**Conclusions**

During the first three sessions, Meredith exhibited evidence that she had some understanding for fraction equivalence as she made multiple models to support a claim that one-fifth equaled two-tenths and that one-sixth equaled two-twelfths. In the fourth session, Meredith presented five number lines on a unit interval where each line showed a different aspect to the complete number line. Her lines suggested that she understood and could work with fractions as operator and as number. Later in the fourth session, Meredith continued to demonstrate her understanding of equivalence between rational numbers by correctly labeling the point named one also as three-thirds, adding verbally that this number could be named four-fourths, five-fifths, or even 100/100.

---

After extending the number line beyond the unit point, Meredith labeled the number named two as one and three thirds and, verbally, labeled it six-thirds. Meredith correctly extended equivalence ideas to negative numbers as she placed fourths between the interval zero and negative one. For the number named negative one, Meredith correctly labeled the number negative four fourths. Meredith showed that she could correctly use fraction, mixed number and improper fractions to alias rational numbers.

Meredith, over the six week interval considered in the study, built on her understanding of equivalence ideas and extended the idea of having multiple names for number to negative rational numbers recognizing that there are multiple names for representing rational numbers.

Discussion

The study supports the findings from Cramer et al. (2002) and provides a trace of how one student, along with her classroom community, extended her understanding of equivalence of unit fractions to integers and rational number ideas. Meredith thoughtfully engaged in communication with other students and the researchers, offering support for her reasoning which provided her with a strong foundation to swiftly extend equivalence notions to more challenging fraction ideas. We can continue to learn from the story of Meredith and her engagement with her classmates.

Meredith and her classmate’s stories are captured on videos that have made possible the tracing of Meredith’s journey with her classmates from an understanding of equivalence of fraction ideas to rational number ideas. Studying these videos can provides insight into how these ideas about fractions can be built by students in a classroom setting. There is potential to provide a valuable set of tools for professional development, especially in contexts such as Lesson Study where teachers have opportunities to take these ideas directly to their classrooms. The session videos of Meredith and her classmates along with accompanying transcripts, student work, and other metadata (i.e., data about data) are available on Rutgers Video Mosaic Repository², Interested teachers and educators are invited to visit the website.

The title of our presentation comes from the conference in which Piaget first realized the isomorphisms between mathematical and psychological structures. Our presentation introduces a new psychological structure isomorphic to a mathematical group. “The splitting group” contributes to a better understanding of how students develop measurement concepts, especially for fractions. We designed written assessments and performed statistical analysis to test our model of a related structure and its formation among sixth-grade students. Results affirm the validity of the model and indicate the roles partitioning and iterating play in students’ development of measurement concepts.

Introduction

As the name implies, PME conferences seek to bring psychologists and mathematicians together to share ideas and deepen our collective understanding of psychological processes at play in mathematics education. In 1952, a similar conference (whose title we borrow here) brought together psychologist Jean Piaget and mathematician Jean Dieudonné. The result of that meeting provided a logico-mathematical foundation for structuralism (Piaget, 1970b), as recalled by Piaget:

Dieudonne gave a talk in which he described the three mother structures [algebraic, topological, and order]. Then I gave a talk in which I described the structures that I had found in children’s thinking, and to the great astonishment of us both we saw that there was a very direct relationship between these three mathematical structures and the three structures of children’s operational thinking (Piaget, 1970a, p. 26).

In our paper, we focus on algebraic structures, but note that various coordinations of the three mother structures produce additional structures—both mathematical and psychological.

Algebraic structures, such as groups, rely upon a set of elements that can be composed with one another under particular rules, or axioms. In mental structures, the elements are operations (internalized actions). For example, partitioning operations enable students to mentally break a continuous whole into a specified number of pieces. Piaget (1970b) has provided examples of several group-like structures in children, but he noted that some of these structures lack associativity. The mathematical term for such a structure (one that satisfies the properties of a group, except that it may lack the associative property) is loop.

Psychological loops are isomorphic to mathematical loops: There is an identity element, which does not transform the other elements; elements can be composed so that the results of composition are also elements of the structure; and each element in the system has an inverse element, with which composition yields the identity element. Unlike mathematical groups, loops are not necessarily associative, and, sometimes, tautology (A+A=A) precludes associativity because, “if we write A+A–A, where we put the parentheses makes a difference in the result” (Piaget, 1970a, p. 28). Piaget (1971) described the psychological/mathematical connection in the following way:
Operations are actions coordinated into reversible systems in such a way that each operation corresponds to a possible opposite operation that renders it void.... Identity is then to be considered a product—the product of the composition of direct or reversed operations—and not a point of departure. The group of such transformations is therefore the source of conservation principles; and identity (or more precisely the “identical operation”) is merely one of the aspects of this group system, an aspect inseparable from transformations themselves (p. 36).

The purpose of this paper is to present a new loop—the splitting loop—that might contribute to a better understanding for how students develop meaningful understanding of fractions, if our model of the loop can be validated. The loop consists of three operations (partitioning, iterating, and splitting), which we discuss in the next section. We then share methods and results for quantitatively testing our model of the splitting loop: Do statistical analyses support the validity of the splitting loop as a model for understanding students’ development of fractions knowledge? Finally, we describe some implications for teaching and research. Among the research implications is a fresh consideration of the three mother structures and their coordination.

**Theoretical Model for the Splitting Loop**

**Partitioning**

Several researchers have affirmed the value of engaging students in activities involving sharing or partitioning sets of objects, in support of students’ construction of initial fractions concepts (e.g., Kieren, 1980; Lamon, 2007; Mack, 2001). Steffe (2002) described the corresponding interiorized action—the partitioning operation—as the mental projection of a composite unit (e.g., 5 as five 1’s) into a given, continuous whole, which enables the child to imagine how to share the whole equally among, say, five friends. However, research has indicated limitations in fraction conceptions that rely too heavily on partitioning. For example, Mack (2001) found, “students’ informal knowledge of partitioning did not fully reflect the complexities underlying multiplication of fractions” (p. 291). Subsequent research has indicated that understanding of fractions as measures (Kieren, 1980) requires iterating operations as well (Olive & Vomvoridi, 2006; Steffe, 2002; Tzur, 2004).

**Iterating**

Iterating in a continuous context involves mentally repeating a given length or area to produce a connected whole that is $n$ times as big as the given part. In two separate teaching experiments, Tzur (2004) and Olive and Vomvoridi (2006) demonstrated that teachers can support students’ conceptualizations of fractions as measures by bringing forth students’ iterating operations. Tzur (2004) found that fourth-grade students could learn to iterate unit fractional parts to produce other proper fractions. For example, students can produce $3/8$ as three iterations of a $1/8$ part.

**Splitting**

Once students have constructed partitioning and iterating operations, two new constructions become possible: the equi-partitioning scheme and the splitting operation. Steffe has described the equi-partitioning scheme as the sequential application of partitioning and iterating, for the purpose of creating equal parts within a continuous whole: The partitioning operation serves to create the equal parts, and the iteration operation serves to test whether one of those parts...
reproduces the whole when repeated the appropriate number of times (Steffe, 2004). In contrast, the splitting operation involves simultaneous application of partitioning and iterating: “In the splitting operation, the child’s awareness of a multiplicative relation between a whole and one of its hypothetical parts is produced by the composition of partitioning and iterating. In other words, they are realized simultaneously” (Steffe, 2002, p. 303). Figure 1 illustrates tasks designed to elicit children’s use of the splitting operation.

1. The stick shown below is 5 times as long as another stick. Draw the other stick.

2. The stick shown below is 3 times as long as another stick. Draw the other stick.

3. The amount of pizza shown below is 6 times as big as your slice. Draw your slice.

4. The amount of pizza shown below is 3 times as big as your slice. Draw your slice.

Figure 1. Tasks designed to elicit splitting

Each task in Figure 1 requires the student to use partitioning in service of an iterative goal—finding a part that, when iterated $n$ times, produces the given stick or pie. Students who have not composed partitioning and iterating will often iterate the given stick or pie piece instead (Steffe & Olive, 2010).

Composition

In the splitting loop, partitioning and iterating are inverse operations. Splitting is both the identity element of the group and the group’s fundamental aspect. To understand this, consider that splitting composes partitioning and iterating so that each operation reverses the other before any action is carried out. This aspect enables children who split to comprehend and solve the tasks shown in Figure 1. Now, until students can reconcile the products of recursive partitions or recursive iterations—which Hackenberg (2007) attributes to the construction of three levels of units coordination—compositions of two partitions or two iterations are governed by tautology. In other words, partitioning each part of a partition remains indeterminate beyond being another partitioning, until students can coordinate the units involved. Thus, the loop is initially non-
associative and contains only three elements: the operations of partitioning, iterating, and the splitting identity.

The splitting loop resembles one Piaget described for partitioning in discrete contexts: “The initial operation is, then, in effect, dividing or sectioning, while the assembling of parts or pieces in a total object is its inverse operation” (1974, p. 30). Thus, partitioning and uniting operations are described as inverses (Steffe, 2004). “This division and reconstruction of the unit (whole) is a central feature of fraction knowing” (Olive, 1999, p. 281). However, if one of the parts is disembedded from the others, a student cannot reproduce the whole from that part by simply reassembling parts; the single part must be repeated, or iterated. The equi-partitioning scheme (EPS) (Steffe, 2002) involves carrying out those actions sequentially, in order to produce a piece that, when iterated a specified number of times, reproduces the whole. Thus, the role of the equi-partitioning scheme as an intermediate between partitioning and iterating, on the one hand, and splitting, on the other, fits naturally. Figure 2 illustrates the model and includes path coefficients representing the relationships between the different operations and schemes. In the next two sections, we describe our methods for obtaining and interpreting these values.

![Figure 2. Model of the splitting loop](image)

**Methods**

In noting the prevalence of theoretical models (like the one we just shared) in mathematics education research, Kilpatrick (2001) lamented the fact that most of these models remain untested by quantitative analysis. We began to address the issue in a previous paper (Norton & Wilkins, 2009), in which we shared methods and initial results from a quantitative study designed to test hypotheses about students’ fractions schemes and operations. We have extended those methods to the splitting loop by designing a cluster of four written items to assess each of the schemes and operations in the model (see Figure 2). The items for the splitting operation are those shown in Figure 1. We share a single item from each of the other clusters in Figure 3. Additional items within each cluster varied in the same way as the splitting items (numerically and contextually).

We administered the 20 randomized items to all sixth-grade students in a rural Southeastern school (n=66) and independently assessed student responses to determine whether or not to attribute each scheme or operation to each student. We used Cohen’s kappa to measure inter-rater reliability for each scheme or operation and achieved the following results: Perfect agreement between the two raters for the partitioning operation (K = 1.00); “almost perfect agreement” for the equi-partitioning scheme (K = .83, p < .05) and the splitting operation (K...
= .93, p < .05); and “moderate agreement” for the iterating operation (K=.57, p<.05) (Landis and Koch, 1977). Overall the evidence suggests high reliability between the raters. We discussed any differences in ratings and reconciled these differences to create one rating for each student.

A. Suppose the stick shown below is a piece of candy. Show how someone could share it equally among 5 friends.

B. Make a stick that is 7 times as big as the one shown below.

C. What fraction is the smaller stick out of the longer stick?

Figure 3. Sample assessment tasks for partitioning (A), iterating (B), and equi-partitioning (C)

In order to quantitatively test the theoretical structure of the splitting loop and students’ development of it, we created contingency tables for pairs of schemes and operations. We measured associations using gamma statistics and tested for directionality using exact binomial tests. We then conducted a series of path analyses to test the model illustrated in Figure 1. An indirect effect represents a relationship between two variables that is mediated by another variable. Such an indirect effect is represented in the model (Figure 2) by the paths leading from both ITERATING and PARTITIONING through EPS (the equi-partitioning scheme) to SPLITTING. A reduction in the direct effect of ITERATING and PARTITIONING on SPLITTING as a result of adding EPS to the model would provide evidence of the mediating effects of EPS. In addition, finding a statistically significant indirect effect of ITERATING and PARTITIONING on SPITTING (through EPS) would further indicate the mediating effects of EPS.

Results

Table 1 shows a strong directional association between the equi-partitioning scheme and the splitting operation, with equi-partitioning developmentally preceding splitting. Similar tables show strong directional associations (all with Exact Binomial p-values of less than .01) indicating that partitioning and iterating precede both equi-partitioning and splitting. In fact, assessments indicated that none of the 66 students constructed the splitting operation without first constructing both partitioning and iterating operations. Path analyses provide for further understanding of these relationships.

Note. Gamma = .87, p < .0001, one-tailed; Exact Binomial p (one-tailed) = .006.
In the first path analysis, we regressed SPLITTING on ITERATING and PARTITIONING to determine the direct effects of iterating and partitioning on the construction of splitting without including EPS in the model. ITERATING and PARTITIONING were found to be positively and statistically correlated ($r = .54$). In addition, controlling for each other, both ITERATING ($b = .38, p < .05$) and PARTITIONING ($b = .28, p < .05$) were found to have a statistically significant positive effect on SPLITTING. These effects can be interpreted in terms of standard deviation increases. For example, on average, for one standard deviation increase in student iterating scores there was an average increase of 0.38 of a standard deviation in the average splitting score, controlling for partitioning scores.

When we included EPS as a potential mediating variable between ITERATING, PARTITIONING, and SPLITTING, both ITERATING ($b = .37) and PARTITIONING (b = .35) were found to have a statistically significant positive relationship with EPS ($p < .05$); and EPS ($b = .34, p < .05$) was found to have a statistically significant positive relationship with SPLITTING. After including EPS in the model, the effect of ITERATING ($b = .26, p < .05$) and PARTITIONING ($b = .16, p > .10$) on SPLITTING were reduced in magnitude when compared to their effects without EPS in the model, and in the case of PARTITIONING, the effect was no longer statistically significant.

In the model, EPS is hypothesized to mediate the effects of ITERATING and PARTITIONING on SPLITTING. These indirect effects are calculated as the product of the individual direct effects (e.g., ‘path coefficient for the direct effect of PARTITIONING on EPS’ x ‘path coefficient for the direct effect of EPS on SPLITTING’ = ‘indirect effect of PARTITIONING on SPLITTING,’ or $0.35 \times 0.34 = 0.12$). PARTITIONING ($b = .12, p < .05$) and ITERATING ($b = .12, p < .05$) were both found to have a statistically significant positive indirect effect on SPLITTING. These statistically significant indirect effects provide evidence of the mediating effects of EPS on the construction of splitting.

**Conclusions**

A loop is a set of elements closed under composition, such that one of the elements serves as an identity and each element has an inverse. The results from our study support the idea that splitting forms a loop of three elements under composition: splitting, partitioning, and iterating. In that loop, partitioning and iterating are inverses of each other and, as the simultaneous composition of those two operations, splitting serves as the identity. We demonstrate the claim by reviewing its theoretical basis in the literature, and by using the path analyses shown in Figure 2 to argue that splitting closes the loop.

In our study, and particularly in our task design, we adopted Steffe’s (2002) definition of splitting. He identified this operation through his teaching experiments with children, during which some children seemed able to carry out operations of partitioning and iterating simultaneously (splitting), while others only carried out these operations sequentially (equi-partitioning). For example, one pair of fourth-grade students, named Jason and Laura, could carry out iterations of a unit fraction once they had produced the unit fraction through partitioning a whole, but, initially, neither student could posit a hypothetical part to satisfy the kinds of tasks illustrated in Figure 1. Over the course of the yearlong teaching experiment, both students began to solve such tasks, apparently by carrying out the two operations simultaneously.

There appears to be a discontinuity between the equi-partitioning scheme and splitting operations. In the former, partitioning and iterating are operations that are more or less
sequentially performed, whereas in the splitting operation, the child’s awareness of a multiplicatively related between a whole and one of its hypothetical parts is produced by the composition of partitioning and iterating (Steffe, 2002, p. 303).

The results illustrated in Figure 2 support Steffe’s view by demonstrating that equi-partitioning does, in fact, meditate the construction of splitting from partitioning and iterating. Furthermore, none of the students in our study constructed splitting operations without first constructing both partitioning and iterating. Whereas students with equi-partitioning schemes coordinate iterating and partitioning in order to test the accuracy of their partitions, splitting completes (closes) the system so that, for each operation, the other “renders it void” before it is even enacted (Piaget, 1971, p. 36). As such, splitting constitutes one of those psychological structures that Piaget found isomorphic to mathematical structures known as loops.

**Implications**

Initially, students may treat the composition of two partitions or two iterations as tautological: A partition of a partition is just some other partition; likewise for iteration. Thus, the composition of two partitions and one iteration (or vice versa) might depend upon the order in which the student carries out the pair-wise compositions. The splitting loop will lack associativity until the student can anticipate the product of two partitions or two iterations. Steffe (2004) has termed the first of these coordinations “recursive partitioning” and posits that such coordinations require the student to create a unit of units of units. For example, determining the product of ¼ and 1/3 requires the student to distribute one partitioning across each of the other partitions so that each third, say, is partitioned into four parts. Then the student must coordinate the three levels of units involved: One twelfth is one of four parts, which collectively form one-third of the whole (or, conversely, the whole as three equal parts, each of which is made up of four equal parts).

Hackenberg (2007) has identified three levels of units coordination as a necessary development—beyond splitting—in the construction of iterative fraction schemes, which enable students to treat improper fractions as “numbers in their own right” rather than mixed numbers (p. 27). Thus, we can think of the splitting loop as a mathematical group when students have conceptualized all fractions, including improper fractions, as multiplicative size relations with the whole. However, units coordination has its own structure—of order relations (Piaget, 1970b).

Just as Dieudonné (and the Bourbaki) did for mathematics, Piaget identified algebra, topology, and order as the three mother structures for psychology. Furthermore, he described a meta-structure, called the INRC group, which governs the synthesis of mental structures. In particular, “measurement is constructed by synthesizing partition and order relations” (Piaget, 1970b, p. 66). Our study contributes to a better understanding for how students might develop measurement concepts (especially for fractions). Students can develop partitioning within the splitting loop, where the operation is composed with its inverse—iterating. Synthesis with order relations becomes possible once students are able to coordinate the three levels of units involved in recursive partitions, or recursive iterations. At that point, improper fractions might become measures for students, and students’ splitting loops become splitting groups.

When we consider the nature of mathematical thinking, it is not so surprising that mathematical loops and groups appear in psychological studies of students’ mathematical development. As Piaget (1970b) noted, the essential property of logico-mathematical operations—both psychological and formal—is their reversibility. “Because every operation is reversible, an ‘erroneous result’ is simply not an element of the system” (p. 15). Loops and
groups are very basic reversible systems. However, identifying mathematical structures, like the splitting loop, may help researchers focus on mental operations fundamental to students’ mathematical development. In one direction, we begin to understand simple operations, such as partitioning and iterating, as part of a larger closed system of compositions. In the other direction, we begin to unpack more complex operations, such as splitting, into their constituent parts. The loop model may also inform us as to the completeness of the system and help us identify which additional operations, such as units coordination, students need to develop in order to grow their structures into larger systems for operating.

This study explores the development of students’ strategies going from primary to secondary school when solving proportional and additive problems. The goal is to identify characteristics of the development of proportional reasoning and how the use of integer and non-integer ratios and the discrete or continuous nature of quantities influence this development. The findings indicate that primary school students used systematically the additive strategy in all problems and that secondary school students present a wider variety of strategies that are also used systematically in the solution of all the problems. The type of ratio and the nature of the quantities influenced differently the development of these strategies.

Introduction

In recent years, proportional reasoning has been considered synonymous with the ability to solve proportional missing-value problems (Cramer, Post, & Currier, 1993); that is tasks that include three quantities of a proportion and the fourth quantity is unknown and has to be computed. Recently researches (De Bock, Verschaffel, & Janssens, 1998; Fernández, Llinares, & Valls, 1998; Modestou & Gagatsis, 2007; Van Dooren, De Bock, Janssens, & Verschaffel, 2008) have suggested that proportional reasoning does not imply only the ability to solve missing-value proportional problems but also the ability to discriminate proportional from non-proportional situations. For example, Modestou and Gagatsis (2010) suggested the existence of a new model of proportional reasoning where proportional reasoning does not coincide exclusively with success in solving a range of proportional problems, as routine missing-value and comparison problems, but it also involves handling verbal and arithmetical analogies, as well as the awareness of discerning non-proportional situations from other situations.

The present study focuses on the development of proportional reasoning when moving from primary to secondary school, analyzing the strategies used by students to handle proportional and non-proportional situations. In particular, the main aim of this study is to explore the influence of the different types of ratios (integer or non-integer) and the nature of quantities (discrete or continuous) on this development.

Theoretical Framework

A proportion is “a second order relationship that implies an equivalent relationship between two ratios – and can be expressed as \( \frac{a}{b} = \frac{c}{d} \)” (Christou & Philippou, 2002). According to Freudenthal (1983), the ratio is a function of an ordered pair of numbers or quantities of magnitude. There are two kinds of relationships among quantities: “within” relationships (internal ratio), which are relationships between quantities of the same nature, and “between”
relationships (external ratio), which relate quantities of different nature. Take, for example, the problem “Six kilos of potatoes cost €2. If you want to buy nine kilos of potatoes, how much will you pay?” If we relate the weight with the price, we obtain a “between” relationship (2 euro / 6 kilos), whereas if we relate the first weight with the second weight we have a “within” relationship (9 kilos / 6 kilos). Vergnaud (1983) considered two measure spaces (in our example, euro and kilos) and the transformations can be carried out within or between the variables-measures. These transformations reflect the different methods-strategies that students can use to solve the problems (Karplus, Pulos, & Stage, 1983; Modestou & Gagatsis, 2009).

The literature on proportional reasoning reveals a broad consensus that proportional reasoning develops from qualitative thinking, to build-up strategies, to multiplicative reasoning (Inhelder & Piaget, 1958; Kaput & West, 1994; Karplus et al., 1983; Noelting, 1980). These strategies represent different levels of sophistication in thinking about proportions. The qualitative thinking is characterized by the use of comparison words, such as bigger and smaller, more or less, to relate to the quantities of the questions. Build-up reasoning is an attempt to apply knowledge of addition or subtraction to proportion. In this strategy students note a pattern within a ratio and then iterate it to build up additively to the unknown quantity. For example, in the above problem, “3 kilos cost 1 euro, then 3+3+3 kilos cost 1+1+1 euro”. Strategies based on multiplicative approaches are based on the properties of the linear function: \( f(a+b) = f(a)+f(b) \) and \( f(ma) = mf(a) \) taking into account the transformations between or within ratios. Inhelder and Piaget (1958) regarded students’ mature use of proportional reasoning as indication of the formal operational thinking in which students observed the consistency of a covariational relationship between and within variables (measure spaces).

A characteristic in the development of proportional reasoning is the difficulty of students in distinguish proportional from non-proportional situations revealed by the erroneous use of additive strategies in proportional situations and by using erroneous proportional strategies in non-proportional situations (Fernández, Llinares, Van Dooren, De Bock, Verschaffel, 2009; Modestou & Gagatsis, 2007; Van Dooren, De Bock, Hessels, Janssens, & Verschaffel, 2005). The erroneous additive strategy used in proportional problems consists of the use of the difference between the numbers in the ratio and then the application of this difference to the third number to find the unknown quantity (Hart, 1984; Tourniaire & Pulos, 1985). For example, in the proportional problem “Peter and Tom are loading boxes in a truck. They started together but Tom loads faster. When Peter has loaded 40 boxes, Tom has loaded 160 boxes. If Peter has loaded 80 boxes, how many boxes has Tom loaded?” the erroneous additive strategy would be “As the difference between the boxes loaded by Peter and Tom is 160-40 = 120 boxes, then Tom has loaded 120+80 = 200 boxes. On the other hand, the use of erroneous proportional strategies in additive problems can be exemplified by the following non-proportional problem that is modeled by \( f(x) = x + b, b\neq 0 \) “Peter and Tom are loading boxes in a truck. They load equally fast but Peter started later. When Peter has loaded 40 boxes, Tom has loaded 160 boxes. If Peter has loaded 80 boxes, how many boxes has Tom loaded?” An erroneous proportional method used to solve this problem is, “as Tom has loaded 4 times more the boxes loaded by Peter (160:40=4), then Tom has loaded 80×4 = 320 boxes.”

Method

The sample of the study consisted of 755 primary and secondary school students; 65 fourth graders, 68 fifth graders, 64 sixth graders, 124 seventh graders, 151 eighth graders, 154 ninth graders, 125 ninth graders, and 154 tenth graders.
graders and 129 tenth graders. The participating schools were situated in different cities and pupils came from different socio-economic backgrounds.

Students were given a test consisting of 12 missing-value word problems, four of which were proportional (P), four additive (A) and four buffer problems. Additive situations referred to situations reflecting \( f(x) = ax + b, b \neq 0 \). Buffer problems were included so as to create a variation of the given tasks and avoid the effects of learning as well as stereotyped replies.

Discrete situations (D; e.g. loading boxes) and continuous situations (C; e.g. skating a certain distance) were used. For each situation, proportional and additive problems were created by manipulating only one sentence. For example, where in the proportional situation (P) the sentence “They started together but Tom loads faster” was used, in the respective additive situation (A) the sentence “They load equally fast but Peter started later” was used. In a second step, two different versions were considered, one with integer relationships between quantities (I, P1) and another with non-integer relationships between the quantities (N, P2). In this way a total of eight problems were obtained. Table 1 shows the problems used and their characteristics.

Students had approximately 50 minutes to complete the test. They were allowed to use calculators but were asked to write down all the operations they had conducted, so as to be able to follow the problem solving path they used.
Students’ strategies were analyzed and categorized into five groups, by taking into account the way students handled the relationships between the given numbers in each situation. Table 2 shows these categories and some examples:

</table>

The use of a strategy in a problem was codified as 1 and the absence as 0. In this way, in each problem the presence of the five categories of strategies was encoded, and therefore 40 variables arose (eight problems × five categories of strategies). An Implicative Statistical Analysis with the use of the computer software CHIC was conducted (Gras, Suzuki, Guillet, & Spagnolo, 2008), first with primary school students’ data and then with secondary school students’ data. The similarity diagrams that arose from this analysis allowed the arrangement of the strategies into groups according to the homogeneity, indicating the way they were applied by students.

**Results**

The similarity diagrams of the strategies used by primary school students and secondary school students are presented first. A comparison of these similarity diagrams follows, in order to identify possible changes in the strategies used.

**Primary school students**

Figure 1 shows the similarity diagram of the strategies used by primary school students in the different problems of the test. The similarity diagram was generated only with 23 variables clustered in three similarity clusters (i.e., groups of variables). Cluster A consisted of variables referring to the use of additive strategies in all additive and proportional problems. It indicates that primary school students used this strategy systematically, without being able to discriminate proportional or additive problems. Furthermore, the way in which the use of the additive strategy in the different problems has been grouped suggests that the nature of quantities has an influence on its use. Two sub-groups appear: one with the problems including discrete quantities (SAdd1, SAdd2, SAdd5, SAdd6) and other with the tasks with continuous quantities (SAdd3, SAdd4, SAdd8).

Cluster B referred to the use of other strategies in discrete situations (SOth1, SOth2, SOth5 and SOth6), and in the additive problem with continuous quantities and integer ratios (SOth7). This way of grouping suggests that the discrete nature of quantities had also an influence on the use of other strategies.
Finally, Cluster C grouped three strategies, the category “Other strategies” in the problems with continuous quantities (SOth3, SOth4 and S0th8); the use of ratios (internal or external) in problems with integer multiplicative relationships between quantities (SR3, SR5 and SR7) and the use of building-up methods in problems with non-integer ratios (SBU2, SBU4 and SBU6). This grouping indicates, firstly that the integer multiplicative relationship between the given numbers implied the use of the ratios regardless of the additive or proportional character of the problems, and the presence of non-integer multiplicative relationships implied the primary school students’ use of building-up strategies. This fact can be easily explained as for primary school students the relation 160:40 = 4 is easier than the relation 100:40. In this sense, when the multiplicative relationship was easy, primary school students were more prone to use it (ratios), but when the multiplicative relation is non-integer, they derive to use build-up methods.

Figure 1. Similarity diagram of the strategies used by primary school students

Finally, the way in which these clusters have been formed indicates that the similarity groups are formed based on the strategies used and not on the proportional or additive character of the tasks. In addition, the formation of the sub-groups (defined by the use of strategies) is mainly based on the nature of quantities (discrete or continuous) or on the number structure (integer or non-integer ratios) and not on the proportional or additive character of problems.

Secondary school students

Figure 2 shows the similarity diagram of the strategies used by secondary school students in the different problems of the test. In this case, six similarity clusters grouped all the 40 variables. Cluster A grouped the use of additive strategies in all problems, where Cluster B grouped the use of other strategies. The use of building-up strategies in problems with integer multiplicative relationships were grouped in Cluster C, and the use of building-up strategies in problems with non-integer multiplicative relationships were grouped in Cluster D. Finally, the use of ratios (Cluster E) and the use of the rule of three (Cluster F) were grouped in two other distinct clusters.
The similarity groups are formed in the same way as in the case of the primary school, based on the strategies used and not on the additive or proportional character of the tasks. This data suggest that secondary school students were systematic in the use of strategies in each type of problem. That is to say, secondary school students that used additive strategies (Cluster A), they used them in all problems. The same pattern appeared for all the other different strategies. This data indicate essentially that secondary school students do not differentiate between additive and proportional situations, and handle them in the same way.

Only in Cluster B, the type of problem (additive/proportional) appears to have a minor affect on the use of other strategies. Cluster B is formed by two groups. Firstly, the group formed by the use of other strategies in proportional problems (SOth1, SOth2, SOth3, SOth4), and secondly the group formed by the use of other strategies in the additive problems (SOth5, SOth6, SOth7, SOth8). This grouping suggests that the type of the problem (additive or proportional) influence on the approach adopted by the students when they did not use additive or proportional strategies. Regarding Cluster C and D jointly, it shows that the use of building-up strategies were grouped considering the integer and non-integer ratios in the problem. Cluster C grouped the use of building-up strategies in problems with integer ratios (SBU1, SBU3, SBU5 and SBU7) and Cluster D grouped the use of building-up strategies in problems with non-integer ratios (SBU2, SBU4, SBU6 and SBU8). These data suggest that the type of ratio affects the use of the building-up method.

