be proved." (Luchins & Luchins, 1990, p. 38). Perhaps values of the mathematics community have been used to judge teachers' mathematics-for-teaching talk and marginalize some mathematics-for-teaching competencies that facilitate student learning. Is it appropriate to apply the same criteria to mathematical pedagogical discourse? An elegant mathematical proof leaves out any indication of the messy work that led to it. If teachers and students are engaging in reasoning and proof, it is likely that the majority of their classroom talk will be ugly by mathematical standards. Additionally, mathematical proofs are written with others in the same discourse community as the intended audience. Teachers' audiences vary widely in regards to culture, age, children's backgrounds, and the like. Acknowledging that teaching mathematics requires more than classical mathematical knowledge means assuming that the discourse of mathematics-for-teaching will be different than the discourse of classical mathematics, in part because the context is different.

My initial perceptions of the teachers were possibly based on how they identified themselves—that is, their own perceptions of their mathematical sophistication. Jonathan identified as "the math guy" and identified as mathematically competent by including mathematics-for-teaching in the content of his talk. Glynnis identified as "not a math person" and identified as less competent by avoiding mathematics-for-teaching in the content of her talk. Glynnis seems to be performing knowledge she is not even aware she has. What would be the influence teachers' practices if they recognized and valued the mathematics-for-teaching competencies they bring to the classroom?

Looking at the form of teachers' discourse for their *mathematics-for-teaching competencies* revealed competencies that the field has formerly overlooked. This study challenges narrow notions of competence. Further attention to the context-specific nature of mathematics for teaching is warranted, as is more work aimed toward broadening our notions of what counts as mathematics-for-teaching, so we can imagine, value, and build on a wider range of competencies teachers bring to the work of mathematics teaching.

## Theoretical Framework

This work is grounded in theories about cognition (i.e., knowledge) and teacher beliefs. Núñez, Edwards, and Matos' (1999) theory of cognition is based on a situated approach that incorporates linguistic, social, and interactional influences. In essence, this theory claims "there is no activity that is not situated" (Lave & Wenger, 1991, p. 33). However, Núñez et al. (1999) argue that thinking and learning are also situated within biological and experiential contexts that shape our understanding of the world. These researchers contend that "knowledge and cognition exist and arise within specific social settings . . . and that the grounding for situatedness comes from the nature of shared human bodily experience and action, realized through basic embodied cognitive processes and conceptual systems" (p. 46). Thus, cognition is a multifaceted social phenomenon that is observed in daily practice and is encompassed by "mind, body, activity and culturally organized settings" (Lave, 1988, p. 1), such as methods courses and everyday mathematics classrooms.

Beliefs are defined as existential presumptions, which are the personal truths everyone holds and are characterized by making judgments and evaluations about phenomena, subject matter, and individuals (Abelson as cited in Parajes, 1992). Individual beliefs endure even when they are contradicted by reason, evidence or experience (Parajes, 1992). Lortie (1975) contends that beliefs about teaching are developed at early ages and are well-established before students enter college. However, changing preservice teachers' beliefs is possible if they have a gestalt shift (Pajares, 1992). Since classroom behavior is the result of beliefs that have been filtered by experience, altering preservice teachers' experiences has the potential to change their beliefs (Parajes, 1992). Teachers' beliefs must be inferred by analyzing their belief statements and behaviors (Goodman as cited in Parajes, 1992). Examination of these belief statements and behaviors are critical to understanding teachers' beliefs about teaching and learning mathematics.

## Purpose of the Study

The purpose of the study was to examine the influence of a reform-based mathematics methods course on elementary preservice teachers' content knowledge and educational beliefs. The research questions that guided these studies were: 1) How did elementary preservice teachers' mathematics content knowledge compare before and after taking a reform-based mathematics methods course? 2) How did elementary preservice teachers' educational beliefs compare before and after taking a reform-based mathematics course?

## Methodology

*Setting and Participants*

Participants were enrolled in one section of mathematics methods during the fall semester of 2004 ($n$ = 25): females (23) and males (2). The study was conducted at a large research university situated in an urban city in the northeastern U.S. The College of Education had an enrollment of approximately 2,100 undergraduate students during the 2004-2005 academic year. The participants constitute a convenience sample since they were arbitrarily enrolled in the reform-based mathematics methods course.

*Data Collection, Data Sources, and Data Analyses*

Mixed methods (quantitative and qualitative) were used to collect data in this study. Quantitative methods were used to compare preservice teachers' content knowledge and efficacy beliefs before and after taking the reform-based mathematics methods course. To measure the development of MCK we used a content knowledge test that measured what elementary teachers were required to teach (Ball et al., 2005). The tests consisted of 50 open-ended items that primarily addressed conceptual and procedural knowledge of fractions, decimals, and percents. We used case studies to collect and analyze qualitative data in this study. Case studies are often focused on a select number of participants for in-depth study (Lincoln & Guba, 1985).
The cases in this study were selected based on the preservice teachers' content scores to obtain a representative sample and to show how beliefs and content knowledge may be related. We used the average scaled score on the pretest ($M$ = 63) and half the standard deviation to determine the cut scores for each category: high (>70); moderate (56-70); low (<56). We used stratified random sampling to select three participants from each category for cross-case analysis to obtain nine cases.

Qualitative data sources included hand-written journals. Preservice teachers' made 8 - 10 journal entries. They were asked to reflect on their previous mathematics background knowledge for the first entry and on what they believed they learned during the semester for the last entry. Using the Constant-Comparison Method (Glaser & Strauss, 1967), we analyzed the preservice teachers' journals to note changes or lack of changes in their belief system. Preservice teachers' belief statements were coded and categorized based on the data that emerged. We used these data to support quantitative data collected in this study and to explain how preservice teachers' belief systems are intertwined with content knowledge.

## Results

*Mathematics Content Knowledge*

Bridget taught one section of elementary mathematics methods in the fall semester of 2004. Participants included 25 preservice teachers who took the mathematics content pretest in early October 2004. However, only 24 preservice teachers took the posttest in December of the same year. As shown in table 1, the results of a paired samples $t$-test (two-tailed) show a statistically significant difference between pretest ($M$ = 63.17, $SD$ = 16.418) and posttest scores ($M$ = 80.04, $SD$ = 12.067), $t(23) = -7.766$, $p$ = .000. The effect size of these results found using Cohen's $d$ was 1.17, which is considered to be a large effect size (Cohen, 1992).

*Preservice Teacher Beliefs*

We selected nine cases (Joy, Mandy, Erin, Edith, Jamie, Yvette, Cathy, Joan, & Anita[9]) for qualitative analysis. Preservice teachers' responded to queries about their mathematics background and beliefs at the beginning of the course and reflections on their beliefs and practices at the end of the course. These data were read and coded by Bridget and another mathematics educator who taught mathematics methods courses in the College for member checks. Analysis of the journals reveal eight factors related to educational beliefs emerged in the case study participants' journals at the beginning of the reform-based methods course: (1) beliefs (i.e. judgment/evaluation); (2) values; (3) educational history; (4) affective states; (5) verbal

[9] Pseudonyms were used for anonymity in Studies 1 & 2.

persuasion; (6) vicarious experiences (7) mastery experiences; and (8) content knowledge. Three additional factors, for a total of 11 factors, related to educational beliefs emerged from case study participants' journals at the end of the reform-based methods course: (9) new knowledge; (10) personal teaching efficacy (i.e. self-efficacy); and (11) teacher efficacy (i.e., outcome expectancy). A descriptive analysis of their belief patterns are shown in Table 3. Preservice teachers' educational belief statements will be compared and contrasted before and after taking the methods course.

*Comparison and Contrast of Educational Beliefs at Beginning and End of Course*

*Belief statements.* Belief statements (i.e. judgments/evaluations) were made about mathematics as a subject domain and/or mathematics teaching and/or learning in all nine cases at the beginning of the methods course. For example:

> *I am a strong believer that children will learn better through inquiry and active learning.* (Mandy)
>
> *Many people dislike mathematics.* (Yvette)

In comparison, preservice teachers made beliefs statements in all nine cases at the end of the course just as they did at the beginning of the course. However, the belief statements were more robust at the end of the course:

> *If math teachers would stop forcing students to memorize facts and lecturing and add hands-on activities, such as the ones we presented in class, math would be a more enjoyable subject. If the children enjoy it, they will perform better.* (Anita)

*Value.* Yvette was the only preservice teacher to make a value statement at the beginning of the course: *I believe that math is very important because it is used in our everyday lives.* However, Yvette's statement, in conjunction with the one highlighted above, reveals some preservice teachers can dislike mathematics and still value it. Likewise, Cathy's case was only one to refer to values at the end of the course: *I still maintain the belief that math is essential and is everywhere.* However, what is not clear from either of the journal entries is how these two preservice teachers might go about helping students to value mathematics.

*Educational history.* In eight cases (all but Joy), preservice teachers included statements about educational history at the beginning of the course. Statements about educational history were prompted by Bridget's request that preservice teachers' describe how their educational background influenced their learning of mathematics in their initial journal entry. For example, Jamie stated:

> *Math was one of those subjects that I used to love. My worst experiences were in 3rd grade and 10th-grade algebra.*

The data in Jamie's case as well as several others were consistent with the findings of Charalambous et al. (2008) and Swars, Hart, Smith, Smith, and Tolar (2007), which suggest that educational histories influence teacher belief systems about mathematics content.

Joan's was the only case to refer to educational history at the end of the course:

> *I was the student that just needed an example from the teacher in order to learn how to use a math concept. I never used interesting materials with math, which may be the reason I never enjoyed math class. Some students need to learn math with a hands-on approach.* (Joan)

However, what is compelling about Joan's statement is she did not allow her educational history to stand in the way of the students' needs. She realized that all students do not learn mathematics in the same way. Yet, it is unclear whether this was a modified, new, or sustained belief.

*Affective states.* Preservice teachers also made statements about their affective states in all nine cases in the beginning of the course. However, the affective statements of preservice teachers who were immigrants in the U.S. provided interesting caveats:

> *I used to attend school in Bahrain. I had to memorize everything. I remember disliking having to memorize the times tables and doing long division.* (Joy)
>
> *I really don't like mathematics. Many people dislike math. I don't like a subject where there can only be one right answer to a solution. I am a foreigner in the U.S. and have been in this country for eight years. My country is now called Ukraine, but my native tongue is Russian. Coming from a place where mathematics was the key to a successful education, I can honestly say that in my former country math was something that you had to know how to do or else.* (Yvette)

These two cases illustrate that emphasis on memorization could have a negative impact on students' belief systems (beliefs, attitudes and values) as they relate to learning mathematics regardless of their country of origin.

In contrast, affective statements were made about mathematics and mathematics teaching in six cases (Joy, Erin, Edith, Jamie, Yvette, & Joan) at the end of the course. In three of these cases, feelings about mathematics changed as a result of the course:

> *This class has opened my eyes to see that math can be fun.* (Joy)
>
> *I am happy to say that I no longer hate math, but I am intrigued at the endless possibilities I have in teaching math.* (Erin)
>
> *Since taking this course, my feelings about math have changed. The practicum had a lot to do with this because I learned how to make math lessons iterative and engaging for students. In this course I saw how important it is to use manipulatives in math lessons. I have never really liked math.* (Joan)

While these statements are encouraging, Parajes (1992) reminds us that newly acquired beliefs are vulnerable. On one hand she states that her beliefs had changed, and on the other hand she admits she "*never really liked math.*" Yet, it was Joan who realized that her dislike for mathematics may have been connected to how it was presented to her and not mathematics itself. Joan's mixed message reveals the importance of field experiences in improving preservice teachers' negative feelings toward mathematics (Hart, 2002).

*Verbal persuasion.* Verbal persuasion was inferred from statements made in three cases (Cathy, Joan, & Anita) at the beginning of the course. One example of verbal persuasion is:

> *My teacher told my parents that I was a "wiz at math."* (Joan)

Interestingly, all statements related to verbal persuasion were made in cases where the preservice teachers had high content knowledge. No statements were made in the journals that could be classified as verbal persuasion at the end of the course.

*Vicarious experiences.* Mandy was the only case study participant to include statements about vicarious experiences at the beginning of the course. She referenced Kay Toliver after watching *Good Morning Ms. Toliver* on the first day of class.

> *I never learned math like that and saw [in Kay Toliver video] how much the kids were learning while they were having fun and connecting it to the real world.*

In contrast, vicarious experiences were mentioned in four cases at the end of the course (Joy, Mandy, Erin, & Edith). In two cases (Mandy & Erin), the influence of Kay Toliver tapes on preservice teachers' belief was evident. These statements support Yoon et al.'s (2006) contention that teachers' beliefs and efficacy can be improved with videos. Interestingly, all four of these preservice teachers also mentioned the positive impact that peer teaching had on their beliefs and efficacy. For Edith, peers had a profound impact on her beliefs:

*Another part of this semester that I truly enjoyed was the learning community we developed. Everyone who was in my practicum was also in science and math methods courses. This was beneficial because we truly got to know and learn from our peers.*

Edith's comment also provides a rather unique finding that suggests the importance of establishing a learning community. One's peers can provide the support needed to sustain newly acquired knowledge and beliefs. Joy's case pinpoints the importance of peer modeling on her beliefs:

*Having my classmates teach lessons also added to my collection of lessons that I could teach to my future students.*

This is also a unique finding that is not prevalent in the literature. Microteaching was a part of the mathematics methods course because Bridget did not believe she could evaluate preservice teachers' pedagogy without seeing actual practice. The influence of peer teaching was a powerful finding that we did not expect, and it reinforced the importance of a positive learning community (Lave & Wenger, 1991; Lowery, 2002).

*Mastery experiences.* In the beginning of the course, Mandy was the only case study participant to refer to mastery experiences:

*Being that math is my favorite subject to teach, I have already experimented with math lessons. For example, during a multiplication review, I had different centers with different games (Multiplication Bingo, dice, and flash cards). I have also visited many math websites and got some good ideas.*

Interestingly, Mandy connects the vicarious experience provided by watching the Toliver tape to her educational history and the mastery experience to her affective state. Moreover, the influence of the Kay Toliver videotapes enhanced the influence of her educational history. The visual images of students learning and having fun in the mathematics classroom was enough to inspire Mandy to try some ideas of her own. These statements support Parajes' (1992) claim that teacher beliefs about best practices can be changed and Bandura's (1997) contention that affective states influence efficacy.

Likewise, mastery experiences were mentioned in one of nine cases at the end of the course:

*I realize from my practicum that my students loved to make music and dance so I came up with a way to use graphs to plot their dance moves. I then reflected on how my students loved treasure hunts and solving mysteries and put that all together to come up with the game: On our way to the treasure spot. Though there was a lot of work that had to go into this lesson, I loved it because it fun and involved learning that was meaningful for my students.* (Jamie)

Jamie's willingness to think outside of the box to develop an authentic task to teach coordinate graphing provided her students with high-quality mathematics teaching. In order for such practices to be sustained, teachers' beliefs must be reinforced with sufficient practice (i.e, time and use) (Parajes, 1992).

*Content knowledge.* Finally, belief statements made in these cases provide information about these preservice teachers' content knowledge before taking the reform-based course. Content knowledge statements, both implicit and explicit, were evident in five cases (Joy, Erin, Cathy, Joan, & Anita). For example:

*Math has always been my poorest subject.* (Joy)

*I was becoming familiar with the multiplication tables. Upon entering school, I found myself ahead of the other children. My interest in math did not wane.* (Cathy)

Joy's statement about content is also a belief statement or judgment about her mathematics ability in relation to other subjects. Cathy's statement suggests a relationship between content knowledge and interest in mathematics. Research studies that explore how content knowledge and interest are linked are needed to shed more insight on these two constructs.

At the end of the course, preservice teachers made references to content in four cases (Joy, Erin, Joan, & Yvette). Joy's belief statement was related to the PRAXIS as well as the mathematics content test:

*This class has been helpful for me because I have been practicing for the Praxis. If I were to take the content test again, I am confident that I would pass.* (Joy)

*Additional Preservice Teachers' Belief Statements at the End of the Methods Course*

Three additional factors related to mathematics teaching and/or learning emerged from the cases at the end of the course: acquisition of new knowledge, personal teaching efficacy and student outcomes. Each of these factors will be discussed in order.

*Acquisition of new knowledge.* Acquisition of new knowledge was evident in five cases (Joy, Erin, Yvette, Joan, & Anita). A few examples of these statements are:

*I have learned so much through this course in the way of teaching theories, strategies, problem solving variations, teaching materials, and numerous math processes* (Erin).

*Honestly, I do not know how I would teach math without this course. Throughout the semester, I have seen that it is not the actual content but the way you present it that really matters. I have also learned that there are many different ways in which children learn best. Some children perform better in a more structured environment, whereas others prefer a less structured environment.* (Yvette)

*I have learned some important things in this class, such as memorization is not the goal of math. As a teacher, I want students to be able to critically think and come up with solutions to everyday problems.* (Anita)

These data imply that Bridget's reform-based mathematics methods course influenced these preservice teachers' learning in a myriad of ways. What is compelling is that Yvette realized that different students had different needs.

*Personal teaching efficacy.* Preservice teachers also made comments about confidence and preparedness to teach mathematics in five cases (Mandy, Erin, Edith, Jamie, & Cathy):

*I feel that the math/science practicum has prepared me to teach, particularly in the areas of math.* (Jamie)

*Through this course and my math/science practicum, I have much more confidence in my teaching abilities.* (Erin)

*Outcome expectancy.* Anita's case was the only one of the nine to address student outcomes. Moreover, her comment specified what she believed to be the relationship between content and student outcomes:

*Knowing how to process information or manipulate facts to come up with sound solutions can increase one's achievement.*

Student outcomes and achievement variables also shape teacher beliefs (Ernest, 1989). Teachers' perceptions of students and their ability to learn mathematics will dictate their classroom behaviors (Walker, 2006). In some cases, negative perceptions of students lead to self-fulfilling prophecies that continue the cycle of low achievement, especially in large urban public schools (Cousins-Cooper, 2000; Walker, 2006).

## Summary

Data show the reform-based mathematics methods course had a huge impact on preservice teachers in these nine cases. Preservice teachers' content knowledge improved considerably. We were particularly pleased that this was true in the cases were preservice teachers' content knowledge fell into the low category. Furthermore, the three cases with the lowest initial content scores (Joy, Mandy, & Erin) had more robust belief statements ($M = 5.00$) as a group than preservice teachers in the moderate ($M = 4.00$) and high groups ($M = 3.67$) at the end of the reform-based methods course. These two findings show the reform-based course had a positive impact on these preservice teachers' content knowledge and educational beliefs. While these data are sparse, they also suggest that content knowledge changed along with educational beliefs. Additional research is needed to validate this assumption.

The study supports previous findings that methods courses and field experiences improve preservice teachers' content knowledge (Ball et al., 2005; Kahan et al., 2003), which is situated in biological and experiential contexts (Lave & Wenger, 1991; Núñez et al., 1999). Content knowledge is also intertwined with educational beliefs, which are not context free (Parajes, 1992). Most of the preservice teachers in the cases understood the importance of teaching mathematics in ways that students learn best: manipulatives, authentic tasks, games, and problem solving. Five cases reveal the importance of personal teaching efficacy (i.e, self-efficacy) on the teaching of mathematics. One case (Anita) reveals the importance of teacher beliefs and student outcomes. In light of these and other findings related to efficacy beliefs, a follow-up study to examine efficacy beliefs and its relationship to MCK is forthcoming.

# A COMPARISON OF INSTRUMENTS TO EXPLORE DIFFERENT ASPECTS OF MKT FOR ARITHMETIC

Simon Mochon
Center for Research and Advanced Studies, Mexico
smochon@cinvestav.mx

Susana Andrade Neyra
Center for Research and Advanced Studies, Mexico

*We have developed a research and educational project that has the aim of improving teachers' mathematical knowledge for teaching (MKT) in elementary and secondary schools in Mexico. Here we describe a part of this project that has the purpose of exploring the arithmetic knowledge for teaching of elementary school teachers. To this end, we designed and applied four different methodological instruments: classroom observations, an open questionnaire, a closed questionnaire and interviews. This diversity obeys our interest of comparing these instruments to determine their advantages and limitations to give a description of the teachers' MKT. This article describes the results of this case study with eight teachers.*

## Introduction

A lot of evidence has been gathered with national and international evaluations, showing no substantial advances in students' achievements, in spite of the curricular changes, new teaching materials and new technologies introduced in Mexico during the past few years at the elementary level. This, points to a very important factor which probably has been overlooked in all these policy changes: teachers' knowledge.

To remediate this situation, we have developed an educational project that has the purpose of improving teachers' math knowledge for teaching at the elementary and secondary level. This started by piloting workshops at different educational levels, designed to help teachers to reflect on their practices and to learn through the interaction with other teachers, guided with an agenda and reading materials provided to them. This part of the project is being reported elsewhere. Parallel to the workshops, we designed and applied several instruments (classroom observations, open and closed questionnaires and interviews) to explore the advantages and weaknesses of each one of them in assessing the specialized knowledge teachers required in their practice within some topics of arithmetic. Our main objective is to gather information about the actual level of teacher's knowledge, to guide us in better defining an effective teachers' development program. This article will report on the findings of an inquiry about the usefulness of these four instruments in revealing and evaluating the specialized mathematical knowledge for teaching held by teachers in some particular topics of arithmetic.

## Theoretical Framework

One fundamental aspect, the mathematical education research community has focused its attention on, is the different kinds of interrelated knowledge a teacher might need in his own practice. The general term Pedagogical Content Knowledge (Shulman, 1987) refers to a complex mixture of knowledge related to many components like content, pedagogy, organization of topics and problems, student conceptions, models, representations, activities, curriculum, etc. Some facets of this teachers' knowledge are more closely related to the mathematical content, like understanding and extending student methods of solution, deconstructing one's own knowledge into its elemental parts to make it more evident (Ball, 2000) or knowing the structure and connections of mathematical concepts and procedures. Ball and Bass (2000) associated this special knowledge with the term: Mathematical Knowledge for Teaching. It is described as an "unbundled" complementary mathematical knowledge teachers need, to manage routine and non-routine problems. These authors identified four core activities related to this knowledge: i) Unpacking math ideas and procedures; ii) Choosing representations to effectively convey math ideas; iii) Figuring out what students understand; iv) Analyzing methods and solutions different from one's own. Teachers' MKT represents a fundamental factor on students' achievement. Evidences of this can be found in Hill, Rowan & Ball (2005).

Based on different frameworks and methods of inquiry, there have been a number of research studies connected to teachers' professional development projects in different countries. Amato (2006), within a mathematics teaching course to student teachers, conducted a study to improve their relational understanding in fractions, playing games (like trading on a decimal board). The author reported improvement in their understanding of mathematical and pedagogical knowledge, especially in multiple modes of representation.

In a study investigating the Pedagogical Content Knowledge (PCK) of elementary school teachers in the topic of decimals, Chick, Baker, Pham and Cheng (2006) proposed a framework with three categories: 1. *Clearly PCK*. Elements included: teaching strategies (math related), student thinking, cognitive demands, representations, resources, curriculum and purposes; 2. *Content Knowledge in a Pedagogical Context*. Elements included: profound understanding of fundamental mathematics, deconstructing content, mathematical structure and connections, procedural knowledge and methods of solution; 3. *Pedagogical Knowledge in a Content Context*. Elements included: goals for learning, student focus and classroom techniques.

Powell and Hanna (2006) explored how teachers develop their MKT in the discursive interaction of practice. They extended the epistemological component of teachers' knowledge, defining it as the teachers' inferential awareness of the students' existing and evolving math knowledge. This knowledge is essential for the teacher to make sense of students' productions, ideas and arguments. Also, like some other previous authors, Seago and Goldsmith (2006) studied the possibility of using classroom artifacts like students' work and classroom videos to assess and promote MKT.

In addition to the quality of the mathematics content and pedagogy knowledge held by teachers, effective learning requires students to construct their own knowledge through exploration and interaction. According to Askew, Brown, Denvir, & Rhodes (2000), this process is productive if the next four components meet some necessary requirements: (a) *Tasks* are challenging, meaningful and interesting; (b) *Talk* facilitates learning and includes all sorts of teacher and students interactions; (c) *Tools* cover a range of modes and types of models; and (d) *Relationships and norms* help towards a social construction of knowledge.

Using a case study approach within a collaborative action research Cooper, Baturo and Grant (2006) uncovered some characteristics of instructional interactions that lead to positive results in student learning. The main result of this study was that highly successful collaborations contained all of the following three levels of pedagogies: i) *Technical* – Practical "tips" related to a particular activity; ii) *Domain* – Teaching strategies proper to a particular topic; iii) *Generic* – Teaching methods valid across math topics, like Krutetskii's: "being flexible", "reversing" and "generalizing" or Hershkowitz's: "use of non-prototypic examples".

## Methodology

The study took place in three public schools in Mexico City, with eight, fifth and sixth grade teachers participating (identified here by PE, MT, AD, OL, MA, CA, MI and YO), with an experience in teaching of between 8 to 27 years. We applied the instruments in the sequence: 1. Classroom observation; 2. Open questionnaire; 3. Second classroom observation and 4. Closed questionnaire (for PE, MT, AD and OL) or an interview (for MA, CA, MI and YO).
The day and subject matter of the classes observed were chosen by the teachers themselves and were videotaped. Their analysis was based on two separate lines. The mathematical content was assessed according to the four core activities of MKT listed before, identified by Ball and Bass (2000). The pedagogical techniques were evaluated according to Askew's four components: tasks, talk, tools and norms.

The open and closed questionnaires were designed taking as a model the questionnaires constructed and used by the group: Learning Mathematics for Teaching, of the School of Education at the University of Michigan (Hill, et al., 2003; Hill and Ball, 2004). The open questionnaire contained twelve items and the closed questionnaire consisted of thirteen multiple choice items, both covering different topics (operations with natural numbers; mental calculation and estimation; fractions and decimals; proportionality and units conversion) and related to the four aspects of Ball and Bass mentioned before. In the results below we reproduce and analyze three items of the Open Questionnaire, addressing the following aspects and topics: OQ2 – Students' errors in additive problems; OQ4 – Illustrations and representations in division of integers; OQ9 – Methods and solutions in estimation; and two of the Closed Questionnaire: CQ5 – Students' thinking in fractions; CQ11 – Evaluating claims or explanations in decimal numbers. The teachers' interviews were based on some of the items of the closed questionnaire, but probing further the answers and knowledge of the teachers. The closed questionnaire and the teachers' interviews were left at the end since they contain the type of knowledge we wanted to find out from the teachers, so we didn't want to give them this information before the classroom observations took place and the open questionnaire was administered.

## Results

*Classroom Observations*

We will describe first some of the classroom observations that took place (the teacher is identified with boldface letters).
**MA:** Used a coin of 20 pesos as unit to talk about percentages. Other coins were related to it through percentages. He directed the lesson through questioning and sometimes requested the students to explain their answers. He often didn't express himself in a precise manner and let the students do the same, which generated some confusion (for example, when asking "How much do I have here?" he expected a percentage answer but the students, not knowing, answer in pesos). In one of the interventions, he wrote on the board: "5 = 1/4 = 25%" trying to clarify things. He evaded the wrong answers given by the students, by asking "Are you sure?" or by re-asking the same question.
**CA:** The content of the lesson was the fraction as a ratio, using a drawing and writing a list of questions on the blackboard about it. A lot of time is spent on just copying this. Even before the students had time to answer them, he wrote another two unrelated ratio questions on the board. It was very hard to detect anything. There were no explanations. The drawing was the only

representation. Only a very few questions were asked orally and when one of the answers was wrong, it was sanctioned with a frown.

**PE:** The content of the lesson was the decimal system. He showed 10 bars representing the numbers 1 through 10, each of different color and size, and then tried to distinguish between their absolute and relative value. He explained for example that the red "has two absolute values: the two and the red." And that "the absolute value is the real value." Then he wrote on the blackboard "M C D U" and puts the red bar in different positions to ask its value now. At the end, they represented in this way, four digit numbers. The time was spent mostly on introducing the material. Again we observed the teacher put across ideas in a very imprecise manner and corrected the wrong answers of his students without any explanation. The "homemade" material used was somewhat ineffective.

**MT:** Also the content was decimal system. From a textbook, he read aloud some rules for the students to write down in their notebooks and then followed them to form numbers with a "homemade" material, which the same teacher has trouble using. He dictated the numbers wrong: "8 units, 40 tens (instead of 4 tens), 500 hundreds (instead of 5 hundreds)…" He even told his students to write the number 503 in "expanded form" as 30500 (instead of $3 + 0\times10 + 5\times100$). This caused some students to write 126809 when the number 908621 was read by him. In general, the inquiries and explanations of the teacher were in great part confusing to the students. The teacher could not detect the errors made by the students.

We observed a second class of this teacher, now on addition of fractions. His explanations were, in general, confusing and many times wrong. When adding two fractions, he illustrated it by representing other fractions with squares. The students added numerators and denominators, guided in part by the teacher. In another exercise on the blackboard, the teacher simplified the fraction 3/4 to 1/2, saying that the 4 you can half it but the 3 you cannot but you can take a third of it (by the same reasoning, he simplified 14/5 to 7/1). In the verbal problem: "… a wood frame of 3/4 thickness is hammered into a wall with 1 and 1/4 nails. How much of the nails got introduced into the wall?" the teacher used the wrong operation getting 8/4. Here we observed a very deficient common math knowledge of the teacher.

**MI:** This class was about units and subunits. He insisted that the students know the table: "Kl (kiloliters), Hl, Dl, l (liters), dl, cl, ml (milliliters)" and how it tells you how to move the point a certain number of places in a conversion. So the teacher centered the learning on rules and memorization. In some problems, he applied the "rule of three" to solve them. After a few exercises, he moved to the table of grams, following the same procedures.

In a second class on fractions, this teacher wrote on the blackboard a "conceptual map of the fraction", connecting it to seven boxes (Reading, Types, Parts, Problems, Equivalence, Conversion and Operations), each of which, was connected to some ideas. For example, the box of Equivalence was connected with i) multiplication makes it bigger and ii) division makes it smaller. Then he illustrated equivalence of fractions with several exercises.

**YO:** He worked a few examples of the addition of fractions, following the usual algorithm (finding a common denominator) and then solved a few problems. There were no explanations. He centered the lesson on how to do the procedures. Errors of the students are not really addressed but just dismissed by saying "you are wrong".

**AD:** This teacher worked on decimal numbers. First he wrote on the blackboard a "conceptual map about the decimal point" (somehow giving its characteristics), which lacks meaning to the students and they only copied it. He then compared a list of decimal numbers, but the exercise was unchallenging because it could be solved ignoring the decimal parts. At the middle of the lesson, the teacher changed to the topic of percentages. Again, we observed some imprecisions and conceptual errors. For example, for the number 2563.50, the teacher expressed that “the fifty are tenths”, and when a student wrote the result of 500 – 391.90 as 109.90, the teacher seemed not to notice it.

**OL:** The subject was the decimal system. He organized a “cashier” game with dice and bills, and the children played on each table. Although he didn’t ignore the students’ errors, he also didn’t do anything to find out more about the source of the problem.

In general we observed many ambiguities on the expositions given by the teachers. These, often confused students. Most noticeable was the emphasis on the mechanical aspects of math, learning by repetition. In general, the teachers gave very few reasons or explanations related to the procedures followed. The orientation was towards “how to do it”. Although, it is hard to assess inside the classroom the breadth of the mathematical knowledge for teaching (since teachers teach what they feel they know and students don’t challenge this knowledge), it was clear that, in some cases, there was a lack even of common math knowledge.

Only one of the eight teachers guided the lectures through questions and requested the students to explain their answers (but only when they were right). The rest of the teachers, asked questions that needed a “yes” or “no” answer, or “the result”, which then the teacher proceeded to explain. The representation models used were mostly concrete materials or drawings of the situations that had only a visual support. The teachers didn’t try to explore the sources of the students’ mistakes, avoiding their wrong answers by repeating them in a questioning mode, or by saying “Are you sure?”, or by repeating the question.

This small sample of eight teachers in Mexico City gives a “statistical sample” of what to expect in general, but it is not even representative of the whole country where we anticipate less prepared teachers. Thus, this shows the need of a comprehensive teachers’ program, putting in evidence what areas should be emphasized.

*Open Questionnaire (some of the items)*

Here we will describe the answers given to three of the items (2, 4 and 9) of the open questionnaire (OQ). The questions presented to the teachers are given first.

**OQ2**. “In a store, the cash register has $254 at the beginning of the sales day and $967 at the end of the day. How much was sold that day?” Some students wrote the answer $1221. How would you explain to them how to solve the problem?

Most of the teachers articulated that they would tell the students that “subtraction is the correct operation” or that “they have to take the difference”. They also said that they would show how to make the subtraction with concrete material. However, there were not explanations of why this was the correct operation instead of a sum, except that one teacher (OL) said that he would tell them that “the result cannot be more”, and another teacher (MI) would represent this problem as: 254 + ? = 967.

**OQ4.** For 100÷15, write several problems which are related to different concepts or interpretations of this division, and represent their solutions accordingly.

Five of the eight teachers (MA, CA, MI, YO and OL) gave a partitive type situation like: “There are 100 chocolates which have to be distributed between 15 children.” Only two (YO and AD) gave a measurement type situation like: “How many pair of socks can I buy with $100 if each one cost $15?” Two didn’t give any problems. PE said “I have no idea” and MT even wrote an incorrect result: “100/15 = 15”.

No representations were given except for the standard algorithm of the division.

**OQ9.** a) Estimate the total of the following bill (explain how you did it):

| | |
|---|---|
| 2 Shirts | $ 388.50 each |
| 6 pairs of socks | $ 24.20 each |
| 2 pants | $ 173.90 each |

b) A student wrote: 1000 + 120 + 400 = 1500. Explain and evaluate what he did.
Four teachers "estimated" the result as: 1400 (MA), 1300 (MI), 1280 (AD) and 1276 (OL). The other four, calculated the exact result (CA with an error).

With respect to part (b), three (CA, MI and AD) said that the student rounded, but AD said that "the student exceeded on his rounding." Two (PE and MT) said that the student made an approximation of each multiplication without being exact. The other three teachers (MA, YO, OL) stated that the student didn't take into account the 20 in the sum and MA added that he would ask the student to review his result.

The open questionnaire was very revealing about the specific teachers' ideas and conceptions explored in each of the items.

*Closed Questionnaire (some of the items)*

Here we will describe the answers given to two of the items (5 and 11) of the closed questionnaire (CQ). The questions presented to the teachers are given first.

**CQ5.** In an activity, several students ordered some fractions, from small to large, in the following way: $\frac{7}{8}, \frac{6}{7}, \frac{5}{4}, \frac{4}{3}$, 1. What criteria are they using to do this?

The bigger the denominator, the bigger the fraction. The unit is the biggest of all the fractions.
The bigger the numerator, the smaller the fraction. The unit is bigger than the proper fractions but smaller than the improper.
The bigger the denominator, the smaller the fraction. The unit is the biggest of all the fractions.
The bigger the numerator, the bigger the fraction. The unit is the biggest of all the fractions.

In this question, only one teacher could identify the right answer (c). All the others chose (b) or (d) as their answers.

**CQ11.** Consider the three decimal numbers: 0.245, 0.2 and 0.0069. Mark with a check ☑, from the following assertions, those which are correct.

The number 0.245 is the biggest because contains more digits different from zero.
The number 0.0069 is the smallest because it gets to the fourth decimal position.
If I multiply 0.245 by 10 we get 2.45 because thousandths are converted into hundredths, hundredths are converted into tenths…
If I divide 0.0069 by 1000 we get 6.9 because we must move the point three positions.
A decimal number divided by 0.1 always gets smaller.

In this item only 40% gave the correct responses. Parts (b), (d) and (e) were the most difficult, in which only about 25% of the teachers gave a correct answer! (Random answers would yield 50%!)

One of the difficulties with the close questionnaire is that random answers produce a "background noise" that can make them somewhat unreliable. In addition, it is a very delicate instrument since in reality, the items might need to be redesigned and recalibrated for different groups of teachers being evaluated.

*Interviews*

The interviews with four of the eight teachers were based on some items of the closed questionnaire, where the interviewer asked the teachers to make explicit their reasoning. Due to the space constraints, we will not show specific results of this instrument, but, like the open questionnaire, it also gives very specific and useful information about teachers' knowledge and their ways of thinking. This however depends strongly on the questioning skills and extent of the knowledge of the interviewer.

*Comparison of Different Instruments*

In the following table, we compare, in a somewhat coarse manner, the results of the different instruments applied. The B represents "one of the best in that instrument" for the group of eight teachers, and W, "one of the worst".

| Teacher: | Classroom: | OQ complete | CQ complete | Interview |
|---|---|---|---|---|
| MA | B | | – | |
| CA | W | | – | W |
| PE | | W | W | – |
| MT | W | W | | – |
| MI | | B | – | B |
| YO | | | – | |
| AD | W | B | B | – |
| OL | B | | | – |

The table shows a strong consistency across the instruments applied. The only teacher that has both, W and B, in different instruments is AD. However, analyzing further this case, although he showed a good content knowledge in both questionnaires, the classroom itself requires more of a mixture of pedagogical and content knowledge, where this teacher showed a deficiency in pedagogical techniques and students' knowledge, which would have helped him decide what proper and challenging tasks are for his students.

The classroom observations give substantial information about the pedagogical knowledge of the teacher, but not so much about his content knowledge, because, the teacher decides the specific subject-matter he wants to discuss in class. In contrast, the interviews and the open questionnaire provide a good look at the math knowledge for teaching, because they can be targeted to specific topics and concepts.

If well designed, a closed questionnaire has the advantage that it can be applied to a large number of teachers, either, giving some comparisons between different groups of teachers or, the changes that a group of teachers might have "before and after". However, it is sensitive to random answers. Its biggest disadvantage is that you cannot observe and examine the teachers' thinking as in an open questionnaire or an interview. These last two can perform very effectively as statistical indicators of the knowledge of the whole population of teachers.

## Conclusions

The classroom observations confirmed our suspicions that teachers, on the pedagogical side, have a reduced knowledge in teaching strategies, representations and purposes of math topics. The whole instruction is geared towards the operational aspect of math, learning by repetition and practice. Also, with respect to their interaction with their students, we observed that it is kept to a minimal level of a few questions and very short responses without argumentation. They ignore or evade wrong answers and thus, they do not address the errors and confusions of their students. We also noticed some shortages and conceptual difficulties on their content knowledge.

It is evident from this study that there should be efforts to improve the teachers' (common and specialized) mathematical knowledge and their ideas on pedagogical knowledge. This should be done very closely to their actual practice; taking into account their deficiencies and helping them make better use of their textbooks and materials.

Finally, one of the most essential elements of MKT, "Profound" Understanding of Fundamental Mathematics, has to be looked at more closely and defined more precisely. Comprehending math concepts or ideas could be achieved at very different deepness levels. It would be practically impossible for a teacher to "master" all the subject matter with a great deal of insight. So it would be important to define in what degree teachers' knowledge is needed in their practice, for each specific concept or idea.

# COLLABORATIVE EFFORTS BY MATHEMATICS AND SPECIAL EDUCATION TEACHERS FOR THE INCLUSIVE MATHEMATICS CLASS

Hea-Jin Lee
Ohio State University-Lima
lee.1129@osu.edu

Leah Herner-Patnode
Ohio State University-Lima
herner-patnode.1@osu.edu

*This study investigates effective interventions for students with learning disabilities (LD) and healthy ways to collaborate between special education and mathematics teachers. Twenty-four teachers were interviewed and responded to Likert-scale questions. The results indicate teachers' knowledge, attitudes, and perceptions vary according to their job role. Both groups see inclusion as successful if they consistently employ certain strategies and those appear to increase the academic progress of the student with LD. These strategies are shared in the paper. The two groups have different views about benefits and challenges of inclusion, which suggest the needs of further discussion on the communication part of collaboration.*

## Introduction

Students with learning disabilities have often struggled with acquiring the needed skills to succeed at mathematics at their grade level. There are suggestions and research based practices widely available, but there is a gap between teachers' knowledge and the instruction that provides access to the general education curriculum. Collaboration between special and general educators, as well as training on current best practices, could benefit all students.

Principles and Standards for School Mathematics (NCTM, 2000), No Child Left Behind (NCLB, 2001) and the Individuals with Disabilities Education Act (IDEA, 2004) mandate that all students receive access to age appropriate curriculum, but this is not easily achieved. NCLB was amended in 2007 with this issue in mind (http://www.ed.gov/legislation/FedRegister/finrule/2007-2/040907a.html). The amendment stated that a small number of students may not meet IEP goals, even with appropriate instruction. This amendment was meant for students with severe cognitive disabilities, so its impact on the instruction of students with learning disabilities will be minimal, but this indicates that the government is beginning to recognize the many factors that go in to successful teaching for students with disabilities. It does not, however, lessen the burden on general and special education teachers to meet the goal of improving results and functional outcomes for students with disabilities.

## Theoretical Framework

Students with mathematical disabilities can benefit from many types of interventions. Early intervention can provide benefits, but continued remedial intervention is generally necessary for students with mathematical deficits (Fuchs & Fuchs, 2001; Fuchs et al., 2008; Maccini & Hughes, 1997). It is also imperative to identify the exact nature of the deficit. Interventions for computation may be different from interventions for difficulties in understanding word problems. Students with mathematical disabilities often struggle with counting and are not able to retrieve answers from memory (Fuchs et al., 2008). It is common for students to have deficits in both computation and problem solving, but the remediation should still be specific to the area of need (Fuchs et al., 2008).

Direct instruction, which involves teaching problem solving strategies, rules and principles in an explicit manner, has been shown to be effective for students with learning disabilities and those at risk for academic difficulties (Baker, Gersten, & Lee, 2002). Explicit instruction focuses on a great deal of teacher modeling to help the students learn to ask questions that lead to solving problems (Cardelle-Elawar, 1992).

Effective assistance includes tutors who have been trained in computation remediation. These tutors can teach strategies and help reinforce effective techniques (Baker, Gersten, & Lee, 2002; Fuchs et al., 2008). Peer assisted learning can encourage a low achiever to continue their attempts to master a skill. It also assists the teacher, because it allows more students to be engaged, with one-on-one assistance, in the same amount of time as teacher led instruction (Kunsch, Jitendra, & Sood, 2007). A meta-analysis of peer mediated intervention research indicates more success when the interventions were conducted in general education classrooms (Kunsch, Jitendra, & Sood, 2007). Helping general and special educators learn these specific instructional strategies may benefit the students who are included for mathematics instruction. "For inclusion to be successful, several factors are important: (a) qualified personnel, (b) available support services, (c) adequate space and equipment to meet the needs of all children, and (d) positive teacher attitude toward inclusion" (Leatherman & Niemeyer, 2005, p.23). Collaboration among professionals has to go along with the strategies, training and equipment. Research has shown that collaboration between general and special educators is the key to successful inclusion (Cole & McLeskey, 1997; DeSimone & Parmar, 2006; Lerner, 2006; Proctor & Niemeyer, 2001). When both professionals use their knowledge of specific strategies to modify lessons for students with learning disabilities then they can fill in the gaps between content knowledge and knowledge of effective strategies (van Garderen, Scheuermann, Jackson, & Hampton, 2009). This means helping the general education teacher to do more than offer a seat to a student with a disability. The teacher must provide substantial and specific feedback throughout the lesson (DeSimone & Parmar, 2006).

This study was designed to examine inservice teacher knowledge and attitudes toward inclusion, interventions, and collaboration between special education teachers and mathematics teachers. This study is an effort to investigate perceived effective interventions and healthy ways to collaborate between special education teachers and general education teachers. The specific research questions for this study are as follows: (a) What are the factors that influence teacher attitudes toward inclusion, and (b) What were special education teacher and mathematics teacher perceptions about effective ways to collaborate in the inclusive classroom?

## Method

### *Participants*

The participants of this study were 24 currently employed inservice teachers. They taught in Kindergarten- 8th grade. Their areas of certification included K-12 Intervention specialist, 1-8 Elementary Education, Middle Childhood Mathematics, Language Arts, and Social Studies. Seven teachers were currently teaching special education and seventeen teachers were currently teaching general education classes. The median number of years in the teaching field was 17 years. This group expected to teach students with learning disabilities in the mathematics content area on a daily basis.

### *Data Collection*

Two data sources, questionnaire responses and interview data, were used for this study. Twenty-four practicing teachers were surveyed and interviewed about their views concerning collaboration, knowledge in mathematics and special education, and what would help them better include students with learning disabilities in their mathematics instruction. In the survey, participants were asked to respond to a four point scale with 0 being no knowledge to 3 being very knowledgeable about the area. The survey questions also include open ended questions regarding their perceptions of the benefits to collaboration between special education teachers and mathematics teachers, as well as challenges to collaboration. The survey questions can be found in Table 1.

Structured interviews were used in this study to provide insight into practitioners' knowledge and attitudes toward inclusion and collaboration between mathematics teachers and special education teachers. The interview questions were used to identify possible factors related to the teachers' knowledge and attitudes toward inclusion and collaborative instructional procedures used in the classroom. Twenty open-ended interview questions allowed the participants to discuss the issues encountered implementing interventions and collaboration with other teachers in inclusive classrooms. These questions helped the authors to understand the teacher's attitude toward inclusion, collaboration, and the correct way to implement new interventions in the classroom. The individual interviews that were conducted lasted from 20 minutes to 1 hour.

The participants were asked about their knowledge of mathematics and interventions, including strategies they routinely use to assist students with mathematical learning disabilities; when and how they assist these students; their understanding of the mathematics curriculum; mathematics concepts they feel the most comfortable teaching; kinds of professional development they obtained to improve their teaching of mathematics; their familiarity with the RIT (Response to Intervention Techniques); ways of documenting the intervention techniques they use; and the IEP process. Participants' perceptions about the IEP process, including students with learning disabilities for mathematics with same age peers, and inclusion in mathematics instruction for all the stakeholders were also investigated. Also, participant teacher attitudes toward inclusion and collaboration were investigated in the areas of: collaborating with other teachers to adapt the learning environment for mathematics lessons; ways to collaborate together to adapt the environment; collaborating with other teachers to modify mathematics lessons; and collaboration strategies/techniques they routinely use.

*Data Analysis*

Survey data were analyzed using a spreadsheet to summarize descriptive data including frequencies and percentages. The interviews were analyzed for themes as they evolved from the written transcription. Similar ideas from survey data and interviews were placed into broad categories, and specific categories were defined within each question. After all the information from the data sources was categorized by topics, a content analysis was conducted to extract similar themes and ideas within each teacher's case (Patton, 1990).

## Results

Results indicate that the majority of participants perceive themselves as somewhat knowledgeable about collaboration, utilization of response to intervention techniques, mathematical content, and IEPs (see Table 1).

Figure 1 depicts the perceived benefits and challenges of inclusion that the teachers experienced or viewed. The participants indicated gaining knowledge, sharing ideas, teaching better, and collaboration were the perceived benefits. The mindset/skills of other teachers was the most often listed challenge, followed by time, assessment and ownership. Two participants noted no challenges. The survey results informed the researchers that the participants considered themselves to have the knowledge to teach the subject matter. The fact that they felt sharing ideas was beneficial indicates that this group was open to learning more about effective teaching practices. The mindset and skills of other teachers was listed as a challenge by 75% of the participants. This indicates that perceived equity in knowledge and collaboration skills are very important and should be addressed by schools if they want successful inclusion.

Table 1
*Knowledge, Attitudes, and Perceptions*

| Questions | Mathematics (%) | | | | Special education (%) | | | |
|---|---|---|---|---|---|---|---|---|
| | No | Little | Some | Very | No | Little | Some | Very |
| Assisting students with learning disabilities to access the general education mathematics curriculum for my grade level. | 0 | 12 | 82 | 6 | 0 | 0 | 75 | 25 |
| Collaborating with other teachers to modify mathematics lessons. | 0 | 12 | 76 | 12 | 0 | 25 | 25 | 50 |
| Collaborating with other teachers to adapt the learning environment for mathematics lessons. | 0 | 35 | 59 | 6 | 0 | 25 | 25 | 50 |
| Understanding the mathematics curriculum 75 my grade level. | 0 | 6 | 35 | 59 | 0 | 0 | 75 | 25 |
| Utilize response to intervention techniques. | 6 | 47 | 35 | 6 | 0 | 0 | 75 | 25 |
| Understand the IEP process, in regards to mathematics goals, for students with learning disabilities assigned to my classroom. | 0 | 29 | 65 | 6 | 0 | 0 | 50 | 50 |

*Teacher Knowledge in Mathematics, Interventions, and Inclusion*

Both mathematics and special education teachers felt most comfortable teaching mathematics concepts from their own grade level. Areas that mathematics teachers felt needed improvement were mainly mathematics content areas, achievement, and technology (Smartboard™); special education teachers wanted to learn about assisting students with LD, different strategies, collaboration with a special education teacher, and number sense. Both mathematics and special education teachers wanted to learn more, student-centered, hands-on activities, and algebra.

Surprisingly, 22 of 24 participant teachers were not very knowledgeable about Response to Intervention Techniques (RIT). Mathematics teachers responded that they decide appropriate intervention strategies for the following reason (in the order of frequency): based on student's need, intervention teacher's suggestion, team decision, trial and error, and/or based on data (student achievement). Special education teachers' reasoning is in the following order: use various data, do not use any, trial and error, based on student's need, and/or Ohio Standards.

With regard to including students with disabilities, the participant teachers had different views. Half of the special education teachers felt that including students with learning disabilities for mathematics with same age peers at their school was unsuccessful, and the other half of them felt unsure. Mathematics teachers' responses were divided: not sure, need to include them, and no success.

> I think [inclusion is] unsuccessful at our school cause it rarely happens. Now that special ed kids, IEP kids are to pass the OAT, the Ohio Achievement Test, oh my goodness, the regular teachers are getting really interested in seeing that the special ed kids are successful. So there's more openness and more nervousness from them. The only thing is I'm starting to feel like there is a lot of finger pointing blaming the special ed teacher, me, for the students' lack of abilities and skills and when I receive a student he/she may be behind or deficit 2-3 years already. (Special education Teacher W)

> I do [think inclusion works]. When I first started teaching mathematics I had a pull out class and they didn't have any examples as to what, they didn't have any higher level thinkers in there. So every time you would come up with a question they wouldn't understand. You had no peer interaction, no discussion, nothing to go from. So having them in a regular classroom helps them tremendously because they have that discussion to go off of and basically I don't want to say peer tutoring, but peer examples as to how things are being solved other than just the teachers. (Mathematics Teacher I)

Both mathematics and special education teachers stated that team work is the key for the success of inclusion. Mathematics teachers addressed students' group work (interacting) and peer examples (watching others) as benefits of inclusion.

*Strategies to Assist Students with Mathematical Learning Disabilities*

The participant teachers believed that mathematics teachers should know that students with LD learn differently and teachers should teach them differently. They shared more than ten strategies to teach students with LD. Some strategies were used by both special education and mathematics teachers; some seem to be used only by either special education or mathematics teachers. Common strategies routinely used by mathematics teachers were: modifying lessons (slower pace and lower level content), working (helping) with the kid(s) individually, giving extra time, group work, and/or getting help from volunteer tutors.

> I might pair them up with someone who does get it. Allow them manipulatives and might spend more time with them if no one else needs my assistance at the time and just use different ways to approach the same question. Use visual cues, auditory cues, manipulatives, kinesthetic, actually doing it. (Mathematics Teacher M)

Some strategies were reported only by special education teachers: using textbook, daily facts practice, and reading out loud.

> For mathematics we used a text book and followed the text routinely through each chapter following the standards. We also did a daily facts practice to work on time. When it came closer to the OET tests we did practice questions that were similar to the OET test questions. That is when we let go of the book to focus more on the OET. (Special education Teacher A)

Some strategies were only reported by mathematics teachers: lecturing, reteaching, assistance from volunteer tutors, using different cues, and/or retaking tests. Most special education teachers (and 12 % of mathematics teachers) reported that they use manipulatives to assist students with LD. Some other strategies reported by both groups were: demonstration, intervention based on a specific student need, and physically relocating students (to the front) (closer to the special education teacher).

*Collaboration among Mathematics and Special Education Teachers*

According to the participant teachers, physical convenience or common needs/interest promoted collaboration: among same grade teachers, same subject (mathematics) teachers, and/or special education teachers in the building. More than 50% of participants viewed talking to other teachers as the most routinely used collaboration strategy. Mathematics teachers co-plan and have grade level meetings more frequently than special education teachers. Collaboration occurs quite informally whenever they have time (lunch, before or after school, child's special) and/or during a team meeting.

According to the interview data, mathematics teachers collaborate together to adapt the environment in various ways. The majority of them work together by planning together, holding team meetings, and creating group work. A small number of teachers responded that they do not know, do not change the environment, or do nothing. Also, technology (Smartboard™), hands-on, pull out (reading the test aloud), seating the children in a quiet place or close to the teacher were considered the collaboratively adapted environment by the rest of the mathematics teachers.

> A lot of times we do it, we have a large class teaching, but also we have the kids sitting and we put their tables together so they have smaller groups of where their desks are. We have them work in the hall. We have other areas where we will sit the kids in a quiet place. We have different areas where they can get a lot of manipulatives. They can work there or the computer area, so I guess we kind of do it around the room like that. (Mathematics Teacher M)

Having a wheel chair in the room and using new techniques were unique responses by special education teachers.

The participant teachers suggested the following strategies for enhancing student learning: more interactive approaches; understanding the child; planning together-working together; data driven instruction; smaller class size; being patient, creative, hands-on; more resources, discovery approach, teacher knowledge, multiple approaches, new methods, and being open minded.

Concerning teaching students with LD, the participant teachers wanted to learn more about: ways to include students more, more learning strategies/alternative ways, more hands on, how to reach them more, be open to new ideas, more of the resources, other intervention techniques, assessment, how to motivate them, and what causes a learning disability.

## Discussion/Implication

According to this study, the factors that influence teacher attitudes toward inclusion are many and sometimes depend on which position they have, mathematics teacher or special education teacher. The special education teachers may have the perception that the general education teachers care more about the students currently because of mandated testing. If the special education teachers feel the success or failure of a student still rests only on their shoulders, they may feel unsupported by peers and administration, and therefore determine that inclusion is not successful. The mathematics teacher may feel that inclusion is successful if the students show more skills in the included setting, but if the students are not making acceptable progress, they are also apt to determine that inclusion is not successful. Both groups see inclusion as successful if they consistently employ certain strategies and those appear to increase the academic progress of the student with LD.

Special education teacher and mathematics teacher perceptions about effective ways to collaborate in the inclusive classroom also vary according to their job role. In general, perceived benefits include gaining knowledge, sharing ideas, improved teaching skills and collaboration. The challenges included: the mindset/skills of other teachers, time to plan, ways to assess students with LD, and ownership in terms of the responsibility of teaching the student with LD.

In order for teachers to have more positive attitudes toward inclusion, professional development focusing on children with disabilities and hands-on activities for students with special needs, administrative support, and appropriate support personnel in the classroom are needed (Leatherman & Niemeyer, 2005).

Addressing the perceived challenges and bolstering strengths should be a top priority for administrators seeking improved collaboration and a better whole school attitude toward inclusion. The need for training in the areas mentioned, such as RIT, by the participants is important, but more important is the level of communication between both groups. Both groups list benefits of inclusion, but they list different benefits. Sharing ideas, gaining knowledge and teaching better were perceived benefits for mathematics teachers, while collaboration, helping others and meeting student needs were perceived benefits for special education teachers. An astute administrator would see that each group values slightly different things. While the mathematics teachers hopes to gain knowledge about working with the students with LD the special education teacher hopes to find someone to collaborate and share the responsibility of meeting the students' needs. Time needs to be allotted, not just for planning, but for communicating each professional's needs and strengths. A good partnership means that the teachers learn from each other and understand what skills they can bring to the classroom. After they understand each other they can be more effective at knowing how best to meet students' needs.

# THE MATHEMATICAL KNOWLEDGE FOR TEACHING (MKT) OF NEW YORK CITY TEACHING FELLOWS

Sunita Vatuk
Graduate Center – CUNY
svatuk@gc.cuny.edu

Michael Meagher
Brooklyn College – CUNY
mmeagher@brooklyn.cuny.edu

## Introduction

The New York City Teaching Fellows (NYCTF) Program was started in 2000, in part, "to address the most severe teacher shortage in New York's public school system in decades" (NYCTF, 2008) and to replace uncertified teachers who were concentrated in high-needs schools (Keller, 2000; Stein, 2002). The NYCTF program currently supplies over 60% of new mathematics teachers in New York City Public Schools—more than 300 new mathematics teachers in 2007 alone. Fellows come to the program from a variety of backgrounds, with the majority being either recent college graduates or career changers.

## Objectives and Purposes of the Study

In this paper, we discuss how Fellows' Mathematical Knowledge for Teaching (MKT) (Bass, 2005; Ball and Bass, 2000) interacted with other aspects of the Fellows' teaching. The paper arises from a pattern we saw over the course of some 90 observations. We found that many of the Fellows, in collaboration with their coaches and other mentors, are designing lessons and fostering classroom cultures that are in line with the "process strands" of the New York State Mathematics Core Curriculum (NYSMCC). The NYSMCC promotes having students present alternative solution strategies, using different representations of mathematical ideas, and forming connections between different areas of mathematics, and so on. This approach to teaching puts extra demands on teachers that they are not always equipped for. We found that in the majority of cases the opportunities created by the Fellows were not exploited, due to what we perceive as limitations in their MKT.

## Perspective(s)/Theoretical Framework

In Shulman's (1986) seminal paper he develops the concept of pedagogical content knowledge which he defines as content knowledge but "the particular form of content knowledge that embodies the aspects of content most germane to its teachability [which includes] the most useful forms of representation of those ideas, the most powerful analogies, illustrations, examples, explanations, and demonstrations - in a word, the ways of representing and formulating the subject that make it comprehensible to others." (p.9) Shulman's work was important in expanded the domain of interest in teacher's knowledge beyond pure content knowledge and pedagogical knowledge to include forms and representations of knowledge that are particular to, for example, teachers of mathematics as opposed to mathematicians.

In the aftermath of Shulman's work from researchers such as Ball & Bass (2000), Bass (2005), Ferrini-Mundy & Senk (2006) has attempted to examine the implications of his work for the teaching of mathematics. Ball & Bass (2005) seek to complement the concept of PCK by developing the concept of Mathematical Knowledge for Teaching (MKT). In developing this concept Ball and Bass seek to reflect "the dynamic interplay of content with pedagogy in teachers' real-time problem solving" (p.88). Ball and Bass are particularly interested in the mathematical knowledge that must be brought to bear in order to, in real-time, deal with choosing representations, asking questions, parsing and analyzing student responses etc. They argue that this is specialized mathematical knowledge "not known by many other mathematically trained professionals, for example, research mathematicians. Thus, contrary to popular belief, the purely mathematical part of MKT is not a diminutive subset of what mathematicians know (Bass, 2005, p. 429).

The concept of MKT is treated at length in Ball and Bass (2000) and Bass (2005) and is parsed into four categories namely (1) Common mathematical knowledge; (2) Specialized mathematical knowledge; (3) Knowledge of mathematics and students; and (4) Knowledge of mathematics and teaching. We are particularly interested in the second and fourth categories here as we focus on specific pedagogical paths promoted by the NYSMCC (use of inquiry-based activities, discussion of multiple solution paths, etc.) and carried out by the Fellows in their teaching and how those decisions interplay with the MKT of the teachers. In particular, in analyzing our data we noted a few occasions in which the Teaching Fellows were deficient in their Common mathematical knowledge, but much more common, and of greater interest to us, were instances of deficiency in MKT. Specifically, we found many instances where good faith and committed efforts to teach for understanding made by the Fellows were stymied in the full potential of their implementation because the Fellows lacked the MKT for full and effective implementation of their choices.

## Methods and Modes of Inquiry

The data from this study comes from a large study examining the New York City Teaching Fellows both in their teaching practice and in their growth as professionals as they both certify to teach and work as full time professionals in schools. The primary data sources for the study are regular interviews with eight Fellows and video observations of their teaching (approximately ten times per school year). The observation data is supplemented by post-observation reflections on the class written by the Fellows and post-observation interviews conducted by a researcher with the Fellow. For the larger project this data is further supplemented by student surveys; student focus groups; out of class observations; and interviews with administrators, mentors, and coaches.

### *Observational Data*

We collected observational data in the form of fieldnotes, videotape, and audiotape on average ten times throughout one full school year. The coding scheme that we used to analyze our fieldnotes was produced collaboratively with a larger group of researchers who were also collecting data on mathematics Fellows. Our coding scheme for the fieldnotes included such codes as: teacher math questions, opportunity for meaning making, and student mathematical behavior. For the purposes of this paper we found the code "opportunity for meaning making" particularly useful in identifying occasions when the pedagogical choices of the Fellows proved to be inadequately supported by their MKT. Having identified instances where issues with Fellows' MKT, we chose four vignettes which represented a variety of situations where we can see this interplay of pedagogical decision-making and MKT.