Cluster E grouped the use of the ratio approach in proportional and additive problems. However, the way of grouping does not provide a clear indication about the influence of the nature of quantities, the type of ratio or the additive or proportional character of the problems. Finally, Cluster F is formed by two groups. One grouped the use of the algorithm “rule of three” in the proportional problem with discrete quantities and integer ratios (SRT1), in the additive problems with continuous quantities (SRT7 and SRT8) and in the additive problem with discrete quantities and non-integer relationships between quantities (SRT6). The other group is formed by the use of the same algorithm in the proportional problems with continuous quantities (SRT3
and SRT4), in the proportional problem with discrete quantities and non-integer ratios (SRT2) and in the additive problem with discrete quantities and integer relationships between quantities (SRT5). However, the way in which the groups are formed in Cluster F indicate that the type of ratio (integer or non-integer) determined the first sub-group (P-D-I and A-C-I form a group, and A-D-N and A-C-N the other group), but the nature of quantity (discrete or continuous) determined the second sub-group (P-D-N and A-D-I form one group, and P-C-I and P-C-N the other group).

Comparison of the primary and secondary school students’ data

When the two similarity diagrams (Figure 1 and 2) are compared, differences appear. Firstly, primary school students’ similarity diagram grouped only 23 variables, while the secondary school students’ similarity diagram grouped all the 40 variables. Clusters were always formed in a way that they grouped the use of one strategy in all problems. This indicates that primary and secondary school students were systematic in the use of strategies independently of the additive or proportional character of the problem. On the other hand, the variables’ nature of quantities and the presence or absence of integer or non-integer ratios affected more primary school students’ use of a particular strategy than secondary school students’ decisions. In fact, the nature of quantities does not seem to affect secondary school students, whereas the number structure only affects the use of proportional strategies.

Discussion

The main goal of the present study was to explore the development of students’ strategies when solving proportional and additive problems along primary and secondary education and identify how number structure and nature of quantities affect this development. This was put forward through the identification of similarities or disparities along different age groups (primary and secondary), when solving additive and proportional problems with different characteristics (integer and non-integer multiplicative relationships and discrete or continuous quantities).

Primary school students used additive strategies and building-up methods to solve proportional and additive problems and secondary school students also applied other strategies as the use of ratios and the rule of three. The additive and proportional character of tasks does not seem to have an influence on primary and secondary school students’ strategies because they used systematically the same strategy to solve all type of problems. This study supports the idea that proportional reasoning not only implies the ability to solve missing-value problems but also the ability to discriminate proportional from non-proportional problems (De Bock, Verschaffel, and Janssens (1998); Fernández, Llinares, and Valls (1998); Modestou and Gagatsis (2010); Van Dooren, De Bock, Janssens, and Verschaffel (2008), in the sense that there are students who solve correctly proportional problems but solve incorrectly additive problems.

A characteristic of students’ development of strategies is that primary school students use the ratios (internal or external) in proportional problems with integer ratios but also in additive problems with integer multiplicative relationships between quantities. However, these students use the building-up method to solve the non-integer versions (proportional and additive). On the other hand, secondary school students do not change the strategy when solving different problems. On the contrary they systematic use the same strategy. Therefore, the effect of number structure on the use of different strategies by secondary school students was lower and there was not a strong effect of the nature of quantities.

EXTENDING THE DISCUSSION OF INTENSIVE QUANTITIES: THE CASE OF FRACTION MULTIPLICATION

Zelha Tunc Pekkan
Carnegie Mellon University
zelha@cs.cmu.edu

In this presentation, my aim is to discuss how fraction multiplying schemes produce intensive quantities and extend the categories that Schwartz (1988) suggested in relation to the forms of intensive quantities to include the special case of fraction multiplication. Even though the results of fraction multiplying schemes are the same type of units presented in the proposed situations (e.g., 1/7 of 3/5 of a candy bar is 1/35 of the candy bar)—because of which the fraction multiplication might be thought as a referent conservation operation so extensive quantities are produced—the mathematical operations carried out (by the participants of the study) imply that the production of results of fraction multiplication is no less advanced than the production of intensive quantities that is discussed in the literature. There is a co-varying relationship between two quantities of the same type (such as 1/7 of each 1/5 of a liter (5/5 of the liter) results in a thirty-fifths of a liter when seven mini-parts per part is distributed) unlike the co-varying relationship between two different types of quantities as discussed in the literature by Schwartz. In addition, we need to pay attention to children’s construction of fraction multiplication schemes since it is not a straightforward process, as one would expect in the construction of extensive quantities. Extensive quantities are usually produced by the arithmetical operations [addition and subtraction] on same type of quantities. Therefore, the view of, and emphasis on fractions and fraction multiplication/multiplying schemes should naturally be related to intensive quantities in early grades. As Schwartz (1988) suggested, we should not assume intensive quantities, such as “the concept of derivative,” can play a role only in the upper school mathematics curriculum or in algebra. I will provide data and analysis of the necessary mathematical operations with which a pair of 8th graders constructed a fraction multiplying scheme in order to discuss how intensive quantities are rooted in the construction of fractions and fraction multiplication

HOW STANDARDS-BASED CURRICULA AND CONVENTIONAL CURRICULA INFLUENCE STUDENTS’ LEARNING OPPORTUNITIES

Qintong Hu
University of Tennessee
qhu@utk.edu

Ji-Won Son
University of Tennessee
sonjiwon@utk.edu

This study examined four sets of curriculum materials on the topic of multiplication and division of fractions: two conventional textbooks—Scott Foresman-Addison Wesley (Charles, Crown, & Fennell, 2006) and Prentice Hall Mathematics (Buice, 2006) and two standards-based textbooks—Connected Mathematics (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2004) and Middle Grades MathThematics (Billstein & Williamson, 2005). Although each curriculum developer claims that their mathematics textbook attempts to develop conceptual understanding, there is not much research that examine whether standards-based curricula provide learning opportunities that are substantially different from traditional textbooks. We analyzed problems used in each of the textbooks according to four criteria: (1) Number of steps required, (2) contextual feature, (3) response type, and (4) cognitive expectation.

Analysis revealed that regardless of textbook type, a large portion of problems in all four textbooks required single step procedure for launching solution. With respect to the contextual feature criterion, more than 60% of problems in Connected Mathematics were presented in illustrative contexts whereas more than 70% of problems in other textbooks were presented in pure mathematics context. Relative to the response type criterion, a larger portion of problems in all four texts required numerical answer only. However, Connected Mathematics had higher percentage of problems requiring explanation than any other textbooks, which implies that Connected Mathematics provided more opportunities for students to explain and justify their solutions. With respect to the cognitive expectation of tasks, similar to other findings, Connected Mathematics had higher percentage of problems that required problem solving, representation, and mathematical reasoning whereas a large portion of problems in other textbooks required use of procedural knowledge. Interesting to note here is that although MathThematics is considered as standards-based curricula, we did not notice any differences between MathThematics and other traditional textbooks. This study provides implications for teachers, curriculum developers and researchers.

MIDDLE SCHOOL STUDENTS’ UNDERSTANDING ABOUT PRIME NUMBER

Kyoung Hee Cho  
Gyeonggi Science High School  
cho0114@snu.ac.kr

Oh Nam Kwon  
Seoul National University  
onkwon@snu.ac.kr

The goals of this study are to inquire middle school students’ understanding about prime number and to propose pedagogical implications for school mathematics. As a fundamental concept in number theory, the concept of prime number is introduced in the early stage of secondary mathematics curriculum in Korea. However, despite of simplicity of its definition, literatures highlight the difficulty in grasping the idea about prime number (Davis, 2008; Zazkis & Liljedahl, 2004). This research investigated characteristics of students’ understanding about prime number.

This research focused on the following questions: how do students define about prime and composite numbers and how do students understand their relation? Written questionnaire were given to 198 Korean seventh graders to explore their understanding of concepts and procedures relating to prime numbers. They were asked to provide explanations for all their answers. After the written questionnaire, 20 students among them participated in individual in-depth interviews.

The analysis showed that 97 out of 198 students defined prime number following their textbook definition saying that a natural number greater than 1 is prime if its only natural number divisors are itself and 1. 36 students defined prime number as a number having exactly distinct two natural number divisors. On the other hand, 37 students defined composite number as natural number greater than 1 that is not prime number. 76 students defined composite number as a number having more than 3 natural number divisors. In defining prime and composite numbers, the students focused on distinguishing one from another. However, they hardly recognize the mathematical connection between prime and composite number based on the multiplicative structure of natural number. In determining primality of $31 \times 47$, most students performed actual multiplication and long divisions to conclude that it is a prime number. Furthermore, many students did not notice that prime numbers hardly appear among big natural numbers. This finding indicates that the mathematical meaning behind a procedure was disregarded. Thus, the results of our study suggest that it is necessary to emphasize the conceptual relationship between divisibility and prime decomposition and the prime numbers as the multiplicative building blocks of natural numbers.

UNDERGRADUATES (MIS)UNDERSTANDING OF PERCENTAGES

Jennifer Jacobs  
Rutgers University  
jajacobs@ruccs.rutgers.edu

Rochel Gelman  
Rutgers University  
rgelman@ruccs.rutgers.edu

People of all ages have difficulty with rational number representations in decimal and fraction formats (Humberstone & Reeve, 2007). This is despite the fact that every day, people are inundated with rational numbers all around them. Using multiple representations for a math problem aids both the learning and teaching of mathematical concepts (Gelman, 1986). Rittle-Johnson & Star (2007) improved seventh-grade students’ conceptual and procedural abilities by having them compare alternative algorithms. This study looks at undergraduates’ performance on problems dealing with representations of rational numbers that they see in everyday life—the proportional increases or decreases in the cost of goods. We explore the following question:

Does representational format influence accuracy on rational number problems?

- Is training with a specific kind of rational number format more helpful than training with other rational number formats?
- Is there transfer from training on one rational number format to problem solving in another?

Twenty seven undergraduates (25 Females) at Rutgers University participated in the study. Each subject received 7 questions in the pretest, a training task, then 7 questions in the posttest. A logistic regression was used to evaluate the participants’ overall performance (proportion correct) and the effect of the training models. Responses were binary; they were coded as Incorrect or Correct. There was a main effect of Question Representation ($p = .003$). Subjects performed better on bar graph questions than on other question types across both the pretest and the posttest. There was a main effect of Training ($p = .049$); subjects differed in overall performance depending on whether they received decimal versus fraction training. When presented with a single percent increase (or decrease) in a problem, the direction did not affect performance ($p = .731$). When there exists more than one process within a problem, participants encountered a significantly greater deal of trouble (i.e., less than 25% of these problems were answered correctly). When given 1 type of question each in the pretest and posttest dealing with multiple processes, the level of previous math knowledge did not seem to matter. It was the case that 2/3 of subjects in both math groups failed to answer any of these problems correctly.

kienlim@utep.edu

Miguel Mendoza
University of Texas at El Paso
mmendoza6@utep.edu

Impulsive disposition refers to one’s proclivity to spontaneously proceed with an action that comes to mind without checking its relevance. Analytic disposition refers to one’s proclivity to analyze a problem situation and establishes a goal to guide one’s actions. An instrument, called the likelihood-to-act survey, was developed to measure students’ impulsive-analytic disposition. In this study, we sought to test and refine this instrument by analyzing 92 participants’ written responses to open-ended questions that were adapted from items in the likelihood-to-act survey. We found relatively strong correlations between participants’ disposition scores for written responses and those from the likelihood-to-act survey.

Introduction
In solving mathematics problems, “doing whatever first comes to mind … or diving into the first approach that comes to mind” (Watson & Mason, 2007, p. 307) is commonly observed among students. To demonstrate, consider the following problem:

Sue and Julie were running equally fast around a track. Sue started first. When she had run 9 laps, Julie had run 3 laps. When Julie completed 15 laps, how many laps had Sue run?

Cramer, Post and Currier (1993) observed that 32 out of 33 pre-service teachers solved the problem by setting up a proportion such as $9/3 = x/15$. Instead of analyzing and reasoning through the problem situation, these students had “blindly” applied the proportional strategy familiar to them. Lim, Morera, and Tchoshanov (2009) use the term impulsive disposition to refer to students’ proclivity to spontaneously proceed with an action that comes to mind without checking its relevance.

A contrast to impulsive disposition is analytic disposition. When one approaches a problem with analytic disposition, one “analyzes the problem situation and establishes a goal … to guide one’s actions” (Lim, 2008, p. 45). We have developed a survey instrument that seeks to measure one’s problem-solving disposition in the impulsive-analytic dimension. This instrument, called the Likelihood-to-Act (LtA) survey, consists of six-point Likert items where participants are asked to indicate how likely they are to respond to a given mathematical problem in the described manner (Lim, Morera, & Tchoshanov, 2009). In order to increase the reliability of the instrument, we have increased the number of LtA items from 18 to 32. A study was recently conducted to investigate the validity and reliability of the 32-item version of the LtA survey. Three other instruments—an open-ended questionnaire, a classification test, and a multiple-choice mathematics test—were developed and administered in conjunction with the LtA survey. This paper focuses on participants’ written responses to questions in the open-ended questionnaire and a question that asked participants what they thought the LtA survey was trying to measure.

Theoretical Background
Students are impulsive because they tend to approach a problem with conceptual tools that are familiar to them. In the famous water jar experiment (Luchins, cited in NRC, 2000), subjects, after solving many problems using one approach, spontaneously used the same approach to solve other problems that could have been easily solved using a different approach. This phenomenon

of solving a given problem in a fixated manner even when a better approach exists is called the Einstellung effect. In the context of mathematical problem solving, the Einstellung effect is described by Ben-Zeev and Star (2001) as a spurious correlation, which involves a two-phase process: A person first conceives an association between a problem feature and an algorithm for solving the problem, and then uses the algorithm upon perceiving the feature in another problem. In their study, Ben-Zeev and Star found that students not only relied on surface-level features in solving problems but “also generate[d] and use[d] correlations between irrelevant surface-level features and solution strategies” (p. 272). Even experienced students were found to be susceptible to this tendency. We call the tendency of making spurious correlations impulsive disposition.

Einstellung effect, spurious correlation, and impulsive disposition refer to the same phenomenon but emphasize different aspects. Whereas the Einstellung effect refers to a mental fixation and spurious correlation refers to a process, impulsive disposition refers to a proclivity. We chose to focus on impulsive disposition because it can be conceived as a negative habit of mind (Cuoco, Goldenberg, & Mark, 1996) or an undesirable way of thinking (Harel & Sowder, 2005) that can be changed to analytic disposition. Our research is motivated by the intent to create an awareness of impulsive disposition among mathematics teachers so that they can be mindful in teaching their students and avoid propagating a culture where “doing mathematics means following rules laid down by the teacher, knowing mathematics means remembering and applying the correct rule when the teacher asks a question, and mathematical truth is determined when the answer is ratified by the teacher” (Lampert, 1990, p. 31).

Spurious correlations tend to lead to errors, which Radatz (1979) would classify as “errors due to incorrect associations or rigidity of thinking” (p. 167). Impulsive disposition is generally inferred from such errors, examples of which include overgeneralizing proportionality in solving non-proportional missing-value problems (Lim, 2009) and misapplying a procedure for solving linear equations to solve linear inequalities (Tsamir & Almog, 2001). Examples of the latter include $x^2 < 16$ implies $x < \pm 4$ and $\frac{2x-2}{x+1} < 1$ implies $2x - 2 < x + 1$. We also infer impulsive disposition when students use an inefficient strategy to solve a problem that could be solved using a simpler method (i.e., when the Einstellung effect occurs).

We regard an instrument that can assess one’s impulsive-analytic disposition to be a viable way to motivate teachers and students to progress from impulsive disposition to analytic disposition. The LtA survey was developed with this purpose in mind. To investigate the validity of the LtA items and to improve them, we developed an open-ended questionnaire to find out the initial steps participants would take to solve a mathematics problem. Our objectives were two-fold: (a) to investigate the validity of the 32-item version of the LtA survey, and (b) to improve the LtA items.

In this paper we address the following research questions: (a) What solution strategies were mentioned in participants’ responses to the items in the open-ended questionnaire? (b) How well did the impulsive-analytic disposition scores for the open-ended questionnaire correlate with their impulsive-analytic scores in the LtA survey? And (c) What did the respondents think the LtA survey was trying to measure?

**Method**

*Data Collection*

Two groups of participants completed the open-ended questionnaire. The first group consisted of 27 in-service teachers and 10 pre-service teachers who were enrolled in a program.
for improving mathematics and science education in El Paso. The second group consisted of two mathematics classes for pre-service EC-8 (Early Childhood to Grade 8) teachers: 33 and 22 students. A convenience sample of pre-service and in-service teachers was used because the purpose of this round of data collection was to investigate the validity of the instruments rather than to test hypotheses. Since the LtA survey was the prime instrument that we sought to investigate, we administered it prior to the open-ended questionnaire.

Likelihood-to-Act Survey. The 32-item survey that was administered is comprised of the following categories: algebra, word problem, fraction, and non-mathematically-specific description. Each of the four categories includes four impulsive and four analytic items.

\[ A_{1i} \ (x - 5)(x - 8) = 0. \text{ When asked to solve for } x, \text{ how likely are you to multiply out the terms (i.e., FOIL) and then solve } x^2 - 13x + 40 = 0 \text{ using the quadratic formula?} \] [impulsive]

\[ A_{1a} \ (x - 7)(x - 4) = 0. \text{ When asked to solve for } x, \text{ how likely are you to study the equation and predict the solution?} \] [analytic]

\[ A_{2i} \ 30 \text{ workers took 8 hours to complete Project P whereas 20 workers took 3 hours to complete Project Q. When asked to determine which project was bigger in size, how likely are you to compare rates (e.g., comparing 30/8 to 20/3)?} \] [impulsive]

\[ A_{2a} \ 26 \text{ workers took 10 hours to complete Project ABC whereas 18 workers took 7 hours to complete Project XYZ. To determine which project was bigger in size, how likely are you to visualize the two scenarios and predict the answer without doing any computation?} \] [analytic]

\[ B_{6i} \ \frac{55}{95} + \frac{11}{95}. \text{ When asked to find the answer without using a calculator, how likely are you to use the invert-and-multiply rule, obtain } \frac{55}{95} \times \frac{95}{11}, \text{ and then simplify the answer?} \] [impulsive]

\[ B_{6a} \ \frac{46}{82} + \frac{11}{82}. \text{ When asked to find the answer without using a calculator, how likely are you to study the two fractions and predict the answer?} \] [analytic]

Three measures can be derived from the LtA survey: (a) the analytic subscale is based on the 16 analytic LtA items, (b) the impulsive subscale is based on the 16 impulsive items, and (c) the analytic-impulsive difference is computed based on the difference between the analytic score and the impulsive score for each pair of items.

Opinion-seeking Question. Appended to the end of the LtA survey is a page with the following question: “In your opinion, which aspect(s) of problem-solving disposition do you think the 32-item survey is trying to quantify (i.e., measure)?” The intent of this question was for us to get a sense of what the participants thought the survey was about.

Open-ended Questionnaire. In this questionnaire, six open-ended questions were posed to uncover participants’ initial approaches for solving selected impulsive items in the LtA survey. Two versions were created to cover the 12 mathematically-specific impulsive items (i.e., the four non-mathematically specific impulsive items were excluded). Of the 92 participants, 47 took Version A and 45 took Version B. Below are three of the 12 open-ended questions.

\[ A_{1} \text{ What are the first few actions that you would take when asked to solve } (x - 5)(x - 8) = 0 \text{ for } x? \]
A2 30 workers took 8 hours to complete Project P whereas 20 workers took 3 hours to complete Project Q. What are the first few actions that you would take when asked to determine which project was bigger in size?

B6 What are the first few actions that you would take when asked to find the answer for \( \frac{35}{95} \div \frac{11}{95} \) without using a calculator?

Data Analysis

The authors and a graduate student coded all the responses in Version A. Another team of a full-time research assistant and a final-year doctoral student coded all the responses in Version B. Members from both teams met to analyze the responses in a training set. Five responses per item were selected for training. They included typical responses as well as challenging responses. The purpose was for both teams to establish consistency in coding and to agree on a set of guidelines such as analyzing a response in its entirety instead of automatically assigning a code based on the presence of a particular strategy or keyword.

Each written response was first analyzed in terms of solution strategies. Strategies that were similar were grouped together to form a category. The response was then assigned a code according to whether the response had a strong or a weak indication of analytic disposition (A+ or A-) or impulsive disposition (I+ or I-). In situations where a response was incomplete or irrelevant and we could not decide one way or the other, we coded the response as unsure (U). The inter-rater reliabilities for the two teams were 0.89 and 0.96 respectively. The codes, I+, I-, U, A-, A+, were later quantified using a five-point scale for statistical analysis.

We also attempted to quantify participants’ depth of mathematical understanding. However, because the participants were only asked to describe the initial steps that they would take instead of actually solving the problem, we found it difficult to infer depth of understanding. Hence, we used a two-point scale: “0” for a response that contained major error(s) and “1” for a response without any major error. The inter-rater reliabilities were 0.93 and 0.98 for the two teams.

Participants’ comments on the LtA survey were analyzed in two rounds to find common themes. In round one, the first author noted specific descriptions within each response in order to generate categories which were then collapsed. In round two, the second author used these categories to code the data. Since the purpose was to get a sense of how participants perceived the survey, we did not proceed to establish inter-rater reliability.

Results and Discussion

Solution Strategies

Table 1 shows the distribution of strategies from most common to least common for the 12 open-ended items. Strategies were not the same across items. For example, the top four strategies for Item A1 were: (a) using the FOIL method; (b) setting the two factors, \( x - 5 \) and \( x - 8 \), equal to 0; (c) using a guess-and-check approach; and (d) analyzing the problem or following a proper procedure; whereas the top three strategies for Item A2 were: (a) dividing 30 by 8 and 20 by 3 or comparing two ratios; (b) setting up a proportion and/or using cross-multiplication; and (c) commenting that more information was needed in order to solve the problem.

The most common strategy (Strategy 1) for all the items, except B6, in the open-ended questionnaire was consistent with the act described in the corresponding impulsive LtA item. For example, the most common strategy among respondents for Item A1 was using the FOIL method and the act described in the LtA Item A1i was “multiply out the terms (i.e., FOIL) and then solve \( x^2 - 13x + 40 = 0 \) using the quadratic formula.” The top two strategies for Item A5 (using a
The top three strategies for Item B6 were: (a) immediately cancelling out the common number 95; (b) inverting and then simplifying; and (c) inverting and then multiplying across. In terms of impulsive-analytic disposition, the difference between the first two strategies is subtle. For several students who “cancelled” out the 95s, we found it difficult to determine whether or not they spontaneously applied the invert-multiply strategy (i.e. invert the second fraction prior to canceling the 95s). We ended up replacing items B6i and B6a by a different pair of items in the revised LtA survey.

**Coding for Impulsive-Analytic Disposition**

Table 2 shows the distribution of disposition codes assigned to responses for all 12 items in the open-ended questionnaire. The frequency of I+ is highest for all the 12 items. This result might be a consequence of participants’ working on the LtA survey before working on the open-ended questionnaire. Participants’ initial exposure to the LtA items might have influenced their subsequent written responses for the open-ended items.

In general, the disposition code (I+ = strong indicator of being impulsive, A+ = strong indicator of being analytic) was dependent on the solution strategy associated with the response. Take responses to Item A1, for example. Out of 31 responses that were categorized as impulsive (I+ or I-), 27 mentioned using the FOIL method to arrive at a solution. These participants said that they would use the FOIL method probably because they could do something to those factors rather than analyze the form of the equation. Some participants commented that they would combine like terms and then solve for \( x \).

For example, the response in Figure 1 contains a minor computational error when adding -8\( x \) and -5\( x \) and a major error in assuming that the quadratic equation, with three terms, could be solved by isolating \( x \). We inferred impulsive disposition when there was evidence of spurious
correlations such as associating the FOIL method with the factored form and associating isolating $x$ with solving an equation for $x$. We are aware of the inaccuracy of inferring students’ problem-solving disposition based on written responses alone, especially given the lack of detail in the descriptions. A more reliable way to infer impulsive-analytic disposition is to conduct task-based interviews (see Lim, 2008).

Figure 1. Using the FOIL method and combining like terms

Correlation between Coded-Disposition Score and LtA Subscales

Table 3 shows for each open-ended item, the mean value (1 = strong indicator of being impulsive, 5 = strong indicator of being analytic), its correlation with the Impulsive LtA subscale, the Analytic LtA subscale, and the difference between the two subscales. All the mean values are below three which is the midpoint on a five-point scale. This result suggests that the solution strategies were more indicative of being impulsive than being analytic. The mean value for each open-ended item was negatively correlated with the Impulsive LtA subscale and positively correlated with the Analytic LtA subscale. Seven of the 12 open-ended items were significantly correlated with the impulsive LtA subscale, but only three items were significantly correlated with the analytic LtA subscale. These results might be due to the items in the open-ended questionnaire being constructed based on the impulsive items in the LtA survey.

</table>

*p < .05, **p < .01.
Eight of the 12 items have significant correlations with the analytic-impulsive difference score. Items that did not have strong correlations (A2, A5, B5, and B6) were considered for refinement or replacement. For example, after studying items A2i and A2a critically, we modified them to highlight the number of hours worked by each worker. The revised version for item A2i now reads “Project P took 30 workers, each working 8 hours, to complete. Project Q took 20 workers, each working 3 hours, to complete. When asked …?”

Item B6 was the least correlated with the analytic LtA subscale score. The supposedly-analytic act described in B6a might be considered likely-to-act for someone who would spontaneously invert the second fraction, cancel the 82s, and predict 4 as the answer.

Hence, in the revised version items B6i and B6a were replaced with the following pair of items:

- \(3875.4 + 367.9 - 875.4\). When asked to find the answer without using a calculator, how likely are you to begin by adding 3875.4 and 367.9 and then subtract 875.4?
- \(1545.9 + 694.8 - 545.9\). When asked to find the answer without using a calculator, how likely are you to study the decimals and obtain the answer almost instantly?

<table>
<thead>

<td>Coded-disposition Score</td>
</tr>
<tr>
<td>Coded-correctness Score</td>
</tr>
<tr>
<td>(p &lt; .05, \ *p &lt; .01).</td>
</tr>
</tbody>
</table>

Each participant took either Version A or Version B of the open-ended questionnaire. We added the disposition scores for all six items in each version to produce the Coded-disposition score for each participant. We added the six correctness scores to produce the Coded-correctness score. Table 4 shows the correlations between the two coded scores and the two LtA subscales. The strong correlations between the coded-disposition score and both the LtA subscales strengthen our confidence in the validity of the LtA survey.

**Opinion on Purpose of LtA Survey**

Of the 92 participants who were asked to write what the survey was designed to assess, three participants did not respond. From the remaining 89 responses, 48 categories were initially generated and subsequently collapsed into 13 categories. Because more than one category could be assigned to a response, we ended up with a total of 200 counts. Table 5 shows the number of responses for each category and its rank based on frequency count.

The first three categories are related to analytic disposition and the next three categories are related to impulsive disposition. The other categories are not directly related to impulsive or analytic disposition, including the highest-count category (e.g., “find out the way you would answer a given problem situation”) and the third-highest category (e.g., “measure critical thinking skills in problem solving”).

Predicting was the fourth-highest category and this might be a consequence of the word “predict” being used in 11 of the 16 analytic LtA items. We intended “predict” to be interpreted as an analytic act, but only 9 of the 17 respondents who thought that the survey was about predicting viewed predicting in the manner we intended (e.g., “predict and think about a problem rather than solving it immediately”). Five respondents viewed predicting in opposition to analytic
disposition (e.g., “automatically begin to predict a solution before analyzing a problem”). The remaining three respondents viewed predicting in a neutral manner (e.g., “what problems they would predict rather than solve”). Knowing that “predict” might be misinterpreted as guessing without analyzing, we revised several items. For example, the original version of an analytic LtA item reads: “Given that 6 bottles of mineral water cost $2.10. When asked to find the cost of 30 bottles, how likely are you to notice a relationship and predict that the answer is $10.50?” The revised version reads “… how likely are you to notice that 5 times $2.10 will give you the answer?” In addition, we reduced the number of times “predict” was used from 11 in the original version to 6 in the revised version.

| Table 5. Number of Responses and Rank for Each Category about the LtA Survey |
|---------------------------------|------------|----------|
|                                   | Count   | Rank   |
| Analyzing or identifying relationships | 30      | 2       |
| Interpreting or understanding the problem | 13      | 6       |
| Finding an easier way, a shortcut, or alternative ways | 7       | 10      |
| Following procedures | 14      | 5       |
| Acting quickly without thinking | 8       | 9       |
| Assessing fastness in solving problems | 7       | 10      |
| Finding out how one approaches a problem | 43      | 1       |
| Assessing knowledge/skill/problem-solving | 26      | 3       |
| Predicting | 17      | 4       |
| Commenting about teaching and learning | 13      | 6       |
| Visualizing or mentally computing | 11      | 8       |
| Assessing competence in specific math topics | 6       | 12      |
| Others | 5       | 13      |

Note: Total count = 200 > 89 because the 13 categories are not mutually exclusive.

Conclusions

In this paper, we reported our analysis of students’ written responses to open-ended questions with the intent to investigate the validity of the items in the likelihood-to-act survey, which was designed to measure students’ problem-solving disposition along the impulsive-analytic dimension. We found that in each question, except Item B6, the most-mentioned strategy was consistent with the act described in its corresponding impulsive LtA item. We also found significant correlations, for 8 of the 12 open-ended questions, between the assigned disposition code for written responses to these questions and the analytic-impulsive difference LtA score. In addition, the Coded-disposition score for the open-ended questionnaire was positively correlated to the analytic subscale and negatively correlated to the impulsive LtA subscale, both with \( p < .01 \). Less promising results were taken as opportunities to improve the LtA survey items. We are currently administering and testing the revised LtA survey to more than 400 pre-service teachers.

INDICATORS OF MULTIPLICATIVE REASONING AMONG FOURTH GRADE STUDENTS

James A. Carrier
University of North Carolina at Greensboro

Building upon the genre of research focused on understanding the development of multiplicative reasoning, this study examines the thinking of 14 fourth graders and concludes that the levels of multiplicative reasoning can be further defined in terms of indicators and refined in terms of student strategies.