## Results

In the following, we discuss two classroom vignettes in detail and briefly describe conclusions taken from other vignettes.

*Karen: Exploring Addition and Subtraction*

In this vignette we see a teacher, Karen, engaging with several of the state process standards in her work on addition and subtraction of integers with 7th Grade students.

In the vignette we see Karen working with a chips model with black chips representing positive integers and red chips representing negative integers. In interviews, Karen indicated that she was having them work with this model because she wanted them "to really understand" how to add and subtract when there were negative addends involved, and to understand the relationship between addition and subtraction better.

In using the chips Karen is addressing several state process standards: 7.R.1, (use physical objects… as reps) 7.R.2 (explain … using representations) 7.R.4. (explain how different reps express same relationship) 7.CN.1 (understand and make connections among multiple reps of the same math idea).

First Karen demonstrates addition using the chips and the problem 6 + (-9). She draws 6 circles with + signs in each, and 9 circles with - signs in each. She calls on Zahara who suggests "You can remove the zero pairs."

Karen presents a word problem that involves subtracting four from nine, and asks the class "What does subtraction mean?" Kate says "Taking away one number from another number." Karen: "Good." She repeats what Kate has said, and then says "In the word problem it has nine take away four equals five."

At this point, Enrico raises his hand and asks "When you subtract is it the same as when you add with positive and negative numbers?" It's not entirely clear what Enrico means here but, although she answers "Yup," Karen goes on for the rest of this class to insist on interpreting subtraction as a literal "taking away" of the appropriate number of appropriately colored chips. Most of the students in this class comply with her interpretation. However, several students push the idea of subtraction as adding a negative. They do not succeed in persuading Karen to consider it despite her stated desire for them to understand the relationship between addition and subtraction.

Karen then poses the question "What if we have negative six minus negative two?" Dayanna answers "Don't you just draw six negatives? And then you take away … since it's red you take away two." Karen draws a circle around 2 of the red "chips" and then an arrow indicating they are being removed. At this point, Chris asks "I'm confused by this because when you … take more away from a negative number doesn't it become a lower number? … Isn't it supposed to be going that way?" He gestures to the left. There is a long pause. Karen asks Chris if he is thinking of the number line. He and other students say "yeah." At which point Karen says "I want us to the put the number line totally out of our heads." She makes a gesture of casting out the idea from her head. Then she turns to the number line above the board, which has been up there all year. She takes down the number line, to gasps, cries of "no," and a few cheers.

When she has finished taking down the number line, she turns back to Chris and says "And right now, we are going to picture it this way," pointing to the problem on the board. "Okay, Chris? Cause this is what we've been picturing all year and sometimes it gets really confusing when you're thinking about negatives and sometimes positives, okay? I'm going to move on. It will all get clearer when we get through the next few problems."

While this is certainly the most dramatic example of KW refusing to consider the relationship between different representations of a mathematical idea, she showed a similar unwillingness in other observations. In this case, despite her avowed goal for introducing the model as a way "to really understand”, she only worked with the model as an alternative computational method, rather than as a springboard to understanding addition and subtraction differently.

In the next part of the lesson Karen presents the problem: “Eric earned $5. He owes Laura $7. He pays her $5. Show this subtraction on the chip board.” The students are able to solve this immediately, yelling out “two” and “he still owes her two.” Karen ignores several suggestions from students as she goes through this problem. She adds two red and two black chips, and then “takes away” the seven black, leaving the two red chips. Chris proposes starting with the seven red “cuz that’s how in debt he is” and then adding five black to represent what he earned. He is essentially proposing that the problem is -7 + 5 rather than 5 - 7. Karen objects to this, because “the number sentence says to start whatever is here on the left,” pointing to the five.

Again we see an opportunity to explore the meaning of subtraction as something more than “taking away” and we see Karen insist on the “take away” approach.

In this vignette we see Karen, who states that she is interested in her students gaining a deeper understanding of addition and subtraction of integers, employ strategies drawing on several process standards (multiple representations, use of physical objects etc.). However, her implementation is constrained in practice by her insistence on the exclusive use of certain models and by privileging of certain approaches.

*Paul: Exploring Multiple Solutions Paths*

(Unless otherwise noted, the quotes are from Paul, Fieldnotes, January 9th).

There are several learning standards in the NYSMCC that relate to having students present multiple solution strategies, and Paul appears to be committed to this pedagogical path. This places extra demands on his content knowledge – he not only needs to be able to solve the problems he assigns, which he is clearly able to do, but he needs to be able to quickly recognize the validity of solutions he had not foreseen, and to be able to relate different strategies to one another. This requires a different type of knowledge than that gleaned in a typical math content course, where prospective teachers are usually asked to produce a single solution to a problem and while, in a methods course, a prospective teacher will explore several rich problems using multiple solutions paths, it is, of course, not possible that he or she will have a chance to cover the entire curriculum systematically. In this vignette we see Paul taking the pedagogical decision to encourage multiple solution paths, but being unable to take advantage of the alternate solution strategies proposed by the students.

The problem: If you got 6 questions from 7 right, what was your percent score on the exam? Paul’s approach was to set up the proportion 6/7 = n/100 and to solve for n using cross multiplication: “I believe what we were trying to accomplish was, I think I was just trying to get a basic, bare bones cross products, how do you do cross products, how do you set up a proportion?” (Paul, Reflection, January 9th). He reported after the class: “I think they have difficulty understanding … what exactly a proportion is. … They have difficulty seeing the relationship between 2 quantities. Repeatedly throughout the week, I try to have them, before they start setting up a portion to solve, they set up, they take the 2 quantities that are being compared and put them into a ratio. And that always seems be a very hard step for them.” (Paul, Reflection, January 9th).

Although he saw the problem as a proportion problem, he had a student present another solution, even though this added significantly to the amount of time spent on what was supposed to be a quick introductory problem. We interpreted his willingness to take that extra time as evidence of his commitment to respecting alternative solution strategies.

After the students have been working on the problem for a few minutes Paul circulates the room to check on the students work. Of the 8 students who produced work on the problem 6 of them divided 100 by 7 to get the percentage value of one question and then multiplied by 6 to get the percentage score. He notices Jennifer's work and they have the following exchange:

PH: "Can you explain how you got that?"

Jennifer: "So I multiplied what I got – and there are six of them."

PH: "I liked what you did, but you're not getting the answer that I got."

Paul is showing his willingness to let students do the problems in ways that he did not intend.

In her initial work at this point Jennifer has divided 7 into 100 using long division but has made two errors: firstly she got 13.285 . . . rather than 14.285. . . and secondly she has rounded this to 13.2 before multiplying by 6 to get 79.2 rather than 79.71. Paul noticed that this answer must be wrong and has Jennifer check by adding 13.2 to 79.2 which gives 92.4. Jennifer agrees that the answer should be 100 and continues to work on the problem, redoing her calculations and working with another student.

Here Paul is demonstrating how one might use mathematical knowledge for teaching effectively—he is able to recognize quickly that she must be making a mistake and suggest a way for her to find her error.

A few minutes later Jennifer writes her solution on the whiteboard. The long division results in 14.28 (she stops at two decimal places) which she multiplies by 6 and gets the result 85.68. For some reason she then erases her working of the multiplication and simply writes:

```
 14.28
x 6.00
---------
  85.2
```

which is picking up her earlier error again. Paul asks her to explain her work to the class which results in the following exchange:

Jennifer: "What I did, was I divided seven into a hundred. Because it said, there were seven questions on the quiz, and I got I multiplied six times fourteen point twenty eight. Because Umm. It said you only answered six of them. And then I got eighty -five point."

Paul: "Okay."

Jennifer: "Then I got eight-five point." (*inaudible*)

Paul: "So, your answer is … What was your final answer?"

Jennifer: "Eighty five point two."

Paul: "Then your answer is eighty-five point two what?"

*Silence*.

Paul: "What is the question asking?"

A few students: "Percent."

Nobody has noticed Jennifer's mistake. Instead of trying to figure out, as he did before, where the problem is, Paul chooses to move on to his own solution.

Paul: Okay so this is one way to do it. And there are a couple of other ways too. Yesterday we saw two ways to solve percent problems. This is nothing more than a percent problem. Just like what we were doing yesterday. The words are a little different but we can still do it the same way. Let's try another way."

Paul takes the students through a problem they did yesterday and asks them to relate it to the new problem. The students don't make this connection so eventually Paul changes tack and writes on the whiteboard:

Part

--------- =
Whole
and says: “It’s going to be a ratio of some kind. What about the percent? … Look back on your notes from yesterday. Actually turn the page. Percents like what? Percents over one hundred. Like What? Percent over one hundred. Do I know the percent? … We got n over a hundred. Of 6 and 7, what’s the part what’s the whole?”
Jennifer: The part is six the whole is seven
Paul: Why?
Jennifer: Because...
Paul: How many questions are on the test? There are seven questions on the test. That’s the whole test.”
Jennifer: “… and he only did six and that’s the part.”

$$\frac{\text{Part}}{\text{Whole}} = \frac{\%}{100}$$

$$\frac{6}{7} = \frac{n}{100}$$

Paul then guides the students through using cross multiplication to get an answer of 85.7%.
Paul then asks the class:
Paul: ‘Why are they different?’ (referring to 85.7% and 85.2% written on the board)
No one answers. With no one responding, PH responds to the class.
Marietta: The two and the seven.
Paul: That’s how they are different, but why are they different? Why are these two numbers different? [*pause*] I would accept either of these answers, depending on how you did it. Why are they different?”
Student: “Because they want to be.”
*Pause.*
Paul: ‘I’ll save that one for later.’

*Conclusion*

This is a very unhappy resolution to the work on this problem. It seems that Paul is not, in this moment, able to reconcile these two results. Indeed, he tells the students that he would accept both answers “depending on the method you used.” We argue that this is because he is concerned with fidelity to his pedagogical decision to embrace multiple solution paths. Unfortunately the value of the multiple approaches is lost because Paul is unable to reconcile the differences. We argue that with more developed mathematical knowledge for teaching, he would see that these solution paths (as well as the third approach that he attempted at one stage) must result in the same arithmetic operations, and therefore the same answer, and so the difference must be accounted for by either a rounding error or an arithmetic error. We see here in his initial interaction with Jennifer, and we have seen in other observations, that Paul has the mathematical ability to find the error were he to look for it. As it happened, we end up with a set of most likely confused students who are unlikely to develop an appreciation for the connections between the two different approaches, unlikely to value the idea of using multiple approaches to solve problems, and perhaps more convinced than ever of the arbitrariness of mathematics as a discipline.

*Other Vignettes*

In other observations of teachers in the study we see other cases of teachers attempting to employ standards-based approaches but failing through lack of facility in a particular kind of mathematical knowledge. In one case this lack of facility is manifested by a teacher who asks her students to work on an activity designed for students to "discover" a formula for the sum of the interior angles of a convex polygon. The full potential of the task, however, is not realized because she does not seem exhibit the necessary MKT to marshal the various student representations and focus on the important mathematical process of generalizing. There is no doubt that the teacher could do this task herself nor is there any doubt that she understands the relationship between the formula (s – 2) * 180 and the breaking of a convex polygon into triangles. However, her lack of MKT seems to be restricted her ability to see how several different student representations are equivalent to her understanding and how certain student representations are limited in their claims to generality.

In another vignette, we see a teacher trying to make connections between algebra and geometry but he chooses a poor example and runs the risk of leaving his students with the impression that a particular result is a general result.

## Discussion and Conclusions

The need for additional mathematical support shown in the vignettes above is not wholly addressed by the current training and mentoring the Fellows are receiving: both Fellows and coaches tell us that their mentoring is more focused on issues of classroom management and student motivation. We have seen how the developing Pedagogical Content Knowledge (PCK) of the Fellows, as well as their pedagogical decision making in the classroom is affected and complicated by their MKT, and we can begin to determine what kind of mathematical understanding is needed to effectively use these opportunities.

# MISLEADING STRATEGIES USED IN A NON-STANDARD DIVISION PROBLEM

Erkki Pehkonen
University of Helsinki
Erkki.Pehkonen@helsinki.fi

*Here we focus on Finnish pre-service elementary teachers' (N = 269) and upper secondary students' (N = 1434) understanding of division. In the questionnaire, we used the following non-standard division problem: "We know, that 498:6 = 83. How could you conclude from this relationship (without using long division algorithm) what is 491:6?" The problem mainly measures adaptive reasoning. Based on the results we conclude that division seems not to be fully understood: only one fifth of the participants produced a completely correct solution. The most central reason for mistakes was insufficient reasoning strategies.*

## Introduction

Teacher education programmes face a major challenge in trying to affect elementary teacher students' views of mathematics, that is, their beliefs, attitudes and knowledge. This paper draws on the work of the research project "Elementary teachers' mathematics" financed by the Academy of Finland (Project No. 8201695), in which data were collected on 269 pre-service elementary teachers at three Finnish universities (Helsinki, Turku, Lapland). Two questionnaires were administered in autumn 2003 to assess the pre-service teachers' knowledge, attitudes and skills in mathematics at the beginning of their mathematics education course. The aim of the questionnaires was to measure their experiences of mathematics, their views of mathematics and their mathematical proficiency in certain topics. As part of the project we also collected comparison data on 1434 upper secondary students (grade 11, average age 17–18 years) from 34 Finnish schools selected at random. In the paper we concentrate on pre-service teachers' and upper secondary students' understanding of division and reasoning strategies used, especially their erroneous strategies.

In the Finnish comprehensive school curriculum (NBE 2004) one of the principal goals already in the second grade is that pupils should master and understand basic calculations. But earlier studies show that also pre-service teachers and upper secondary students have clear weaknesses in understanding of division (e.g. Simon 1993; Campbell, 1996; Merenluoto & Pehkonen, 2002). One of the main reasons for these weaknesses seems to be that pre-service teachers have primitive models of division (e.g., Graeber et al., 1989; Simon, 1993).

## Theoretical Framework

The division task used in this study measures several of the strands of mathematical proficiency mentioned by Kilpatrick (2001), for example, conceptual understanding, procedural fluency and adaptive reasoning. Yet, we view our task as measuring adaptive reasoning above all: to solve the task participants must reflect on and give justification of mathematical arguments, especially the relationships between operations.

### *Understanding Division*

Division is an important but complex arithmetical operation to consider in elementary teacher education. There are many reasons for its complexity: (a) division is taught as the inverse of multiplication, so understanding of division requires good understanding of multiplication; (b) division involving big numbers requires good estimation skills; (c) within the models of equal groups and equal measures two aspects of division can be differentiated: quotitive division (how many sevens there are in 21) and partitive division (21 divided by 7). (e.g., Anghileri et al., 2002)

People can use very different strategies in solving division problems. Some of them are useful and some are misleading. Prior research has identified the following useful strategies (e.g., Heirdsfield et al., 1999): (a) several different counting strategies: skip counting, repeated addition and subtraction, chunks; (b) using a basic fact; (c) holistic strategies.

In a study by Graeber et al. (1989), 129 female pre-service teachers had high scores on solving verbal problems involving the partitive model of division. They were less successful on the quotitive division problems, and these primitive models influence pre-service teachers' choice of operations. Primitive models seem to reflect an understanding whereby a student separate things into equal size groups. In Simon's (1993) study of pre-service elementary teachers the whole-number part of the quotient, the fractional part of the quotient, the remainder, and the products generated in long division did not seem to be connected with a concrete notion of what it means to divide a quantity.

Campbell (1996) studied 21 pre-service elementary teachers' understanding of division with remainder. He conducted clinical interviews with the students, who tried to solve four tasks with abstract contexts. The task we use here has some similarities in contrast to the following task used by Campbell (1996): "Consider the number $6 \cdot 147+1$, which we will refer to as A. If you divide A by 6, what is the remainder? What is the quotient?" (p. 179). In Campbell's study of the 19 participants who tried to solve this task, 15 calculated the dividend although it entailed additional trouble. Of those 15 respondents 9 calculated the dividend and relied upon long division in solving the task. Of those 4 who did not calculate the dividend, only 2 correctly identified the remainder and the quotient.

Zazkis and Campbell (1996) investigated 21 pre-service elementary school teachers' understanding of divisibility and the multiplicative structure of natural numbers in an abstract context. The following is an example of the tasks used: "Consider the numbers 12 358 and 12 368. Is there a number between these two numbers that is divisible by 7 or by 12?" Many pre-service teachers used long division as the procedural activity, but some degree of conceptual understanding was evident as well.

In a study by Silver et al. (1993), a total of 195 sixth, seventh and eighth graders from a large middle school solved three quotient division problems involving remainders with a real-world context (the number of the buses needed). The symbol forms of the word problems were (a) 540:40, (b) 532:40, and (c) 554:40. Of the respondents, 91% used appropriate procedures, and 73% of them applied long division. Only 43% of the participants understood that the result—the number of buses—was an integer.

*Focus of the Paper*

In this paper we focus on the following research question: What kind of erroneous reasoning strategies do pre-service elementary teachers and upper secondary students use in solving a certain non-standard division task? How do these erroneous reasoning strategies used by pre-service elementary teachers and upper secondary students differ from each other?

## Empirical Research

*Research Participants and Data*

The study forms a part of the research project "Elementary Teachers' Mathematics" being carried out in three Finnish universities (Helsinki, Turku, Lapland). Of the 269 pre-service elementary teachers participating in the research, 35% have completed advanced studies in school mathematics in upper secondary school. Two questionnaires were designed, the first measuring the pre-service teachers' mathematical proficiency in certain topics, and the second their attitudes towards mathematics at the beginning of their university studies. The questionnaires were administered at the first lecture in mathematics education studies in all universities in autumn 2003. Students had 60-minutes time for the questionnaires and were not allowed to use calculators. Additional results of the project are described in Kaasila et al. (2008).

The initial proficiency test contained a total of 12 mathematical tasks. The focal content areas were the rational numbers and related operations (in particular, division), because previous research indicates that these are problem areas (e.g. Hannula et al., 2002). All in all, the initial proficiency test focused on content knowledge different from that tested in upper secondary school and on the mathematics component of the matriculation examination.

In conjunction with the project we also collected comparison data with the same questionnaires from upper secondary school. Altogether 50 schools were selected at random from all Finnish upper secondary schools. A letter was sent to the directors of the schools in the sample, in which they were asked to select from their school one group of students in the general course and one in the advanced course in second-year mathematics. We received responses from 34 schools representing a total of 65 student groups. Thus, we obtained in total data from 1434 students.

The non-standard division task we used is the following:

"We know that 498:6 = 83. How could you conclude from this relationship (without using the long division algorithm), what is 491: 6 = ?"

*Data Analysis*

We did not find in the research literature a task similar to the one used in this study. As mentioned earlier, our task shares certain features with one used by Campbell (1996). However, it also differs in a number of respects: First, in the task used by Campbell, the dividend is explicitly mentioned as the 'right hand side' of the division algorithm, whereby respondents have an opportunity to directly identify the quotient and the remainder. In our task, the starting equation is given in the form of division and does not involve a remainder. Second, unlike Campbell, we do not mention in the context of our task the concepts of remainder and quotient. Third, the participants in our study did not have permission to use the long division algorithm or a calculator, which were central aids in Campbell's study.

In the first phase of this study (see Kaasila et al., 2005) we broke the 269 pre-service elementary teachers' solutions down into main categories and subcategories by applying analytic induction. This involves scanning the data for categories of phenomena and for relationships among such categories, developing typologies upon an examination of initial cases, and then modifying them on the basis of subsequent cases (cf. LeCompte, Preissle, & Tesch, 1993).

In the second phase of the study (see Hellinen & Pehkonen, 2008), a deductive approach was used: the 1434 upper secondary students' solutions were categorized using essentially the same classification as in the first phase when analysing pre-service elementary teachers' solutions. A number of categories were identified in addition to those formed in the first phase.

In the third phase we harmonised the categories found in phase one and two by reanalysing a part of the pre-service elementary teachers' solutions. At the end we compared the pre-service elementary teachers' reasoning (or solution) strategies with the upper secondary students' reasoning strategies. For more details see Kaasila et al. (under review).

## Results

The problem was solved totally correctly by one fifth of the pre-service teachers and the upper secondary students. The categories of erroneous strategies used by the pre-service teachers and the upper secondary students are presented in Table 1. More details on results can be found in the paper Kaasila et al. (under review).

Table 1

*Main Categories of Erroneous Strategies Used by the Pre-Service Teachers*

| ***Successful strategies*** | ***PST*** | ***%*** | ***USS*** | ***%*** |
|---|---|---|---|---|
| **All** | **54** | **20** | **221** | **19** |
| ***Erroneous strategies*** | ***PST*** | ***%*** | ***USS*** | ***%*** |
| **Almost correct strategy** | **60** | **22** | **231** | **20** |
| **Thinking limited to integers** | **59** | **22** | **165** | **14** |
| **Clear misconception** | **12** | **5** | **42** | **4** |
| **Other mistakes / irrelevant strategies** | **84** | **31** | **494** | **43** |
| **All** | **215** | **80** | **932** | **81** |

*Note.* (PST, N = 269) and the upper secondary students (USS, N = 1434); the share of successful strategies is given in the same table.

*Erroneous strategies*

Misleading or otherwise erroneous strategies were used by 80% of the pre-service teachers and by 81% of the upper secondary students. We divided these strategies into four main categories, each of which was further divided into subcategories.

*Almost correct strategy*. 22% of the pre-service teachers and 20% of the upper secondary students solved the task almost correctly. The solution of this group indicates a fairly high level of conceptual understanding but all the phases of the solution were not accurately reported, or students made some slippery mistakes. The almost correct strategies can be divided into three subcategories:

In the cases of inaccurately reported reasoning (7% vs. 11%), respondents obtained the correct solution, but some important phases of the solution were not accurately reported or the reasoning used was not indicated at all. In the following, the pre-service teacher did not justify in detail why the remainder was 5.

Example 1. 498–6 = 492. So 492:6 = 82; 491:6 = 81 remainder 5. (3093[1])

The reasoning is essentially correct, but at the end the fractional part was added in the wrong direction (11% vs. 5%):

Example 2. 498–491 = 7, from this it follows that 491:6 must be one unit less than 492:6 with one unit remaining (7–6 = 1), i.e. the answer is 82 remainder 1. (2065)

The most common slippery mistake was an error when calculating the difference between the dividends (4% vs. 4%).

Example 3. Since 6 goes into 498, 83 times and 498–491 = 6, 6 goes into 491 one time fewer than into 498, or 82 times (5802).

*Thinking limited to integers*. 22% of the pre-service teachers and 14% of the upper secondary students were not able to calculate the quotient. These strategies can be divided into three subcategories:

The respondent knew that the answer was not an integer, but he/she was not able to deal with the remainder (12% vs. 9%):

Example 4. The number 491 is 7 units smaller than 498. Therefore 6 should go one time fewer into 491. I can't think of any explanation for the fact that 6 goes into 491 only 81 times. (3016)

In these cases the respondents did not even seem to think that the answer might be something else than an integer (10% vs. 4%).

Example 5. The number 491 is 7 units smaller than 498. Consequently, the answer is 82, but one unit is left over… But perhaps it can be ignored or should the answer be a decimal? (3055)

Here the respondent was aware that division in question was not even, so they thought that there can be no solution to the task (0% vs. 1%).

Example 6. It could not be an integer, because $498–491 \neq 6n, n \in Z$ (5077)

*A clear misconception*. 5% of the pre-service teachers and 4% of the upper secondary students had clear misconceptions in their answers. We divide these answers into two subcategories:

The remainder was considered a decimal (tenths) instead of sixths (3% vs. 1%).

Example 7. 498–491 = 7; 7–6 = 1. The result is 82.1 (1012)

In these cases, the respondents seemed to understand division such a way that the dividend and the quotient change at the same rate (2% vs. 3%).

Example 8. 498–491 = 7; 83–7 = 76. (3057)

*Other mistakes/irrelevant strategies*. 31% of the pre-service teachers and 43% of the upper secondary students obtained no answer at all or presented a solution that was not relevant to the research. These cases are grouped into four subcategories:

The answer was reached by experimenting or in some way without using the connection given in the task (1% vs. 2%). This type of reasoning strategy usually produced erroneous results, but there were also correct ones.

Example 9. 6 goes 50 times to 300, this leaves 191 = > where $30 \cdot 6 = 180$; this then leaves 11, which into which 6 goes almost 2 times; thus 491:6 = > 50+30+2 (almost) ≈ 82 times. (5687)

Correct result without reasoning (3% vs. 6%).

The results were very inaccurate and/or reasoning irrelevant (10% vs. 24%).

The respondents in this category did not produce any result, or anything that made sense (17% vs. 11%).

Example 10. I can't do it without a calculator (3079).

## Discussion

The results indicate that the task was very challenging: only about one fifth of the participants were able to produce a totally correct solution. More than half of the participants either produced no result at all or used misguided strategies. Although division is known to be a difficult operation that has many interpretations, the result is still surprisingly poor. We were surprised that so many pre-service teachers and upper secondary students failed to provide justification with their responses, although it was specifically asked for in the instructions for the task.

We identified three main reasons for mistakes or incomplete solutions: (a) Staying on the integer level: 10% of the pre-service teachers and 4% of the upper secondary student gave their answer as an integer, and it seems that in these cases they did not even think that the answer might be something else than an integer; (b) Inability to handle the remainder: Some of the respondents seemed to understand that the result was not an integer but a fraction, but they could not handle the remainder. For example, they expressed the remainder in the answer in tenths not in sixths (cf. Campbell 1996). It seems that in school dealing with remainders has been a procedural matter, with too little attention focused on the idea that the fractional part of the quotient provides different (yet related) information from the remainder (Simon, 1993); (c) Insufficient reasoning strategies: A little more than a fifth of the participants solved the task almost correctly. In these cases, all the phases of the solution were not accurately reported. The reason for insufficient reasoning strategies may be a lack of language skills because the respondents had great difficulties in providing written explanations of their reasoning (see also Silver et al., 1993).

On the basis of this study we can suggest some guidelines for the content of mathematics courses in teacher education and in school: learners need (a) a concrete, contextualised knowledge of division and (b) the ability to examine division as an abstract mathematical object (cf. Simon, 1993). Above all learners need (c) tasks and situations through which they can develop their adaptive reasoning skills. According to our study, a lack of reasoning skills may be the main factor causing students difficulties when solving non-standard division tasks.

## Endnote

1. The four digit number in the bracket after the example refers to the test participant. When referring to pre-service teachers, the first number is 1, 2, 3 or 4 and when referring to secondary students the first number is 5 or 6.

# TEACHER-DESIGNED QUESTIONS ABOUT A MATHEMATICAL STORY

Mary L. Garner
Kennesaw State University
mgarner@kennesaw.edu

*The purpose of this study was to examine the cognitive level of questions produced by teachers about a mathematical story entitled The Number Devil. The hypothesis was that the mathematical story would inspire higher-level cognitive questions involving exploration of important ides of mathematics as well as philosophical musings about the nature of mathematics. Ten teachers from grades 6 through 12 were asked to read the book and design questions about the important mathematics from each of the 12 chapters. The questions were categorized according to cognitive demand as described by Stein, Smith, Henningsen and Silver (2000). Most of the 455 questions (61%) were of lower-level cognitive demand, procedural in nature, with only 9% of the highest level of cognitive demand, open-ended and conceptual in nature, and only 3% philosophical in nature.*

## Background and Purpose

In a series of articles, Borasi, Siegel, Fonzi, and Smith (1998) and Siegel, Borasi, and Fonzi (1998) described the benefits of reading "mathematical stories" (mathematics-related texts, not technical in nature) in the mathematics classroom. The authors presented evidence that use of such stories can awaken students' interest, stimulate discussion, promote sense-making, provide a variety of opportunities for learning mathematics, and support a constructivist inquiry-based culture in the classroom. By various reading strategies, students are encouraged to ask questions as they read the text, but questions from the teacher also play a role in how the students engage with the text. Indeed, questions that teachers ask are critical in the realization of the vision set forth in the Curriculum and Evaluation Standards for School Mathematics (2000). Regardless of whether the questions are part of a formal assessment or part of the teacher's daily routine of introducing new topics or focusing student attention on a text, questions communicate implicitly what it means to do and know mathematics and establishes expectations (Borasi, 1990; Cooney, Badger, Wilson, 1993).

Teacher-designed questions can vary widely according to the cognitive demands placed on students. In a study by Cooney, Badger, and Wilson (1993), 201 teachers were asked to "write or draw a typical problem that you gave students that you believe tests a deep and thorough understanding of the topic" (p. 241). The problems were categorized according to four levels, depending the requirements of the problem: (1) Simple computation or recognition. (2) Some comprehension (e.g. a one-step word problem). (3) More comprehension (e.g. a multi-step problem). (4) Non-routine reasoning, open-ended. The researchers found that most of the teachers created an item at level 1 or 2. They suggest that reliance on questions that require lower-level cognitive demands, simple reproduction of procedures and generation of an answer, reflect a traditional view of mathematics and mathematics teaching. Reform-based teaching, on the other hand, calls for more non-routine problem solving that places greater cognitive demands on students.

The purpose of this study was to examine the cognitive level of questions produced by teachers about a mathematical story entitled *The Number Devil*. The hypothesis was that the mathematical story would inspire the teachers to design higher-level cognitive questions

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

involving exploration of important ides of mathematics, even have some fun with the mathematics, as well as philosophical musings about the nature of mathematics.

## Theoretical Perspective

In *Implementing Standards Based Mathematics Instruction*, Stein, Smith, Henningsen and Silver (2000) presented a scheme for analyzing tasks according to cognitive demand. In their work, tasks were placed into one of four categories as shown below in Table 1. The first two categories are tasks that represent a low-level cognitive demand, while the second two categories represent tasks with a high-level of cognitive demand. The authors note that "opportunities for student learning are not created simply by putting students into groups, by placing manipulatives in front of them, or by handing them a calculator. Rather, it is the level and kind of thinking in which students engage that determines what they will learn." (page 11). The level and kind of thinking in which students engage depends upon the questions that teachers ask and how cognitively demanding those questions are.

Table 1
*Method of Categorizing the Level of Mathematical Tasks as Described by Stein, Smith, Henningsen and Silver (2000)*

| Category | Description | Characteristics |
|---|---|---|
| 1 | Memorization | Iinvolves reproducing previously learned facts, is not ambiguous, does not involve procedures, has no connection to concepts. |
| 2 | Procedures without connections to understanding, meaning, or concepts | Is algorithmic, not ambiguous, focused on producing correct answer, requires no explanations, focuses solely on describing the procedure that was used, requires limited cognitive effort. |
| 3 | Procedures with connections to understanding, meaning, or concepts | Requires some conceptual understanding of the procedures to complete the task, focuses on use of procedures for the purpose of developing deeper levels of understanding of mathematical concepts, may rely on multiple representations, requires some cognitive effort. |
| 4 | Doing mathematics | Requires complex non-algorithmic thinking, requires exploration, requires understanding of mathematical concepts or processes, requires self-monitoring, requires students to analyze task and possible solutions and access relevant knowledge, requires |

| | | |
|---|---|---|
| | | considerable cognitive effort and may involve some discomfort. |

## Methodology

The teachers who participated in the study were 10 middle-grades and secondary teachers enrolled in a Master of Education program with a specialization in mathematics education at Kennesaw State University. The students were enrolled in a course entitled “MAED 7720: Mathematics in the Humanities.” Over a three-week period the students were asked to read the book “The Number Devil” and complete the following task:

> For each chapter, design four questions that you would ask your students about the most important mathematics in the chapter (to see if they understood the chapter and to get them thinking about the mathematics). Describe how you would answer the questions.

The Number Devil is a 253 page book consisting of 12 chapters, aimed at ages 9 through 12. In each chapter, a middle-grades boy named Robert recounts his night’s dream about “The Number Devil” a trickster who teases him into making observations about numbers. For example, in Chapter One, “The First Night,” the devil shows Robert how you can do almost anything with the number 1, even experience the infinitely large and the infinitely small. On the second night, the devil reveals the power of zero and discusses Roman numerals, place value, and powers. Prime numbers, rational numbers, irrational numbers and roots are the topics of Chapters Three and Four. Triangular numbers are introduced in Chapter Five. Fibonacci numbers are explored in Chapter Six. Pascal’s triangle is introduced in Chapter Seven and used in Chapter Eight to calculate permutations and combinations. Sequences and series are the topics of Chapter Nine. The golden ratio and Euler’s formula are explored in Chapter Ten. Chapters 11 and 12 are the most difficult chapters with discussions of proof and the nature of mathematics and its history.

The questions were assigned to levels 1 through 4 according to the scheme described above by Stein, Smith, Henningsen and Silver (2000). Two additional levels were used: level 5 was a new category for philosophical questions about the nature of mathematics or attitudes towards mathematics; level 6 was created for questions regarding the history of mathematics.

## Results

The teachers provided a total of 479 questions but 24 of the questions contained mistakes, were incomplete, or were difficult to interpret; therefore 455 were analyzed. Samples of questions in each category are shown in Table 2.

Table 2.
*Examples of Questions in Levels 1 through 6*

| Level | Sample questions |
|---|---|
| 1 | 1. What kind of triangle do these 'triangle numbers' (triangular numbers) make when written as dots?<br>2. Prima donnas (the number devil's word for prime numbers) can only be divided by 1 and itself. What types of numbers do these represent?<br>3. What operation is like multiplying in reverse?<br>4. What is meant by rutabaga (the devil's word for square root)?<br>5. Why did the number devil say the Romans had such a difficult time with numbers?<br>6. Give an example of how we used Pascal's Triangle in Algebra 2? |
| 2 | 1. Can you figure the $16^{th}$ triangle number (triangular number)?<br>2. What is the $20^{th}$ Bonacci number (the devil's word for Fibonacci number)?<br>3. Can you write in Roman Numerals the year you were born?<br>4. What is 10!<br>5. In how many different ways could 4 of Robert's classmates be seated? |
| 3 | 1. How does the graph of the function $f(x) = 1/x$ for $x \geq 0$ represent the concepts of "an infinite number of numbers" and "an infinite number of infinitely small numbers."<br>2. Can negative numbers be prima donnas?<br>3. When do you know if you are going to get a remainder and when are you not?<br>4. How does the number devil explain infinity?<br>5. Explain how you would get 1111111 x 1111111 without using a calculator. |
| 4 | 1. Why wouldn't 11111111111 x 11111111111 work as the Number Devil said the other would?<br>2. Why does the sum of two consecutive triangular numbers equal a square number?<br>3. Write your own rule like Bonacci's and create your own set of numbers. Write out the first 13 of them. Do you notice any patterns?<br>4. In your own words, write a definition for infinite.<br>5. The number devil says the following comment, "… proving that no proof exists is a proof in itself…". What do you think he meant by this?<br>6. Why do you think proofs are necessary in mathematics?<br>7. Starting with just one dot, create your own pattern like the coconut triangles (triangular numbers). What patterns can you find? |

| | |
|---|---|
| 5 | 1. Why do you feel that Robert thinks math is a waste of time?<br>2. Why do you think that the number devil changed the names of mathematical concepts into ordinary terms?<br>3. The number devil said that guessing is not allowed in mathematics. What do you think? Should guessing ever be acceptable in mathematics? Explain.<br>4. Can you relate to Robert's frustration to math? Describe a story when you felt like Robert on page twenty-five.<br>5. Why did the Number Devil say that mathematics is an endless story? What do you think?<br>6. The Number Devil talks about another number devil called the Man in the Moon. He talks about proving a certain math rule. However, the Number Devil said another number devil came along and proved him wrong. What does this tell you about math? |
| 6 | 1. Who developed the triangle mentioned by the Number Devil (Pascal's triangle)?<br>2. Who is Fibonacci and what mathematical concept is he known for in mathematics history?<br>3. Where else does the "blankety blank" number (the golden ratio) show up in nature? |

Level 1 questions often connected the text to previously learned facts or vocabulary, or involved simple identification of some fact offered in the text. Questions assigned to level 2 were most often questions that asked the student to reproduce the procedures demonstrated in the text or connect the text to some previously learned procedures. Questions assigned to level 3 involved taking procedures described in the text and requiring the students to explain the procedures or apply the concepts described in the text in new contexts; they also included questions in which students were asked to explain how the number devil or Robert came to certain conclusions. Questions assigned to level 4 required something quite beyond what was provided in the text, including explanations of why certain observations made by the number devil were true or how those observations could be extended to new situations, new sequences or series.

The teachers produced 479 questions but 24 of those questions contained mistakes, were incomplete, or were difficult to interpret. As shown in Table 3, of the remaining 455 questions most were of lower-level cognitive demand (61%) and surprisingly few were of a philosophical nature (3%). Only 33% were of a higher-level cognitive demand and only 9 percent were classified as level 4. Certain teachers tended to questions of higher-level cognitive demand (teacher 4) while others tended to questions of lower-level cognitive demand (teacher 9). Note that most of the philosophical questions and the level 4 questions could be attributed to teacher #3.

Table 3.
*Cognitive Level of Teacher-designed Questions*

| Cognitive level | Teacher #: | | | | | | | | | | Total |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| 1 | 11 | 8 | 8 | 1 | 9 | 7 | 21 | 24 | 37 | 10 | 136 (30%) |
| 2 | 9 | 21 | 9 | 13 | 16 | 24 | 15 | 17 | 5 | 14 | 143 (31%) |
| 3 | 18 | 16 | 8 | 23 | 11 | 9 | 2 | 5 | 2 | 14 | 108 (24%) |
| 4 | 3 | 3 | 10 | 3 | 5 | 2 | 5 | 1 | 1 | 10 | 43 (9%) |
| 5 | 1 | 0 | 6 | 4 | 0 | 0 | 0 | 0 | 1 | 1 | 13 (3%) |
| 6 | 5 | 0 | 5 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 12 (3%) |

## Conclusion and Discussion

The purpose of this study was to examine the cognitive level of questions produced by teachers about a mathematical story entitled *The Number Devil*. The hypothesis was that the mathematical story would inspire higher-level cognitive questions involving exploration of important ides of mathematics as well as philosophical musings about the nature of mathematics. As shown in Table 3, the hypothesis was not supported. As in a previous study by Cooney, Badger, and Wilson (1993), even in the context of a whimsical, imaginative story about a boy who is teased with interesting facts about mathematics, teachers largely produced questions of a lower-level cognitive demand.

According to Cooney, Badger, and Wilson (1993), the tendency for teachers to use questions that involve lower-level cognitive demands could be attributed to their understanding of mathematics as a series of procedures. They state "As long as mathematics is viewed as consisting primarily of a series of steps to be applied in isolated contexts, teachers will view moves toward alternative methods of assessment as peripheral to the 'real curriculum.' As a consequence, a promising vision evaporates into a mirage" ( page 247). In this study, procedures or recall of vocabulary appeared to be the focus of 90% of the questions, despite the opportunities for exploration and more in-depth inquiry. The high occurrence of procedural questions may be a reflection of the teachers' traditional view of mathematics, but it may also be due to the teachers' inexperience with designing questions of higher cognitive demand, compounded with their inexperience with using mathematical stories in the classroom.

Further research is needed to explore ways to raise the cognitive level of teacher-designed questions, as well as how such mathematical stories can promote student questions of a high cognitive level and support mathematical inquiry.

# THE DEVELOPMENT OF PEDAGOGICAL CONTENT KNOWLEDGE IN COLLABORATIVE HIGH SCHOOL TEACHER COMMUNITIES

Ilana Horn
University of Washington
lanihorn@u.washington.edu

*To support student understanding, math teachers need to develop pedagogical content knowledge (PCK) that contributes to conceptually rich instruction. This analysis tracks the development of PCK in two mathematics teacher workgroups in urban high schools. Using video data, this analysis highlights the differences in the teachers' collaborative discourse as they made sense of students' mathematical difficulties. In the newer group, the teachers elaborated students' mathematical difficulties but their instructional response did not address the scope of difficulties identified. In the more mature group, the teachers' analysis of students' mathematical difficulties was more tightly coupled with instructional responses. This analysis illuminates the ways in which collegial conversations support the development of PCK and highlights professional learning through the discourse of collaborative teacher communities.*

## Objective and Purpose

The improvement of secondary mathematics instruction continues to be a pressing issue in the United States. Several recent studies indicate that math students routinely engage in classroom activity without understanding connections to important mathematics and scientific ideas (e.g., Banilower, Smith, Weiss & Pasley, 2006). In an observational study, Banilower et al. (2006) found that only 14% of all lessons in a national sample had a climate of intellectual rigor. In addition only 16% of lessons incorporated questioning that was likely to move students' thinking forward and two-thirds of all lessons lacked sense-making discourse. Inattention to these kinds of classroom discourses is compounded by teachers' limited understanding of students' conceptions, thus making it difficult to adjust instruction accordingly.

But how do we move teachers toward this kind of conceptually rich instruction? A number of studies point out that this kind of mathematics instruction depends on teachers' pedagogical content knowledge, or PCK (Ball, Thames, & Phelps, 2008; Hill, Rowan, & Ball, 2005; Shulman, 1986). By pedagogical content knowledge, researchers refer to mathematical understanding that includes the most useful forms of representing and communicating content, as well as how students best learn the specific concepts and topics of a subject.

If conceptually rich instruction depends on teachers' PCK, how might we support the development of PCK? One possibility comes out of another line of educational research on equitable teaching. Namely, equitable student outcomes — meaning that students' race or class is not strongly predictive of mathematical attainment — are best achieved when teachers work together with a focus on student learning (Gutièrrez, 1996; Lee & Smith, 2001; McLaughlin & Talbert, 2001). It has been posited by a number of researchers that such teacher collaboration can, among other things, foster the kind of PCK that supports teaching for understanding.

For the past five years, on the *Adaptive Professional Development* project[v], we have engaged in a design experiment aimed at increasing access to and rigor in secondary mathematics through intensive, ongoing professional development work in urban high schools. A primary goal of this project is to support conceptually rich mathematics instruction for diverse students. We work toward this goal by providing professional development that places student learning at the center of teaching practice and supporting teachers' ongoing collaboration around student thinking. We started our work at Septima Clark High School,[vi] and after our initial success there, we added other schools to our network. Before the intervention at Clark, student pass rates in first year mathematics hovered just under 50%. After year one, they increased to 70%. Similar improvements were seen on standardized mathematical achievement tests, indicating that the changes in teachers' practice had an effect on student learning, particularly for poor students and African and African American students, two demographics of particular concern in this setting. After two years of deliberate work on improving their teaching practices, the teachers saw pass rates on 10th grade state mathematics assessments rise for both low-income students (from 21.2% to 40.0% passing) and for African and African American students (from 15.7% to 30.1% passing).

We understand these results to be the outcome of at least two things. First of all, with the support of our project, the teachers' worked together in a more focused way than they had previously, giving them opportunities to coordinate expectations for students. This provided a clearly articulated curriculum, from the broader level of pacing down to the finer details of instructional language. Such consistency seems to have raised the level of expectations across the classrooms while providing students with easier transitions between them. Second, the teachers' intensive engagement in professional development coupled with the building-level teacher team collaboration provided rich opportunities for professional learning. It is this second aspect of the phenomenon that I investigate in this paper. Over the course of the project, our inquiry was organized by the question: *how do teachers develop more equitable mathematics teaching practices through targeted and situated professional development?* Unpacking the relationship between professional development activities and teacher learning will contribute to other efforts toward improvement of secondary mathematics education. In this analysis, I focus on how teacher collaboration contributes to PCK that supports teaching mathematics for understanding.

## Theoretical Framework

The study of teachers' professional learning in the context of their workplace groups requires a framework that can account for learners and their settings. Thus I use a situative lens to study the teachers' learning (Greeno, 2006). As Greeno describes, a situative approach to the study of learning is different from a purely cognitive approach: "Instead of focusing on individual learners, the main focus is on activity systems: complex social organizations containing learners, teachers, curriculum materials, software tools, and the physical environment" (p. 79). In this case, the social organization of the teachers' collaborative work provides a social context for the teachers as learners.

The study of learning demands a conceptualization of both mechanism and telos. A situative perspective highlights the role social interactions and contexts play in shifting learners' understandings. In Lave and Wenger's (1991) terms, the mechanism for learning is the shift from peripheral to central participation in an activity. In previous work, I have operationalized this notion in the context of teacher community by looking at the context of teachers' collegial conversations, investigating the ways that discourse patterns over time provide the means for teachers to become more central participants in these interactions (Horn, 2005, 2007, in press). The telos, or goal, of learning in this case is teaching mathematics for student understanding. Thus we would anticipate a stronger and more specific understanding of student thinking and appropriate instruction as teachers learn.

This project conceptualizes teachers' learning about teaching mathematics for understanding as something that can be traced, in part, through their interactions with colleagues. By investigating the nature of those interactions and what might make them more effective in deepening teachers' understanding, this study contributes to educational research by furthering our understanding of teacher learning in workplace contexts. At the same time, there are important practical implications for this analysis since professional learning communities are becoming a more common way for schools to organize teachers for instructional improvement.

## Methods

*Research Context*

For the larger study, we pursued the question: *How do teachers develop more equitable mathematics teaching practices through targeted and situated professional development?* We have approached this project as a design experiment (Barab, 2006; Brown, 1992), where we have used precepts about student learning and teacher learning to develop interventions with the teachers to refine our understanding of how these work. Through active participation for the five years of the project, we have collected hundreds of hours of field notes of professional development activities, yearly interviews with participating teachers, audio and video recordings of teacher collaboration meetings, video tape recordings of teachers' classrooms, and student achievement data.

As described earlier, our work started in Septima Clark High School in the 2004-2005 academic year. In Fall 2005, the Clark teachers formed a Freshman Team to focus on improving instruction for students in first year math classes. Team members consisted of the subset of the mathematics department who taught at that grade level. They were given a common planning period in addition to the regular preparation time.

Because of their initial success, in Fall 2006, teachers at Lotus High School also formed a Freshman Team using a similar structure and principles. The Lotus team faltered somewhat the following year due to staffing issues and a lack of support, but has re-emerged this academic year (2008-2009) under new leadership and with the hiring of committed mathematics teachers.

Theoretically, we view these collegial groups as providing us with a cross-sectional sample of teacher communities in different stages of development. Both groups meet criteria in the literature for professional learning communities: the teachers expressed shared norms and values; they focused together on student learning; they collaborated; deprivatized their practice; and used reflective dialogue in their conversations (Louis, Marks, & Kruse, 1996). While these criteria provide an important starting point for identifying teacher professional learning communities, the field needs a better understanding of not only how such communities might emerge, but how they might evolve over time. We see the differences in the how the Clark and Lotus teachers' collaborate as one way of understanding the evolution of professional learning communities. The question that guides the present analysis is: *How do high school mathematics teachers' collaborative teams support their understanding of equitable teaching practices?* By looking cross-sectionally at professional communities at different points of evolution, this analysis seeks to hone in on the types of interaction that support the development of PCK, particularly as it relates to teaching mathematics for understanding.

*Participants*

The participants featured in this analysis are the current teacher teams at Lotus and Clark high schools. The Lotus team consisted of 3 teachers: Claire (with 9 years experience), Betty (5 years experience); and Kieran (Claire's student teacher). The Clark team consisted of Rose (over

25 years experience), Darla (10 years), Linda (5 years), Wendy (2 years), Anh (Linda's student teacher) and Trevor (Darla's student teacher). All of the teachers demonstrated a commitment to the project of teaching for understanding and had participated in professional development to support the development of these teaching practices. Because the Clark teachers have collaborated longer than the Lotus teachers, we conceptualize them as a more developed teacher community.

*Data*

Since we seek to understand the development of discourse that supports PCK in mathematics teacher workgroups, we have collected data that allows for longitudinal within group analysis as well as cross-sectional across group analysis to make sense of changes in discourse over time. Our primary data for this analysis are videotapes of the teachers' collaborative work. Currently, we have video taped 2 two-hour collaborative meetings at both Clark and Lotus from the start of the school year. In addition, we plan to tape 2 two-hour collaborative meetings at each site in the middle and end of the school year. This will provide us with 12 hours of video data for the analysis. As secondary data, we have collected weekly fieldnotes of the teachers' meetings to help us situate the video data in terms of the groups' overall trajectory, to determine the typicality of the focal events, and to corroborate and refine our preliminary analysis. In this analysis, I focus on a cross-sectional analysis across the two groups.

*Analytic Methods*

To investigate the teachers' learning in their collaborative groups, we parsed the videotapes using a unit of analysis called *episodes of pedagogical reasoning* (EPRs, [Horn, 2005, 2007, in press]). That is, we looked for units of teacher talk where the teachers reveal their reasoning about pedagogical issues. Usually these begin with questions or assertions about practice that are accompanied by a statement of reason, explanation, or justification. EPRs can be single-turns of talk ("I'm not doing that activity because it takes too much time") or more elaborate, multiparty co-constructions. We locate EPRs based on topic shifts in the conversations. Longer EPRs frequently consist of sub-EPRs, as teachers explore different facets of the same problem.

For the present analysis, I focus on two EPRs, a five-minute episode from Lotus and a three-minute episode from Clark. These EPRs were selected for analytic comparison because the teachers are focusing on students' mathematical confusion about algebraic topics, providing insight into the kinds of pedagogical reasoning that might support PCK. In particular, I trace the kinds of pedagogical content knowledge that the teachers assert during these episodes and how they relate it to their instructional decisions. Investigating how the teachers reason about these confusions and then develop pedagogical responses illuminates the role that professional communities can play in the development of PCK as well as influencing teaching practice.

## Results

*Figuring Out Students' Confusion with Linear Equations at Lotus Overview of Episode*

This five-minute EPR comes out of an hour-long collaboration meeting. The Lotus teachers are working to understand why an activity on linear graphing was not successful in their classes. Prior to this meeting, all of the teachers used the activity in their classes, and they have agreed that it did not lead to the kinds of student understanding that they had hoped for. The original goal of the activity was to help students understand the graphical consequences for changes in slope ($m$) and y-intercept ($b$) in linear equations in the form $y = mx + b$. The first part of the episode is spent diagnosing what students had trouble with in the activity. At the end of the episode, the teachers decide upon an appropriate instructional response.

*Pedagogical Content Knowledge Discussed*

In diagnosing the trouble students had with the graphing activity, the teachers invoke a number of issues that relate and represent their pedagogical content knowledge. First, Betty points out that the students' trouble with the scales on the axes led to graphs that did not highlight the contrasts between the different linear equations, as was fundamental for the success of the activity. Kieran, Claire's student teacher, thinks that the students' trouble came out of their difficulty with the task's instructions. Betty, drawing on a similar activity the group did earlier, hypothesizes that the negative numbers students needed to use in this activity led to difficulty, since their integer arithmetic is not strong. Betty then further suggests that students may have had different scales for graphs they were supposed to compare, which obscured the contrasts in the graphs that were critical to the activity. Kieran and Claire did not see the problem with the integer arithmetic in their students' work. When Betty asks them where their students had trouble, they point to issues of scale: students did not keep the intervals constant, particularly around the graph's origin. Claire adds that some of their students were having trouble plotting points correctly. Betty agrees that some of her students' points were not plotted correctly, but she thinks it was because they used scales that were not appropriate for the numbers they were plotting (e.g., using intervals of 20 when the x values were between 1 and 10). Claire also reports student graphing troubles arising from interval choices, but she tells of students using intervals like 3 and having trouble finding even numbers on the axis, leading to non-linear looking graphs.

At the end of this diagnostic talk, the teachers turn to figuring out their instructional response for the follow-up activity, which is similar in structure to the one they have been analyzing. They invoke an ongoing tension in their decision making, described by Betty as "whether or not we want to do give into them and have them started independent of us and how much we want to make sure and clarify questions." They conclude that, because of the extent of the difficulties students are having, they need to do more to "scaffold" students. They decide to do this by "modeling" the task before having students do it independently in their small groups. Betty illustrates this modeling through a *teaching rehearsal* (Horn, 2005, 2007, In press), an imagined or anticipatory narration or enactment of classroom interaction that teachers use when making sense of practice with their colleagues. Betty uses a teacher voice and gestures her graph on an imaginary white board while she says, "'So I'm gonna draw my axes…' 'Everybody check, make sure they're numbered correctly.' And then like, 'Here are my lines, I'll label them like this.'" Her rationale for the modeling follows the rehearsal, when she explains, "just to kind of do a speeded up version of it where you're not giving accurate points, not doing whatever but to actually do those instructions." Her colleagues agree to this strategy for addressing the students' troubles.

*Relationship between Diagnosis of Student Confusion and Instructional Decisions*

The diagnosis of student confusion takes up much of this episode (approximately 4 of 5 minutes). This diagnosis requires the teachers' PCK, as they talk through the ways students understand and interact with the content of linear equations. A number of sources of trouble in students' understanding are elaborated, ranging from instructional (unclear directions) to students' skills (difficulty with integer arithmetic) and conceptual understanding (choosing appropriate intervals for a given set of data). While the teachers reach some consensus about the sources of the student confusion, their agreed upon response only addresses the first type of problem. By resolving the similar student difficulties by modeling the new activity, the teachers planned response helps with the procedural aspects of the tasks without addressing the underlying mathematical issues. In particular, Betty's suggestion to do a "speeded up version" of the activity as a demonstration before the students work independently does not allow a discussion of some of the deeper issues of linear graphing that they have identified, such as choosing appropriate scales for a given set of data, or keeping scales consistent so that students can make comparisons between graphs.

*Understanding Students' Confusion with Solving Systems of Equations at Clark Overview of episode*

This three-minute EPR comes out of a two-hour collaboration meeting. The teachers are focusing on the problems students have using the "elimination method" of solving systems of linear equations. The elimination method refers to taking *n* equations in *n* variables and systematically finding values for the variables that satisfy all *n* equations by eliminating like terms across the equations. In this introductory unit, students were looking at systems of two equations in two variables, typically *x* and *y*. This required that they eliminate one variable (say *x*) across the equations by creating like terms with opposite coefficients and then solving for the value of the remaining variable (*y*), which could then be substituted in one of the original equations to find the first variable (*x*).

Two of the teachers, Darla and Wendy, have taught the unit on solving systems of equations using the team's shared curriculum, while the other teachers around the table are new to this particular unit. Wendy leads the discussion of student difficulties, interweaving her instructional responses. Her diagnosis is supported and elaborated by Darla.

*Pedagogical Content Knowledge Discussed*

Wendy starts the discussion of student difficulties by using a discourse structure I have called a *teaching replay* (Horn, 2005, 2007, in press). Teaching replays provide blow-by-blow accounts of actual and sometimes ongoing classroom events, often with teachers often narrating or acting out their part as teacher. In this instance, Wendy replays a student's confusion over the elimination method, specifically the combining of like terms when the coefficients are not opposite values ("'Okay, I know that goes away, right? […] So I know the 3y and the -3y go away, but what's 4x + -2x?'"). She offers an instructional suggestion to lessen student confusion by sticking "strictly to addition."

Darla agrees with Wendy's diagnosis and adds that, in the past, her students did not have trouble using the strategy of multiplying through one of the equations by a negative one to create opposite like terms that "make zeroes." This, Darla explains, means that students do not need the support of the lab gear, a time-intensive algebra tile-like manipulative that the teachers use in some of their instruction. However, she cautions that while students could carry out the procedure successfully, they still did not recognize why they needed to use it. She illustrates the student confusion through another replay, one that expands on Wendy's: "'Cause you know how Wendy did the – 'this goes away?' Right? […] 'Okay, why does it go away?' No idea." This replay inserts a teacher response to the student confusion portrayed by Wendy.

Wendy supports Darla's elaboration and adds another example of student confusion, the "common mistake" that like terms "go away." She replays a student-teacher interaction to illustrate prototypical instructional dialogue around this confusion, which Darla follows up with a replay of her own: "'What do you mean it goes away?' They're like, 'It eliminates.' I'm like, 'Why?!' They just have no..." Despite the teachers' consensus that students do not understand the mathematics behind the elimination method, Darla adds that the team is making headway in building the conceptual foundation for future years ("in future years, when kids have the language of making zeroes much more strong […] we should have a much easier time").

Nonetheless, they are currently working against student beliefs that “math is just tricks” and does not require deeper understanding.

*Relationship between Diagnosis of Student Confusion and Instructional Decisions*

In this episode, the teachers’ diagnosis of student confusion is tightly coupled with instructional responses. From the beginning, when Wendy signals students’ troubles with combining like terms, she suggests an instructional response (“stick strictly to addition”). Darla further diagnoses the extent of students’ understanding, noting that they can carry out the procedure of multiplying through by negative one, which she also ties to appropriate instruction (“I don’t think they’ll need lab gear for that”). However, she is careful to distinguish between procedural success and conceptual understanding, pointing to the idea that underlies the students’ confusion —terms eliminate when they are of opposite value and “make zero.”

## Discussion

In both of these conversations, there is a clear focus on student learning. Both groups of teachers work together to make sense of students’ mathematical performance and elaborate on the kinds of understanding that students bring to their work. In both groups, an important facet of PCK is highlighted: namely, the kinds of difficulties students have in learning important topics in algebra. According to many scholars of teacher communities, this focus on student learning is a hallmark characteristic of professional learning communities (Louis, Kruse, & Marks, 199x; McLaughlin & Talbert, 2001).

However, the difference between the two conversations seems significant and consequential for teaching mathematics for understanding. While the teachers in the first conversation (Lotus) diagnose many of students’ troubles with linear graphing, the planned instructional response does not fully account for the range of difficulties they identify. In particular, by focusing on students’ procedural rather than conceptual troubles, the teachers miss an opportunity to help students develop a stronger understanding of some of the critical issues in linear graphing. The teachers in the second conversation (Clark) also diagnose students’ conceptual difficulties with an important algebraic topic, solving systems of equations. However, in contrast to the first conversation, the teachers consistently link an assessment of student understanding to instructional responses.

It is interesting to compare the representation of instructional dialogue in both groups. In earlier work in which I studied the conceptual resources for teachers’ pedagogical reasoning, I found that highly collaborative teacher groups tended to use more rehearsals and replays in their talk, and that these tended to represent both student and teacher sides of classroom interactions (Horn, 2005). Similarly, the Lotus teachers do not make much use of teaching rehearsals or replays in their pedagogical problem solving. When it does occur, it is a one-sided representation of teacher talk. In contrast, teaching replays permeate the Clark conversation from the very beginning. Many of the instructional responses, in fact, are represented through a replay of student-teacher dialogue. Further analysis will have to confirm that the Clark teachers consistently use these kinds of interactive representations in their conversations to represent the interactivity of the classroom. If this proves to be the case, this would contribute to the finding that the interactivity represented in these classroom snippets may signal a more tightly bound understanding of student confusion and instructional responses.

This paper makes several contributions. First, I have illustrated the kinds of pedagogical content knowledge that may emerge in teacher collaborative talk. Second, this analysis elaborates the ways in which a focus on student learning can be more tightly linked to instruction in a professional learning community. Finally, the findings here may signal developmental differences in teacher workplace groups. This last implication supports practitioners, be they teacher leaders or school coaches, seeking to develop professional communities in their own schools.

# A CASE STUDY OF ONE SECONDARY MATHEMATICS TEACHER'S IN-THE-MOMENT NOTICING OF STUDENT THINKING WHILE TEACHING

Adam Colestock
Northwestern University
a-colestock@northwestern.edu

*Given the complex nature of the classroom and the instructional flexibility that teachers are expected to demonstrate, understanding how teachers are paying attention to and making sense of what happens during instruction is an important area of research. This study investigates the in-the-moment noticing of one secondary mathematics teacher using a wearable camera with after-the-fact recording capability. When using the camera in his classroom to capture "interesting moments", the teacher focused almost exclusively on his students' mathematical thinking. We discuss the range of student thinking captured and the function that such noticing might play in this teacher's practice.*

Recent research in mathematics education has drawn attention to the importance of understanding how teachers are attending to and making sense of what is happening in their classrooms (Mason, 2002; Jacobs et al., 2007; Sherin, 2007). A focus on this component of teacher thinking is particularly timely given recent calls for mathematics teachers to be flexible and adaptive to student thinking in their instruction (NCTM, 2000). Furthermore, having teachers focus on student thinking and adjust what they are doing based on formative assessment places high demands on teacher's subject matter and pedagogical content knowledge (Ball & Bass, 2003). Yet, understanding the knowledge needed for teachers to be able to make these types of instructional decisions involves not only being able to systematically articulate the kinds of knowledge that they must have, it requires also developing models of how that knowledge is activated and applied in actual teaching situations (Sherin, Sherin, & Madanes, 2000; Schoenfeld, 1998). Understanding this in-the-moment noticing and sensemaking is therefore an important goal for teacher thinking research.