Introduction

The difficulties encountered by students in their transition to advanced mathematical thinking may be explained by a lack of understanding of many concepts taught in early school years, especially multiplicative reasoning (e.g. Confrey, 1994; Dreyfus, 1991; Harel & Sowder, 2005). By its nature, advanced mathematical thinking relies on a cumulative foundation of prior mathematical experiences. Students cannot comprehend advanced mathematical topics such as differential equations unless they understand underlying concepts, such as differentiation. Differentiation requires conceptual understanding of the idea of functions and that assumes the student understands variables. Understanding variables is dependent upon the students’ understanding of number, which is dependent upon understanding of quantification, which requires comprehension of serial correspondence. In other words, there is a structural order with each previous topic serving as a foundation for the next levels of mathematics and therefore we focus here on investigating children’s multiplicative reasoning.

Multiplicative reasoning

The concept of unit with respect to addition is quite different than the concept of unit with respect to multiplication. Addition and multiplication involve hidden assumptions. The hidden assumption in addition is that the unit is one, which children readily understand; whereas, the hidden assumption in multiplication is that the unit is one as well as more than one simultaneously (Chandler & Kamii, 2009). Splitting, Confrey’s (1994) contribution to understanding multiplicative reasoning, speaks to conditions under which reunitizing occurs after the split in multiplication. Park and Nunes (2001) suggest that children’s concept of multiplication originates in their schema of correspondences and not in the concept of addition. Under this definition the concept of multiplication is defined by a constant relationship between two quantities known as ratio and is a core meaning of multiplicative reasoning. The ratio or rate is the constant unit that is called the multiplicand and acted upon by the multiplier. Children employ the schema of correspondence in order to represent fixed relationships between variables and solve multiplication problems.

Clark and Kamii (1996) identified five developmental levels that can be systematically observed in participants progressing from additive to multiplicative thinking. We propose an expansion of the multiplicative reasoning markers listed in Table 1 to a more detailed list of markers. Our focus is to identify observable behaviors of fourth grade students to expand the ideas found in Table 1. Towards this goal we considered the following questions:

1. What are the indicators of multiplicative reasoning among fourth grade students?
2. What strategies do fourth grade students utilize in solving word problems that require mathematical reasoning?

**Theoretical Framework**

Beginning with the work of Clark and Kamii (1996) we identified five levels of reasoning. The five developmental levels described below emerged from a review of the literature and provided the framework for this study. The multiplicative reasoning levels, described by Thorton and Fuller, 1981; Karplus and Lawson, 1974; Clark and Kamii, 1996, are summarized in Table 1 and provide a framework for this study.

(Adapted from Thorton & Fuller, 1981; Karplus & Lawson, 1974; Clark & Kamii, 1996)

**Methodology**

**Participants**

In cooperation with the administration of a large urban school district in North Carolina, the participants were recruited from the fourth grade at a Chapter I school. The participants were age nine or ten and were recommended for study by the school’s math specialist as being among the strongest math students in fourth grade. Overall fourteen participants of varying ethnicity, nine of whom were female and five of whom were male, were engaged in the study.

**Instrument**

The participants were asked to engage in a dialog while being interviewed. Because the computer can provide an environment that can enhance children’s own construction of multiplicative reasoning via interaction with the teacher (Olive, 2000), the computer was employed as a research tool. An instrument consisting of ten questions was devised to invoke varying levels of multiplicative reasoning. Items were adapted from paper and pencil instruments developed by previous researchers (Thorton & Fuller, 1981; Karplus & Lawson, 1974; Clark & Kamii, 1996). The test instrument was developed in Microsoft Visio such that the participants were able to drag and drop green fish into the larger yellow fish to demonstrate their understanding of the multiplicative reasoning problems presented (see Figure 1). Also provided were manipulatives that included a magnetic aquarium containing green and yellow fish, two
pizza pans for test item nine, and manipulatives such as paper clips, buttons, and stick figures for participants to demonstrate their understanding of test item ten.

Figure 1. Sample Multiplicative Reasoning Problem

Data

The researcher employed two video cameras, one focused on the computer keyboard, computer screen, and hands of the participant, and the other focused on the participant’s written workspace. In addition to the video recordings, the participant responses were collected by the Microsoft Visio program. The participants also provided written work supporting their thinking during the interviews. Transcriptions of the participants’ verbal responses were also made. By reviewing the video recordings, in conjunction with the Microsoft Visio files, the written work of the participant and the transcriptions, the researchers explored indications of the emergence of participants’ multiplicative reasoning.

Analysis

The data were examined for indications of the emergence of multiplicative reasoning utilizing the following techniques. Participants’ data were first coded with respect to the framework introduced in Table 1 by observing the manner in which the participants responded to each question. Coded selections were then reexamined for key words, similarities, and differences within each of the five levels. When analyzing the participants’ data, it became apparent that there were indicators not found as descriptors in the original five levels identified in Table 1. These indicators were inserted into Table 2 and then the participants’ data were reanalyzed using this expanded framework.

Results

The researcher placed the participants’ key words, transcripts, utterances, written work, schemes, and drawings for each question into one of the twelve strategies based on the following criteria found in the indicators column in Table 2. If the participant exhibited non-preservation of the quantification of objects, then the participant was placed at Level 1 Non-quantifier. For example, if the participant placed 32 fish into a fish that could clearly not hold 32 fish, this would be an example of non-preservation of the quantification of objects. If the participant

arrived at the answer through guessing, then the participant was placed at Level 1 Spontaneous Guesser. For example, a demonstration of Level 1 Spontaneous Guesser behavior was exhibited when the participant noted that a particular fish should be fed 7 fish because 7 was his favorite number.

</tr>
</tbody>
</table>

When the participant specifically indicated a need to multiply because the problem had the word “times” (or some other keyword such as twice), the participant was placed at Level 2 Keyword Finder, because the participant derived the answer by invoking the multiplication algorithm. When the participant counted the fish and uttered answers where it was easily

observed that the answers were related to a one-on-one mapping with the whole number system, the participant was placed at Level 2 Counter.

Table 2 presents the strategies employed by the participants on the research instrument. The reference column in Table 2 identifies experts in the field who agree that the indicators in column three signify the emergence of multiplicative reasoning. Table 2 assists in answering research question one: what are the indicators of multiplicative reasoning among fourth grade students?

Participants who arrived at their answers via addition, and plainly indicated so by writing or saying that they were adding more fish for each fish, were placed as a Level 2 Adder. Quite often, because participants had success utilizing additive strategies, they tended to utilize additive strategies when they did not have a plan, perhaps because they had been successful in the past. However, utilizing an additive strategy demonstrated more understanding than simply guessing because their answers corresponded to the size of the fish. When participants made good use of the fact that \( A < B < C \), then the participants were placed as a Level 2 Quantifier. When participants could not find the answer via multiplication they sometimes would measure the relative size of the fish, thus measuring the fish on the computer screen or the manipulatives and derive an answer through measurement. When the participants derived their answers via measurement, then the participants were placed as a Level 2 Measurer.

Sometimes the participants understood that additive strategies were not successful and attempted, but did not succeed, at utilizing multiplicative reasoning strategies. Often participants utilized repeated addition to obtain the correct answer. They would demonstrate this by writing or uttering \( 3 + 3 + 3 = 9 \), for example. When such repeated addition was utilized, the participants were placed as a Level 3 Repeated Adder.

In many cases the participant may have understood that additive strategies were not sufficient and succeeded at utilizing multiplicative reasoning by demonstrating a good ability to coordinate the objects, numbers and operations defined within the word problem. Such participants often obtained the correct answer but did not or were not able to articulate the method or schema utilized to achieve the correct answer. Such demonstrations provided support for the participant being placed as a Level 3 Coordinator.

If the participant articulated an adequate mathematical sentence, either on paper or verbally, which fully described the mathematical relationship between the fish, the numbers, and the operations, then the participants would be placed as a Level 4 Multiplier. Additionally, some participants spoke or wrote the word “cut” or a similar word to indicate the need for division. In such a case, the participants were placed as a Level 4 Splitter.

When the participants provided a new quantity as a unitizing factor, articulated an adequate mathematical sentence, and successfully completed the problem using either multiplication or division, then the participants were placed as a Level 5 Predictor. In the case of Question 10, the participants exhibiting Level 5 Predictor should have stated something similar to “6 is to 4 as \( y \) is to 6 and since 6/4 reduces to 3/2 which equals 1.5 (this is the new unitizing factor) then 1.5 \( \times 6 = 9 \)”.

The literature provides a clear baseline for understanding multiplicative reasoning outlined in Table 1. Yet the participant data reveal that a more detailed analysis can further identify the building blocks underlying the learning of mathematics for fourth grade students. Table 2 identifies multiplicative indicators of these fourth graders along with additional strategies that expand the ideas in Table 1. These expanded strategies and indicators are then employed to re-analyze each of the 14 individual participant’s performance on the instrument. The columns in
Table 3 explains the frequency of the strategies used by the participants. The rows indicate the individual participant’s use of strategies. This analysis addresses our second research question concerning strategies.

Examining the results reported in Table 3, we observed the frequency of individual participant’s strategy use. It was interesting to note the spread of strategies and indicators occurring over these fourth-grade participants. Therefore we sorted the participants’ strategies into three categories. Those who were consistent in their choice of level 4 strategies or above (more than 70% of the time) we label as multiplicative reasoners. Pre-multiplicative are those participants who consistently chose strategies below level 4 in their attempts to solve the problems. Those participants who used a range of strategies we label as emergent. Emergent participants are considered non-multipliers. Table 4 summarized these findings.

Summary and Implications

The indicators of multiplicative reasoning are specific writings, utterances of keywords, and behaviors of these participants as they engaged in problem solving. From these indicators 12 strategies were identified that these fourth grade participants utilized in solving multiplicative reasoning word problems. It was interesting to note that each of the 12 strategies was used at least three times. Separating the participants into three categories provided additional insights into the vast spread of multiplicative understandings present in Chapter I schools in fourth grade. In the future, we propose to investigate the strategies and indicators of older children and younger children with the research instrument to provide validation for our findings reported here.

The practical implication of our findings is that they provide teachers with another tool to diagnose and assess students’ understanding of multiplication. Teacher observations and informal assessment techniques can be used in conjunction with the list of indicators generated in Table 2. This list is another way for teachers to assist students’ progress towards understanding multiplication. The list of indicators and strategies is also useful in determining the trajectories of students’ multiplicative reasoning so that teachers can remediate and develop steps towards additional understanding (Ball, 2003; Richardson, Berenson, and Staley, 2009).

References

This research examined the relationship of the cognitive demand levels of mathematical tasks done in class over the course of a school year and related tasks assigned for homework. In total, 66 mathematical tasks were evaluated to assess the level of cognitive demand. Results from this research showed that approximately two-thirds of the time mathematical tasks assigned for homework were different levels with those explored in class. Implications for student learning, achievement, classroom practice, and for further research will be discussed in light of these findings.

Introduction

From very early on in formal schooling most children are asked to do some form of homework. The recent Trends in International Mathematics and Science Study (TIMMS) (Mullis, Martin, & Foy, 2008) reports that the amount of time spent on mathematics homework by children varies significantly between countries and grades. On average, the amount of time devoted to mathematics varies between countries from two to three times per week with no more than 30 minutes at any one time, to three to four times a week with more than 30 minutes homework at one any one time. While the time spent on homework varies, these results show nevertheless that a considerable amount of time at home is spent by students on mathematics homework. According to Trautwein, Niggli, Schnyder, and Lüdtke (2009), there are three primary functions of homework. First, homework permits teachers to extend time learning well beyond that of the regular classroom hours. Second, homework enables students to rehearse what they have learned, extend their knowledge, and even exercise their working and long term memory. Third, homework enhances student motivation and self-regulation.

Results from empirical studies show mixed results between homework and achievement that have been related to numerous factors including parental involvement (Patall, Cooper, & Robinson, 2008; Tam & Chan, 2009), teacher implementation and beliefs (i.e., assessed versus not assessed, taken up in class, etc.) (Simplicio, 2005), learning disabilities (Sheridan, 2009), and student motivation and self-regulation (Hong, Peng, & Rowell, 2009). Research about homework points to the fact that context, pedagogical, socio-cultural, economic, psychological, and so forth, all contribute differently and perhaps uniquely to homework efficacy.

While some studies compared the types of homework assigned in relation to the types of tasks experienced in classrooms (e.g., Fife, 2009), surprisingly, no studies were found that analyzed the cognitive relationship between student learning and mathematical tasks done in class and those assigned for homework. While the types, duration, and relation to achievement of homework is interesting and indeed useful, an understanding of the way in which the homework is cognitively aligned to classroom learning may be more pertinent to supporting students in rehearsing prior learning at a remediation level, rehearsing new learning, extending new learning independently, and increasing achievement.
As a result, our goals in this research were as follows: (1) to examine the cognitive demand levels of mathematical tasks done in class and related mathematical task assigned for homework, (2) to contemplate the implications of compatibility or discord in cognitive demand levels for student learning and for classroom instruction, (3) to make preliminary conjectures about student achievement in relation to and cognitive demand levels, and (4) to recommend potential research directions in light of our analysis.

Theoretical framework

Mathematical Task

This research draws extensively on the theoretical assertions posited by Stein and colleagues (Stein, Grover, & Henningsen, 1996; Stein, Smith, Henningsen, & Silver, 2000) about mathematical tasks and cognitive demand levels. According to Stein, Grover and Henningsen (1996), a mathematical task is defined as a classroom activity intended to focus students’ attention towards a particular mathematical idea, where the activity is ongoing until such time that the “underlying mathematical idea toward which the activity is oriented changes” (p. 460). Stein and colleagues’ suggest that a mathematical task may be (and likely is) comprised of multiple related activities rather than just one singular activity, and that the multiple related activities are ongoing until such time that cognitive change occurs on behalf of the student.

Stein et al. (1996; 2000) claim that a central aspect about mathematics tasks the potential for them to be transformed and changed during three phases: “first, as curricular or instructional materials; second, as set up by the teacher in the classroom; and third, as implemented by students during the lesson” (p. 460). Implementation at any of the phases of the mathematical task may shift the intended goals or benefits of the mathematical task. That is, the mathematical task is highly influenced by factors such pedagogy, content knowledge, prior knowledge, social and psychological contexts of learning, and so forth (Henningsen & Stein, 1997).

The potential for mathematical tasks to be transformed has important implications for student learning. As Boston and Smith (2009) have pointed out, over a decade of research has demonstrated that high quality learning environments that are sustained throughout instruction are most effective in occasioning increased student achievement (Boaler & Staples, 2008; Hiebert et al., 2004; Stigler & Hiebert, 1999). Stein et al.’s (2000) framework only considered transformation of the mathematical task during instruction and not transformations that may take place at the homework level which may have differing and unique implications for student learning.

Consequently, it is our assertion that there is (at least) one additional phase should be included in Stein and colleagues’ (1996; 2000) framework: student implementation during homework. This fourth phase reflects the fact that while some students may have a shift in their mathematical idea orientation during the lesson, others may not until they revisit and rehearse the material independently during homework. As Stein et al., claim a mathematical task may change once “unleashed in a real classroom” (p. 460). The same may be true during homework.

Cognitive Demand Levels

Stein et al. (1996) define cognitive demand “as the cognitive processes in which students actually engage as they go about working on the task” (p. 461). The authors make the distinction between mathematical “tasks that engage students at a surface level and tasks that engage students at a deeper level by demanding interpretation, flexibility, the shepherding of resources, and the construction of meaning” (p. 459.) Stein and colleagues (1996; 2000) distinguish.
between low and high cognitive demand levels of mathematical tasks. Low cognitive demand levels are those that predominantly involve memorization and or engagement in mathematical processes in the absence of connections between mathematical ideas, whereas mathematical tasks with high cognitive demand make connections between mathematical ideas and require “doing mathematics” such that students are engaging in self-reflection, -regulation, and so forth.

Previous studies, such as Stein and colleagues’ (1996) research, have focused on mathematical task implementation at the classroom level. Taking Stein’s definition of mathematical tasks as those that continue until such time that the underlying orientation to the mathematical idea changes, research on cognitive relationship between mathematical tasks assigned for homework to provide rehearsal, emphasis, and so forth, those in the used in the classroom is critical and necessary to provide a fuller picture of the implications to student learning and to classroom instruction.

Methods

This research took place in the third author’s eighth-grade classroom and spanned the full academic year (i.e., from September to June). The school in which the research took place was located in an economically, socially, and culturally diverse urban setting. Duane’s class consisted of 28 students, 14 male, and 14 female. All students were between 13 and 14 years of age. Data for this study was drawn from a larger body of data collected from this class exploring the relationship of homework in mathematics to classroom practices.

In previous years, Duane had attended numerous professional development sessions held through his school board and provincial mathematics associations where he had learned about teaching mathematics through problem-solving in order to develop deeper thinking and understanding about mathematics (Twomey Fosnot & Dolk, 2001). Lessons were predominantly structured around mathematical tasks. All of the mathematical tasks analyzed in this research took place in small group settings (i.e., two to four students). Some of the mathematical tasks were structured around a real-world context, while others were not. Often the exploration of the mathematical tasks took place over two or more consecutive days.

Over the course of the school year, Duane used 33 mathematical tasks in class (approximately one per week) to explore five mathematical strands: data management, geometry, measurement, patterning and algebra, and number sense and numeration. At the beginning of each week, Duane would distribute a homework sheet to each student. The homework sheet consisted of at least one mathematical task that was intended to parallel the mathematical task explored during class, plus additional problem sets related to the mathematical strand.

All coding was done by the first and the third authors. The first step of the data coding involved explicitly linking the intended parallel homework question from the assigned homework to the related mathematical task explored during class. Related here implies (a) the use of similar mathematical processes between the mathematical tasks (e.g., reasoning and proving, communicating, connecting, reflecting, selecting tools and computational strategies, etc.), and (b) the same mathematical strand (i.e., data management, patterning and algebra, number sense and numeration, geometry, or measurement). Therefore, a total of 66 mathematical tasks (33 paired mathematical tasks) formed the primary basis of the data set. Also included for the analysis were the mean achievement levels of the students (n = 26, since two left the school mid-year) in the class for each mathematical strand.

Once the mathematical tasks were paired, we each independently evaluated each mathematical task using as our instrument a modified IQA Academic Rigor: Mathematic Rubric

for the Potential of the Task from Boston and Smith (2009) (see Appendix A). This instrument was used by Boston and Smith (2009) to investigate mathematical task implementation of secondary school mathematics teachers following professional development. The rubric is modified from the two levels proposed by Stein et al. to four levels for a more nuanced analysis. At the conclusion of our independent evaluations we compared our results and discussed differences until consensus on the evaluation of the mathematical task according to our rubric was achieved.

Descriptive statistics were computed to summarize cognitive demand levels of class and homework mathematical tasks, differences between the cognitive demand levels of the mathematical tasks, and means of student achievement across mathematical strands. The Wilcoxon matched-pairs signed ranks test was conducted to evaluate whether the median level for classroom and for homework mathematical tasks differed and was significant. Also, Spearman’s Rho correlation coefficient was calculated to examine the predictive relationship between class and homework mathematical task levels, and achievement means from the mathematical strands from the students in the class.

Results

We hypothesized at the onset of this research that there should be a relationship between cognitive demand levels of class and homework mathematical tasks, and that the cognitive demand level would overall be predominantly high (i.e., level 4) given the classroom context (i.e., significant focus on thinking, reasoning, problem-solving). Descriptive statistics revealed that 75.7% of mathematical tasks selected and implemented in class were at a cognitive demand level three or four. In comparison, 94% of mathematical tasks assigned for homework were at a cognitive demand level of three or four (see Table 1). However, mathematical tasks at a cognitive demand level of four that were planned for class instruction occurred 18% more than those assigned for homework.

No significant differences were found between the median levels of the mathematical tasks in-class and those assigned for homework (Wilcoxon, n = 33, Z = -0.052, p = 0.958, 2-tailed). Mean level (standard deviations in parentheses) of cognitive demand for both classroom and homework mathematical tasks was 3.3 (0.847, 0.585, respectively), with more variation between cognitive demand levels for the classroom mathematical tasks. Noteworthy is the finding that 30.3% of mathematical tasks assigned for homework were lower in cognitive demand level than the paired mathematical task from the class (see Table 2). In contrast, 36.4% of homework mathematical tasks were higher than the classroom mathematical tasks. These results suggest that, at least for this data set, almost two-thirds of the homework questions did not represent a sustained cognitive demand level into the homework phase, although approximately one-third did represent an increase in cognitive level demand.

</tbody>
</table>

The mean (with standard deviations in parentheses) for achievement across strands was 74.26 (0.98779). There was asymmetry across the mathematical strands in the number of tasks per strand. Number sense by far had the most amount of mathematical tasks (n = 19), compared to geometry (n =2), which was the lowest. There was also asymmetry across the cognitive demand levels within the strands. Some strands had cognitive demand levels that were the same between classroom and homework mathematical tasks, higher classroom mathematical tasks, and higher homework mathematical tasks. The asymmetrical distribution of mathematical tasks and cognitive demand levels across the mathematical strands make it difficult to assess from the current research the implications of cognitive demand levels on mathematical achievement. Further and different research is needed to assess this relationship.

Spearman’s Rho correlation coefficients were calculated to examine the predictive relationship between mathematical strand, mean achievement on mathematical strands, as well as classroom and homework mathematical tasks. As anticipated, the mathematical strands were moderately correlated ($r = 0.53$) to the mean achievement in the mathematical strand at the level of 0.01. The correlation between cognitive demand levels of classroom mathematical tasks and homework mathematical tasks was negative and not significant ($r = -0.03$, n.s.) These results suggest that there does not appear to be a predictive relationship between the cognitive demand levels and the mathematical tasks.

Discussion

The findings from this research suggest that while the mean and median levels cognitive demand levels were found to be consistent for both classroom and homework mathematical tasks, approximately one-third of the time, assigned homework in this class had a higher, lower, or parallel cognitive demand level with the paired mathematical task from class. Additionally, the cognitive demand level of the mathematics task in class was not predictive of the cognitive demand level of the homework mathematical task. While these findings cannot be generalized because of the sampling methods of this research, they nevertheless raise important and interesting questions about homework and the relationship to classroom practices.

If Stein’s (1996) proposed phases at which mathematical tasks can be transformed are extended to include the homework phase, then there are numerous pedagogical considerations that must be contemplated. If the pedagogical goal of homework is to extend the instructional time from the classroom to home so that students can rehearse learning that occurred during class time then the same cognitive demand level between the classroom mathematical task and that assigned for homework may be appropriate. If the pedagogical goal is to extend learning that was started during classroom instruction, then perhaps a higher level than the cognitive demand level between the classroom mathematical task and mathematical task assigned for homework would be more appropriate. A higher cognitive demand level in the homework mathematical task than that of the classroom mathematical task could present additional challenges for a student who may not be able to independently work through a more difficult mathematical task and may not have home support to rely upon (Patall et al., 2008; Pezdek, Berry, & Renno, 2002).
We contemplated whether there would be any case where the homework level should be lower than the level of the classroom mathematical task? Our collective conclusion was no, and we further suggest that cognitive demand levels of homework that are consistently lower than those of the classroom may foster adverse effects to student motivation towards homework.

**Implications for Education and Research**

Given that sustained high cognitive level instructional environments have been shown to benefit student learning, it may be useful and necessary to utilize a cognitive demands framework for structuring classroom learning and related homework to be sure that are cognitive demand levels sustained into the homework phase. We found that cognitive demand levels between classroom and homework mathematical tasks differed more than two-thirds of the time. This may pose serious implications for learning.

A limitation of this research is in the assumption made that the level of cognitive demand of the classroom mathematical tasks remained untransformed throughout classroom instruction (Stein et al., 2000). It may be that this was not the case. While the transformation of the mathematical tasks was not the focus of this research, we recognize that this remains an important area for further research that takes into explicit consideration the final phase mathematical task implementation proposed in this research, that of homework. In light of our results, our research raises more questions: Provided that a cognitive demand level is sustained during classroom instruction, what might the implications to learning of a different cognitive demand level at the homework phase? Are there learning occasions that would warrant a difference in cognitive demand level between the three phases of instruction and the final proposed phase during homework completion? What are the implications of cognitive demand levels of class and homework mathematical tasks and mathematics achievement?

PRODUCTIVE FAILURE IN LEARNING THE CONCEPT OF VARIANCE

Manu Kapur
National Institute of Education, Singapore
manu.kapur@nie.edu.sg

In a study with 140, ninth-grade mathematics students on learning the concept of variance, students experienced either direct instruction (DI) or productive failure (PF), wherein they were first asked to generate a quantitative index for variance without any guidance before receiving direct instruction on the concept. Whereas DI students relied only on the canonical formulation of variance taught to them, PF students generated a diversity of representations and formulations for variance but were ultimately unsuccessful in developing the canonical formulation. On the posttest however, PF students performed on par with DI students on procedural fluency, and significantly outperformed them on data analysis, conceptual insight, and transfer items. These results challenge the claim that there is little efficacy in having learners solve problems targeting concepts that are novel to them, and that direct instruction alone is the most effective approach for teaching novel concepts to learners.

Introduction

Proponents of direct instruction bring to bear substantive empirical evidence against un-guided or minimally-guided instruction to claim that there is little efficacy in having learners solve problems that target novel concepts, and that learners should receive direct instruction on the concepts before any problem solving (Kirschner, Sweller, & Clark, 2006). Kirschner et al. (2006) argued that “Controlled experiments almost uniformly indicate that when dealing with novel information, learners should be explicitly shown what to do and how to do it” (p. 79). Commonly-cited problems with un-guided or minimally-guided instruction include increased working memory load that interferes with schema formation (Tuovinen & Sweller, 1999), encoding of errors and misconceptions (Brown & Campione, 1994), lack of adequate practice and elaboration (Klahr & Nigam, 2004), as well as affective problems of frustration and de-motivation (Hardiman et al., 1986).

Klahr & Nigam’s (2004) often-cited study compared the relative effectiveness of discovery learning and direct instruction approaches on learning the control of variable strategy (CVS) in scientific experimentation. On the acquisition of basic CVS skill as well as ability to transfer the skill to evaluate the design of science experiments, their findings suggested that students in the direct instruction condition who were explicitly taught how to design un-confounded experiments outperformed their counterparts in the discovery learning condition who were simply left alone to design experiments without any instructional structure or feedback from the instructor (we will return to this study in more detail in the discussion section). Further experiments by Klahr and colleagues (Chen & Klahr, 2008; Strand-Cary & Klahr, 2008), and others as well have largely bolstered the ineffectiveness of discovery learning compared with direct instruction (for a review, Kirschner et al., 2006).

Be that as it may, the above findings do not necessarily imply that there is little efficacy in having learners solve novel problems, that is, problems that target concepts they have not learnt yet (Schmidt & Bjork, 1992). To determine if there such an efficacy, a stricter comparison for direct instruction would be to compare it with an approach where students first generate representations and methods on their own followed by direct instruction. Expectedly, the
generation process will invariably lead to failure, that is, students are rarely able to solve the problems and discover the canonical solutions by themselves. However, this very process can be productive for learning provided direct instruction on the targeted concepts is subsequently provided (Kapur, 2008; Koedinger & Aleven, 2007; Schwartz & Bransford, 1998; Schwartz & Martin, 2004). As a case in point, I present evidence from an on-going research program on productive failure (Kapur, 2008, 2009) in mathematical problem solving.

**Designing for Productive Failure**

There are at least two problems with direct instruction in the initial phase of learning something new or solving a novel problem. First, students often do not have the necessary prior knowledge differentiation to be able to discern and understand the affordances of the domain-specific representations and methods underpinning the targeted concepts given during direct instruction (e.g., Schwartz & Martin, 2004). Second, when concepts are presented in a well-assembled, structured manner during direct instruction, students may not understand why those concepts, together with their representations, and methods, are assembled or structured in the way that they are (Schwartz & Bransford, 1998).

To overcome these two problems, a learning design should focus squarely on first engaging students in processes that serve two critical cognitive functions, which in turn, prepare students for subsequent direct instruction: a) activating and differentiating prior knowledge in relation to the targeted concepts, and b) affording attention to critical features of the targeted concepts.

Productive failure (PF) is one such learning design. It comprises two phases—a generation and exploration phase followed by a direct instruction phase. In the generation and exploration phase, the focus is on affording students the opportunity to leverage their formal as well as intuitive prior knowledge and resources to generate a diversity of structures—concepts, representations and solution methods—for solving a complex problem; a problem that targets concepts that they have not been formally taught or learnt yet. Research suggests that students do have rich constructive resources (diSessa & Sherin, 2000) to generate a variety of structures for solving novel problems (Schwartz & Martin, 2004). At the same time, research also suggests that one cannot expect students, who are novices to the target content, to somehow generate or discover the canonical representations and domain-specific methods for solving the problem (Kirschner et al., 2006).

However, the expectation for the generation and exploration phase is not for students to be able to solve the problem successfully. Instead, it is to persist in generating and exploring the affordances and constraints of a diversity of structures for solving the problem. This process functions to not only activate but also differentiate prior knowledge (as evidenced in the diversity of student-generated concepts, representations and methods). Furthermore, a comparison and contrast between the various structures also affords opportunities to attend to critical features of the targeted concepts (more on this in results section). Consequently, the generation and exploration phase provides the necessary foundation for developing deeper understanding of the canonical concepts, representations, and methods during direct instruction.

Empirical evidence for the above theoretical conjectures embodied in the PF design come from several studies that suggest that conditions that maximize performance in the shorter term are not necessarily the ones that maximize learning in the longer term (Schmidt & Bjork, 1992). Examples of such studies include VanLehn’s (2003) work on impasse-driven learning, Schwartz and Martin’s (2004) work on inventing to prepare for learning, diSessa’s (1991) work on meta-representational competence, Koedinger and Aeven’s (2007) work on the assistance dilemma.
as well my own work on productive failure (Kapur, 2008, 2009). Collectively, these research programs support the argument for designing conditions for learners to persist in the process of solving novel, complex (from the learners’ perspective) problems without instructional support structures initially. Even though such a process invariably leads to failure in the shorter term, the extent to which this process affords learners opportunities to generate and explore multiple representations and methods for solving the problem, the process can be germane for learning. The purpose of this paper is to report findings from an on-going, classroom-based research program in Singapore on productive failure.