To suggest that mathematics teachers are adaptive in their instruction is not to deny that they walk into the class having some idea of what they would like to accomplish that day. Numerous researchers have documented the kinds of lesson images and agendas that teachers develop in planning for instruction (e.g., Leinhardt & Greeno, 1986; Morine-Dershimer, 1978). However, once in the classroom, teachers must be alert to how the lesson is progressing and make modifications as necessary. In previous work that we have done to study teacher noticing, we have relied heavily on the use of having teacher's view episodes of instruction on video and discuss what they noticed (Sherin & van Es, 2009). Other research has also tried to make use of video to study teacher noticing (Borko et al., 2008; Santagata, Zannoni, & Stigler, 2007.) This work has led to some interesting findings about noticing and how it can be influenced. For example, Sherin and van Es (2009) demonstrate that teacher noticing can be influenced based on participation in video clubs and Star and Strickland (2007) show that a pre-service course resulted in teachers being able to recall more detailed and varied information from a teaching episode they viewed on video. While this work has provided some insight into how teachers' noticing occurs while watching video, the processes of noticing and making sense might differ substantially while they are in the act of teaching. In more recent work and in this study we have begun to try to investigate teacher noticing in-the-moment of instruction.

## Research Design and Methodology

In this work we use a new digital video technology, first used by Sherin and colleagues (2009), which helps provide online access to what teachers pay attention to during instruction. The Deja View CamWear Model 100 (Reich, Goldberg, and Hudek, 2004) is a compact wearable camera that records from the perspective of the teacher, capturing what is in their field of vision rather than from the perspective of the researcher as is often the case in classroom videography. In addition, the camera exhibits an *after-the-fact* capability that enables users to decide to save a record of their experience *after* an event has occurred. The camera maintains a continuous buffer of 30-second activity and when an event occurs that the user wants to record, pressing the capture button saves the previous 30 seconds into digital clip that can later be downloaded onto a computer.

This after-the-fact feature of the technology allows a teacher to wear the camera during class and decide while in the midst of teaching when a noteworthy event occurs that they would like to save for further reflection. We are using the technology as part of a larger ongoing research project to study math and science teachers' noticing during instruction (see Sherin et al., 2009 for a more detailed discussion of the value of this technology for this purpose). For that project we recruited ten secondary math and science teachers of varying experience from a large urban area in the Midwest to use the technology in their classrooms. Here we focus on one mathematics teacher, Mr. Leavenworth (all names are pseudonyms), who received a BS in Mechanical Engineering and became a teacher through an alternative certification program. He was in his fourth year of teaching, his third at this particular school, and taught courses that included Advanced Algebra/Trigonometry, Advanced Mathematics, and an International Baccalaureate AP Calculus class. He had previous experience using video to reflect on issues of teaching and learning with colleagues. For this study he used the camera for four days in his AP Calculus class during the fall of the 2008-09 school.

Before class on the day of taping, Mr. Leavenworth was fitted with the camera and informally discussed with the researcher his plan for the lesson. Mr. Leavenworth was instructed to "press the record button on the camera when something interesting happens in class, when something seems interesting to you." The prompt was intentionally open-ended to allow the teachers to define "interesting" in their own way while teaching. No limit was given on the number of moments the teacher could capture. During class the researcher also video recorded the entire lesson using a camera positioned in the back of the room.

Following each lesson the researcher interviewed the teacher for 30-40 minutes. They first discussed what it was like to use the camera that day and whether it affected the teacher or students' behavior. The researcher and teacher then watched each of the captured moments until the teacher remembered why he had captured that moment. If he could remember, the teacher then explained what was interesting about that particular moment. After viewing all of the clips the researcher also asked the teacher a few questions about whether he had captured what he had intended and whether he was aware of using any specific criteria to select interesting moments. While there was a standard protocol, the interviews were relatively unstructured and conversational in style.

## Results

In the following we briefly discuss the nature of the clips Mr. Leavenworth collected and highlight three aspects of his noticing that emerged from the data analysis. We describe how:

1) A majority of the moments that Mr. Leavenworth captured related to students' ideas about mathematics.
2) Mr. Leavenworth's noticing is structured so that he is on the look out for specific mathematical ideas that are important for students' understanding during instruction.
3) At certain junctures during instruction when a particular conceptual idea or solution strategy is needed, Mr. Leavenworth notices the absence of those ideas needed at that point in the lesson. In response to this situation he has two different kinds of instructional methods that allow him to introduce the necessary ideas into the classroom.

*Collected Clips*

Mr. Leavenworth's instruction can be described as a switching back and forth between public whole group discussions in which new material is being introduced or a problem set is being discussed and private small group or individual seat work on problems as he circulates the room. During the three days that Mr. Leavenworth used the camera he collected a total of 55 clips of "interesting" activity during both of these classroom activities. However, Mr. Leavenworth seemed to demonstrate a slight preference for capturing moments that occurred during the large group discussion component of his classes. Although only 58% of class time was devoted to this public work, 72% of the moments that he captured occurred during this type of activity. Next we examine his reflections on these moments in the post-interview to understand more about what he found interesting.

*A Focus on Student Thinking*

In the post-interview, Mr. Leavenworth discussed each of the clips he captured and explained what he had found interesting about what was happening at that moment. As a first step in characterizing his explanations we applied the set of codes developed by Sherin et al (2009) to describe teacher's reasons for capturing each moment. Table 1 provides a description of each of the codes and indicates the percent of Mr. Leavenworth's clips coded in that category.
We coded his reflection as Student Thinking when the focus of his comments was on the substance of student's mathematical ideas. A Discourse code was applied when his reflection related to process of how ideas were being communicated in the classroom. We coded his reason for capturing the clip as Teacher Moves when he the focus of his comments is on some instructional decision or action that he made. And Student Engagement referred to those reflections in which he was focused on the quality or quantity of student participation in the class activities.

In his reflections Mr. Leavenworth describes an overwhelming percentage (94%) of his captured moments as "interesting" because of the substance of students' mathematical thinking. Whereas he found only a relatively small percentage "interesting" because of Discourse (8%), Teacher Moves (17%) or Student Engagement (2%). Note that the total percentages add up to greater than 100% because double coding was permitted if he cited multiple reasons for finding a moment "interesting". The strong focus on Student Thinking while capturing moments distinguishes Mr. Leavenworth from the other teachers using this camera who have typically only focused on student thinking about one third of the time (Luna, Russ, Colestock, in press; Sherin et al., 2009).

In examining the kinds of Student Thinking moments that he captured, it becomes evident that he was interested in a range of different kinds of student thinking. In Table 1 we briefly describes a few of the specific moments that he captured in order to anecdotally communicate the range of student thinking phenomenon which drew his attention.

Table 1. *Examples of Student Thinking Moments Captured by Mr. Leavenworth*

**Student justification of solution** : When stating her answer to an activity that involved trying to match up a differential equation with its corresponding slope field a student refers to the order of the function as a useful factor to consider. Mr. Leavenworth captures the moment and explains, *"So it was nice that she mentioned [the order of the function] and something that we can build on tomorrow."*

**Student thinking through a problem**: Moments after Ethan's question Daniel is explaining his idea about how they might adopt the methods they are using for solids of revolution to find the volume of a pyramid, Mr. Leavenworth captures the moment and later reflects, *"I thought it was interesting to kind of see him working through what he thought we should do."*

**Student difficulty solving a problem:** The teacher walks over to help a who student was trying to use his graphing calculator in a way that resembled what they had been doing several weeks earlier but that would not work within the context of the problem that they were working on and Mr. Leavenworth captures this interaction *"because I thought it was interesting that he tried to do that."*

**Insightful mathematical question**: On another occasion a student asks if they would always use pi to calculate the volume of other 3-dimensional solids and in reflecting on this captured moment Mr. Leavenworth remarks, *"I thought it was an interesting insight and it was a good question about how [pi] can keep showing up [when calculating the volume of solids of revolution] but is it always that way."*

*Noticing for the Purpose of Monitoring Instructional Progress*

We learn more about Mr. Leavenworth's almost exclusive focus on students' mathematical ideas by examining his discussion about criteria he used in the moment to decide if an event was interesting. During the post-interviews Mr. Leavenworth cited his goals for the lesson as one of the primary criteria for identifying interesting moments. For example, on day three he says:

**Researcher:** How would you characterize the criteria that you were using to decide which moments to capture?

**Teacher:** … My goals for the lesson are to understand the two parts [of the Fundamental Theorem of Calculus]. . . students need to understand that the antiderivative and the derivative are the inverse of each other and just the idea of limits, how you can manipulate definite integrals, the limits of definite integrals. So when I heard those things [in class] then I would press the button.

Mr. Leavenworth's claim that his goals for the lesson influenced what he found worth capturing on this day is supported by an examination of the moments that he collected during this lesson. Nine of the fourteen clips captured on that day involve student comments or questions that relate to the mathematical goals that he explicitly identified for that day.

A later interview with Mr. Leavenworth indicates one role these goal-fulfilling moments of student mathematical thinking may serve for him instructionally. He describes how, "It was almost like I had a checklist of things that I wanted to come out." It seems that Mr. Leavenworth notices moments of student mathematical thinking that indicate to him how the lesson is proceeding – whether it is "working" and going well. That he captures moments of student misconceptions suggests that he also notices when the lesson is progressing differently than he had expected. In other words, one aspect of his noticing seems to involve detecting alignment or misalignment with the lesson image (Schoenfeld, 1998) that he had developed in planning for the day. Attention to student mathematical thinking allows Mr. Leavenworth to monitor the progress of his instruction as it relates to student understanding of the content.

It is possible that Mr. Leavenworth did not actually use the lesson's mathematical goals as a criterion in the moment of collection but instead created an ad hoc theory that accounts for the clips after observing them all together. However, the fact that he mentions mathematical lesson goals as a primary criterion on several different days suggests that it might be a more stable component of his noticing rather than something that is created by engaging with this camera technology.

*Noticing and Improvised Teaching Episodes*

Mr. Leavenworth comes to class with some idea of what he needs to accomplish and his noticing is at least partly directed towards monitoring whether those mathematical understandings emerge at the appropriate time. However, rather than merely telling students an important mathematical insight Mr. Leavenworth will often, and perhaps even prefers, to use student voices to articulate conceptual understanding or generate approaches to a novel kind of problem. For example, when reflecting on one of his captured moments Mr. Leavenworth describes his plan to use student ideas generated in small groups in order to address an interesting but problematic idea that a student posed earlier during public discussion. "Between Eric, Daniel, and there was a few others, [I think we had]… an alternative to what we had started with." In the class discussion following this episode, Mr. Leavenworth calls on one of the students to introduce his alternative to a student's earlier solution. In this case, the students produced the ideas that Mr. Leavenworth needed in order for the lesson to proceed. However, what can a teacher do if he gets to a point in instruction when he notices the absence of some mathematical idea or solution strategy that is supposed to "come out" but has not?

Below we describe two episodes from the class that demonstrate how Mr. Leavenworth will react during his teaching if he notices the absence of a particular mathematical idea that he thinks is necessary at some point during the lesson. From his discussion of the noticed moments we identify two possibilities for how he generally proceeds when faced with this dilemma: either he provides the key conceptual insight on his own or he extends a lesson segment with an improvised teaching episode to help the students voice the required insight.

The first episode takes place after Mr. Leavenworth uses relatively straightforward examples to introduce part of the Fundamental Theorem of Calculus that exploits the inverse nature of derivatives and antiderivatives (integrals). He then presents the students with an extension problem to work on individually or in small groups, which involves limits of integration that are functions instead of constants. He writes the following question on the overhead:

$$\text{Find } \frac{dy}{dx} \text{ for the function } y = \int_1^{x^2} \cos t \, dt$$

Mr. Leavenworth captures a moment in which one student asks "Do you have to take into account the $x^2$ or can you just ignore it?" Mr. Leavenworth considers this a very good question and asks the other students for their opinions as to the answer. When no students are able to provide a reason for ignoring the function or a suggestion as to how to proceed, Mr. Leavenworth says "It is a really great question, here's what we are going to do…" and instructs them to use the Chain Rule that they learned previously to solve the problem.

In the first episode Mr. Leavenworth poses the new problem to the students and gives them some opportunity to grapple with how to deal with the apparent mathematical difference between it and the previous examples. He indicates in his reflection on the moment that he is pleased with the student's thinking that directs the class's attention to the relevant feature of the problem. However, when the students do not offer up any productive suggestions of how to deal with this difference, he is forced to supply the needed insight himself.

Later in the same class Mr. Leavenworth gives the students another problem in which both the lower and upper limits of the antiderivative are functions:

$$\text{Find } \frac{dy}{dx} \text{ for the function } y = \int_{2x}^{x^2} \frac{1}{2+e^t}\,dt$$

During their private work Mr. Leavenworth captures one student's idea for dealing with this new type of problem and later during the large group discussion he captures a series of moments in which different students offer suggestions. However, we can infer that he did not find any of these ideas instructionally tractable as he does not build upon or develop them further. Instead, after several minutes of trying to elicit student suggestions, Mr. Leavenworth walks to the front board and sketches up a representation in which each of the functions in the limit is represented by runners in a race with the 2x slower runner behind the $x^2$ faster runner. He highlights how "the distance [between the functions] is changing all of the time, so as x gets bigger, x squared is getting way out in front... Is there any reference point that we could use to figure out where these guys or girls are in relation to each other?" When a student suggests they use the starting point Mr. Leavenworth relates the idea of the start as a reference to having a lower limit of integration of 0. He asks if they can make the antiderivative they are working on have a lower bound of 0, and another student suggests that they rewrite their integral as two separate integrals by manipulating the upper and lower limits.

In the second episode Mr. Leavenworth did not simply provide the needed insight, but improvised and actively worked towards having students develop an approach that would work for this problem. His improvisation involved using the metaphor of a race to demonstrate how the functions are increasing at different rates but the starting point can be used to measure the distance to each of the runners. This appears to have activated students' prior knowledge of working with definite integrals sufficiently to have a student suggest the appropriate technique.

In both of these episodes Mr. Leavenworth notices students' mathematical thinking and from that thinking assesses the lesson's progress. These episodes provide evidence that Mr. Leavenworth has multiple practices in his teaching repertoire that he can draw on when his lesson image does not proceed as he has expected. It is not clear whether Mr. Leavenworth is aware of these alternative approaches to handling the teaching situation in which students do not provide the ideas that he seeks. However, by examining the moments he captures with the camera, his post-class reflections, and his instructional moves we are able to distinguish these two improvisational instructional strategies.

## Discussion

Through the use of a wearable camera implementing a selective archiving architecture we have examined one high school mathematics teacher's instruction and noticing in-the-moment during four days of his teaching. By asking the teacher to try to capture moments that occurred during class that he found interesting, we were hoping to gain more immediate access to the teacher's thinking and noticing during instruction than other methodologies used to date have been able to provide. Though we cannot say with certainty that the reflections about each clip provided during the post-interview actually represent exactly what he was noticing and thinking during the moment of instruction, we suspect that trying to characterize the moments that he captures and his reasons for capturing them and triangulating that with other elements of his instruction is a productive route towards better understanding Mr. Leavenworth's noticing.

Based on the data on his own teaching that Mr. Leavenworth collected, he seems to have a strong focus on attending to the mathematical substance of the students' ideas. He came into each lesson with some sort of agenda that can loosely be represented by a series of goals and actions that he wanted to have happen in developing the mathematical content for the day. We also observed a general instructional tendency to have students voice important conceptual ideas that might stem from a desire to actively involve students in the class or beliefs about how students learn. This observation was supported in the way that Mr. Leavenworth characterized his noticing during the post-interviews. The desire to have students involved in voicing important conceptual ideas creates a teaching dilemma generated from the unpredictability of student thinking. We highlight two episodes that illustrate how Mr. Leavenworth might react to a situation in which an idea does not arise at the expected moment by providing the idea himself or by doing some more work to try to get students to see the idea for themselves. We suspect that understanding how and when each of these two kinds of events occur represent a rich sight for research into teacher thinking and noticing and in the future plan to continue to use a similar methodology to further investigate these phenomena.

# TEACH FOR AMERICA TEACHERS' (TFA) MATHEMATICAL KNOWLEDGE AND BELIEFS

Brian R. Evans
Pace University
bevans@pace.edu

*This study intended to measure mathematical content knowledge both before and after the first year of teaching in the classroom and taking graduate teacher education courses in the Teach for America (TFA) program, as well as what attitudes toward mathematics TFA teachers held over the first year. To determine TFA teacher mathematical content knowledge and attitudes toward mathematics and teaching, participants were given a mathematical content test and two attitudinal questionnaires at the beginning and at the end of their first year teaching and taking graduate education courses.*

There has been a recent interest in studying the effects of TFA teachers in America's classrooms (Darling-Hammond, Holtzman, Gatlin, & Heilig, 2005; Xu, Hannaway, & Taylor, 2008). Darling-Hammond et al. studied the effects of TFA teachers in elementary school classrooms. Xu et al. claim to have produced the first study examining the effects of TFA teachers at the secondary level. However, there have not been any known studies that specifically focus on the mathematics content knowledge and attitudes toward mathematics and teaching for TFA teachers. This study addresses a much needed focus on secondary TFA teachers' mathematical content and attitudes, two areas much neglected in the literature.

## Research Questions

1. What differences exist between Teach for America (TFA) teachers' mathematical content knowledge and attitudes toward mathematics and teaching in the beginning and at the end of their first year teaching and taking teacher education courses in a graduate program?
2. Is there a relationship between TFA teachers' mathematical content knowledge and their attitudes toward mathematics and teaching before and after their first year teaching and taking teacher education courses in a graduate program?
3. How positive are TFA teachers' attitudes toward mathematics and teaching at the end of their first year teaching and taking teacher education courses in a graduate program?

There was a significant increase in both mathematical content knowledge and attitudes toward mathematics over the TFA teachers' first year teaching. Additionally, several significant correlations were found between attitudes toward mathematics and content proficiency. Finally, it was found that TFA teachers, after a year of teaching, had significantly better attitudes toward mathematics and teaching than neutral.

# A STUDY OF WEB-BASED INSTRUCTION ON PRE-SERVICE TEACHERS' KNOWLEDGE OF FRACTION OPERATIONS

Cheng-Yao Lin
Southern Illinois University Carbondale
cylin@siu.edu

*This study describes an intervention to compare the effectiveness of web-based and traditional instruction on pre-service teachers' knowledge of fractions. A sample of 48 pre-service teachers was assigned to an experimental and a control group. The experimental group received web-based instruction on fractions whereas the control group received traditional instruction on the same topic. Pre-post-tests comparisons showed that the experimental group achieved significantly better results in the post-test than the control group.*

## Introduction

Research has shown that the effective use of multimedia or interactive web-based modules can increase student learning (Aberson, Berger, Healy, Kyle, & Romero, 2003; Bliwise, 2005). This study determines whether web-based instruction (WBI) represents an improved method for helping pre-service teachers learn fraction operations in procedural and conceptual knowledge (Hiebert and Lefevre, 1986). The purpose was to compare the effectiveness of web-based instruction (WBI) with the traditional lecture in mathematics Content and Methods for the Elementary School course.

## Method

A sample of 48 pre-service teachers was assigned to an experimental and a control group. The experimental group received web-based instruction on fractions whereas the control group received traditional instruction on the same topic.

## Results and Conclusion

The results of this study suggest that the use of web-based instruction (WBI) in learning fraction operations is more effective. In this study, we found that the computer program for the web-based instruction helps to capture the pre-service teachers' attention because the programs are interactive and learner-centered. Second, we found that the interactive websites used for web-based instruction provide a dynamic and animated tool for improving students' visual and conceptual abilities in learning mathematics concepts.

# ANALYSIS OF GEOMETRY LEARNING STORIES OF ELEMENTRAY SCHOOL PRE-SERVICE TEACHERS

Fatma Aslan Tutak
University of Florida
aslanfat@ufl.edu

Teacher knowledge is one of the most important components of teacher quality because the content knowledge of a teacher strongly impacts the enactment of pedagogical tools of the teacher. Brown and Borko (1992) asserted that pre-service teachers' limited mathematical content knowledge is an obstacle for their training on pedagogical knowledge. Ball and a group of researchers developed *mathematical knowledge for teaching* (MKT) which addresses how a teacher uses mathematics for teaching while emphasizing the importance of mathematics knowledge in the teaching settings (Ball, 2000). Research studies show that using student work to facilitate teacher learning results in teachers' deeper subject matter knowledge (Kazemi & Franke, 2004). Furthermore, content knowledge of teachers is important for every subject including geometry, often a neglected topic in the curriculum. The limited number of research projects focusing on knowledge of geometry for teaching showed that beginning teachers are not equipped with necessary content and pedagogical knowledge for teaching geometry (Jones, 2000, Swafford, Jones & Thornton, 1997). Therefore, the purposes of this study are (i) to investigate the effective geometry learning experiences for pre-service elementary school teachers during elementary methods course and (ii) to design set of geometry activities to use in methods course

This study took place at an elementary methods course in a large southeastern public university in the US. The individual interviews of three participants, classroom observations and classroom artifacts were analyzed by narrative analysis (Labov, 1972) and thematic analysis (Coffey & Atkinson, 1996). As a result of narrative analysis two main kinds of stories emerged: *as a learner* and *as a beginning teacher*. The thematic analysis results yield to three themes: (a) *history of learning geometry*, (b) *what is geometry?* (c) *experiences in methods course*. These results were combined with literature on using student work, and they emerged into a two-phase protocol to address pre-service teachers' needs and perceptions during the methods course in order to enhance their geometry learning. The first phase of the protocol consists of geometry activities for pre-service teachers and the second phase consists of studying elementary school students' geometry work.

# PROJECT-BASED CURRICULUM: TWO TEACHERS' USE OF STANDARDS-BASED MATHEMATICS CURRICULUM MATERIALS FROM AN ENACTMENT PERSPECTIVE

Stephanie L. Behm
Georgia State University
scross@gsu.edu

*This poster highlights two teachers' curriculum development process as they created and enacted project-based curriculum for math instruction. Different from typical studies focused on the use of Standards-based mathematics curriculum materials, this study presents findings from a curriculum enactment perspective. Pictures, project files, and sample student work will be presented.*

Pinar et al. (1995) stated that "teaching is commonly characterized as the means by which curriculum is implemented" (p. 745). The term "implementation," however, has come to mean many different things. Snyder, Bolin, and Zumwalt (1992) categorized three differing perspectives on curriculum implementation: (a) the fidelity perspective, (b) the mutual adaptation perspective, and (c) the enactment perspective. Researchers who perceive curriculum with a *fidelity* lens are interested in studying the degree to which a planned curriculum is implemented by teachers in ways intended by curriculum writers. The role of the teacher is one of a consumer who should "implement the curriculum as those possessing curriculum knowledge have designed it" (p. 429). Further along the continuum is *mutual adaptation*. Researchers falling within this perspective view curriculum knowledge as either residing in the outside experts who developed the curriculum or as a combination of external curriculum knowledge coupled with practitioners' curriculum knowledge. Most research focused on teachers' uses of *Standards*-based mathematics curriculum materials tend to fall within this perspective (see e.g., Cohen, 1990; Remillard & Bryans, 2004). Finally, researchers viewing curriculum implementation from an *enactment perspective* view the actual or enacted curriculum as their focus. They are interested in how the curriculum is shaped *and* how it is experienced by teachers and students. Curriculum knowledge is viewed as an ongoing process and is not necessarily dependent on an externally created piece of curriculum as the center of the study. Researchers from this viewpoint view the role of the teacher and students as critical as there would be no curriculum without them.

This poster highlights the experiences of one mathematics teacher, one science teacher, and 88 middle school students from a curriculum enactment perspective. Although *Standards*-based mathematics curriculum materials were utilized by teachers throughout the study, the focus remained on the daily process of curriculum enactment. Drawing on Jurow's (2005) description of figured worlds and project-based curriculum, this poster highlights an alternate research perspective on the use of *Standards*-based mathematics curriculum materials for mathematics teaching and learning. Planning notes and reflections from teachers, as well as final projects and reflections from students are included. Finally, this poster offers overall suggestions and reflections on project-based learning in middle school mathematics and science.

# LINKING COLLEGE PRE-CALCULUS STUDENTS' USES OF GRAPHING CALCULATORS TO THEIR UNDERSTANDING OF MATHEMATICAL SYMBOLS

Rachael Kenney
Purdue University
rhkenney@purdue.edu

*This study examined ways in which students make use of a graphing calculator and how use relates to comfort and understanding with mathematical symbols. Analysis involved examining students' words and actions in problem solving to identify evidence of algebraic insight. Findings suggest that lack of symbol sense can lead students to turn to a graphing calculator as a tool for prompting a way to start a problem, or for providing a guess or confirmation. Certain symbols also lead some students to believe that they cannot use a calculator at all. Implications for teaching with a graphing calculator are included.*

## Introduction

Students often have access to graphing calculators and use them to help solve many types of problems. However, teachers and researchers are often unaware of how and why students use graphing calculators and how their use relates to their mathematical thinking, particularly about mathematical symbols. In this study, I address the research question: How are students' uses and understandings of graphing calculators related to students' uses and understandings of symbols?

Symbols are components of mathematical language that allow a person to communicate, manipulate, and reflect upon abstract mathematical concepts. However, symbolic language is often a cause of great confusion for students (Rubenstein & Thompson, 2001). Expert mathematicians or teachers are able to manipulate and to interpret mathematics through its symbolic representations, whereas students may struggle in this endeavor; they often need to be told what to see and how to reason with mathematical symbols (Bakker, Doorman, & Drijvers, 2003; Kinzel, 1999; Stacey & MacGregor, 1999). Arcavi (1994) explains that working fluently with symbols in mathematics requires developing strong *symbol sense* which includes, for example, understanding when to call on or abandon symbols in problem solving, understanding the need to compare symbols meaning with one's own expectations and intuitions, and knowing how to choose possible symbolic representations. Arcavi sees development of symbol sense as a necessary component of general sense making in mathematics. It is a tool that allows students to read into the meaning of a problem and to check the reasonableness of symbolic expressions.

Difficulties with symbol manipulation in mathematics may be one reason that students turn to graphing calculators for assistance in problem solving. Unlike calculators with computer algebra system (CAS) capabilities, most graphing calculators (e.g., TI-83, TI-84, TI-85, Casio FX-9750) cannot algebraically manipulate symbolic equations to produce useful results. Some work with symbols can be done with a non-CAS calculator; for example, symbolic expressions can be entered and viewed in the *Y*= menu, and values can be stored as a variable and substituted into an expression. However, a large benefit of these tools is that users can explore other representational forms of symbolic expressions, such as graphs, tables, or matrices.

## Framework

Pierce and Stacey (2001) used Arcavi's (1994) notion of symbol sense to develop a conceptual framework for looking at what is needed to take a mathematical problem, work with it using the tools and language of the calculator, and interpret and use the results using regular mathematical notation and forms. Pierce and Stacey define *algebraic insight* as a subset of symbol sense that enables a learner to interact effectively with a computer algebra system (CAS) when solving problems. They suggest that the nature of algebraic insight is the same whether work is done by-hand or with a CAS. Thus, I contend that the framework for assessing algebraic insight can also be appropriate for examining students' problem solving with graphing calculators that do not have symbolic manipulation capabilities. The two components that make up algebraic insight, *algebraic expectation* and the *ability to link representations*, elaborate instances and examples of algebraic insight that may be identifiable when analyzing students' work with graphing calculators. Table 1 shows the elements of the algebraic insight framework.

Table 1
*Algebraic Insight Framework (Pierce & Stacey, 2001)*

| **Aspects** | **Elements** | **Common Instances** |
|---|---|---|
| Algebraic Expectation | 1.1 Recognition of conventions and basic properties | 1.1.1 Know meaning of symbols<br>1.1.2 Know order of operations<br>1.1.3 Know properties of operations |
| | 1.2 Identification of structure | 1.2.1 Identify objects<br>1.2.2 Identify strategic groups of components<br>1.2.3 Recognize simple factors |
| | 1.3 Identification of key features | 1.3.1 Identify form<br>1.3.2 Identify dominant term<br>1.3.3 Link form to solution type |
| Ability to Link re-presentations | 2.1 Linking symbolic and graphic reps | 2.1.1 Link form to shape<br>2.1.2 Link key features to likely position<br>2.1.3 Link key features to intercepts and asymptotes |
| | 2.2 Linking symbolic and numeric reps | 2.2.1 Link number patterns or type to form<br>2.2.2 Link key features to suitable increment for table<br>2.2.3 Link key features to critical intervals of table |

This framework specifically addresses ways to plan, assess, and reflect on students' understanding when working with technology to solve mathematical problems (Pierce & Stacey, 2001). Using this framework assists in the task of identifying ways in which students' uses and understandings of mathematical symbols relate to how and why they use a graphing calculator.

## Methods

The method of inquiry for this research is a multi-case study, where a case represents an individual college pre-calculus student. Students were selected for this study using a survey that assessed familiarity with and use of graphing calculators. All invited participants indicated having at least average familiarity with graphing calculators and using graphing calculators at least one-half of the time on homework, but reported varying levels of success in previous mathematics course. Six students agreed to participate in the study and have the pseudonyms: Jill, Nina, Molly, Beth, Elyse, and Shawn.

The data sources in this study include a collection of work on tasks, video recordings of interviews, and computer recordings of calculator keystrokes for work completed on a graphing calculator. For the latter, I connected TI-84+ graphing calculators to a computer via a TI-Presenter device, and Windows Movie-Maker software captured and recorded videos of students' calculator keystrokes (c.f. McCulloch, 2007).

The findings reported in this paper are one piece of a larger doctoral thesis study. Students participated in three different interview settings during the course of the larger study. The results in this paper come from individual task-based interviews that took place near the beginning of the semester. In these sessions, students worked on secondary school-level algebra problems (i.e., problems to which students should have had prior exposure, but which had not recently been covered in class). As they worked on four different tasks (given in Table 2), students talked aloud about their thoughts and actions. They shared reasons for making use of a graphing calculator and discussed the specific activities that they were employing. If a student did not use the graphing calculator at all, I asked them to discuss why it was not useful on the problem and to consider ways in which they could have used it.

Table 2
*Interview Tasks*

| | |
|---|---|
| Task 1 – Solve a rational equation: | $\frac{x-16}{x^2-3x-12}=0$ |
| Task 2 – Solve a polynomial equation: | $x^3+2x-4=8$ |
| Task 3 – Setup and solve a linear word problem: A theater manager sold 5200 tickets and the receipts totaled $32,200. The adult admission is $8.50, and the children's admission is $6.00. How many adult patrons were there? | |
| Task 4 – Solve a linear inequality*:* | $\lvert 3x-\frac{2}{7}\rvert+1.2>5$ |

Transcriptions of videos of work on graphing calculators made it easier to follow students' work with this tool. I began by assigning basic codes indicating the manner of calculator use to the lines of the transcripts to help identify students' uses of the tool (e.g., graphed, used a table, computed, etc). I then looked in-depth at students' words and actions when using a graphing calculator and identified elements of symbol sense that were both evident and lacking in students' work by using the algebraic insight framework.

## Findings

Findings are organized around the four interview tasks. Each of the following subsections explains specific ways in which students engaged with the graphing calculator in activities. Instances of algebraic insight indicate details about students' symbol sense in their work.

*Task Type: Solve a Rational Equation*

Given the rational equation, $\frac{x-16}{x^2-3x-12}=0$:

- Jill and Molly graphed the numerator and denominator separately;
- Molly looked at a table to find the *y*-value when *x*=0;

- Elyse used the graphing calculator for computation only;
- Jill tried to see if linear or quadratic regression could work;
- Molly typed the left side of the equation into the main calculator screen to see if the calculator would "breakdown" the problem or solve for *x*;
- Beth, Nina, and Shawn did not use the graphing calculator at all.

These activities suggest that some students had the symbol sense to know that it was possible to abandon symbolic manipulation. However, the specific ways in which they used the graphing calculator indicate a lack of understanding of what the calculator could do. For example, Molly started by typing a function into the main screen, hoping that the calculator could "give a break down" of the problem. She explained, "The calculator is not simplifying for *x* here. It's not solving for *x*. There's a way to solve for *x*, isn't there?" It seems that she remembered using a graphing calculator in the past to solve for *x*, but could not remember what to do.

Molly and Jill chose to graph the numerator and denominator as separate graphs. This suggests a lack of algebraic insight for linking the rational form to the shape of the graph, which might not be surprising if they did not have experience with graphing rational functions. The linear form of the numerator and quadratic form of the denominator may have been more familiar and may be forms that they could easily link to shape and know what to expect in the graph. However, after graphing the two functions, neither student knew how to use the graphs to solve the given question. Molly looked at a table and found values when *x* equaled zero, saying, "I'm hoping that the calculator will be able to tell which one of the equations I'm supposed to use." Jill abandoned the graphs and attempted to see if linear regression would be useful instead.

Other students gave reasons for not using the calculator here. Beth explained that it could not tell her what steps to follow, saying, "It doesn't tell the mechanics of the problem that you have to do. It just gives you a number." Elyse expressed similar frustration, saying, "I don't know of a way where you can put an *x* in. The only thing I can think of is if you substituted something for the *x* maybe." Both Elyse and Beth were comfortable using the calculator for numeric calculations, but struggled to understand how to use the tool with algebraic symbols.

*Task Type: Solve a Polynomial Equation*

Given the polynomial equation, $x^3 + 2x - 4 = 8$, students used a graphing calculator in the following ways:

- Beth graphed only the left side of the equation
- Molly graphed the function on the left side and evaluated at $x$=8;
- Nina and Beth set the equation equal to zero and graphed to evaluate at $x$=0;
- Beth, Molly, and Shawn used the calculator for computations;
- Nina and Shawn used a table to determine the *x*-value when *y* equaled zero;
- Shawn set the equation equal to zero and looked at the graph to see how many *x*-intercepts existed;
- Jill and Elyse did not use the graphing calculator at all.

Nina and Shawn exhibited evidence of algebraic insight for linking key features to intercepts and to critical intervals for a table. However, both students only chose to use the graphing calculator after prompting from the researcher. Nina admitted that she would never have chosen to use a table to solve the problem on her own, and Shawn had already found an answer on paper and only used the calculator because he was not completely satisfied with his answer.

Shawn and Nina did not entirely trust the answers they found using the calculator. Shawn noticed that the graph only crossed the *x*-axis one time, and found one answer of $x$=2 from the table, but he had found three different answers on paper. Nina also anticipated finding three answers to the problem and expected that there were more answers than the calculator was telling her. This anticipation for a certain number of answers connects to students' algebraic insight for linking the problem form to the solution type and linking symbol meaning to prior experiences. Shawn also exhibited symbol sense for linking key features to critical intervals of a table when he noticed that two of his answers on paper had been decimal values and the table he was using only counted by integers. Neither student, however, made a clear link between the symbolic and graphical representations, which provided strong evidence that there was only one zero for the function $x^3 + 2x - 12$.

Other students struggled with the meaning of symbols and with identifying the dominant term needed for finding the solution (e.g., looking at $x$=0 instead of $y$=0). Molly misinterpreted the meaning of the equation and felt that she was supposed to substitute the value 8 in for $x$. Her trust in this interpretation allowed her to ignore the fact that the calculator produced a result of $y$=524, even though she had anticipated finding a value for $x$. Nina performed a similar action by evaluating the function at $x$=0 to find the zero. However, the calculator's result of $y$=-12 caused her to realize her mistake and change her activity to find $x$ instead of $y$.

*Task Type: Setup and Solve a Linear Word Problem*

Students used a graphing calculator sparingly on Task 3 in the following ways:

- Jill tried to graph an equation with two variables, but stopped when she could not determine how to enter both variables;
- Molly graphed two equations with the same variable;
- Beth, Nina, and Elyse used computations to make sense of the information;
- Molly, Jill, and Shawn computed values to find an answer;
- Nina used computation to see if her equation made sense.

Molly and Jill used the calculator as a numeric tool that could help them abandon symbolic manipulation for a guess and check strategy. Jill had created two useful symbolic equations with two variables and was using the calculator to guess and check instead of solving the equations simultaneously, while Molly was unable to create an equation. With symbolic forms for reference, Jill was able to continually link her results to the meaning of the symbols in the problem, while Molly lost sight of key information and was not able to reach a solution.

Beth, Nina, and Elyse struggled with the symbol sense to select or create possible symbolic representations, and used the calculator in the hopes of discovering a useful relationship in the given information. For example, Elyse tested to see if all of the tickets could be adult tickets by dividing 32200 by 8.50, but was disappointed to get a decimal answer. She explained, "Maybe if it divided evenly, I may believe it was only adults." Nina and Beth both used a similar calculation, but also divided 32200 by 6.00 to see if this value divided evenly. Beth continued dividing all given values by each other in the hopes of finding a number that might work as an answer to the problem. These students tried to manipulate numbers on the calculator to answer the problem and avoid the need for creating symbolic equations.

*Task Type: Solve a Polynomial Inequality*

Due to time constraints in the study, only four of the participants worked on the following inequality problem: Solve for $x$ given $|3x - \frac{2}{7}| + 1.2 > 5$. Students used the graphing calculator as follows:

- Jill, Beth, Nina, and Elyse used the calculator for computations;
- Beth used the calculator to convert decimals and integers into fractions;

– Elyse used the calculator to check a hypothesis.

Beth answered this problem by plugging one number in and using her calculator to compute a value on the left and seeing that the result was greater than five. She made comments such as, "Seeing that that (on paper) and this (on screen) looks the same, then you think, well I must be doing something right," suggesting that she did not realize that copying the direct computations from the calculator was not the same as doing the problem by hand. In this case, she did not recognize her dependence on the calculator for helping her manipulate the values on paper. The other three students manipulated the problem as though it was a linear equation, sometimes paying attention to the sign inside the absolute value symbol or the direction of the inequality. None of the students demonstrated algebraic insight for linking the form of this problem to a proper solution type, and their actions were restricted to numeric manipulations suggested by the operation signs in the problem. They used the calculator for calculating with fractions and decimals only.

When asked if a graphing calculator could be useful for this problem in other ways than as a computational tool, students responded in a variety of ways. Beth said that she did not know of a way to use it. Nina said she could not use it because she did not know how to handle the inequality sign, while Jill said she did not recall how to input absolute value. Elyse answered, "It's algebra so you can't just plug the whole thing in and get your answer." Thus, three of these students identified particular symbols in the problem (absolute value, inequality sign, and the *x*-variable) as the reason for not using the graphing or table features of the calculator. At the same time, numeric symbolic structures such as fractions and decimals were identified by all four students as important reasons for needing the calculator for computations.

## Discussion

A detailed examination of students' use of graphing calculators and what they said while using them can provide insight into the relationship between students' understanding of symbols and understanding of graphing calculators. By looking closely at specific details surrounding students' graphing calculator use, I identified two themes that address the research question:

*1. Lack of Symbol Sense Caused Students To Use a Graphing Calculator For Help.*

Students had some dependence on the graphing calculator as a tool for abandoning symbolic manipulation and finding an answer or a procedure to follow. At times, students treated the tool as a partner (Goos, Galbraith, Renshaw, & Geiger, 2003) that could help in the following ways: (a) by providing directions or a prompt, (b) by providing an accessible answer, and (c) by providing confirmation. The following paragraphs illustrate these categories of use.

Students often had difficulty trying to decide how to start a problem. In these instances, they sometimes turned to the graphing calculator to prompt an activity. For example, Molly wanted the calculator to tell her how to break down the rational equation in the initial interview. She entered the function into the main screen in the hopes that it would tell her something about the manipulations needed for the problem. She also graphed the numerator and denominator of the rational equation, saying that she was hoping for the calculator to tell her which function to use. She turned to the calculator for directions on how to solve the problems.

In some situations, students tried to avoid working with the symbols on paper and worked on the graphing calculator to try to find an answer. For example, Beth, Nina, and Elyse sought answers from the calculator on the linear word problem when they divided different given numbers in the hopes some value would divide evenly into another. They struggled to create symbolic equations for the problem, and tried to avoid a need for symbols by seeking an easy, familiar looking numeric solution from the calculator.

Some students recognized that a calculator was useful for confirming an idea or checking the reasonableness of an answer. For example, while working on a polynomial equation, Molly, Nina, and Shawn all used graphs and tables to find an answer to the problem and compared the calculator's answers with work they had done on paper. This caused problems when calculator answers did not match their expectations, and caused some students to mistrust the calculator.

*2. Lack of Understanding of a Graphing Calculator's Abilities to Handle Symbolic Forms Kept Students From Using Them or Using Them Correctly.*

Many of the students had difficulty knowing when and how to interact with a graphing calculator when solving symbolic problems. Difficulties were due to both misunderstanding of the technology and misconceptions about the mathematics involved in the problem. One fact that was evident from students' work is that they often did not know many of the features that the technology offered. For example, Beth and Elyse insisted that they could not use the graphing calculator when there was a variable in the equation. Similarly, Jill did not think she could enter an absolute value sign on a calculator, and Nina did not think there was a way to work with inequalities on the calculator. None of the students seemed to be familiar with menu options such as MAXIMUM or ZERO or INTERCEPT when working with graphs. Most of the students chose to use TRACE to find points on a graph instead, which does not provide exact values for answering a question. The students often struggled to see a use for the graphing calculator in problem solving because they were not aware of the powerful options it provided.

## Implications and Conclusions

Students were uncomfortable with and not proficient with using graphing calculators, despite their claims for being so on the initial survey. However, these students still had a certain amount of dependence on the graphing calculator for helping them postpone or abandon symbolic manipulation when it was causing them trouble. The fact that graphing calculators provide students with a way to do mathematics without using algebraic manipulation techniques has been identified in the research as a reason that some teachers give for opposing calculator use, especially at the college level (Hennessy, Fung, & Scanlon, 2001). However, other researchers have found that students' use of a calculator in this way is critical for helping them explore a problem to consider expectations before attempting an analytical solution (Quesada & Maxwell, 1994). Data from this study suggests that graphing calculators could be especially useful with weaker students (such as those taking or retaking college pre-calculus) as a tool for helping students gain more experience with important mathematical symbols and concepts. The teachers in this study did not teach or assess with graphing calculators and, consequently, restricted classroom examples and test questions to easy functions (e.g. no fractional coefficients, quadratic functions that could be factored, etc.). This practice may increase students discomfort with less used symbols such as inequality signs, absolute values, fractions, square roots and high powers of $x$. Many mathematical problems cannot or should not be solved by hand, but the students in this study did not seem aware of this possibility (e.g. the polynomial inequality in Task 2 was best solved using a calculator, but all students expected there to be an accessible pen and paper solution method). Awareness and understanding of how a graphing calculator can serve a student's needs when encountering mathematics inside and outside of the mathematics classroom is an important part of teaching mathematics, especially at the college level.

When students have access to a graphing calculator, and do not know how to use it or do not understand or remember what it is capable of doing, they can use it in creative and inefficient ways. Gray and Tall (1994) suggest that students who did not have a strong understanding of the different uses of symbols may develop different, incorrect techniques for problem solving due to their personal interpretations of the symbols. The same idea may apply to students who do not have a strong understanding of how and when to use a graphing calculator. Teachers need to be aware of some of the non-standard uses that students can create to seek assistance from a graphing calculator as they try to avoid or abandon symbolic manipulation.

For the students in this study, understanding how to work with mathematical symbols on paper had a connection to their choices of how and when to use a graphing calculator. However, students demonstrated limited algebraic insight for linking representations and connecting what they were doing on the calculator to their work with symbols on paper. When teaching with a graphing calculator, teachers must be careful not to treat the tool as a different way of approaching a problem, but instead integrate it into a problem and help students reflect on how the work displayed on the screen relates to the symbols on paper.

# TRIGONOMETRY, TECHNOLOGY, AND DIDACTIC OBJECTS

Kevin C. Moore
Arizona State University
kevin.c.moore@asu.edu

*Students have difficulty constructing coherent understandings of trigonometry and trigonometric functions (Brown, 2005; Weber, 2005). This study conjectured that their weak understandings of angle measure and compartmentalized knowledge of right triangle and unit circle trigonometry are sources of the problem. The response was to devise an instructional sequence to promote these foundational understandings and connections. A critical part of this instruction was the use of dynamic applets. These applets were intended as didactic objects to facilitate meaningful conversations supporting student learning. This report discusses the design and implementation of these applets and their role in promoting discourse that facilitated knowledge construction.*

## Background

Trigonometric functions are a common topic of undergraduate mathematics. It is also the case that various topics of physics, engineering, and other sciences rely on trigonometric understandings (e.g., projectile velocities and wave behavior). However, it is frequently the case that students have difficulty when asked to reason about topics reliant on trigonometric function understandings (Brown, 2005; Thompson, 2008; Weber, 2005).

Two different settings are often used to introduce trigonometric functions in the US mathematics curriculum: right triangle trigonometry and unit circle trigonometry. Student difficulties relative to trigonometric functions may be the result of mathematics curriculum frequently treating these two trigonometries as unrelated (or only slightly related), resulting in students not constructing coherent understandings of trigonometric functions. One potential solution to this lack of coherence is to fully develop student conceptions of angle measure and use this foundation as a base to both trigonometries.

This study reports on both the design and implementation of a lesson intended to develop student conceptions of angle measure such that these conceptions enabled coherence between the two trigonometries. In order to enable coherence between the two trigonometries using angle measure, the focus of the lesson was to support students in conceptualizing angle measurement as the openness of an angle and to develop a method for quantifying this measurement. Furthermore, the classroom exploration was conducted such that it attempted to promote student images of angle measure that included variation of an angle's openness. This was especially important relative to future explorations of periodic motion (e.g., a situation where the argument of a trigonometric function varies).

Central to the lesson design and implementation was the use of technology to aid in the development of student understandings. The lesson included the use of *The Geometer's Sketchpad* (GS) applets (Key Curriculum Press, 2002). These teaching aids were intended to promote discussions that reflected the structure of the mathematical understandings that formed the instructional goals of the lesson. The results presented in this report discuss the design and implementation of the various GS applets and the student discussions these applets generated in the context of student learning.

## Theoretical Perspective

The theoretical foundation for this study rests on the idea that all learning begins and ends with the learner, a main stance of radical constructivism (Glasersfeld, 1995). Building from the stance of radical constructivism, a researcher or teacher must consider each individual's knowing his or her own. That is, each student's knowledge is self-constructed and considered fundamentally unknowable to any other individual.

A useful tool in promoting student construction of knowledge is a *didactic object* (Thompson, 2002). A didactic object is designed as an object to talk about in a way that enables and supports reflective mathematical discourse. As Thompson notes, an object is not considered didactic in and of itself. An object is only didactic when it is conceptualized in a manner that enables reflective mathematical discourse. Reflective mathematical discourse refers to discourse focused on mathematical topics, where the discourse becomes an explicit object of student reflection. Students participating in reflective discourse have the opportunity to construct deeper understandings and cognitive connections.

The use of dynamic applets developed using Geometer's Sketchpad was intended to serve as didactic objects on which the teacher and student could engage in meaningful conversations about foundational trigonometric ideas. The desired student conceptions drove the design and implementation of the applets. The role of the dynamic applets during instruction was to generate discussions and reflections not possible without their use.

The use of dynamic applets as didactic objects was intended to generate discussions that resulted in students engaging in covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002) and quantitative reasoning (Smith III & Thompson, 2008). Covariational reasoning (e.g., the coordinating of two varying quantities while attending to the ways in which they change in relation to each other) has been shown to be critical for concepts of calculus (Carlson, et al., 2002). In response, the designed applets were intended to engage students in coordinating and discussing varying angle measures in order to prepare students for trigonometric functions, which formalize the relationship between the covariation of angle measure and a ratio of lengths.

In the description of covariational reasoning by Carlson et al. (2002), an individual is described to be reasoning about quantities and relationships between these quantities. These quantities to be reasoned about are thus implied to be conceptual objects derived from experience that have qualities that we can call mathematical, or can be "mathematized." Quantitative reasoning refers to the type of reasoning that is situation sensitive and places an emphasis on the development of conceptual objects (quantities) that individuals are to reason about. Quantitative reasoning is the mental actions of an individual making sense of a situation, constructing an image of measurable quantities composing the situation (*quantification*), and reasoning about relationships between these quantities (e.g., covariational reasoning).

The design of the applets intended to promote quantitative reasoning by aiding the students in visualizing situations and supporting discussions that focused on the quantities they were to reason about. As an example, the applet presented in Figure 1 offered a visualization of a subtended arc-length as a measurable attribute of an angle's openness. The applet was created with the goal of supporting the understanding of angle measure as a subtended arc-length's fraction of a circle's circumference. The applet was also designed to allow an investigation that included discussing a *varying* angle measure and a *varying* radius of the circle used to measure the angle. Thus, the applet was intended to enable and support discussions that centered on a dynamic, opposed to static or discrete, exploration of the relationships between values of arc-length and circumference (e.g., regardless of the unit of measurement, the ratios are equivalent).

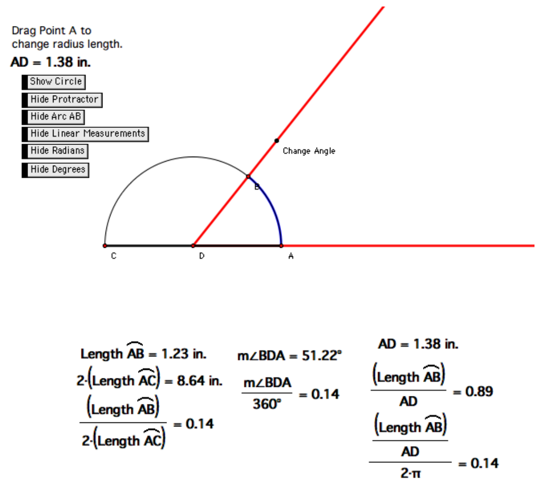

*Figure 17.* Angle measure applet.

## Research Questions

This report is set within a broader investigation that focused on investigating student conceptions of trigonometric functions and topics foundational to trigonometry, where the two main questions driving the research were:

- What understandings of trigonometric functions do students construct during an instructional sequence that is designed on foundations of quantitative and covariational reasoning?
- How do the foundational understandings of angle measure, the radian, and the unit circle influence student understandings of trigonometric functions in the context of the unit circle and right triangles?

An element of this focus was on the role of curriculum relative to student development. This report specifically focuses on the use of computer software in the context of student learning.

## Methodology

This study was conducted with three students from an undergraduate precalculus course at a large public university in the southwest United States in which the researcher (myself) was the instructor. The subjects were chosen on a volunteer basis and monetarily compensated. The precalculus classroom from which the subjects were drawn was part of a design research study where the initial classroom intervention was informed by theory on the processes of covariational reasoning and select literature about mathematical discourse and problem-solving (Carlson & Bloom, 2005; Carlson, et al., 2002; Clark, Moore, & Carlson, accepted). All three subjects were males (Brad, Charles, and Travis). The classroom instruction consisted of direct instruction, whole class discussion, and collaborative activity.

I conducted a three session teaching experiment (Steffe & Thompson, 2000) with the three subjects of the study. The teaching experiment focused on i) developing angle measure in terms of arc-length and circumference, ii) developing the use of a radian as a unit of measurement, iii) and investigating circular motion and the unit circle (e.g., any circle is the unit circle if the unit of measurement is the length of a radii). A witness attended each session and debriefed with the instructor after each instructional session. Each class session was videotaped and digitized. In addition, all student products (white board, activity sheets, homework assignments, etc.) from the teaching sessions were captured digitally for analysis.

The classroom sessions were analyzed following an open coding approach (Strauss & Corbin, 1998). Discrete instances believed to reveal insight into student conceptions were identified and then analyzed in an attempt to determine the mental actions that contributed to the emerging behaviors. The mathematical constructions and interactions that occurred between the subjects and the instructor were examined in an attempt to model and understand the thinking of the subjects. Specifically, this report focuses on the discussions generated through the use of the GS applets in the context of student learning.

## A Brief Conceptual Analysis Of Trigonometry

Before presenting the results of the study, a brief description of the understandings driving the instructional goals is provided. Angle measure is a measure of an angle's openness, which is measured by determining the fraction of circle's circumference that is subtended by the angle. For instance, an angle of measure one degree subtends $1/360^{th}$ of the circumference of any circle centered at the vertex of the angle. Note that the focus of angle measure is on the arc-length subtended by the angle as an attribute that can be measured.

Next, just as the degree is a unit of angle measurement that refers to $1/360^{th}$ of a circle's circumference, the radian is a unit of angle measurement that refers to $1/(2\pi)^{th}$ of a circle's circumference; just as 360 degrees revolve any circle, $2\pi$ lengths of a radius revolve any circle, allowing the length of a radius to be a unit of angle measure. The radian measure of an angle can also be defined as the ratio of an arc-length to the corresponding length of a radius, which gives the fraction of one radius.

With an input quantity of angle measure (arc-length), sine and cosine have an output that is a ratio of two lengths, regardless of the setting. With regards to the unit circle, the output of sine is the ordinate of the terminus of the arc subtended by the angle and cosine is the abscissa of the terminus of the arc subtended by the angle, with both outputs measured as a fraction of one radius. With regards to right triangle trigonometry, sine and cosine are approached in the same manner. Although sine and cosine are often used only to find the lengths of the sides of right triangles, this is simply using one pair of input-output values. Because angle measure corresponds to measuring an arc-length, one can use the hypotenuse of the right triangle as the length of a radius and construct a circle centered at the vertex of the measured angle. Hence, sine and cosine remain the abscissa and ordinate of the terminus of the arc subtended by the angle, with both outputs measured as a fraction of one radius (or hypotenuse).

## Results

What follows is a brief discussion of the results of implementing various GS applets during instruction. As an example of the use of the applet presented in Figure 1, the students were first asked to discuss each measurement of the applet in order to support a discussion focused on the quantification of the situation. When asked about the second value (e.g., the proportion of arc-length to the radius), Brad used the projection of the applet to explain, "How many lengths of AD it takes to get your total arc-length of AB." Charles also added, "How many radians there is in the arc-length." These responses by Charles and Brad imply that they had constructed images of the ratios as representing a proportion of a circle's circumference, images that appear to be aided by referencing the applet.

At this time the dynamic applet was used to focus the students on considering a varying radius and varying angle measure:

1 Instructor: So, what's going to happen…if I increase my radius?
2 Charles: The angle will remain the same, so the amount of radii it will take to
3 make the arc-length will still remain the same.
4 Instructor: Ok, so the three values (*referring to the far right column*), which are
5 going to change and which aren't? Travis, what do you think? Which
6 ones are going to change?
7 Travis: The radius is going to change. (*pause*)
8 Instructor: The radius is going to change, it will increase.
9 Travis: The rest will stay the same.
10 Instructor: The rest will stay the same, right? (*Increasing the radius on the*
11 *applet*) Do we get what we expect?
12 Students: Yes. (*Nodding in agreement*)
13 Instructor: Right, because our angle measure's not changing. Now what if I
14 change the angle?
15 Travis: The…
16 Charles: The, go ahead. (*Pointing to Travis*)
17 Travis: The bottom two will change (*referring to the far right column*).
18 Instructor: Lets say I decrease my angle. What's going to happen to the bottom
19 two?
20 Brad: They'll decrease.
21 Instructor: They'll decrease right. Now how 'bout the three proportions along
22 the bottom there?
23 Brad: They'll all stay equal. (*Instructor decreases angle measure*)

During this discussion, the students were first asked to describe how the values would vary before the applet was used to increase the radius. Both Charles and Travis were able to correctly describe the direction of change of each value (lines 2-3, 7, 9), implying that both of the students had developed images of the quantities of the protractor and angle applet that included their directional covariation relative to an increasing radius. With the conjectures made, the applet was then used to increase the radius in order to verify the students' conjectures (lines 10-11). The instructor then used the applet in a similar manner to investigate a decreasing angle measure. The students were first asked to use the image of the applet to conjecture the result of varying the angle measure (lines 13-14) and then the result of decreasing the angle measure (lines 18-19). This resulted in the students (correctly) referencing the values on the applet and how they would change in relation to a varying angle measure (lines 17, 20, 23). With these conjectures given, the instructor used the applet to verify the responses of the students (line 23). Thus, this applet appears to have supported a visualization of the situation such that the students could conceive of and discuss the values and quantities of interest. Also, the applet supported conjecture-verify sequences of the students imagining and then describing the dynamic situation in relation to the varying quantities. From these sequences, the instructor was able to infer that the students were constructing understandings consistent with the instructional goals.

Drawing on the foundations of angle measure that informed the design of the first applet (Figure 1), a second applet was designed to investigate and discuss circular motion (Figure 2). When "Animate Point" is chosen on the applet, a point moves around the circle counter-clockwise at a constant rate. This was used to promote discussions and connections between the numerical, contextual, and graphical representations of the *covarying* quantities of arc-length and vertical height above the center of the circle. Also, the applet enabled a discussion of these representations relative to the motion of the point. These dynamic connections were conjectured to be critical in developing an understanding of the sine function, as the sine of an angle measure cannot readily be algebraically computed. The use of this applet also occurred before formally introducing the sine function. Thus, the applet was used to generate and reflect on a graph between the covarying quantities before formalizing the relationship as the sine function.

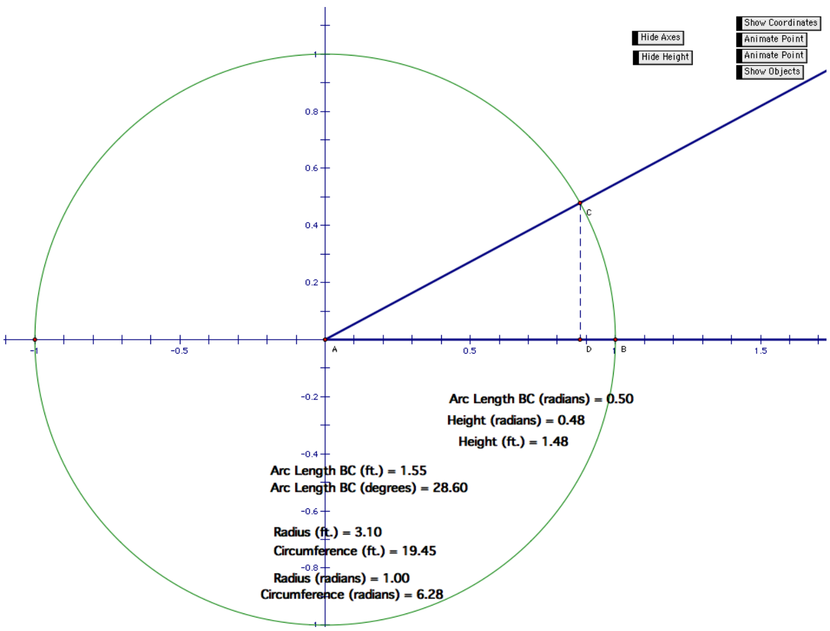

*Figure 2.* Motion on a circle applet.

One result of the use of the applet in Figure 2 was investigating corresponding amounts of change of vertical distance and arc-length. The instructor chose this use of the applet after the students had constructed a non-linear graph but remained unable to correctly describe why the graph should not be composed of linear segments:

Instructor: Ok, so we move along from 0.15 (*radians*) and our height becomes what (*moving an arc-length of* 0.15)?
Brad: 0.15 radians.
Instructor: 0.15. Now, should it be exactly 0.15? Does that make sense?
Brad: No, because you have a curve.
Instructor: So why does us having a curve matter? (*long silence*) So why does us having a curve matter Brad?
Brad: Well because you don't have a, uh, the curve for your arc-length is going to be different because of the curve. Because, uh, you'll have a longer distance over the curve than I think height, over a straight line (*making a reference to the image of the applet*).
Instructor: Ok, so we know it should be less that 0.15 then, right? Because if we move 0.15 along the arc-length, we didn't move completely that on the vertical. What do we expect if I move another 0.15?

Brad: Should be less.
Instructor: If I move a distance of 0.15 radians, what should we have? Well let's see (*moving and arc-length of 0.15 radians*). What was my change in height now?
Brad: 0.14.
Instructor: Was it less? Was that what we expect?
Students: (*nodding heads yes*)
Instructor: What if I move another 0.15? What do we expect?
Brad: It would be less again.
Instructor: It would be less again (*moving an arc-length of 0.15 radians*). What if I move another 0.15?
Brad: Less again.
Instructor: So what's less again? (*moving an arc-length of 0.15 radians*)
Brad: The height, the change in height.

During this interaction, the applet enabled a discussion that focused on the students coordinating arc-length and vertical distance, a coordination the students were having difficulty with previous to the applets use. The instructor first chose to use the applet to represent a change in arc-length of 0.15 radians and question the students on the change of vertical distance. This questioning resulted in Brad describing that the change in height would be less than the change in arc-length. Brad also used the image of the applet to explain that the curve was longer than the linear vertical height (lines 8-11). This explanation by Brad thus appears to have been supported by the applet aiding in his visualization of the situation. After Brad described the result of another change of arc-length, implying he was coordinating changes of arc-length and vertical distance, the instructor made the move to have the students *conjecture* the result of another sequence of increases in arc-length (lines 22 and 24-25). Brad then correctly identified that the change in height would be less than previous (lines 23, 26, and 28), which was verified by using the applet.

Although Brad was the only student to verbally respond in this interaction, both Charles and Travis explained (explanations that were verified using the applet) other sections of the motion in terms of amounts of change of arc-length and amounts of change of vertical distance and how this was reflected in the graph. Thus, the use of this applet supported an investigation and discussion of how a changing arc-length, opposed to static positions, related to changes of vertical distance and how this relationship was represented using the graph. The implementation of the applet was first in a manner that had the students observe and identify changes of vertical distance in relation to changes of arc-length. Then, after the instructor observed the students correctly coordinating the covarying values, the students were asked to conjecture the result of changes of arc-length and these conjectures were verified using the applet.