Method

Participants

Participants were 140, ninth-grade mathematics students (14-15 year olds) from an all-boys public school in Singapore. Students were almost all of Chinese ethnicity. Students were from four mathematics classes; three classes taught by one teacher (teacher A), and the fourth class by another teacher (teacher B). Students had no prior instruction on the concept of variance, although they had learnt the concepts of mean, median, and mode in grades 7 and 8.

Research Design

A pre-post quasi-experimental design was used with two classes (n = 31, 35) taught by teacher A assigned to the ‘Direct Instruction’ (DI) condition, and the other two classes (n = 35, 39), under teachers A and B, assigned to the ‘Productive Failure’ (PF) condition.

First, all students took a five-item pretest (α = .75) on the concept of variance. Not surprisingly, not a single student demonstrated canonical knowledge of the concept, and there was no significant difference between the four classes either, F(3,136) = 1.665, p = .177. Next, all classes participated in five, 55-minute periods of instruction on the concept as appropriate to their assigned condition. Finally, all students took a six-item posttest (α = .74) comprising items on procedural fluency, data analysis, conceptual insight, and transfer.

In the DI condition, the teacher first explained the concept of variance and its canonical formulation as the square of the standard deviation (SD² = \( \frac{\sum (x_i - \bar{x})^2}{n} \)) using a data analysis problem. Next, the teacher modeled the application of the concept by working through several data analysis problems, highlighting common errors and misconceptions, and drawing attention to critical features of the concept in the process. The data analysis problems required students to compare the variability in 2-3 given data sets (e.g., comparing the consistency of performance of three soccer players). Thereafter, students worked face-to-face in triads on more data analysis problems. The teacher then discussed the solutions with the class. After each period, students were given similar data analysis problems for homework, which the teacher marked and returned to the students, usually by the following period.

The PF condition differed from the DI condition in only one important aspect. Instead of receiving direct instruction upfront, students spent two periods working face-to-face in triads to solve one of the data analysis problems on their own. The data analysis problem presented a distribution of goals scored each year by three soccer players for a twenty-year period. Students were asked to generate a quantitative index to determine the most consistent player. During this generation phase, no support or scaffolds were provided. Following this, three periods were spent on direct instruction just like in the DI condition. Note that because students in the PF condition spent the first two periods generating an index for variance, they solved fewer data analysis problems.
problems overall than their counterparts in the DI condition. To make this contrast even sharper, PF students did not receive any data analysis problems for homework.

Hypothesis. The hypothesis tested was that productive failure will be more effective than direct instruction in learning the concept of variance. That is, expecting to replicate earlier work on productive failure (Kapur, 2008, 2009), I hypothesized that students from the PF condition will be able to generate and explore various representations and methods for generating an index for variance (diSessa et al., 1991), but will not be successful in developing or discovering the canonical formulation on their own (Kirschner et al., 2006). However, this seeming failure would be integral for: a) engendering the necessary prior knowledge differentiation (evidenced in the diversity of student-generated structures), and b) drawing attention to critical features of the concept of variance (evidenced in the comparisons between the student-generated structures), which may help students better understand the concept when presented by the teacher during direct instruction subsequently. This better understanding would result in better procedural fluency, data analysis, conceptual insight, and transfer.

Process Results

Process data included group-work artifacts produced on A4 sheets of paper. These provided a rich source of data about the nature of problem representations and methods generated by the students in the PF and DI conditions. In the PF condition, groups produced four major and progressively sophisticated categories of methods and representations. The four categories were: a) central tendencies, b) qualitative methods, c) frequency methods, and d) deviation methods.

Category 1: Central Tendencies. Groups started by using mean, median, and in some cases, mode for data analysis. This was not surprising because students had been taught these concepts in the earlier grades. However, relying on central tendencies alone, it was not possible to generate a quantitative index for variance because the problem was designed in a way to keep the central tendencies invariant.

Category 2: Qualitative methods. Groups generated graphical and tabular representations that organized the data visually and were able to discern which player was more consistent. The visual representations (see Figure 1) afforded a qualitative comparative analysis between the players, but did not provide a quantitative index for measuring consistency even though the ideas of spread and clustering are quite evidently important qualitative conceptual underpinnings for the concept of variance.

Category 3: Frequency methods. Groups built on the qualitative methods to develop frequency-based measures of consistency. For example in Figure 2, groups used the frequency of goals scored within certain intervals to argue that the player with the highest number of goals in the interval containing the mean was the most consistent. Other groups counted the frequency with which a player scored above, below, and at the mean. Frequency methods demonstrated that students could quantify the clustering trends that the qualitative representations revealed.

Category 4: Deviation methods. Figure 3 presents some examples of the deviation methods. The simplest deviation method generated was the range (Deviation method 1, or simply D1). Some groups calculated the sum of year-on-year deviations (D2) to argue that the greater the sum, the lower the consistency. Among these, there were those who considered absolute deviations (D3) to avoid deviations of opposite signs cancelling each other—an important conceptual leap towards understanding variance. Finally, there were some groups who calculated deviations about the mean (D4) only to find that they sum to zero. For both the D3 and D4
categories, some groups further refined their method to consider not the sum of the deviations, but the average (D5).

In both the PF classes, all groups demonstrated representational competence at the Category 3 level or greater. Only 2 groups from PF-A and 1 group from PF-B did not reach Category 4.
Consistent with the hypothesis, none of the groups were able to develop let alone use the canonical formulation on their own. More importantly, note that these structures evidence the hypothesis that students will in fact be able to generate a rich diversity of structures to solve the problem without having first learnt the targeted concept of variance, and that comparisons between these structures will afford students the opportunities to attend to deep conceptual features of the concept. The latter needs more elaboration:

i. Comparing central tendencies with qualitative representations afforded an opportunity to attend to the feature that central tendencies alone cannot convey information about variance, and that different distributions with the same mean can have different variance.

ii. A comparison between the frequency methods and the qualitative methods afforded the opportunity to attend to the quantification of qualitative data into a mathematical index that returns a value for consistency.

iii. Because the deviation methods consider the relative position of a data point, a comparison with the frequency methods afforded students the opportunity to attend to the feature that, for consistency, it is not only important to count a point but also consider its position in relation to other points.

iv. Comparing the Range (D1) with other qualitative or deviation methods afforded students the opportunity to attend to the feature that considering just the extreme points may not be a good measure of consistency, because it tells us nothing about the distribution in the middle.

v. A comparison between D2 and D3 afforded students the opportunity to attend to the feature of why deviations must be positive. The comparison clearly shows that when deviations are left with their signs intact, positive and negative deviations cancel out resulting in a case where the variance could be highly underestimated.

vi. A comparison of D3 and D4 methods afforded students the opportunity to attend to the feature of why the reference point must be a fixed point (e.g., the mean), or else the index is sensitive to ordering of data. If the reference point for the deviation is not a fixed point, then a re-ordering of the data will result in a different value of consistency for the same formulation.

vii. A comparison between the D5 and D3/D4 methods afforded the opportunity to attend to the feature that dividing by the \( n \) helps compare samples of different sizes.

In the DI condition, all students relied only on the canonical formulation to solve data analysis problems. This was not surprising given that the canonical formulation is relatively easy to compute and apply, and was corroborated further with data from their homework assignments. The average performance (i.e., percentage of problems solved correctly) on the homework assignments was high, \( M = 92.3\%, SD = 7.4\% \). These process findings serve as a manipulation check demonstrating that students in the PF condition experienced “failure” at least in the conventional sense, whereas DI students demonstrated successful application of the canonical formulation to solve several data analysis problems.

**Results**

*Post-test.* The six-items on the posttest comprised: a) one item on **procedural fluency** (calculating SD for a given data set), b) two items on **data analysis** (comparing means and SDs of two samples; these items were similar to the data analysis problems covered during instruction), c) two items on **conceptual insight** (one item dealing with sensitivity to ordering of data points,
and another with outliers), and d) one item on transfer (item requiring the development of a normalized score for comparing incommensurable distributions. Note that normalization was not taught during instruction, and therefore, students needed to flexibly adapt and build upon what they had learnt.

Maximum score for each item was 10; two raters independently scored the items using a rubric with an inter-rater reliability of .96. Performance on the four types of items formed the four dependent variables. Controlling for the effect of prior knowledge as measured by the pretest, $F(4, 134) = 1.890, p = .112$, a MANCOVA revealed a statistically significant multivariate effect of condition (PF vs. DI) on posttest scores, $F(4, 134) = 16.802, p < .001$, partial $\eta^2 = .33$. There was no significant difference between the classes within the PF or DI conditions, nor was there any significant interaction between prior knowledge and experimental condition.

i. On the procedural fluency item, there was no significant difference between the PF condition, $M = 7.66, SD = 3.97$, and the DI condition, $M = 7.98, SD = 3.89$, $F(1, 137) = .819, p = .367$.

ii. On the data analysis items, students from the PF condition, $M = 14.11, SD = 4.20$, significantly outperformed those from the DI condition, $M = 11.38, SD = 4.86$, $F(1, 137) = 10.290, p = .002$, partial $\eta^2 = .07$.

iii. On the conceptual insight items, students from the PF condition, $M = 16.40, SD = 6.41$, significantly outperformed those from the DI condition, $M = 8.20, SD = 6.15$, $F(1, 137) = 51.359, p < .001$, partial $\eta^2 = .27$.

iv. On the transfer item, students from the PF condition, $M = 4.13, SD = 3.47$, significantly outperformed those from the DI condition, $M = 3.17, SD = 2.35$, $F(1, 137) = 3.218, p = .075$, partial $\eta^2 = .02$.

**Discussion**

These findings are consistent with previous studies on productive failure with other mathematical topics and profile of students (Kapur, 2008, 2009), and also with other studies (e.g., Schwartz & Martin, 2004; Koedinger & Aleven, 2007; Van Lehn et al., 2003). Notwithstanding the limitations of what can be achieved in a single study carried out within a particular domain, context and classroom-based setting, implications arising from the findings are simple and significant: There is indeed an efficacy in having learners generate and explore representations and methods for solving problems on their own even if they do not formally know the underlying concepts needed to solve the problems, and even if such un-supported problem solving leads to failure initially. The process analysis showed that this seeming failure was integral for: a) engendering the necessary prior knowledge differentiation (evidenced in the diversity of student-generated structures), and b) drawing attention to critical features of the concept of variance (evidenced in the comparisons between the student-generated structures), which may help students better understand the concept when presented by the teacher during direct instruction subsequently (Schwartz & Bransford, 1998).

This study contributes to the ongoing debate comparing the effectiveness of direct instruction with discovery learning approaches (e.g., Kirschner et al., 2006; Klahr & Nigam, 2004); discovery learning being often epitomized as the constructivist ideal. It is perhaps worth clarifying that a commitment to a constructivist epistemology does not necessarily imply a commitment to discovery learning. Simply leaving learners to generate and explore without

---

consolidating is unlikely to lead to learning, or at least learners cannot be expected to “discover” the canonical representations by themselves as indeed our findings suggest. Instead, a commitment to a constructivist epistemology requires that we build upon learners’ prior knowledge. However, one cannot build upon prior knowledge if one does not know what this prior knowledge is in the first place. It follows that at the very least the burden on the designer (e.g., teacher, researcher) is to first understand the nature of learners’ prior knowledge structures; the very structures upon which the claimed “building” will be done. Designing for productive failure presents one way of doing so.

Interestingly, one could argue that Klahr & Nigam’s (2004) study supports the above contention although it is often cited as a stellar example of the superior effectiveness of direct instruction over discovery learning. A careful reading of the study suggests that before assigning students to either a direct instruction or a discovery learning condition, Klahr and Nigam conducted a baseline assessment where they asked students to design four experiments on their own. As expected, only 8 out of the 112 students were able to design four un-confounded experiments, that is, the success rates before any instruction on the control of variables strategy (CVS) were very low. Students who were subsequently assigned to the discovery learning condition simply continued to design these experiments but without any instruction on CVS or any feedback. However, for students in the direct instruction condition, the instructor modeled and contrasted the design of both confounded and un-confounded experiments with appropriate instructional facilitation and explanation to make them attend to critical features of why CVS helps isolate the effects of a factor whereas confounded experiments do not. It was not surprising therefore that Klahr and Nigam found direct instruction to be more effective than discovery learning as described earlier in this paper.

From the perspective of productive failure however, the baseline assessment in Klahr and Nigam’s (2004) study seems to function very much like the generation and exploration phase where students generate their own structures (in this case, experiments) to solve a problem that targets a concept (in this case, CVS) that they had not learnt yet. If so, the very effects that Klahr and Nigam attribute to direct instruction alone seem more appropriately attributed to a generation and exploration phase (their baseline assessment) followed by direct instruction. Therefore, much as Klahr and Nigam set out to show, in part, that there is little efficacy in students exploring and solving problems requiring concepts they have not learnt yet, their findings can be reinterpreted to support precisely the contrasting contention that such exploration can in fact be efficacious provided some form of direct instruction follows, for without it, students may not learn much (as indeed the performance of the students in the discovery learning condition revealed).

Findings from productive failure are also consistent with Schmidt and Bjork’s (1992) review of psychological science research on motor and verbal learning. They argued that under certain conditions, introducing “difficulties” during the training phase, for example, by delaying feedback or increasing task complexity, can enhance learning insofar as learners engage in processes (e.g., assembling different facts and concepts into a schema, generating and exploring the affordances of multiple representations and methods) that are germane for learning. Thus argued, designing for a certain level of failure (as opposed to minimizing it) in the initial learning phase may well be productive for learning in the longer run. Future research would do well not to (over)simplistically compare discovery learning with direct instruction, but instead understand conditions under which these approaches can complement each other productively.

EARLY ELEMENTARY STUDENTS’ REPRESENTATION CHOICE AND USE DURING WORD PROBLEM SOLVING

Lucia M. Flevares
The Ohio State University
flevares.1@gmail.com

The current study investigates early elementary children’s preferences and repertoire for representing their solutions during problem solving. Participants completed a series of grade-level basic operations story problems to evaluate their problem-solving behaviors. The first- and second-grade students used external representation a high rate overall, but differences emerged in the type of external representations, both within and across grades. The differences follow a predicted shift from more concrete to more abstract external representations. Most participants, especially in the second-grade cohort, used more than one type of external representation. Potential gender effects are also considered.

Introduction

An assumption embedded within common mathematics education practices, and in both Piagetian and Vygotskian perspectives on development, is that children should be aided to move from concrete representations of quantities to more abstract (National Council of Teachers of Mathematics, 2000), especially in the early childhood and early elementary years (Ball, 1992). Learning mathematics can entail not merely dual representations (e.g., DeLoache, 1995), but multiple forms of mathematical expression (Gentner & Ratterman, 1991). Many representational tools and symbols are introduced and available to these novice mathematics learners, but much is yet to be understood about how children use and select these symbols. The current study investigates which representations children prefer and how they use these representations.

Offering a choice of materials (concrete counters and blocks, paper and pencil for drawings, tallies, or other written symbols, a 100 chart, and a number line) to express their ideas creates the opportunity for children to use any one of the available tools or none or to use multiple representations (e.g., Fennell & Rowan, 2001) to express their answer and for the researcher to study children’s choice and use of multiple symbolic forms. The open-ended story problems used, modeled after the Cognitively Guided Instruction program (Carpenter et al., 1999) do not specify a solution strategy, facilitating examination of children’s strategic thinking (e.g., Verschaffel & Decorte, 1993).

The present investigation also addressed potential gender-based differences in problem solving. Carr and Jessup (1997) suggested that first-grade girls prefer physical representation more often than boys who tend to use retrieval strategies and no external representation more often. Siegler’s (1999) work implies that with a higher confidence interval for offering an answer, girls may have higher rates of correct answers.

Method

Participants.

Participants all attended the same suburban Midwestern primary school and reflected the diversity of that school. Twenty kindergartners, 22 first graders and 30 second graders participated in the sessions. The preliminary results come from the sessions for 15 first-grade students (average age at first test = 88 months; 7 boys and 8 girls) and 16 second-grade students.
(average age at first test = 98 months; 7 boys, 9 girls). All children attended the same school and received instruction with the same National Council of Teachers of Mathematics reform-based curriculum and thus could all be assumed to have some familiarity with word problems.

**Procedure**

A longitudinal, cross-sectional, quasi-microgenetic (e.g., Siegler, 2002) design was used. Children participated in 3 sessions: the first two approximately one month apart in Spring, with a delayed follow-up session in late autumn. Each child answered 6 grade-level word problems (Carpenter et al., 1999) per session; [See Appendix A examples]. Children participated in individual videotaped sessions. The Time 2 problems paralleled those from Time 1 except for the numbers used; the Time 2 problems were used again at Time 3 (delayed follow-up). The experimenter read each problem two times and repeated it as many times as requested. After time to solve the problem, either the child volunteered an answer or the experimenter prompted for one and then asked, “Can you tell me how you figured that out?”.

**Materials**

The interviewer informed the students that could use any of the provided materials and any methods of their choice. The students were asked for their answer and the method they used for each question. The materials provided by the interviewer included: 100 charts, pencil and paper, base 10 blocks, unifix cubes, a number line from 1 through 25 and wooden cubes. The students were well acquainted with the materials from their classroom experience, ruling out the possibility of novelty.

Prior to beginning the problem solving, the experimenter told the participant: “I brought some math tools that you can use if you’d like. There’s paper and pencil and markers if you want to write anything or draw anything, there’s 100 charts, there’s a number line that goes from 0 to 25, and three types of blocks: the base-ten pieces, the unifix cubes, and the wooden cubes. You can use any of these if they help you solve the problem, but you don’t have to. If you don’t want to use any of them, that’s fine too. It’s totally up to you. Solve the problems in whatever way makes the most sense to you.” The materials were all placed within the child’s reach but the experimenter never encouraged or prompted a child to use them.

**Coding**

The use of external representations was coded from video, noting the use or creation of any representation during problem solving and subsequent explanation. Gesture was credited when a student counted on fingers or held up fingers to keep track of counting or during the explanation. On-paper representations were categorized as either child-created number expressions (e.g., 43-17 = 26) and drawings (including tally marks or more iconic drawings, such as a tree with birds in it) or use of the preprinted two-dimensional representations, either the number line or the 100 chart. Use of concrete manipulatives was credited for any non-play use of the blocks during problem solving.

**Results**

Preliminary results are reported herein on a subset of the data. Analyses of the entire set will be conducted with categorical data analysis, chi-squared tests or where appropriate, Fisher exact tests, depending on the expected frequencies.
Students’ solutions

Few participants used only one type of representation during a session (first grade, x = 5.67, n = 15; second grade, x = 2.33, n = 16). Using Fisher exact 3x2 tests, rates did not differ by time period or grade. Additionally, this provides an index that children, especially those in the second-grade cohort, used multiple external representations rather than favoring one representational type.

Examining students’ problem-solving actions over the set of problems completed per session reveals a high rate of use of external representations. Note that the first-grade set included 6 problems for 15 children at each time point (and thus 90 problems), while the second grade included 6 problems for 16 children at each time point (and thus 96 problems).

![Figure 1. The rate of students’ use of external representations during problem solving and explanations](image)

Every child used or created a symbol on at least one of the problems in each session (See Appendix B for sample comments regarding representations). Participants in both grades decreased their use of gesture over the sessions and significantly increased their rate of drawings or written equations. Second-grade participants increased their use of pre-printed 2D materials, particularly the 100 chart, perhaps stemming from increased classroom experiences with this form of number sequence representation for arithmetic problem solving.

The next analysis examined the frequency of students’ use of multiple external representations on any one problem. Significantly more 2nd graders used multiple external representations for any single problem than 1st graders (Figure 2). Note that although 4 children used multiple external representations on at least one problem at Time 1, Time 2, and Time 3, these were not necessarily the same children. Across the three sessions, 8 different students used more than one external representation on a single problem. Similarly, all but 2 of the 2nd graders used a combination of external representations on at least 1 problem. This result provides evidence that this cohort of 2nd graders may have had more confidence and fluency in coordinating multiple external representations.

Examining these results together, a subset of children from each grade could be considered consistently eclectic in their use of external representations, using multiple forms across the 6 problems for a session, but many of their peers used multiple external representations only occasionally, raising the question of whether their use of multiple representations was situational.

---

Lastly, on the analyzed subset of data, the observed gender-based trends were in the predicted direction: Boys tended to use counting and retrieval strategies more often than girls, and girls used more direct modeling strategies, on average, than boys. These trends will be further explored with the full data set.

![Figure 2. The number of students who used more than one external representation type during their problem solving](image)

**Discussion**

The children spontaneously opted to use external representations, but displayed differences in the type and frequency of their use, and changes from session to session in favor of creating two-dimensional representations and referring to manipulatives less. These results recall a hypothesized evolution of children’s symbol use in mathematics from concrete to abstract (e.g., Carpenter et al., 1999). Given that signs and symbols may mediate learning (e.g., Uttal, 2000), this investigation addresses children’s preferences for symbolizing quantities and has potential implications for instructional interventions.

The use of concrete objects to stand for quantities does not guarantee that a child will identify the intended meaning of these tools (e.g., Baroody, 1989, Clements, 1999). Given the widespread use of concrete objects as problem solving and problem representation tools, it is important to document how individual learners understand and use these objects. Then, even given successful use of manipulatives for problem solving, the mapping to more abstract representations, such as writing an equation, cannot be assumed to be an easy or transparent process for a young learner. As noted by Uttal, Scudder, and DeLoache (1997) “Connections must be established for both numerical symbols and operation symbols. (Wearne & Hiebert, 1988, p. 372)” (p. 48). Young learners’ mappings or translations between representations must be supported.

**Educational Implications**

Teachers or other adults cannot take the intended symbol mappings as transparent for the children (e.g., DeLoache, 1995; Hughes, 1986), and by observing their representation choices can gain insight into which external representations students find the most representationally clear. Teachers should offer explicit scaffolding in the use of external representations to increase the likelihood that the representation will be used as intended (e.g., Uttal, Scudder, & DeLoache, 2010).
1999). Educators’ observation and assessment of learners’ preferences for types of external representations may facilitate the scaffolding of their use of other types and recognition of the similarity in intended referents of that other representation type. In particular, when moving from concrete to abstract, learners need to be scaffolded to see the relations between elements such that, for example, the ten base-ten block maps onto a line drawn on paper while the unit piece maps onto a dot drawn on paper. Understanding how students prefer to represent their thinking during solutions and explanations can enable educators to support the learning of the multitude of symbols used in mathematics.

**Appendix A: Example problems**

Kindergarten:
*Shelly had 9 jellybeans. Some are red and some are blue. 4 of the jellybeans are blue. How many jellybeans are red?*

1st grade: *David has 3 bags of candies. There are 4 candies in each bag. How many candies does David have altogether?*

2nd grade: *Ms. Baker’s class has 29 students. 15 of the students are boys. How many are girls?*

**Appendix B: Examples of Children’s Spontaneous Comments about External Representations**

- 2nd grader EY: “This is how we learned to do it in class. A line stands for ten and a dot stands for one and that way we don’t have to draw them out like the base-ten blocks (…) Sometimes it’s hard to keep track when I trade a ten for ones.”
- 1st grader CD on using the 100 Chart, “Ugh, I forget which number I started on.”
- 2nd grader JM: "I don't use any of that stuff. I just do it in my head," but then he went on to use both written and concrete representations on some problems. On the ones that he solved only in his head, he had some difficulty keeping track of his numbers.
- 2nd grader AO on the base-ten blocks: "These are easier than those (the unifix snapcubes) because those you have to count by one, but these you can just take 1 piece and say "10"."  
- 1st grader NC: "I think I'm going to use these (the unifix connecting cubes) cubes right here because they're easiest to work with."
- 1st grader BH, working with paper and pencil: "This is hard." E: Can you think of a different way to figure it out? BH: Yes! (takes out unifix cubes) (...) I knew it was wrong and I thought the cubes might help.
IS IT POSSIBLE TO IMPROVE THE STUDENTS’ CRITICAL THINKING DISPOSITIONS THROUGH TEACHING A COURSE IN PROBABILITY?

Einav Aizikovitsh-Udi  
Ben Gurion University of the Negev  
einavai@bgu.ac.il

Miri Amit  
Ben Gurion University of the Negev  
amit@bgu.ac.il

The purpose of this initial study was to explore whether teaching our specially designed learning unit would enhance the students’ critical thinking dispositions. The unit “Probability in Daily Life” was taught to a group of tenth-grade students, with the purpose of encouraging critical thinking dispositions such as open-mindedness, truth-seeking, self-confidence and maturity. The teacher encouraged class discussion and planned investigative lessons. The students completed a pre and post CCTDI test. A minor improvement was detected, but we believe that these initial results are the first step in showing that it is possible to train students’ critical thinking dispositions.

Introduction

Our ever-changing and challenging world requires students, our future citizens, to go beyond the building of their knowledge; they need to develop their higher-order thinking skills, such as system critical thinking, decision making, and problem solving (Profetto-McGrath, 2003; Riddell, 2007; Sezer, 2008). There have been significant changes in the past decades in the field of education. Whereas earlier the teacher was at the center and the emphasis was put on what to teach, today’s education involves teaching how to think, and in particular, how to be a critical thinker. Critical thinking is necessary in every profession, and it allows one to deal with reality in a reasonable and independent manner (Harpaz, 1996, 1997; Lipman, 1991, McPeck, 1994).

Critical thinking has been investigated largely in terms of thinking skills that involve the cognitive domain. For decades, promotion of students’ thinking has been the focus of educational studies and programs (Facione, 1996; Facione & Facione, 2000). Each of these programs has its own definition of thinking and/or of skills. Some use the phrase ‘cognitive skills’ while others refer to ‘thinking skills’ (Resnick, 1987; Zohar & Dori, 2003), but they all distinguish between higher- and lower-order skills. Resnick (1987) maintained that thinking skills resist precise forms of definition; yet, higher order thinking skills can be recognized when they occur.

Thus, there seems to be no clear consensus as to what exactly critical thinking is. Some see it as simply “everyday, informal reasoning” (Halpern, 1998), whereas others feel differently. Lipman considers it to be different from ordinary thinking because it is both more precise and more rigorous, as well as self-correcting. It has also been described by Halpern (1996) as being ‘purposeful, reasoned, and goal-directed’. There are taxonomies which set out a list of the reasoning skills involved in critical thinking: for instance, Ennis' taxonomy proposes twelve skills according to Ennis, (1987).

Nonetheless, it seems evident at this point that the ability to think critically is not something that we are born with but a learned ability that needs to be taught. Our research is underpinned by several questions raised by Passmore (1980): what do we mean by teaching a student to become a critical thinker? How can this be accomplished successfully? Does it merely involve giving the necessary facts or rather nurturing the student's disposition, molding the personality, or is something else involved? Is being a critical thinker a matter of habit? Passmore does not

---

have answers to all these questions, but in his article he does claim that in the process of developing critical thinking we have to stress the student's “natural disposition.”

Facione and Facione (1994, 2000) propose a taxonomy of dispositions that includes such elements as cognitive maturity, searching for truth, open-mindedness, systematocity, analyticity, self-confidence, and curiosity. They developed the California Critical Thinking Disposition Inventory (CCTDI) which was originally intended to be used to measure critical thinking dispositions in college students but has been successfully adapted to be used in high school. Another question then arises as to whether dispositions are something that can be changed or improved. Through our research, we hope to shed some light on these questions.

Methodology

The pilot study reported here was conducted over the period of one academic year in the framework of a larger PhD research and involved one group (n=30) of tenth-grade students in regular high school. The group consisted of thirty students, all high achievers, aged fifteen to sixteen. The teacher was one of the researchers.

The learning unit “Probability in Daily Life” (Lieberman & Tversky, 1996) comprised fifteen lessons, each lasting ninety minutes, and was modified by the researchers to combine critical thinking skills with the probability topics it initially contained (Aizikovitsh & Amit, 2008). This unit in probability studies, which is part of the formal mathematics curriculum of the Ministry of Education was chosen because of its rationale of "learning issues relevant to the daily life, which include elements of critical thinking" (Liberman & Tversky, 2001, p.3). In the unit the student is required to analyze problems, raise questions and think critically about the data and the information.

The purpose of the unit is to teach the students not to be satisfied with a numerical answer but to examine the data and their validity. In cases where there is no single numerical answer, the students are required to know what questions to ask and how to analyze the problem qualitatively, not only quantitatively. Along with being provided with statistical instruments, students are redirected to their intuitive mechanisms to help them estimate probabilities in daily life. Simultaneously, students examine the logical premises of these intuitions, along with misjudgements of their application. This unit examines the term “probability” regarding everyday problems. The uniqueness of the original Lieberman and Tversky’s unit lies in the fact that it allows one to learn interesting subjects of everyday relevance through mathematics. This involves critical thinking elements such as: tangible examples from everyday life, questioning the reliability of information, accepting and dismissing generalizations, rechecking quantitative data, doubting, etc.

The Uniqueness of the “Probability in Daily Life” Learning Unit Modified for Infusion Approach Teaching

The main characteristic that distinguishes the new (intervention) learning unit "Development of Critical Thinking by Means of Probability in Daily Life" modified by the researchers (Aizikovitsh & Amit, 2009) for infusion approach teaching (Swartz, 1992) from the original one is the innovative, ‘different’ teaching method that lies at the basis of this unit. Teaching in the infusion approach necessitates a different structure of teacher-student interaction in class that diverges from the traditional one used in most ‘traditional’ math lessons. This method is known in literature as "dialogical teaching" or "negotiating knowledge" and is characterized by classroom discussions between the teacher and the students and among the students themselves.
during the lessons, so that the teacher won't be the only person speaking in class (Nystrand, 1997; Pape, Bel, & Yetkin, 2003).

The teacher's role is to encourage the students to make changes in their systems of perceptions and concepts, to convince them that such changes should be made, and to help the students to make these changes (in particular, by allowing the students to talk the topic over among themselves and discuss it together in small groups, in a less 'threatening' form than doing it in the larger forum of the whole class).