## Discussion

The two applets described above offered objects the students could conceptualize in a way that supported student discourse and the construction of knowledge. For instance, the second applet (Figure 2) led to a graph, including concavity, emerging out of the students covarying the value of two quantities (e.g., arc-length and vertical distance). Also, the applet allowed the creation of the graph to be related to the *dynamic* contextual situation. The sine function cannot be computationally evaluated with ease; hence it is necessary for students to construct a contextual image of the relationship the sine function defines. Furthermore, the contextual images students construct must include measurable quantities that they can reflect on and reason about. The applets were designed an implemented with this in mind, which included the intention of promoting students constructing and reasoning about *varying* quantities.

What appears to be an important implementation of the applets as didactic objects was encouraging that students predict how the values of quantities would vary before enacting the dynamic features of the applets. This had the possible influence of the students constructing an image of each of the quantities and then *imagining* motion and corresponding variations of each quantity. Then, when the applet was used in a dynamic manner, the students had an opportunity to reflect on their conjectures relative to the values and motion of the applets. This reflection could then result in the students modifying their image of covarying quantities, and hence their conception of trigonometric functions or angle measure.

In conclusion, the use of GS applets allowed a dynamic investigation of trigonometric topics not as readily available without the applets. The design of the applets was focused on creating objects that enabled and sustained discussions that supported the students constructing understandings consistent with the instructional goals. This design included taking advantage of the dynamic abilities of the applets in order to promote discussions that focused on the quantification and covariation of quantities.

*Students have many opportunities for learning mathematics content outside of school. These informal interactions can be rich resources for students and teachers as they weave connections between the mathematics they study in school and the mathematics they experience outside of school. In this study we explored possible connections between formal and informal mathematics by investigating the mathematical reasoning used by students as they played online games. We report on students' interactions with the embedded mathematical content of the online games used in this study. Noting, in particular, the ways in which students engaged in increasingly more sophisticated mathematical reasoning as they progressed through the various levels in the games. These shifts in gameplay were detectable, not only through in-person observations, but also via data mining of online tracking data. Implications for the use and study of children's use of educational games as contexts for informal and formal learning of mathematics are discussed.*

This research was funded as part of a grant from the National Science Foundation (DRL-0723829). We also thank the *Cyberchase* production team (especially Sandra Sheppard, Frances Nankin, and Michael Templeton).

Mathematics educators have long recognized the importance of helping students make connections between the mathematics that is offered in school and their everyday experiences and interests (see NCTM, 2000). Realizing those connections, however, has been elusive, as researchers have found stark differences in how students use mathematics outside of school and how they perform school tasks (e.g., Nunes, Schliemann, & Carraher, 1993). Yet, contexts in which mathematics is studied play an important role in helping students understand how, when and why particular concepts, procedures, and skills are used, but also see what makes them worth knowing. Grounding mathematics in experiences that are meaningful to students continues to be an important though challenging goal for mathematics education.

Children's natural love for playing games and the growing availability of electronic media, make online games an obvious choice for exploring connections between informal and formal encounters with mathematics. It is no secret that children spend a great deal of time interacting with electronic media. Even before they start school, children interact with all sorts of electronic media. Research reports that children 6 months through 6 years of age spend an average of 2 hours daily with screen media, and that 50 percent of 4-6 year olds play regularly with computer games (Rideout et al., 2003). Although it is widely recognized that children spend a great deal of time interacting with electronic media outside of school, and increasingly with online computer games, the educational value of such experiences are often called into question. Educators in particular often raise concerns as to whether online games can successfully elicit sophisticated mathematical thinking from children (as opposed to for example simple drill and practice).

Although there are many concerns about the educational content of electronic media, the reality is that electronic games, as Gee (2000) suggests, accomplish many educational goals that are too often not met in school classrooms. Minimally, electronic games teach (and entice) players to learn how to play and get better at playing in spite of many persisting difficulties. Gee and others have posed theoretical arguments in favor of the educational potential of electronic games, but there is little empirical evidence to support those claims, and hence a motivation in our project to explore more specifically the question about how children reason when playing with online mathematical games. In addition, we were curious about children's informal interactions with mathematics in an online game environment (we used *Cyberchase* online games as the context for this investigation) and how and whether these interactions were similar to the sorts of strategies and understandings students use when working with regular school mathematics tasks.

## Theoretical Background

Research on how students use mathematics in and out of school often highlights the vast differences between these two contexts (i.e., Lave, 1998). In addition, researchers have also highlighted the tensions that arise when real life mathematics is brought to school (Civil, 2002; Sierpinska, 1995). We join this conversation by taking a different approach. Here we focus on the connections between students' engagement with informal mathematics and the mathematics they study in school. We chose an online game environment as the setting for this investigation because of its prevalence as an out of school activity for many children, but also because of its potential to make visible the sorts of connections we were interested in exploring.

Researchers who study human-computer interaction have sometimes drawn on established theories of human cognition to explain users' thinking while playing games (e.g., Mayer & Moreno, 2003; Moreno, 2006), and have noted similarities that exist between online and offline thinking and behavior (e.g., Gee, 2003). Indeed, research has shown that users' interactions with machines are influenced by the same sorts of social schemas that govern their interactions with other people -- regardless of whether the device in question is an animatronic, talking doll (Strommen, 2003) or a desktop computer (Reeves & Nass, 1996). By the same token, when children play online computer games, we might expect their reasoning to follow the same sorts of paths that they use while figuring out similar educational content in real (offline) life.

The field of computer-assisted instruction (CAI) represents a long history of teaching and assessing knowledge via interactive games (e.g., Price, 1989; Rudestam & Schoenholtz-Read, 2002; Suppes & Macken, 1978). However, unlike the kinds of software traditionally used in CAI, the online *Cyberchase* games that served as the context for this study were not originally designed for assessment. In addition, whereas assessment in CAI frequently focuses on measuring the state of users' knowledge or skills (to determine the types of exercises that the software will provide next; e.g., Corbett & Anderson, 1995; Gunzelmann & Gluck, 2004), we were more interested in observing the evolution of children's problem-solving strategies and mathematical thinking over the course of playing a game. We wondered whether gameplay in the *Cyberchase* games we focused on for this project would reflect children's understanding of educational content and strategies for problem solving that they would have encountered in their mathematics classroom; and if so, what sort of data might we collect to explore this learning?

## Methods

This study is part of a larger research project exploring children's interactions with multiple types of electronic media and their learning of mathematics. The context for this larger project and for the smaller study we report on here is the animated *Cyberchase* television series that airs daily on PBS. *Cyberchase* features three diverse youngsters who are summoned into cyberspace to foil the dastardly Hacker. Each half-hour episode sends the team on a mystery based on a mathematics concept. Through their adventures, the series models mathematical reasoning, problem-solving, and positive attitudes toward mathematics. Its underlying themes are that mathematics is everywhere and is infinitely useful. Nearly five million viewers – 40% of them African- American or Hispanic – tune in each week. A web site *Cyberchase Online* (*http://www.pbskids.org/cyberchase)* complements the series with interactive games and puzzles, based on the same mathematical content as the series. The site is one of the three most-visited sites on PBS Kids Online, with over 1.3 billion page views to date, and average use of more than 1 hour per visit (a marked contrast to the average of 19 minutes for the rest of the PBS Kids site).

Our research team observed 74 third and fourth graders (27 girls and 47 boys) in person as they played three *Cyberchase* online games, regarding decimals, quantity/volume, and proportional reasoning. For example, in the "Railroad Repair" game (*http://pbskids.org/cyberchase/games/decimals/)*, players fill gaps in a train track by using pieces labeled with decimals between .1 and 1.0 (Fig. 1).

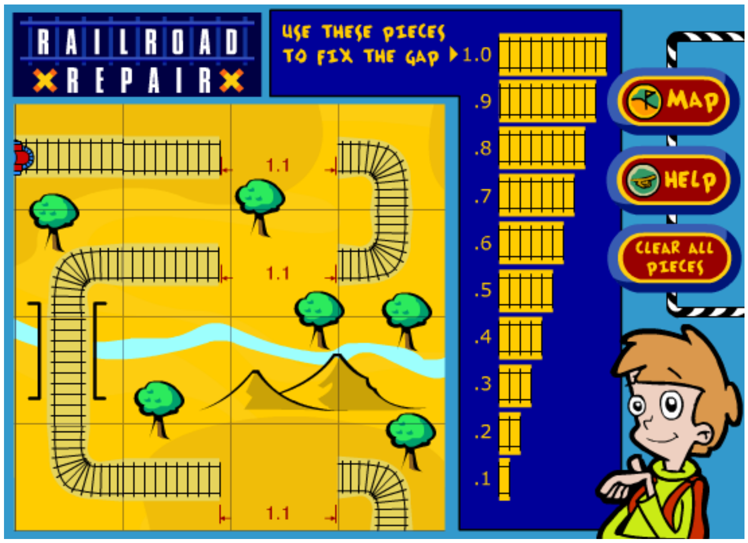

*Figure 1.* Sample screen from *Cyberchase* Railroad Repair game.

In this game multiple correct solutions are possible. However, each length of track can be used only once per screen, thus requiring children to find multiple ways to make sums and plan ahead to make sure that all of the necessary pieces will be available when needed. Children in our study played the games in pairs, to facilitate conversation that could reveal ideas and strategies as they played. Simultaneously, their gameplay was recorded with a custom built tracking software that recorded their mouse clicks and keyboard input automatically. This tracking software was arranged initially for two of the games: Railroad Repair and Sleuths on the Loose. This latter is a game about measurement and proportional reasoning (*http://pbskids.org/cyberchase/games/bodymath/)*. Afterward, children were interviewed explicitly about their strategies for playing each game and solving its mathematical problems.

## Results

Our observations of children's gameplay in Cyberchase online games environments are that children use a range of sophisticated mathematical strategies when solving complex tasks—regardless of whether those tasks are school tasks or out of school ones. Furthermore, the children in our study who used more sophisticated strategies, just as it is reported about children solving rich school mathematics tasks (e.g., Lesh et al., 2000), often did not apply them immediately. Rather, they engaged in cycles of problem solving that began with less sophisticated strategies and then became more sophisticated when necessary.

Consider the following excerpt of conversation from two children in our study while playing the Railroad Repair online game. As they tried to fill gaps in the game's railroad track, they had the following exchange:

> *"I think we're supposed to use the 1 and then the 10."*
> *"Uh-oh. Can we subtract?"*

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

*"This is too confusing."*
*[They clear the pieces from the screen, then start again with a different strategy]*
*"This time, we'll start with the mini-pieces…"*

What is noteworthy here is that when the children had tried something that did not work, and were pretty stuck (above statement: "this is too confusing,"), they changed their approach and tried again. They did not seek outside help, and on their own decided to change and try another strategy. Here we can see several of Gee's (2000) learning principles at work. Most notably what he calls the "psychosocial moratorium" principle, that is, that these learners are able to take risks in a space where there are no serious consequences. After all, they can try and try again without being judged about not solving this problem quickly or having made a mistake (and no real world consequence of having a train potentially derail should they fail to fix the problem).

Another of Gee's principle that is noteworthy here is what he calls the "ongoing learning principle," meaning that as the game progresses the learner must undo their routinized strategy to adapt to the new or changed conditions. This moves the learner through cycles of new learning, automatization, undoing automatization, and new reorganized automatization. In the sample conversation, a strategy that had worked well earlier in the game failed and the players had to adapt and tweak a solidly mastered strategy to the new condition. This is not a small fit, as we know too well from seeing students get stuck using their well learned strategy (say adding) even when that strategy fails or becomes too inefficient in new problem situations (say multiplication situations).

In Railroad Repair, many children began by using a *matching strategy* in which they matched the decimals shown (e.g., a .8 piece of track to fill a .8 gap). When this strategy later proved insufficient (e.g., they ran out of .8 pieces or needed to fill a larger gap), some switched to an *additive strategy* (e.g., combining .6 and .2 to fill a .8 gap). When this strategy, too, proved insufficient (e.g., the .2 piece was needed later), some adopted an *advanced* strategy in which they planned ahead, considered alternate ways to make sums, and reserved pieces they would need later.

Comparisons of observation, interview, and online tracking data revealed that these strategies could be detected via data mining too. Tracking data showed consistent patterns of online responses reflecting each strategy (matching, additive, or advanced), and clusters of errors when children's strategies broke down and they shifted to new ones. Consider, for example, some partial output of the tracking software for one player while playing Railroad Repair. On the first screen, the tracking software shows evidence of the player adopting a matching strategy, picking up a .4 piece (*piecepress*) and placing it (*piecedrop*) to fill a .4 gap. After accidentally putting the piece in the wrong location (row 2 in the example below), the player then places it correctly (row 4):

| **Row #** | **Event** | **Piece** | **Round** | **Successful placement?** | **Elapsed time** |
|---|---|---|---|---|---|
| 1 | piecepress | track4 | 1 | n/a | 7.161 |
| 2 | piecedrop | track4 | 1 | wrong | 7.272 |
| 3 | piecepress | track4 | 1 | n/a | 8.172 |
| 4 | piecedrop | track4 | 1 | success | 10.2 |

On the next screen, the player continues the matching strategy, using a .8 piece to fill a .8 gap (rows 5 – 6 in the example below). However, there is more than one .8 gap on this screen and only one .8 piece. Thus, after using the .8 piece, the player switches to an additive strategy, using two pieces (.7 and .1) to fill the second gap. After accidentally misplacing the .1 piece (rows 9 – 10), the player places it successfully (rows 11 – 12):

| **Row #** | **Event** | **Piece** | **Round** | **Successful placement?** | **Elapsed time** |
|---|---|---|---|---|---|
| 5 | piecepress | track8 | 2 | n/a | 22.09 |
| 6 | piecedrop | track8 | 2 | success | 24.101 |
| 7 | piecepress | track7 | 2 | n/a | 25.329 |
| 8 | piecedrop | track7 | 2 | success | 26.942 |
| 9 | piecepress | track1 | 2 | n/a | 28.503 |
| 10 | piecedrop | track1 | 2 | wrong | 28.711 |
| 11 | piecepress | track1 | 2 | n/a | 29.099 |
| 12 | piecedrop | track1 | 2 | success | 30.91 |

For the next several screens, the player continues to use the additive strategy, until arriving at a screen where this strategy is no longer sufficient. After filling several large gaps, the player combines a .5 piece and a .4 piece to fill a .9 gap (rows 13 – 15), only to find that all of the smaller pieces have been used up, which makes it impossible to fill the remaining small gaps on the screen. Recognizing this, the player hits the "clear" button to clear the screen and start over (row 16). Then, the player starts over by using an advanced strategy, in which the smaller gaps on the screen are filled first (rows 17 – 20), to ensure that the smaller pieces are available when needed. Afterward, the player uses the remaining pieces to fill the larger gaps, which have more flexibility in the variety of ways they can be filled:

| **Row #** | **Event** | **Piece** | **Round** | **Successful placement?** | **Elapsed time** |
|---|---|---|---|---|---|
| 13 | piecedrop | track5 | 5 | success | 280.019 |
| 14 | piecepress | track4 | 5 | n/a | 282.065 |
| 15 | piecedrop | track4 | 5 | success | 283.587 |
| 16 | clear | n/a | 5 | n/a | 285.864 |
| 17 | piecepress | track6 | 5 | n/a | 289.234 |
| 18 | piecedrop | track6 | 5 | success | 290.996 |
| 1 | piecep | tr | 5 | n/a | 291. |

| | | | | | |
|---|---|---|---|---|---|
| 9 | ress | ack5 | | | 982 |
| 2 0 | pieced rop | tr ack5 | 5 | success | 293. 233 |

As the above examples illustrate, we found that children's shifts in strategies were detectable, not only via in-person observations or interviews, but through online tracking data as well. Changes in strategies were often associated with either clusters of errors (indicating the player trying unsuccessfully to use different pieces to fill a gap), use of the "clear" button (indicating the player's recognition that a strategy was not working), and/or simply not having the necessary pieces available to fill gaps that remained on the screen. Thus, we could identify – and differentiate among – instances when children either failed to progress beyond basic strategies, proceeded through more difficult problems via trial and error (without necessarily employing a fundamental change in their thinking), or shifted to more sophisticated strategies over the course of a game.

## Discussion

Taken together, the observation, interview, and tracking data of the Cyberchase games we explored in this study hold implications for researchers and practitioners interested in exploring and bridging connections between computer games and mathematics education. From the standpoint of those interested in children's use of educational games, the parallels between online and offline reasoning highlight the degree to which gameplay is influenced, not only by players' experience and skill level in playing games, but also by their knowledge and skills regarding educational content embedded in such games. This point is not limited to interactive media. For a similar point regarding children's comprehension of educational television programs, see Fisch, 2000, 2004. As in school mathematics, children often do not display the same level of sophistication throughout a game (even if they are capable of relatively sophisticated reasoning). Rather, their mathematical reasoning may begin at a fairly basic level but become more sophisticated over the course of a game, when necessary to respond to the demands of the game.

From the standpoint of math educators, this study offers that online games can provide a good setting for helping students use and make connections between the strategies and reasoning they use when playing online games and those they might use to solve school mathematics tasks. The similarity between online and offline reasoning we discussed suggest that this might be a productive setting to pursue such in and out of school connections.

Additionally, we also found that even in the absence of in-person observations, data mining of online tracking data can provide a window into rich processes of reasoning and problem solving. When recorded and coded appropriately, such data can reflect, not only the outcomes of problem solving, but the process as well. (As a result, we have chosen to include tracking software among the assessments in our current research on children's learning from *Cyberchase* media.)

Yet, our experiences also point toward several challenges that must be overcome if tracking data are to be used effectively as a measure of reasoning. First, as anyone who has analyzed any sort of Web-based tracking data knows, users' clicks produce massive amounts of data. The sample data presented above is taken from a single session – and even that one game produced a spreadsheet containing more than 120 rows of data. When multiplied by the literally thousands of users who might play an online game in a single day, the volume of data can become staggering, posing challenges for both storage and analysis (even if the analysis can be partially automated).

Second, online tracking data must be limited to information that can be collected legally. The Children's Online Privacy Protection Act (COPPA) places strict limitations on the kinds of information that can be collected from children online. To help interpret data on gameplay, reasoning, or problem solving, researchers naturally look to characteristics of the players (e.g., age, gender, level of experience or prior knowledge), but COPPA can make it difficult to gather such information online. Since our project was part of a larger research study, and we had parents' signed consent for their children's participation, we designed the tracking software to record data only for players whose user names matched those in our study. Outside the context of such studies, however, researchers must either find alternate ways to gather demographic data, or do without it.

Third, tracking data are effective only for behavior that players perform clearly and unambiguously on the screen. Whereas the use of tracking data was highly successful for Railroad Repair, it was only partially successful for "Sleuths on the Loose," a game about measurement and proportional reasoning (*http://pbskids.org/cyberchase/games/bodymath/*). In Sleuths on the Loose, we could accurately record and code the answers that children provided, but it was harder to gauge their use of measurement for two reasons. Instead of using the on-screen "ruler" that served as a measuring tool, some children measured via alternate means such as holding their fingers up to the screen; the software could not detect these sorts of offline behavior. In addition, even when children did use the on-screen ruler, tracking data alone was not always a reliable indicator of whether a player was attempting to measure, because some children simply moved the ruler idly around the screen while thinking. Thus, we could tell whether players' answers were correct or incorrect, and identify some instances when players used the on-screen ruler for measurement (by establishing parameters for valid placement of the ruler). However, other cases of measurement could be identified only via in-person observation.

Understanding children's facility with educational content (outside of the confines of school classrooms) is important. As our experience in this study makes clear, educational games can provide a rich environment for studying children's mathematical reasoning in an informal context. However, games and tracking software must be designed carefully in order to not only accomplish educational goals but also produce useful, reliable data. But if they are designed properly, data mining can provide us with deep insight into children's thinking and reasoning -- without our having to peek over children's shoulders at all times.

# A COMPARISON OF MATHEMATICS TEACHERS' AND STUDENTS' VIEWS ON THE NEW GENERATION HANDHELD TECHNOLOGY

S. Aslı Özgün-Koca
Wayne State University
aokoca@wayne.edu

Thomas G. Edwards
Wayne State University
t.g.edwards@wayne.edu

*Forty-five teachers and 54 middle school students shared their views about the TI-Nspire calculator after their first experience with it. The analysis of teachers' views about both benefits and weaknesses of this technology helped us reflect on why and how teachers come to adopt technologies in their teaching or not. The analysis of the student data empowered us with a student perspective that might have differed from that of the teachers. However, the analysis of our data revealed more similarities than differences.*

## Objectives

The main objective of this study is to analyze mathematics teachers' and students' initial opinions of a novel technology, TI-Nspire. With the advances of this new generation of handheld calculators, many new technological capabilities make novel classroom activities possible. But the main question is whether teachers are willing or ready to use these powerful new calculators in their classrooms. The analysis of teachers' views about both benefits and weaknesses of this technology helped us reflect on why and how teachers come to adopt technologies in their teaching or not. The analysis of the student data empowered us with a student perspective that might have differed from that of the teachers. A comparison of these views enabled us to see the similarities and differences between the views of these students and teachers.

## Perspectives

A large research base confirms the influence teachers' beliefs about teaching and learning mathematics have on their students' learning (Ball, Lubienski, & Mewborn, 2001; Stipek, Givvin, Salmon, & MacGyvers, 2001; Thompson, 1992). Specifically, teachers' beliefs about the roles of graphing calculators have been associated with the use and roles of calculators in mathematics classrooms. Therefore, it is imperative to study teachers' beliefs about the use of calculators in mathematics instruction, particularly with the advent of a new generation of graphing calculators. With this aim in mind, the current study investigated the views of a sample of pre-service and in-service mathematics teachers on the TI-Nspire.

With the advances of this new generation of handheld calculators, many new technological capabilities make novel classroom activities possible. For instance, TI-Nspire brings the dynamic, interactive, and linkage properties of these technologies to new levels. Now some of the linkages among representations become two-way. When using the old generation calculators, the linkage between a graph and its equation was one-way. We needed to enter different values for the coefficients of a function to be able to observe the effects of changes in the symbolic form on the graphical representation. However, manipulating the graph directly to see the effects of that manipulation on the symbolic form as well makes this approach even more powerful. TI-Nspire allows students to dynamically manipulate the graph and observe the immediate effects of that manipulation on the symbolic form.

## Conceptual Framework

Following Shulman's (1986) analysis of teachers' knowledge as a complex structure including content knowledge, pedagogical knowledge, and his introduction of the concept of pedagogical content knowledge, research in this area has become effectively grounded on his framework. With Mishra and Koehler's (2006, Koehler & Mishra, 2005) and Niess' (2005, 2006, 2007) introduction of the concept of the teachers' Technological Pedagogical and Content Knowledge (TPACK), technology-related research in the teachers' professional development and education field has gained a rich new conceptual framework or "analytic lens for studying the development of teacher knowledge about educational technology" (Mishra & Koehler, 2006, p. 1041).

TPACK involves content knowledge, pedagogical knowledge and technological knowledge and their combinations, as depicted in Figure 1. In this study, the content knowledge is 6-12 school mathematics. The pedagogical knowledge includes teaching methods and learning theories. The technological knowledge includes knowing how to operate technological tools (such as graphing calculators) and being able to adapt to ever-changing, novel technologies.

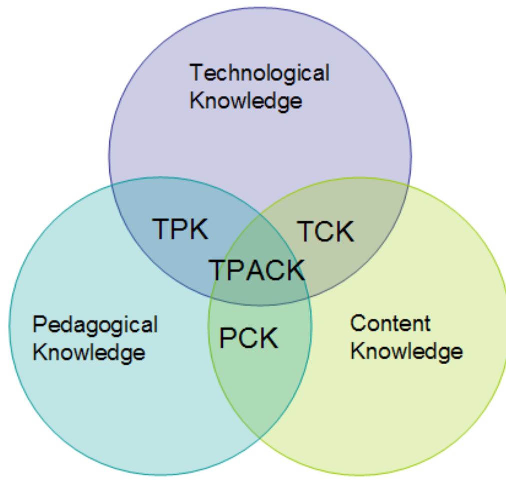

*Figure 1.* Re-creation of Mishra and Koehler's TPACK model.

Looking at the combinations, Pedagogical Content Knowledge (PCK) (Shulman, 1986) focuses on the mutual relationships between content and pedagogy. For example, depending on the specific mathematics content, a certain method could be chosen, or teachers can reflect on how particular pedagogical methods might help (or hinder) students' learning of specific mathematics content. Another combination is Technological Content Knowledge (TCK). In discussing TCK, Mishra and Koehler (2006) note that "teachers need to know not just the subject matter they teach but also the manner in which the subject matter can be changed by the application of technology." (p.1028). On the other hand, Mishra and Koehler believe that "technological pedagogical knowledge (TPK) is knowledge of the existence, components, and capabilities of various technologies as they are used in teaching and learning settings, and conversely, knowing how teaching might change as the result of using particular technologies" (2006, p. 1028). TPACK is at the heart of all of this knowledge and takes all of these factors into consideration (see Figure 1) as "an integrated whole 'Total PACKage'" (Thompson &Mishra, 2007, p. 38).

## Data Collection Methods

Since the new generation calculators bring many new capabilities, it might be difficult to focus on all of them at once. Creating instructional materials focusing on one capability at a time could be easier for students and teachers to make their transition from the old to the new generation. Therefore we created an activity using TI-Nspire, in which users explore the effects of manipulating the graph of a quadratic function on its symbolic representation (Özgün-Koca &

Edwards, 2008). We used this activity with teachers and students to introduce them to TI-Nspire.

We asked 19 pre-service teachers, 26 in-service teachers, and 54 middle school students to reflect on the novel capabilities of this new technology. Our main data collection method for the teacher data was a survey that included open-ended questions that followed an activity using TI-Nspire.

Middle school students experienced the same activity over a three-day period. Our main data collection methods for the student data were surveys that included Likert type and open-ended questions. In addition to that, we videotaped students working with the TI-Nspire in the classroom. Portions of the videos will be shared during the presentation. The data gathered with the Likert type questions were analyzed with descriptive statistics. For the analysis of the qualitative data obtained through the survey, data were coded and analyzed qualitatively to reveal patterns and themes. Data triangulation and peer debriefing were used to ensure the trustworthiness of the data. Results revealed differences and similarities among the middle school students, pre-service teachers, and in-service teachers' views on the use of TI-Nspire in mathematics instruction.

**Results**

We observed that students were eager to learn about this novel technology and they were very motivated. As a response to mid-survey, students stated that they liked both the technical (more features or applications) and physical (larger screen or alpha keys) novelties of the TI-Nspire.

> I liked that the new TI-Nspire calculators have different things that we cannot do on the normal TI-84 plus calculators.

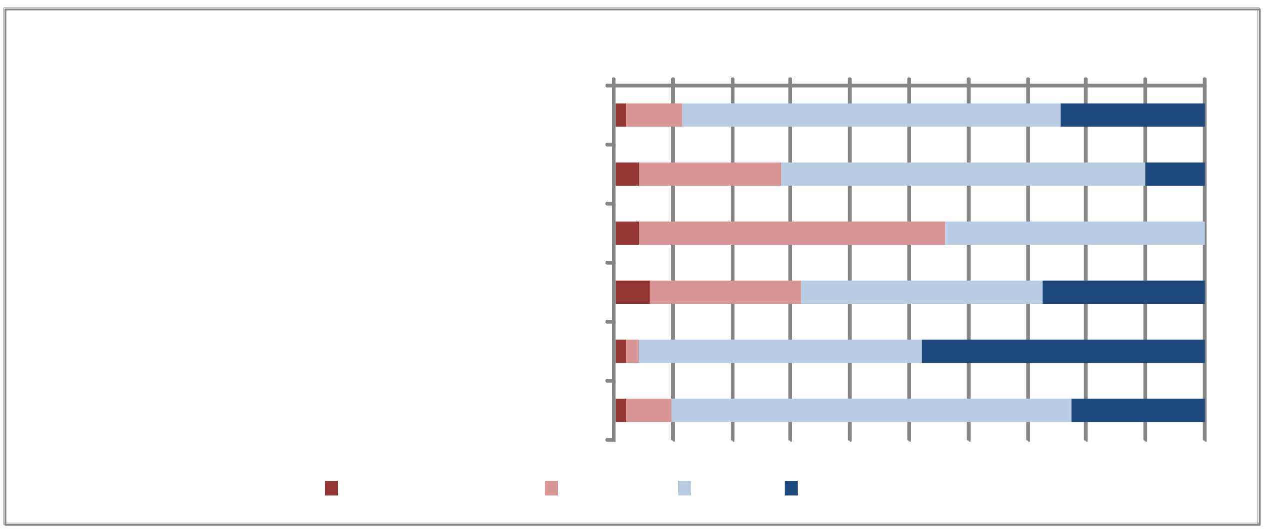

*Figure 2.* Student exit survey.

An overwhelming majority (89%) of the students liked doing mathematics with Nspire. Seventy-two percent of the students agreed that Nspire helped them to better understand the math lesson. While 56% of the students disagreed that Nspire helped them to be more confident during the math class, 44% of them agreed. However 68% of the students agreed that it was difficult to follow the Nspire lesson. Another overwhelming majority (96%) liked being able to move the

*S*
*N*
*C*

graph and observe the equation. Similarly an overwhelming majority (89%) liked multiple representations.

In the following sub section, the TPACK model is used to frame our analysis of teachers' knowledge, but at the same time students' views are discussed at appropriate places. The main objective here is to focus on the technological, pedagogical or content related comments separately.

*Technology in* ***T****PACK*

First, we focused on the technological part of TPACK. Seventy-four percent of the pre-service teachers and 42% of the in-service teachers thought that TI-Nspire was more difficult to use than other calculators they had worked with. Some simply said that it was more difficult to use, but many also mentioned that it might become easier with time and more experience. Some of the reasons for the difficulties they cited included:

> There is so much to learn about the calculator-it can be overwhelming.
>
> [TI-Nspire is more difficult] only because I am used to the TI-83 technology.

In contrast, twenty-one percent of the pre-service teachers and 42% of the in-service teachers thought TI-Nspire was easier to use: "I thought the technology was easy to use. I like how the menus were easy to use."

Sixty-nine percent of the students agreed that it was difficult to follow Nspire math lessons. One stated that "it was very difficult for me to follow these math lessons because I didn't know where any of the buttons were and how to get to places on the calculator." As with the teachers, some students stated that it was only their first experience: "It went kind of fast and was very complicated. With some lessons, I could probably understand it better."

Participants found TI-Nspire different from other calculators that they have used before. They were comparing this novel technology to other technologies using their previous technological knowledge:

> It makes a TI-84+ look like a small scientific calculator (Teacher)
>
> I liked that the new TI-Nspire calculators have different things that we cannot do on the normal TI-84 plus calculators. (Student)

At the same time, some students also mentioned that they would prefer working with TI-84s, because they were more familiar with them: "[TI-Nspires] were really confusing. They are very difficult to graph when you are so used to the TI-84 Silver Edition."

Forty-two percent of the pre-service teachers, 50% of the in-service teachers, and some students mentioned that TI-Nspire had more capabilities and features when compared to other technologies and calculators:

> This is 'better' technology than what I have used. It seems that this calculator has many more functions and abilities than others I have used. There are many features and applications that are great (Teacher)

A few teachers and students compared TI-Nspire to a home computer:

> They are more comparable to a computer with the drop down menu screens (Teacher).
>
> [Nspire has] potential features computer like accurateness and format. Because it acts as accurately as a computer but as portable as a calculator (Student).

Twenty-one percent of the pre-service teachers and 46% of the in-service teachers also mentioned that being able to directly manipulate graphs was a key technological difference: "This calculator allows greater manipulation of equations and graphs. It allows students to see immediately the relationship between vertex forms of the graph as well the graph and other equations." Similarly 96% of the students stated that they liked moving the graph around to see what happened to the equation: “That helped me see how the equation changed with the parabola.”

The novel technological capabilities that students liked were separate buttons for the letters, a bigger screen, and many applications. However, at the same time, they did not like that the buttons were scrunched together.

*Pedagogy in T**P**ACK*

One teacher stated that “this calculator is different because you can move the line and see what it does to slope…Before you had to change the equation to see the line change.” While talking about the technological capabilities of this machine, this teacher made a connection to his or her TPK. In doing so, s/he considered how the new capability of the Nspire might help students who are learning the connection between the symbolic and graphical representations of linear equations. We believe that this teacher was also visualizing the use of Nspire in his or her own classroom. The construction of such a vision has been posited as a necessary condition for the implementation of an innovation (Shaw & Jakubowski, 1991; Simon & Schifter, 1991). A couple of the teachers also used the word “hands-on” when discussing novel features of Nspire and how these new capabilities might help improve the teaching and learning environment.

Interestingly, two pre-service teachers mentioned similarities to a paper and pencil environment: “Anything you want to do can be done by typing exactly what I see on paper into the calculator.” At this point, these teachers saw a resemblance between this new environment that Nspire provided and a very traditional and old teaching and learning environment. This new feature might have attracted their attention, because it was different from the old generation of calculators.

Seventy-two percent of the students agreed that Nspire helped them to better understand the math lesson. Most of the pre-service and in-service teachers were in agreement with the middle school students and believe that TI-Nspire would positively influence student learning. While explaining their reasons for this comment they were using TPK while focusing on their “knowledge of students’ understandings, thinking, and learning with technology” , which was mentioned as a part of TPACK by Niess (p. 197, 2006). The main reasons for this belief appeared to be the ability to create an exploratory learning environment, being able to provide an interactive environment with dynamic linked multiple representations, and being able to increase student motivation.

*Creating an exploratory learning environment*. Thirty-two percent of the pre-service and 23% of the in-service teachers shared that TI-Nspire could be beneficial in creating an environment for discovery. One teacher stated that:

> It allows them to more easily test conjectures. It also allows them to better make connections and see representations. This technology will be as difficult for students as for teachers, but I think a lot of guided activities would have students breezing through its use by the end of the year. I think it allows teachers to develop more discovery/inquiry-based approaches to teaching and learning.

Indeed, we observed this in the classroom, and so did one of the students: “These calculators are very helpful in my learning because they introduce hands on learning and promote good experimenting.”

*Providing an interactive environment with dynamic linked multiple representations.* Twenty-six percent of the pre-service and 46% of the in-service teachers stated that TI-Nspire could bring unique opportunities for students to experience new forms of representations:

> It could help them see how you can bend the parabola and how the coefficients change as it

> gets smaller or larger. This technology is very interesting. I would love to learn to use it so that I could use it in my classroom.

Ninety-one percent of the students agreed that they liked being able to represent a parabola in several different ways (graph, equation, or spreadsheet table): "It was interesting to see how function and graph related to each other so much."

*Student motivation*. Eleven percent of the pre-service and 27% of the in-service teachers mentioned things that have been associated with increased student motivation (Middleton & Spanius, 1999): "I think students would be excited about using these calculators, thus increasing their learning." We observed that students were very eager to use Nspire and 89% of the students stated that they liked doing mathematics with Nspire: "I liked using the new calculators because they were very high-tech and really fun to use. Also it made graphing easy and fun!"

Sixteen percent of the pre-service teachers were not sure or do not think that this technology will help students' learning: "I just worry that this technology may detract students from learning math content, because they get caught up with how to use the calculator and not how the math corresponds to the calculator and display." Some pre-service teachers (21%), but only one in-service teacher agreed that TI-Nspire could be helpful in students' learning, but they fear calculator dependency:

> I believe that this technology will encourage students to ask and find out "why" more often since the work needed will not only be less tedious, but also more fun to do. I think the "why's" of math will be easier for students to learn and therefore their understanding of concepts and connections will increase. I fear that the more advanced technology becomes, the more dependent students will become on it.

*Content Knowledge in TPA**C**K*

The main categories that pre-service teachers discussed were the technological and pedagogical parts of TPACK. It is understandable that when we come across a novel technology, the first thing that we reflect on would be the technology itself. And then the second thing would be how learning and teaching might change with this new technology. Content or curriculum related issues should also be considered, but perhaps not as soon as technological or pedagogical issues. Perhaps as teachers become more knowledgeable with technology, content/curriculum related issues will come more into play.

The activity that we used in this study focused on the effects of the coefficients in the quadratic function (*f(x)=ax^2+bx+c*) on its graph . In a traditional curriculum, the effects of *a* and *c* are studied more commonly than the effects of *b*. With the availability of the new capabilities of TI-Nspire, the way to study the effects of *a* and *c* is enhanced and the effects of *b* may also be studied much more easily.

## Discussion and Educational Importance of the Work

In this section, we first compare pre-service and in-service teachers' views of Nspire. Next we compare teachers' views of with those of students, as well as our observations of the students while they were using Nspire. Finally, we discuss implications for teacher education.

*Comparison of Pre-service and In-service Teachers' Views*

As a result of this analysis, we observed that more in-service teachers found Nspire easier to use as compared to pre-service teachers and the students. Moreover, more in-service teachers than pre-service teachers emphasized the novel capability of Nspire-being able to manipulate the graphical representation physically in the virtual environment. Perhaps having more experience with graphing calculators in classroom instruction and having more knowledge about the graphing calculators' capabilities and limitations might have influenced these differences. Moreover, the larger experience base of the in-service teachers may have helped them to create a more fully developed vision of what using Nspire during instruction might look like in their classrooms. If this analysis is correct, it helps to explain most of the differences between pre-service and in-service teachers that we observed. Finally, when reflecting on the potential effects of the use of Nspire on students' learning, both pre-and in-service teachers articulated similar positive influences of the use of this technology on the teaching and learning environment. Moreover, teachers views about the potential pedagogical issues when teaching with Nspire were very close to the reality we observed in the classroom with students, such as being able to create exploratory environments and an increase in students' motivation.

*Comparison of Teachers' and Students' Views*

Based on our analysis of these data and our observations of students working with Nspire, we saw more similarities than differences in the views of teachers and students. About the only difference we noted was that students were far more likely than teachers to mention the separate buttons for letters of the alphabet as an advantage of the new calculators. We speculate that this might be due to students' past experiences in text messaging.

In most cases the views of students paralleled those of teachers. What was particularly noteworthy is the degree to which the students' views of their work with Nspire tended to confirm the teachers' views of the potential pedagogical benefits of using Nspire. Moreover, our observations of the students' working with the new calculators further confirmed these potential benefits.

*Implications for Teacher Education*

NCTM's vision of school mathematics includes students in grades 9-12 "using technological tools to represent and study the behavior of polynomial, … functions" (NCTM, 2000, p. 297). Moreover, we believe that when students use dynamic geometry tools to manipulate graphs linked to their symbolic algebraic representations, they will be empowered "to convert flexibly among these representations" (NCTM, 2000, p. 360). In doing so, they will experience firsthand "the power of mathematics [that] comes from being able to view and operate on objects from different perspectives" (NCTM, 2000, p. 360). In order for that vision to become a reality, teachers of mathematics, including pre-service teachers, must be able to envision the use of technology in their own classrooms in appropriate ways. We believe that modeling for teachers activities such as we did in this case can help them form new visions of what their classroom might be like. However, while doing so may be a necessary condition, it is clearly not sufficient, as our data vividly show. They would need more experience with the technology in their education and profession.

In methods courses, students could focus on the potential effects of the use of an instructional technology in their teaching. In content courses, they could focus on how the use of this technology might have helped or hindered their learning. Teacher education programs offer pre-service teachers the knowledge and experience that they will need in their profession. However, it is crucial to remember that their belief system and views about their pedagogical implications are also developed during their teacher education program. Therefore, it is essential to identify these beliefs and views in order to inform the teacher education program itself and present opportunities to pre-service teachers to reflect on their beliefs and views on important educational issues.

*This study investigates how mathematics educators make use of the digital capabilities of online resources both in and out of the classroom. The digitally adept 17 pre- and in-service teachers in a graduate technology in mathematics education course failed to capitalize on the unique abilities afforded by the Internet using resources primarily for lesson planning.*

## Theoretical Background

Today's incoming teachers represent the first generation with personal access to technology in our ever-evolving digital world. Pre-service and novice teachers are in their early to middle twenties, with post-1980 birth years that are suggested for "digital natives" (Palfrey & Gasser, 2008). According to the U.S. Department of Education (2000), as new teachers who have grown up in a technology-rich environment enter the profession, their comfort and skill with technology will lead to increased use of computers for instruction. Most pre-service mathematics teachers enter their mathematics education courses as competent users of the Internet and general-purpose computer software (e.g., word processing and spreadsheets), having gained some experience with these technologies during previous university or K-12 classes (Goos, 2005). Teachers who have been in the profession for 1-6 years have been found to be more comfortable with technology than those who have taught longer (Russell, Bebell, O'Dwyer, & O'Connor, 2003).

A study of over 2000 teachers of grades 4-12 found that mathematics teachers tended to use internet resources very differently and less frequently than other teachers (Becker, 1999). This finding is supported by a similar study from over 4000 grade 4-12 teachers (Becker, 2001). When internet usage was ranked by teachers' subject matter, the 538 mathematics teachers placed second to last with 11% of respondants using the Internet. In the later half of the 1990's, less than one-half of eighth grade mathematics teachers claimed to use computers at all (Technology Counts, 1997).

Policy makers claim that high access to computers in classrooms leads to major improvements in teaching and learning; however, such access has not ensured high use by classroom teachers (Cuban, Kirkpatrick, & Peck, 2001). 82% of teachers surveyed reported using computers for home use at least once per week, yet claimed to utilize computers very seldom for classroom instruction. Describing the incremental changes that occur in pedagogical practices as access to technology increases, the Cuban et al. study showed that while technology can promote student-centered instruction, teacher-centered instruction often remains dominant. Teachers have reported that they used computers primarily for classroom preparation (Technology Counts, 1999). In 2001, Cuban et al. hypothesized that in the absence of major changes to the obstacles facing technology in the classroom such as allocation of time, teacher preparation, reliability and functionality of technology, and increased internet speed, only modest alterations would be made in teaching and learning.

## Research Questions

The data reported here is part of a larger grounded theory study, which used both quantitative and qualitative data, to explore how and how frequently pre-service and novice mathematics teachers make use of digital resources. The study purposely targets a small group of pre-service and novice teachers, teachers in the first wave of digital natives or exceptionally proficient digital immigrants, to determine their use of online resources. This paper will primarily focus on teachers' use of digital resources by addressing the following series of questions:

1. What types of digital resources do mathematics teachers use?
2. For what educational purposes and how frequently do teachers use digital resources?
3. Do teachers capitalize on the unique capabilities afforded by online technology?
4. Who do teachers see as the end users of mathematics education websites?

## Methodology

The participants of the study included graduate students enrolled in an elective course on technology in mathematics education in a department of learning and instruction at a large research university in New York State. As a part of a technology-infused teacher education program, the course was able to incorporate more than four of the strategies suggested by Kay (2006) for pervasive computer use by teachers. The study participants included 9 pre-service, 7 novice in-service teachers, and 1 veteran teacher (henceforth referred to collectively as teachers), with mathematics emphasis educational backgrounds all living in a 50-mile radius of each other. All grew up in what could be described as middle class homes with reasonable access to technology. The veteran teacher was certified to teach grades K-12. Five of the participants were childhood teachers with a mathematics emphasis, certified (or working toward certification) to teach up to grade 6 or grade 8. Ten were secondary teachers certified (or working toward certification) to teach from grade 5 (or grade 7) up to grade 12. All but three of the teachers were in their early to middle twenties, hence, digital natives. The other three teachers had extensive technology experience and could easily be identified as proficient digital immigrants.

The initial research team consisted of the instructor of the course and a doctoral student in mathematics education, who acted as a participant-observer during the course. As a validating step, the team then recruited another doctoral student in mathematics education who had taken the course two years prior to help review the related literature, the data, and initial research team's conclusions.

Data was collected during the fall semester ranging from August 2008 through mid-January 2009. Employing an inductive process of generative data collection, constant comparisons of data from varying instruments were made. The data reported in this study were collected via researcher-generated surveys, participant-generated surveys, and informal interviews.

At the end of the technology class, the participants were asked to submit 5 to 10 websites they felt were the best mathematics education sites. The list of submissions was compiled into a cumulative list of top websites for the class. Using this cumulative list, the teachers were next asked to complete a website-use survey composed of 19 Likert-scale items to evaluate. For those sites with which they were familiar, they indicated their use of each website as well as who they saw as the end-users of those sites. Following the website use survey, participants created two-question surveys in groups using web-based software as a course assignment. The data compiled in the participant-generated surveys were used to further develop digital consumer profiles, and to ensure reliability of the data found with researcher-generated instruments.

## Results

In addition to enrolling in an elective course entitled *Technology in Mathematics Education*, the data in the following relative frequency tables speak to the general digital consumption and digital facility of the teachers in addition to their use of technology for teaching mathematics.

Digital Consumer Profile: General

| **Do you use/visit the following weekly?** | **Percent** |
|---|---|
| Cellular Telephone | 100 |
| Internet | 100 |
| E-mail | 94.1 |
| Text Messaging | 58.8 |
| Wikis and Online Dictionaries/Encyclopedias | 56.3 |
| Online Social Networking (e.g., MySpace, Facebook) | 52.9 |
| Blogs | 17.6 |
| Social Bookmarking sites (e.g. Del.icio.us) | 5.9 |
| Online Survey/Calendar sites (e.g., Survey Monkey, Google Calendar) | 0.0 |
| Video Sharing sites (e.g., YouTube) | 0.0 |

Digital Consumer Profile: Teaching

| **In my teaching I use (*type of technology*) weekly** | **Percent** |
|---|---|
| Word Processing Software | 100 |
| Internet | 94.1 |
| Equation Editor | 82.4 |
| Graphing Calculator | 70.6 |
| Spreadsheet Software | 47.1 |
| Internet-Based Applets | 46.7 |
| Exam Generator Software | 41.2 |
| Presentation Software | 23.5 |
| Dynamic Geometry Software | 5.9 |
| Downloaded Videos | 5.9 |

The data in both profile tables was collected from items generated by the research team. To ensure the credibility of the data results from the researcher-generated surveys, data are reported that were generated by teacher groups as a part of a class assignment learning to use online survey websites. This information can be found in the *Teacher-Generated Items Related to Teachers' Digital Consumption* table on the next page.

When polled on the best mathematics education sites, the teachers submitted a total of 49 sites. However, when asked to assess the 49 best sites, the teachers only felt familiar enough with 37 of the initial 49 sites submitted to actually evaluate them. Of the 37 sites that were evaluated, only 12 sites were evaluated by at least 25 percent of the participants. The data on the 12 "most used" sites is reported below and includes the relative frequency of teachers who are familiar with the site, the frequency of use for each site, the teachers' ideas about who would be the sites' end users, and the Google pagerank for each site. Note that teachers were able to mark more than one end user, so the relative frequencies reported for end user data represent the percentage of teachers making the recommendation. Google uses a combination of key words and pagerank to return websites on a given search. Using a scale of one to ten, those sites with higher pageranks are more likely to be returned on a search with a given set of key words, than those sites with a lower pagerank given the same key words (Craven, 2009).

Teacher-Generated Items Related to Teachers' Digital Consumption

| Question | Mean | SD |
|---|---|---|
| How often do you use computers for school related activities? (1 = rarely, 5 = very often) | 4.87 | 0.35 |
| How often do you use websites to help create math lessons for your classroom? (1 = rarely, 5 = very often) | 3.56 | 0.89 |
| How likely are you to search websites for existing worksheets rather than create your own? (1 = highly unlikely, 5 = highly likely) | 3.13 | 0.50 |
| Would you use a website if there was a fee for use/membership? (1 = no, 2 = only if paid by district, 3 = maybe, 4 = yes) | 2.75 | 0.58 |
| What do you feel is the most important when choosing technology that will be used in the classroom? (1 = not important, 5 = very important) | | |
| relevant to topic | 4.67 | 1.05 |
| student interaction | 3.60 | 1.24 |
| Fun and interesting | 3.40 | 1.24 |
| state standards | 3.07 | 1.22 |
| national standards | 2.00 | 1.20 |

Most Used Websites for Mathematics Education

| | Website | Percentage of sample familiar with site | Frequency of use (1 = less than once a year, 6 = daily) | | Percentages of Intended Site End User(s) | | | | Google Pagerank (1 = low, 10 = high) |
|---|---|---|---|---|---|---|---|---|---|
| | | | Mean | SD | teacher | student (in-class activity) | student (as a reference) | parent | |
| 1. | Illuminations | 66.7 | 5.00 | 0.82 | 100 | 16.7 | 42.7 | 0.0 | 6 |
| 2. | NCTM | 61.1 | 4.45 | 0.94 | 90.9 | 0.9 | 0.0 | 0.0 | 7 |
| 3. | The Math Forum | 55.6 | 4.00 | 1.00 | 90.0 | 10.0 | 80.0 | 50.0 | 8 |
| 4. | NLVM* | 50.0 | 4.22 | 1.09 | 100 | 55.6 | 66.7 | 44.4 | 6 |
| 5. | Purple Math | 38.9 | 4.14 | 0.90 | 100 | 0.0 | 71.4 | 28.6 | 6 |
| 6. | Regents Prep | 38.9 | 4.67 | 1.03 | 85.7 | 28.6 | 85.7 | 71.4 | 5 |
| 7. | Cool math | 33.3 | 3.83 | 0.75 | 66.7 | 33.3 | 100 | 50.0 | 4 |
| 8. | edHelper | 33.3 | 3.67 | 1.21 | 100 | 0.0 | 33.3 | 33.3 | 6 |
| 9. | Mathbits | 33.3 | 4.17 | 0.98 | 83.3 | 33.3 | 66.7 | 50.0 | 6 |
| 10. | BrainPop | 33.3 | 3.71 | 1.11 | 83.3 | 50.0 | 66.7 | 16.7 | 8 |
| 11. | AAA Math | 27.8 | 4.00 | 1.10 | 100 | 40.0 | 100 | 40.0 | 6 |
| 12. | School Island | 27.8 | 4.80 | 0.84 | 80.0 | 100 | 40.0 | 40.0 | * |

* NLVM represents the National Library of Virtual Manipulatives.
** *Note.* Schoolisland.com is unrankable, (has no pagerank) as is common with commercial, educational tool sites.

To ensure that the data represented mathematics teaching interests across the K-12 landscape, the research team considered the ratio of primary and secondary teachers' responses. For 11 of the 12 most used sites, the ratio of primary and secondary responses was proportional to the ratio of primary and secondary teachers in the study. Purple Math, a site dedicated to algebra, is the only datum on the list that was selected solely by secondary teachers.

The list of the 12 most used websites is comprised of sites that provide a variety of educational resources for mathematics teachers. Several of the sites listed deal with the national and state standards. Illuminations and the NCTM site provide numerous resources that are based on the principles and standards for K-12 mathematics proposed the National Council of Teachers of Mathematics (2000) including activities, applets, lessons, and access to professional development materials. NLVM provides an array of standards-based interactive manipulatives organized by NCTM's content standards and grade bands. Regents Prep provides practice for and addresses issues pertinent to mathematics testing in New York State.

The Math Forum is a comprehensive site that offers a variety of users a wide range of materials related to lesson creation, course material development, homework help, and review of mathematics concepts. Purple Math is a text-dominant algebra review site that includes occasional static images to accompany the text. Cool math is a conglomeration of mathematics lessons, games, and puzzles.

Several sites selected by the participants emphasize the availability of printable materials on their site. With a focus on mathematics and programming, mathbits.com provides printable and multimedia materials including movie clips and instructional guides. EdHelper is a source of worksheets with a limited number of puzzles. AAA Math is a collection of worksheets with built in self-assessment that allow for feedback based on user input. Similarly, schoolisland.com allows for automatic feedback on self-administered worksheets in addition to addressing certain administrative aspects of teaching.

Two sites on the list are accessible by fee. BrainPop, is a multidisciplinary site with a collection of animated educational videos in mathematics as well as other school subjects. School Island is a commercial website that provides teachers with content authoring and course management functions that allow them to create and assess assignments as well as track student progress.

The teachers were asked to report on exactly how they utilized the initially submitted 49 "best" sites. As previously stated, teachers only evaluated those sites with which they were familiar. The information is reported in the *Website Use Survey*.

The four most frequently cited reasons for using a website, Tier 1, primarily addressed teachers' instructional planning. These responses were teacher-centric and focused on the teachers' lesson preparation. The next four responses cited, Tier 2, were more oriented towards the generation of products to be used by the students in class, or were of a more interactive nature. These items included accessing puzzles, games, interactive materials, etc. This tier also included the procurement of worksheets for students.

Three of the following four items, Tier 3, focused on state math assessment, related to state mathematics standards, or national mathematics standards. The final seven items on the list, Tier 4, dealt with components that some view as peripheral to teaching. These sites included information on topics such as student contests, professional development, funding opportunities and historical information related to mathematicians or mathematics, recent developments in mathematics education, and real world data to be used in mathematics lessons.

After considering the data in the *Most Used Websites in Mathematics Education* and *Website Use Survey* tables individually, the data was compared. Of the 12 most used sites, both NCTM (site 2) and The Math Forum (site 3) were identified as meta-resource websites that cut across

Website Use Survey*

| | **I will or have used the sites to: (1 = never, 5 = very often)** | **Mean** | **SD** |
|---|---|---|---|
| Tier 1 | get ideas for lessons | 2.97 | 1.20 |
| | get examples | 2.95 | 1.23 |
| | help develop course materials | 2.91 | 1.27 |
| | help refresh my knowledge/learn more about a topic before I teach it | 2.37 | 1.23 |
| Tier 2 | get mathematical games, like puzzles or riddles for students | 2.29 | 1.19 |
| | get applets, virtual manipulatives, videos, etc. that I will use for interactive demonstrations | 2.27 | 1.40 |
| | get applets, virtual manipulatives, videos, etc. for interactive explorations | 2.26 | 1.39 |
| | get worksheets | 2.23 | 1.25 |
| Tier 3 | provide examples, practice for students on state math assessment instruments | 2.20 | 1.33 |
| | help me learn how what I teach ties in with other subjects/math topics | 2.10 | 1.15 |
| | get information on state math assessment instruments/expectations | 1.94 | 1.24 |
| | learn more about how the standards apply to a lesson/topic | 1.85 | 1.17 |
| Tier 4 | get mathematical support materials like graph paper, coordinate axes, bar graph templates, etc. | 1.65 | 0.94 |
| | get information on important, developing issues in mathematics education. | 1.52 | 1.01 |

| | get information on conferences/other professional development opportunities | 1.49 | 0.99 |
| | get information on competitions for students | 1.45 | 0.89 |
| | get information on funding opportunities for teachers | 1.43 | 0.88 |
| | gather historical information related to a lesson/person in mathematics | 1.42 | 0.73 |

* *Note*. Responses have been grouped into tiers for ease of reference.

Teacher-Identified End-Users

| | | **End-user** | | | |
|---|---|---|---|---|---|
| | **Primary Focus** | teacher-user | student-user (in-class activity) | student-user (as reference) | parent-user |
| Tier 1 | instructional preparation | 92.3 | 9.8 | 50.2 | 23.1 |
| Tier 2 | student materials, interactivity | 89.1 | 29.8 | 67.2 | 37.5 |
| Tier 3 | state assessment, natl. standards | 97.4 | 36.2 | 46.5 | 28.2 |
| Tier 4 | “peripheral” components | 95.2 | 5.2 | 38.1 | 23.8 |
| *Most Used Websites* (cumulative) | - | 91.1 | 26.8 | 59.0 | 32.2 |

the properties from all four tiers. Sites 1, 2, 3, 5, 7, and 8 from the *Most Used Websites for Mathematics Education* list provide materials that are aligned with the website uses found in Tier 1 of the *Website Use Survey*. Sites 2, 3, 4, 7, 8, 9, 10, 11, and 12 from the list provide materials that align with Tier 2. Sites 1, 2, 4, and 6 from the list provide materials that align with Tier 3. Finally, sites 2 and 3 from the list provide materials that align with Tier 4.

Teachers were asked who would be using the resources found on the list of *Most Used Websites for Mathematics Education.* A weighted average was used to compile the percentage of teachers identifying the four given categories as potential end-users for the 12 sites. Using data analyzed further in the discussion section, the calculated percentages combine information from the *Most Used Websites in Mathematics Education* and the *Website Use Survey* tables. The *Teacher-Identified End-users* table reveals these percentages. Note that the top line of the end-user table represents the cumulative results from all tiers.

## Discussion

### *Teachers: Primary End-users of Mathematics Education Sites*

Teachers overwhelmingly see themselves as the primary end-users for the variety of mathematics websites found in their *Most Used Websites*. They perceive students as using the websites for in-class activities mostly in relation to high stakes testing and standards related material. Students were perceived to use the sites as references far more frequently than as a part of in class activities. Parents were viewed as end-users less frequently than students; however, both peaked in the same tier (2) with those sites that dealt with student materials and interactivity.

### *Digital Capabilities Not Fully Exploited*

The *Website Use Survey* shows teachers use the websites more for instructional planning than accessing any of the unique capabilities these digital resources provide. This confirms the Russell et al. (2003) findings that K-12 educators use technology for the preparation of teaching. A large percentage of the teachers were facile with social networking technology, which includes the features typical of and unique to digital resources like networking, hyperlinks, photo and video sharing, etc. However, these teachers do not make use of websites that offer these types of features in their professional lives. Many of the mathematics education websites provide text with static embedded figures. Notable exceptions include the applets available through Illuminations and NLVM, and the input/feedback worksheets on AAA Math. None of the websites seemed to tap into the power of hyperlinking that is seen on popular websites such as Facebook and Wikipedia.

### *Inconsistencies Related to State Assessment/National Standards*

Teachers saw their students using Tier 3 sites, sites related to standards and state assessment, more than other types of sites for their in-class activities. In addition, the third most frequently used site of the *Most Used Websites* was the New York State Regents Prep site with a mean of 4.67 (SD = 1.03). However, when asked on the *Website Use Survey* about providing examples and practice problems for students on the state mathematics assessment exam or about getting information on state mathematics assessment instruments/expectations, these items received relatively low means of 2.20 (SD = 1.33) and 1.94 (SD = 1.24), respectively.

Further, in the *Teacher-Generated Items* table, the teachers indicated that state standards played a higher role than national standards in their decision to use technology in the classroom. With a mean of 3.07 (SD = 1.22) versus 2.00 (SD = 1.20), the state standards were ranked a full point higher than the national standards. Despite this, there was a marked absence of the New

York State Department of Education site on the initial list of the 49 best websites, even though this site was made available to the teachers via presentation and as a part of the course's homepage as one of the key external links. Moreover the 12 *Most Used Websites* included three national standards-based sites (1, 2, and 4) but only one state site (Regents Prep), a site that deals directly with high stakes testing.

*Limitations of Study/Future Work*

The research team acknowledges the limited scope of the homogeneous population involved. Transferability of the study is high and as such future work should focus on the size of, and heterogeneity of, the sample. This study serves as a first look, a catalyst, for others to investigate how the first wave of digital native mathematics teachers make use of and disseminate digital resources. Despite the fact that many of the obstacles for technology implementation presented by Cuban et al. (2001) have been overcome, we are still seeing the ad hoc applications of technology that have further sustained traditional teaching practices. The importance of this study is to caution teacher educators against making assumptions that future and novice mathematics teachers' digital facility implies they will fully exploit the digital capabilities of online resources.

# A PROBLEM BASED ON-LINE MATHEMATICS COURSE AND ITS AFFECT ON CRITICAL THINKING, REASONING SKILLS AND ACADEMIC ACHIEVEMENT

Beth Bos
Texas State University, San Marcos
bb33@txstate.edu

*Teaching students to reason and use high-order thinking skills has been problematic for many years. With innovative thinking and problem solving skills becoming the main stay for success in today's society this study looks at whether critical thinking, reasoning skills, and academic achievement are affected by the use of a hybrid on-line problem-based mathematics course.*

## Objective or Purposes of the Study

In current national and international educational research there is a widespread acceptance that critical thinking development is an important dimension of education (Meadows, 1996; Paul et al., 1995; Perkins, 1993; Gadzella et al., 2006). David H. Jonassen, Chad Carr, and Hsiu-Ping Yueh (1998) believe that rather than using the power of computer technologies to disseminate information, they should be used in all subject domains as tools for engaging learners in reflective, critical thinking about the ideas they are studying.

This study examines students who participate in a hybrid (teacher supervised) on-line technology-based mathematics course with an emphasis on real-world problem solving (TBC). The purpose of this research is to determine if a relationship exists between critical thinking, reasoning skills and student achievement as indicated by the Test of Everyday Reasoning (TER) and Texas Assessment of Knowledge and Skills (TAKS) Test in TBCs. Specifically, we looked at changes in critical thinking skills and reasoning skills, (analysis, evaluation, inference, inductive and deductive reasoning) after using a TBC with a pre-post test model. We also looked at differences in scores according to gender and ethnicity to examine their roles as factors impacting critical thinking and reasoning.