To fulfill this function, the teacher can use various teaching methods at his/her disposal: oral explanation, texts, experiments, demonstrations, videos, computer programs, the students' own work, group discussions, etc. The method of negotiating knowledge in the classroom emphasizes that the use of any teaching method or tool must be accompanied by dialog between the teacher and the class, and among the students themselves, i.e. by classroom and group discussions. Such discussions may have different purposes (according to specific situations). During such discussions the students may, for example, express their opinions about the topic currently studied, present the insights they acquired as a result of different learning and teaching strategies, ask questions, make comments, argue about interpretations, and so on. It is important to emphasize that the main characteristic of these sessions is a meaningful, authentic dialog where the students feel free to express their original thoughts instead of the ideas the teacher expects them to learn. We believe that this teaching method creates in class an optimal atmosphere in which the students are most likely to follow their dispositions towards critical thinking and thus there is a chance that these dispositions will be strengthened and the students will learn to apply them in a more consistent, aware and systematic way.

*The California Critical Thinking Dispositions Inventory (CCTDI)*

CCTDI is a Likert test based on the seven positive aspects of the disposition for critical thinking. It was designed to measure general dispositions profile of the students. CCTDI is divided into seven sub-tests: truth-seeking (sub-test T), intellectual openness (sub-test O), analyticity (sub-test A), systematicity (sub-test S), self-confidence in critical thinking (sub-test C), inquisitiveness (sub-test I) and maturity (sub-test M). The following descriptions of the sub-questionnaires are based on Facione et al. (1996) and Facione (2000). The sub-test T deals with the inclination to investigate in order to arrive at the fullest and most adequate information possible in a given context, raising questions in a courageous way, as well as honesty and objectivity in searching for information, even if this information goes against the investigator’s personal interests or opinions. For instance, those who incline for truth-seeking will not agree with the following claim: “All people, including myself, always present claims that follow from their personal interest,” or, “If there are four reasons ‘pro’ and one ‘contra’, I will be in favor of the four.” The sub-test O deals with the inclination for intellectual openness and tolerance towards other opinions, while remaining aware of the fact that one’s own opinions are different. People who are not tolerant towards views different from their own will agree with the claim “It’s important for me to understand what other people think on various issues.” The sub-test A focuses on application of cause and proof, awareness of problematic situations and an inclination to predict outcomes. For instance, students are asked to answer “agree” or “disagree” to the following statement: “People need reasons for disagreeing with someone else’s opinions.” The sub-test S checks organization, order, focus, and commitment to investigation, and uses test statements of the following kind: “My opinion on controversial issues depends mostly on the last person I have had a conversation with.” The sub-test C measures the person’s confidence in his/her own thinking process, and uses test statements such as “I do better in exams that demand
thinking, not only memorizing,” or “I take pride in my ability to understand other people’s opinions.” The sub-test I measures the keenness to acquire knowledge and find explanations, even when this knowledge does not seem immediately applicable. Representative test-statements are: “No matter what the topic, I am keen to learn more about it,” or “Learn all you can, you never know when you may need to use this knowledge.” Finally, the sub-test M measures the person’s inclination to be critical about his/her own decision-making. A mature person who thinks critically can be defined as a person who approaches problems inquisitively and makes decisions while knowing that some problems are inherently poorly constructed, and others have multiple solutions. The CCTDI total score is a measure that estimates one's overall disposition toward critical thinking. A person may be positively and strongly disposed toward seeking to solve problems and address questions using reflective judgment, that is, critical thinking; alternatively, they may be ambivalent toward that, or even negatively disposed and hostile toward that approach. The total score is based on all 75 items. Facione (2000) report correlations that support the simultaneous validity between scores in CCTDI sub-tests and psychological tests.

Results

Chart 1 represents the post vs. pre average CCTDI test sub-scale scores for “High School 1” (the exact t-test values are presented in full in Table 1). Both the chart and the table reveal that in the first round there was a significant improvement in the sub-scales of systematicity, maturity and analyticity, whereas there was no improvement in the other sub-scales. Points on the diagonal represent cases where the pre and post scores were equal. Consequently, the area above the diagonal is where an improvement was observed. Table 1 of the paired t-test results reveals that in the first iteration there was a significant improvement in maturity, whereas there was no improvement in others parameters.

Findings of Interviews with Students

The following two examples are representative of many more similar answers. One student replied as follows to our question regarding the importance and practical function of critical thinking: "I think CT is important when you study mathematics, when you study other topics and when you read the paper, but it is most important when you deal with real life situations, and you
need the right instruments in order to do so (deal with these situations)." Another student was asked about applying important components of critical thinking that were capitalized on during the last few classes, and she answered: “First we should check the information source’s reliability and despite all the numerical data, I don’t accept the researcher’s conclusion.”

Additional data, consistent with these two examples, suggest that infusion of CT into the formal curriculum in mathematics can sharpen the students’ critical thinking dispositions and make them more aware of the nature and importance of these dispositions and their applicability to a wider range of disciplines as well as daily life situations.

Discussion

In much of the literature on critical thinking we see that there is no significant improvement in all the sub-tests during one year of learning (Barak & Dori, 2009; Ben-Chaim, Ron, & Zoller, 2000). In the sub-tests of our group we did see a marked improvement in systematicity, analyticity, and maturity. On re-examining these sub-tests we noticed that they consisted of a group of questions involving a certain experiment where all the information was presented in the form of tables. During this learning unit we repeatedly worked with tables and we therefore came to the conclusion that the familiarity of the students with the tables enabled them to deal with the statements made and answer these specific questions more easily. The improvement in maturity was more difficult to analyze. At this stage of our research we feel that we don't have sufficient data to explain why there was an improvement at all, or why. Also, the deterioration that occurred in confidence still remains to be explained.

As this paper was being written, the study was expanded to six additional groups. We are eagerly waiting to see the results of these groups which will hopefully shed light on our findings presented here. The interviews that we conducted with the students also gave us information as to how the unit had affected the students. We saw that the students' approach to solving problems started to change. While in the past they would often accept data given to them at face value, now they started questioning their validity. Earlier they would be satisfied with manipulating numbers and arriving at "the answer", whereas now they began searching for other possible answers. The students started thinking about critical thinking.

Conclusion and Implementation

The pilot-scale research described here constitutes a small step in the direction of developing additional learning units within the traditional curriculum. It is apparent that if a teacher makes a decision to focus on improving higher order thinking and perseveres over time, the chances are good that the teacher will succeed. This study showed that it is possible to incorporate into regular schools activities that will develop the students' critical thinking dispositions. The subject matter was part of the high-school curriculum; therefore it does not take time away from the regular syllabus. It also does not take the teachers extra time or effort in order to prepare the unit. What is most essential is the teacher's understanding of the importance of developing the critical thinking abilities in their students.

The general educational implications of this research suggest that we can and should leverage the intellectual development of the student beyond the technical content of the course, which can be done by creating learning environments that foster critical thinking, and which will, in turn, encourage the student to investigate the issue at hand, evaluate the information and react to it as a critical thinker. It is important to note that, in addition to improving the dispositions discussed above, the students also gained intellectual skills such as conceptual thinking during this course and developed a class culture (climate) that fostered critical thinking. To conclude, this research shows the possibility of working in the direction of developing critical thinking dispositions in the framework of the established contents of the mathematics curriculum.

THE DEVELOPMENT OF NOTATIONAL SYSTEMS—A CREATIVE ENDEAVOR

Erik Tillema
Indiana University Purdue University Indianapolis
etillema@iupui.edu

The role of symbol systems in learning mathematics has received a significant amount of attention recently in mathematics education. However, relatively few studies have traced out how individual student’s systems of notation evolve across teaching sequences. The purpose of this paper is to trace out the evolution of an eighth grade student’s system of notation as he solved combinatorics problems. The problems were part of a sequence of teaching episodes designed to help students develop a formula for the sum of the first n whole numbers. The teaching episodes were part of a three-year teaching experiment with middle grades students.

Introduction

In 1991 Kaput noted that the following question had been under researched in mathematics education: “How do material notations and mental constructions interact to produce new constructions (p. 55)?” Meira (1995) echoed Kaput’s sentiments stating that, “not many studies in the mathematics education literature treat children’s production of material representations (e.g., on paper) as the central issue in any significant way” (p. 270). Since that time, a small number of studies have tracked the evolution of students systems of notation in the context of their problem solving activity (e.g., Brizuela, 2004; Izsak, 2000; Lehrer, Carpenter, Schuoble, & Penner, 2000; Meira, 1995). These studies have contributed to researcher’s understanding of how students learn to produce and use systems of notation in powerful ways, but the issue remains a significant and under researched problem in mathematics education (Yackel, 2000). The purpose of this paper is to trace out the evolution of one eighth grade student’s system of notation for solving combinatorics problems. In doing so, I demonstrate how a student’s system of notation became progressively more advanced in the context of his problem solving activity. The following research question guided the study:

(1) How do students develop and refine systems of written notation, and in this process how do their systems of notation become more advanced?

Theoretical Framework

Elsewhere I have situated students’ symbolizing activity in a radical constructivist framework for communication (see Thompson, 1999 for the communication framework), and I have examined how symbolizing activity functions in student-teacher communication aimed at learning (Tillema, 2010). In doing so, I defined symbolizing activity as any type of material component that a person produces during the functioning of his or her schemes (cf. Ernest, 2006; Hoffman, 2005; Kaput, Blanton & Moreno, 2008; Nemirovsky & Monk, 2000; Radford, Bardini, & Sabena 2007; Sfard, 2007).

For example, consider the following problem:

The Outfits Problem: You have three shirts and four pairs of pants. An outfit consists of one shirt and one pair of pants. How many outfits can you make?
To solve the Outfits Problem a student might label the shirts “1”, “2”, and “3”, and label the pairs of pants “A”, “B”, “C”, and “D”, and say aloud, “there is A1, A2, and A3; there is B1, B2, and B3” etc., while writing “A1, A2, A3, B1, B2, B3”, etc. In this case, the student’s symbolizing activity would include both the verbal expression and notation. More generally, symbolizing activity includes verbalizing, notating, as well as gesturing, and I consider symbolizing activity to be an expression of the schemes (and mental operations that make up these schemes) that a person uses to constitute experiential situations.

For the purposes of this paper, I focus my discussion exclusively on the evolution of a single student’s notating activity. Throughout the paper, I use the terms notation and notating activity broadly to mean any type of graphic record that a student produces during the functioning of his or her schemes (cf. Kaput, Blanton, & Moreno, 2008, p. 29; Lehrer, Schauble, Carpenter, & Penner, 2000).

**Methods and Methodology**

The data presented in this paper is from a three-year constructivist teaching experiment (Confrey & LaChance, 2000; Steffe, & Thompson, 2000) with middle grades students, which was conducted in North Georgia from October 2003 to May 2006. In the experiment, four pairs of students were taught during their sixth, seventh, and eighth grade years twice weekly in 30-minute episodes for two to three weeks, followed by a week off. I and one other researcher formed the core of the research team for the three-year experiment, with other researchers joining for shorter time periods. All teaching episodes were videotaped with two cameras, one focused on the students’ work, and one focused on the interaction. The two video files were then mixed into a single video file for analysis. In the rest of this section, I provide details about the student participants in the experiment, my procedures for data analysis, and the design of the teaching episodes reported on in the data analysis.

**Participants**

In September and October of 2003 the research team conducted 20-minute selection interviews with 20 sixth-grade students out of a pool of approximately 100 students, all of who had the same classroom mathematics teacher. A member of the research team observed four of this teacher’s five mathematics classes, and she consulted with this teacher to identify students to interview. The intention of the research team was to select three pairs of students who were each at different levels of multiplicative reasoning, and one pair of students who were pre-multiplicative reasoners (see Hackenberg & Tillema, 2009 for information about the different levels of multiplicative reasoning). During the selection interviews, we used whole number and fraction tasks to make initial assessments of students’ current multiplicative concepts. Upon completion of the interviews, we consulted again with the teacher, the school counselor, and the principal in order to select students who attended school regularly and were likely to remain in the district for the duration of the experiment. This article reports on one student during the first four teaching episodes of his eighth grade year. During the selection interviews, he exhibited the second level of multiplicative reasoning, and during his eighth grade year he was in an Algebra class—the highest course offered at the school for eighth grade students.

**Analytic Procedures**

In teaching experiment methodology, data analysis occurs in two phases—ongoing and retrospective analysis (Steffe & Thompson, 2000). The purpose of ongoing analysis is to develop
working models of students’ reasoning, and to plan tasks for each teaching episode. During ongoing analysis, the research team met between each teaching episode. I documented these meetings, which included a written record of the problems presented to students, changes to the problems presented, and reasons for these modifications as well as my initial impressions of the students’ reasoning about and notation for problems.

The purpose of retrospective analysis is to create second order models of students’ ways of operating and changes to these ways of operating (Steffe & Thompson, 2000). A second order model is a researcher’s constellation of constructs to account for another person’s way of operating, which in this study focused on a student’s notating activity. Constructing second-order models involved me in repeated viewing of video files, creating notes, and then notes on notes (Cobb & Gravemeijer, 2008), in order to identify moments that captured (1) regularities in the student’s system of notation, and (2) changes to this system of notation.

Design of the Teaching Episodes

The four teaching episodes reported on in this study was designed to investigate how two students would use combinatorics problems to construct and evaluate sums of whole numbers, and in this context how they would develop a system of notation that accounted for ordering outcomes. I planned to begin the set of four teaching episodes with the Outfits Problem, mentioned earlier. The goal of posing this problem was to see how students would solve and create notation for a “basic” combinatorics problem that did not involve ordering. I planned to introduce the students to three different ways of notating the solution to this problem—using lists (e.g., A1, A2, etc.), tree diagrams, and arrays. However, rather than present students with these ways of notating the problem, I planned to ask the students to solve the problem without giving specific direction about how to notate their solutions. Once the students solved the problem I planned to introduce them to other ways of notating their solutions.

I planned to continue to pose problems similar to the Outfits Problem during the first two teaching episodes, and during this time to ask the students to explain and interpret each other’s notating activity as well as to use multiple types of notation for their solution of a single problem. The purpose, then, of the first two episodes was to familiarize students with the three ways of notating problems like the Outfits Problem.

During the third teaching episode, I planned to pose the Flag Problem.

The Flag Problem: You are the President of a new country. You need to design a flag that has two stripes. You have 15 colors to choose from. How many possible flags could you make?

The Flag Problem differs from the problems from the first two episodes in two ways: (1) the statement of the problem only refers to one type of quantity (i.e., colors) that students could use to make flags, as opposed to two distinct types of quantities (e.g., shirts and pants) that students could use to make outfits; (2) students’ solution of the Flag Problem holds the potential for them to establish an order for the stripes (e.g., a top and bottom stripe).

During the fourth teaching episode, I planned to present the Handshake Problem.

The Handshake Problem: There are 10 people in a room. Each person wants to shake hands with all of the other people. How many handshakes would there be?
I expected that the Flag Problem would provide a foundation for solving the Handshake Problem because the Flag Problem held the potential for students to order the outcomes. I anticipated students might solve the Handshake Problem by ordering the handshakes, which would enable them to count each handshake twice (e.g., count both the first person shaking the second person’s hand and the second person shaking the first person’s hand), and then eliminate the duplicate handshakes. Neither student in the study solved the Flag or Handshake Problem precisely as I had anticipated, but in solving the problems they did create a system of notation that could account for ordered outcomes. I examine how one of the students did so in the data analysis.

**Data Analysis**

*Michael’s Notating Activity for the Outfits Problem*

On 10/17/05, I presented Michael and his partner with the Outfits Problem. Initially, Michael solved this problem using tally marks (Figure 1a). His partner created a picture of three shirts and four pairs of pants, labeling the shirts “1”, “2”, and “3”, and the pairs of pants “A”, “B”, “C”, and “D”. His partner then listed all of the outfits “A1”, “A2”, “A3”, etc. When both students were done with their solutions, I asked them to explain to the other what they had done. After both did so, I requested that Michael use notation similar to his partner’s notation to solve the problem. In response, Michael produced Figure 1b and 1c. The notation Michael produced in Figure 1a and 1b was representative of the type of notation he produced throughout the first two episodes for problems like the Outfits Problem. During these episodes, he did use tree diagrams and arrays, but only at my request, and he specifically stated that he did not fully understand arrays despite his partner’s explanation of them.

![Figure 1a (left), Figure 1b (middle), & 1c (right) Michael’s notation](image)

*An Analysis of Michael’s Notating Activity*

Michael’s use of tally marks did not create a clear record of the result of putting a shirt with a pair of pants to make an outfit. Rather, the outfits were recorded each time he connected tally mark in the bottom row with a tally mark in the top row, leaving a jumble of lines between the two rows of tally marks. For this reason I requested that Michael use notation similar to his partner (Figure 1b & 1c). Using this notation entailed recording each outfit in a separate location, Figure 1c, and thus his notating activity in Figure 1c clearly recorded the outfits. It also entailed him in differentiating the two types of quantities (shirts and pants) in the problem by using a different type of character (letters and digits) for each. Using the letters and digits to differentiate between the two types of quantities was an essential first step in creating a system of notation that could account for order. That is, using letters and digits opened the possibility for him to use one type of character to denote the first element in an ordered pair and the other type of character.

---

to denote the second element in an ordered pair where the difference in character type might help him to distinguish between the meaning of the first and second character.

Michael’s Notating Activity for the Flag Problem

During the third teaching episode, I presented Michael and his partner with the Flag Problem. In order to orient them to the Flag Problem, I asked that they each make two-striped flags in The Geometer’s Sketchpad (GSP). During this time, the boys discussed whether to count a flag that had two stripes that were the same color (e.g., red in the top stripe and red in the bottom stripe), and the boys created flags in GSP where they used red in the top stripe (e.g., red in the top stripe and orange in the bottom stripe), and used red in the bottom stripe (e.g., black in the top stripe and red in the bottom stripe). However, we did not have an explicit discussion about the difference between, for example, a red-orange and an orange-red flag.

After the boys made six representative two-striped flags in GSP, I asked each boy to determine all of the possible flags they could make. Michael replied, “I’ll do what I do”, began by making a list of all of the colors. Then at my suggestion he associated a number with each color (e.g., writing “Red = 1”, etc.), and recorded flags as shown in Figure 2. After he was done recording flags, I asked why he began his second column of notation with “2-2” instead of “2-1.” He replied, “you have one to two, but you can’t do two to one again because it’s already used.”

**Figure 2. Michael’s notation for the flags**

An Analysis of Michael’s Notating Activity

Michael’s notation for this problem differed from his notation in the Outfits Problem—he listed the possible flags using two digits (e.g., “1-1”) as opposed to a letter and a digit (e.g., “A1”). This modification in his system of notation indicates that he considered that the outcomes were produced from a single type of quantity (colors), as opposed to two different types of quantities (e.g., the shirts and pants). Considering the outcomes to be produced from the same type of quantity is an essential precursor to establishing a system of notation that includes ordered outcomes. That is, there is no impetus to order outcomes when there are two different types of quantities: Shirt A paired with pants 1 is the same as pants 1 paired with shirt A precisely because the two quantities being paired cannot be considered the same. In contrast, when a person creates outcomes from a single quantity, the question of whether color 1 paired with color 2 is different from color 2 paired with color 1 arises because the quantity used to create these pairings is the same, and so a person may use some other relevant feature of the problem to distinguish between these outcomes (e.g., by position, as in a top and bottom stripe).
In his solution, however, Michael did not seem to consider the difference between the flag notated as “1-2”, and the flag notated as “2-1”. Instead, his comment “you have one to two, but you can’t do two to one again because it’s already used” indicates that he seemed to consider the flag “2-1” and the flag “1-2” to be identical. So although Michael considered the flags to be produced by a single type of quantity, he had not yet differentiated between two outcomes based on the position of the stripe. Nonetheless, he had modified his system of notation for solving combinatorics problems—he used the same type of character (i.e., digits) to denote each stripe of the flag because he considered the creation of a flag to entail only a single type of quantity—an important step towards creating a system of notation that accounted for ordering.

**Michael’s Notating Activity for the Handshake Problem**

During the next teaching episode on 11/09/05, I presented Michael and his partner the Handshake Problem.

Excerpt 1: Michael’s notating activity during the Handshake Problem

M [writes “10 people” on his paper]: So its one A [Michael writes “1A”. He stops writing and looks up at the teacher.] A can’t shake his own hand, can he? [Michael clasps his left and right hand and moves them up and down as if to shake his own hand.]

T: No, A can’t shake his own hand.

M [Michael erases the “A” and replaces it with a “B”. He continues his notation writing “1C, 1D, 1E, 1F, 1G, 1H, 1I, 1J”]. No, wait. B is person 2. [Michael proceeds to write subscripts after each of the letters in his notation. After he writes “2A1” (Figure 3b), he says to himself]: But didn’t they [person 2 and person A] already shake hands? Yes. [Michael erases “A1”, replacing it with “B2”]. Noooo. [Michael erases “B2”, replacing it with “C3”]. I could have just wrote two three, two four, two five [i.e., “2-3”, “2-4”, “2-5”]. Oh well. [Michael continues until he has produced Figure 3c].

**Figure 3a (left), 3b (middle), & 3c (right). Michael’s notation for the Handshake Problem**
Analysis of Michael’s Notating Activity

The statement of the Handshake Problem, like the Flag Problem, referred to only one type of quantity, ten people. However, Michael did not notate the Handshake Problem as he had notated the Flag Problem. Instead, he used one letter and one number to notate handshakes, which was similar to his notation for the Outfits Problem. Choosing to use one letter and one number provides indication that, at least initially, Michael was differentiating between what was symbolized by the letter and number—one symbolized a person who was doing the handshaking (the “handshaker”), and the other a person who was having his hand shaken (the “handshakee”). After Michael wrote down “1A” for the first handshake, he stopped and asked the teacher whether a person could shake his own hand—indicating that he considered person A and person 1 to be the same person, despite his initial differentiation between “handshakers” and “handshakees”. After the teacher clarified that self-handshakes were not legitimate, Michael erased “1A” replaced it with “1B”, and continued with his notation (Figure 3a).

Prior to listing the handshake “2B”, which would have also symbolized a self-handshake, he stopped listing the handshakes, and said to himself, “No, wait. B is person 2.” He, then, returned to the top of his list of handshakes, and used subscripts to identify which letters and digits symbolized the same person (i.e., he wrote “1B₂” to show that person B and person 2 were the same person). He continued to write subscripts after each letter, and after writing “2A₁”, he stopped and said aloud, “But didn’t they already shake hands? Yes.” Michael’s original intention of writing the subscripts was so that he could more easily identify and eliminate self-handshakes. However, by creating the subscripts he also identified handshakes that he had already counted, and eliminated these handshakes as well. Doing so meant that in the process of creating his notation for the Handshake Problem Michael had to consider the difference and similarity between the handshake he symbolized as 1B and the handshake he had symbolized as 2A, and with his addition of subscripts he determined that they symbolized the same handshake.

His use of letters and digits, and his subsequent introduction of subscripts enabled him to use features of his notation for the Outfits Problem and features of his notation for the Flag Problem. That is, he initially used letters and digits to differentiate between handshakers and handshakees, which was similar to what he had done in the Outfits Problem. Subsequently, he associated a number with each letter using subscripts, which enabled him to identify person B and person 2 as the same person. Making this association enabled him to conclude that he could have used two digits (rather than a digit and a letter) in order to notate this problem, stating, “I could have just wrote two three, two four, two five”. Although he drew this conclusion, his more complex system of notation that included subscripts seemed essential to his progress towards developing a system of notation that accounted for ordering. It was essential to his progress because when he used only digits to notate the Flag Problem, he did not make a differentiation between a top and bottom stripe whereas in this problem he did differentiate between the first person shaking the second person’s hand and the second person shaking the first person’s hand in his system of notation.

Discussion

Michael’s progress towards developing a system of notation that accounted for ordering outcomes was a dynamic process in which he used and modified his notation from earlier problems in his solution of later problems. For instance, in creating notation for the Flag Problem, he used two characters to notate each outcome as he had in the Outfits Problem, but he introduced using the same type of character (i.e., two digits) to denote each flag. By modifying

his notation, he was able to capture progressively more complex aspects of the problem situations, and therefore his system of notation became more advanced over the course of the four teaching episodes. Moreover, the process of developing and refining a system of notation was both creative and time consuming (cf. Mason, 1996). It was creative in that it entailed Michael using notation in unconventional ways—he used subscripts to denote the equivalence of two people, an unconventional, but creative, usage of subscripts. It was time consuming in that it took approximately two hours of teaching time for him to develop a distinction that I probably could have suggested to him in a matter of moments (e.g., “you should use identical characters, and have the first character denote the top stripe and the second character denote the bottom stripe”). However, if students development of systems of notation is integral to their developing powerful mathematical reasoning, then it is critical for students to have experiences that offer the time and creative license to develop and refine these systems during their mathematics education. In turn, it is critical for researchers to map out trajectories for how students develop and refine systems of notation in a range of mathematical domains in order to design instructional sequences that can support this development.

THE ROLE OF PRECALCULUS STUDENTS’ QUANTITATIVE AND COVARIATIONAL REASONING IN SOLVING NOVEL MATHEMATICS PROBLEMS

Eric D. Weber  Marilyn P. Carlson
Arizona State University  Arizona State University
eric.d.weber@asu.edu  marilyn.carlson@asu.edu

This paper reports results of an investigation of precalculus students’ thinking as they responded to novel, precalculus-level applied problems. The subjects were six precalculus students and the data was gathered as the students were completing a one semester precalculus course. A primary goal of this study was to gain insights into the process by which these students made sense of the words in applied (word) problems. The study revealed the critical role of quantitative reasoning and the importance of students’ building a mental structure of a problem’s quantities and their relationships when orienting to novel applied problems.

Background

Mathematics educators have focused on the necessity of students having the ability to think about functions by attending to patterns of change (Kaput, 1985; Monk & Nemirovsky, 1994; National Council of Teachers of Mathematics, 2000; Vinner & Dreyfus, 1989). The National Council of Teachers of Mathematics (NCTM, 2000) Standards suggested that students should be able to analyze patterns of change in data and understand how to represent these patterns using various function representational contexts, such as formulas, graphs and data. It is well documented that high performing precalculus and calculus students have weak understandings of the function concept and have difficulty reasoning covariationally, or modeling function relationships involving the rate of change of one variable as it continuously varies with another variable(Carlson, 1998; Oehrtman, Carlson, & Thompson, 2008; Thompson, 1994). This ability to reason covariationally has been shown to be critical in using functions to model dynamic events (Carlson, 1998; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Thompson, 1994). While the ability to reason covariationally and construct quantities has been shown to be foundational for understanding key ideas of calculus, there is little research that explains in what ways covariational and quantitative reasoning affect students’ ability to respond to novel problem tasks. Thus, this study was designed to address this gap in the research literature.

Objectives and Research Question

In response to the widely reported difficulties students have using functions, we designed a study to investigate how a curriculum that focused on developing quantitative and covariational reasoning impacts students’ development of these abilities. The purpose of our research was to understand what role quantitative and covariational reasoning played in a student’s orientation to a novel problem that required students to use the function concept to represent how two quantities are related. Our research goals were to:

- Describe the ways of thinking students used to solve novel mathematics problems prior to receiving instruction in a redesigned precalculus course.
- Describe and explain how students’ ways of thinking and problem solving abilities changed or remained the same over the course of one semester.
- Explain the role that construction of quantity and covariation of quantity played in students’ orienting to novel applied precalculus problems.

Theoretical Framework

The study draws from Glasersfeld’s (1995) view of radical constructivism that learning begins and ends with the learner. He claimed that each learner’s mathematical reality is independent and unknowable to others in any absolute sense. Thus, we as researchers cannot be completely confident in our understanding of a student’s mathematical reality, but we can describe ways of thinking so that, were a student to have them, would, from the student’s perspective, give coherence and sense to their actions. The classroom is a place for students to develop ways of thinking about mathematics, although each student will use a personal way of thinking, since the reality he/she experiences is fundamentally tied to his/her prior experiences.

Quantitative and Covariational Reasoning

Quantitative and covariational reasoning are both explanatory and descriptive research frameworks. Each takes as central that the individual student constructs his/her reality. Specifically, both quantitative and covariational reasoning do not aim to describe reality as the student sees it, but instead the goal is to identify ways of thinking that explain students’ responses and behavior in solving mathematical tasks.

In Thompson’s (1990, 1993) characterization of quantitative reasoning, he described a quantity as a conceived attribute of something that one can imagine being measured. Quantity is a cognitive object specific to the individual student and because it is a cognitive object, a quantity is not the same for every learner. According to Thompson (1994), quantitative reasoning is the analysis of a problem-solving situation in terms of the measurable attributes of objects within a situation as conceived by an individual. A quantitative structure is a network of quantities and relationships between those quantities that comprise the student’s conception of the situation. Quantitative reasoning focuses on the importance of developing students’ ways of thinking to conceive of problem situations in terms of measurable attributes of objects within the described situation. As students engage in sense making in the orientation phase of problem solving, they conceptualize quantities; then form a basic notion of function by relating quantities in terms of invariant relationships among their values—as the quantities’ values vary, the relationships remain the same (e.g., Bob’s age is always 5 years greater than Jane’s). We refer to this sense-making process as building a quantitative mental structure. Once an individual has built this mental structure, we conjecture, as does Thompson, that the structure that emerges from seeing how two quantities are related is what allows students to construct meaningful formulas and define functions relating measurable attributes of a situation.

Carlson, Jacobs, Coe, Larsen & Hsu (2002) indicated that covariational reasoning involves attending to the values of two quantities and how they change together. Specifically, covariational reasoning is a way of thinking that involves first understanding that if two quantities vary simultaneously, at any time that one quantity has a measure, the other quantity has on a measure too. Engaging in covariational reasoning involves the learner initially constructing a sustained mental image of two or more coupled quantities, and understanding that those quantities could take on different values—and those values are systematically related by the quantitative relationships as conceived in the situation. Carlson et al. (2002) delineated a framework of five ways of thinking about how two quantities’ values change in tandem. Together, covariational and quantitative reasoning assume students’ mathematical realities are distinct and independent from any other mathematical knower and allow one to describe how students’ mental imagery affects their thinking. As a result, the frameworks are particularly
powerful for documenting and explaining students’ responses and actions in response to novel mathematical tasks.