## Theoretical Framework

The National Council of Mathematical Teachers (NCTM) emphasizes the importance of reasoning and sense making in the Process Standards: Problem Solving, Reasoning and Proof, Communication and Representation. All are interlinked and essential in the teaching and learning of mathematics (NCTM, 2000). Yet the report of the Programme for International Student Assessment (2007) suggests that United States students are lagging in their ability to apply mathematics "to analyze and reason as they pose, solve and interpret problems in a variety of situations" (p. 7).We know that globalization and the rise of technology are presenting new economic and workforce challenges (Friedman, 2006). The traditional mathematics curriculum is not sufficient for students entering many fields (Ganter & Barker, 2004). According to the Task Force on the Future of American Innovations 2005, the Committee on Science, Engineering and Public Policy 2006, and Tapping America's Potential 2008, the United States is in danger of losing its leadership position in science, technology, engineering, and mathematics.

In light of what we know about learning, the computer and other technology when used as tools for meaningful problems is a reasonable method for engaging students in problem solving and critical thinking (Muir, 1994; Peck & Dorrricot, 1994). Studies suggest that research interests need to focus on designing computer environments that foster a disposition for critical thinking (Facione, Facione, & Sanchex, 1994; Taube, 1995; Wiburg, 1996). This restructuring of the classroom includes the use of computer to provide active learning, authentic tasks, challenging work, complex problem solving, and higher-order thinking skills (Dalton & Goodrum, 1991; David, 1993).

This study examined students who participated in a technology-based mathematics course with an emphasis on real-world problem solving (TBC). The real-world problems were based on the following problem-based learning (PBL) criteria:

- Problems engage students; they provide a meaningful, authentic context for problem solving (Blumenfeld, et.al.,1991; Van Haneghan et al., 1992), and students have meaningful input into a process or solution (Torp & Sage, 1998).
- Problems allow knowledge to be a tool; students learn what it is for and when and how to use it relative to the context in which it is acquired; this facilitates recall and utility in new problem situations.
- Problems include multiple assessments that will help students build learning on prior knowledge and challenge misconceptions (National Research Council, 2000).
- Problems require students to apply understanding versus apply step-by-step algorithms or unrelated calculations (Wiggins & McTigue, 2005; National Research Council, 2000); the focus is “doing with understanding” (Barron et al., 2000).
- Students learn from others' insights, articulating arguments will help students clarify their own thinking (Wiggins & McTigue, 2005). Support structures help focus students' attention, students learn to research the information they need to know (Torp & Sage, 1998).

The first research question is to determine if students’ reasoning skills, using TER, predicts academic achievement, as shown by TAKS Mathematics Test, when using TBC. Based on the studies of Yeh and Wu (1992) and Frisby (1992), there is a high correlation between critical thinking and academic performance. Yet the findings of the Third International Mathematics and Science (TIMS) study indicate the correlations between critical thinking and school achievement were not considered significant. Therefore, we believed these contradicting results require additional investigations in this area.

The second research question is: How does TBC affect academic achievement as shown by the TAKS Mathematics Test? Due to the above stated research, we believe academic achievement improves significantly with the use of TBC.

The third research question: How does the TBC environment affect students’ abilities to analyze, evaluate, make inferences, and reason inductively and deductively, as indicated by TER? We believe there is evidence to believe that the ability to analyze, evaluate, make inferences and reason inductively and deductively improves significantly with the use of TBC. We looked at overall results as well as test specific results; and when significant, we looked at the effect of gender and ethnicity.

## Method

*Design*

We examined the relationship between critical thinking and reasoning skills as determined by the TER and mathematical achievement as determined by TAKS Test for Mathematics to determine predictability. A regression was used to determine this relationship.

A quasi-experimental pretest-posttest control-group research design was used to test the hypothesis of the study that the use of TBC would affect critical thinking, reasoning skills and academic achievement.

*Participants*

186 students from a large urban/suburban school district in the Greater Dallas area enrolled in algebra or geometry were included in the study. The study involved four schools, a middle school and three high schools. Students ranged from 8$^{th}$ graders to 10$^{th}$ graders, and students from a gifted and talented program, to on-level students. Student's ethnicity varied as well as socio-economic standing. The study groups represented a cross section of students from a suburban/urban school district. Students were divided into two groups, a control and treatment group.

*Instrumentation*

The TER from California Critical Thinking Skills Test series was used to measure the dependent variable, ability to analyze, evaluate, make inference, and use inductive and deductive reasoning. Subsequent studies have been conducted to validate the test's usage (Facione, 1990a; Giancarlo, 1996; Ricketts, 2003). The theoretical framework for the critical thinking part of this study is supported by the Delphi study of Peter Facione (1990a). The TER is designed for test takers in secondary school or the first two years of post secondary education, and for adults of all ages in the general population. The TER is a 35 item multiple choice test that is administered in 50 minutes. The Flesch-Kincaid Readability Level is 6th Grade. No specialized content knowledge is required. Test questions engage the test-takers' reasoning skills using familiar topics and contexts. Different questions progressively invite test-takers to analyze or to interpret information presented in text, charts, or images; to draw accurate and warranted inferences; to evaluate inferences and explain why they represent strong reasoning or weak reasoning; or to explain why a given evaluation of an inference is strong or weak

The content validity refers in general to how the specific items comply with two standards: (a) if the items represent the entire set of possible test items within a specified domain and (b) if 'sensible" methods of test construction are employed. TER complies with (a) standard of representation of all possible test items since every item of TER was carefully selected for its theoretical relationship to the Delphi Critical Thinking conceptualization. In regard to standard (b) the appropriateness of a multiple-choice test format to measure critical thinking must be established. Authors of measurements texts agree that higher order cognitive skills can validly and reliably be measured by well-crafted multiple-choice items (Haldyna, 1994: 28). Most of the critical thinking assessment experts who participated on the Delphi panel (Facione, 1990a) agree to this point. Furthermore, the construct validity of TER is grounded on the results of relative research indicating that it is strongly correlated (0,766) with "California Critical Thinking Skills Test" (CCTST) (Facione et al., 2002; 1990b; 1990c; 2001).

In the test manual (Facione, 2001, p. 16) four separate Kuder-Richardson 20 coefficients are presented as a statistical evaluation of the internal consistency of TER derived from four different samples which range from 0,72 to 0,89 (N=145, KR-20=0,78; N=201, KR-20=0,76; N=582, KR-20=0,72; N=113, KR-20=0,89).

The TAKS Mathematics Tests were used to determine mathematical achievement, another dependent variable. Content validity for this instruments is reviewed each year and includes an annual educator review, revision of all proposed test items before field-testing, and a second annual educator review of data and items after field-testing. In addition, each year panels of recognized experts in the fields of mathematics meet in Austin to critically review the content validity of each of the high school level TAKS assessments to be administered that year. This critical review is referred to as a content validation review and is one of the final activities in a series of quality-control steps designed to ensure that each high school test is of the highest quality possible. For internal consistency, the Kuder-Richardson Formula 20 was used with reliabilities in the.80s and.90s (Texas Education Agency, 2008). The standard error of measurement was calculated "using both the standard deviation and reliability of test scores and represents the amount of variance in a score resulting from factors other than achievement" (Texas Education Agency, 2008).

*Treatment*

The Experiment Group received instruction in a self-enclosed classroom where each student had access to a portable laptop. The students followed the curriculum as provided by the on-line program which was problem-based, modeled problem-solving strategies and heuristic thinking, and used concepts as tools. The curriculum followed the state mandated Texas Essential Knowledge and Skills objectives. Students were tested using TER during the first six week session and tested again using TER during the sixth six week session.

The Control Group also received instruction in a self-enclosed classroom according to the district curriculum that followed the state mandated Texas Essential Knowledge and Skills objectives. Teacher directed lessons were followed by guided practice that was then taken home to be completed as homework.

The TAKS test was given to both groups of students according to their grade. The ninth graders took the TAKS mathematics test for ninth graders and the tenth graders took the TAKS mathematics test for tenth graders in April of 2007.

*Data Analysis Procedure*

When evaluating the TER and the TAKS Test scores for predictability, a regression was used. The data collecting procedures described in the previous section were analyzed using Analysis of Covariance procedures in which the dependent variable was critical thinking and reasoning skills: analysis, evaluation, inference, deductive, and inductive reasoning; and academic achievement. The Control Group served as the covariant. The ninety-five percent confidence level ($p$ <.05) is the criterion for determining statistical significance. The criterion level for educational significance is one-third a standard deviation ($d$ = 0.33) (Cohen, 1988).

## Results

The first research question in study asks: Do students' abilities to analyze, evaluate, make inferences, and use inductive and deductive reasoning as indicated by the TER predict student achievement as shown by the TAKS 9$^{th}$ Grade Mathematics Test when using a TBC. The study tested the following directional research hypothesis: Students' abilities to analyze, evaluate, make inferences and use inductive and deductive reasoning as indicated by the Test of Everyday Reasoning can predict student achievement as shown by the TAKS test when using a TBC. The results obtained when the data relevant to this hypothesis were analyzed using a regression are shown below.

Table 1.
*Regression Analysis Summary for Test of Everyday Reasoning Predicting Texas Assessment of Knowledge and Skills Test*

| Variable | *B* | *SEB* | β |
|---|---|---|---|
| Ninth Grade Mathematic Texas Assessment of Knowledge and Skills Test | .58 | .08 | .54 |

Note: $R^2$ = .29 ($N$ = 144, $p$ < .001)

Students' ability to analyze, evaluate, make inferences, use inductive and deductive reasoning as shown by the TER significantly ($p <$ .01) predicted academic achievement as shown by the TAKS 9th Grade Mathematics Test, β= -.54, $N$(144) = 7.56. The change in TER scores also explained a significant proportion of variance, $R^2$ = .29, $F$(1, 143) = 57.20, $p$ < .01.

The second research question posed by the study: How does TBC affect academic achievement as shown by the TAKS Mathematics Test? The study tested the directional research hypothesis: Student's academic achievement as shown by the TAKS Mathematics Test showed statistically significant improvement after using TBC. The third research question in study asks: How does the TBC environment affect students' abilities to analyze, evaluate, make inferences, and reason inductively and deductively, as indicated by TER? The study tested the following directional research hypothesis: Students' abilities to analyze, evaluate, and make inferences, use inductive and deductive reasoning, shown by the Tests of Everyday Reasoning indicate statistically significant improvement after using TBC. The results obtained when the data relevant to this hypothesis were analyzed are shown below in Table 2 and Table 3.

Table 2.
*Mean Scores, Standard Deviations, and Analysis of Covariance (ANCOVA) for Measures of Mathematical Achievement and Test of Everyday Reasoning*

| | Control | | | | Experimental | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Pretest | | Posttest | | Pretest | | Posttest | | ANCOVA | |
| | *M* | *SD* | *M* | *SD* | *M* | *SD* | *M* | SD | *F*(1, 183) | *d* |
| TAKS Mathematics | 38.21 | 6.31 | 40.78 | 5.51 | 39.92 | 7.84 | 43.12 | 6.33 | 90.42** | .37 |
| TER | 14.85 | 8.10 | 16.79 | 7.72 | 20.02 | 5.86 | 21.65 | 6.23 | 21.14** | .16 |

Note: TAKS = Texas Assessment of Knowledge and Skills Mathematics Test.
TER = Tests of Everyday Reasoning. **$p$ < .001

As shown in Table 2, the Analysis of Covariance yields an F- ratio of 90.43 for Texas Assessment of Knowledge Skills that was statistically significant ($p$ < .001) and had an effect size ($d$ = +0.37) that is considered educational significant. The analysis of covariance also yields an F score of 12.14 for the TER that was statistically significant ($p < .001$) and has an effect size ($d = +0.16$) that is considered small (Cohen, 1988). Both ethnicity and gender were analyzed for statistical significant and none were found.

Table 3.
*Mean Scores, Standard Deviations, and Analysis of Covariance (ANCOVA) for Groups Tested for Measures of Critical Thinking and Reasoning Skills*

| | Control | | | | Experimental | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Pretest | | Posttest | | Pretest | | Posttest | | ANCOVA | |
| | *M* | *SD* | *M* | *SD* | *M* | *SD* | *M* | SD | *F*(1, 174) | □ |
| Analysis | 4.32 | 1.74 | 4.94 | 2.19 | 5.43 | 1.74 | 5.80 | 1.66 | 12.42* | .09 |
| Inference | 6.53 | 3.39 | 8.59 | 3.17 | 8.53 | 2.94 | 9.43 | 2.86 | 28.90** | .37 |
| Evaluation | 4.05 | 2.96 | 4.16 | 3.05 | 6.04 | 2.18 | 6.39 | 2.39 | 1.87 | .02 |
| Deduction | 8.21 | 4.59 | 9.27 | 4.07 | 10.45 | 3.69 | 11.47 | 3.54 | 19.25** | .37 |
| Induction | 6.81 | 3.83 | 7.46 | 3.84 | 9.53 | 2.69 | 10.22 | 3.16 | 10.56* | .15 |

* $p < .01$ ** $p < .001$

A descriptive analysis as part of the Multivariate Analysis of Covariance was conducted to evaluate the hypothesis that scores improved for the TER's subtests, after using TBC. The dependent variable was the change in TER subtest scores before and after the use of TBC. The ANOVA was significant for subtests: Analysis $F(1,174) = 12.42$, $p < .01$, Inference $F(1,174) = 28.90$ $p < .001$, Deduction $F(1,174) = 19.25$, $p < .01$, and Induction $F(1,174) = 10.56$, $p < .01$. The subtest Evaluation did not show significance. The strength of relationship between the treatment subtests and the change in scores, assessed by □ was strong for Inference accounting for 37% of the variance of the dependent variable and Deduction accounting also for 37% of the variance of the dependent variable. The strength of relationship was moderately strong for Analysis accounting for 9% of the variance variable and Induction also accounting for 15% of the variance of the dependent variable. The strength of relationship was low for Evaluation accounting for 2% of the variance variable.

## Conclusions and Discussions

The findings of this study suggest that a TBC environment can stimulate critical thinking and reasoning skills and improve academic achievement. Of the specific skills studied, evaluation, perhaps the most difficult to achieve and measure, needs additional support in a TBC. It is believed by the researchers that more rationalizing through discourse within the context of the problems would affect student's ability to evaluate and function at a high-order thinking level. Nevertheless, this study suggests academic achievement improvement can occur in a TBC environment that is educationally significant, and the authors believe this learning environment deserves further study and emphasis in a growing technological world.

# USING TECHNOLOGY TO SUPPORT COGNITIVE ACTIVITIES AND TO EXTEND COGNITIVE ABILITIES: A STUDY OF ONLINE MATHEMATICS LEARNING

Douglas McDougall
OISE/ University of Toronto
dmcdougall@oise.utoronto.ca

Zekeriya Karadag
OISE/ University of Toronto
zkaradag@oise.utoronto.ca

*This study investigates secondary students' technology use while solving mathematics problems in computer environments. The students explored their math problems in an online dynamic mathematics environment and performed all solution steps in the computer environment. Their work were recorded by using a screen capturing software and analyzed in terms of using technology as a cognitive tool, more specifically using technology as a partner and as an extension of self. It is documented that the students participated in this study used technology in both ways and that these two types of use are inversely related.*

## Introduction

Recent innovations in technology challenge researchers, math educators, and policy makers with new ways of thinking about mathematics teaching and learning by using technology. In a report prepared for the Ontario Ministry of Education, the role of technology in mathematics classrooms is described as "enabling easier communication, providing opportunities to investigate and explore mathematical concepts, and engaging learners with different representational systems which help them see mathematical ideas in different ways" (Suurtamm & Graves, 2007, p. 50) Their report proposes to connect practice and research in Ontario context and projects onto the global. The focus of their description lies on the use of technology in investigation and exploration of mathematics which is rather challenging in traditional environments. In other words, they describe technology as a tool to extend the current learning opportunities. They also point out to improve students' understanding of mathematical ideas by "different representational systems" such as symbolic and visual representations and the connection between them. The connection between various representations is known as linked representation since early 90s (Kaput, 1992).

Similarly, the Ontario Ministry of Education (2007) delineates the use of technology by suggesting: "students can use calculators and computers to extend their capacity to investigate and analyse mathematical concepts and to reduce the time they might need otherwise spend on purely mechanical activities" (Ontario Ministry of Education, 2007, p. 19). It appears that technology in their description is conceived as a tool to extend students' abilities on the tasks which are challenging or impossible in paper-and-pencil environments. These tasks could be to perform complicated arithmetic operations or to draw complex graphs.

Moreover, the importance of various representations and the connection among these representations are addressed as a goal:

> Representing mathematical ideas and modeling situations generally involve concrete, numeric, graphical, and algebraic representations. Pictorial, geometric representations as well as representations using dynamic software can also be very helpful. Students should be able to recognize the connections between representations, translate one representation into another, and use the different representations appropriately and as needed to solve problems. … When students are able to represent concepts in various ways, they develop flexibility in their thinking about those concepts" (Ontario Ministry of Education, 2007, p. 21).

However, the practice of these recommendations is rather challenging. Some of these challenges are: “limited access to technology, lack of teacher understanding or confidence in using technology, and a lack of technology leadership in some school boards” (Suurtamm & Graves, 2007, p. 55). As seen in the report, the main focus is still on the technology use because limited access to technology could be solved in time. However, teachers’ concern about the use of technology seems to remain a challenge for awhile. Teachers in school experience difficulty in understanding the proper way of using technology and in connecting the technology to the current topics of mathematics.

These recommendations and teacher concerns lie on one side of the coin. What about the other side of the coin? How do students cope with technology and more importantly, how do they use technology in mathematics? Despite the theoretical and practical concerns in integrating technology into mathematics education, students widely use technology in their daily life with an increasing rate. Because these students were born in the information age, they are confident enough in using technology; and even they have no idea about a life without technology, say internet and computer. There is no doubt that they can use technology effectively, and many studies document that they use technology as anticipated (Artigue, 2002; Izydorczak, 2003; Karadag & McDougall, 2008; Kieran, 2007; Kieran & Drijvers, 2006; Lagrange, 1999; Moreno-Armella & Santos-Trigo, 2004; Moyer, Niexgoda, & Stanley, 2005). However, the question is whether or not they use technology in mathematics when they are alone. A further question could be if they use technology as recommended in the literature.

Therefore, we designed this study to track students’ technology use while they are solving mathematics problems. The research question of this study was to explore how secondary school students use technology while solving mathematics problems. The following sections provide a theoretical framework on the use of technology, a detailed description of the study, a detailed presentation of the data and the results, and a discussion of the results and the research.

## Theoretical Framework

Research and theoretical discussions about the use of technology in mathematics education have been mainly focused on the cognitive tools (Galbraith, 2006; Pea, 1985; 1993; Perkins, 1993; Salomon, 1985; 1993; Sweller, 1999; 2003). Salomon (1993) describes the effective use of technology as “a characterization of computer tools (as contrasted with more independently functioning programs and intelligent tutors) as not being autonomous in their operation, thus requiring the active operation by and mental involvement of students” (p. 193). Many scholars believe that computers change “how effectively we do traditional tasks, amplifying or extending our capabilities, with the assumption that these tasks stay fundamentally the same” and some others assert that “a primary role for computers is changing the tasks we do by reorganizing our mental functioning, not only by amplifying it” (Pea, 1985, p. 168). In another paper, Pea (1993) states that “whereas amplification suggests primarily quantitative changes in accomplishments, what humans actually do in their activities changes when the functional organization of that activity is transformed by technologies” (p. 57).

Salomon (1993) identifies two types of computer use in education: performance-oriented tools and pedagogic tools. The performance-oriented tools are used as intelligent partners, and “cognitions become 'distributed' in the sense that the tool and its human partner *think jointly*” (Salomon, 1993, p. 182). He seems to assume that computers have thinking mechanisms such as artificial intelligence and criticizes this type of cognition share. He argues that this way of cognition share will increase students' performance during the partnership and that no cognitive residue and improvement in students' abilities will be obtained when the technology is removed. That is why he calls the outcomes obtained from this type of technology use as the "effects with technology" (Salomon, 1993; 1985).

Furthermore, he describes the pedagogic tool as an "intellectual partnership of the division of labor" (p. 182) so that computer does "tedious, labor and memory intensive lower level processes that often block higher order thinking" (p. 181) and leaves higher order thinking such as drawing conclusion, making conjectures, reasoning, thinking causal relationships, and testing conjectures to the learner. Any labor can be shared but thinking should not be shared with any type of tools. He also argues that performance-oriented use can be regarded if a cognitive residue in the human partner is left. Additionally, he suggests that the performance-oriented tools must allow their human partners to function at a higher level and to enter increasingly higher levels of new partnership with themselves at later stages.

The use of virtual manipulatives falls into the pedagogic tools whereas the use of Computer Algebra Systems (CAS) as a black box could be an example of the performance-oriented tool. However, the use of CAS to create patterns and to make numeric and symbolic relationships explicit has to be considered as an example of the pedagogic tool.

Pea (1993) criticizes the contemporary practice of technology use by arguing “many schools, technology developers, and researchers now use technologies to ‘enhance’ education by making the achievement of traditional objective more efficient” (p. 71). He also states that “objectives for education are not reconceptualized; the computer is conceived as a means for ‘delivering’ key components of instructional activity not for redistributing intelligence and new uses of students’ potentials for activity and participation” (Pea, 1993, p. 71). He seems to suggest more advanced use of computer than performing only complicated numeric and symbolic calculation or drawing graphics. Rather than using computers in labor and time intense purposes only, he suggests incorporating computers into our thinking processes. Dynamic learning tools allowing multiple representations and a linkage among these representations fall into this category because they visualize mathematization and make mathematics explicitly visible for students.

Galbraith (2006) provides a more general framework for the use of technology and identifies four types of technology use in mathematics education: technology as a master, technology as a servant, technology as a partner, and technology as an extension of self. The first category, technology as a master, points out the use of technology as a black box, meaning that students do not know why a certain outcome appears and use what is provided by technology as it is. The second type, technology as a servant, describes the use of technology as a tool to save time and make the things happen easier. The third type of use, technology as a partner, includes the use of technology to support the user’s cognitive activities such as keeping some information in databases and serving it when it is needed and correcting typing or calculation mistakes. The use of technology as extension of self is the fourth type and describes to use technology to extend students’ cognitive abilities and to improve their understanding.

In this study, we followed the framework provided by Galbraith (2006) and focused on the last two types of technology use. These two types of technology use, such as a partner and as an extension of self, fit into the definitions provided by Salomon (1993) and Pea (1993).

## Methodology

In this qualitative research, five Grade 12 students were recruited, and pseudonyms are used instead of their original names. We trained the students on how to use software, Geogebra and

Wink, via email conferencing. The Geogebra is a free, online, and user-friendly software, and the students used Geogebra to explore their mathematics problems. The Wink is also a free and user-friendly software, and the students used this software to record their problem solving processes performed in computer environments.

The students were given four assignments each containing four open-ended problems to be explored in the Geogebra. They recorded their problem solving processes by using Wink. Once they recorded their solutions, they put them on CDs and delivered to the researchers. We used the frame analysis method to analyze the data gathered in the study. The frame analysis method is a microgenetic approach aiming to focus on the development of a task performed in a very short period of time. Since we asked students to set up the software recording rate as two frames per second (24 frames per second in regular video recording), we were able to focus on each half second of their problem solving.

The study summarized in this paper is part of a larger study. The data was analyzed both qualitatively and quantitatively in the main study. However, since the focus of this paper is related to the technology use, we present mostly quantitative results and refer qualitative results in the main study as needed.

## Results

As a first step in the frame analysis method, we described and interpreted students actions performed on the computer screen. We performed two types of analyses on these descriptions. First, we documented the number of their technology use as a partner in each assignment, and then we calculated the period of their technology use as an extension of self. These analyses and the results obtained from analyses are explained in detail in the following sections.

*Use of Technology as a Partner*

The use of technology as a partner means that technology is used to provide some specific information when needed, to correct writing and calculation errors, or to extend the student's memory. We use this term to describe the use of technology to record information such as using a notepad, to keep information in a particular format such as using Geogebra as a picture, and to benefit from specific features of computer and software such as spell check and auto-correction.

We developed a specific index to describe the level of technology use as a partner. We counted the number of times the students were using these features in an assignment and divided this number by the number of the frames of the assignment to create the index. Since the numbers were very small, we multiplied them by 1000 to round them off to the nearest integer. Thus, the index of technology use as a partner is defined as:

$$I = \frac{\text{The number of the technology use as a partner in an assignment}}{\text{Total number of frames in that assignment}} x1000$$

After analyzing the data according to the formula, we tabulated the results to see the full picture of the data (table 1).

Table 1. *The Index of Technology Use as a Partner*

| | Teresa | Ursula | Ru | Andrea | Nancy | Average |
|---|---|---|---|---|---|---|
| Assignment 1 | 5.18 | 7.76 | 0.8 | 6.54 | 6.65 | 5.39 |
| Assignment 2 | 4.46 | 6.24 | 5.68 | 5.39 | 8.26 | 6.01 |
| Assignment 3 | 2.06 | 1.84 | 2.48 | 6.92 | 2.16 | 3.09 |
| Assignment 4 | 4.62 | 2.73 | 3.07 | 6.51 | 6.53 | 4.69 |

The lower values of index denote less use of technology as a partner whereas higher values mean more frequent use. The less use of technology as a partner could be caused by various reasons including using in a more advanced way and being unfamiliar to use technology in mathematical purposes. For example, the averages of the assignments illustrated in the last column reveal that the index values vary from 3.09 (third assignment) to 6.01 (second assignment). It appears that these students used technology as a partner more in the second assignment than the third one. This difference could be explained by the difficulty level of assignments. The third assignment contained more challenging problems and demanded more exploration. This result may suggest that the index of technology use as a partner could be task-dependant.

Teresa’s and Andrea’s patterns seem to be steadier whereas Nancy’s pattern has more fluctuations. It can be interpreted that Teresa’s and Andrea’s number of use of technology as a partner remains similar whereas Nancy’s use varies with assignments. There is a fall in the Ursula’s index values in the third and fourth assignments. This fall could be explained by her familiarity with the medium and becoming less dependant to this type technology use as she gets experienced.

The data in the first assignment illustrates that Ru’s index is considerably lower than others’ indices. Interestingly, Andrea’s index in the third assignment is the second unusual case and considerably higher than others’. In the next section, we will provide a possible explanation for these unusual sharp changes in the patterns.

*Use of Technology as an Extension of Self*

Galbraith (2006) describes the use of “technology as an extension of self” as “the partnership between technology and student merging to a single identity” (p. 286) which is highest intellectual way to use technology. This type of technology use extends the user’s mental thinking and cognitive abilities because technology acts as a part of user’s mind. For example, linked representation (Kaput, 1992) between symbolic and visual representation could be a relevant example for this type of use because manipulations done in one of the representations affect the others.

In our study, the features of Geogebra serve this type of use and extend students’ cognitive abilities to beyond what they usually do in symbolic and paper-and-pencil environments. This type of use is a continuous action, occurs in a period of time, compared to the use as a partner, and it is quite easy to state accurately when the action starts and ends. That is why we measured the time spent and took the percentage of this period of time with respect to the total time spent in that assignment by a particular student to create a new index.

$$P = \frac{\text{time spent while using technology as an extension of self}}{\text{time spent in that certain assignment}} x100$$

As a result, we created a table to see the full picture of the data gathered (table 2).

Table 2. *The Percentage of Technology Use as Extension of Self*

| | **Teresa** | **Ursula** | **Ru** | **Andrea** | **Nancy** | **Average** |
|---|---|---|---|---|---|---|
| Assignment 1 | 7.7 | 10.7 | 16.9 | 12.9 | 17.5 | 13.14 |
| Assignment 2 | 11.5 | 12.7 | 14 | 16.4 | 12 | 13.32 |
| Assignment 3 | 27.4 | 22 | 23.1 | 15.9 | 34.8 | 24.64 |
| Assignment 4 | 25.8 | 34.1 | 31.8 | 24.2 | 33.3 | 29.84 |

The table provides an overview and a general idea about results and reveal that the percentage derived from the data is both person- and assignment-dependant. For example, a particular student having a lower index in a row may have a higher index in the other rows comparing to her friends.

The student who has a high index value in a certain assignment uses technology as an extension of self for a longer period in that particular assignment. The reasons affecting this longer use could be students' familiarity with using technology and confidence in technology use and task's demand for exploration. Students' familiarity in technology use seems to have a significant effect because the average of the index values increases with the number of assignment. In other words, the students used technology longer in later assignments.

It appears that the students all used the technology in a similar way in the second assignment because the pattern remains steady. The reason could be the nature of the problems because the problems in this assignment do not require advanced use of technology. The indices in the first and second assignments are smaller than the others. This result is reasonable because the students were becoming more experienced, and they may have become more advanced users of technology in the third and fourth assignments. The percentages of Teresa and Nancy in the third assignment are higher than others. This means that they started to use the technology earlier than others and at a higher level. Ursula's use seemed low at the beginning but she made a sharp increase in the last assignment. Andrea demonstrates an increase only in the fourth assignment. It appears that assignment four appears is the one in which technology is used as an extension of self, due to students experience and they moved to a stage where they could use technology for more advanced purposes.

When these two tables are compared to each other, it appears that the index of technology use as a partner could be inversely related to the percentage of the technology use as extension of self. This inverse relation seems unsurprising because the more students use technology for advanced purposes, the less they may use technology for novice purposes. That is, as they become confident with technology and familiar with its features, they may prefer using technology for more advanced purposes. This may explain Ru's and Andrea's unusual index values in technology use as a partner which is discussed in the previous section.

## Discussion

Despite the four ways of using technology in education by Galbraith (2006), the use of technology as a cognitive tool has been limited with two ways. These ways of using technology have been described as technology use to support cognitive activities and technology use to extend cognitive abilities (Galbraith, 2006; Pea, 1985; 1993; Salomon, 1985;1993).

In the study, I documented three ways of technology use, two of them being cognitive tools. The first type, which is not related to cognitive activities, is to use technology for writing, deleting, and drawing. This type of use is identified as using technology as a servant (Galbraith, 2006) and was not considered related to the study.

The second type, technology as a partner (Galbraith, 2006), was documented while students were using technology for elementary purposes. These elementary purposes include taking notes, storing notes and images, and spell check feature of the software and served to support the working memory of the students. Sweller (1999; 2003) explains this type of memory support by cognitive load theory. He analyzes the cognitive capacity of working memory and the reasons increasing the cognitive load of the memory and suggests techniques to increase the capacity or to decrease the cognitive load. For example, he suggests that using long-term memory or cognitive tools instead of storing all information in the working memory. The students' use of computer features to store information falls into this category.

The third type of technology use documented in the study was to use technology as an extension of self (Galbraith, 2006). The students used Geogebra to extend their cognitive capacity of imagination, to create mathematical objects, and to manipulate these objects. This type of using technology affected their "nature of understanding mathematics" (Heid, 2005, p. 357) because students perceived graphs and points as living bodies. Instead of describing their properties as a static image or concept, they were describing them as if these objects were moving bodies. Moreno-Armella, Hegedus, & Kaput (2008) identify this effect as an evolution in students' mathematical thinking.

In conclusion, students use technology in various ways. However, we can categorize the ones related to cognitive activities in two main groups based on their roles. These roles include use of technology to support cognitive activities (technology as a partner) and to extend cognitive abilities (technology as an extension of self) and were found inversely related with the other.

# A COMPARISON OF MATHEMATICAL DISCOURSE IN ONLINE AND FACE-TO-FACE ENVIRONMENTS: INVESTIGATING CONJECTURES

Shawn D. Broderick
University of Georgia
sdbroder@uga.edu

Keith R. Leatham
Brigham Young University
kleatham@mathed.byu.edu

*This report is from a study that investigated the similarities and differences of student mathematical discourse in online and face-to-face course delivery systems. Here we focus on similarities and differences between patterns of student mathematical discourse while investigating conjectures. Students proposed their mathematical conjectures and solutions similarly in both environments. However, the rigor of their investigations after such proposals contrasted greatly, with the face-to-face students deliberating and further developing their mathematical ideas more often and in more meaningful ways than the online students. We discuss the implications of these findings for online mathematics education.*

In education today, there are generally two ways students take courses: distance education or face-to-face education. Until recently, the portion of students using distance education has been small. This portion has grown tremendously, however, with the advent of the Internet. Vasarhelyi and Graham (1997) found that in 1993 there were only 93 schools devoted to online learning, but in 1997 the number had jumped to 762. Engelbrecht and Harding (2005) estimated that the e-learning market went from $10.3 billion in 2002 to $83.1 billion in 2006, and projected that it will eventually swell to over $212 billion by 2011.

The growth of online education is due in large measure to its advantages over face-to-face education, as it provides "unique alternatives for reaching larger audiences than ever before possible… traditional or non-traditional, full-time or part-time, and international—who perhaps have had limited access to advanced educational opportunities" (Bartley & Golek, 2004, p. 167). Bartley & Golek further reported that online classes, degrees, and certificates are especially valuable to those with demanding work, family, and social schedules. In addition, online education allows students to spend less time in class, less money on travel, and more time learning at home (Beard, Harper & Riley, 2004).

Although there are many advantages to online courses, there are disadvantages as well. According to Coates, Humphreys, Kane, and Vachris (2004), younger undergraduate students who were found to lack the technological skills and discipline necessary to survive and participate in online courses felt inundated with course demands and soon dropped out. They found that the overall student dropout rate was higher for online courses. Piotrowski and Vodanovich (2000) pointed out that piracy issues are a disadvantage to the online environment because when students submit their work online, there is no way to verify if they are the ones who actually did the work. They also found that there were times when technological problems prevented access to the course materials, pointing out that these issues of piracy and course access often became more of a focus for students and teachers than course content.

## Purpose

Researchers have studied the effectiveness of distance education primarily through measuring student success (i.e., midterm test scores, final test scores, final grades). Such studies tend to report that there is no significant difference with regard to student success between online or face-to-face modes of delivering instruction (e.g., Akkoyunlu & Yilmaz Soylu, 2004; Aragon, Johnson, & Shaik, 2002; Brown, Stein, & Forman, 1996; Cooper, 2001; Ellis, Goodyear, Prosserz, & O'Hara, 2006; Russell, 1999; Smith, 2004). Such studies, however, look almost exclusively at courses that are taught quite traditionally. Traditional face-to-face courses typically feature a teacher lecturing to their students. Afterward, the students go home, do the homework, and learn the mathematics with their notes and book. This format is similar to that of traditional online courses which begin with instruction for the student through a video recorded lecture or other media. Then, after they receive the instruction, the students do the homework, and learn the math with their notes and book. Thus, the role of the student remains the same, regardless of the environment. There is little wonder, therefore, that when researchers compared course grades, the differences between online and face-to-face learning were insignificant—students in both environment were learning the material in essentially the same way.

Consistent with postmodern epistemologies such as social constructivism, reform educators seek to organize their classrooms and lessons in ways that facilitate and make explicit students' construction of mathematical knowledge (Ball, 1993; Lampert, 1990). In such classrooms, students are given opportunities to solve meaningful mathematics problems and to discuss with their peers their solutions and interpretations. This discourse is seen as an intrinsic part of the learning process. Social constructivism has had a huge impact on the way educators envision effective face-to-face classrooms, but its impact on the vision of online education is still largely unknown. Although live chat, email, and discussion boards are avenues that some have used to discuss mathematical ideas and resolve conflicts, there is still relatively little known about the extent to which such avenues have the potential to moderate meaningful mathematical discourse. The purpose of this study was to characterize and to compare the discourse of students as they discussed mathematical tasks online and face-to-face. We used these findings as one way to evaluate the online medium as an alternative to the face-to-face environment. This paper focuses on one particular aspect of student discourse—the investigation of conjectures.

## Theoretical Framework

The NCTM *Professional Teaching Standards* (1991) outlined a vision of the role that students are to fulfill as they discuss mathematics in a reform classroom environment:

> The teacher of mathematics should promote classroom discourse in which students—[1] listen to, respond to, and question the teacher and one another; [2] use a variety of tools to reason, make connections, solve problems, and communicate; [3] initiate problems and questions; [4] make conjectures and present solutions; [5] explore examples and counterexamples to investigate a conjecture; [6] try to convince themselves and one another of the validity of particular representations, solutions, conjectures, and answers; [7] rely on mathematical evidence and argument to determine validity. (NCTM, 1991, p. 45).

In this paper, we focus on how and how often students explored conjectures and solutions in online and face-to-face environments. For us, student mathematical discourse consists of the dialog and mannerisms students use as they converse about and solve mathematical tasks. Additionally, student mathematical conjectures consist of any comment from a student submitted to the group for consideration as a proposal for a part of or the entire solution. In order to understand how students investigated conjectures, we first needed a way to recognize how their conjectures were initiated. As students discussed mathematics, whether online or face-to-face, they began by initiating the problems in the task. This initiating was done in a couple of ways. Sometimes students asked for initial thoughts on how to approach the problem. At other times students first worked on the problem individually then came together to discuss their initial work. After this initiation, students had debates over or gave explanations of how the task could be solved. We revered to this initiation as the making of conjectures and to the debating or explaining as investigating conjectures. Eventually the students agreed on a solution, often through yet more investigation. We referred to this latter stage as making and investigating solutions.

Face-to-face students have the opportunity to initiate problems by negotiating the direction they would take in a mathematical task quickly because they are together in the same room at the same time. They can converse about their initial ideas for the solution of the problem by showing their work and working out their differences in real time. They can make, explain, and negotiate conjectures so all can understand and agree. Eventually, a common idea would surface, which the group takes as their solution. Face-to-face students usually carry out this process one problem at a time, in one sitting, until the task is complete.

In the online environment, all the above things can be done, but it all takes more time to develop. Students are not all together at the same time. Therefore, they intermittently attend to the same process the face-to-face group does in order to complete the task; each phase of the process thus necessarily takes longer to complete. In addition, students usually make and independent decision as to how much of the task they want to complete in the first post to the group. They must achieve a balance of covering enough information, but not too much, in order to have a cohesive discussion. If the right amount of material is proposed as a conjecture for discussion, then the next stage of making and investigating conjectures can go well. In addition, students can formulate explanations and arguments to prove their conjectures as they type out their post before they are entered into the conversation. This formulation thus has the potential to be more coherent and less spontaneous than face-to-face discourse.

Our guiding question for this paper is as follows: What are the characteristics of how students make and investigate conjectures and solutions in the online and face-to-face environment and how do these characteristics compare?

## Methodology

This study compared the mathematical discussions of two lab sections of an Introduction to Calculus class at a large university in the Western United States. One lab section was conducted online and the other face-to-face. Each lab section was composed of about 25 students. The students were divided up into groups of five and given tasks to complete. We collected data from the students' work on three tasks that dealt with derivatives. The online students discussed the task questions using a discussion board. The conversations from the discussion board were saved for analysis. The face-to-face students discussed the task questions in a classroom. Their discussions were video recorded and transcribed for analysis.

We first analyzed the online data for evidence of when students initiating and investigating conjectures and solutions. We noticed and recorded a number of patterns during this initial pass through the data. We built a set of codes from these patterns and then returned to the data and coded them according to those patterns. For example, one such pattern was that when a conjecture or solution was presented, the subsequent comments, or investigations, tended to either state agreement or state disagreement, often in the form of a new conjecture based off the old one. The most apparent characteristic of the investigations that agreed with the initial conjectures was that usually there was no mathematical evidence given to back these claims. We therefore, looked at all cases of initiating and investigating conjectures and analyzed them according to the degree to which mathematical evidence was used to back them up. We used a similar approach to analyze the face-to-face data, using the codes derived from the online data and adding to them as needed.

## Results

*Characterization Of Online Students Investigating Conjectures And Solutions*

Approximately 70% of students' mathematics discussions were coded as either initiating or investigating conjectures or solutions, about evenly distributed between initiating and conjecturing. In only 29% of those investigations did students use mathematical evidence to support or refute the preliminary conjecture or solution. There were three primary approaches that students took when they investigated a conjecture or solution: (1) students posted that they agreed with the mathematical idea, (2) students posted that they disagreed with the mathematical idea, or (3) students posted their own conjecture (whether it be the same or different) without agreement or disagreement with the current conjecture. In each approach students either backed up their response with mathematical evidence or they did not. We now describe each of the three primary approaches according to whether students used mathematical evidence.

*Without mathematical evidence.* Forty percent of the investigations students did online stated that they agreed with the initial conjecture/solution without showing mathematical evidence. They would post single comments like, "I got the same answer!" or "Everything is correct for Parts A and B." In essence students agreed but gave no evidence of *why* they agreed.

The next largest category of how students investigated conjectures without mathematical evidence was when students replied to a conjecture with a new conjecture without stating whether they agreed or disagreed. This was done 20% of the time. For example, a response like, "I think the answer is 48," was common in this category. Although the "I think" provides some evidence that this student was aware that their answer of 48 was different from the previous post, the response gave no indication of why or how the student came to the solution. Other responses in this category merely gave a different solution or conjecture, with no mathematical evidence to back it up, but also with no evidence that the student was even aware of the previous post.

About 11% of the time students' posts were explicit about the fact that they disagreed with a previous post, yet did not provide mathematical evidence for the correctness of their response or the incorrectness of the prior post. For example, one post stated, "Hey! I got almost the same answers as you but I got a 6 instead of an 18 in 1b, but I could be wrong." The post ended here, with no discussion of how the student arrived at "6" or how they thought the other student may have arrived at "18".

*With mathematical evidence*. The most frequent investigation approach that included mathematical evidence was when students offered a new conjecture for the group to consider in place of the old one, without stating explicitly whether they agreed or disagreed with the initial conjecture. They did this 18% of the time. For example, students occasionally borrowed new conjectures from other groups, prefacing their posts with statements like, "Here is how someone else went about doing these problems." Such posts often included some mathematical evidence to back them up, but did not indicate whether the borrowed response agreed or not with the groups' current strand (nor, by the way, did such posts indicate to what extent the borrower agreed with the borrowed conjecture).

Ten percent of the time when students investigated conjectures, they used mathematical evidence to demonstrate why they agreed with the initial conjecture. For example, a student might respond to the initial conjectures from the group by stating, "That is the right way to do it," then go on to elaborate on the procedure and reiterate the perceived correct answers. Finally, there was only one instance in the online discourse where a student explicitly disagreed with an initial conjecture and then used mathematical evidence to back up their argument.

*Characterization Of Face-To-Face Students Investigating Conjectures And Solutions*

Approximately 60% of students' face-to-face discourse was coded as initiating or exploring conjectures and solutions, with exploring making up about 60% of these instances. In 53% of these group explorations, the students used mathematical evidence to support or refute the preliminary conjecture or solution. When students investigated a conjecture or solution, they: (1) agreed with the conjecture or solution without discussing the mathematical evidence, (2) gave clarifications to a conjecture or solution, (3) gave additional explanations to further illustrate conjectures and solutions, (4) agreed with a conjecture or solutions and showing mathematical evidence to support, (5) disagreed with showing mathematical evidence, and (6) disagreed without showing mathematical evidence.

*Without mathematical evidence*. Face-to-face students agreed with proposed conjectures and solutions about 44% of the time without using mathematical evidence. It was usually a brief assessment of the conjecture/solution. The students would usually listen to a conjecture and then think about its correctness. The conjectures made were usually mathematically correct. Usually, all that a student wanted to do was to understand the process, agree with it, and move on. Comments made by students that portrayed this type of investigation were: "Okay," "It sounded good to me," "I agree," "Right," or "Yeah."

The students in this environment disagreed with other's conjectures and solutions with out using mathematical evidence only a few times. For example, a group was working on a task that asked them to find the average rate people arrived on a beach from 3:45 to 4:00 p.m. The group was using an average rate formula given them. Kim began by simply stating her answer of 7.75. She did not say how she got it. Josh stated his as well, 14. He also did not say how he got it. Kevin stated another number considerably higher, 3258. Gary asked Kevin how he got that number and Kevin went into a procedural description of how he got it using operations without explanations. In the end, Gary seemed to have been successful in copying down the procedures Kevin used, but was still left with questions like why Kevin used certain values in the denominator of the formula and what they represented in the problem.

*With mathematical evidence*. The most frequent way (22% of the time) students in the face-to-face environment investigated conjectures using mathematical evidence was to make clarifications on proposed conjectures or solutions. There were times when certain students in the group did not understand where another student came up with their conjecture or solution. The students then investigated the conjecture further by making clarification statements or asking clarification questions. An example of this type of investigation began with Jayden making a conjecture about the proper procedure in a specific calculation pertaining to the problem:

Jayden: And then you would have to put 60 over point 5.

Gary: Did you put 60 times 2.5 or did you say point 25?

Jayden: Sixty over point 5. Oh, 16 times point 25.

After Jayden made his conjecture, Gary asked a clarification question. This caused Jayden to reexamine his conjecture and investigate it further. After he did, he realized that he had made an incorrect operation.

The next most frequent way (17%) students investigated conjectures face-to-face using mathematical evidence was to provide an additional explanation of the conjecture either for the benefit of themselves or another member of the group. An example that illustrates this came from when the group had been struggling to determine the average rate. They approached their average rate calculation by finding the average distance traveled divided by the time that elapsed over the distance change. They discussed several intervals to use for the time. Kim made a conjecture that they needed to focus on the meaning of the variables in their formula for average rate and reexamine their computations they used from it. Jayden gave the following additional explanation to show what they were not getting right and what the average rate time interval should be. “So, it’s going to be between 1.5 and 2. We were doing it between zero and 1.5. We need to be doing it between 1.5 and 2 cause that’s the last half-second [of the time interval].” The students were previously working with the incorrect interval and thus obtaining results that did not make sense (i.e., values that were obviously too fast or too slow). Jayden’s additional explanation, which investigated the conjecture to reexamine their computations, called the group’s attention to the error and its resolution.

Students in the face-to-face environment simply agreed with the group’s conjectures and solutions and followed their agreement with mathematical evidence 8% of the time. Students would make comments saying, “Yes, it is correct because…” and then explain why in response to a numerical answer.

With a frequency of 6%, students investigated conjectures by using mathematical evidence to back up a disagreement with the group’s or student’s conjecture or solution. Here is an example where Kim, Jayden, and Ashley were discussing a question regarding the path of a rocket. Kim was asking about the moment when the rocket reaches its highest point during the flight:

Kim: Ok, so is that 2 seconds?

Jayden and Ashley: Eight point five.

Ashley: Wait, that’s for [Question] 2, right?

Jayden: Yeah.

Kim: Why would you say it’s 8.5?

Jayden: Because the velocity is positive until that point. Because this is the graph of the derivative, not, it’s not a normal function. If it were a graph of distance over time, it would be one thing but it’s not showing the distance of the rocket, it’s showing the velocity.

Jayden and Ashley disagreed with Kim’s conjecture. Then Ashley made sure that Kim was on the same question that they were on. Kim asked why they thought the answer was 8.5 (rather than 2) and Jayden used mathematical evidence to back up his assertion.

## Discussion

With respect to mathematical discussion in the online and face-to-face environments, students in both environments investigated mathematical conjectures about the same amount of time. However, the subsequent discussion differed greatly. Table 1 outlines the similarities and differences in how the students investigated conjectures in each environment. Investigating conjectures is a vital component of effective mathematical discourse. Although the frequency of such investigations was similar for each environment, the nature of these investigations were significantly different. The 69% for the online environment and the 60% for the face-to-face environment only reflected the first investigation made by a student about a conjecture given previously. In the face-to-face environment 62% of the time conjectures were investigated they did so with more than one look, which means the idea was picked up by the group and deliberated. This uptake happened only half of the time in the online environment. The amount of mathematical evidence used in these investigations greatly favored the face-to-face environment: 53% to 29%. This means that even though students in both environments investigated their conjectures about the same amount of time, the investigations face-to-face were deeper and more mathematically rich, and more consistent with reform visions of mathematics classrooms (Ball, 1993; Lampert, 1990; NCTM, 1991; Yackel & Cobb, 1996).

Table 1
*Comparison of Online and Face-to-Face Mathematical Discourse—Investigating Conjectures*

| Discourse Aspect | Online Environment Frequency | Face-to-Face Environment Frequency |
|---|---|---|
| Investigating Conjectures | 69% | 60% |
| Further Investigations | 51% | 62% |
| Mathematical Evidence Used | 29% | 53% |

The nature of the environment seemed to significantly influence the degree to which students used mathematical evidence in their investigation of conjectures. The face-to-face students were able to have dynamic conversations and to show each other their mathematics as they made and investigated conjectures and solutions by pointing to their work and verbally discussing it. When students made and investigated conjectures online, they would have to type out all their work and all their discussions. It is not as easy to type out everything as it is to show it and discuss it verbally (see Ellis, 2001; Meyer, 2003; Tiene, 2000 for nuances).

Although the online environment certainly has the potential for productive mathematical discussion, there are some key differences in the ways students used (or did not use) this environment from the face-to-face environment. If students do not receive more guidance from the teacher in the online environment, their mathematical conjectures and solutions will not tend to be rooted well in mathematical evidence. Even with such intervention, the instantaneous and dynamic nature of face-to-face discourse will be difficult to replicate in the online environment. When the nature of mathematical discourse is considered, there are indeed significant differences in the opportunity to learn mathematics in the face-to-face and the online environments.

# TRANSFERABILITY OF AN EXISTING FRAMEWORK FOR ANALYZING TEACHERS' LEARNING IN AN ONLINE PROFESSIONAL TEACHING COMMUNITY

Chrystal Dean[1]
Appalachian State University
deanco@appstate.edu

Jason Silverman
Drexel University
silverman@drexel.edu

*In order to document the emergence of a community of practice and the collective learning of the teachers in an online context, we consider the transferability of an existing interpretive framework for analyzing the emergence and concurrent learning of professional teaching communities intended for use with face to face interaction to an online context.*

## Introduction

The findings of a number of investigations indicate that teachers' participation in communities of practice (CoPs) or, more specifically, professional teaching communities (PTCs) can be a crucial resource as they attempt to develop instructional practices that place student reasoning a the center of instructional decision making (Cobb & McClain, 2001; Franke & Kazemi, 2001; Gamoran, Secada, & Marrett, 2003; Kazemi & Franke, 2004; Little, 2002; Stein, Silver, & Smith, 1998). As a consequence, designs for supporting teachers' learning that involve guiding the initial emergence and subsequent development of professional teaching communities have become increasingly common.

We are in the beginning phases of a project that seeks to extend the current research on PTCs to the online environment. We do so for two primary reasons. First, we have found that the online environment offers significant affordances that are not present in face-to-face settings. In addition to providing "anytime, anywhere" learning that can easily fit into learners' busy lives, the online environment (1) provides teachers with opportunities to devote significant amounts of time to thinking about the mathematics at hand, ideally in multiple sessions of thinking and reflecting, recording, analyzing, and revisiting the initial thoughts, comments and reflections of their colleagues and (2) automatically records a permanent record of each participant's thinking, solutions, or questions that provides an opportunity for others to comment on, question, and discuss each individual's work. Secondly, and just as important, we feel that the online environment holds great potential for scaling and can "serve" teachers in traditionally marginalized areas: rural and urban schools and districts without access or resources to ongoing, mathematics specific professional development activities.

## Theoretical Perspective

At the core of Wenger's (1998) definition of a CoP is the practice that is the source of coherence in the community. Against the background of that practice, Wenger then discusses three interrelated dimensions that clarify what distinguishes a community of practice from a group: a joint enterprise, mutual engagement, and a shared repertoire. Joint enterprise is a shared purpose that is more than a goal; it "creates among participants relations of mutual accountability that become an integral part of the practice" (Wenger, 1998, p. 78). Mutual engagement includes the social complexities and relationships that are developed in pursuit of a joint enterprise, as well as the norms of participation that are specific to the community. A shared repertoire includes historical events, tools, styles, discourses, actions, stories, artifacts, and concepts that have been produced or appropriated by the community in the course of its existence and have become a part of its practice.

Our overarching goal is to support the emergence of an online professional teaching community that focuses on the practice of “doing mathematics” with an eye to instruction. More specifically, it would be normative for the members of the group to engage in:

(1) Making mathematical thinking, and not just solutions, public
(2) Focusing on understanding each others’ mathematical thinking
(3) Making public reflections about aspects of others’ understandings that are consistent or inconsistent with one’s own
(4) Collaborating on ways to improve mathematical understanding (with a focus on hypothesizing, generalizing, connecting, etc.) and *generating* mathematics
(5) Connecting mathematical activity with classroom instructional practice

These five normative ways of acting are based on our work with Online Asynchronous Collaborations in Mathematics Education (OAC) (Clay & Silverman, 2008, 2009; Silverman & Clay, submitted). Briefly, OAC involves cycles of individual, small group, and whole class interaction and collaboration. We begin with providing a private workspace for students to draft a solution, initial approach, or questions on a set of purposefully selected, open-ended mathematics tasks. At this point, we do not expect that everyone in the class will be able to complete each of these activities, but we do expect each student to attempt the assigned task and either pose a solution method and solution or ask relevant questions or wonderings that would assist in the completion of the activity. Students have approximately four days to post and revise their postings. After the individual work phase, each student’s initial postings are made public and students add comments, respond to questions, or ask for clarifications. Finally, we tie up loose ends in an asynchronous discussion.

## Prior Research Results

We have reported elsewhere that OAC has been effective at supporting mathematical interaction (Clay & Silverman, 2008, 2009). Consider the following excerpts from teachers’ work on *Pig Pens*, a Math Forum Problem of the Week that we have successfully used in OAC. The problem is as follows: Farmer Mead has 36 guinea pigs on her farm. She wants to build one rectangular pen they can all run around in. She must allow one square meter of area (1 $m^2$) for each guinea pig in the pen. The fencing costs one dollar per meter. Find three different rectangular pens that have exactly the area needed for 36 guinea pigs.

> ***Marcy*[2]:** The first thing I noticed about the problem is that it asks for 3 different types of pens, and my first thought is why 3 different pens a rectangle is a rectangle, just make a simple rectangular pen and be done with it. Things I’m still wondering about: Why three pens? While I haven’t attempted to solve the problem yet, I wouldn’t have thought that the shape of the rectangle will make a difference in price, but evidently it does considering the question.

First, note that Marcy’s post was unpolished and provided insight into her conceptions about some of the big mathematical ideas involved in the problem. We contend that such unrefined insight, especially for *each* student, is virtually impossible in a synchronous learning environment. The class, and Noelle in particular, took up Marcy’s post as a focus for discussion:

> **Noelle**: A rectangle isn't a rectangle. There are short and fat rectangles, there are rectangles with even or nearly even sides. Look around your house, your door is one style of a rectangle, but your phonebook is a different type of rectangle. If you will have noticed from the other responses that there is quite a bit of difference between the cheapest pen 6x6= $24 and the most expensive pen 1x36 = $74. That is more than double the price. Then you started to figure it out, you were on the right track. I think you need to revisit perimeter vs area and then it might make a little more sense to you. I agree that you were over thinking the problem. After looking at the others, does it make more sense now?

It is important to note that Noelle answers Marcy's original question about rectangles by careful questioning and not through recapitulating her solution method. By engaging Marcy's current understanding and not imposing her own on the conversation, we believe that Noelle was able to help Marcy with crucial idea behind her troubles. Moreover, the entire class was able to observe and discuss this crucial pedagogical step.

Our second excerpt provides an example of the ability of OAC to position students to learn from the public discourse. Marcy, continuing her initial post from above, noted:

> **Marcy**: If the total area is 36 square meters for the pen then no matter what the length and width are it is still going to be 36 square meters which should not change the price. The dimensions can be w= 4m X L = 9m or they can be w=3m x L=12m or they can be 6m x 6m. Nope this is wrong. I need 4 sides because I know the perimeter of a rectangle = 2L+2w. Ok I will come back to this. Then there is the price. I don't think this is correct but to get the price, ok there are 36 square meters 36(36) which equals 1,296. 1 meter costs $1.00. So how many meters are in 36 square meters?

Derek M. and Betsy S. followed up on Marcy's post:

> **Derek**: Don't feel silly, your conversation sounds very much like one I have heard from my wife. … [Remember:] "a number that is squared" is not the same as "squaring a number." … The question says that you have 36 pigs, and that each one needs "1" Sq. Meter each to run around in.

> **Betsy**: A number that is squared and squaring a number are the same thing. Meters squared is the unit of measurement for area because Length in meters multiplied by the width in meters is meters times meters which becomes meters squared.

> **Derek**: Betsy, You are right, let me rephrase that, when we see a number such as 36 Sq Meters, it has already been squared. The fact that the question mentioned that it needed to be 36 Sq Meters does not mean that you had to square 36 meters. What I was trying to say was that it is easy to confuse the note of Sq Meters or Feet as having to automatically squaring a number. It is important to determine what the number represents. Thank you for pointing this out, it is easy to forget that what runs through my mind and what I write are not always the same.

Derek attempts to address issues that seem to trouble Marcy, though he does so with less clarity than Noelle did. This begins an exchange that diverges from Marcy's learning to Derek's learning and the learning is about mathematical communication rather than content, which will be crucial to teaching. Finally, Derek is able to learn from Betsy and displays his learning to which Betsy answers kindly.

Through all of the communication about her problem, much of which likely resulted in her classmates' learning, Marcy also shows evidence of learning. She is able to learn from Derek and Betsy, not only from their discussion of her work but also from their original posted solutions. We have noticed that on many occasions, students refer to learning from the other posts, even though the posts were not available as they generated their initial solutions. It is also important to notice that Marcy believes that her learning will affect her practice. While these are self-reported, they are evidence that these teachers have begun to reconsider their pedagogical practices; comments such as these are much more common than we expected and plan to further analyze the effects of them.

> **Marcy**: Dave & Betsy, THANK YOU!! so much for your posts. The square meters is what screwed me up. I kept thinking 36 square meters is 36 square meters no matter what the dimensions are. But I now see that it is the perimeter I was pricing out. I actually feel kind of foolish because it seems so simple to me now. This is what happens to me all the time. Dave what you posted helped so much to clarify my confusion and then when I saw Betsy's drawings it really made sense. Thank you Betsy. I will draw everything out from now on.

> **Marcy**: Ok, now that I understand the problem, I would definitely use manipulatives to explain this problem to my students. I think I would like to make a fence with cardboard and put a bunch of little plastic pigs or something small that would represent the pigs inside the different dimensions. Then I would label each side, having at least 4 possible dimensions, I would discuss the multiples of 36 so everyone understood that and I would demonstrate how to find the perimeter having the students put together their fences and add up the 4 sides.

Finally, it is also important to note that Marcy ended up revising her solution:

> **Marcy**: I realized that I did not use the multiples of 36 to figure out the perimeter. I know that Perimeter of a rectangle 2L + 2W Therefore the using the multiples of 36: 1*36 = 1+1+36+36= 74 @ $1.00 per meter = $74.00 12*3=12+12+3+3= $30.00 4*9= 4+4+9+9=$26.00 6*6 = 6+6+6+6=$24.00 6X6 = is the cheapest pen.

During OAC, we consistently get a copious amount of interaction. This allows for making mathematical thinking public, understanding each others' mathematical thinking, reflecting on aspects of others' understandings that are consistent or inconsistent with one's own, collaboratively working to improve mathematical understanding, and connecting mathematical activity with classroom practice. We can say with confidence that individuals have or continue to engage with these practices, as evidenced by the above excerpts and many others. The evidence provided to this point, although promising, has been rather anecdotal and focuses on the individual learning of one participating teacher. In order to document the emergence of a community of practice and the collective learning of the teachers in this online context, we consider the transferability of an existing interpretive framework for analyzing the emergence and concurrent learning of professional teaching communities (Dean, 2005) intended for use with face to face interaction to an online context.

## Purpose of Investigation

The purpose of this study is to examine the feasibility of using the evolution of norms in a social grouping to document the evolution of an online CoP. This is based on an existing framework for investigating the emergence and concurrent learning of professional teaching communities (Dean, 2005). Dean’s framework was developed in order to analyze the *collective* learning of the teachers as they participated in face-to-face professional development work sessions. Pragmatically, the need for an interpretive framework of this type derives from the increasing attention that researchers on teaching are giving to teachers' participation in pedagogical communities. Theoretically, an interpretive framework of this type documents the evolution of communal norms that constitute the immediate social setting of the participating teachers' learning

Methodologically, it is important to clarify that norms are identified by discerning patterns or regularities in the ongoing interactions of the members of the professional teaching community. A norm is therefore not an individualistic notion but is instead a joint or collective accomplishment of the members of a community (Voigt, 1995). A primary consideration when conducting analyses of this type is to be explicit about the types of evidence used when determining that a norm has been established so that other researchers can monitor the analysis. A first, relatively robust type of evidence occurs when a particular way of reasoning or acting that initially has to be justified is itself later used to justify other ways of reasoning or acting (Stephan & Rasmussen, 2002). In such cases, the shift in the role of the way of reasoning or acting within an argument structure from a claim that requires a warrant, to a warrant for a subsequent claim provides direct evidence that it has become normative and beyond justification. A second, robust type of evidence is indicated by Sfard’s (2000) observation that normative ways of acting are not mere arbitrary conventions for members of a community that can be modified at will. Instead, these ways of acting are value-laden in that they are constituted within the community as legitimate or acceptable ways of acting. This observation indicates the importance of searching for instances where a teacher appears to violate a proposed communal norm in order to check whether his or her activity is constituted as legitimate or illegitimate. In the former case, it would be necessary to revise the conjecture that a particular activity was normative whereas, in the latter case, the observation that the teachers’ activity was constituted as a breach of a norm provides evidence in support of the conjecture (cf. Cobb, Stephan, McClain, & Gravemeijer, 2001). Finally, a third and even more direct type of evidence occurs when the members of a professional teaching community talk explicitly about their respective obligations and expectations. Such exchanges typically occur when one or more of the members perceive that a norm has been violated.

## Discussion

The types of evidence we have outlined were developed to document the emergence of norms within a group interacting in a face-to-face setting. Our question is whether they are appropriate for analyzing interaction and the emergence of normative practices in an online setting. Using the examples of the online interactions above as the context, we are exploring potential issues when using the face-to-face interpretive framework discussed above to analyze the emergence of norms in an online community. Following are three of the issues we are currently investigating.

*How Are Online "Whole Group" Discussions Different from Whole Class Face-to-Face Discussions?*

Initially, our concern was claiming something was normative when there was no "whole group" discussion in an online context. For example, when a group of people are in a room and someone makes an utterance, everyone hears it. In contrast, when a group of people are "in" an online discussion and someone makes a posting who knows if they read it? Upon further investigation, we concluded that the technology provides us with information about how many times a participant accessed a particular online discussion. Of course that does not mean the participants have legitimately engaged with the content, but what guarantee do we have of that in a face-to-face discussion? Just because someone is present in the room, does not mean they are engaged in the conversation. This is a particularly important issue when addressing social norms of the community. It is important to note, in the online environment, spending time in a discussion board is a first level of engagement with a particular post. Replying to that task is a second level of engaging with a post. We are currently seeking to understand how these two levels of engagement are correlated with "being present in a room".

*Talking at the Same Time*

We were concerned about the fact that there are often multiple conversations going on at the same time in the online context. That being the case, it further problematizes the notion of a whole group discussion. While participants can be posting to the Discussion Board, there is no guarantee that everyone engages with a particular utterance in a particular thread. In response to this, McConnell (2000) notes that

> the various activities of [a] group are not discrete in the way they often are in a face-to-face group. Members work on multiple issues at the same time. And because the issues are introduced by the participants themselves and are about important concerns and interests they have in relation to the work of the group, there is a different quality to the group members relationship with the issues. (p. 78)

In other words, while there are multiple conversations going on at once, the conversations are, by and large, organic and arise based on the perceived needs and goals of the group. Again, in this case, the significant factor seems to be the social norms, namely that participants are obliged to engage and to do so in a particular way.

*Is There Time?*

We also note that engaging in the multiple conversations legitimately takes time and, as such, this is another challenge to online communities: Is there time to engage with each utterance. This is methodologically important as claims about normative practices are based on posts but also the form and function of the replies to posts. McConnell (2000) notes that "The permanent nature of the group and its work … and the way in which members are able to "rejoin" at any time, means that participants seem to carry the work of the group with them in their everyday lives" (p. 78). Topics that are addressed in an online thread are chosen by the participants and therefore demonstrate the legitimacy of the topic. Thus, time to engage with each utterance is not necessary. Given the permanency of online conversations (i.e., there is a permanent record of all conversations) threads that were previously ignored can gain legitimacy. Therefore, practices consistent with productive social norms are often present in part of the group at the constitution of the group and, as such, there is a need to add weight to patterns in change in the violators, not just the responses to the violators.

## Conclusion

Given the growing number of universities and professional developers that utilize online settings, it is imperative that we have a feasible framework for analyzing participants' learning. This paper is an initial attempt to investigate this issue. Using the background of an investigation of Online Asynchronous Collaborations in Mathematics Education, we have highlighted the issues we are currently exploring while investigating the transferability of an existing framework for analyzing the normative practices of a professional teaching community. Given the outlined issues, we conjecture that Dean's framework is a viable starting point for exploring the emergence and concurrent learning of an online community of practice.

## Introduction

This paper reports on a study of a group of 20 pre-service teachers enrolled in a first-semester mathematics teaching methods course. Course activities included participation in two separate field experiences in neighboring school districts. The methods class placed considerable emphasis on the use of advanced digital technologies in the teaching and learning of mathematics, with particularly extensive use of the TI-Nspire. The field experiences varied in the extent to which technology was used from virtually nil in some classrooms to full implementation in others.

The methods course in which the pre-service teachers in this study participated was designed to introduce candidates to inquiry-based learning with open-ended questioning. The course proceeded from the premise that the use of advanced digital technologies can be a useful method for teaching in such a manner. In our experience, pre-service teachers generally fall into three categories with regard to their beliefs regarding the utilization of technology in mathematics classrooms: (a) "naysayers" who would like to minimize use of technology; (b) "Yes, buts" who believe that students should learn concepts first and only then have access to technology; and (c) "Yes, ands" who believe that technology should be used as an integral part of learning concepts. As pre-service teachers are developing a teaching identity it is interesting to observe the influences that push them in one direction or another. It seems to remain the case that most pre-service teachers have achieved their own mathematical success by being proficient in traditional environments (especially at the college level where use of technology is often outrightly discouraged) and, therefore, tend, in our experience, to be either "naysayers" or "yes, buts." Educators generally do not fall naturally into the third position without some coaxing, and the methods course was taught in a manner which might persuade the pre-service teachers to, at least, consider this position.

The data of our study shows that the methods class and the field placements served to challenge the pre-service teachers to clarify where they stand in this categorization and what they imagine the place of technology to be in their future careers as mathematics teachers.

The study was on a small scale with a limited number of participants and a limited number of cooperating schools, but the principal conclusion of the study is that there seems to be a crucial, perhaps, decisive effect that modeling of exemplary practice in the field placement has on candidate attitudes regarding the use of advanced digital technologies in their teaching, that is to say, in creating the possibility that they may become "Yes, ands." Many of the preservice teachers in this study were resistant to the extent of the emphasis on technology in the methods class but, with one exception, students whose field placement was in a school where technology was used extensively developed a positive attitude to technology. Not surprisingly, candidates with positive technology-oriented experiences in the field express stronger desires to incorporate technology into their own teaching. There is evidence that the pre-service teachers' experiences in the classroom primed them for the possibilities of technology but it takes the experiencing of exemplary practice to convince them of the benefits of working to incorporate technology in their own teaching.

A secondary conclusion is that while there was a general improvement in the quality of the lesson plans written by the pre-service teachers as the semester progressed, the lesson plans written by those students with field placements in technology-rich environments showed more sophistication, not just in the use of technology, but in terms of implementing inquiry-based and open-ended instructional approaches.

## Theoretical Context

There is a growing body of research which indicates that digital technologies, including graphing calculators and CAS-enabled calculators, can enhance young students' conceptual and procedural knowledge of mathematics (Dunham, 2000; Thompson & Senk, 2001). Research has also shown the benefits to students of dynamically linked representations (Kaput, 1994; Rich, 1996) whereby upon altering a given representation, every other representation is automatically updated to reflect the same change.

As technology has become more sophisticated and functionalities of hand-held calculators have increased dramatically, there is a need for research that explores the extent to which teachers are able to employ technology effectively (Koehler & Mishra, 2005; Niess, 2005) and the extent to which students are able to work effectively in such technology-rich environments (Edwards, 2004; Meagher & Brown, 2007).

After Shulman’s (1986) analysis of teachers’ knowledge as a complex structure including content knowledge, pedagogical knowledge, and his introduction of the concept of pedagogical content knowledge, the research in this topic has become effectively grounded on his framework. With Mishra and Koehler’s (2006, Koehler & Mishra, 2005) and Niess’ (2005, 2006, 2007) introduction of the concept of the teachers’ Technological Pedagogical Content Knowledge (TPCK), technology-related research in the teachers’ professional development and education field has gained a new rich conceptual framework or “an analytic lens for studying the development of teacher knowledge about educational technology” (Mishra & Koehler, 2006, p. 1041). The TPCK model involves the content knowledge, the pedagogical knowledge, and the technology knowledge required to teach in technologically-rich environments (see Figure 1). Furthermore, the TPCK model discusses the combination of that basis knowledge such as technological content knowledge (TCK) versus technological pedagogical knowledge (TPK). For TPK, Mishra and Koehler (2006) discuss TCK as follows “teachers need to know not just the subject matter they teach but also the manner in which the subject matter can be changed by the application of technology” (p.1028). On the other hand, “technological pedagogical knowledge (TPK) is knowledge of the existence, components, and capabilities of various technologies as they are used in teaching and learning settings, and conversely, knowing how teaching might change as the result of using particular technologies” (Mishra & Koehler, 2006, p. 1028). Finally technological pedagogical content knowledge, according to Mishra and Koehler (2006) is:

> the basis of good teaching with technology and requires an understanding of the representation of concepts using technologies; pedagogical techniques that use technologies in constructive ways to teach content; knowledge of what makes concepts difficult or easy to learn and how technology can help redress some of the problems that students face; knowledge of students’ prior knowledge and theories of epistemology; and knowledge of how technologies can be used to build on existing knowledge and to develop new epistemologies or strengthen old ones (p.1029).

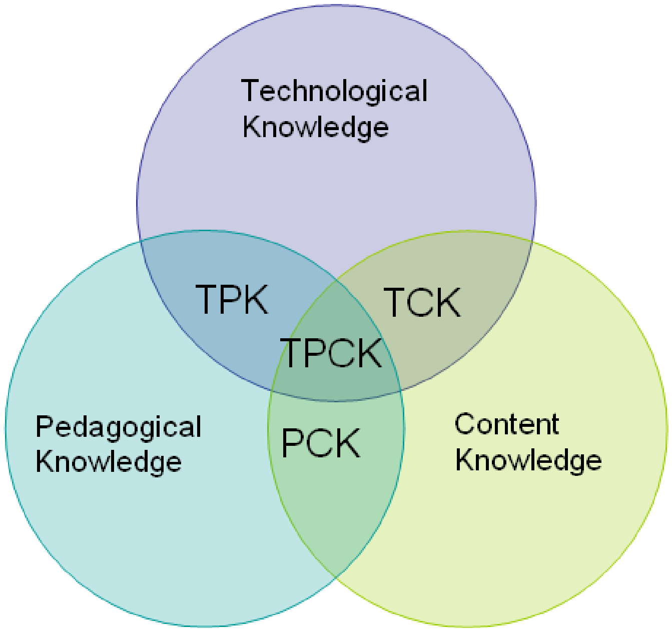

*Figure 1*. Re-creation of Mishra & Koehler's TPCK model.

Clearly, there is much to consider when studying pre- and in-service teachers' knowledge, views, beliefs, attitudes, and decisions about the use of technology in their classroom. Niess (2006, 2007) discussed how teachers' beliefs about teaching mathematics with technology play a crucial role in the development of TPCK. Moreover, Niess (2005) explained that there are four basic components of TPCK:

1. An overarching conception of what it means to teach a particular subject such as mathematics integrating technology in the learning.
2. Knowledge of instructional strategies and representations for teaching particular mathematical topics with technology.
3. Knowledge of students' understandings, thinking, and learning with technology in a subject such as mathematics.
4. Knowledge of curriculum and curriculum materials that integrates technology with learning mathematics(p.197).

Increasingly pre-service teachers are asked to incorporate technology into their teaching (NCTM, 2000). The extent to which they are willing or able to do so is influenced by a number of factors including their own experience with technology, constraints imposed by their teaching placements, and the quality of their training in the technology (Bullock, 2004; Moursund & Bielefeldt, 1999).

## Data Collection

The pre-service teachers (n=20) were engaged in routine activities that comprise a mathematics teaching methods course at a small Midwestern university and were using the TI-Nspire handheld regularly. The course was designed specifically for pre-service secondary school mathematics teachers, with the subjects engaging in activities focused primarily on pedagogical issues (e.g. constructing lesson plans and grading rubrics, creating technology-oriented math activities) and content issues (solving mathematics problems, assessing student work).

Specific activities included:

- Field Experience Reports: On two separate occasions, candidates researched, developed, and implemented mathematics lessons as part of the field teaching component of the class. The first critique focused on student behavior, teacher/candidate interactions, and instructional effectiveness. The second critique focuses on problem-posing and analysis of student mathematical thinking.
- Activity Writeups: The teachers submitted five secondary grades math activities that they constructed (either wholly original or modified from pre-existing materials). The teachers were encouraged to use these materials in their field teaching (if possible).
- Graphing Calculator Teaching Project: Candidates conducted original research dealing with the teaching of a secondary mathematics problem (or set of related problems) using the TI-Nspire graphing calculator. The problem(s) selected for study were subject to instructor approval to be well-suited for study with graphing calculators. The research was to meaningfully include the TI-Nspire in the investigation of the problem(s).

In addition to the routine activities of the methods class, the preservice teachers completed a *Mathematics Technology Attitudes Survey* and three short surveys, each of which consists of a mixture of multiple choice and open-ended items (administered electronically in weeks 4, 8, and 13 of the study). Finally they completed an open-ended exit survey with more general questions than those asked in the Week 4, 8, and 13 surveys.)

## Data Analysis and Discussion

Our analysis of the data focuses on two principal dimensions: (a) the interplay between the effects of the methods class and of the field placement on the pre-service teachers' experiences of and attitudes to technology, and (b) the evolution of the pre-service teachers' lesson plans over the course of the semester.

*The Interplay between the Methods Class and the Field Placement and the Influence of the Field Placement*

Looking at the open-ended exit survey we see a correlation between the pre-service teachers' field placement and their disposition to the use of technology in the future. Despite the emphasis placed on technology in the methods class, half of the students whose field placements had minimal or no technology did not develop a positive attitude to the use of technology in the teaching and learning of mathematics. One teacher who commented that "I found that my field teachers did not use technology in their classroom. I found their teaching methods to be more practical, and I will probably lean more towards their style," had said about the technology that "I found the TI-Nspire to be too complicated and not worth the hassle figuring it all out. I spent more time trying to figure out how to use it than I did learning about math." On the other hand, almost all of the teachers (there was one exception) who had been exposed to exemplary practice in technology-rich environments were eager to incorporate technology in their future practice. One student commented "My two field experiences were on different ends of the technology spectrum. One school barely had any technology and the other school had a lot." These two experiences resulted in this student declaring that "I am now more likely to use technology in my teaching. Technology offers so many advances for students and can relate to many different learning styles." Another student commented that "I will definitely want to use technology" having been in a school where “there was a grant for TI-89s in one class, for laptops in another and … their teacher was proficient in all of these technologies.”

It can be difficult for the students to make the connection between the practices developed and encouraged in their methods classes without exemplary experiences in classroom of how these ideas can be put into practice. The students who made comments such as “I am less likely because of un-user friendly the TI-Nspire was,” were not students who saw the TI-Nspire being used in a classroom. This correlation between the development of a positive disposition toward teaching with technology and exemplary experiences in a technology-rich environment calls for the development of a closer school-university partnership to allow students to make meaningful connections between their methods classes and he reality of classrooms. We see this as further evidence that students are primed with a certain level of TPCK in their Methods class but their ability to consolidate and implement these ideas is sensitive to the field placements both in terms of their willingness to implement good practice in using technology and their ability to implement good practice.

*Lesson Plans*

Lesson plans were written by the students at four different stages in the semester: two before their field placements, one between the first and second field placements and one in conjunction with the second field placement The lesson plans were scored along three dimensions: Implementation of Technology [Active (1); Neutral (0); Passive (-1)]; Implementation of Inquiry Based Methods (Adapted from Northwest Regional Educational Library (NWREL - http://www.nwrel.org/msec/science_inq/answers.html)

[Student initiated (1); Guided inquiry (0); Structured Inquiry (-1)]; and Quality of Problem Solving [Active (1); Neutral (0); Passive (-1)]. See Appendix 1 for the full rubric.

Analysis of the scores showed that the students struggled along all three dimensions but improved in all three areas as the semester progressed.

| | Technology | Inquiry | Problem solving |
|---|---|---|---|
| Lesson 1 | -0.25 | -0.5 | 0.25 |
| Lesson 2 | -0.5 | -0.375 | 0.125 |
| Lesson 3 | -0.25 | -0.125 | 0.5 |
| Lesson 4 | -0.125 | -0.375 | -0.125 |
| Lesson 5 | 0 | -0.25 | 0.375 |

The first two sets of lesson plans were generally poor and reflected the fact that novice pre-service teachers constructed the materials. The second set shows some improvement over the first but are still very teacher-centered. Several of the lesson plans explicitly use language such as "the teacher will lead students …” In most of these lessons, technology still seems like an afterthought for most teacher candidates, an "add on" rather than a tool to drive instruction. The third set of lesson plans, while far from high in quality, show marked improvement over the first two sets. This highlights the growing experience of the students and is reflective of the fact that these lessons were written after the first field placement.

The students’ use of technology was very slow to develop and, before the second field placement, the use of technology in the lesson plans is not very sophisticated. For example, the use of Dynamic Geometry Systems (DGS) in the set of lessons focused on the Pythagorean Theorem, most of the pre-service teachers only require students to draw a particular instance of a problem rather than using DGS to generalize and/or form conjectures. It is further noteworthy that in the set of lesson plans where the use of technology was optional, several students chose not to use technology at all while other suggest the use of technology for "High Level kids only." Those that did employ technology in their lesson plans tend to focus on "what buttons to press" rather than rich opportunities for student discovery.

There is a rather sharp improvement in the student scores on Lesson 5. At one level this is unsurprising as one might expect the students to reach a maturity point late in the semester. We argue however for a more significant factor: the second field placement during which Lesson 5 was written. Support for this thesis is borne out when the scores for the lesson plans are disaggregated into two groups: those that had a minimal technology second field placement (MT) and those that had a technology-rich second field placement (TR):

| | Technology | | Inquiry | | Problem Solving | |
|---|---|---|---|---|---|---|
| | MT | TR | MT | TR | MT | TR |
| Lesson 1 | -0.25 | -0.25 | 0 | -0.5 | 0 | 0.5 |
| Lesson 2 | 0 | -0.75 | -0.25 | -0.5 | 0.25 | 0 |
| Lesson 3 | -0.25 | -0.25 | 0 | -0.25 | 0.5 | 0.5 |
| Lesson 4 | 0 | -0.25 | -0.25 | -0.5 | 0.25 | -0.5 |
| Lesson 5 | -0.25 | 0.5 | -0.5 | 0 | -0.125 | 1 |

The lesson plan scores for both sets of teachers are similar for the first four lessons. There is, however, a quite dramatic difference in Lesson 5. The teachers in technology-rich field placements score much higher in the use of technology, which is to be expected but, significantly, they score higher in Implementation of Inquiry Based Methods and much higher in Quality of Problem Solving. In the presence of technology, they developed more pedagogically sound activities and their TPK and TPCK skills were clearly developing.

A significant feature of the lesson plans written in the technology-rich environment is that the tasks were formulated so that the use of technology was a necessary component of the lesson i.e. the tasks were designed assuming access to and ability to use technology. For example, one pre-service teacher designed a lesson centered around the classic birthday problem which involved the use of repeated simulations on the graphing calculator. This would be virtually impossible to replicate in a single classroom without technology. Another candidate posed a problem to students involving systems of inequalities. In the lesson, students attempted to construct a closed region satisfying the following constraints using TI-Nspire:

1. The system includes at least four linear inequalities
2. The graph of the system generates closed region
3. At least one pair of lines in the system is perpendicular
4. Every line has to have slope (i.e. not zero or undefined slope)

This lesson was markedly richer than this students' previous lesson plans, not just in the use of technology but in terms of inquiry-based teaching and problem solving.

We argue that an important element in the pre-service teachers developing calculator active tasks, perhaps becoming “Yes, ands” is their placement in a technology-rich environment. The modeling of exemplary practice and the mentorship available to them was, we believe, significant in this move. As one pre-service teacher commented on his placement in his Field Report:

> Overall, this class [i.e. the field placement class] had many students eager to work with the new technology. It was exciting to enter the classroom at a point when new and innovative techniques are being introduced and see the results the calculators had not only on the willingness of students to engage in the material, but also on their abilities to construct good solutions to challenging problems. I hope that more students will have access to this new technology in the future to fuel new mathematic interest, just as the Nspires did for the students in Mr. C's class.

It is interesting to compare the analysis of the Lesson Plans with the pre-service teachers responses when they were asked in the surveys to discuss the extent to which they were thinking and working with technology as they design activities. Several pre-service teachers mentioned and complained that the use of TI-Nspire was *required* at Week 4. However, others stated that they liked working with TI-Nspire and it capabilities: "I have been able to incorporate things such as the TI Nspire and GSP into my activity write-ups, and I think that incorporating these types of technology into lessons helps to make them more multifaceted and thus easier for a larger percentage of the students in a classroom to understand." Again here this student was considering students' learning with the help of technology. S/he was reflecting on her TPK.

The pre-service teachers had, of course, seen many activities in the methods class by this stage which showed the possibilities for advanced digital technologies in the class but without a model of exemplary practice the teacher quoted here was struggling with how they themselves could actualize this practice.

## Conclusions and Future Directions

The overall conclusions of this study are that (a) if pre-service teachers' are to develop a positive attitude to the use of advanced digital technologies in their instructional practice they require more than a methods class to develop TPCK and that modeling of exemplary practice in the field placement has a crucial, perhaps, decisive effect on the student's attitude, and (b) that the most significant improvement in the quality of the pre-service teachers' lesson plans, in terms of being inquiry-based and open-ended, came when students had field placements in technology-rich environments.

This significant influence of the field placement suggests further direction for research. Specifically it calls for the development of school university partnerships so that students can engage in the following learning cycle: (i) A class of preservice high school teachers will work with the TI-Nspire to develop lessons/short units designed for technology-rich environments; (ii) experienced inservice will review the lessons/short units and present an initial redesign; (iii) the inservice teachers will teach the lessons, observed by the preservice teachers; (iv) the preservice teachers and inservice teachers will meet together to reflect on and redesign the lesson based on their experiences in the classroom. Engagement in such a cycle allows students to gain the benefit of exemplary practice in task design and use of advanced digital technologies and allows them to focus on this aspect of practice without having to also deal with the early pedagogical aspects which arise from teaching the class themselves i.e. classroom management, questioning etc.

We believe that the implementation of such a cycle in conjunction with a methods class would allow students to develop a more inquiry-based approach to their teaching and to see how the use of advanced digital technologies can facilitate that approach.

# HIGH SCHOOL TEACHERS' USE OF GRAPHING CALCULATORS: PROFESSED BELIEFS AND OBSERVED PRACTICE

Levi Molenje
Grand Valley State University
molenjel@gvsu.edu

*This study investigated secondary mathematics teachers' professed beliefs about graphing calculators, the teachers' use of graphing calculators when teaching the concept of function, and the extent to which the professed beliefs explain the teachers' use of graphing calculators. Survey and interview data indicated that the teachers believed that they usually balanced among the various representations of functions. However, classroom observations showed that equations and graphs seemed to dominate more than tables.*

## Purpose of the Study

Research has shown that when teachers use graphing calculators, their roles tend, in general, to shift to those of fellow investigators, facilitators, or consultants, while their teaching strategies tend to involve higher level questioning and more in-depth problem solving, and the classroom discourse grows richer (Simonsen & Dick, 1997). It cannot be overemphasized that some teaching styles are more compatible with the use of graphing calculators than others. Teaching styles that use more open-ended questioning and involve engaging students in discovery activities seem to be more compatible with the use of graphing calculators than those styles that are more teacher-centered. Research also shows that when teachers use graphing calculators there is an increase in cooperative learning where students not only take more responsibility for their own learning but also work together with their peers and learn from each other as well (Harskamp, Suhre, & Van-Streun, 2000).

However, some studies have also shown that teachers who have always taught in teacher-centered classrooms are sometimes uncomfortable with the unpredictability that may arise as a result of introducing graphing calculators, while other teachers are often reluctant to use graphing calculators in creative ways because of their beliefs about what mathematics is and what their role as teachers should be (Milou, 1999; Simmt, 1997). Such teachers tend to confine the graphing calculator to performing computational roles and hence deny their students opportunities to exploit the powerful capabilities of graphing calculators. Yet other studies have shown that there are disagreements in terms of teachers' attitudes and beliefs towards graphing calculators. Some studies have pointed out that there is a link between teachers' philosophical orientation and attitudes and beliefs about graphing calculator use and called for continued investigation of this issue (Aguirre & Speer, 2000).

Even though a substantial amount of research has been done involving graphing calculators, there is still need for more studies to be done in this area. For example, we need to know teachers' perspectives regarding the effects of graphing calculators in exploring various representations of functions as well as their views regarding the extent to which they would let their students explore with the graphing calculators. Since it is true that in general what one reports about himself or herself may not always be consistent with his or her practice, a good study on these issues is one that is designed to investigate the consistency or variance between what teachers report and what they do in their classrooms. This study attempts to address this by (a) investigating secondary mathematics teachers' professed beliefs about graphing calculators,

(b) investigating how these teachers use graphing calculators to teach linear and quadratic functions, and (c) investigating the extent to which the professed beliefs explain the teachers' use of graphing calculators.

## Theoretical Perspectives

This study draws on Vygotsky's (1978) sociocultural theory of learning. According to Vygotsky, education is both a theory of development and a process of enculturation whereby mediated activity helps shape higher human mental functions. The mediator may be a sign system (e.g., language, tabular or graphical representation of a pattern) or a technological tool (e.g., computer, graphic calculator). Vygotsky contends, "if one changes the tools of thinking available to a child, his mind will have a radically different structure" (p. 126). In this study, I take the position that the graphing calculator is an instrument of access to the knowledge, activities and practices of a social group that is the mathematics classroom (Meira, 1998). In this case, using the calculator can be seen as an external activity (using graphs, tables, and numbers to manipulate mathematical concepts), which is then transformed into an internal activity (gaining an understanding of the mathematical concepts).

In addition to Vygotsky's sociocultural theory, I also draw on a theoretical framework developed by Salomon, Perkins, and Globerson (1991) for studying the interaction between technology and user. Salomon and his colleagues define intelligent technologies as those that can be used in partnership in a manner that they can "assume part of the intellectual burden of information processing (such as mental or pen and paper calculations)" on behalf of the user (p. 3). Graphing calculators qualify as intelligent technologies under this definition. In this framework, Salomon, Perkins, and Globerson distinguish between two sets of *principal effects* that arise from this kind of partnership, namely (1) *principal effects with* the technology and (2) *principal effects of* the technology. For purposes of clarity, I will refer to the first set as *planned principal effects,* and the second set as *emergent principal effects.* The work of Goos, Galbraith, Renshaw, and Geiger (2003), which provides metaphors for studying the interaction between calculator and user, is closely related to this partnership framework and so I seek to draw parallels to the metaphors when discussing the principal effects.

Characteristics of *planned principal effects* include elaborate planning (laying out the specifics concerning how the calculator will be used), executing the plan (using the calculator in the desired ways), and interpreting the results. The teacher here predetermines exactly when it will be appropriate to turn to the calculator during problem solving and in what ways this should be done. For example, the teacher may plan when it will be necessary for a particular graph to be displayed, or when he or she will need to enter a certain equation or table of values in the calculator. When there will be need to transform the function in certain ways, the teacher will plan to modify the equation or table in particular ways. Jones (1993) notes that this interaction allows the user to operate at a higher level than otherwise possible, provided he/she constantly monitors the information given by the calculator to ensure that it is consistent with his/her understanding of the problem at hand. Jones (1993) cautions, however, that passing over the entire cognitive responsibility to the calculator, what Goos et al. (2003) refer to as "technology as servant" (p. 78), can be counterproductive and may lead to misconceptions. According to Goos and her colleagues, it is not worthwhile to use technology as "a supplementary tool that amplifies cognitive processes without using it in creative ways to change the nature of activities" (p. 78). They cite using the overhead projection panel as an electronic chalkboard to provide a medium for demonstrating calculator operations to the class as an example of inappropriate use of technology. Goos et al. contend that using technology in this manner only helps reinforce the teacher's preferred teaching methods and this may not be beneficial to students. They suggest that teachers should use the graphing calculator in conjunction with other material resources in ways that further enhance the calculator's capacity for linking multiple representations of concepts. Jones (1993) advises that teachers must develop instructional strategies that promote the formation of intelligent partnerships between their students and the calculator. The relationships between users and calculators in such partnerships should be complementary rather than dependent.

*Emergent principal effects* are characterized by spontaneity, that is, effects that the teacher does not intentionally plan for. These effects then "carry over to other related but not calculator dependent mathematical activities" (Jones, 1993, p. 214). Using the metaphor of technology as partner, Goos et al. (2003) refer to this level of using a graphing calculator as the "cognitive re-organization effects" (p. 79). According to Goos and colleagues, these effects are characterized by using technology to explore new tasks or new approaches to existing tasks and to mediate mathematical discussion in the classroom between students and teacher or between small groups of students. They suggest, "instead of functioning as a transmitter of teacher input, the overhead projection panel can become a medium for students to present and examine alternative mathematical conjectures" (p. 79). Goos' metaphor of "technology as extension of self" is also consistent with emergent principal effects. According to this metaphor, a teacher who attains this level would write unit plans that support integrating technology into the teaching program. That is, the teacher would incorporate technological expertise as a natural part of his or her mathematical and/or pedagogical repertoire. For meaningful emergent principal effects to arise in a classroom, the teacher must be willing to allow his or her students to explore new areas with the calculators and guide the students into discussions that will help them make sense of their findings.

## Research Questions

1) What are secondary mathematics teachers' professed beliefs about using graphing calculators in the teaching and learning of linear and quadratic functions?
2) How do secondary school mathematics teachers use graphing calculators when teaching linear and quadratic functions?
3) What are the relationships between the teachers' professed beliefs about graphing calculators and observed practice?

## Methodology

I conducted the study using a two-phase design. In the first phase, I sent out a survey about graphing calculator use to secondary mathematics teachers ($9^{th}$ - $12^{th}$ grade) in a mid-sized city school district and the neighboring school districts in a northeastern state in the United States. I developed survey instrument using items adapted from Fleener (1995). In addition to demographic information, this instrument consisted of 24 items with Likert-type responses on a five point scale with SA=Strongly Agree, A=Agree, N=Neither agree nor disagree, D=Disagree, and SD=Strongly Disagree. One of the questions on the demographic part asked participants to state how often they used graphing calculators in their classes. I used the responses to this question to categorize the teachers into three groups of frequent users (nearly every lesson), moderate users (once every 2 or 3 lessons), and infrequent users (once every 4 or 5 lessons). I then selected, on a voluntary basis, three teachers from each of the frequent users and moderate users groups to participate in the second phase of the study. I intentionally excluded teachers from the infrequent users group.

The second phase of the study comprised of semi-structured interviews and classroom observations. Data sources included one task-based interview (Goldin, 1999) with each teacher prior to classroom observations, three classroom observations for each teacher with pre-observation (planning) interviews and post observation (debriefing) interviews, copies of teachers' lesson plans, teacher notes, instructional activities and/or tasks. In order to collect focused information during the observations I used the electronic classroom observation (ECOVE) software.

## Results

Analysis of the survey data indicated that on the most part teachers believe that graphing calculators are valuable for students in the study of linear and quadratic functions. The teachers also in general feel confident about their knowledge of graphing calculators and they believe that they make use of graphing calculators whenever opportunities for doing so are available. Additionally, the results from the interviews showed that the teachers believed that they balanced between the various representations of functions.

On the other hand, classroom observations revealed that teachers preferred graphical approaches and algebraic approaches over tabular approaches. For example, in their instructional tasks, the teachers specified algebraic approaches the most (in 36% of all tasks analyzed), followed closely by graphical approaches (in 31% of all tasks analyzed), then tabular representation approach in 17% of the tasks, and another 16% of the tasks not being specific on any of the three representations. This is contrary to what they stated in the interviews about balancing between representations. It should be noted however, that specifying a representation in a task did not restrict the teachers to sticking within that representation alone. The teachers shifted from the specified representation to other representations once instruction began. This shifts mainly resulted from the teachers guiding students through the tasks and so leading the way towards using other representations but on other occasions they came as a result of students being involved in negotiating the problem solving process.

Also revealed from the classroom observation data was the fact that when graphical approach was specified in the tasks the shift to algebraic approach (and vice versa) dominated the shift to tabular approach – about 70% to 30% overall. This goes further to show how much graphical and algebraic representations dominated over tabular representations. A near balance in representations appeared to be achieved when the specified representation was tabular as the percentages of shifts to graphical or algebraic representations differed only slightly – 54% and 46% respectively. However, this apparent balancing between representations was overshadowed by the fact that there were very few tasks in which tabular representation approaches were specified. Moreover, when only verbal representation was specified the teachers switched to algebraic representation more than four times as they did with tabular representation.

## Discussion

The teachers in this study generally believed that they usually balance among the various representations of functions. However, classroom observations seemed to reveal a different story. Analysis of the classroom observation data showed that equations and graphs seemed to dominate more than tables. Most instructional tasks made specific reference to either an equation for which a graph would be drawn and various explorations done on it, or a graph on which various explorations would be done. Only a handful of tasks directly specified use of tables. In cases involving word problems, it was common to see equations being generated then graphs drawn.

*In this report we analyze how students integrate information from a wiki to expand, verify, improve, and complete their solution to an open-ended mathematics problem as they work in an online synchronous environment. Significant research has analyzed collaborative problem solving, but virtually no research exists that investigates online collaborative problem solving of open-ended problems. This report uses an established research model to analyze a new type of discursive interaction.*

## Purpose

Policymakers and educators in organizations such as the Consortium for School Networking and the International Society for Technology in Education believe that online learning has both educational and social value. In states like Alabama and Michigan, high school students must complete at least one online course to graduate (Hu, 2009). However, advances in digital technologies and their introduction into society seem to outpace the typical timeframe needed for researchers to investigate meaningfully the potential of new digital technologies for education. For instance, Web 2.0 has ushered in possibilities for collaboration across physical boundaries with such technologies as blogs, file sharing, social networking, and wikis. In mathematics education, research is needed to understand the possibilities and problems of digital technologies to enhance student engagement with and development of mathematical thinking.

This research will investigate how students construct knowledge using a wiki, a Web 2.0 tool. Through a model focused on student discourse, we analyze student integration of material in a wiki to become part of a collaborative solution by a group. We expand the use of the model to include inscriptions. Though we monitor student discourse, teacher intervention in this research is limited largely to task construction. The problems in this research are combinatorics tasks that are not covered in traditional high school mathematics curricula and therefore the students spend significant time in each session constructing problem-solving techniques.

## Theoretical Framework

Our research focuses on the interactions of students in an online environment. We use the interaction analysis model (IAM) introduced by Gunawardena, Lowe, and Anderson (1997) to analyze students' online communications. Several studies (Hou, Chang, & Sung, 2008; Jeong, 2003; Marra, Moore, & Klimczak, 2004; Sing & Khine, 2006) have used this coding scheme to analyze online discussions. Table 1 illustrates the coding scheme we used to analyze how information from a wiki, an interactive webpage that allows for collaborative editing, is integrated into another online environment.

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

Gunawardena, Lowe, and Anderson (1997) developed the interaction analysis model to study the construction of knowledge in an online debate. They used grounded theory to develop the model through content analysis with a focus on knowledge construction by a group and on change in individual understanding through the group interaction. The five phases in Table 1 occur when there is discrepancy or inconsistency that needs to be resolved by a group. Gunawardena, Lowe, and Anderson concluded that the debate format influenced the participants in such a way that they offered mostly P1 comments (191 of 206 postings) and very few of the meta-cognitive skills needed for P4 and P5. They cited that the debate format was a possible limitation to the construction of knowledge and therefore to the collaboration that occurred.

Table 1. *Gunawardena, Lowe, and Anderson (1997) Interaction Analysis Model (IAM)*

| Code | Phase | Operation |
|---|---|---|
| P1 | Sharing or comparing information about discussion topics | Statement of observation or opinion; statement of agreement among participants |
| P2 | Discovery and exploration of dissonance or inconsistency among participants | Identifying areas of disagreement, asking, or answering questions to clarify disagreement |
| P3 | Negotiations of meaning or co-construction of knowledge | Negotiating the meaning of terms and negotiation of the relative weight to be used for various agreement |
| P4 | Testing and modification of proposed synthesis or co-construction | Testing the proposed new knowledge against existing cognitive schema, personal experience, or other sources |
| P5 | Agreement statement(s) or application of newly constructed meaning | Summarizing agreement and meta-cognitive statements that show new knowledge construction |

The process began by asking two questions: 1) Was knowledge constructed within the group by a process of social negotiation? and 2) Did individual participants change their understanding or create new personal constructions of knowledge as a result of interactions within the group?

The use of wikis in education will expand as teachers, students, and administrators become familiar with Web 2.0 tools and as online education becomes more prevalent. Tonkin (2005) offers four different categories for educational wikis: Single-user Wikis, Lab Book, Collaborative Writing, and Knowledge-Based. The wiki used in this research is concentrated in the Knowledge-Based wikis, which are defined by Tonkin as a place where teams can retain their experiences and have quick access to the data.

## Method

The participants in this research are students in the *e*Math project, which connects two different schools in New Jersey: Rutgers Preparatory School (RPS), a suburban independent school, and Long Branch High School (LBHS), an urban public school. The RPS students are in an Advanced Algebra and Trigonometry class and the LBHS students are in a Contemporary Mathematics class. The students have completed Algebra 2 and decided to take a full-year math course at the next level, which is not required. One student at RPS is a junior and all other students in the project are seniors. The teams in the online environment have three or four students with no more than two students from any one school. In this project all of the tasks are open-ended mathematics problems that are not seen in traditional mathematics classes. In the fall semester of 2008, the *e*Math project conducted seven online sessions. This report focuses on the fourth and fifth sessions, October 23rd and 29th, respectively. During the October 23rd session, the students worked on the Pizza Problem with Halves with questions one through three (Figure 1). For the October 29th session, we augmented the task with a fourth question, indicated in Figure 1 below the horizontal line.

**PIZZA PROBLEM WITH HALVES**

A local pizza shop has asked us to help them keep track of pizza orders. Their standard "plain" pizza contains cheese with tomato sauce. In addition, a customer may order toppings on the whole or half of a pizza. A customer can then select from two different toppings: peppers and pepperoni.

1. How many different choices for pizza does a customer have?
2. Work together with your teammates to list all the possible different selections.
3. With your teammates, write a report of your findings for questions 1 and 2 above. It should include a justification that you have accounted for all possible pizzas. You want your report to convince others who are not in your team that your findings are correct. Post your report to the Summary tab.

---

4. After the last session, the owner of the pizza shop was confused by the different solutions she received from the different teams. The owner desires that your team urgently respond to these two requests:
   a) From the Wiki tab, read the solution of each of the other teams. If your team agrees with another team's solution, explain why in the Summary. If you do not agree with any other team's solution, present a numbered list of all possible pizzas when choosing from the two toppings.
   b) The owner is considering making available another topping—sausage—and wants your team to develop a numbered list of all possible pizzas when choosing from the three toppings. The owner needs to be certain that your list is complete and, therefore, wants you to convince her that your group's solution is indeed correct.

*Figure 1*. The pizza problem with halves.

The students communicate through an online synchronous environment, the Virtual Math Teams Chat (VMT Chat), developed under a grant from the National Science Foundation by researchers at Drexel University (Stahl, 2006). The VMT Chat (Figure 2) is Java-based and facilitates Internet communication through several interrelated spaces: a whiteboard, chat, Wiki, Summary, Browser and Help pages. The whiteboard and the chat spaces are where a majority of the students' interactions occur. The whiteboard is a shared, dynamic workspace where students can enter textboxes, draw lines and ellipses, and use other tools similar to those in popular word processing software. The other main communicative space is the chat on the right side of the screen where each member of a chat team has a distinct color for their typed entries. In all spaces of the environment, students' contributions become visible to other members in the room once they click outside the entry or press the return key. On the upper left side of Figure 2, the second tab is the Summary where members of a chat team write a collective summary of their process and solution. The Topic tab allows the students to read and review the statement of a task. The Wiki tab contains the webpage that has links to screenshots of each team's summary from the previous session (Figure 3). The Browser and Help tabs are available, but they remain unused as we direct the students to use VMT as their only means of communication and ask them to consult the members of their team for technical questions regarding the environment. A referencing tool, seen in Figure 3, is also available for students to direct teammates' attention to a particular part of the whiteboard, summary, topic, or chat. While the students are working on laptops in their classroom they are arranged around the perimeter of the room in such a pattern as not to be in close proximity to the other member of their team. All interactions between a student's computer and the server are recorded for later review by the researchers.

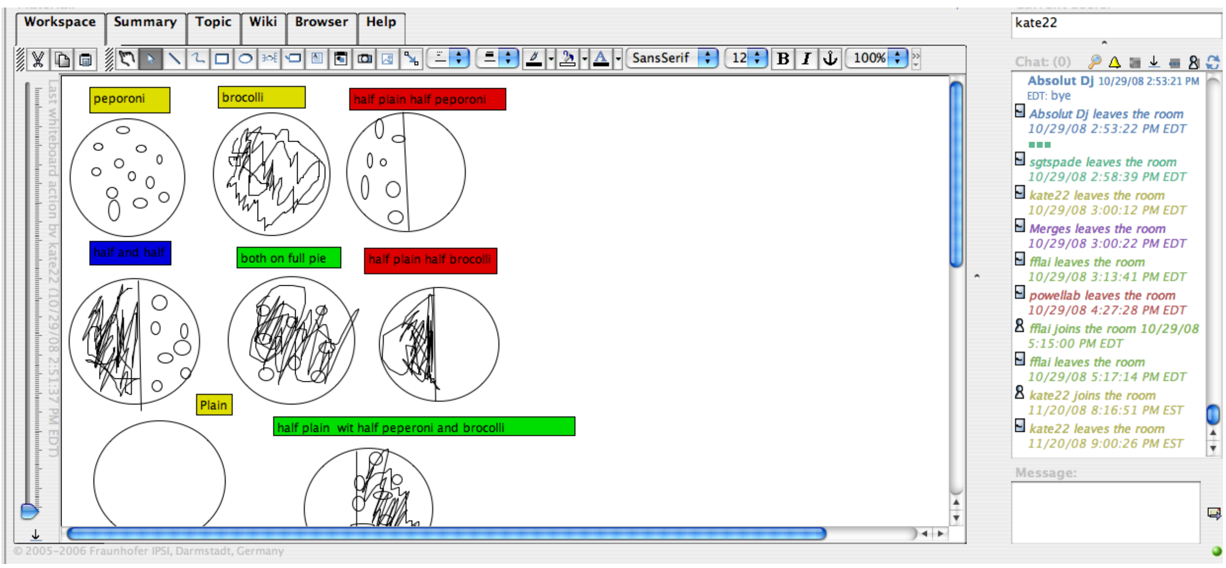

*Figure 2.* A screenshot of VMT Chat dual interactive spaces: dynamic whiteboard and text chat.

Students in each of the four VMT Chat rooms had access to the wiki. Upon clicking on the wiki tab the participants are able to see four links to wiki pages. Each link contains .jpg images of screenshots of the summaries students posted during the October 23rd session. The students were informed that content in the summary tab is a public space to which other teams would have access. The whiteboard remained the team's private workspace.

We observed participants during each research session but did not intervene during the session. We read scripts prior to each session to convey pertinent information to the students in each school. The task design also was an interventional method as we constructed each session's task to further probe students' ideas evidenced in the prior session.

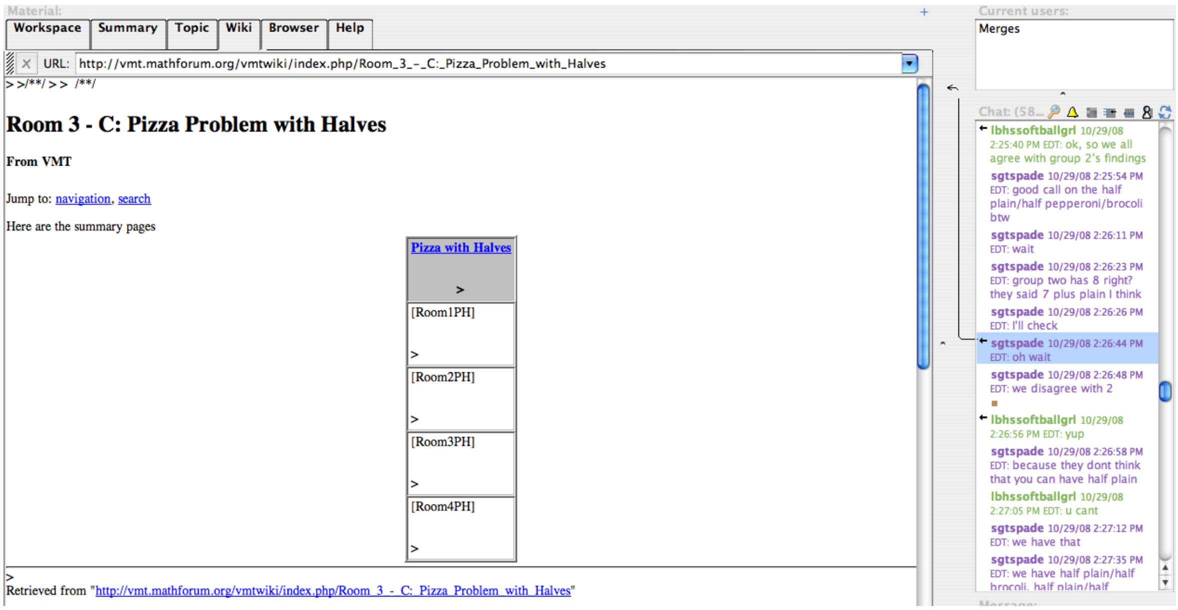

*Figure 3.* Wiki page viewable by participants after clicking on the wiki tab in VMT Chat.

After analyzing the session on October 23rd, we decided that it would be appropriate to implement the wikis during the session on the 29th. Prior sessions' scripts included an emphasis on using the Summary as a space that would be shared with other groups. A portion of the October 13th script stated that "sometimes you will be asked to contribute some work to the Summary tab, which is a more public space. The audience for the work you place in the Summary tab will be the other teams." In both schools, the teacher in the room read the following script at the start of the October 29th session.

Script for eMath Research Session of Wednesday, 29 October 2008
Rutgers Preparatory School and Long Branch High School

1. Before opening your room, click on the wiki link (green symbol with red circle on top) and read the summaries of last sessions for each of the four rooms. The entries in each box of the table will connect you to a screenshot of the solution to the The Pizza with Halves Problem offered by another team. Please review each of the other team's solution before entering your room. When in the room there is a wiki tab if you need to remind yourself of a group summary.

2. Please re-read The Pizza with Halves Problem since it has been altered to include an additional question. This question—number 4— should be the focus of your work today.

*Figure 4.* Script read to students in the classroom before they entered VMT Chat.

For each session and each team, there are four formats in which we can analyze the data: 1) The Concert Chat Player (Figure 5), 2) HTML line-by-line code with an author column to denote to which participant performed the action or chat entry, 3) HTML line-by-line, but each participant has a separate column instead of the one column for all authors, and 4) Excel spreadsheets or Word documents with tables of HTML files (Table 1). The spreadsheets and tables allowed for the addition of columns for coding purposes. The player files can be reviewed at variable speeds of real-time. There are sliding bars to move to a specific time or position on the page as needed. An automated transcriber transforms every recorded interaction with the environment into a table in HTML. The HTML tables can then be copied into Word and Excel tables and spreadsheets so that coding can be added.

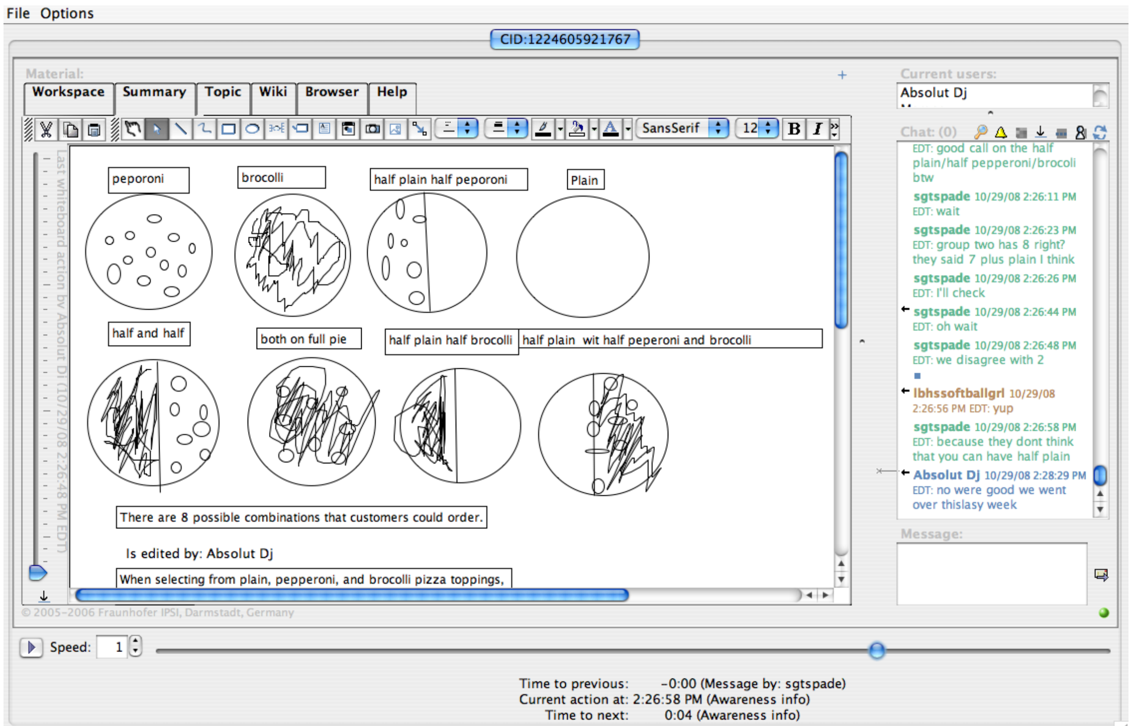

*Figure 5*. Concert Chat player with participant discussion of comparison of summaries in wiki.

## Results

Sgtspade, one of the students, engaged the linking tool as he reviewed each step of the wiki page. His actions as viewed in the HTML table, allowed us to track the pages as they were viewed. It is assumed that it was unintentional referencing because sgtspade never mentions, nor directs, teammates to look at the pages he references. In prior and subsequent sessions, sgtspade and others used the referencing tool and commented in the chat space directed at the point of interest. Nevertheless, he does discuss the specific material viewed on the wiki pages in his chat messages.

A limitation that was found during this research was categorizing. Once in the P4 code and once in the P5 code entries we recorded entries that were images and not typed chat. The VMT environment allows participants to communicate through their inscriptions in the chat and on the whiteboard. The creation of an object, or series of objects, on the whiteboard is a form of communication with the other team members in the chat room. In the case of the P4 stage, Absolut DJ creates a series of ellipses to represent the pizza with two toppings on one half. This action is interpreted as an integration of ideas from observing the wiki as well as dialogue with his team. Absolut DJ is testing this new knowledge and proposing a new idea that was previously not considered to be in the solution set. Later, Absolut DJ writes, "When selecting from plain, pepperoni, and broccoli pizza toppings, there are 8 possible combinations that can make up any one pie. As can be seen from the diagram above, once all possible half and full pie combinations of toppings are accounted for, there are exactly 8 different pizzas that can be ordered." While he summarizes this possible solution with his team, he enters this in the whiteboard as a textbox, which we code as P5. Entering textboxes is a common practice amongst the participants because we request that the students write a team summary. Since the placement of the text on the screen makes it an image as well as text, we alter IAM to include image and text as separate codes in each stage as students might respond differently to images and to text.

Table 2 is an example of the Excel spreadsheet used in the analysis, and shows a discussion that occurred during the October 23rd session. In this data, lbhssoftballgrl introduces one pizza not included in the original answer the team offered at the end of the October 23rd session. After a review of the wiki in the subsequent session the group decided that they had overlooked this pizza. In this chat lbhssoftballgrl asked "can u put two toppings on one half of the pizza?" Sgtspade did not think that it was possible, but he asks what the group thinks. The discussion closes when Absolut DJ says, "na lets keep it out." The students in this discussion consider the original statement and discuss an area of dissonance. It seems plausible that this interaction on October 23rd establishes the idea in the group and makes it easier to adopt as part of the solution on October 29th when it is seen that other groups include this as part of their solution.

Table 2. *Chat of Students During October 23rd Session with IAM Coding in Right Column*

| Chat Index | Time Start Typing | Time of Posting | Author | Content | IAM code |
|---|---|---|---|---|---|
| 69 | 13:41:26 | 13:41:36 | lbhssoftballgrl | can u put two toppings on one half of the pizza? | P1 |
| 70 | 13:41:44 | 13:41:47 | Sgtspade | No i dont think so | P1 |
| 71 | 13:42:43 | 13:42:46 | Sgtspade | That is a good question though | P2 |
| 72 | 13:42:46 | 13:42:52 | Sgtspade | it doesn't really say if we can or not | |
| 73 | 13:43:28 | 13:43:40 | Sgtspade | What do you guys think we should do? | P2 |
| 74 | 13:43:40 | 13:43:55 | lbhssoftballgrl | well it doesnt say we cant, so i think it would be safe to do so | P2 |
| | 13:44:29 | 13:44:43 | Sgtspade | [sgtspade has fully erased the chat message] | |
| 75 | 13:44:54 | 13:45:00 | Absolut DJ | na lets keep it out | P2 |

After initial introductions, during the October 29th session, Lbhssoftball enters, "[OK] so I think there are 8 pies when we really looked at it again right?" The students recognize that an eighth pizza is necessary. While reviewing the wikis of the other three teams, this team realized that they had not considered a pizza that was half plain and half peppers and pepperoni. Viewing the wiki allowed the group to reconsider this pizza and include it in their solution.

During a review of the data eight references to the wiki were found. An example of the referencing is available in Figure 3. Five of the eight references to the wiki were directed at wiki images of the other *e*Math teams. This referencing tool can be used to reinforce integration of ideas into team solutions.

## Discussion

In our data, we found 40 entries that relate to the use of the wiki in the VMT environment and coded them using the IAM framework. We coded ten entries as P1 and ten as P2, six as P3, eight as P4, and six as P5. Our data shows 35% of the codes in the P4 and P5 areas of meta-cognitive skills which differs greatly from the findings of Gunawardena, Lowe, and Anderson (1997) where over 92% of the codes were recorded as P1, sharing and comparing information, but not processing the information and drawing conclusion. It is possible that the technology and construction of the task created a setting for comments that were in a wider range of stages. The nature of a debate through an asynchronous forum is different from a question that asks students to work as a team and compare their solution with that of other groups. The effect of task design could explain the increased percentage of higher-level thinking. Further research in this field is necessary to study the ways technological advancements can be used by teachers to increase student use of meta-cognitive skills in problem solving and analysis of information.

# LEARNING ABOUT PROOF BY BUILDING CONJECTURES

Agida Gabil Manizade
Radford University
agidam@gmail.com

Beth Lundquist, M.S.
Charleston College
blundquist@charlestoncollegiate.org

*In this paper we propose a geometry technology-based activity appropriate for the middle school level that can be used to improve reasoning and proof writing skills. The activity uses the free, open source software GeoGebra and gives the student practice in conjecture building, an activity found to help students understand and improve proof writing skills. By building and testing conjectures, students can engage in advanced mathematical skills at their own level of expertise.*

The goal of the mathematics teacher is for her/his students to engage in advanced mathematical thinking at any grade level (Tall, 1991; Dreyfus, 1991). Building conjectures in geometry that lead to formal and informal proof is one example of advanced mathematical thinking (Boero, Garuti, Lemut, & Mariotti 1996; Hanna, 2000). NCTM (2000) recommends reasoning and proof be a fundamental part of the mathematics curricula at all levels, from pre-kindergarten through grade 12. Researchers identify proof writing as one of the most challenging aspects of the mathematics curricula in the U.S. and internationally (Senk, 1985; Healy & Hoyles, 2000; Galbraith, 1981). While introducing proof in the early grades might seem difficult, researchers find that even upper elementary students can deal with proof ideas and can be successful in mathematical activities related to proof (Lester, 1975). Educators tend to see proof as something obtainable only for a small minority of students and, therefore, attention to proof writing in the classroom although desired is often neglected (Knuth, 2002). One way to booster proof writing skills may lie in the ability to make conjectures or hypotheses based on empirical results. There is a direct connection between reasoning skills associated with conjecturing and reasoning skills used in proof writing (Boero, Garuti, Lemut, & Mariotti, 1996). Researchers argue that during the process of making a conjecture, the student must work through internal arguments and sort through which are plausible, similar to the activity a mathematician goes through when building a proof (Boero, Garuti, Lemut, & Mariotti, 1996). These researchers propose that the process of building conjectures should be emphasized more in mathematics instruction. The process of making and testing a conjecture is made easier by the increased use and popularity of dynamic geometry software (Clements & Battista, 1992; Hanna, 2000; Edwards & Jones, 2006).

In this paper, we explore the use of a free, open source, interactive geometry software, GeoGebra, to introduce a conjecturing activity at the middle school level. By building the students' reasoning and conjecturing skills, we are laying the groundwork for their future success in formal proof and logic.

## The Role of Technology in Building Conjectures and Constructing Proofs

Researchers have explored the possible benefits and drawbacks of the increased use of technology in the classroom (Harel & Sowder, 2006; Mariotti, 2000; Hadas, Hershkowitz, & Schwartz, 2000; Hanna, 2000). Educators express a concern that technology might give students a disincentive to seek a more formal proof (Harel & Sowder, 2006). However, there is strong evidence that using dynamic geometry software can help students realize a need for formal proofs (Marrades & Gutierrez, 2000; Hadas, Hershkowitz, & Schwartz, 2000). Although the transition from empirical to abstract ways of conjecture and justification can be a slow process, dynamic geometry software, such as Cabri, Geometer Sketchpad, and GeoGebra, have been shown to improve proof writing skills (Marrades & Gutierrez, 2000).

In this paper we use the GeoGebra software package to present a geometry activity that allows students to make and test assertions and prepare for more formal proof writing. We chose this particular software because it is freely available on-line, it is supplemented with a variety of dynamic worksheets, and it is user friendly (www.GeoGebra.org). The unique feature of GeoGebra is the integration of dynamic geometry software and a computer algebra system into a single tool for mathematics education (Hohenwarter & Preiner, 2007; Edwards & Jones, 2006). Students can build a geometric construction and simultaneously observe how changes in a formula in the algebra window are affected by manipulation of the construction and vice versa. Teachers can use GeoGebra to create interactive web pages or dynamic worksheets to develop student activities as we have done here. By participating in the technology based activity below, the student will engage in advanced mathematical thinking that leads to building conjectures.

## A Proof Enriching Activity for the Middle School Classroom

In the first challenge of this activity, students are asked to divide a rectangular garden into two equivalent regions. Students are asked to find as many possible solutions as they can. The dynamic software allows them to easily manipulate the fence line as well as observe changes in the area of each region (see figure 1).

The dynamic geometry software also allows the student to construct a conjecture about a common feature of all presented solutions. In this problem, the generalization is as follows: Every line segment that goes through the center of the rectangle, the point of intersection of the diagonals, will divide the rectangular region into two equivalent areas.

Based on our classroom experience, students first typically present four solutions (see figure 2) and, after further experimentation, may find other possible segments (see figure 3).

The second challenge in this activity describes a rectangular garden that must be built around a fixed rectangular structure. The objective is still to divide the garden with a straight fence into two equivalent regions (see figure 4). The conjecture students' developed in the first challenge assists them in finding a solution to this more advanced problem. The generalization for the second challenge is as follows: Regardless of the position or the size of the enclosed rectangular structure, the line segment that goes through both rectangle centers will divide the region into two equivalent parts. Depending on the level of the students' geometry development, the teacher may chose to extend the activity further by replacing the interior rectangular structure with another geometric figure (e.g. a circle, triangle, or pentagon) and asking similar questions. A further extension could be a 3-dimensional model of this problem, replacing the rectangle with a prism and the line segment with a 2-dimensional plane.

This activity presents an equal challenge regardless of the students' content background and can be easily adapted for students at various levels of geometric development. Activities such as the one presented, show students how mathematicians think through a problem, using reasoning to construct and test conjectures. By building and testing conjectures with technology as a tool, students make further progress toward advanced mathematical thinking.