Mathematical Problem-Solving

Based on the assumption that students create independent mathematical realities, this study assumed mathematical problem solving was an active, multi-tiered, internal process in which the students pose, use, reflect, and revise understandings in attempting to make those understandings fit the mathematical reality they experience. A great deal of literature has been written on mathematical problem solving (Blum & Niss, 2004; DeBellis, 1997; Goldin, 2000; Lesh, 1985; Lesh & Akerstrom, 1982; Romberg, 1994). Carlson, in (Carlson & Bloom, 2005) synthesized seminal studies in students’ solving novel, applied mathematics problems and proposed a problem solving taxonomy focused on the processes and behaviors students exhibit and progress through in a common problem-solving approach. Their work, coupled with quantitative and covariational reasoning, was the basis for analyzing and describing students problem solving behaviors and utterances while working on applied mathematics problems. The mathematicians under observation in this study were efficient in constructing a picture or describing a mental image of the problem situation. Carlson & Bloom (2005) referred to this problem-solving phase as orientation. Making sense of the problem, organizing information, and constructing possible solution approaches were the key behaviors associated with the orientation phase. The orientation phase also includes the construction of a picture or mental image, which is a focal point of quantitative and covariational reasoning. The findings of this study suggested the need for further investigation of the role that quantitative reasoning plays in orienting to a novel applied problem, and the role that covariational reasoning plays in constructing meaningful representations of the functions that related the two quantities.

Method

Subjects and Setting

The authors tracked six students over the course of a one-semester, redesigned, precalculus course. All subjects participated voluntarily and received monetary compensation for their time. Two students were female and four were male. All were enrolled in a redesigned precalculus course that focused on developing students’ ability to reason conceptually about functions and quantity as they solved complex mathematical problems. These students were identified as high-performing, middle-performing, and low-performing based on a pre-calculus assessment instrument designed to predict a student’s success in a conceptually based precalculus course (Carlson, Oehrtman, & Engelke, 2009). Two students earned a C in the course, three earned a B, and one student earned an A. Three of the six students planned to enroll in calculus I the following semester.

Data Collection

All six students attended every class session over the course of the semester. The research team interviewed each student in an individual clinical interview at six different times during the course. The sequence of six interviews focused on gaining insights into students’ understanding of function, exponential growth, and trigonometric relationships. The students attempted to solve three mathematics problems in each interview session that were not presented during class. In addition, at the beginning of each interview we asked each subject if she/he had remembered seeing the problem before. If the student remembered the problem, that problem was excluded...
from that subject’s interview. This issue occurred only once, resulting in our eliminating the interviews on this problem from our study. Students were videotaped, with permission, during classroom sessions and clinical interviews. Students’ written work was scanned as a backup if the camera was not able to capture what the student wrote during the interview or classroom session.

Analysis

We synthesized and coded using a combination of open and axial coding as described by Strauss & Corbin (1998). We initially employed open coding with the video data to identify episodes we believed fell into the orienting phase of problem solving. The next level of coding broke these episodes into specific categories of making sense of the problem, organizing information, and constructing possible modes of solution. The video data was then coded for episodes the authors believed the students used quantitative and covariational reasoning to orient to a problem. Other emergent categories included coordinating changes in number, anticipating the behavior of numbers, and anticipating the behavior of function thinking about quantity. We used axial coding to characterize how the coded categories were related. For example, we intended to explain how the initial sense making of the problem related to the student anticipating the behavior of numbers. In this way, we took over thirty emergent categories from open coding and abstract them into four major categories. The major explanatory categories that emerged from the data were identified as covariation of number, covariation of quantity, formation of quantity, and quantitative structure.

Results

Students oriented to problems by attending to the numbers in the situation, and students often explicitly described numbers as measuring an aspect of a situation. The results discussed here focus on students’ work on the box problem that initially prompted students to develop a formula for the volume of a box formed by cutting equal sized square cutouts from a 14 inch by 17 inch piece of cardboard. We present two students’ work that is representative of the larger group of six students we tracked during the semester.

Orienting with Numbers: Adam

Three of the six students approached the box problem by focusing explicitly on the numbers in the problem. This specific example displays the student orienting to the problem by focusing on given numbers, and attempting to find a formula given a specific cutout length. The student’s focus on number is most apparent when he states that, “to be really sure, you would have to check as many numbers as you could until you knew the formula was right.” Over the course of the semester, this student reconceptualized his approach to problem solving, even stating that, “I have to think about what the numbers represent before I try to use them”, at the conclusion of the semester.

1 INT: We talked earlier about volume, now I’d like to focus on that.
2 STU: Okay.
3 INT: The problem asks you to construct a formula for the volume of the box. What does that make you think might be useful?
4 STU: Well, I need. Well, what I would do is in math I usually try something and try out a few things to see if it fits.
INT: Could you say more about what you mean?

STU: Well, basically in this case I just come up with a formula, and I am used to plugging in a few values to see if it works.

INT: Okay, I think I see what you mean, but why don’t you show me what you mean?

STU: Alright, so I have this formula \((14-2(1.5))(17-2(1.5))\)

INT: Okay, so what led you to that formula?

STU: Well, I took the numbers out of the problem, so I know the length and the width of the box, which are 14 and 17. Then I decided to try out if I cut a square corner that had sides 1.5 inches, so then I would multiply \((14-2(1.5))(17-2(1.5))\), oh I would probably have to multiply by 1.5, so it’s length and width and height.

INT: Can you tell me why you think your formula is accurate?

STU: Well, I am pretty sure, to be really sure, you would have to check as many numbers as you could until you knew the formula was right.

Figure 1. Orienting with number

**Orienting with Quantity: Brad**

Brad approached the box problem by attending to quantities. Brad focused on the formula as secondary to thinking about the relationship between the length of the side of the cutout and the volume of the box. Approaching the problem by thinking about the relationships between quantities allowed Brad to imagine the behavior of the box as the cutout changes, rather than needing to explicitly calculate the volume using numbers. As a result, the numbers for cutout length were simply a specific representation of a number of possible values measuring a quality of an object rather than a number in and of itself.

INT: The problem asks you to construct a formula for the volume of the box. What does that make you think might be useful?

STU: Well, the volume of the box is formed by the length, width and height of the box. The length, width, and height of the box all depend on how big you make the cutout.

INT: Okay, I think I see what you mean, but why don’t you show me what you mean?

STU: Alright, so I have this formula \(x(17-2x)(14-2x)\).

STU: Well, it’s not hard to figure out what’s happening to each piece of the formula. The length and width get smaller as you increase \(x\), which is the cutout size. But the height, which is the same as your \(x\), gets bigger. So you kind of have to figure out how the decrease in the length and width balance the increase in height.
INT: That’s really interesting, could you say more about what you mean by balance?

STU: Well, you have to think about the volume, and the volume depends on umm… the length, width, and height of the box. So if the increase in the height outweighs the decreases in the length and width, the volume should increase. Umm… [long pause]. I’m just not sure how to determine the outweighing, I’d probably plug some values in.

---

**Figure 2. Orienting with quantity**

*Thinking Covariationally: Adam*

Brad conceptualized measurable attributes of the box in the box problem was able to consider the issue of “balancing” the length, width and height of the box. Like Brad, Adam was able to imagine all possible values for the length and width of the box by constructing the qualities of the object and imagining those qualities having measures, and represented these values on the x axis. Adam’s image of a quantity’s measured attribute resulted in his image of a continuum of values represented by x, which allowed him to describe the volume as increasing to a certain point, then decreasing.

INT: What can you say about how the volume of the box changes with respect to the cutout length?

STU: Well, it goes up to a certain point, then it goes down, then it gets negative.

INT: What are you thinking about as you tell me how the volume changes?

STU: Well, my calculations show that the volume increases to a certain point, then it decreases.

INT: Does your description match what you understand about the box?

STU: Yeah, I guess so. I guess I got the formula from the parts of the box, and then I can imagine plugging in all sorts of numbers to each part of the formula and then multiply those numbers to get the volume. Like, once I have the box, I have that box, and the formula is all I need to find the volume, so I don’t need to think about the box.
Figure 3. Covarying quantity

Discussion

The students’ responses indicate that construction and covariation of quantity are central to student’s problem solving approaches to novel tasks. Covariation of quantity is in contrast to covariation of number. The former involves the student’s mental construction of a measurable attribute of an object and imagining that attribute having a range of measures, while the latter focuses on numerical representation without understanding the context that produced the number. In orienting to a problem solving task, if a student makes sense of the problem by thinking purely about plugging numbers into a formula he or she might be able to answer a question that asks about the volume of the box for a specific cutout value. However, that student might have great difficulty considering a problem that asks students to consider a dynamic situation like the box problem. If a student’s mental image of a situation consists of measurable attributes of an object, he/she can imagine the attribute’s measure varying. Imagining varying measures of an attribute supports a student developing a sustained image of two quantities changing in tandem. For students in this study, orienting to a problem by constructing quantitative relationships allowed them to think about the result of an action (changing the cutout length) on the length, width, and height of the box. Understanding how each attribute of the box changed allowed them to anticipate how the volume of the box varied while imagining varying values of the cutout length. The results suggest that it is critical for students to construct a mental image of the situation by reasoning quantitatively to solve novel problems with numerous related parts.

THE ROLE OF THE RADIUS IN STUDENTS CONSTRUCTING TRIGONOMETRIC UNDERSTANDINGS

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

Multiple studies have identified students and teachers having difficulty constructing meaningful and coherent understandings of trigonometric functions. Furthermore, research has revealed that students have difficulty reasoning about topics foundational to trigonometry, such as angle measure and the radius as a unit of measurement. This study conjectured that these foundational understandings are central to constructing coherent understandings of trigonometric functions. Stemming from this conjecture, an instructional sequence was designed to promote students constructing and leveraging understandings of the radius as a unit of measurement. This report discusses the results of an undergraduate precalculus student’s interactions with these materials.

Background

Although trigonometry was once labeled “forgotten and abused” in mathematics education (Markel, 1982) due to the limited focus given to trigonometry by mathematics educators, multiple studies have recently shed light on the difficulties students encounter when reasoning about the sine and cosine functions. As one example, Weber (2005) found that students have difficulty constructing the geometric objects of the various trigonometry contexts as tools of reasoning (e.g., the unit circle and right triangles). Other studies have revealed that students have difficulty reasoning about topics that are foundational to trigonometry (Brown, 2005; Fi, 2003; Moore, 2009), such as angle measure and the radius as a unit of measurement.

Thompson (2008) recently called attention to the important role that ideas of angle measure and the radius play in conceptualizing the sine and cosine functions. He also outlined an instructional approach that he conjectured would promote students developing meaningful conceptions of the sine and cosine functions. This study builds on Thompson’s ideas by investigating the implementation of instructional tasks whose design was based on the conjectures provided by Thompson.

Specifically, this study reports results of one student’s interactions with instructional tasks designed to promote students constructing robust understandings of angle measure and the radius as a unit of measurement. The curriculum was also designed such that students could leverage these understandings when reasoning about the sine and cosine functions as the covariation of an angle measure and a second quantity. The design of the curriculum was also informed by research on reasoning abilities the researcher deemed critical for success in trigonometry, such as quantitative and covariational reasoning (M. Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Smith III & Thompson, 2008). The results presented in this report describe the student’s thinking as he solved the instructional tasks. The student’s actions reveal him constructing a coherent system of ideas of the radius as a unit of measurement and the sine and cosine functions.

Theoretical Perspective

Quantitative reasoning (Smith III & Thompson, 2008) provides a theory that emphasizes a learner centered approach to mathematics. Quantitative reasoning describes the processes of a learner conceiving of quantities and relationships between quantities such that these mental
structures promote mathematical reasoning. More specifically, quantitative reasoning refers to the mental actions of an individual conceiving of a situation, conceptualizing measurable attributes of this situation (called quantities), and reasoning about relationships between these quantities. The mental structure generated from these processes offers a foundation upon which the student can reflect on and subsequently construct mathematical understandings.

As an example, a student might conceive of a ball traveling in a circle around some central point. As the student refines her or his image of this situation such that he or she constructs attributes admitting measurement processes (e.g., the quantities of a traversed arc length and a vertical distance above the central point), the student can subsequently engage in covariational reasoning (M. Carlson, et al., 2002). That is, the student can investigate the nature of the dynamic relationships between the relevant quantities. These investigations can lead to the production of mathematical representations (e.g., graphs and formulas) and understandings that emerge from the student’s image of the situation. This process of a student engaging in quantitative reasoning and reflecting on this reasoning formed a central intent of the instructional sequence.

The main questions driving this study were: i) “What understandings of the radius as a unit of measurement do students construct during the designed instructional sequence?” and ii) “How do these understandings influence their conceptualization of the sine function in the contexts of the unit circle and right triangles?” Overall, the study investigated students’ understandings of the cosine function in addition to the sine function, but for the purposes of this report only a student’s conception of the sine function is discussed.

**Methodology**

The results of this study focus on one student, Zac, who was drawn from an undergraduate precalculus course at a large public university in the southwest United States. The precalculus classroom was part of a design research study where the initial classroom intervention (M. P. Carlson & Oehrtman, 2009) was informed by theory on the processes of covariational reasoning and select literature about mathematical discourse and problem-solving (M. Carlson, et al., 2002; M. P. Carlson & Bloom, 2005; Clark, Moore, & Carlson, 2008). The classroom instruction consisted of direct instruction, whole class discussion, and collaborative activity. The head of the precalculus curriculum design project was the professor of the course and the student discussed in this report was chosen on a volunteer basis. Additionally, the student was monetarily compensated for his time.

The study used a teaching experiment methodology (Steffe & Thompson, 2000) to gain insights into the student’s thinking. The researcher (myself) conducted six ninety-minute teaching sessions with Zac and two of his peers, where the researcher acted as the students’ instructor. Additionally, multiple interviews totaling four hours were conducted with Zac at various points during the study. The interview sessions offered additional insights into Zac’s thinking as a result of the one-on-one setting of these interviews. The interview sessions followed a clinical interview protocol (Clement, 2000), with the added feature of the researcher presenting “on the fly” problems to Zac in response to the solutions he provided. A witness, who was a fellow researcher on the precalculus research team, attended all teaching and interview sessions and frequently met with the researcher to discuss their observations. Also, the researcher relied on video observations between teaching sessions to inform the design of the instructional and interview tasks.
All classroom and interview sessions were videotaped and digitized. Upon completion of the study, all video data was first transcribed (for both utterances and visual actions) and subsequently analyzed using an open coding approach (Strauss & Corbin, 1998). The researcher analyzed Zac’s behaviors in an attempt to determine the mental actions driving Zac’s solutions. Then, the researcher attempted to identify connections and consistencies in Zac’s thinking in an effort to identify the relationship between Zac’s conception of the radius as a unit of measurement and his reasoning.

A Brief Conceptual Analysis Of Trigonometry

In order to provide a background for the analysis of Zac’s actions and the intentions of the instructional activities, this section briefly outlines the system of ideas that informed the instructional goals. A central goal of the study was to support the student in constructing a process, or derivation, of measuring an angle. As Thompson (2008) described, one coherent understanding of angle measure is the image of measuring the length of an arc subtended by the angle. In this approach, the degree is a unit of an angle’s measure that corresponds to an angle subtending 1/360th of any circle’s circumference, and the radian is a unit an angle’s measure that corresponds to an angle subtending 1/(2π)th of any circle’s circumference (provided the circles are centered at the vertex of the angle). In the case that the radius is used as the unit to measure an angle, the measure also conveys that the subtended arc length is so many times as large as the radius of the corresponding circle.

In order to leverage an image of measuring an angle that is reliant on a subtended arc length, as well as the radius as a unit of measurement, the sine function was introduced within the context of circular motion. The sine function was presented as the mathematical formalization of a covarying arc length and a vertical position. Also, the output of the sine function was defined as a measurement relative to the radius (Figure 1). This design decision was made to create a quantitative meaning of the output of the sine function that enabled the student to reason about the radius as a unit of measure for a circle of any size.

Results

Zac entered the teaching experiment with a self-admitted limited understanding of angle measure. When presented with an angle and the angle’s measure during the pre-interview, Zac was unable to describe a clear meaning of the angle’s measure. Zac claimed, “I never really thought about [angle measure].” Zac was then unable to measure an angle when given the supplies of a compass, a ruler, and a piece of string. After the researcher gave Zac the supplies, he immediately claimed that he was unable to accomplish the goal of measuring the angle.

also described geometric objects as having predefined angle measures (e.g., a straight line is 180 degrees), but he was unable to describe these measurements as the result of a process of coordinating quantities.

In response to the difficulties Zac encountered during the pre-interview, the instructional tasks were designed to engage Zac in creating tools (e.g., a protractor) to measure an angle. After Zac constructed an understanding of degree measurement that was consistent with the instructional goals (e.g., measuring a fraction of a circle’s circumference subtended by the angle), Zac engaged in an activity prompting him to create a circle using a piece of string as the radius. He was then asked to measure the circumference of the circle in a number of string lengths. After Zac identified that $2\pi$ string lengths, or radii, rotate along a circle’s circumference, the researcher asked Zac to explain using the radius as a unit of arc measure. Zac responded, “it simplifies a circle…the circumference of a circle is equal to two pi $r$, where the radius is the unit, not inches, or anything like that. So it simplifies it…using [the radius] as an actual unit…one radius, and then the circumference is six point two eight radius.” Zac’s actions reveal that he imagined measuring the circumference and radius of a circle in a number of radii, which implies that he conceptualized the radius “as an actual unit” of arc measure. This image enabled Zac to conceive of $2\pi$ radii rotating through any circle’s circumference and a circle having a radius of “one radius” (e.g., the unit circle).

The Arc Problem

Using the following diagram, determine an algebraic relationship between the measurements $r$, $\theta$, and $s$.

![Diagram of a triangle with sides $r$, $\theta$, and $s$.]

After Zac conceived of arcs as measurable in a number of radii, he flexibly solved problems requiring him to reason about radian angle measures. For instance, he had no difficulty converting between a linear measurement of an arc (e.g., a number of inches) and a number of radians. He justified his calculations by reasoning that an angle’s measure in radians conveys the number of radii along the subtended arc for a circle (centered at the vertex of the angle) of any size. Also, he was able to generalize his conception of radian angle measures such that his reasoning did not rely on numerical values and executing calculations. As an example, consider his solution to The Arc Problem, and note that the symbolic relationship between the three quantities was not formalized previous to Zac’s attempt to solve this task.

After establishing that the angle’s measure was in radians, Zac constructed an algebraic relationship between the various measurements (Excerpt 1).

<td>Alright. We'll say theta equals radians (writing $\theta = \text{rad}$), very very simple then. $r$ theta is equal to $s$ (writing $r\theta = s$). 'Cause theta is in radians, that means a percentage of the radius. Which would then be equal to this length (tracing arc length). So you multiply the percentage of the radius by the radius, you'll get the arc length.</td>

Zac conceived of theta (a number of radians) as representing a fractional amount of the radius length (lines 2-4). Zac’s image of a radian measure conveying a multiplicative comparison between an arc and the length of the radius led to his ability to anticipate multiplying the percentage of a radius length by the radius to obtain an arc length (lines 3-5). That is, Zac’s algebraic representation stemmed from his ability to reason about measuring an undetermined arc length as a fraction of a radius length.

After Zac created his formula, the researcher prompted Zac to explain the formula \( \theta = \frac{s}{r} \). As opposed to providing a procedural explanation (e.g., dividing both sides of his previous formula by \( r \)), Zac explained, “Well this is… a percentage of a radius length over a radius… a ratio, that’ll give you a percentage of \( r \)” Thus, Zac’s ability to conceive of a subtended arc length as a percentage of a radius enabled him to interpret a presented formula relative to a relationship between the quantities of the situation.

The Ferris Wheel Problem

Consider a Ferris wheel with a radius of 36 feet that takes 1.2 minutes to complete a full counter-clockwise rotation. April boards the Ferris wheel at the bottom and begins a continuous ride on the Ferris wheel. Construct a function that relates the total distance traveled by April and her vertical distance from the ground.

As Zac progressed through the study, his ability to reason about measuring a quantity as a fraction of a circle’s radius enabled Zac to imagine measuring various attributes of circular motion in a number of radii. As an example, consider Zac’s actions on The Ferris Wheel Problem. Zac first recognized that he needed to measure the distance along an arc from April to the standard position (e.g., 3 o’clock). He then constructed the expression of \( \frac{Td - 56.5}{36} \) to represent this distance, while explaining that \( Td \) represented the number of feet April traveled along the arc swept out by her ride. Zac then explained that the entire expression represented the measure of the angle April swept out in a number of radians. He also explained that dividing her distance along the arc in feet by thirty-six represented a number of radius lengths from the standard position.

Next, Zac constructed the expression of \( \sin \left( \frac{Td - 56.5}{36} \right) \) and stated that this expression represented “the vertical distance… a percentage of the radius length, which I then need to multiply by thirty six.” In this case, Zac leveraged his understanding of the sine function outputting a quantity measured relative to the radius in order to convert the output unit. This resulted in Zac constructing the function \( vd = f(Td) = 36 \sin \left( \frac{Td - 56.5}{36} \right) \).

Zac continued modifying his solution and explained that the output of the sine function is a vertical distance above the center of the Ferris wheel, and that the correct function is \( vd = f(Td) = 36 \sin \left( \frac{Td - 56.5}{36} \right) + 36 \) (e.g., a vertical distance from the bottom of the Ferris wheel). Thus, Zac’s solution process included various refinements that reflected reasoning about the quantities of the situation and measuring these quantities in a fraction of the radius. Zac’s ability to reason about measuring lengths as a fraction of the radius enabled Zac to convert between units of measurement as needed, while representing these conversions in his function.

The Empire State Building Problem

While site seeing in New York City, Bob stopped 1000 feet from the Empire State Building and looked up to see the top of the Building. Given that the angle of Bob’s site from the ground was 56 degrees, determine the height of the Empire State Building.

Similar to his actions during The Ferris Wheel Problem, Zac frequently used the radius as a tool of reasoning within the various contexts of the instructional activities. For instance, during the first instructional activity that presented a right triangle context (The Empire State Building Problem), Zac used the hypotenuse of the right triangle to construct a circle and right triangle in the same orientation as Figure 1. Zac then correctly solved the problem using the sine and cosine functions while continually referencing the hypotenuse as “the radius.” In response to Zac creating a circle and reasoning about a radius, the researcher asked Zac to further describe his actions (Excerpt 2).

1  Int: So what told you to put this in a circle like this? Why did you make that choice?
2  Zac: Um, to make it easier to understand. How I was originally taught was just with triangles. Now that we've started using circles it makes a whole lot more sense to me.
3  Int: So could you say a little bit about why it makes a little more sense now?
4  Zac: Uh, because I always just thought hypotenuse was, you know, just a side of a triangle. You know, you could use Pythagorean's Theorem to find out what it was very easily. And now that we've figured out, you know, now I'm looking at it and seeing it's the radius, it makes a lot more sense to be able to find, the horizontal and vertical distance according to the radius (waving tip of pen across the radius).

Zac’s descriptions suggest that he found value in “using circles” to relate an angle measure and another quantity (lines 3-5). Also, Zac explained that he conceived of the hypotenuse as only a side of a triangle previous to participating in the teaching experiment (lines 7-8). He then explained that his understanding now consisted of conceptualizing the hypotenuse, or radius, as a unit of measurement (lines 9-12). Thus, Zac’s image of the radius as a unit of measure created a tool of reasoning that enabled him to imagine using the hypotenuse of a right triangle as a unit length, as opposed to “just a side of a triangle.”

Discussion and Conclusions

Zac’s actions offered insights to his conceptualization of the radius as a unit of measurement and the reasoning abilities that followed from this conceptualization. Zac entered the study with a self-admitted limited understanding of angle measure, but his participation in the teaching experiment led to him constructing meaningful conceptions of angle measure. Specifically, Zac conceptualized measuring along a subtended arc in a number of radius lengths. This image enabled Zac to imagine the radius of any circle as a unit length, regardless of the size of the circle. Also, Zac conceptualized that measuring along the circumference of any circle in units of the radius yielded a measurement of $2\pi$ units. In other words, Zac’s ability to imagine measuring quantities in a number of radii enabled him to conceive of any circle as the unit circle. Zac also

explained that measuring quantities relative to the radius made circular contexts “easier” because this action simplified any circle to a circle with a radius length of “one radius.”

Zac’s conceptualization of the process of measuring a quantity in a number of radii also led to Zac conceiving of radian measures in terms of a quantitative relationship. Specifically, Zac fluently reasoned about radian measures as a multiplicative comparison between indeterminate measures of a length and the radius. For instance, Zac generated the formula of \( s = r\theta \) without having to perform calculations between numerical values.

Zac engaged in similar reasoning in order to use the sine and cosine functions with circles of any size. On The Ferris Wheel Problem, Zac leveraged his quantitative understanding of the radius as a unit length to reason about measuring the distance traveled and the vertical position of a rider relative to the radius. His image of the quantitative relationship conveyed by a measurement relative to the radius enabled him to anticipate converting between measurement units without carrying out numerical calculations. This led to him defining a function that modeled the individual’s ride on a Ferris wheel.

The reasoning abilities exhibited by Zac also led to him creating coherence between right triangle trigonometry and unit circle trigonometry, which has been reported to be a difficult task for both students and teachers (Thompson, Carlson, & Silverman, 2007; Weber, 2005). Zac’s flexible conception of the radius as a unit of measure led to him imagining the hypotenuse of a right triangle as the radius of a circle. This enabled him to reason about measuring the legs of a right triangle relative to the hypotenuse. This image resulted in Zac using the sine and cosine functions in ways consistent with their use in a unit circle context (e.g., the outputs of the functions represented measurements relative to the hypotenuse, where the hypotenuse formed the radius of the circle).

Zac’s actions illustrate the importance of a student conceptualizing the radius in ways that it becomes a tool of reasoning. A student that develops an image of the radius such that they can imagine measuring quantities relative to the radius (by making a multiplicative comparison) is prepared to coherently use the radius and trigonometric functions in multiple contexts. The student can imagine measuring quantities relative to the radius (or hypotenuse) for a circle (or right triangle) of any size, while flexibly converting between the given measurement unit and a number of radii. That is, the student can conceive of any circle as a circle with a radius of one unit or any right triangle as a triangle with a hypotenuse of one unit. These reasoning processes can enable a student to fluently use the sine function (and cosine function) in novel situations that consist of circular motion or right triangles.

It is widely agreed that the development of problem-solving ability should be viewed as the primary goal of school curriculum and instruction. While this goal has been a persistent part of mathematics education community for over a century, issues regarding how to develop problem solving skills among learners continues to be a major dilemma. There is little known about how students' problem-solving ability develops over time and ways in which these skills might be nurtured along a developmental trajectory. In our study we administered three non-routine problems to approximately 350 students in grades 5 and 8 to trace their mathematical problem solving skills at the end of elementary and middle grades. The content of problems concerned proportional reasoning, geometry and visualization and probability. These areas were selected since they have been identified as core content areas in K-8. The approaches from 5th and 8th graders to the same problems were studied, categorized, and using theoretical framework provided by Silver (1987). In particular, we sought evidence of pattern recognition, representation, understanding, memory schemas among children’s work and ways in which the choices of children changed from 5th to 8th grade. Our results indicate an improvement in the area of “understanding of problems” from 5th to 8th grade, which could imply the existence of better content knowledge related to these problems. Preference to more "mathematical" approaches (i.e. equations and formulae) increased as the increased. According to Siegler (2005), students choose adaptively among the strategies they knew when they came across a problem. Thus the result indicated that more students were familiar with those strategies and were able to apply them based on the understanding of the problems. The memory schemata in the context of probability content were found to be poorly developed.

Standardized approaches and textbook representations were noted most frequently in higher grades. Variety and creativity, which are important features of mathematical thinking, were less distinguished. Various types of examples need to be used and the use of multiple representations when solving problems needs to be more encouraged in classroom instruction in order to expand memory schemata among children.

IDENTIFYING THE REASONING STRATEGIES STUDENTS USED WHEN SOLVING RELATED RATES PROBLEMS

David Sousa  
California State University, Fullerton  
davidsousa@csu.fullerton.edu

Nicole Engelke  
California State University, Fullerton  
nengelke@fullerton.edu

Related rates problems serve as a source of difficulty for first semester calculus students. While many studies have investigated concepts related to solving related rates problems, there are few that focus on related rates problems themselves. Engelke (2007a, 2007b) found that students fixated on procedural steps, which prevented them from building a mental model of the situation. Without having a mental model of the situation, the students were less likely to engage in transformational and covariational reasoning about the problem situation, which led to procedural traps. We hypothesized that students who participated in a Supplemental Instruction (SI) workshop would engage in debates that would promote higher levels of reasoning while working on related rates problems. These higher levels of reasoning would foster the development of their mental models for the problem situations.

The students in our study were first year calculus students that are coming from two or more standard lecture courses and have the option to participate in an SI workshop. During five SI sessions the students worked in small groups to solve problems provided by the SI leaders. These sessions were videotaped and transcribed for analysis, and we were able to determine what types of reasoning structures the students were utilizing.

The coding process sought to locate, identify, and count the number of times the students used one of the four types of reasoning processes described by Lithner (2003, 2004): Global Plausible Reasoning (41%), Local Plausible Reasoning (24%), Identification of Similarities (15%), and Established Experiences (20%). While the students frequently began the problem solving process using the superficial reasoning strategies of IS and EE, they frequently progressed to plausible reasoning strategies as a result of engaging in debates about the problem solving process. It appears that the SI model created an environment that promotes LPR and GPR by having the students work on challenging problems, and subsequently strengthened the students’ problem solving abilities. The workshop setting moved students toward the LPR/GPR strategies; working on one’s own does not create the cognitive dissonance necessary to spark the debates.

“I JUST DON’T GET IT”:
READING AND COMPREHENDING MATHEMATICS TEXT

Jean M. Mistele 
Virginia Tech 
jeanm@vt.edu

Patterson Rogers 
SUNY-Albany 
pr774936@albany.edu

Our study examines the notion that many undergraduate students do not read their mathematics textbook due to weak reading comprehension skills. The National Council of Teachers of Mathematics (NCTM) Standards promotes mathematical discourse and writing yet fails to address the connection to reading comprehension skills. Sanacore and Palumbo (2009) describe the fourth grade slump, where students make a transition from learning to read, to reading to learn. They contend the transition requires that students possess strong comprehension skills and that students must acquire the capacity to transfer their knowledge of comprehension techniques for narrative text to informational context. Hall (2007) informs us that researchers “have typically focused on how to help content area teachers implement strategy instruction into their classrooms…. [perhaps] strategy instruction alone … [are] not sufficient” (p. 307). There is limited research linking reading techniques to mathematics. Hyde (2006) informs us that many teachers focus on key words in a word problem as an instructional method to solve them, but this approach unintentionally tells students, “you don’t have to read; you don’t have to think. Just grab the numbers and compute” (p 3). In addition, Donahue (2003) indicate that many teachers in the middle grades and secondary grades “resist teaching reading because they think it is ‘someone else’s job’…” (p. 26).

We believe students’ struggle in mathematics courses may be attributed to their weak reading comprehension skills. Our study examines three reading comprehension techniques that may improve mathematics understanding, knowledge and may promote students’ learning of mathematics.

As constructivism becomes more prominent in special education and inclusion classrooms, general and special education teachers need teaching methods designed to help students with learning disabilities succeed within constructivist mathematics curriculum (Woodward & Montague, 2002). To develop these methods, special education researchers need to study the experiences of students with learning disabilities in constructivist mathematics to determine any special needs they may have. Certain characteristics of constructivism, such as multistep problems with heavy cognitive load and students presenting lengthy rationale for solutions, can potentially create difficult situations for students with learning disabilities who commonly have working memory deficits. While storage of information appears to be a primary cause of difficulty, processing efficiency and level of understanding of mathematical concepts are also potentially interrelated factors (Keeler & Swanson, 2001). The researchers in this study examined the experiences of a fourth grade student with a learning disability and working memory deficits within constructivist mathematics curriculum (Simon & Tzur, 2004). The participant was more motivated and successful with the curriculum when the instructor accommodated for her disabilities by helping her with storing information (sometimes by helping her develop her own strategies for storing and organizing information) and clarifying what the problem was asking.

We investigated the secondary school teacher’s role in engaging students in the process of proving. Classroom practices of two experienced mathematics teachers were examined. In particular, verbal exchanges between the teacher and student(s) that promoted students’ need for and refinement of coherent arguments are discussed. Teachers used a variety of techniques to promote discourse about proof, including selection of rich tasks, use of strategic questioning, and peer critiquing of proofs. Students’ recognition of and adoption of discursive rules of the mathematical community were evident in student critiques of peer proofs.

Introduction

There is no shortage of evidence that high school students struggle with reasoning and proof (Balacheff, 1988; Chazan, 1993; Harel & Sowder, 1998; Senk, 1985, 1989). Authors have speculated about the sources of student misconceptions by examining typical high school classroom interactions (Herbst, 2002a, 2002b). Researchers, educators, and policy makers have postulated that overemphasis on (or inappropriate use of) two-column proofs, focus on proving self-evident statements, and lack of attention to the purposes of and need for justification in mathematical settings contribute to the poor outcomes that have been documented (NCTM, 1989; Weiss, Herbst, & Chen, 2009).

In courses that emphasize mathematical proof and reasoning, teachers aim to help students learn to value, recognize, and produce valid mathematical justification. In this paper, we define mathematical justification as both a process and a product. The process of justifying requires that the justifier recognizes a need for a mathematical argument, analyzes the relationships and facts in a situation, and then constructs an argument that she or he finds convincing. It is also understood that in any social community, the argument or justification has limited value unless it also convinces others and helps them develop a deeper understanding of the underlying concepts (Hanna, 2000; Thurston, 1995). We use the phrases “mathematical argument” and “mathematical justification” interchangeably to mean a valid rationale for a mathematical claim. Such justifications may be presented verbally, pictorially, or in writing.

The goal of helping students learn to formulate clear, concise, and mathematically viable arguments is a lofty one. Not only must the students develop understanding of the facts and relationships in the subject matter, but, additionally, they must have sufficient facility with the language of mathematics to express their ideas in a way that is consistent with norms of the discipline. They must also possess sufficiently strong general communication skills to translate the ideas they form in their own minds into logically ordered statements that conform to mathematical syntax, as well as the syntax of the language in which they are communicating.
Again, for those who spend time in U.S. mathematics classrooms, it is clear that making meaningful progress in all of these areas is a tall order.

The goal of this study was to examine the classroom practices for teaching proof used by teachers who are recognized by colleagues, supervisors, and other informed observers as being particularly effective. We hope that by closely examining various aspects of the pedagogy used by these teachers, we might glean information about teaching practices that enable students to successfully learn to develop robust mathematical arguments.

**Theoretical Perspectives**

There are many factors that influence teaching and learning in a high school classroom. Among these factors are student motivation, school ethos, community values, access to educational resources, and family priorities. Although we acknowledge that such factors influence what happens in school, our investigation was focused on classroom events, decisions, and actions within the control of the teacher. In particular, we examined the verbal exchanges between teachers and students to characterize classroom events, teacher actions, and students’ responses. Sfard (2000, 2001) characterized thinking as communication and learning as gaining access to a disciplinary discourse. She also described *object-level rules*, rules governing content of a discipline, and *meta-discursive rules*, rules governing the flow of information exchange within a discipline. Using her description, students’ understandings may be assessed by determining the extent to which they are able to follow these discursive rules. Sfard’s (2000) research also revealed that differences in classroom environments and expectations could lead to differences in students’ perceptions of the meta-discursive rules. This suggests that to make inferences about students’ justifications, researchers must gather evidence by means of verbal or written communication and should consider the meta-discursive rules of the classrooms in which the students participated. If the learning experience is successful, students’ communications should reflect the rules and norms of the classroom, or, better yet, the rules and conventions of the discipline. If their communications are at odds with the meta-discursive rules of the learning environment or the discipline, we should reflect on why this has happened.

Maher (2009) asserted that proving can arise naturally from activities that teachers create for their classrooms and the questions that they ask. Elementary-school students in her study developed more sophisticated arguments when they were pushed by the researcher to elaborate on why they knew that their assertion was correct. Weber, Maher, Powell, and Lee (2008) showed that group discussion can promote improved reasoning by putting students in a position to have their warrants challenged. In this study, we sought to determine how the teacher’s role in developing a discourse-rich environment, including the facilitation of group discussion, may influence students’ developing awareness of meta-discursive rules for communicating mathematical justifications or object-level rules about the nature of proof in mathematics.

**Research Questions**

Three research questions guided our observations and data collection:

1. What practices were used by two experienced, highly recognized mathematics teachers to support a discourse-rich classroom environment?
2. What practices were used by the teachers to promote mathematical justification?
3. What evidence was there that students were able to communicate using the meta-discursive rules of the discipline?

Methodology

The first author spent several weeks observing and videotaping the geometry classes of two experienced, highly recognized high school mathematics teachers. One teacher’s school was in a suburb of a large Midwestern city in the United States. His classes were proof-based, honors-level geometry courses. The other teacher’s school was in a predominantly rural community in the Midwest. His classes were proof-based geometry courses and did not have an “honors” designation. Classes were videotaped and field notes were taken to record noteworthy events. Videos were reviewed in search of patterns of teacher behavior, particularly those that pertained to the teaching and learning of proof; more specifically, we looked for teacher practices that enhanced the quality and/or quantity of student participation in discourse related to justification and/or proof. We used an open-coding strategy (Glaser & Strauss, 1967) to look for patterns across the data for the two participants, resulting in such categories as directing [possibly modified] questions back to the student, directing students to question other students, probing for elaboration, posing discourse-promoting tasks, etc. Some videos were also transcribed as a way to analyze the discourse more carefully.

Results

Promoting Discourse

Both teachers used several common practices that may have contributed to the development of a discourse-rich environment. First, both teachers had chosen, independently, not to use the typical two-column proofs in their courses, but rather to have students write paragraphs to support their claims. The requirement that students speak and write arguments in their own words in both classrooms contributed to high levels of student engagement in lessons, as well as to a sense that there was not one correct way to formulate an argument.

Likewise, both teachers had their classrooms arranged in groups, with three or four students in a group. The teachers regularly incorporated group tasks into their lessons and asked students to consult one another about the viability of their arguments. Both teachers spent a majority of the class time circulating around the room, posing questions to groups and to individuals within the group. The teachers’ questions were strategically constructed to encourage students to clarify or refine their mathematical ideas and arguments. These questions often included a restatement of the student’s initial query or claim, followed by a request for greater clarity, a challenge about the student’s claim, or a provocation to generalize and to connect with other ideas. Teacher questions were also used to draw group members into the conversation by directing specific students to comment on or to identify conflicts with prior assertions made by an individual in the group. Although such questions served to guide students’ thinking by drawing attention to particular issues, the teacher questions did not typically offer additional information to the student about the correctness of the student’s thinking. The suburban teacher was particularly adamant about not providing an evaluation of students’ arguments, but rather, forcing the group or the entire class to assess the work of their peers.

The teachers’ expertise at posing strategic questions was particularly evident when they were interacting with small groups. The following excerpts from classrooms discussions illustrate how teachers promoted discourse as well as an awareness of processes and norms of proving.

Teacher: I’m looking at your work and I’m looking at number 1 and you’re saying that \( x \) has to be more than 12. Is that fair?
Students 1, 2 and 3: Yeah.
Teacher: Now, how did you get that?
Student 1: You’re given that DF is greater than DE. And that means that angle E must be greater than angle F since they’re opposites.
Teacher: OK.
Student 1: Since DF is opposite of E.
Teacher: OK. What can we use from yesterday’s class to kind of put that into a more compact form? (Pause.) What rationale can we provide? What you said is fine, but what do we have from yesterday?
Student 3: The shortest side is opposite the shortest angle.
Teacher: Is that what’s happening here? (Students agree.) So, I’ve had a look at what you have so far, but I’m wondering, I see x has to be more than 12 (what students had written), but it is possible for me to have x is, uh, 200? Is that ok? It’s more than 12.
Student 1: Oh, wait.
Teacher: You just said, “Oh, wait.” But why do you have to wait here?
Student 1: It can’t be greater than, the angle measure can’t be greater than 90.
Teacher (to Student 4): What were you about to say?
Student 4: That’s what I was going to say.
Student 1: Both of these angles can’t be greater than 90.
Teacher: So, is there an added level of restriction that you have to address here?
Student 1: Yeah.
Teacher: Figure it out. Call me back. (Leaves the table.)
The teacher moved to the next table, and looked at students’ work. He called back to the previous table, “Student 1, come over here and have a conversation with Student 5 about number 1. Don’t give it away; ask her the same question I asked you.”
The following exchange happened at yet another table:
Teacher: So what’s the minimum side?
Student 6: 12
Teacher: In this particular case, but what about the general case?

We see that the teacher used a combination of questions to advance students’ reasoning about the problem and to promote the normative practice of justification through communication. He asked specific questions about the problem under investigation; for example, “You’re saying that \( x \) has to be more than 12. Is that fair?” which probes to see whether the students are committed to their claimed answer. He also encouraged students to support or generalize their ideas; for example, in asking, “[True] in this particular case, but what about the general case?” the teacher directed students to broaden their thinking and to extend their ideas to assert mathematical generalizations. Also, this teacher used the tool of playing devil’s advocate as a method for getting students to reexamine their work. For example, when one group had accepted a condition for a problem without thoroughly considering all possibilities, he asked “I see \( x \) has to be more than 12 (what the students had written), but it is possible for me to have \( x \) is, uh, 200?” This teacher also used students as questioners of other students, both as a method of more efficiently circulating around the room, as well as a way for different groups to gain insights from the mistakes or better strategies of the other groups. For example, “Student 1, come over here and have a conversation with Student 5 about number 1. Don’t give it away; ask her the same question I asked you.” This further illustrates the teacher’s effort to instill a norm of student-to-student questioning and justifying within the classroom community.
Promoting Justification

In order to help students see the need for mathematical justifications, the teachers chose rich, argument-eliciting tasks, used strategic questioning (as described in the previous section), and required students to formulate arguments in writing. Both teachers began their teaching about proofs with connections to real-life examples and with emphases on writing. The suburban teacher used the following task based on an actual court case (Abelson, 2006) to open the discussion about mathematical justification.

**Is a burrito a sandwich?**

Work with your group to WRITE a response to the above question. Be prepared to present to the class and defend your position with your peers.

What are your underlying assumptions? What entails a convincing argument? Can you predict any counter-arguments from other groups? Can you defend your position?

Students engaged in extensive debate about the question and then read their justifications aloud to the class. The activity led to a need for clear definitions (e.g., “what is a sandwich?”), as well as the development of informal arguments about how to show that the criteria in a definition have been met. For example, one group stated that a burrito is not a sandwich because a sandwich requires two pieces of bread with stuff in the middle and the burrito only has one outer layer twisted and turned around the stuff in the middle. But another group claimed that a burrito is a sandwich, but a sandwich is not a burrito, just like a square is a rectangle, but a rectangle is not necessarily a square.

The teacher in the rural setting had students engage in the checkerboard problem (Fendel, Resek, Alper, & Fraser, 1998). The problem asked, “How many squares are there altogether on the [8-by-8] checkerboard?” A follow-up question asked students to generalize the solution to checkerboards of any size. Although the primary focus of the task was problem solving and communication, the emphasis on the “write-up” of the solution incorporated elements of generalization and reasoning. Students were given explicit detail about how to write complete solutions that included: a restatement of the problem; a description of the process used to solve the problem, including diagrams; a complete solution, including reasoning and a discussion of generalizations included; and possible extensions to the problem. After completing their own solutions, students were presented with a rubric for rating solutions and sample papers to illustrate performance levels. Although students had struggled with explaining their thinking before the activity, the use of rubrics to rate student writing helped reinforce the teacher’s expectation that writing should be clear and detailed enough so that the reader could follow the thinking of the solution writer. Later in the semester, the teacher was able to connect proof writing expectations to the criteria for high-quality mathematics writing articulated by students during this exercise.

Evidence of Adoption of Meta-Discursive Rules

There was evidence that students in the suburban class, in particular, became fluent in some of the meta-discursive rules of the discipline. In particular, students began to value efficient (i.e., concisely worded) arguments as well as fluid arguments in which ideas flowed logically in a manner that helped guide the reader through the proof. This evolution of students’ ideas was the result of intentional work done by their teacher to prompt students to articulate the rules or guidelines in making an effective argument. The teacher prompted this articulation in a variety of
ways. Proofs were shared for public critique in small groups and in the whole-class setting. Typically, one proof was examined at a time and the teacher facilitated discussion about the validity of the proof. In those circumstances, students were left to draw inferences about the value of their own proofs based on their perceived connections to the proof under discussion. But in some instances, the teacher spent most or all of a class period having students critique each other’s proofs in pairs and in small groups. Using this mechanism, students were given explicit feedback on their own writing, in a setting other than formal assessment by the teacher. It was during these discussions, that students heard evolving values of the class applied to their own work and had an opportunity to apply their developing standards for high-quality proofs to the work of others.

In the following excerpt, the teacher visited a student group in the midst of critiquing each other’s proofs. The students illustrated their values about high-quality proofs in the critiques they offered each other. In particular, they demonstrated a preference for readability, conciseness, and efficiency.

Student 7: Move the angles in your proof. Maybe that would make it a little easier to understand. Do you get what I’m saying? Because you’re doing ASA. You proved side first and then the two angles. So it would just be easier to understand if you did Angle, Side, Angle [referring to the order that the corresponding congruencies were presented in the proof].

Teacher: So are you making comments about readability or are you making comments about…?

Student 7: About flow.

Teacher: Ok. So does the fact that he wrote it out of order make it less powerful, or less accurate, or is it just…

Student 7: No.

Teacher: Better for readability?

Student 7: Yeah.

Teacher (to student whose proof was being discussed): Does that make sense?

Student 8: Yes.

Teacher: Student 8 had a comment here…

Student 9: Do you take points off for lengthwise, how big it is [the length of the proof]

Teacher: (shrugs)

Student 9: Do you have to make it even less [referring to the length of her proof]?

Teacher: Let’s take it to your friends who are reading your work. What do you think of hers?

I know hers tend to be a little bit longer, right? So what about it is longer? Is it extra stuff that should not be there or is it things that she has put in for extra clarity? Why is it longer?

Student 10: Well she puts in some stuff that doesn’t make it any clearer. It’s just there. And you could shorten it up a lot easier. Like, instead of saying, “CD is congruent to FQ because if two segments are congruent to the same segment, they are congruent,” you could just say, “the transitive property.” They both work.

Teacher: They both work. But one is a little bit more efficient than the other, right? Does that make sense?

Student 9: Yeah.
Teacher: So maybe what you want to look for as you’re writing and as you’re reading is: “If I were to shorten mine up, am I going to take away from the proof, or am I going to be more efficient in writing?” Good comments. Thank you.

The process of having students critique and refine each other’s work is not typically observed in secondary schools, but was used very effectively in this setting. Each student took the responsibility to critique others’ work, as well as offering his or her own work for examination. This activity puts students in the position of having to publicly demonstrate their understanding of the meta-discursive rules governing proof writing. Thus, we can see that students have embraced some of the discipline’s standards for communicating mathematical ideas via proofs.

Discussion

The results of the study demonstrate that secondary mathematics teachers can develop the type of classroom environments that promote deep mathematical justification that lead to more effective student engagement in formal mathematical proof. Maher (2009) also described similar findings related to elementary children’s experiences with proof and justification. Maher noted that proving can be an extension of children’s natural desire to engage in sense making. The present work complements Maher’s work and demonstrates how such sense making and proving might be promoted in high school classroom settings.

Students, in our study, began to demonstrate that they were thinking about proof in ways that are consistent with the values and practices of the discipline of mathematics, as Sfard advocated (2000). For example, in these classrooms, we observed students making conjectures, pushing other students to consider solutions and constraints more carefully, and constructively critiquing each other’s work to make their arguments and solutions more efficient.

This study focused on the work of two teachers, recognized by peers and supervisors as particularly effective. Both teachers provided students with rich tasks to discuss in collaborative group settings. Beyond that basic structure, the strategic questioning used by the teachers prompted students to justify their thinking, their strategies, and their choices to their peers and to the teacher. The requirement that students publicly critique proofs made overt students’ emerging values about what constitutes a convincing argument. Those values were consistent with those of the discipline, and provided evidence that meta-discursive rules related to proof had been adopted by students. Some of these effective practices are consistent with findings of Stylianides and Ball (2008), who concluded that knowledge of different kinds of proving tasks and knowledge of the relationship between proving tasks and proving activity were critical components of teacher’s knowledge for teaching proof.

What needs further clarification is how the school environment or other factors contribute to developing teachers who are effective at helping students become adept at proving. Likewise, further exploration about links between teacher knowledge and effective teaching practices should be examined. If the techniques used by these teachers are so effective, why aren’t all teachers using such techniques? We suspect that the techniques used by these teachers are not easy to acquire; they appear to require a significant understanding of the content, students’ thinking, and the role of proof in the discipline of mathematics. We leave consideration of these possibilities open for further discussion and study.

AN EXPLORATION OF FIFTH GRADERS’ JUSTIFICATION SCHEMES WHEN ENGAGED IN PATTERN FINDING TASKS

Jessie C. Store  
University of North Carolina  
Greensboro  
jcstore@uncg.edu

Sarah B. Berenson  
University of North Carolina  
Greensboro  
sarah_berenson@uncg.edu

Pattern finding tasks were used to teach algebraic reasoning to a class of 25 fifth graders. The tasks involved students in generalizing rules and justifying their conjectures. Students’ written work and data from the transcripts of the video and audio tapes of the class sessions and group discussions were sources of data. Results indicated that these fifth graders used analytic schemes, empirical schemes and also external authorities to justify conjectures. Implications for teaching and learning early algebra concepts are discussed.

Introduction

Increasing numbers of researchers and educators recommend that justifications and reasoning should be the core of any branch of mathematics education (For example, Mueller & Maher, 2009; National Council of Teachers of Mathematics (NCTM), 2000; Sowder & Harel, 1998). Justifications among other purposes support students’ understanding of generalizations (Lannin, 2005), and are ways of verifying that a proposition is true, and why it is true (Bell, 1976; Healy & Hoyles, 2000). Additionally justifications are tools for understanding mathematical concepts (Hanna, 2000; Tsamir et al., 2009). Realizing the importance of justifications in mathematics education at all levels, NCTM (2000) includes justification proficiency as one of the requirements for elementary to high school students. Despite such importance, justifying conjectures proves to be a challenge to most middle grade students (Ellis, 2007; Lannin, 2005), high school students (Healy & Hoyles, 2000), preservice teachers (Richardson, Berenson & Staley, 2009) and inservice teachers (Knuth, 2002).

Since justifications are linked to understanding mathematical concepts (Hanna, 2000), and because analyzing students’ reasoning as they justify conjectures is instrumental to identifying effective teaching strategies (Mueller & Maher, 2009; Sowder & Harel, 1998), the objective of our study is to analyze students’ justifications for their algebraic conjectures. Thus, our research question is, how do fifth graders justify their algebraic conjectures when engaged in pattern finding tasks?

Research related to this question has tended to focus on justifications and proofs of students engaged in either different mathematical activities or different age groups and grade levels. In a study with sixth graders, Mueller and Maher (2009) reported students’ reasoning and justification strategies while working on tasks involving fractions. The students used direct reasoning, reasoning by contradiction, reasoning by cases and noting the lower and upper bounds of a set to argue for what set an element belongs to. In another study with sixth graders working on pattern finding tasks, Lannin (2005) observed that students used deductive reasoning, giving empirical and generic examples, and also appeal to external authorities to justify their conjectures. Bergqvist (2005) found similar results in a study with students in their 11th year of schooling. Despite NCTM (2000) including pattern finding and reasoning behind conjectures in elementary grade levels curriculum, there seems to be a scholarly gap on how elementary school students justify their conjectures when involved in pattern finding tasks (Lannin, 2005). This
study contributes to this area by analyzing fifth graders justification schemes so as to inform educators’ choices of teaching strategies that will help develop students’ mathematical reasoning.

**Theoretical Framework**

Proof schemes, according to Sowder and Harel (1998), are ways of ascertaining to oneself and persuading others about the truth or falsity of conjectures or any mathematical idea. These ways or arguments differ from person to person and an individual’s schemes may differ from context to context. Sowder and Harel (1998) categorized the justification schemes into externally based schemes, empirical schemes and analytic schemes. These form the framework of our study.

Externally based schemes are arguments that are based on outside sources. They are divided into authoritarian scheme, ritual scheme and symbolic scheme. A student using authoritarian arguments refer to reference materials and people they assume to be more knowledgeable than themselves as basis for their justifications and not at the sense and correctness of the reasoning itself. Similarly, the ritual scheme is based on the form of the argument and not the reasoning. Symbolic schemes on the other hand, involve manipulation of symbols. The manipulation might be meaningless or meaningful but do not give reference to the context of the problem.

Empirical justification schemes are categorized as perceptual and example-based schemes. The example-based schemes involve inductive reasoning whereby one uses examples to verify a general case. Students using perceptual schemes would use images but disregard the generality of the context. Hence they may not be able to justify the same scenario when the images are transformed. In contrast, transformational analytic scheme uses deductive reasoning and takes into consideration the generality of the context. And lastly, an axiomatic scheme is a form of an analytic argument that is deductively organized and uses forms of axiomatic systems.

We adapted this framework to relate it to the context of pattern finding activities and elementary school students’ cognitive abilities. Our interest was not on the formal organization of the justification but on the reasoning being evidenced (see Table 1). Therefore, the purpose of the study is to focus on fifth grade students’ reasoning schemes and how schemes influence their abilities to justify algebraic ideas. Our specific research question is, what justification schemes do fifth graders use to verify and to convince others of the validity of mathematical conjectures when engaged in pattern finding tasks?

**Methods**

The participants in this study were 25 elementary school students in a fifth grade class at one of the science magnet schools located in a rural county in the South East of the United States. This class consisted of 14 girls and 11 boys, one African American, one Latino and 23 Caucasians. According to the class teacher, the ability of the students ranged from average to above average. One researcher taught the class for the three day teaching experiment, while others collected data through observations, audio and video recordings. The students’ written work was also collected as a source of data. Pseudonyms were used during the teaching experiment and in this report too.

With an aim of teaching algebraic reasoning, the teacher/researcher created a constructivist classroom environment where students worked in small groups, shared their ideas with the whole class and established sociomathematical norms of justifying their conjectures (Store, Berenson & Carter, 2010). Each lesson or session lasted for 90 to 120 minutes. All the students were encouraged to write an input/output table to collect and organize their data. Students were asked

---

to predict and justify how many people may sit around a train of 100 and n tables in pattern tasks (see Figures 1, 2 & 3) that were given during the teaching experiment.

![Figure 1. Day 1 pattern task (square tables).](image)

![Figure 2. Day 2 pattern task (triangle tables).](image)

![Figure 3. Day 3 pattern task (hexagon tables).](image)

We used the categories in Table 1 developed from Sowder and Harel’s (1998) justification framework to analyze students’ justifications. The researchers coded and recorded the data until a consensus on the category of justification scheme was reached.

<table>

</table>

Table 1. Justification Analysis Codes (adapted from Sowder & Harel, 1998).

**Results**

Different justification schemes were evident on each day of the teaching experiment. During the first part of the session of the first day, a significant number (9/25) of students used non-contextual manipulation of symbols as a justification scheme. This scheme was not evident on the second and third days. In all the three days, analytic schemes and empirical schemes were evident. This section presents the results of the analysis for each day that includes examples and evidence of students’ reasoning schemes that were representative of all the schemes in this class.

Day 1 Task Justifications Schemes

On this day, when students were asked to predict how many people could sit around a train of 100 tables, some conjectured 220 people and others 202 people. They all conjectured that 2n+2 people could sit around a train of 100 square tables. In justifying these conjectures, the following justification schemes were evident.

*Externally based scheme.* This scheme was evident when students were verifying their conjecture of 220 as number of people who can sit around 100 square tables. Students did not explain further than stating that, since 22 people can sit around 10 tables, and that 100 is 10 times 10, therefore 10 times 22 gives the correct number of people for 100 tables just as in episode 1. In this argument (See Episode 1), there is no reference to the context of the problem posed:

Janice: I got 220 people.
Teacher: Alright, we have 202 or 220. How are we going to be sure which is right?
Janice: Ten tables equals 22 people and so I did ten times 22 and got 220.

*Empirical scheme.* To verify that 202 people could sit around 100 tables, some students used their general rules to compute number of people that may sit around 4, 5, 6, …100 tables and used that to argue for the validity of their prediction. Example based scheme was evident when students were verifying that the rule 2n+2. Episode 2 contains an example of the computations used to verify the rule.

\[
\begin{align*}
(1 \times 2) + 2 &= 4 \\
(2 \times 2) + 2 &= 6 \\
(3 \times 2) + 2 &= 8
\end{align*}
\]

Episode 2

*Analytic schemes.* A perceptual scheme that recognized the general features of this problem was another common scheme on this day. Episode 3 illustrates an example of such a scheme.

In justifying that 202 was the correct number of people who could sit around 100 tables, the student in Episode 4 used his conviction of the model discussed in episode 3 and also his conviction that the rule 2n+2 was valid to support his conjecture by illustrating that the 220 conjecture contradicts these axioms.

Day 2 Task Justifications Schemes

On this task, to justify the rule n+2 for n triangle tables, the students were asked to explain the +2 in this rule. The following schemes were observed.

Empirical schemes. Episode 5 illustrates such reasoning from a student’s written work and an explanation during class discussions. He explained that, he tested his rule by plugging his input values from the t-table in his rule. Then he checked if the result from this operation was equivalent to the output values in the t table. When this worked for a few examples, he then concluded that his rule is valid.

Student: I did the number of tables plus two equals the number of people. And then I put each number in the T table (the t values) plus two equals (which gave me) the number in the people column right beside it.

Episode 5

Perceptual schemes were also evident on this task. To verify that n+2 was the rule for finding number who could sit around n triangle tables, some students used their visual observation that in building the train model, 2 seats were being added each time a table was added while others considered their perceptual observation that 2 seats were being removed from the sides that the tables were being joined. Episodes 6 from students’ written work and episode 7 from transcripts of students’ discussion illustrate this reasoning.

Episode 6

Brenda: Okay, this table (triangle).
Dan: Mm-hmm.
Brenda: Then you take away this (one side of the triangle) right here. They’re (two triangles are) getting ready to be put together. So if you have this table and you put it together with this table you have to take this chair away (close one open side of the triangle) and on this table you have to take this chair away (close one open side of another triangle). And then you put them together.

Episode 7

Analytic Schemes. To argue for the +2 in the rule, some students used the general difference between the input and output values that they observed in t-table (episode 8) while others who used this scheme argued that the number the number of people will be the same as the number of tables on the train plus the 2 people who will sit at end sides of the train (episode 9).

Episode 8

Day 3 Justifications Schemes

Empirical scheme. To test his rule, Wizard calculated number of people who can sit around 1 table, 2 tables, until 100 tables. He did this after finding the general rule for finding number of people who can sit around n hexagon tables as 4n + 2. Still, in his justification, he did not consider the generality of the context. Below are some of his written calculations (See Episode 10).

Analytic schemes. In justifying that 402 people could sit around a train of 100 hexagon tables, some students argued that each table was contributing 2 seats at the top and 2 seats at the bottom of the train, and that there were 2 seats at the ends of the train. The image in episode 11 was used to explain this thinking.

An axiomatic scheme to justify the rule for finding number of people who would sit around a train of hexagon tables was also used. In episode 12, the student used an already established fact about square train tables (2n+2 = P) and the characteristics of its model (one person sit at the top and another one person at the bottom of the model for each square table) to deduce that 4n + 2 = P for hexagon tables. Her written work shows this line of reasoning.

Conclusions

The purpose of this study was to identify justification schemes that the fifth graders used in this teaching experiment. The results of the analysis show that fifth graders are capable of justifying using both analytic schemes and empirical schemes and that they may also justify using externally based schemes. The type of questions that prompted students to justify was one of the factors that contributed to the range of justifications in the class. For example, justification by contradiction was only evident when students had to decide the correctness of one answer against the other. Similarly, using a general perceptual model was not common when working with triangle tables unlike with the other tasks because triangles did not present an obvious geometric model that related to the rule. To use the axiomatic scheme that was evident on day 3,
this student employed the isomorphic characteristics of the tasks used during this teaching experiment to deduce that his conjecture on the 3rd day was correct. Since NCTM (2000) recommends that students should develop fluency with different forms of justifications, and because justifications are instrumental to mathematical understanding, we recommend that teachers provide contexts that support the development of both empirical and analytic schemes.