# INCORPORATING WEB TECHNOLOGY INTO THE DEVELOPMENT OF MATHEMATICS TEACHING MATERIALS

Fenqjen Luo
University of West Georgia
fluo@westga.edu

*This study reports thirteen school teachers' efforts to develop standards-based mathematics teaching materials on an interactive Website. The merits of Web technology demonstrated by participating teachers in their development of mathematics teaching materials were addressed. Participating teachers' limitations on incorporating Web technology into the development of mathematics teaching materials were also discussed.*

## Introduction

Considering the enormous growth of the Web and the educational attention to it, school teachers should use the Web in an effective manner. Most Web education literature focuses on Web-based instruction and learning rather than promoting the development of Web itself. In order to develop and optimize school teachers' adaptability in using the Web, all participating teachers in this study would be expected to develop standards-based mathematics teaching materials on their own Websites.

## Theoretical Framework and Research Questions

The theoretical framework of the Learning Cycle Approach recommended by Gabel (2003) was adopted for use in the development of mathematics teaching materials. The Learning Cycle Approach involves three phases: exploration, invention, and application. Two research questions guided this study: (a) what merits of Web technology are demonstrated from the participating teachers' development of mathematics teaching materials; and (b) what limitations are demonstrated from the participating teachers' use of Web technology on their development of mathematics teaching materials?

## Methodology

At the exploration phase, participating teachers were asked to explore a challenging mathematics topic that they intended to work on but lacked sufficient supporting materials from the Web society of mathematics education. At the invention phase, teachers would need to support their chosen topic by inventing standards-based mathematics teaching materials across three or more grade levels. At the application phase, teachers were required to incorporate the merits of Web technology into their newly developed mathematics teaching materials.

## Findings

This study found that participating teachers acquired valuable information to support their invention of teaching materials via Web exploration. They enriched their mathematics teaching materials by linking to various supporting Websites, and shared their own mathematics teaching materials via their own Websites. Several teachers invented unique mathematics teaching materials on their Websites. However, participating teachers did not incorporate the benefit of interactive Web capabilities by soliciting ideas to enrich their teaching materials. Several determined topics did not reflect a high level of difficulty and did not meet with the needs for the

Web society of mathematics education. Dynamic Web communications and collaboration did not occur among participating teachers. Several teachers had difficulty coping with technical issues such as condensing file sizes and editing video clips, and showed limitations in incorporating various technology tools and resources into their development of teaching materials.

# INCORPORATING ICT IN MATH AND SCIENCE HIGH SCHOOL CLASSROOMS

Veronica Hoyos
AA4, National Pedagogical University (UPN), Mexico
vhoyosa@upn.mx

*This contribution presents five different teacher ways of incorporating ICT in mathematics high school classrooms. They were instrumented by 15 teachers after they had participated in an on line training course of six months (see "Specialization on Mathematics and Technology", at: http://upn.sems.gob.mx). Observational data were issued from the videos participant teachers did at the end of the course, showing the meaning they had assigned to their math and technological experience acquired along the six mentioned months by accomplishing series of pedagogical activities and tasks using mathematics technology (Zbiek & Hollebrands, 2008).*

## Theoretical Underpinnings, Methodology and Results

Ruthven (2007) proposes examining teacher response to new technologies, based on Kerr's (1991: 121) assertion that "If the technology must find a place in classroom practice, it must be examined in the context of class life, [just] as the teachers life it." (Cited by Ruthven, ibidem: 3).

There were some pedagogical tasks included in the on line course that resulted specially productive in according with Kerr´s point of view: to (a) choose one math topic from the high school curriculum, along with digital materials you would like to use in your class; b) organize the instrumentation of the activity into the classroom; c) video-record that work session; d) upload a seven minute version of that recording to YouTube; and e) finally upload to the training platform (http://upn.sems.gob.mx) a descriptive report of the video's content together with its URL. From teachers' accomplishment of this task series we obtained the data that allowed us to construct the case study we are reporting here, on the incorporation of technology into high school classes. In addition, the on line teacher training course included pedagogical sequences of activities on the use of dynamic software (eg. Logo, Geogebra, Aplusix, Excel, RecCon, FunDer), along with the exploration of a wide range of possibilities set up on the Internet, as the library of virtual materials of Utah University (see: http://nlvm.usu.edu/en/nav/vlibrary.html).

From the obtained data, we found five different ways that teachers used to incorporate mathematics technology in the classroom: a pattern of incorporation that flowed from the classic approach to teaching; a modified version of this pattern that added teacher interaction with the students, basically by means of teacher questioning; instrumentalization of the activity directed by a script; orchestration (Trouche, 2000) of the activity using different instruments or artifacts, plus group negotiation of meaning; and finally, organization of cooperative work centered on student appropriation of technology.

# MATHEMATICAL HABITS OF MIND

Kien Lim
University of Texas at El Paso
kienlim@utep.edu

Annie Selden
New Mexico State University
js9484@usit.net

*The idea of "mathematical habits of mind" has been introduced to emphasize the need to help students think about mathematics "the way mathematicians do." There seems to be considerable interest among mathematics educators and mathematicians in helping students develop mathematical habits of mind. The objectives of this working group are: (a) to discuss various views and aspects of mathematical habits of mind, (b) to explore avenues for research, (c) to encourage research collaborations, and (d) to interest doctoral students in this topic. To facilitate the discussion during the working group meetings, we provide an overview of mathematical habits of mind, including concepts that are closely related to habits of mind—ways of thinking, mathematical practices, knowing-to act in the moment, cognitive disposition, and behavioral schemas. We invite mathematics educators who are interested in habits of mind, and especially those who have conducted research related to habits of mind, to share their work during the first working group meeting. If you would like to give a 10-minute presentation, please contact Kien Lim or Annie Selden in advance.*

## An Overview of Mathematical Habits of Mind

There are several terms and points of view in mathematics education that are somewhat similar or support each other, and might be brought together under the single phrase "mathematical habits of mind." We discuss several of these views that we see as related.

*Habits of mind* were introduced by Cuoco, Goldenberg, and Mark (1996) as an organizing principle for mathematics curricula in which high-school students and college students think about mathematics the way mathematicians do. They asserted:

> The goal is … to help high school students learn and adopt some of the ways that mathematicians *think* about problems. … A curriculum organized around habits of mind tries to close the gap between what the users and makers of mathematics *do* and what they *say*. … It is a curriculum that encourages false starts, calculations, experiments, and special cases. (p. 376)

They identified two broad classes of habits of mind: (a) general habits of mind that cuts across every discipline, and (b) content-specific habits of mind for the discipline of mathematics. General habits of mind include "pattern-sniffing," experimenting, formulating, "tinkering," inventing, visualizing, and conjecturing. Mathematical habits of mind, or mathematical approaches to things, include *talking big thinking small* (e.g., instantiating with examples), *talking small thinking big* (e.g., generalizing, abstracting), thinking in terms of functions, using multiple points of view, mixing deduction and experiment, and pushing the language (e.g., at first assuming the existence of things we want to exist, such as $2^0$).

Habits of mind have two important characteristics: the "thinking" characteristic and the "habituated" characteristic. In addition, habits of mind are reflexively related to classroom practices. Below we discuss various related views of habits of mind.

### *The Thinking Characteristic*

Harel's (2007, 2008) notion of *ways of thinking* underscores the thinking aspect of habits of mind. Harel (personal communication) regards habits of mind as internalized *ways of thinking*. In

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

Harel's view, mathematics consists of two complementary subsets: (a) the first consists of institutionalized *ways of understanding*, which is a collection of established definitions, axioms, theorems, proofs, problems, and solutions that have been accepted by the mathematical community; and (b) the second is a collection of ways of thinking, which are conceptual tools that are useful for the generation of the first subset (Harel, 2008). The distinction between ways of thinking and ways of understanding underscores the importance of mathematical habits of mind, which tend to be neglected in traditional mathematics curricula.

According to Harel's *duality principle* (2007), "Students develop ways of thinking only through the construction of ways of understanding, and the ways of understanding they produce are determined by the ways of thinking they possess" (p. 272). This principle asserts that ways of thinking cannot be improved independently of ways of understanding, and vice versa. Hence, Harel advocates that both ways of understanding and ways of thinking should be incorporated as learning objectives for students.

In their introductory article to a special issue on advanced mathematical thinking that considered symbolizing, mathematizing, algorithmatizing, defining, and reasoning, Selden and Selden (2005) stated:

> Sometimes referred to as "mathematical habits of mind" or "mathematical practices," these [aforementioned specific] ways of thinking about and doing mathematics may be fairly widely regarded as productive, but are often left to the implicit curriculum. (p. 1)

Also, according to Bass (2005), mathematical habits of mind are critical to many aspects of the educational process. He argued that:

> the knowledge, practices, and habits of mind of research mathematicians are not only relevant to school mathematics education, but that this mathematical sensibility and perspective is essential for maintaining the mathematical balance and integrity of the educational process—in curriculum development, teacher education, assessment, etc. (p. 418)

Bass (2008, January) has considered habits of mind as *practices*—things that mathematicians do. Such practices include asking 'natural' questions, seeking patterns or structure, consulting the literature and experts, making connections, using mathematical language with care and precision, seeking and analyzing proofs, generalizing, and exercising aesthetic sensibility and taste. Bass claims that children can, and should, cultivate these practices from their early school years on. By capitalizing on children's curiosity their inquisitive minds can be harnessed. Goldenberg (2009, January) offered some strategies that capitalize on children's phenomenal language-learning ability and abstracting-from-experience ability to develop certain algebraic ideas such as *breaking* [apart] *numbers and rearranging parts* (commutative property, associative property), and *breaking arrays and describing constituent parts* (distributive property). Goldenberg provided evidence to show that children can indeed use "algebra" as a language to describe a process or a pattern and to express what they already know.

For Leikin (2007), "employing habits of mind means inclination and ability to choose effective patterns of intellectual behavior" (p. 2333). With respect to the mental habit of solving problems in different ways, Leikin considers a problem-solving strategy as a habit of mind when it is within one's "personal solution spaces of many problems from different parts of [the] mathematical curriculum" (p. 2336). One goal of mathematical instruction is then to move solutions from students' *potential solution spaces* (containing solutions that are produced with the help of others; i.e., solutions that are within one's *zone of proximal development*) into their *personal solution spaces*.

*The Habituated Characteristic*

The *habituated* character of habits of mind is underscored in Goldenberg's description of habits of mind, which "one acquires so well, makes so natural, and incorporates so fully into one's repertoire, that they become mental habits—one not only can draw upon them easily, but one is likely to do so" (p. 13). Mason and Spence's (1999) notion of *knowing-to act in the moment* accentuates this habituated character. They have differentiated between two types of knowledge. The first type, referred to as *knowing-about*, consists of Ryle's (1949, cited in Mason & Spence) three classes of knowledge: *knowing-that* (factual knowledge), *knowing-how* (procedural skills), and *knowing-why* (personal stories to account for phenomena). The second type, referred to as *knowing-to*, is tacit knowledge that is context/situation dependent and becomes present in the moment when it is required. This distinction is important because "knowing to act when the moment comes requires more than having accumulated knowledge-about . . ." (Mason & Spence, 1999, p. 135).

> Knowing-about … forms the heart of institutionalized education: students can learn and be tested on it. But success in examinations gives little indication of whether that knowledge can be used or called upon when required, which is the essence of knowing-to. (p. 138)

Mason and Spence advocate the practice of reflection as a means to help students improve their knowing-to act in the moment. Students should be encouraged to reflect on (a) what they have done after an action, and (b) what they are doing while enacting it, which were termed by Schön (1983) *reflection-on-action* and *reflection-in-action* respectively. With respect to reflection-in-action, students should routinely ask themselves "What do I know?" and "What do I want?" (Mason & Spence, p. 154).

The habituated character of habits of mind is also reflected in Lim's (2008) notion of *spontaneous anticipation* by a student—when he or she immediately anticipates and carries out an action for a situation based on the first idea that comes to mind. Whereas Cuoco, Goldenberg, and Mark's (1996) notion of habits of mind has a positive connotation, Lim's spontaneous anticipation can be either desirable or undesirable. *Interiorized anticipation* is desirable in that "one spontaneously proceeds with an idea without having to analyze the problem situation because one has interiorized the relevance of the anticipated action to the situation at hand" (p. 45). Interiorized anticipation is similar to Mason and Spence's notion of knowing-to. *Impulsive anticipation*, on the other hand, is undesirable in that "one spontaneously proceeds with an idea that comes to mind, without analyzing the problem situation and without considering the relevance of the anticipated action to the problem situation" (p. 44).

Lim notes that a habit of mind can also be regarded as a *cognitive disposition*—a tendency to act, mentally, in a certain way in response to certain situations. When a person has a particular habit of mind, he or she has a disposition to act according to that habit of mind. Lim (2009, January) uses the term *impulsive disposition* to refer to the proclivity of "doing whatever first comes to mind … or diving into the first approach that comes to mind" (Watson & Mason, 2007, p. 207). Lim (2009, January) offered the following strategies to address impulsive disposition: (a) do not teach algorithms and formulas prematurely; (b) pose problems that necessitate a particular algorithm or concept, that intrigue students, that require students to attend to the meaning of numbers and symbols, and that require students to explain and justify; (c) include contra-problems to promote skepticism; and (d) include superficially-similar-but-structurally-different problems on tests and examinations.

Selden and Selden (2009, January) have conceptualized (small) habits of mind as habitual situation-action pairs or *behavioral schemas*—"a form of (often tacit) procedural knowledge that yields immediate (mental or physical) actions." They are developing this perspective in the context of proving in a design experiment with advanced undergraduate and beginning graduate students (Selden, McKee, & Selden, 2009), and in a teaching experiment with mid-level undergraduate real analysis students. Indeed, the entire proving process might be seen as a sequence of mental or physical actions (that cannot be fully reconstructed from the written proof). The individual actions often appear to be due to the enactment of behavioral schemas (that is, small, simple habits of mind). Here is an example of a common beneficial behavioral schema. The situation is having to prove a universally quantified statement such as, "For all real numbers *x*," and the linked action is writing into the proof something like, "Let *x* be a real number," meaning *x* is arbitrary but fixed. While some students are at first reluctant to write this, doing so can become habitual and automated, that is, become a behavioral schema and eventually just seems to be "the right thing to do." In contrast, a detrimental behavioral schema in proving is focusing on the hypotheses of a theorem too soon, and simply "forging ahead," without first examining the conclusion to see what is to be proved. Selden and Selden think it is likely that some larger, more complex, habits of mind can be decomposed into behavioral schemas. Also, they think this perspective would probably be useful in other kinds of reasoning, such as problem solving, and with K-12 students.

Selden and Selden think that focusing specifically on small habits of mind has two advantages. First, the uses, interactions, and origins of behavioral schemas are relatively easy to examine. For example, behavioral schemas tend to reduce the burden on working memory. Also, the process of enactment of a behavioral schema occurs outside of consciousness, but apparently the triggering situation must be conscious. Thus, such schemas cannot be "chained together" outside of consciousness with only the final action being conscious (Selden & Selden, 2008). For example, one cannot produce the solution to a linear equation without being conscious of the intervening steps. Second, this perspective is not only descriptive but also suggests concrete teaching actions, such as encouraging the writing of the formal-rhetorical parts of a proof at the beginning of the proving process (Selden & Selden, in press). In this way, it is fairly easy for a teacher to devise ways of helping a student strengthen a beneficial, or weaken a detrimental, behavioral schema.

*Relating Habits of Mind and Classroom Practices*

In *Fostering Algebraic Thinking: A Guide for Teachers Grades 6-10*, Driscoll (1999) views habits of mind as ways of thinking, that when used habitually, can lead to successful learning of algebra. He stresses the development of three algebraic habits of mind: (a) *doing/undoing* which involves reversing mathematical processes; (b) *building rules to represent functions* which involves pattern-recognition and generalization; and (c) *abstracting from computation* which involves thinking about computations structurally without being tied to specific numbers, such as recognizing the equivalence of 5% of 7000 and 7% of 5000. He and his colleagues later developed a four-module toolkit for educators to work with teachers to learn how to foster these algebraic habits of mind in their classrooms (see Driscoll et al., 2001). Subsequently in *Fostering Geometric Thinking: A guide for teachers grades 5-10*, Driscoll, DiMatteo, Nikula, and Egan (2007) promote four geometric habits of mind: (a) reasoning with relationships, (b) generalizing geometric ideas, (c) investigating invariants, and (d) sustaining reasoned exploration by trying different approaches and stepping back to reflect while solving a problem. *The Fostering Geometric Thinking Toolkit* was published a year later (see Driscoll et al., 2008).

Cuoco (2008, January) has advocated making mathematical habits of mind a key component of the syllabus because "without explicit attention to mathematical ways of thinking, the goals of 'intellectual sophistication' and 'higher order thinking skills' will remain elusive." He offered some suggestions for helping students cultivate desirable habits of mind: (a) working on problems with students, (b) being explicit about one's own thinking, and (c) making thought experiments an integral part of the learning experience. Rasmussen (2009, January) emphasized the need for teachers to be deliberate about initiating and sustaining particular classroom norms so as to promote certain desirable habits of mind and effect students' beliefs and values.

The RAND Mathematics Study Panel (2003) referred to "mathematical know-how—what successful mathematicians and mathematics users *do*" (p. 29) as *mathematical practices*. They also identified mathematical practices as one of the three foci for a proposed research and development program aimed at improving mathematical proficiency among U.S. school students. The Panel stated:

- "A focus on understanding these practices and how they are learned could greatly enhance our capacity to create significant gains in student achievement, especially among currently low-achieving students who may have had fewer opportunities to develop these practices" (p. 29)
- "These practices are not, for the most part, explicitly addressed in schools. Hence, whether people somehow acquire these practices is part of what differentiates those who are successful with mathematics from those who are not" (p. 32-33)

The Panel recommended the following lines of research: (a) developing an understanding of specific mathematical practices, and their interactions, along the domains of representation, justification, and generalization; (b) examining the use of these mathematical practices in different settings (e.g., in school, at home, at work); and (c) investigating ways for developing these practices in classrooms. Further, the Panel stated that "such [mathematical] practices must be deliberately cultivated and developed, and therefore research and development should be devoted to addressing this challenge." (p. 40)

Many theoretical ideas and pedagogical suggestions related to habits of mind have been raised. However, the research on this topic is still relatively thin. Using Cobb and Yackel's (1996) emergent perspective in which "learning is a constructive process that occurs while participating in and contributing to the practices of the local community" (p. 185), we regard mathematical habits of mind as individual dispositions that are reflexively related to mathematical practices of a classroom community. Cobb and Yackel suggested that "analysis whose primary purpose is psychological should be conducted against the background of an interactionist analysis of the social situation in which the student is acting" (p. 188). Hence, we encourage research on understanding the interaction between individual mathematical habits of mind and classroom mathematical practices, in addition to research on how students develop mathematical habits of mind.

## Purpose of this Working Group

This working group is a follow-up to two panel-discussion sessions on "Helping Students Develop Mathematical Habits of Mind" at two consecutive Joint Mathematics Meetings (JMM) of the American Mathematical Society and the Mathematical Association of America held in 2008 and 2009. The presenters-cum-panelists at the JMM 2008 session in San Diego included Hyman Bass, Al Cuoco, Guershon Harel, and Annie Selden. The presenters-cum-panelists at the JMM 2009 session in Washington DC included Hyman Bass, Paul Goldenberg, Kien Lim, Chris Rasmussen, Annie Selden, and John Selden. Both sessions were well attended and well received by the audience. The second session was in fact an encore of the first session. Based on attendance reactions to these two sessions, there seems to be considerable interest among mathematics educators and mathematicians in this topic. This PME-NA working group can offer a platform for mathematics educators who are interested in this topic to explore research opportunities.

The primary purpose of this working group is to generate interest among mathematics educators for conducting research related to mathematical habits of mind. The second purpose is to encourage research collaborations. The objectives of this working group are:

- To discuss various views and aspects of mathematical habits of mind.
- To explore avenues for future research.
- To facilitate mathematics educators with similar research interests to form research groups.
- To motivate doctoral students who may plan to work on this topic for their dissertations.

## Proposed Activities for this Working Group

Meeting 1

- An overview on mathematical habits of mind.
- Individual presentations, if any, on research related to habits of mind.
- An open forum to discuss theoretical and pedagogical issues related to mathematical habits of mind.
- A brainstorming session to identify worthwhile avenues of research.

Meeting 2

- Small-group breakout sessions to identify research opportunities, formulate research questions, and discuss research designs.

Meeting 3

- Small-group presentations of plans for research.
- Discussion of next steps.

## Anticipated Follow-up

We anticipate that promising avenues for research related to mathematical habits of mind will be identified. The working group may broaden the scope of research for some mathematics educators by integrating their existing research with research on mathematical habits of mind. This working group is likely to continue if there are groups of researchers who plan to conduct collaborative research on this topic. There may be a possibility of eventually having a special issue of a journal dedicated to mathematical habits of mind.

# LESSON STUDY WORKING GROUP

Lynn Hart
Georgia State University
lhart@gsu.edu

Alice Alston
Rutgers University
alston@rci.rutgers.edu

Aki Murata
Stanford University
akimura@stanford.edu

The Lesson Study Working Group met at three previous PME/NA conferences: Merida, Mexico (2006), Lake Tahoe (2007) and Morelia, Mexico, (2008). Over 20 researchers attended each meeting. At the sessions participants shared current research around lesson study and discussed future plans and goals. Several projects shared artifacts from their work. The group discussed at length current trends, issues, and problems facing research and implementation of lesson study. Following is a summary of our discussions.

## Lesson Study: Structures, History, and Variation

Lesson study incorporates characteristics of effective professional development programs identified in prior research: it is site-based, practice-oriented, focused on student learning, collaboration-based, and research-oriented (Bell & Gilbert, 2004; Borko, 2004; Cochran-Smith & Lytle, 1999, 2001; Darling-Hammond, 1994; Wang & O'Dell, 2002; Little, 2001; Hawley & Valli, 1999; Wilson & Berne, 1999). What separates lesson study from other instructional improvement approaches is that it places teachers at the center of the professional activity, with their interests and desire to better understand student learning based on their own teaching experiences. The idea is simple: teachers organically come together with a shared question regarding their students' learning, plan a lesson to make student learning visible, and examine and discuss what they observe. Through multiple iterations of the process, teachers have many opportunities to discuss student learning and how their teaching affects it.

After identifying a lesson goal, teachers plan a lesson. The goals can be general at first (e.g., how students understand equivalent fractions), and are increasingly refined and focused throughout the lesson study process to become specific research questions at the end (e.g., strategies students use to compare 2/4 and 3/6). Teachers choose and/or design a teaching approach to make student learning visible, keeping their lesson goal in mind. The main purpose of this step is not to plan a perfect lesson but to test a teaching approach (or investigate a question about teaching) in a live context to study how students learn. As they plan, they anticipate students' possible responses and craft the details of the lesson. Teachers come to know the key aspects of the lesson, to anticipate how students may respond to these aspects, and to explore different thinking and reasoning that may lie behind the possible responses. During planning, teachers also have an opportunity to study curricular materials, which can help teachers' content knowledge development. During the lesson, teachers attend to student thinking and take notes on different student approaches. During the debriefing after the lesson, teachers discuss the data they have collected during the observation**.**

There are other professional development programs that incorporate many of the characteristics of lesson study (e.g., action research, teacher research). However, what sets lesson study apart is the *live* research lesson. The live research lesson creates a unique learning opportunity for teachers. Shared classroom experiences expose teachers' professional knowledge that may otherwise not be shared: teachers notice certain aspects of teaching and learning, and this implicit and organic noticing does not happen in artificially replicated professional development settings.

In Japan, lesson study has been widely used for over a century. Many Japanese educators attribute success in changing their teaching practice to participation in lesson study (Lewis, Perry, &

Murata, 2006; Murata & Takahashi, 2002: Shimizu, et. al., 2005). As a foundational mechanism to support the improvement of teaching, lesson study is used to examine and better understand new educational approaches, curricular content, and instructional sequences introduced in Japan. In many cases, teachers play the central role in making new approaches adoptable and content accessible. Lesson study makes teaching approaches more practical and understandable to teachers through developing deeper understanding of content and student thinking. In this manner, lesson study works effectively to connect theory and practice.

While lesson study is known in the United States (and other parts of the world) as a small, school-based collaboration, typically in the subject area of mathematics, lesson study comes in many different shapes and sizes in Japan. There is small and school-based lesson study as well as large-scale, national-level lesson study (Murata & Takahashi, 2002; Lewis & Tsuchida, 1998; Shimizu, et. al., 2005). Different formats for lesson study meet different needs and interests of the teachers. A typical Japanese teacher has multiple opportunities to participate in lesson study throughout his/her professional career.

## Introducing Lesson Study to the World

Lesson study came to attract the attention of an international audience in the past decade, and in 2002 it was one of the foci for the Ninth Conference of the International Congress on Mathematics Education (ICME). It subsequently spread to many other countries and more than a dozen international conferences and workshops were held around the world in which people shared their experiences and progress with lesson study as they adopted this new form of professional development in their unique cultural contexts (e.g., Conference on Learning Study, 2006; Fujita, et. al., 2004; Lo, 2003; National College for Educational Leadership, 2004; Shimizu, et. al., 2005).

## Issues of Fidelity of Implementation

There are several issues and concerns around *implementing* lesson study in diverse settings. For example, there are unique issues of implementation with preservice or inservice teachers. Other issues include: content knowledge competency, variations in curricula, time and availability to meet, administrative support and cultural differences. As a result of these difficulties in maintaining fidelity of implementation with the Japanese model, lesson study is being *adapted* to meet unique needs in a variety of settings.

The limited depth of mathematical knowledge of some teacher groups attempting to implement lesson study, particularly at the elementary-level, has raised the question of whether lesson study work can be completely teacher-driven. Related to this issue is the role the outside coach or expert should or could play in such a lesson study community. A second issue is implementation within existing, traditional and/or rigidly structured curricula. Unlike the Japanese mathematics curriculum which provides a loosely defined framework for teachers to build off of, many curricula used in other countries are quite structured or scripted and not conducive to the planning cycles used in Lesson Study. A third issue is a lack of administrative support necessary to alter existing curricula, provide financial support, and schedule opportunities to meet and plan. The daily schedule of most *elementary* teachers prevents regular meetings and opportunities to collaborate. A related issue is the limited extrinsic reward available. Lesson Study presupposes blocks of time for teachers to work together. This frequently must be outside school hours and districts are often constrained by contracts that demand stipends and/or release time. Finally there may be fundamental differences in the cultures of teachers from different communities and countries. It was suggested that the fiercely independent nature of some cultures may limit success in building collaborative groups.

## Research on Lesson Study

The body of knowledge about lesson study is growing, but remains somewhat elusive and composed of discrete research endeavors. While the literature suggests that lesson study can facilitate greater reflection and more focused conversations about teaching and learning than are often realized with other types of professional development (Lewis, 2002), as well as specific and authentic conversations about management, student learning, and impact of significant and subtle changes in lesson design (Marble, 2006), there is still much to be learned.

The Lesson Study Working Group is attempting to explore the existing research on lesson study and synthesize the work into a resource for other researchers and educators. Following are abstracts from current contributions.

*Lesson Study: A Partnership Model for Studying Students' Thinking*

Alice Alston, Lou Pedrick, Kim Morris, and Roya Bassu, (Rutgers University, US)

Faculty and staff of the Robert B. Davis Institute for Learning in the Graduate School of Education at Rutgers are engaged with teachers and administrators of partnering districts in implementing school-based professional development using a modified form of Lesson Study. During a semester a group of ten teachers resourced by two university researchers worked together to develop a series of mathematical tasks intended to embody concepts that are basic to their district's curriculum and address specific mathematical goals that they had identified as important for their students. The series of tasks were implemented in six classes including grades 5 through 8 that were taught by members of the group during several weeks at the end of the term. The teacher-researchers, studying the videotapes, observer notes and student work from their session, select, transcribe and analyze critical events from each class that provide evocative examples of the mathematical strategies and representations of their students, These analyses are shared in follow-up discussions and compiled to produce an overall analysis of the development of the mathematical ideas as evidenced in the mathematical activity of the students across the four grades involved in the Lesson Study project. The research of the university educators is based on data that includes notes from the earlier sessions when goals were set and the tasks developed as well as the videotapes of the implementations,, debriefing discussions, and the subsequent analyses and group discussions of the teachers. This analysis focuses on the teachers' reflections and actions for evidence of a shift from surface characteristics of the classroom activity toward a closer attention to students' thinking and subsequent implications for instruction.

*What's Going on Backstage? Revealing the Work of Lesson Study*

Catherine D. Bruce & Mary Ladky, (Trent University, Canada)

This study describes some of the key findings related to teacher activity during a grade 4-10 lesson study project and provides an enhanced model of the lesson study stages, highlighting the backstage work within the cycle and thereby contributing to a more nuanced understanding of the process of lesson study. We explore some of the less documented teacher activity - what we are calling the "backstage work" - identified by the teachers in our lesson study research as they moved between and from stage to stage. During focus group interviews, researchers asked teachers to describe the activity that took place between the formal stages of the cycle. Further, in whole group discussions, 12 teachers built a new model illustrating their activities beyond the explicit four stages of lesson study that formed the backbone of their work. For example, teachers identified five main backstage activities between stage 1 (goal setting) and stage 2 (planning) of the lesson study cycle. These are: 1) searching for research on the Internet, in data bases, and in teacher resources about the topic in focus; 2) Conceptualizing: brainstorming, self talk and informal conversations, going off on valuable tangents; 3) Investigating the use of manipulatives and technological tools with students to expand the teacher and students' repertoire; 4) Keeping up with details such as on-going student assessment which provides insights into student learning and assists in the planning of the lesson; and 5) Team building and developing trust amongst lesson study team members. Other specific activities between stages 2 & 3, 3 & 4, and 4& 1 were also identified by teacher participants and are described in the paper**.** As researchers, we recognise this backstage work as essential to a successful lesson study cycle, representing the ongoing work and commitment of the teacher teams as they support one another through the process.

*Learning from Lesson study: Power Distribution in a Community of Practice*

Dolores Corcoran (St Patrick's College, Dublin City University, IRE)

Lesson study is a collaborative practice that has been a culturally embedded part of school life in Japan for more than one hundred years (Isoda, 2007). Its value as a means of teacher professional development is recognized outside Japan (Stigler and Hiebert, 1999) and the past ten years saw a burgeoning interest in lesson study in other educational systems, particularly in the US (Murata, Chapter One). Recently, lesson study was adopted in diverse school systems such as Chile and Thailand as a means of developing innovative classroom teaching and learning of mathematics (APEC, 2008). Japanese lesson study protocols are most often associated with professional development of practising teachers, but the study on which this research is based set out to trial lesson study in an Irish pre-service teacher education context. Results from the study shed light on aspects of lesson study that emerged during its use as part of a primary teacher education programme in Dublin, Ireland.

*What Japanese Lesson Study Can Teach Us About Formative Assessment Practice*

Michele D. Crockett (University of Illinois at Urbana-Champaign, US)

In U.S. mathematics classrooms, teaching and learning are often viewed as disparate activities, a significant problem of practice. The purpose of this paper is to frame Japanese lesson study as formative assessment and to consider what it can teach us about the formative assessment practices that promote students' understanding of mathematics. I use excerpts from Fernandez and Yoshida's (2004) account of lesson study as illustrations of what formative assessment looks like in actual practice and what such practice entails – specifying clear lesson goals, making substantive observations, and anticipating student thinking. Japanese teachers are *always* acting formatively when engaged in the lesson study process. Student thinking is central to their pedagogical decision-making. Lesson study as a model for practical action offers an opportunity to take seriously the role of assessment in teaching and learning in teachers' professional development experiences.

*Critical Considerations for Educational Reform through Lesson Study*

Brian Doig & Susie Groves (Deakin University, AU); Toshiakira Fujii (Tokyo Gakugei University, Japan)

This paper presents an argument for focussing, *Lesson Study* approaches to teacher professional development, firmly on the type and rôle of the mathematical task (*hatsumon*) used in the mathematics classroom. Drawing on research conducted in Australia and Japan, the authors argue that not all elements of *Lesson Study*, or particularly the research lesson, are equal in the impact that they have on children's learning. Further, it is demonstrated how Japanese educators place a strong emphasis on task selection, and that this effort is largely ignored by non-Japanese adapters of Lesson Study. Finally, the authors suggest that in order to use *Lesson Study* effectively in non-Japanese mathematics classrooms, it is necessary to build on the current practices of teachers that are commensurate with the elements of *Lesson Study*. Examples, from Japanese and Australian classrooms, are presented as illustrations of how the selection of the task is critical to the outcomes of the lesson.

*Approaches to Lesson Study in Prospective Teacher Education*
Maria Lorelei Fernandez (Florida International University, US) & Joseph Zilliox (University of Hawai'I, US)

The work of two mathematics educators each using a lesson study approach with prospective teachers of mathematics is reported. One educator worked with prospective secondary teachers in a Microteaching Lesson Study context and the other worked with prospective elementary teachers during initial field experiences in K-6 schools. The lesson study experiences in both contexts incorporated important features of Japanese lesson study including operationalizing an overarching learning goal driving recursive cycles of collaborative planning, lesson observation by colleagues and other knowledgeable advisors, analytic reflection, and ongoing revision. The prospective teachers exposed their knowledge, beliefs and practices to the scrutiny of peers and other experts, developing and reconsidering their thinking and practices through collaboration on shared teaching experiences. Similarities and differences in the secondary and elementary prospective teachers' experiences and learning in relation to elements comprising the lesson study approaches are discussed. Similarities included trajectories of their lesson plans toward more student-centered teaching, importance of negotiation for their learning, and value of the cooperative nature of the experiences for sharing varying ideas and perspectives. Differences included development of mathematics knowledge, extent of focus on classroom processes and management, use of videotaped lessons, conduct of oral reports of their group lesson study, and participation of knowledgeable advisors.

*Development of the Habits of Mind of a Lesson Study Community*
Lynn C. Hart (Georgia State University, US) & Jane Carriere (City Schools of Decatur, US)

This paper describes implementation of a Lesson Study project with third grade teachers in a small school district to study the development of the critical lenses (habits of mind) necessary for meaningful Lesson Study work. Adapting the Lesson Study process to meet school system needs, two outside facilitators stimulated development of the critical lenses through mathematics explorations and probing/what if questioning. Using a qualitative methodology and the group as the unit of analysis, data were coded for evidence of and change in the lenses. After one year, the 8 participating teachers showed a qualitative difference in two of the three lenses: the student lens and the curriculum developer lens. No change was seen in the researcher lens.

*Lesson Study: A Case of the Investigations Mathematics Curriculum with Practicing Teachers at Fifth Grade*
Penina Kamina (SUNY College at Oneonta, US) & Patricia Tinto ( Syracuse University New York, US)

Practicing teachers are often at the heart of reform initiatives and often with little professional development or support. Teachers wrestle with shedding their old pedagogical beliefs, understanding mathematical content, and learning how to use curricular materials such as *Investigations* (Putnam, 2003). The discrepancy between the implementers' prior experiences, National Council of Teachers of Mathematics (NCTM) principles, and *Investigations'* objectives presented an important problem for study. A qualitative case study research design was used to explore teachers' implementation of *Investigations'* mathematics in fifth-grade classrooms. Data were collected in the form of lesson plans and audiotape and videotape of lesson study meetings. Results of this study showed that teachers that collaborated with each other in lesson-study meetings were quickly able to establish new classroom instructional approaches and implement new curriculum. Their enhanced content knowledge, pedagogical knowledge, and reformed pedagogical beliefs that emerged from participating in lesson study enabled these teachers to be versatile in implementing the *Investigations* curriculum.

*Lesson Study as a Learning Environment for Coaches of Mathematics Teachers*

Andrea Knapp (University of Georgia, US), Megan Bomer (Illinois Central College, US), Cynthia Moore (Illinois State University, US)

This qualitative study focused on the professional development of two Coaches of mathematics teachers and one classroom Teacher as they engaged in the lesson study process. The Coaches progressively designed, taught, and refined standards-based lessons which they co-taught with the classroom Teacher. Participants developed three aspects of mathematical knowledge for teaching (MKT): knowledge of content and teaching (KCT), knowledge of content and students (KCS), and specialized content knowledge (SCK) (Hill, Rowan & Ball, 2005). KCT developed as the Coaches and Teacher collaborated during lesson study to place a stronger emphasis on inquiry in lessons. In particular, Coaches investigated reform curricula and research which enhanced the Teacher's KCT. In addition, the group developed KCS as they listened to students and observed them on videotape. Furthermore, Coaches developed KCS from the Teacher as the Teacher shared with Coaches his knowledge of student difficulties. Finally, the Coaches and Teacher developed SCK by considering mathematical perturbations from the lesson with the Teacher. Thus, lesson study mutually enhanced the teaching abilities of both Coaches and the Teacher whom they supported.

*Lesson Study: The Impact on Teachers' Content Knowledge*

Rachelle D. Meyer & Trena Wilkerson (Baylor University, US)

This multiple case study examined the effects lesson study had on middle school mathematics teachers' content knowledge. Participants for this study consisted of 26 middle school mathematics teachers, from a large urban school district, who formed eight lesson study groups. The researchers sought to examine the experiences and impact lesson study had on the participating teachers' content knowledge in mathematics from the eight case studies. More specifically, the researchers focused on (1) the need for teachers' content understanding while planning the research lesson and (2) the participating teachers' growth in content knowledge.

This qualitative research used seven measures to gather data which consisted of the following: two baseline surveys; transcripts from planning and reflection sessions; observation notes; lesson plans; and a reflective questionnaire. Analysis of the data consisted of both a within and across case comparison. For the with-in case analysis, each case was first treated as a comprehensive case in and of itself. Once the analysis of each case was completed, a cross-case analysis began in order to develop more sophisticated descriptions and more powerful explanations. Data revealed lesson study did improve teachers' content knowledge for three of eight case studies as a result of teacher collaboration.

*Lesson Study in Preservice Elementary Mathematics Methods Courses:Connecting Emerging Practice and Understanding*

Aki Murata & Bindu Pothen (Stanford University, US)

The paper outlines how lesson study is used in preservice elementary mathematics methods courses to support preservice teachers' connections between their emerging practice and understanding. The course structure is described, and week-by-week course activities and assignments are summarized. Lesson study in preservice teacher education program has a potential to support on-going teacher learning by connecting the course experiences with field-based assignments. By continuously focusing on student learning of mathematics, research lesson teaching ties together the various experiences in the course to help preservice teachers develop new understanding of their practice, therefore a professional vision. Pedagogical content knowledge is meaningfully developed in the collaborative learning settings. Short summary of research findings on teacher learning is presented based on quantitative and qualitative data.

*Lesson Study: A Tale of Two Journeys*

Jo Clay Olson (Washington State University, US), Paul White (Australian Catholic University), Len Sparrow (Curtin University, Australia)

Lesson study is accepted in Japan as an effective model for teacher professional development and growth. There is less evidence that such a model is viable in international settings. This paper adds to the pool of evidence as it reports on the experiences of five elementary teachers with a lesson study approach to professional development over a year. Two groups were formed, but the results of their experiences were different. One group accepted the challenges highlighted by the lesson study process. They reflected on and changed their classroom practice in fundamental ways. The other team rejected the challenges and maintained their traditional pedagogy. System-wide requirements, for example state testing, constrained the development of one team while the ability to personalize insights from the lesson study process and critical reflection became a catalyst to personal professional growth for the other.

*The Intersection of Lesson Study and Design Research: A 3-D Visualization Curriculum Development Project*

Jacqueline Sack (Rice University) and Irma Vazquez (University of St. Thomas )

In this paper, we share how two teacher-researchers and a teacher apply the principles of lesson study in our research process for developing a 3-dimensional visualization program for elementary children. We share a common belief that children learn best through social constructivist approaches (Cobb et al., 2001) with explicit opportunities for differentiated instruction (Tomlinson, C. A. & McTighe, J., 2006). While many lesson-study experiences offer teachers opportunities for personal professional development for deepening their pedagogical content knowledge, our focus is to develop and investigate new curricular materials that enable students to move among various visual and verbal representations (van Niekerk, 1997). We utilize a dynamic computer interface, Geocadabra (Lecluse, 2005) that simultaneously integrates several of these representations. Our goal is to extend the body of knowledge on how children think and learn about geometric space, ultimately to publish instructional materials to support children's development of 3-dimensional and 2-dimensional spatial reasoning skills. Our study takes place in a linguistically- and academically-diverse inner-city school, during its after-school program, with third- and fourth-grade students, for one hour each week for each grade level. We illustrate our adaptation of lesson study as our process for lesson design, enactment, reflection, and iterative re-enactment.

*Preparing for Lesson Study: Tools for Success*

Mary Pat Sjostrom (Chaminade University of Honolulu, US) & Melfried Olson
(University of Hawaiʻi at Mānoa, US)

This paper describes the experiences of one group of elementary school teachers as they engaged in a three-year professional development experience culminating in a one-year lesson study program. The partners in this project, university professors, school administrators and teachers, worked together to modify the professional development plan to serve the needs of the teachers and students. Although lesson study was not part of the original plan, it became the focus of year three. This case study illustrates the difficulties encountered in introducing lesson study, and examines the way in which the components of the first two years, notably the Reflective Teaching Model, collaborative problem solving and analysis of student work, helped pave the way for success in lesson study in year three.

*Towards Improving Pedagogical and Content Knowledge Through Lesson Study: Insights gained from working with schools in the U.S.*

Makoto Yoshida (Center for Lesson Study, William Paterson University, US) &
William C. Jackson (Scarsdale Public Schools, US)

An important issue that has surfaced in conducting lesson study in the U.S. is how lesson study can help improve teachers' pedagogical and content knowledge, particularly in elementary and middle schools. Even though more and more teachers and schools are conducting lesson study in the U.S., we have not found the most effective ways to cope with this issue.

Based on their experiences working with elementary and middle schools in the U.S., the authors share ideas and provide examples on how to address this issue. Important insights, such as improving the research lesson planning process through *kyozaikenkyu* (instructional material investigation), learning to build students' conceptual understanding by studying coherent and focused curricula, understanding the importance of process standards, and using knowledgeable others to support the lesson study process are discussed.

*Lesson Study as a Framework for Pre-service Teachers' Early Field-Based Experiences*

Paul W. Yu (Grand Valley State University, US)

The theoretical framework for this study is based on a review of the literature across two different, yet mutually relevant, areas of research in mathematics education, pre-service teachers' field based experiences (Zeichner, 1981) and Japanese lesson study (Stigler & Hiebert, 1999; Takahashi and Yoshida, 2004). Zeichner (1981) discusses two contrasting issues related to pre-service teachers' field based experiences. First, these field-based experiences are perceived to be a necessary component for teacher preparation. In contrast, some scholars question the significance of the experience other than an enculturation into the existing socio-cultural norms of the teaching profession. An emerging framework for in-service teacher improvement is lesson study.

This paper reflects on the use of lesson study as a framework for pre-service teachers' field-based experiences that takes place early in their collegiate coursework. The goal was to use lesson study to give students a different model for professional development, that is (1) collaborative, (2) focused on children's understanding of mathematics, and (3) exposes the pre-service teachers to the nature of mathematics instruction. The paper describes how lesson study was modified to accommodate the difference between pre-service and in-service teachers' experiences, and reflects on the enactment of these modifications in the collegiate course.

## Future Goals for the Working Group

It is clear that the body of knowledge around lesson study is in its infancy and assembling work that is currently being done would be productive. Plans were initiated for putting together an edited book where individuals conducting research in Lesson Study could share their findings, questions, and other issues. The group agreed that this would be useful to others with interest in implementing a Lesson Study program or with questions about the state of research on Lesson Study. Discussion on the format and conceptual organization of the proposed book is on-going and a primary goal of this working group.

*The Working Group will focus attention both to issues of mathematics teaching and learning and to issues of equity and diversity. This will include topics such as analyzing what counts as mathematics learning, in whose eyes, and how these culturally bound distinctions afford and constrain opportunities for students of color to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This work begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.*

## Brief History

This Working Group will build on and extend the work of the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME is a group of emerging scholars (new faculty and graduate students) who graduated from, or are still studying at, three major universities (University of Wisconsin-Madison, University of California-Berkley, and UCLA). The Center is dedicated to creating a community of scholars poised to address some critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).

The DiME Group (as well as subsets of that group) has already engaged in important scholarly activities. After two years of a cross-campus collaboration dedicated to studying issues framed by the question of why particular groups of students (ie. poor students, students of color, English learners) fail in school mathematics in comparison to their white (and sometimes Asian) peers, we presented a symposium at AERA 2005 (DiME, 2005). This was followed by the writing of a chapter in the recently published *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME, 2007). In 2006, a group of four DiME graduates, currently new faculty at universities across the United States, applied to the NSF for a grant to support work on synthesizing research in the area of Professional Development that addresses both issues of mathematics and issues of equity and diversity. The proposal received good reviews, but was not funded. In an effort to expand the community of scholars interested in this work, DiME, at AERA in 2008, sponsored a one day Professional Development session examining equity and diversity issues in Mathematics Education.

The Center has historically held DiME conferences each summer. These conferences provide a place for fellows and faculty to discuss their current work as well as to hear from leaders in the emerging field of equity and diversity issues in mathematics education. This past summer of 2008, the DiME Conference was opened to non-DiME graduate students with similar research interests from other CLTs such as the Center for the Mathematics Education of Latinos/as (CEMELA), as well as graduate students not affiliated with an NSF CLT. This was an initial attempt to bring together a larger group of emerging scholars whose research focuses on issues of equity and diversity in mathematics education. In addition, DiME graduates, as they have moved to other universities have begun to work with scholars and graduate students with connections to other NSF CLTs such as MetroMath and the Urban Case Studies Project in MAC-MTL whose projects also incorporate issues of equity and diversity in mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Theoretically we have been building on the work of such scholars as Marta Civil (Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Megan Franke (Franke, Kazemi, & Battey, 2007),Eric Gutstein (Gutstein, 2006), Danny Martin (Martin, 2000), Judit Moschkovitch (Moschkovich, 2002), and Na'ilah Nasir (Nasir, 2002). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and again Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

A significant strand of the work of the DiME Center for Learning and Teaching included implementing professional development programs grounded in teachers' practice and focusing on equity at each site. The research and professional development efforts of DiME scholars are deeply intertwined, and much of the research thus far produced by members of the DiME Group addresses issues of equity within Professional Development. Additionally, since the majority of the DiME graduates, as new professors, along with a number of current Fellows, are engaged in teaching Mathematics Methods courses, the integration of issues of equity with issues of mathematics teaching and learning in Math Methods has become a site of interest for research. As suggested, these two areas will be the focus for much of our research plans in the near future. These scholars have learned through their work with DiME that collaboration is a critical component to our work and are eager for an opportunity to continue working together as well as to expand the group to include other interested scholars with similar research interests.

## Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, Professional Development, pre-service teacher education (primarily in Math Methods classes), student learning (including the learning of particular sub-groups of students such as African-American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics.

Existing research tends either to focus on professional development in mathematics (e.g., Barnett, 1998; Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Kazemi & Franke, 2004;

Lewis, 2000; Saxe, Gearhart, & Nasir, 2001; Schifter, 1998; Schifter & Fosnot, 1993; Sherin & vanEs, 2003), or professional development for equity (e.g., Sleeter, 1992, 1997; Lawrence & Tatum, 1997a). Little research exists, however, which examines professional development or mathematics methods courses that integrate both. The effects of these separate bodies of work, one based on mathematics and one based on equity, limits the impact that teachers can have in actual classrooms. The former can help us uncover the complexities of children's mathematical thinking as well as the ways in which curriculum can support mathematical understanding in a number of domains. The latter has produced a body of literature that has helped to reveal educational inequities as well as demonstrated ways in which inequities in the educational enterprise could be over come.

To bridge these separate bodies of work, the Working Group will focus on analyzing what counts as mathematics learning, in whose eyes, and how these culturally bound distinctions afford and constrain opportunities for students of color to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions that the Working Group will consider are:

*Teachers and Teaching*

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving and equitable mathematics pedagogy.
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?

*Students and learning*

- What is the role of student academic and mathematics identity in achievement?
- How do students out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?

*Policy*

- How does an environment of high stakes standardized testing affect whether and how teachers teach mathematics for understanding? How does this play out across a variety of

local contexts? How can we support teachers to teach mathematics for understanding in that environment?
- How do we address issues of tracking/ability grouping and in particular the grouping of students by test designation?

## Plan for Working Group

The overarching goal of the group is to facilitate collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education. The PME Working Group will provide a forum for these scholars to come together with other interested researchers who identify their work as attending to equity and diversity issues within mathematics education in order to develop plans for future research. Our main goal for this year, then is to begin a sustained collaboration around key issues (theoretical and methodological) related to research design and analysis in studies attending to issues of equity and diversity in mathematics education.

In order to support this collaborative research, smaller research groups will be formed from participants in the large Working Group. These groups will be dependent on the research interests of the Working Group participants. For example, a smaller group may discuss research on in-service teachers engaged in Professional Development, or research done within the context of a Mathematics Methods course.

Much of our work is qualitative in nature and we recognize that one way to increase the number of participants is to conduct research across several sites. In order to do this, we need to use the same protocols for data gathering. Our intention is to use some of the PME meeting time to share and/or develop, and revise interview, observation and other research protocols which may be used across a variety of research projects. It is anticipated that one aspect of the sub-group meetings will be to discuss potential funding opportunities. Here we may identify and begin to draft grants proposals to fund research across contexts.

More specifically, we will work across these various areas in the following way.

SESSION 1:

- Presentation and discussion of goals of Working Group.
- Introduction of participants
- Work on such tasks as examining research protocols or sharing existing data. (Sample protocols for classroom observation, video analysis, and interviewing will be available. Plans are in place to invite collaborators to examine existing data sets.)

SESSION 2:

- Sub-group meetings to discuss plans to address research questions such as those set forth in the Focal Issues.
- Further work on examination and refining of protocols and/or data sharing from Session 1.

SESSION 3:

- Sharing and discussion of work from Sessions 1 and 2.
- Planning for further collaboration, including designation of a person who will facilitate each sub-group.
- Developing a tentative agenda for future Working Group meetings

## Anticipated Follow-up Activities

It is anticipated that interested Working Group participants will align themselves with other participants who have similar research programs (as described more fully above). It is also anticipated that Interest Groups will also form along the lines of research protocols. That is, there may be researchers who use video, or classroom observations in their research who are interested in exploring further some video analysis or classroom observation protocols to use in their work. And so it is anticipated that Working Group participants will leave the conference ready to work on developing particular aspects of their research (such as particular data gathering methods) and/or ready to develop a new project in collaboration with other Working Group participants. It is our hope that the work of this group will begin at this Conference in Atlanta in 2009, and we anticipate it will continue for many years.

*This working group continues its focus on the study of preservice elementary teachers' content knowledge in mathematics for teaching. Participants continue the considerations of (a) the types of knowledge needed for teachers of mathematics, (b) principles that guide the design of courses to facilitate the development of such knowledge, (c) research studies that have been conducted in these areas, (d) implications of existing research studies, and (e) identification of further research needs. Dialogues (on- and off line), resource sharing, as well as collaboration among members of the study group will be encouraged and facilitated both during the conference and afterwards.*

## Focuses and Aims of the Working Group

*Defining the Types of Knowledge Needed for Teaching Elementary School Mathematics*

One of the goals of this working group is to further discuss and conceptualize the concept and aspects of mathematical content knowledge for teaching. The definition of the knowledge needed to teach mathematics has been the focus of recent discussions in the mathematics education community. Groups are meeting at various conferences (for example: PME-NA 2007, AMTE 2008, AMTE 2009) to gain a better understanding of what preservice elementary school teachers should know in order to become effective teachers and to explore how mathematics educators can assist preservice and in-service elementary school teachers in developing such knowledge.

Hill, Ball, & Shilling (2008) introduced a framework for distinguishing the different types of knowledge included in the construct of mathematical knowledge for teaching (see Figure 1).

*Swars, S. L., Stinson, D. W., & Lemons-Smith, S. (Eds.). (2009). Proceedings of the 31st annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education. Atlanta, GA: Georgia State University.*

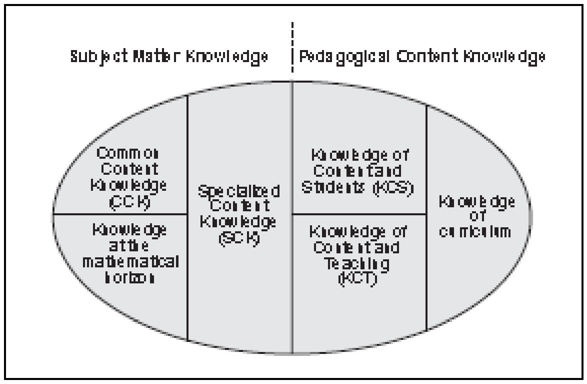

*Figure 1.* Domain map of mathematical knowledge for teaching (Hill, Ball, & Schilling, 2008, p. 377).

This framework distinguishes between subject matter knowledge and pedagogical content knowledge. Subject matter knowledge is subdivided into common content knowledge, specialized content knowledge, and knowledge on the mathematical horizon. Pedagogical content knowledge is subdivided into knowledge of content and students, knowledge of content and teaching and knowledge of curricula. Hill, Rowan & Ball (2005) provide empirical support linking teachers' "mathematical knowledge for teaching" to student achievement gains. In their study, they define mathematical knowledge for teaching as "mathematical knowledge used to carry out the work of teaching mathematics" (p. 373). Examples of such knowledge include "explaining terms and concepts to students, interpreting students' statements and solutions, judging and correcting textbook treatments of particular topics, using representations accurately in the classroom, and providing students with examples of mathematical concepts, algorithms, or proofs" (p. 373).

This framework was discussed among participants of a symposium at AMTE.[10] All participants found the framework to be useful when discussing different types of knowledge they want their preservice teachers (PSTs) to develop. However, the distinctions among the different types of knowledge seemed blurry at times[11]. For example, Hill et al (2008) described common content knowledge (CCK) as "knowledge that is used in the work of teaching in ways *in common with* how it is used in any other professions or occupations that also use mathematics" (p. 377) and specialized content knowledge (SCK) as "the mathematical knowledge that allows teachers to engage in particular *teaching* tasks, including how to accurately represent mathematical ideas, provide mathematical explanations for common rules and procedures and examine and understand unusual solution methods or problems" (p. 377). Considering that we want children to not simply be able apply the correct procedures but be able to go beyond that and understand why the procedures work, the distinction between the two types of knowledge is not clear. In recent years, several influential organizations have called for a focus on conceptual understanding (Kilpatrick, Swafford, & Findell, 2001; Lundin & Burton, 1998; National Council of Teachers of Mathematics, 2000) to help students become successful mathematics learners (Thompson, Philipp, Thompson, & Boyd, 1994). Thus, if a goal of instruction is that children

[10]Christine Browning, Meg Moss, Randy Phillip, Eva Thanheiser, Tad Watanabe
[11] Ball, Thames & Phelps (2008) acknowledge the problem of the fuzzy boundary among their six sub-domains.

understand the underlying concepts (i.e. being able to explain why three digit subtraction works) ) it appears that teachers must be able to support children to develop SCK, or at least part of it? Similar issues were raised when comparing other types of knowledge. For example, in the domain map of mathematical knowledge for teaching, knowledge of content and students resides in the PCK area, however, in recent work (Philipp, et. al. 2007), knowledge of content and students was used as a means to develop specialized content knowledge. Thus a connection to children's mathematical thinking may cross the boundaries between SCK and PCK.

*Developing a Framework for Design Principles for Preservice Elementary School Teacher Courses*

Related to the question of how best to prepare elementary school teachers, the working group will discuss the design principles that guide the development of the mathematics content courses for PSTs and their impact on the development of PSTs' knowledge. The participants of a symposium at AMTE found they share the following principles. The working group will continue to explore components of the structure.

1. Mathematical ideas are built on the PSTs' currently held conceptions.
2. "Model" teaching.
3. Connect to other kinds of knowledge
    - Knowledge of content and teaching
    - Knowledge of content and children
    - Knowledge of curriculum

Participants found their attempts to build mathematical ideas from PSTs' currently held conceptions take two different approaches. For some teacher educators this means identifying what conceptions PSTs hold when they enter our classrooms and building on those conceptions. This approach grows out of a rich cognitive-science paradigm focused upon children's prior knowledge in learning situations, a consideration that is equally important in work with adults (Bransford, Brown, & Cocking, 1999). Once mathematics teacher educators (MTEs) know PSTs initial conceptions we need to understand how those conceptions develop (this is discussed in more detail below). Other teacher educators support the development of PSTs' conceptions by limiting the mathematical ideas that can be used in explorations. Only those ideas developed by the classroom community are allowed. Both of these approaches could be employed simultaneously. For example, rules related to area formulas for polygons would have to be developed as a class, but they could be built on the conceptions of area the PSTs bring with them.

For all of us, modeling instruction means that we teach the way we would like our PSTs to conduct their classrooms. This includes engaging PSTs in creating their own knowledge, facilitating small group and classroom discussions, and conducting formative assessment of PSTs' knowledge and development to inform the instruction. In short, teacher educators model practices consistent with those described in the Principles and Standards for School Mathematics (2000). What is less clear is how modeling impacts PCK knowledge and later practice. This open question is a critical component of the larger research agenda developed by the working group.

Many MTEs believe that content knowledge is connected to and supported by other types of knowledge. A goal of MTEs' practice is the development of connections between knowledge. Pedagogy employed by MTEs' in our attempts to achieve this goal include explicating our own teacher moves (connecting to knowledge of content and teaching), using artifacts of children's mathematical thinking (connecting to knowledge of content and children), and explaining our own curriculum decisions (connecting to knowledge of content and curriculum). For the case of modeling, little is known about the impact of MTEs' pedagogy on PSTs' knowledge and connections within that knowledge. Notable exceptions include Philips et al. (2007) and Harkness, D'Ambrosio, and Morrone (2007) . Both sets of authors demonstrate the impact of particular activities on the development of PSTs beliefs and conceptions.

*Discussing "The Big Ideas" of Preservice Elementary Content Courses*

A recurring theme in discussions of MTEs is focused on curriculum. What "big ideas" should be addressed in the preservice elementary courses? Which mathematics content topics should be included? Structures for preservice education vary across universities. Some have as little as a one semester course devoted to content and methods; others have up to 4 semesters for content and an additional methods course. The rest rank somewhere in the middle. No matter how many courses are included in a program, MTEs agree that we cannot teach PSTs all they need to know. This commonly held view brings us back to the question of focus. What is the essential content for the courses we have devoted to mathematics content and pedagogy? Or is the process of teaching mathematics content more important t than the particular content itself?? Given that MTEs focus on helping the preservice elementary teachers identify what they do not know and then assist them in building knowledge, we are working to help PSTs make sense of what it means to understand mathematics (as well as helping their beliefs and attitudes about learning mathematics). Could our main goal be in teaching this process? Thus far it is not clear yet what effects our preservice teacher education classes have on the PSTs' teaching. There seems to be common agreement among MTEs that we want to prepare our PSTs to be life-long learners. How can this be done? In our working group we will focus on further exploring this question.

*Synthesizing the Research on Preservice Elementary Teachers' Content Knowledge and Identifying Areas of Further Study*

This working group seeks to synthesize the research on PSTs' content knowledge and identify areas of further study. This is essential so we understand our PSTs better when they enter our own classrooms. Some research has been conducted on the subject matter knowledge of preservice and in service teachers. Much of this research has focused on the teachers' lack of mathematical content knowledge needed to teach in key areas such as numbers and operations, (Ball, 1988/1989; Graeber, Tirosh, & Glover, 1989; Kastberg, 2007; Lo, Grant, & Flowers, 2008; Ma, 1999; McClain, 2003; Simon & Blume, 1996; Thanheiser, 2005), probability and statistics (Canada, 2007; Gfeller, Nieses, & Lederman, 1999; Jacobbe, 2007, Leavy & O'loughlin, 2006), geometry and rational numbers (Browning, et al, 2007; Jones & Mooney, 2002; Menon, 1998; Quinn, 1997). For example, Thanheiser (2005) found that only 3 of 15 preservice teachers held a conception of place value that allowed them to explain how and why the subtraction algorithms with three-digit numbers work. MTEs need more empirical evidence of what learning opportunities most contribute to more knowledgeable and confident teachers in order to make more informed changes to their programs (Mewborn, 2000). Large scale studies that help MTEs better understand how, when and where preservice elementary teachers might gain more specialized content knowledge are a critical need in the field (Adler, Ball, Krainer, Lin, Novotna, 2004; Mewborn, 2000)

To help teachers develop the content knowledge needed to teach mathematics educators need to understand the PSTs' currently held conceptions. As the authors of *The Mathematical Education of Teachers* suggest, "The key to turning even poorly prepared prospective elementary teachers into mathematical thinkers is to work from what they *do* know" (CMBS, 2001, p. 17). While some research has been conducted on identifying PSTs' conceptions, for example Thanheiser (2005) introduced a framework for PSTs' conceptions of multidigit whole numbers, there is still much to be learned about preservice teachers' conceptions. A potentially fruitful orientation toward such work includes the examination and testing of learning trajectories developed from work with children. While the trajectories may not have the necessary longitudinal dimension to help explain adult development, they certainly contain elements of use to MTEs as illustrated by the work of McClain (2003). Further research on conceptions and their development is essential for the further development of teacher education courses.

*Developing/Continuing Individual or Collaborative Projects to Move the Field Forward, Support Each Other's Research Efforts, and Keeping Each Other Updated of New Studies, Findings, and Progress in Our Own Work*

A central goal of this working group is to support existing collaborations and develop new ones. Subgroups of the organizers of the proposed working group have met previously at professional conferences including PME-NA at Toronto and Mérida and Lake Tahoe to discuss shared research interests. A discussion group was held at PME-NA in Lake Tahoe. These meetings and discussions have led to a joint symposium for NCTM research pre-session at Atlanta in March 2007 and most recently a joint symposium at AMTE in Orlando, 2009. Our research is similar in its focus pertaining to preservice elementary teachers' content knowledge but varies in specific content, use of prior work (conceptual analysis of content, prior work with children, prior work with adults), and theoretical framework.

At PME-NA 2007 we agreed on the need for the construction of a research base for the study of preservice teacher content knowledge. This includes a need to synthesize and summarize existing (completed and current) research and findings and develop a research agenda. This work can then support the development of research questions focused on areas where findings might inform our understanding of the impact of course work on knowledge development and practice. Additional needs were identified as follows:

- Share results with each other and the wider research community.
- Share resources (tasks, videos, materials, etc.) with each other and the wider research community.
- Explicate theoretical frameworks used by MTEs in research and teaching.

Questions were also raised about the implications of research on PSTs' content knowledge. In particular, participants wondered how the research influences the work of mathematics educators in the classroom. How does this research influence the work of mathematics educators in the classroom? Towards the goal of establishing ongoing collaborations a subgroup of the participants of this working group has started to meet regularly (once a month) via the internet (live chat) to discuss various topics relating to preservice elementary teacher education. The organizers seek to expand this group, sustain conversations, and work toward the production of research syntheses, a research agenda, and elaboration of theoretical frameworks.

*Developing Common Resources for Teaching PSTs*

One of the goals of this working group will be to discuss/share/develop common resources for teaching PSTs. For example, many of us use artifacts of children's mathematical thinking in our courses. In addition to discussing our motivation for doing so and how we use these artifacts to improve content knowledge, there is a need to make such resources (and the rationale for them) accessible to a broader audience. One solution for this might be a website but further discussion is needed on how such a website could be established, maintained and what information should be presented on this website.

## Outline of Working Group Sessions

In our first session, we will start with an introduction and overview of the working group. This will be followed by a brief summary of the last working group (PME-NA 2007) and other activities since (working groups at AMTE 2008 & 2009; symposium at NCTM 2007).

Brief introduction/presentations will be given by some the participants during which they will discuss:

- research s/he is conducting at his/her institution,
- theoretical framework and prior studies,
- current findings,
- plans to conduct further research, and
- challenges s/he sees in conducting this line of research.
- design principles for teaching preservice teachers.

Eva Thanheiser will serve as the moderator to facilitate the discussion. Before the end of the session Christine Browning and Eva Thanheiser will briefly introduce the monthly internet chat meetings and invite everyone to participate. These meetings will be hosted by various participants.

In our second session, we will start by forming small groups to work on the following tasks:

- React to/discuss definitions of the type of knowledge needed for teaching elementary school mathematics.
- React to/discuss design principles for preservice teacher courses.
- React to/discuss "the big ideas" of preservice elementary content courses.
- React to/discuss synthesis of the research on preservice elementary teachers' content knowledge and identifying areas of further study.
  - Generate research questions from the identified areas and brainstorm research methods for investigating this question.
  - Identify the resources needed to support such study.
- React to/discuss individual or collaborative projects that can move the field forward, support each other's research effort, and keep each other updated of new studies and findings in this area.
- React to/discuss ideas for developing common resources for teaching PSTs:

Then each group will take turns sharing their work. We hope to stimulate interest for collaboration through these focused discussions.

In our third session we will synthesize the current status of the working group and discuss modes of communication to sustain collaboration throughout the year. A calendar of discussion chats will be established and published through an online forum.

## Follow-Up Activities

Participants will publish an on-line forum for open discussion of topics of interest. In addition monthly online chat meetings will be established. Possible collaborations may include joint research projects, mini-conferences, and a book proposal to the Mathematics Teacher Education series at Springer.

# WORKING GROUP FOR LEARNING TO REASON PROBABILISTICALLY AND STATISTICALLY THROUGH EXPERIMENTS AND SIMULATIONS

Hollylynne Stohl Lee
North Carolina State University
hollylynne@ncsu.edu

J. Todd Lee
Elon University
tlee@elon.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Robin Angotti
University of Washington, Bothell
rrider@uwb.edu

*Recent foci in the Working Group have been to understand: (1) students' and teachers' reasoning when simulating probability experiments with hands-on materials and computer tools, and (2) connections between probability and statistical concepts such as inference and variability. At PME-NA 31 the group will build on the research agenda that it has been pursuing over the past several years. Group members will discuss recent literature reviews on learning and teaching probability as it relates to statistical reasoning, revisit previous research and discuss designs for cross-national, collaborative research to be conducted in 2010. Emerging research from Working Group members will lead to a set of papers that could comprise a monograph, journal special issue, and/or joint presentations at future conferences.*

## Nature and Topic of the Working Group

This Working Group was formed at PME-NA 20 (Maher, Speiser, Friel, & Konold, 1998) and has convened annually at PME-NA since, except for the joint PME and PME-NA meeting held in 2008 in Mexico. Through shared research, rich and engaging conversations, and analysis of instructional tasks, we continually seek to understand how students learn to reason probabilistically, with particular focus this year on how probabilistic reasoning with simulations can support statistical reasoning.

## Aims of the Working Session

There are several critical aims that guide our work together. In particular, we are examining: (1) mathematical and psychological underpinnings that foster or hinder students' probabilistic reasoning, (2) the influence of experiments and simulations in the building of ideas by learners, particularly with emerging technology tools, (3) learners' interactions with and reasoning about data-based tasks, representations, models, socially situated arguments and generalizations, (4) the development of reasoning across grades, with learners of different cultures, ages, and social backgrounds, and (5) the interplay of statistical and probabilistic reasoning and the complex role of key concepts such as sample spaces and data distributions. Through our work, we have stimulated collaborations across universities and plan to engage in and support additional research related to the complexity of learning to reason probabilistically, particularly when modeling probability situations with tools that enable experiments and simulations.

## Literature Background

The ways in which students reason about the likelihood of an event can be considered in terms of an objective or subjective view of probability (e.g., see Batanero, Henry, & Parzysz, 2005; Borovcnik, Bentz, & Kapadia, 1991). In an *objectivist* perspective, probability is viewed as an inherent property of the event and can be well estimated either through a classical or frequentist approach. A repeated finite set of trials would most likely yield a different experimental estimate of the actual probability and may in fact allow one to change the estimate of the probability based on new data. In a *subjectivist* perspective, probability is viewed as a condition of the information known to the individual assigning the probability and not an objective property of the given event. It is worth remembering that these are perspectives on probability in the real world, and not on the mathematical theory of probability.

The *law of large numbers* is a mathematical theorem used to interpret empirical results in relation to probabilities. This theorem states that for an experiment with fixed probabilities, the likelihood of a large difference between the relative frequency of an event and the events' probability limits to zero as more trials are collected. In various ways it supports the viability of all the above mentioned approaches to probability. From a frequentist approach, an estimated probability should be reasonably close to a probability computed from a classical approach. With a subjectivist perspective, two people may assign different probabilities to the same event based on different *a priori* information, even after they observe the same empirical data. However, after observing large amounts of empirical data, it seems reasonable that two people operating within a subjectivist perspective would assign similar probabilities. As more data is collected, each of their knowledge about the event would include an increasing proportion of shared information.

A frequentist approach to probability, grounded in the law of large numbers, has only recently made its way into curricular aims in schools, which is typically dominated by a classical approach (Jones, 2005). Notably absent is any significant attention to a subjective approach to probability (Jones, Langrall, & Mooney, 2007). Recent curricula recommendations (e.g., NCTM, 2000) encourage teachers to use an empirical introduction to probability by allowing students to experience repeated trials of the same event, either with concrete materials or through computer simulations (e.g., Batanero, Henry, & Parzysz, 2005; Jones, Langrall, & Mooney, 2007; Parzysz, 2003). In these types of curricula, a theoretical model of probability based on a classical approach is not the starting point. Rather, a theoretical model is constructed based on observing that the relative frequencies of an event from a repeated random experiment stabilize as the number of trials or sets of trials (different samples) increases. However, there is general agreement that research on students' probabilistic reasoning has been lacking sufficient study of students' and teachers' understanding of the connection between observations from empirical data and a theoretical model of probability (e.g., Jones, 2005; Jones, Langrall, & Mooney, 2007; Parzysz, 2003).

Mathematical probability concepts are central to understanding theoretical statistics, but the role of probability in developing statistical reasoning is much less clear. Developing sample spaces and computing probabilities via combinatorial arguments is a traditional introduction to probability in the classroom, while the availability of handheld technology has brought a strong frequentist vein of investigations involving simulated trials. And though not a part of most classroom introductions, a view of probability as a measure of information would not go unwelcomed in many statistical applications. Regardless of the nature of a student's understanding of probability, there is still the question of how this understanding impacts a student's statistical reasoning. When a student seeks to infer qualities of an object or a set of objects by gathering data, if the data is gathered via a random experiment, the student is conducting a statistical investigation (Franklin et al, 2005). The level of *understanding* a student has of the inferences that can be made very much depends upon the student's understanding of the ties between data and model in a probabilistic phenomenon.

The working group is aiming to contribute a better understanding to some of these issues, particularly using experiments and simulations to generate empirical data from which students' can reason statistically. Also of importance in this research is how students reason about the process of conducting a probability experiment or constructing a simulation and their understanding of how the experiment or simulation is an appropriate model of the original probability context.

## Summary of Activities from Past Two Meetings of Group

In 2007, twelve researchers (faculty and graduate students) from the United States, Canada, and Mexico met During PME-NA 29 in Lake Tahoe, NV. In 2006, eight researchers (faculty and graduate students) from the United States, Canada, and Mexico met During PME-NA 28 in Mexico. In 2007, members read and discussed the recent literature review on probability learning by Jones, Langrall, and Mooney (2007). In particular we discussed the call for research on understanding more about how students make connections between empirical and theoretical probability. Members shared several simulation environments (ProbLab, Fathom, and Probability Explorer) and discussed a few probability tasks that engaged students in reasoning about theoretical and empirical distributions. We further discussed how these tasks can be interpreted differently by students and teachers. Moreover, discussions focused on issues students face in trying to generate and analyze empirical data to make inferences about an unknown probability distribution. Participants shared tasks that could be used with students and teachers to engage them in conducting probability experiments or simulations. A rich discussion was held concerning the nature of tasks that can be used in further research to help expand the knowledge base on what students understand about probability in contexts where repeated trials are generated and data needs to be analyzed to make a decision or inference. The group expressed interest in pursuing the following questions:

- What are students' intuitions regarding whether real-world phenomena can or cannot be simulated? Are there differences between simulations and modeling tools?
- How do students (and teachers) relate technology simulation models to real-world phenomena?
- How do learners move between empirical data and theoretical models of probability? To what extent do students attend to issues of sample size, variation, sampling distributions, and data collection?
- What metaphors emerge as students engage in probability tasks, and how do these support or hinder the development of probabilistic reasoning?
- What are the key issues in the design of probability tasks in order to promote reasoning about probabilistic events which occur repeatedly in an experiment or simulation? What issues do teachers face in implementing such tasks?
- How can argumentation and justification be used as a tool to increase conceptual understanding of chance and randomness?

Stemming from the work in 2007, several members participated in a research symposium at the NCTM research presession in 2008 focused on different software environments that are designed to promote connections among empirical data and theoretical probability distributions. The papers from that symposium were all submitted to journals. Several group members also attended and participated in the Joint ICMI/IASE Study Conference (http://www.ugr.es/~icmi/iase_study/) held at the Instituto Tecnológico y de Estudios Superiores, in Monterrey, Mexico in July 2008. This study conference was focused on the challenges for teaching and teacher education in statistics education, with several papers specifically addressing issues related to the use of simulation environments in the teaching of statistics.

## Planned Activities for the 2009 Meeting

At PME-NA 31, the group will build on the research agenda listed above. We plan to do the following during the time allotted:

1) Discuss important aspects of conducting a probability experiment or simulation that can provide a venue for students' reasoning about empirical data and its connection to a theoretical model of probability and one's ability to reason statistically;
2) Provide time for members to share recent research endeavors on students' and teachers' engagement in probability experiments or simulation tasks. This will likely include some engagement with simulation tasks and group video analysis;
3) Discuss results of recent research by group members and others in light of summaries and calls for research by Jones, Langrall and Mooney (2007) and the topics of importance raised at the ICMI/IASE 2008 joint conference; and
4) Generate suggestions for further refinement of individual's research and suggestions for additional research by group members that will form the basis of a collection of papers.

We intend for the cumulative research efforts from Working Group members to be compiled as a set of papers for either a monograph or journal special issue. Clearly our proposed activities are closely aligned with Goals of PME-NA, namely "to promote international contacts and the exchange of scientific information in the psychology of mathematics education," "to promote and stimulate interdisciplinary research...," and "to further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof."

# SUPPORTING TEACHERS TO INCREASE RETENTION

Axelle Faughn
Western Carolina University
afaughn@email.wcu.edu

Terran Felter
CSU Bakersfield
tfelter@csub.edu

Barbara Pence
San Jose State University
pence@math.sjsu.edu

*Several national reports have identified the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education. However, providing high quality mathematics education for all students goes beyond the recruitment of knowledgeable teachers. This working group is designed to offer an opportunity to examine the role that professional development and support play in the work and retention of mathematics teachers. Retention will focus on new teachers especially those in urban area and mathematics teachers in hard-to-hire settings. Discussions will concentrate on the study of interventions through professional development and support models. Efforts to deepen our understanding of the complex and multifaceted picture of why teachers leave and why they stay, and how efforts to retain teachers impact their work in the classroom and their decisions to stay or leave will be developed through the sharing of research designs, data collection, and on-going results. This working group will be appropriate for anyone who has work to share or who is thinking about a support for retention project. Throughout, we will address this very complex task both in terms of the opportunities and challenges for the mathematics education researchers to provide quantitative and qualitative input on a major political issue. It is hoped that this working group will enrich the dialogue about a national crisis in mathematics education.*

## Brief History of Working Group

Although teacher retention is a topic being included in many conferences and position papers, this is an initial request for a Working Group to investigate the relationship between Professional Development/Support and the retention of mathematics teachers, thus is not the continuation of any prior Working Group. One of the goals will be to identify the absences in the research so that we may move forward in tackling the complex national issue of mathematics teacher retention.

## Issues of Psychology of Mathematics Education to be Focused On

The study of the relationship between Professional Development and Support Models on the Work and Retention of Mathematics Teachers in grades 7 – 12 merits careful examination. Several national reports have pointed to the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education and maintain the United States' economic competitiveness (National Academy of Sciences, 2007; Glenn Commission, 2000). However, providing high quality mathematics education for all students goes beyond the recruitment of mathematically knowledgeable teachers to encompass issues of teacher support, professional development, and retention. Over the past two decades, analyses of teacher employment patterns reveal that new recruits leave their school and teaching a short time after they enter. Ingersoll, using data from the School and Staffing Survey concluded that in 1999-2000, 27% of first year teachers left their schools. Of those, 11 percent left teaching and 16 percent transferred to new schools (Smith & Ingersoll, 2003). Earlier research revealed that teachers who leave first are likely to be those with the highest qualifications (Murnane & other, 1991; Schlecty & Vance, 1981). This "revolving door" is even higher in large urban districts; for example, 25% of the teachers new to Philadelphia in 1999-2000 left after their first year and more than half left within four years (Neild & other, 2003). In Chicago, an analysis of turnover rates in 64 high-poverty, high-minority schools revealed that 23.3 percent of new teachers left in 2001-2002.

Reasons for the lack of retention of new teachers and teacher in high-poverty schools are often related to "working conditions" and lack of support (Ingersoll, 2001; Smith & Ingersoll, 2004; Johnson et al., 2004), though pay also plays a role (Hanushek, Kain, & Rivkin, 2001). This support includes professional and collegial support such as working collaboratively with colleagues, coherent, job-embedded assistance, professional development, having input on key issues and progressively expanding influence and increasing opportunities (Johnson, 2006). Preparation, support, and working conditions are important, because they are essential to teachers' effectiveness on the job and their ability to realize the intrinsic rewards that attract many to teaching and keep them in the profession despite the profession's relatively low pay (Johnson & Birkeland, 2003; Liu, Johnson, & Peske, 2004; Lortie, 1975).

Recently, a status report on teacher development focusing on professional development and support of teachers (Darling-Hammond et al., 2009) summarized findings and put forth recommendations for effective professional development. The basis for the paper included national surveys with self reported data, a meta-analysis of 1,300 research studies and specific studies. The conclusion is that "well designed" professional development can influence teacher practice and student performance. The paper focuses on what is or could be considered as well defined. One strand of the paper is that of effective support for new teachers. Although half of the states require support for new teachers (Education Week, 2008) it was found that rates of participation in teacher induction programs varied by school types with highest rates in schools with least poverty and lowest in schools with high levels of poverty. Beyond the rates of participation and availability of support, there is the question of what is effective support. An on-going large-scale research project was sited which is currently underway that aims to measure impacts in terms of classroom practices, student achievement and teacher mobility. Initial results seem to reflect the difficulty in identifying the impact of support.

Another study is presently in its second year and is studying the support of mathematics across the State of California. This five year study is looking through the lens of 10 support models to trace the knowledge, classroom practices, professional communities of support, leadership and needed support. Initial results are complex but are showing relationships between sustained professional development and support and teacher retention. In one year the attrition is half what it was over the prior five-year period.

But, what is the relationship between the support and the retention? One of the 10 sites from this study observed that success of a retention initiative takes root in a variety of needs: the need to know your District and its teachers – a necessity that often relies on established, long-term relationships between the university and district leaders; the need to offer sustained support as opposed to punctual interventions in order to break the isolation of beginning teachers and create a sustainable community; the need to establish relevance in the professional development activities proposed by engaging participants in deep introspection of their own knowledge gaps; the need to involve all actors of the community to prevent miscommunication from annihilating attempts made towards change; the need to nurture the community created by moving its members forward into roles and responsibilities they are ready to take on; and last but not least, the need to refine even successful models to keep the momentum (Felter & Faughn, 2009).

As is indicated in the comments above, support comes from multiple sources. Another recent study from Peabody College, Vanderbilt University, finds that principals play a critical role in the support of new mathematics teachers (McGraner, 2009).

This working group is designed to offer a comprehensive, multifaceted examination of the on-going preparation, support and retention of grade 7-12 mathematics teachers based on the results of research studies and ideas of the participants. It is hoped that this working group will enrich the dialogue relating the "support gap" and the work and retention of teachers of mathematics. It is also expected that this working group will propose areas ripe for further research.

## Plan for Active Engagement of Participants in Productive Reflection on the Issues

At this point, people from multiple projects presently involved in related research have been contacted and have indicated an interest in actively participating in this working group. Papers from various groups have been given at MAA, The Eleventh National New Teacher Center Symposium, Curtis Center for Mathematics Teachers Conference, AERA, and NCSM. Models of professional development as well as systematic and sustained support vary. For example, "support" models may include intensive professional development, coaching and mentoring, lesson study groups, school site networking and meetings, data driven reflection, access to resources, online networking support, conference attendance, district and/or school administrative support among others. The impact also varies from teacher knowledge, to student learning, to classroom practices, to building of productive professional collaborative communities, to extended learning opportunities, to teachers' reported value of the support.

Can "support" impact teacher retention? If so, what are key dimensions relating "support" and retention?

If the working group is approved, contacts will be made with interested parties. A possible outline will be developed which will rely heavily on group discussions to bring to bear challenges and opportunities for this area of research. The coordinators submitting this proposal represent one project that involves 10 different sites investigating teacher retention across California. In their initial two years of work, they have identified a decrease in attrition through professional development and support. But, understanding the relationship between retention and "support", the work of the classroom, the network of support and the rewards that help retain teachers is complex and requires an open discussion across multiple projects and perspectives. To bring together researchers across related existing and potential projects offers the type of investment that this topic needs to progress and provide bases for ongoing efforts. Dimensions to be shared and discussed include designs for research, data collection, results and interpretations.

The anticipated structure for the working group will emphasize sharing across questions such as: 1) What is effective professional development and support? For instance, does networking or learning communities increase retention? Why? – 2) What are the challenges for teachers? What models or programs address those challenges? – 3) What are important outcomes? What are some unintended outcomes in these efforts? What issues emerge? – 4) How do we establish studies of the relationship between support and outcomes? What are some promising practices? What evidence indicates this? Do these practices support retention?

In each of these questions we will explore opportunities for and challenges to research efforts on retention. Hopefully we will be able to work through questions, models of inquiry, data, research results in light of participant reflections and knowledge. The overall structure will include introductions, the establishment of key questions, brainstorming relative to the key questions, small breakout group discussions, sharing and whole group grappling with reflections and recommendations. Subgroups may be needed as the initial discussion develops. If so, some potential dimension guiding the formation of subgroups include retention and research issues such as self reported data, guidelines for support including use of technology, school and state policies driving support, job-embedded professional development, or necessary time, content and opportunities for support. Or the determination of the groups could focus on retention and the model of professional development, retention and knowledge, retention and technology, retention and on-site support, retention and equity, and/or retention and leadership. No attempt will be made to identify areas of interest in advance. Small group discussions topics will be determined by the participants and draw from the initial group conversations.

This working group will strive to build a network to collaboratively identify potential research, existing results and establish a guide for further paradigms of teacher professional learning that encourages transformations in teaching practices and rewards resulting in improved retention. An end-of-conference result is outlining a plan for future collaboration among the participants, and also refining and deepening our research efforts.

A more detailed layout of the three working sessions could be as follows: In Session 1, current research projects will be shared as a foundation for discussions. From these discussions we will refine our questions, identify absences in the current research, as well as important themes emerging from the participants' brainstorming. In Session 2, we may ask the participants to choose a subgroup based on the themes previously identified, and explore these dimensions more in-depth among their groups before reporting to the whole group. In Session 3, we will strive to develop a working plan for further collaboration and dissemination, as described in the anticipated follow-up activities below.

## Anticipated Follow-up Activities

Follow-up activities will include ongoing networking and hopefully collaboration on further efforts. One example would be the sharing of developing papers and research. Another would be the development of a weblink. It would be hoped that results of 2009 research could form the basis for the Working Group on Retention for the 2010 PME-NA conference and possibly the development of a series of thematic collaborative papers and/or monograph synthesizing our work on mathematics teacher retention and support. The network will also be included in the development of a conference on Supporting Teachers to Increase Retention scheduled to take place in three years.

zhengt@math.buffalostate.edu

*This paper presents initial points of interest outlined by a working group focused on teacher preparation at the US-Sino conference in June 2008. It was at this conference that a group of mathematics and science educators formed a collaborative to begin identifying critical factors related to content knowledge and understanding in teacher preparation programs. Critical points that emerged related to looking more intimately at university methods and content courses and the experiences provided in them and how these experiences foster the growth of prospective teachers to know and understand the content they are to teach. Some members of this working group would like to continue the efforts in this area and create and/or identify a framework that will guide the development of valuable tasks and experiences prospective teachers encounter in teacher preparation programs in the United States and China.*

## History of Working Group

This Working Group, focused on mathematics and science teacher preparation, was recently created at the US-Sino Workshop on Mathematics and Science Education – Common Priorities that Promote Collaborative Research. The conference was held at Middle Tennessee State University (MTSU) in Murfreesboro, TN from June 22-27, 2008 and was co-hosted by MTSU and Northwest Normal University (NWNU in Lanzhou, P.R. China). The conference had approximately 125 people participating – where approximately 50 scholars were from China and 75 from the United States. The purpose of the workshop was to facilitate the formation of research working groups whose membership would consist of scholars from both the United States and P.R. China. Working groups were formed around six central themes – curriculum, assessment, teacher preparation, professional development, integrating technology into teaching and learning, and reaching underserved populations – which are common to mathematics and science education.

This specific US-Sino Teacher Preparation working group is in its early infancy stage. Members met for the first time at the workshop (with no initial interactions) and had to formulate items of interest to mathematics and science education at that particular time. The group generated two key areas of focus for future study and collaboration prior to the closing of the workshop. They included (1) critically looking at university methods and content courses and what they address from a content perspective and (2) the experiences provided in coursework and how they foster the growth of prospective teachers to know and understand the content they will teach in their future classrooms. This was very much in agreement with what Liping Ma, one of the workshop Plenary Speakers, challenged the mathematics and science education communities to do. She indicated the need for teacher preparation programs to look carefully at what prospective teachers know, what they need to know, and how programs prepare them to teach what they know and do not know. Several points were reiterated (from her book) that teacher education is a strategically vital period during which changes can be made and the educational community needs to assume this responsibility (1999).

Working group members met two to three times at the US-Sino workshop, but since that time, there has been minimal group interaction. Thus, there is a need to find an opportunity for the group to convene and exert efforts on collecting sources of information, making progress towards generating tasks, framing the tasks, and organizing and implementing any short-term or long-term research goals that come out of this collaboration. PME and PME-NA were options for the group to assemble where both United States members and Chinese members could meet and interact face-to-face. In addition, the working group believes this collaborative effort supports this year's conference theme of Embracing Diverse Perspectives. We are interested in identifying perspectives of Chinese teacher preparation programs as well as variations in US preparation programs.

### Teaching Mathematics: What Should It Look Like and How Do We Get There?

In Lampert's *When the Problem Is Not the Question and the Solution is Not the Answer: Mathematical Knowing and Teaching* (1990), the manner in which knowing mathematics is viewed in most classrooms is presented. It is said that "… doing mathematic means following the rules laid down by the teacher; knowing mathematics means remembering and applying the correct rule when the teacher asks a question; and mathematical truth is determined when the answer is ratified by the teacher." Although this research study was carried out almost 20 years ago, it is unfortunate that it paints a familiar image of today's classrooms and the role of the teacher. This image is one that teacher preparation programs must confront and take steps to change.

One "big step" towards making a transformation was in the publication of *The Mathematical Education of Teachers* (Conference Board of the Mathematical Sciences – CBMS 2001). In this report, eleven general recommendations were identified and elaborated upon for all levels of teaching mathematics. The following five recommendations are of varying importance to the progress of this working group: (a) Prospective teachers need mathematics courses that develop a deep understanding of the mathematics they will teach (p. 7); (b) Courses on fundamental ideas of school mathematics should focus on a thorough development of basic mathematical ideas. All courses designed for prospective teachers should develop careful reasoning and mathematical "common sense" in analyzing conceptual relationships and in solving problems (p. 8); (c) Along with building mathematical knowledge, mathematics courses for prospective teachers should develop the habits of mind of a mathematical thinker and demonstrate flexible, interactive styles of teaching (p. 8); (d) The mathematical education of teachers should be seen as a partnership between mathematics faculty and mathematics education faculty (p. 9); and (e) There needs to be more collaboration between mathematics faculty and school mathematics teachers (p. 10). While these five recommendations were identified in some manner at the US-Sino conference, common themes or problems (to China and the United States) narrowed the group to focus on content knowledge and preparing teachers to know and understand the content (both mathematics and science).

NCTM recently updated the *Professional standards for teaching mathematics* (1991) in its 2007 publication of *Mathematics teaching today*. This document articulates that teachers of mathematics should have a deep knowledge of

- sound and significant mathematics,

- theories of student intellectual development across the spectrum of diverse learners,
- modes of instruction and assessment, and
- effective communication and motivational strategies (p. 19).

More specifically teachers must possess the skills to problem solve, reason, communicate, connect, and make use of multiple representations. How to help new teachers develop this repertoire of strategies is the challenge presented to preparation programs of today. *Mathematics teaching today* indicates that teacher preparation programs should ensure that teachers of mathematics are fluent in the language of mathematics and have a deep knowledge of mathematical content including:

- mathematical concepts and procedures and the connections among them;
- multiple representations of mathematical concepts and procedures;
- ways to reason mathematically, solve problems, and communicate mathematics effectively at different levels of formality:
- the cultural contexts for mathematics, including the contributions of different cultures toward the development of mathematics and the role of mathematics in culture and society;
- the evolving nature of mathematical practice and instruction resulting from the availability of technology; and
- the relationship of school mathematics to the discipline of mathematics, to other fields of study, and to mathematical applications (p. 119).

This document, along with other reform-oriented documents and reports (e.g. *Knowing and learning mathematics for teaching,* 2001), echo the importance of teacher knowledge and understanding of content to support students in becoming problem solvers and educated consumers of the future.

In order to attempt to achieve these ambitious challenges, prospective teachers need to be provided with opportunities to reflect upon their experiences in coursework and come to recognize the impact it has on their teaching. Artzt and Armour-Thomas (2002) describe this process as developing into a reflective mathematics teacher who is capable of facilitating student-centered teaching. The growth of the reflective practitioner is also of interest to this teacher preparation group.

## Plans for Engagement and Post-conference Activities

This working group would like to focus on problems, situations, and tasks that compel prospective teachers to reflect upon their own level of understanding of content. As was identified in our working group at the US-Sino conference, we would like to construct/organize some sort of framework to guide in the study of such situations. There is the interest to identify specific tasks and implement them in teacher preparation courses, collect data at our various institutions, and then see what components are congruent or incongruent –in the US and in China. A piece of our working session will be to design some plan of implementation to accomplish this undertaking.

Post-conference activities will involve working group members to return to their respective institutions and carry out the developed situations discussed and/or developed at the conference (or some format similar to what we decide upon). When implementation of the organized materials has been accomplished, we plan to re-convene and continue progress in this area. We anticipate executing a critical analysis of successful problems, tasks, and experiences that promote reflection on knowing and learning mathematics that teachers must teach in their classrooms. Some of this may be done “long-distance,” but other elements will require face-to-face interactions at a future working group venue.

Jeremy Kilpatrick, University of Georgia, Athens
Richard Lesh, Indiana University
Bharath Sriraman, The University of Montana
Guenter Toerner, University of Duisburg-Essen, Germany

## Purpose of Working Group

This working group revolves around the launch of a new book series entitled *Advances in Mathematics Education* by Springer Science, Heidelberg, and in particular on the first book in the series which focuses on Theories of Mathematics Education. This edited book in turn is based on a research forum on Theories of Mathematics Education at PME 29 in Melbourne, 2005, which resulted in two ZDM special issues on theories of mathematics education(issue 6/2005 and issue 1/2006). Since the research forum in Melbourne, numerous advances have taken place in the area of theory development in mathematics education in Europe and in North America. The purpose of this working group on research advances in theories of mathematics education is to integrate, synthesize and present a coherent picture on the state of the art. The working group will attempt to be both summative as well as forward looking by highlighting theories from psychology, philosophy and social sciences that continue to influence theory building, as well as provide participants insights into new developments in feminist, critical and political theories of mathematics education.

## Theory and Its Role in Mathematics Education

Lyn English
Queensland University of Technology

Bharath Sriraman
The University of Montana

Theories are like toothbrushes…everyone has their own and no one wants to use anyone else's."(Campbell,2006)

Abstract: The increased recognition of the theory in mathematics education is evident in numerous handbooks, journal articles, and other publications. For example, Silver and Herbst (2007) examined "Theory in Mathematics Education Scholarship" in the *Second Handbook of Research on Mathematics Teaching and Learning* (Lester, 2007) while Cobb (2007) addressed "Putting Philosophy to Work: Coping with Multiple Theoretical Perspectives" in the same handbook. And a central component of both the first and second editions of the *Handbook of International Research in Mathematics Education* (English, 2002; 2008) was "advances in theory development." Needless to say, the comprehensive second edition of the *Handbook of Educational Psychology* (Alexander & Winne, 2006) abounds with analyses of theoretical developments across a variety of disciplines and contexts. Numerous definitions of "theory" appear in the literature (e.g., see Silver & Herbst, in Lester, 2007). It is not our intention to provide a "one-size-fits-all" definition of theory per se as applied to our discipline; rather we consider multiple perspectives on theory and its many roles in improving the teaching and learning of mathematics in varied contexts.

At the 2008 *International Congress on Mathematical Education*, Assude, Boero, Herbst, Lerman, and Radford (2008) referred to theory in mathematics education research as dealing with the teaching and learning of mathematics from two perspectives: a *structural* and a *functional* perspective. From a structural point of view, theory is "an organized and coherent system of concepts and notions in the mathematics education field." The "functional" perspective considers theory as "a system of tools that permit a 'speculation' about some reality." When theory is used as a *tool*, it can serve to: (a) conceive of ways to improve the teaching/learning environment including the curriculum, (b) develop methodology, (c) describe, interpret, explain, and justify classroom observations of student and teacher activity, (d) transform practical problems into research problems, (e) define different steps in the study of a research problem, and (f) generate knowledge. When theory functions as an *object*, one of its goals can be the advancement of theory itself. This can include testing a theory or some ideas or relations in the theory (e.g., in another context or) as a means to produce new theoretical developments.

Silver and Herbst (2007) identified similar roles but proposed the notion of theory as a mediator between problems, practices, and research. For example, as a mediator between research and problems, theory is involved in, among others, generating a researchable problem, interpreting the results, analysing the data, and producing and explaining the research findings. As a mediator between research and practice, theory can provide a norm against which to evaluate classroom practices as well as serve as a tool for research to understand (describe and explain) these practices. Theory that mediates connections between practice and problems can enable the identification of practices that pose problems, facilitate the development of researchable problems, help propose a solution to these problems, and provide critique on solutions proposed by others. Such theory can also play an important role in the development of new practices, such as technology enhanced learning environments.

What we need to do now is explore more ways to effectively harmonize theory, research, and practice (Silver & Herbst, 2007) in a coherent manner so as to push the field forward. This leads to an examination of the extant theoretical paradigms and changes that have occurred over the last two decades. This was briefly discussed at the outset of this chapter.

*Changes in Theoretical Paradigms*

As several scholars have noted over the years, we have a history of shifting frequently our dominant paradigms (Berliner, Calfee, in Alexander & Winne, 2006). Like the broad field of psychology, our discipline "can be perceived through a veil of 'isms'" (Alexander & Winne, 2006, p.982). We have witnessed, among others, shifts from behaviourism, through to stage and level theories, to various forms of constructivism, to situated and distributed cognitions, and more recently, to complexity theories and neuroscience. For the first couple of decades of its life, mathematics education as a discipline drew heavily on theories and methodologies from psychology. According to Lerman (2000), the switch to research on the social dimensions of mathematical learning towards the end of the 1980s resulted in theories that emphasized a view of mathematics as a social product. Social constructivism, which draws on the seminal work of Vygotsky and Wittgenstein (Ernest, 1994) has been a dominant research paradigm for many years. Evidence of the social turn can be found in Lerman's analysis of articles published from 1990 to 2001 in *Educational Studies in Mathematics* (ESM), *Journal for Research in Mathematics Education* (JRME), and the *Proceedings of the International Group for the Psychology of Mathematics Education* (PME), revealed that, while the predominant theories used during this period were traditional psychological and mathematics theories, an expanding range from other fields was evident especially in PME and ESM. Psycho-social theories, including re-emerging ones, increased in ESM and JRME. Likewise, papers drawing on sociological and socio-cultural theories also increased in all three publications together with more papers utilizing linguistics, social linguistics, and semiotics. Lerman's analysis revealed very few papers capitalizing on broader fields of educational theory and research and on neighboring disciplines such as science education and general curriculum studies. This situation appears to be changing in recent years, with interdisciplinary studies emerging in the literature (e.g., see English, 2008); and papers that address the nascent field of neuroscience in mathematics education

Numerous scholars have questioned the reasons behind these paradigm shifts. Is it just the power of fads? Does it only occur in the United States? Is it primarily academic competitiveness (new ideas as more publishable)? One plausible explanation is the diverging, epistemological perspectives about what constitutes mathematical knowledge. Another possible explanation is that mathematics education, unlike "pure" disciplines in the sciences, is heavily influenced by unpredictable cultural, social, and political forces (e.g., Sriraman, 2007). A critical question, however, that has been posed by scholars now and in previous decades is whether our paradigm shifts are genuine. That is, are we replacing one particular theoretical perspective with another that is more valid or more sophisticated for addressing the hard core issues we confront (Kuhn, 1966; Alexander & Winne, 2006)? Or, as Alexander and Winne ask, is it more the case that theoretical perspectives move in and out of favour as they go through various transformations and updates? If so, is it the voice that speaks the loudest that gets heard? Who gets suppressed? The rise of constructivism in its various forms is an example of a paradigm that appeared to drown out many other theoretical voices during the 1990s (Goldin, 2003). In essence, the question we need to consider is whether we are advancing professionally in our theory development.

## Appreciating *Scientificity* in Qualitative Research

Stephen J. Hegedus
University of Massachusetts Dartmouth, Kaput Center

Abstract: This paper is situated within an educational paradigm that is concerned with the education of itself, its peers and its students. From here, we acknowledge the necessity for knowledge and that *in learning* we discover knowledge either through ourselves, through our peers or through synthesizing a dialectic between the governing bodies of knowledge and an educational system. We might understand that we discover knowledge in an educational setting by processes that are akin to scientific discovery. I propose that we establish knowledge in this very way and in reflecting on our *constructing-knowledge* enterprise, we endeavor to adhere to a *meta-constructionist phenomenology,* which draws upon the learning theory of constructionism (Papert & Harel, 1991) whereby we establish a construction built on a faithful establishment of education and assess the mechanics of the constructed phenomenon through reflexivity and interactivity with the field.

## Mathematics Education as a Design Science

Richard Lesh
Indiana University

Baath Sriraman
The University of Montana

Abstract: We propose re-conceptualizing the field of mathematics education research as that of a design science akin to engineering and other emerging interdisciplinary fields which involve the interaction of “subjects”, conceptual systems and technology influenced by social constraints and affordances. Numerous examples from the history and philosophy of science and mathematics and ongoing findings of M&M research are drawn to illustrate our notion of mathematics education research as a design science. Our ideas are intended as a framework and do not constitute a, “grand” theory (see Lester. 2005, this issue). That is, we provide a framework (a system of thinking together with accompanying concepts, language, methodologies, tools, and so on) that provides structure to help mathematics education researchers develop both models and theories, which encourage diversity and emphasize Darwinian processes such as: (a) selection (rigorous testing), (b) communication (so that productive ways of thinking spread throughout relevant communities), and (c) accumulation (so that productive ways of thinking are not lost and get integrated into future developments)

## Teaching Mathematics through Problem Solving: What We Know and Where We Are Going

Jinfa Cai
University of Delaware

Abstract: Problem solving has a long history in school mathematics. In the past several decades, there have been significant advances in the understanding of the complex processes involved in problem solving. There also has been considerable discussion about teaching mathematics with a focus on problem solving. However, teaching mathematics *through* problem solving is a relatively new idea in the history of problem solving in the mathematics curriculum. In fact, because teaching mathematics through problem solving is a rather new conception, it has not been the subject of much research.

Contemporary discussions of goals for mathematics education emphasize the importance of thinking, understanding, reasoning, and problem solving, with an emphasis on connections, applications, and communication. This view stands in contrast to a more conventional view of mathematics, involving the memorization and recitation of facts, rules, and procedures, with an emphasis on the application of well-rehearsed procedures to solve routine problems. Because teaching mathematics through problem solving has been considered an instructional approach better aligned with the contemporary views of school mathematics, it is receiving increasingly strong support from researchers, educators, and teachers. Although less is known about the actual mechanisms students use to learn and make sense of mathematics through problem solving, there is widespread agreement that teaching through problem solving holds the promise of fostering student learning.

While there is no universal agreement about what teaching mathematics through problem solving should really look like, there are some commonly accepted features of teaching mathematics through problem solving. Teaching through problem solving starts with a problem. Students learn and understand important aspects of a mathematical concept or idea by exploring the problem situation. The problems tend to be open-ended and allow for multiple correct answers and multiple solution approaches. Students play a very active role in their learning—exploring problem situations with teacher guidance and "inventing" their own solution strategies. In fact, the students' own exploration of the problem is an essential component in teaching with this method. In students' problem solving, they can use any approach they can think of, draw on any piece of knowledge they have learned, and justify any of their ideas that they feel are convincing. While students work on the problem individually, teachers talk to individual students in order to understand their progress and provide individual guidance. After students have used at least one strategy to solve the problem or have attempted to use a strategy to solve the problem, students are given opportunities to share their various strategies with each other. Thus, students' learning and understanding of mathematics can be enhanced by considering one another's ideas and debating the validity of alternative approaches. During the process of discussing and comparing alternative solutions, the students' original solutions are supported, challenged, and discussed. Students listen to the ideas of other students and compare other students' thoughts with their own. Such interactions help students clarify their ideas and acquire different perspectives of the concept or idea they are learning. In other words, students have ownership of the knowledge because they devise their own strategies to construct the solutions. At the end, teachers make concise summaries and lead students to understand key aspects of the concept based on the problem and its multiple solutions.

Theoretically, this approach makes sense. Empirically, there is lacking of data confirming the promise of teaching through problem solving. In particular, we need to seek answers to a number of important research questions, such as, (1) Does classroom instruction using a problem-solving approach have any positive impact on students' learning of mathematics? If so, what is the magnitude of the impact? (2) How does classroom instruction using this approach impact students' learning of mathematics? (3) What actually happens inside the classroom when a problem-solving approach is used effectively or ineffectively? (4) What do the findings from research suggest about the feasibility of teaching mathematics *through* problem solving in classroom?

In this paper, I will explore these research questions through reviewing two lines of research. The FIRST line of research includes those recently conducted studies on *NSF-funded* curricular programs that teach mathematics through problem solving and that have been implemented by teachers in classroom. The *NSF-funded* curricula are problem-based curricula, and the intent is to teach mathematics and to build students' understanding of important mathematical ideas through explorations of real-world situations and problems.

The SECOND line of research includes studies based on innovative materials developed by researchers in specific content areas. Unlike the first line of research, in this second line, researchers usually focus on teaching grade-specific mathematical topics using a problem-solving approach. These studies are important because they provide insights into the ways teachers teach specific content topics through problem solving in classroom.

## Networking Strategies for Connecting Theoretical Approaches

Gabriele Kaiser
University of Hamburg (Germany)

Abstract: One of the characteristics of the research community in mathematics education seems to be the large diversity of different theories, research paradigms and theoretical frameworks. This diversity has become an important issue to discuss at many conferences and in many publications. Is diversity a problem or a resource or a barrier for further research? How shall the scientific community deal with this diversity? Internationally different approaches have been developed to cope with this diversity (see Sriraman / English in monograph 1). Under a European perspective the approach of networking strategies, which aim to connect different theoretical approaches using several strategies, has been developed. This perspective bases its work on the assumption that the variety of different theoretical approaches and perspectives in mathematics education research is a *rich resource* upon which the scientific community should build more consequently. This perspectives calls for the connections of different theories and rejects isolationistic tendencies of separating different theoretical approaches. This approach does not intend to develop one grand unified theory, but intends to network local theories, which deal with background theories but use diverging conceptual systems for describing the same phenomena.

Different networking strategies are presented in a landscape, linearly ordered according to their degree of integration. These networking strategies such as comparing or contrasting, combining or coordinating can contribute to the development of theories and their connectivity and offer hence an interesting research strategy for the didactics of mathematics as scientific discipline.

## Feminist Perspectives and Mathematics Education

Helen Forgasz
Monash University, Australia

Abstract: Feminism has many faces. There is, however, a unifying dimension to all the theoretical shades of feminism. Feminism is considered a movement for attaining the right of women to be equal to men in all aspects of life – social, political, legal, and educational. The impact of feminist thinking on mathematics education research is the focus of this presentation. In her article entitled *Feminist pedagogy and mathematics*, which is to be reproduced in the first monograph in the Springer series, *Advances in mathematics education*, Judith Jacobs (1994) concluded that:

> ... previous research and intervention programs designed to promote females … have been based on the assumption of male as the norm, the model of the successful mathematics student or mathematician who is to be emulated if the non-successful are to

> succeed. Little research and work has begun from the assumption that females have strengths, experiences and learning styles that can succeed in mathematics.

Jacobs (1994) provided a theoretical framework for a feminist pedagogy for which the assumption was “that being a woman is the norm for females” (p. 16), and the teacher had the responsibility “to capitalize on females’ strengths and interests in order to facilitate their success in mathematics” (p. 16). Jacobs believed that all students would benefit from this approach which, she claimed, “in no way denies the power or beauty of mathematics” (p. 16).
Leder (in press) has provided a commentary on Jacobs’ (1994) chapter which is also to be included in the Springer monograph). Leder summarised the main points raised by Jacobs (1994) including the caution not to essentialise women as a group in response to research generalisations about differences between women and men.

Drawing on a number of earlier as well as more contemporary sources, Leder also discussed a range of feminist perspectives and their influence on research into gender issues in mathematics education. The feminist links evident in chapters found in the influential edited collection by Rogers and Kaiser (1995) are highlighted and include:

- Kaiser and Rogers’ (1995) five stages of the mathematics curriculum beginning with “womanless” mathematics” and ending with “mathematics reconstructed”; and
- Becker’s (1995) chapter in which Belenky et al.’s (1986) ‘women’s ways of knowing’ are extended to the knowing of mathematics.

Whilst liberal feminism receives much criticism from many feminist theorists, it would appear to underpin and dominate many research endeavours, particularly those which do not specifically identify with any feminism. Many researchers continue to call for the monitoring of all large scale studies involving achievement and/or participation data for gender differences, and caution not to ignore gender as a factor in smaller, more focussed studies. As is evident in Australia today, educational disadvantages once considered to have been addressed can resurface. Recent data revealing the re-opening of gender gaps favouring males will be presented.

## Problem Solving Heuristics, Affect, Representations and Discrete Mathematics

Gerald A. Goldin
Rutgers University
New Brunswick, NJ

Abstract: It has been suggested that activities in discrete mathematics allow a kind of new beginning for students and teachers. Students who have been “turned off” by traditional school mathematics, and teachers who have long ago routinized their instruction, can find in the domain of discrete mathematics opportunities for mathematical discovery and interesting, non-routine problem solving. Sometimes formerly low-achieving students demonstrate mathematical abilities their teachers did not know they had. To take maximum advantage of these possibilities, it is important to know what kinds of thinking during problem solving can be naturally evoked by discrete mathematical situations—so that in developing a curriculum, the objectives can include pathways to desired mathematical reasoning processes. This article discusses some of these ways of thinking, with special attention to the idea of “modeling the general on the particular.” Some comments are also offered on the global ideas of Moreno-Armella & Sriraman (2005) pertaining to the development of representational systems. The discussion focuses on the co-evolution of symbols and their referents, and the shared interpretation of mathematical symbols in a community of practice. Some future directions are suggested.

# VISUAL EXPLORATIVE APPROACHES TO LEARNING MATHEMATICS

Zekeriya Karadag
OISE/ University of Toronto
zkaradag@oise.utoronto.ca

Douglas McDougall
OISE/ University of Toronto
dmcdougall@oise.utoronto.ca

*This discussion group focuses on visual explorative approaches to learning mathematics. We address several issues in the discussion such as technology use in mathematics education and its evolution from static to dynamic in conjunction with the visual characteristics of new learning form of mathematics. Among various representations used in mathematics and mathematics education, visual representations of mathematical concepts, the effects of the implementation of visual techniques, and more importantly the importance of visual exploration of mathematics and its effects to mathematics education will be discussed.*

## Background

The focus of this discussion group will be situated at the intersection of the technology use in mathematics education, representation systems in mathematics education, and developing a conceptual understanding in mathematics. An enormous corpus of literature has been accumulated on these topics, and many researchers discussed the topics in the various national and international meetings such as PME, PMENA, and ICMI (Arcavi, 1999; Duval, 1999; Hitt, 1999; Hoyles, 2008; Kaput, 1999; Kaput & Hegedus, 2000; Leatham, & McGehee, 2004; McDougall, 1999; Moreno-Armella, 1999; Presmeg, 1999; Radford, 1999; Santos-Trigo, 1999; Thompson, 1999). Yet, our main focus will be on the visual exploration of mathematics and on the visual versus algebraic understanding of mathematics, particularly in the technology supported learning environments. We will also explore the distinctions between visualization of mathematics, visual exploration of mathematics, and visual understanding of mathematics. We believe that the result of this conceptual exploration will lead us to improve our understanding of the theories on representational systems (Kaput, 1992) and distributed cognition between human and technology (Pea, 1993).

Interestingly, the importance of exploration and visualization was emphasized in the past PMENA conferences. For example, in a paper presented in 1999 PMENA, the author points out the relationship between technology and representation:

> Technology, in all its forms, modifies, substantially, the process of knowledge production. Learning involves the construction of representations. It is through the construction of representations of an observed phenomena, (or of a mathematical concept) that we make sense of the (mathematical) world. *Representations become mediational tools for understanding* (Moreno-Armella, 1999, p. 99)

Similarly, in another PMENA meeting, the authors explore what we know about technology use and its effects in teaching and learning mathematics:

> Much of what we know about the use of technology in the teaching and learning of mathematics is anectodal and might be referred to as “possibility” research…. What do we really know regarding teaching and learning mathematics with technology? What frameworks, methodologies and collaborations will support the research that will produce this knowledge?(Leatham & Peterson, 2005, p. 1)

Some authors propose new perspectives for the use of technology rather than digital interpretations of traditional paper-and-pencil techniques. They suggest using dynamic, interactive, and collaborative features of technology:

> The advance of dynamic technological environments allows us to combine multiple individual cognitive acts of reference. This is possible since individuals can project their intentions and expressivity through the notations they create and share. They can also realize and generalize the structure of the mathematics through co-active collaboration with these environments. This can be made possible through the advances in representation infrastructures (dynamic mathematics software) and communication infrastructures (social and digital networks). (Moreno-Armella, Hegedus, & Kaput, 2008, p. 110)

*Various Types of Visualizations*

The literature documents at least three distinct meaning for the term visual mathematics such as (1) for studying advanced visual objects, (2) for visualizing algebraic rules, and (3) for exploring mathematics visually. The first one, studying advanced visual objects such as fractals and 3D functions, is a focus where mathematicians use technology to extend their imaginations and to make their ideas visible whereas the other two are related to mathematics education.

Virtual manipulatives (NLVM, 1999; SAMAP, 2006), learning objects (Reis & Karadag, 2004; Sorkin, Tupper, and Harmeyer, 2004), and animations (Tchoshanov, n.d.) are the examples to visualize mathematical concepts, rules, and relationships. The idea behind creating this group of mathematical objects can be described as to make mathematical rules visible in order to improve students' understanding. For example, the example from Tchoshanov's (n.d.) collection visualizes a very well-known algebraic identity (figure 1). He visualizes the identity of $(a+b)^2 = a^2 + 2ab + b^2$ by using animations.

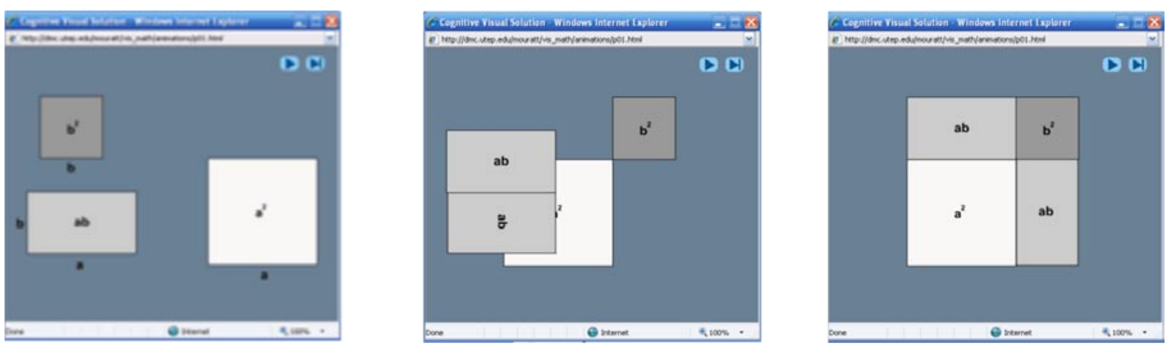

*Figure 18.* Screenshots from Tchoshanov's animations.

Similarly, virtual manipulatives developed by Utah State University team serve for the same purpose. For example, they use virtual algebra tiles to illustrate distributive law of algebra (figure 2). The figure illustrates a geometric representation to explain the rule for the example x (y + z) = xy + 2x.

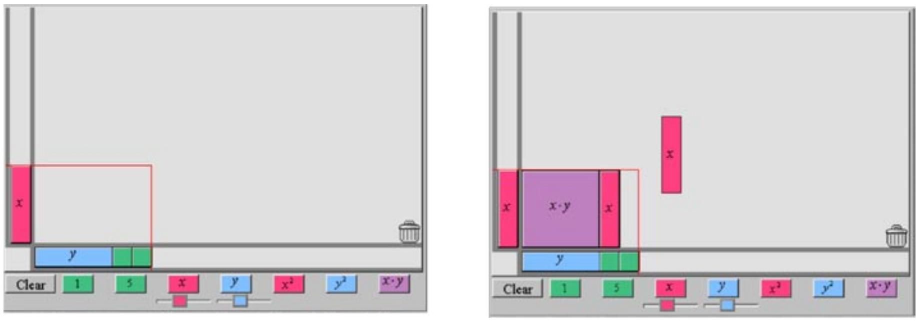

*Figure 19.* Algebra tiles as virtual manipulatives.

However, these virtual manipulatives could also be used to explore mathematics visually. For example, student may develop an insight for patterning while using Towers of Hanoi example (figure 3). This example provides a scenario to encourage students explore the problems illustrated. Students, with or without guidance, are expected to realize the pattern while performing the task.

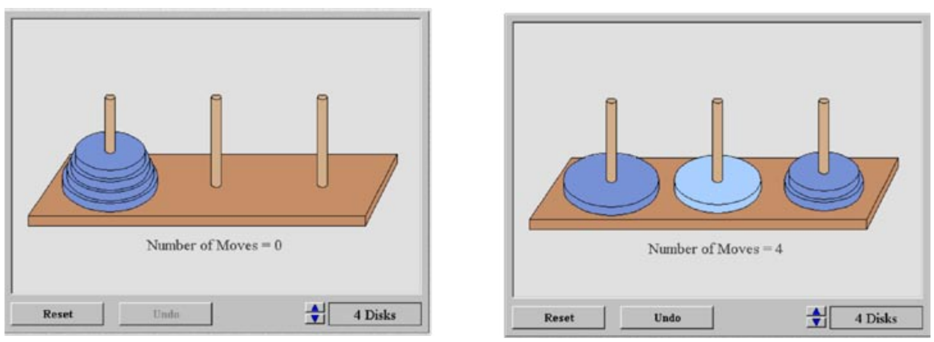

*Figure 20.* The Towers of Hanoi as virtual manipulatives.

Another exploratory environment to encourage students to improve their patterning skills is the Math Towers. The Math Towers provides scenarios such as billiard boards to engage students to develop some patterning relationships (figure 4). The scenarios illustrated in the Math Towers and the Towers of Hanoi aim to engage students to be part of a virtual environment and to explore mathematics visually.

*Figure 21.* The Math Towers.

Moreover, we have dynamic learning environments to create dynamic worksheets. For example, Geogebra, a free online dynamic software, allows us to create mathematical objects and to explore these objects visually and dynamically. In a study, we created a dynamic worksheet illustrating the relationship between unit circle and trigonometric functions (figure 5). We asked students to manipulate these mathematical objects and explore the relationship between them (they were not told that the functions were trigonometric).

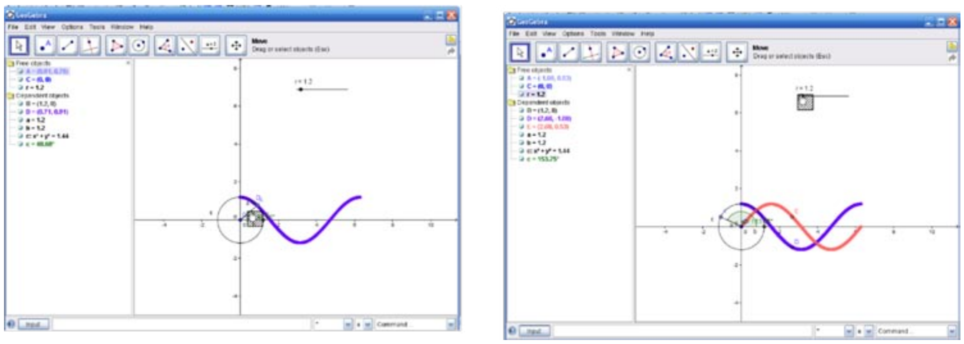

*Figure 22.* Visual exploration in Geogebra.

As seen in the examples described here, there are different types of visualizations. The cognitive collaboration between human and tools seem to be quite distinct in these examples although we call them all as visualization. Thus, it is important to identify this distinction and to develop theories explaining various visualization types.

More importantly, some scholars argue that mathematics education evolves through integration of technology and needs a groundbreaking change to complete its evolution (Galbraith, 2006; Moreno-Armella, Hegedus, & Kaput, 2008). Moreno-Armella, Hegedus, and Kaput (2008) describe symbolic structures as “an environment that enable us to think deeper” (p. 100) and argue that “the nature of mathematical symbols have evolved in recent years from static, inert inscriptions to dynamic objects or diagrams that are constructible, manipulable and interactive” (p. 103). According to their perspective, students may think, reflect on their thoughts, and construct new mathematical knowledge in the dynamic learning environments. The dynamic learning mathematical environments enable students act mathematically, such as seeking visual patterns, define these patterns, and explore the properties of these patterns as they usually do symbolically in paper-and-pencil environments.

## The Rationale and Goals of Discussion Group

The goals of this discussion group are to explore and discuss the dynamic and visual features of technology in mathematics education, to develop awareness on the potential effects of visual exploration in conceptual understanding of mathematics, and to set up a research agenda on the study of visual exploration in mathematics education.

The discussion group will review the past and current use of technology as visual and dynamic cognitive tools and extend the theory of distributed cognition over the participatory mathematical activities. This discussion will deepen our understanding of the effects of visual explorative activities in learning mathematics and seek possible strategies to integrate web 2.0 technologies with dynamic learning tools.

*Objectives*

- To perform a comprehensive review of various representational systems used in mathematics in junction with a linkage among them
- To explore various perspectives of visual learning in mathematics
- To explore the features of dynamic learning systems in conceptual understanding of mathematics
- To identify possible effects of visual and dynamic learning environments in mathematics education
- To explore the possible scenarios for the future of the mathematics education supported with contemporary technologies such as Web 2.0, dynamic learning environments, and visual representation

*Questions to frame our discussion*

- Which representation types are used in mathematics education?
- What types of visualizations do we use and how could they be identified?
- Which representation is more compatible with the nature of human learning?
- Could algebra be a barrier to learn mathematics?
- How can we observe or track the effects of visual versus symbolic representations in learning mathematics and their effects on concept development?
- How could the Web 2.0 technologies and dynamic learning environments be integrated to engage students for visual exploration of mathematical concepts?

## Format for the Discussion Group Meeting

*Day 1: Identifying the Current Situation and Contemporary Perspectives*

The organizers of the group will begin the discussion with a brief introduction of the topic and some quotes from literature. Then, we will ask the participants to reflect on these quotes in small groups and share their reflections with whole group. The second hour of the discussion will focus on the technology, representation, and visualization. We will engage the participants to brainstorm on the expectations of technology in math education, on the various forms of representations used in mathematics, and on the meanings of visualization in small groups and share their reflections with whole group.

- Introducing group members
- Introducing discussion group topics and goals
- Reviewing selected quotes form previous work and engaging participants to reflect on these quotes
- Brainstorming on the expectation of technology in mathematics education
- Brainstorming on the various forms of representations used in mathematics
- Brainstorming on the meanings of visualization

The quotes will be the evolution of the mathematics education (Moreno-Armella, Hegedus, & Kaput, 2008) and the metaphor of the technology use (Galbraith, 2006).

*Day 2: Projecting on the Future*

We will start the meeting by briefing previous day's discussion and by outlining themes emerged from the discussion. Then, we will demonstrate a couple of dynamic worksheets created by Geogebra and ask participants to develop scenarios in their small groups on how to use these dynamic worksheets in classrooms and to share their scenarios with the whole group. During the last half hour, we will encourage the participants to discuss the opportunities of integrating Web 2.0 technologies (i.e. wikis) with these dynamic worksheets.

*Day 3: Summarizing the Discussions and Setting Goals for the Future Collaboration Opportunities*

- Summarizing previous discussions
- Reminding the metaphor by Galbraith (2006) and engaging to brainstorm on the mathematics education for the next fifty years
- Forming an international working group on the topic
- Setting an agenda for the future

**Possible Future Agenda Items**

- Set up a working group for dynamic and visual learning
- Create possible research questions
- Seek possible strategies to disseminate the themes emerged through discussion