A TEXTUAL ANALYSIS OF REASONING AND PROOF IN ONE REFORM-ORIENTED HIGH SCHOOL MATHEMATICS TEXTBOOK

Jon D. Davis
Western Michigan University
jon.davis@wmich.edu

This study examined the presentation and student development of reasoning and proof within one unit of a reform-oriented high school mathematics textbook. In the exposition sections, 24% of the sentences related to reasoning and proof while 12% of the problems asked students to develop reasoning and proof components. The most frequently occurring category within exposition sections was proof building blocks while supporting claims occurred most often in student problems. The text exposition rarely modeled pattern identification or conjecturing. Moreover, students were infrequently asked to identify a pattern, propose a conjecture, and create a proof for a single mathematical idea.

Introduction

Reform documents (National Council of Teachers of Mathematics [NCTM], 2000, 2009) in the United States have advocated the inclusion of opportunities for students in grades K-12 to engage in mathematical proof. Research has examined students’ understanding of proof at a variety of different grade levels and found that they generally struggle in understanding this area (Harel & Sowder, 2007). Research by Healy and Hoyles (1998) suggests that the classroom environment can positively influence students’ understanding of proof. One important component influencing what students learn within the classroom environment is the written curriculum (i.e. mathematics textbooks) that teachers use (Stein, Remillard, & Smith, 2007). However, less research has examined students’ opportunities to engage in reasoning and proof within the written curriculum. An exception is a recent study conducted by Stylianides (2008) in which he examined reasoning and proof in the number, geometry, and algebra units of the grade 6, 7, and 8 middle school mathematics textbook series Connected Mathematics Project (Lappan, Fey, Fitzgerald, Friel, & Phillips, 1998/2004). He found that 40% of the tasks asked students to engage in some kind of activity situated within his reasoning and proof framework. Of these tasks, 3% expected students to make conjectures, 12% expected more formal demonstrations of mathematical truth, and 62% of the tasks expected students to produce rationales or informal arguments. In addition, he found that reasoning and proof was not apportioned evenly across grades and content areas. For example, the grade 6 number unit contained the greatest frequency of proofs. This lack of attention to reasoning and proof within the written curriculum by the research community is a significant omission in our understanding of how students learn this important area as middle school and high school teachers in the United States frequently use mathematics textbooks in the course of their daily instruction (Grouws & Smith, 2000; Weiss, Banilower, McMahon, & Smith, 2001).

Research suggests that teachers interpret curricula in different ways resulting in an enacted curriculum that may differ in significant ways from the written curriculum (Stein et al., 2007). Nonetheless, while the written curriculum may not have a one-to-one correspondence with the enacted classroom lesson it is suggestive of students’ opportunities to engage in a variety of different mathematical ideas. Consequently, this study used a framework adapted from

Stylianides (2008) to examine the exposition sections and student problems within one unit of a reform-oriented high school mathematics textbook for reasoning and proof elements.

**Theoretical Framework**

Stylianides’ (2008) reasoning and proof framework consists of mathematical, psychological, and pedagogical components. The analysis reported in this paper draws upon the mathematical component of his framework, which consists of analyses of reasoning and proof segments by an individual or individuals who are mathematically proficient. However, a number of different adaptations were made to this framework. First, Stylianides conceived of his framework as a table, however, I found it more helpful to consider it as a model as seen in Figure 1, which depicts the relationships between different components. Mathematicians’ accounts of their own work suggest that they begin by identifying patterns, making conjectures about those patterns, and developing arguments to show the validity of those conjectures (e.g., Polya, 1954).

![Figure 1. Reasoning and proof model describing the relationship between pattern identification, conjecturing, and developing arguments within textbook presentation and student development elements of curricular resources](image)

Second, Stylianides’ model focused solely on analyzing student work associated with reasoning and proof. However, an assumption of this study is that the textbook exposition sections can also influence students’ understandings about reasoning and proof. Therefore, the framework was expanded to include textbook presentation. However, the dotted lines in the model suggest that student work or the textbook exposition could begin in one location and be confined to that area of the model or could progress to other components.

Third, the framework was adapted to include the potential role that cognitive tools (Zbiek, Heid, Blume, & Dick, 2007) can play in identifying patterns, making conjectures, and crafting...
arguments. For instance, students may use technology in the form of graphing calculators to examine a variety of representations of quadratic functions in order to make a conjecture about the number of times these functions may intersect the x-axis. Cognitive tools include microworlds, simulations, as well as technologies that enable the user to connect a variety of different representations (e.g., graphing calculators). As Zbiek et al. note, it is important to understand how learning is different within technological environments and this framework takes into account the role of technology in promoting students’ understanding of reasoning and proof within curricular resources.

Fourth, although Stylianides’ (2008) framework involves proofs that seek to concretize new knowledge, the role of this knowledge in the development of other proofs was not highlighted. Thus, there is an arrow leading from proofs to what I describe as proof building blocks. In addition, mathematicians develop other proof building blocks such as definitions (e.g., degree of a polynomial) that can be used in pattern identification or other components of the framework. This work is highlighted in the dashed arrows leading to the different reasoning and proof components.

Fifth, changes were made to the framework to account for the possibility that not only would students make conjectures but also be asked to test them. The student textbook can present a conjecture within the exposition sections and subsequently describe testing its validity or it may ask students to perform this action either with a conjecture that they themselves created or with a conjecture provided by the textbook authors. This conjecture testing may lead to justification in the form of proof or non-proof arguments.

Sixth, although mathematicians must develop complete proofs, a pedagogical device often used by school mathematics textbook developers is to ask students to provide specific components of the outline of a proof. Such an artifact is particularly prevalent in textbooks designed for school geometry where students are asked to fill in blanks for statements or explanations in two-column format. Consequently, the original framework was adapted to admit the coding of proof subcomponents.

Methods
Reasoning and proof has historically resided in the high school geometry classroom (Gonzalez & Herbst, 2006). However, NCTM has advocated the integration of reasoning and proof across different mathematics content strands (2000, 2009). An area of mathematics that many high school students in the United States complete is algebra, thus I was interested in examining how reasoning and proof were integrated within this common mathematics content area. There are a number of different areas within algebra that students have the opportunity to learn in the course of school mathematics. This study examined reasoning and proof within functions as this content area has been identified as a big idea in reform documents (NCTM, 2000) in mathematics and hence of importance in students’ future mathematics studies. One unit on polynomial and rational functions was chosen from the student textbook in the third course of the reform-oriented high school mathematics program Core-Plus Mathematics (Fey et al., 2009). All analyses were conducted on the teacher’s edition of this textbook as it contained the student textbook and expected answers to student problems on facing pages.

A Core-Plus Mathematics unit is broken down into lessons, each of which contains several investigations. Each lesson begins with a launch that is designed to introduce students to a specific context through which students learn about mathematical ideas in the investigation phase of the lesson. At the end of each investigation, students, with the assistance of the teacher,
summarize the main mathematical ideas within the Summarize the Mathematics section. Afterwards, students are provided with additional practice in the Check Your Understanding and On Your Own sections of the text. The unit on polynomial and rational functions examined for this study involves properties of polynomials, operations on polynomials, completing the square, solving quadratic equations through the quadratic formula, vertex forms of quadratic functions, definitions and properties of rational functions, and operations on rational functions.

In order to determine the proportion of the exposition that involved presentation of reasoning and proof components the number of sentences appearing in exposition sections in the unit were counted. Exposition sections were those that included areas outside of numbered questions as well as sentences appearing in question sections that provided the reader with proof building blocks (e.g., definition). The total number of problems appearing in the unit was calculated in order to determine the percentage of problems devoted to reasoning and proof. While the CPM textbook indicates each question that students are to complete with a number or letter, each question may have several problems for students to complete. For example, the following appears as a single question in the student textbook. “5. Sketch a graph of the function \( f(x) = x^2 - 6x + 13 \). Explain how it shows that there are no real number solutions for the equation \( x^2 - 6x + 13 = 0 \)” (Fey et al., 2009, p. 354). However, this was coded as including two problems since students must sketch a graph and develop an explanation. It was also possible to have rational numbers that were not integers as part of the problem count. A problem may have asked students to develop a conjecture and justify this conjecture within one sentence. Thus, this would have been coded as 0.5 for develop a conjecture and 0.5 for developing either a proof or non-proof argument.

Coding of reasoning and proof components within the CPM textbook began by proceeding through the written student textbook line by line. As sentences or questions were encountered in the textbook that were connected to the reasoning and proof framework either by using the definitions for each category described above or using the set of examples in Stylianides (2005) they were transcribed into a written electronic document. In addition, each example was coded for category within the reasoning and proof model (e.g. pattern), type (e.g., conjecture non-precursor), and technology use or not. A problem was considered to include technology if the answer in the teacher resources described the use of technology in the solution, the teacher resources showed work involving technology (e.g., a graphical representation on a calculator screen), or the student textbook asked students to use technology in answering the question in some way. In addition, a detailed justification was provided for each coding and the page number where each occurred in the student textbook was noted. Next, the instances of reasoning and proof in the electronic file were organized into tables by category (e.g., pattern) to facilitate analysis.

Conjectures were distinguished from patterns in two ways. First, the textbook sometimes specifically labeled student work as conjectures as in the following sentence: “Test your conjecture in Part c by graphing quadratic polynomial functions …” (Fey et al., 2009, p. 325). Second, if a sentence asking students to notice a relationship contained uncertainty then it was coded as a conjecture. This is seen in the example, “How do the results of your work on Problems 6 and 7 suggest a strategy for writing any quadratic expression …” (Fey et al., 2009, p. 351, emphasis added).

Rationales were distinguished from proofs using two conditions. First, an argument was considered a rationale if in addition to justifications involving assumed truths it also contained empirical justifications. Second, rationales contained one or more statements that were not
assumed truths and were not justified. Assumed truths were determined by examining the algebra and function units from the third course as well as from previous courses. If these notions appeared within the Summarize the Mathematics section or were justified using proofs they became assumed truths for coding purposes.

The connection between the presentation of proof building blocks in the exposition sections and reasoning and proof components that students were asked to develop was also examined. That is, if a definition is presented in the textbook are students asked to develop conjectures involving this definition or are exposition sections isolated from student work? This analysis was conducted on electronic versions of the teacher’s edition of the textbook, which contains the student textbook and the teacher answers together in one resource. As proof building blocks were encountered in the exposition sections of the student textbook, electronic searches were conducted for these words to determine if they appeared in student problems in later sections within the focus unit.

**Results**

Within the exposition sections of the focus unit there were 189 sentences, 44.5 or 24% of which were related to reasoning and proof. The breakdown of the different categories is shown in Table 1. As seen in the table the majority of the reasoning and proof presentations in the text were proof building blocks. These occurred twice as often as justifications of mathematical claims. The majority of these building blocks were definitions such as the following, “A **polynomial function** is any function with a rule that can be written in the form

\[ f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0, \]

where \( n \) is a whole number and the coefficients \( a_n, a_{n-1}, \ldots, a_1, a_0 \) are numbers” (Fey et al., 2009, p. 323, emphasis in original). Some of these building blocks came in the form of facts since they did not require a formal proof nor did they appear to be more recognized mathematical properties. One fact appeared on p. 342, “For higher-degree polynomials, graphs of two polynomial functions of the same degree can have different shapes.” Only four of the 29.5 sentences associated with building blocks involved the presentation of statements regarded as theorems.

Interestingly, the exposition sections did not model identification of patterns, conjecture development, conjecture testing, or justifying mathematical ideas. Only one proof was provided in the exposition, a visual proof of completing the square involving the expression \( x^2 + bx \). Proof subcomponents in the form of statements were presented in the text for the quadratic formula and the factor theorem. Students were asked to provide the explanations for the statements appearing in these proofs.

Table 2 shows how the proof building blocks introduced in the exposition sections of the student textbook were connected to student problems involving reasoning and proof. Only five of the 29.5 instances of proof building blocks were isolated or not connected to student reasoning and proof problems. Some of the remaining 24.5 occurrences were coded multiple times thus...
there are a total of 28 connections to student problems involving reasoning and proof. Proof building blocks were most frequently connected to students’ opportunities to identify patterns.

Table 2. Use of Building Blocks in Student Textbook

There were a total of 1,114 problems in the fifth unit of the third course of CPM. Of this total, 137 or 12% asked students to answer problems related to reasoning and proof. The breakdown of the different categories is shown in Table 3. Students were rarely asked to develop definitions or test conjectures while identifying patterns and supporting claims were the most frequently occurring reasoning and proof tasks. Students were asked to identify definite patterns only; no plausible patterns appeared in the text.

Table 3. Reasoning and Proof: Development

The CPM curriculum developers frequently expected students to use technology when identifying patterns, developing conjectures, and testing conjectures as seen in Table 4. For instance, within the second investigation of the first lesson the text asks, “How does the degree of a polynomial seem to be related to the number of zeroes of the related polynomial function? Test your conjecture by studying graphs of some polynomial functions of degree five and six” (p. 331). However, there were no demonstrated uses of technology within the exposition sections of the textbook.

Discussion

There were several noticeable shifts from Stylianides’ (2008) analysis of reasoning and proof at the middle school level and this analysis of a high school mathematics textbook unit. First, there were fewer incidences of reasoning and proof found in the tasks from 40% at the middle school level to 12% at the high school level. Second, the majority of arguments that middle school students were asked to construct was in the area of rationales or informal arguments while high school students were expected to create informal and formal arguments with equal frequency. Third, the majority of the patterns at the middle school level were plausible while in this high school unit all of the patterns were definite.

Focusing exclusively on the high school unit examined here, there was evidence of a misalignment between the exposition sections and the problems that students were asked to complete. For example, the exposition sections presented proof building blocks such as definitions while students were rarely asked to perform this work in problems. Students frequently found patterns and developed conjectures using technology, but the authors rarely engaged in this action in the exposition sections. On the other hand, the definitions that were presented in the student textbook were frequently the source of students’ work in other aspects of the reasoning and proof model.

As described earlier, mathematicians’ work typically begins with noticing patterns, developing conjectures on the basis of these patterns, and determining and validity of conjectures through the construction of proofs. While students working on this unit from CPM experienced problems within these different areas they did not frequently travel through these three steps in succession. Students were asked to notice patterns, but rarely did they construct conjectures on the basis of these patterns. Students were asked to develop conjectures, but these did not follow from the patterns they had noted in other problems. When students were asked to explain their work this usually involved statements provided by the authors of the curriculum, not from conjectures that they had previously constructed in response to questions. Thus, there appeared to be a lack of alignment between how mathematics is practiced by mathematicians and the work that textbook authors asked students to perform. These findings suggest how curriculum developers could develop future secondary mathematics curricula. Providing students with more opportunities to develop proof building blocks and use them in all three areas of the framework.

Future steps in this research area include analyzing the reasoning and proof components within an entire textbook, across different courses of the same textbook series, or within different

textbook series. Analyses of reasoning and proof elements within other textbooks could be used to compare textbooks and provide information to teachers who are considering textbook adoption. Additionally, analyses of the written curriculum could provide a springboard from which the enacted curriculum could be examined.

ENCULTURATION TO PROOF:
A PRAGMATIC AND THEORETICAL INVESTIGATION

Susan D. Nickerson

chrisraz@sciences.sdsu.edu

We report on an investigation in a transition-to-proof course of undergraduate students' epistemological shifts in mathematical argumentation and identify pedagogical factors that foster and/or constrain students' ability to create mathematical arguments. We view proof as a social process in which participants of a learning community move from peripheral participation to more full members of a community engaged in the mathematical activity of proving. This report analyzes the impact of a pedagogical intervention that modifies the classic format of a two-column proof and reifies the presentation of a proof and the questions asked by the reader of the proof. We summarize our analysis in a framework that characterizes enculturation to proof.

Introduction

Cobb (2000) describes three prongs that are characteristic of a profound shift in the field of mathematics education. The first shift is described as one from students as information processors to students acting purposefully in a mathematical reality they are constructing. A second shift is described as a view of students’ mathematical activity embedded within the evolving classroom microculture and the larger cultural sphere. The third shift is described as one from theory informing practice to a view of theory and practice guiding each other.

Our work in teaching proof to prospective secondary mathematics teachers reflects all three emergent trends in the following ways. First, our perspective on learning proof is that it is not just a cognitive endeavor. We characterize learning as both a process of individual construction and a process of enculturation. Second, from our perspective, individual student activity is seen to be located within broader systems of activity and the norms constituted in class are reflexively related to shifts in beliefs about mathematics (Yackel & Rasmussen, 2002). Third, we engage in the development of a theoretical framing of students’ enculturation into proof, grounded in classroom settings. In particular, our experience as teachers of a transition to higher mathematics class with an innovative pedagogical intervention evolved into a systematic study of the intervention.

Prior research literature offers a number of different frameworks for classifying students' justifications (e.g., Balacheff, 1988; Chazan, 1993; Harel & Sowder, 1998; Healy & Hoyles, 2000) and it points to a number of difficulties that students have in creating proofs (e.g., Tall, 1991; Selden & Selden, 2003, 2008; Weber, 2001). One of the difficulties that undergraduate students have is that they sometimes see proofs and proving as unrelated to their own ways of thinking (Selden & Selden, 2008). Part of the difficulty with proving involves the need for the learner's increased awareness of and sensitivity to disciplinary norms and what statements in an argument need to be justified.

In contrast to these cognitively-oriented frameworks, we view proof as a social process in which participants of a learning community move from peripheral participation to more full members of a community engaged in the mathematical activity of proving (Lave & Wenger, 1991). Proof is a central practice of the mathematical community. Furthermore, as prospective secondary mathematics teachers, they will likely teach proof. This report analyzes the impact on
students of a pedagogical intervention to help answer the question: How can we characterize the enculturation process as students become more central members in the practice of proof?

**Setting & Participants**

The study reported here was conducted with undergraduates at a large, urban university in the United States. The participants were pre-service secondary teachers enrolled in an upper-division mathematics course intended to be an introduction to proof in upper-division classes. Of the 24 students (13 males and 11 females) in the class, 7 agreed to participate in individual interviews conducted at the end of the semester. The interviewees were 5 males and 2 females. They were all upper-division mathematics students, though four, as seniors, had participated in other upper-division mathematics classes; three were juniors and ‘new’ to proof.

The first author was the instructor of a transition-to-proof course intended for students who are interested in teaching secondary school mathematics. The second author conducted the interviews. This course is intended to precede their upper-division mathematics courses, though in practice this is not always the case. A primary goal of the course is for students to develop expertise writing proofs and solving problems. In this course, we take a view of proof as a convincing argument that answers the question ‘Why?’ Thus, the primary function of proof for the students in our undergraduate educational setting is verification and explanation (Hanna, 2000). Euclidean and non-Euclidean geometry is the content area in which we develop reasoning and communication.

The text, Henderson and Taimina’s (2005) *Experiencing Geometry: Euclidean and Non-Euclidean with History* (3rd Edition) consists of a series of problems that ask students to make conjectures and then to justify the conjecture. A goal of this course is that students will develop personally meaningful solutions to problems by drawing on intuitive notions to understand geometric concepts. They are then asked to communicate their mathematical thinking and activity to others. Zandieh, Larsen, and Nunley (2008) describe the process of developing a proof starting from intuitive ideas and conjectures as consisting of two phases. The first phase is described as ‘getting a feel for why the statement is true” and the second is described as “working out the details” (p. 135). Students are pushed to answer the “why”, using this as an opportunity to develop a more formal argument. Our pedagogy focused on helping students understand why something is true and then, with the help of peers and the instructor, develop expertise in writing proofs more formally.

In this study, the structure of the class meetings typically involved working in small groups of four on challenging problems and presenting the group’s progress on these problems in whole-class discussions. The class developed an expectation that students would also be expected to question and comment on each other’s offerings and preliminary presentations. These questions and comments were usually in the form of questions posed to the presenter of the proof and his or her group.

The first author developed a pedagogical intervention intended to raise awareness of and sensitivity to the need to query support for statements made in mathematical arguments by drawing a line next to the presented proof and recording the questions asked of the proof creator. For example, Figure 1 illustrates one such scenario. A representative from a group presented their tentative argument. Other students in the class asked questions. Their questions were recorded to the right. (See Figure 1.) This intervention was a modification of the classic format of a two-column proof, which facilitates the creation and evaluation of a proof by making explicit statements and reasons (Herbst, 2002). This modified two-column format reifies the
The presentation of a proof and the questions asked by the writer or a reader of the proof. The pedagogical innovation emerged in the semester prior to the study and the instructor intentionally enacted the pedagogical innovation in a subsequent semester. We view the modified two-column proof format as a boundary object (Star & Greismeier, 1989), that is, an interface between the students of the class and the instructor as an experienced member of the community into which they were becoming more central participants. Just as mathematicians internally question their understanding and the validity of the proofs they read, so, too, students learned to ask these questions.

![Figure 1. A portion of a proof along with recorded questions from students.](image)

**Methodology**

**Data**

The data sources for the study drew from instructor’s reflective journal, copies of artifacts collected during the semester, and video-recorded individual interviews. Specifically, the data corpus consisted of the following:

- Transcripts of post-semester clinical interviews with 7 students;
- The instructor’s record of instructional decisions, which sometimes included accounts and interpretations of classroom events, as well as rationales for instructional design decisions;

---

• Captured collective work—for example, overhead transparencies, which include a
group’s convincing argument and a record of the class’ questions in response;
• Students’ relevant written work including responses to exam questions and selected
homework that entails creating and critiquing proofs.

Seven subjects participated in post-semester semi-structured, task-based interviews (Goldin,
2000). The interviews were designed to reveal how students engaged in the practice of proof.
Further, students were prompted to reflect on how they engaged in proof or rather how the
activities and practices of the classroom community might have contributed to their engagement
in practice of proof. Three tasks and reflection on the proof creation and proof critiquing process
comprised the interview protocol.

The first task entailed asking an interviewee to construct a proof for a novel problem. In the
second task, the interviewee was then presented with a student’s convincing argument for the
conjecture posed in the first task. Thus, the interviewee was asked to critique another’s proof of
the task that he or she had just constructed. For the third task, a problem the students had
previously undertaken as homework was represented with another student’s solution. In the
second and third task, the task had the modified two-column format (that is, the pedagogical
intervention students were familiar with from class) labeled Convincing Argument with an
accompanying column for Questions.

After completion of the three tasks, the interviewer asked the students to reflect first on the
process in which they had just engaged as they created convincing arguments and second on the
process, as they had critiqued others’ proofs, and finally, on the practice as situated in the
activity of the classroom community.

Methods
Our initial goal for the analysis was to uncover the diversity of ways in which students were
reasoning about purported proofs, their ability to construct proofs, and their perspective on the
modified two-column format. We therefore engaged in what Strauss and Corbin (1990) refer to
as open coding, which is the process of selecting and naming categories from the analysis of
data. Specifically, we began the analysis for diversity of student reasoning by first examining the
seven end-of-semester interviews. We then triangulated this analysis using the constant
comparison method (Glaser & Strauss, 1967) by examining all documents collected during the
semester that provided additional information on student use of the modified two-column format.
These documents included copies of overheads that the teacher and her students produced in
class, copies of student homework, and copies of student exams.

We then engaged in the process of making explicit connections between categories and sub-
categories. This step is what Strauss and Corbin (1990) refer to as axial coding. The aim of this
step was to put our analysis together in new ways. Specifically, we came to see our analysis as a
paradigm case of the process of enculturation into mathematical proof. As Strauss and Corbin
(1990) argue, a researcher’s ability to see an analysis in new ways stems largely from his or her
theoretical sensitivity. Sources of theoretical sensitivity include the research literature,
professional experience, and personal experience.

Results
A major result from this analysis was the framework in Figure 2. This emergent framework
portrays three dimensions along which we describe the transition of students from newcomer to
more central participants. The central dimensions consist of the Manner in which a learner engages with proof, the Criteria that a learner brings to bear on proof and the Positioning of self with respect to proof. Our analysis revealed critical aspects of students’ positioning in the transition along the continuum of newcomer to more central participant. Each of these dimensions contains several distinguishing features that differentiate newcomer from more central participant in the practice of proof. Moreover, these dimensions can be used to describe both activity as proof creator and proof critiquer. We illustrate briefly here using examples from the interviews of students we characterize as being more central participants or newcomers to the practice of proof.

A student who had some experience with proof prior to and concurrently while participating in this class carefully considered what was to be proven and took on the role of skeptic in proof creation. The initial pass through the proof tended to be wholistic, scoping out what needed to be done before beginning to write. A more central participant framed the proof: “So, now I am convinced that it works in all possible cases. So the next thing I would do is to break down into these cases and prove each case using arguments that I used, you know, and just assign everything variables and what not.” As a proof critiquer, his manner was one in which he tended to review the proof first holistically, paying attention to the structure of the proof and playing the believing game initially. In contrast, a student who was a relative newcomer tended to read proofs to be personally convinced. After creating a proof, he was asked to critique another student’s proof and tended to read the proof to be personally convinced. He said, “They pretty much followed everything I did. That’s why I didn’t question it….I don’t see why I would question it.”

The criteria a learner brings to bear vary in terms of the attention to and certainty about disciplinary norms. These can include, for example, whether in a proof critique, they can rely upon the geometric picture as evidence and the expectations for the efficiency and elegance. A relative newcomer doesn’t provide or expect warrants unless they themselves are having difficulty following the argument. A more central participant is one who expects explicit warrants even in cases where they follow the argument. As one said, “I know it is true and he is not wrong. But if you are doing a proof you need support, you need a reason why and he didn’t state it. It would have made a stronger argument.” A newcomer tended to use variables and notation that encumbered his or her thinking about a problem, whereas a more central participant leveraged notation and tended to be explicit about what they were doing.

Finally, we frame a difference in the individual positioned as a tentative questioner versus one who takes ownership of the critique, who reads for the purpose of understanding someone else’s point of view and speaks as if he or she was a member of a larger group. A tentative critiquer discussed the difficulty in taking on the role of critiquer, “The first time I saw this in class I had a problem with questioning...I feel like for me it is a little negative...like look at this person’s proof. What’s wrong with it?” But it’s not you are just asking questions for clarity.” A more central participant indicated a view of self as teacher/facilitator using language such as “Because it says P has to lie on the outside. It is maybe a special case. I want him to explore it more.” A more central participant reads for the purpose of understanding another’s perspective and sometimes critiques as if he or she is a member of a larger group. A more central participant was comfortable in the role of asking questions: “[As a teacher] I need to be able to ask questions because if I am not asking questions, then what I am doing is giving answers. I need to be able to leave the student to find their own responses or answers…”

We see these three dimensions of manner, criteria, and positioning as derived from the reflexive relationship between a individual and the community in which he or she participates. In the larger sense, the social norms are reflexively related to the beliefs and values of a proof creator and critiquer. The criteria one brings to bear on proof are related to the socio-mathematical norms negotiated within the classroom community. The manner in which they engage in the activity of creating and critiquing proofs is related to classroom math practices.

Conclusions

We propose that our analysis outlines indicators of the journey that students take as they become more central members of practice of creating and critiquing proofs. Our work contributes pragmatically to the pedagogy that fosters enculturation in ways that are commensurate with the discipline (Weber, 2002). In particular, we believe this intervention provides support for their future work as teachers. When asked to reflect on the usefulness of this pedagogical intervention, one student said,

*It has definitely helped me...Just because you get the outside voices coming in. You get your partners telling you, 'I don't understand' and being a prospective teacher you can't be just like 'Here it is” ...You need to be able to respond to questions and ..how you got there.*

Our analysis also showed that the pedagogical innovation played a role in promoting shifts in the positioning or identity as a mathematics teacher. We further propose that our framing of enculturation to proof as human and social activity offers an alternative lens which complements the extensive research on the cognitive aspects of understanding students’ challenges with proof.

JUSTIFICATION IN MIDDLE SCHOOL CLASSROOMS: HOW DO MIDDLE SCHOOL TEACHERS DEFINE JUSTIFICATION AND ITS ROLE IN THE CLASSROOM?

Eva Thanheiser

Portland State University  
asitomer@pdx.edu

A good classroom proof would convince a skeptical mathematician, as well as explain to a naïve undergraduate [or middle school student] (Hersh, 1993, p. 398).

Recent reform movements and standards documents call for all students in all grades to engage in mathematical justification. For this to be possible teachers need to understand mathematical justification themselves and know how they can use justification in their classrooms to promote learning. In this study we examined 12 middle school teachers' concepts of justification and the role they see it playing in their classrooms. Results indicate that 10 of the 12 teachers included 'explaining their students thinking' into their definition of justification. Six of the 10 coupled this with 'explaining why something works' while the other four did not. Eleven of the 12 teachers saw the role of justification in their classroom as helping students learn and 7 teachers used justification for assessment purposes. The teachers’ concepts of justification and their vision of its role impact how they react to student responses.

Introduction

Consider the following two student solutions to the problem \( \frac{1}{2} + \frac{1}{4} \) (see Figure 1).

<table>
<thead>
<tr>
<th>Claire’s Response</th>
<th>Ahmed’s Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>I know that ( \frac{1}{2} ) is the same as two ( \frac{1}{4} )s. So, altogether I have three ( \frac{1}{4} )s, or ( \frac{3}{4} ).</td>
<td>I found a common denominator, which was 4, and then I added ( \frac{2}{4} ) and ( \frac{1}{4} ) to get ( \frac{3}{4} ).</td>
</tr>
</tbody>
</table>

![Figure 1. Two student solutions to ½ + ¼](image)

Would you consider either (or both) of these solutions a justification? Why or why not? We encourage the readers to take a minute to decide their answer and reasoning before proceeding. Pondering the answer to this question raises the next question: A justification of what? There are two things that could be justified in this example, one is the answer (3/4) and one is the process...
of getting the answer. So we see that answering the question of whether either (or both) solutions are justifications is not as straightforward as one may think. Whether one determines either Claire’s response or Ahmed’s response a justification will depend on two things: (a) one’s own definition of justification and (b) how one sees the role of justification play out in a specific context (such as a middle school classroom). The literature provides several definitions for justification (or proof) that may also apply in the middle school classrooms. For example, “proof [or justification] is just a convincing argument, as judged by competent judges” (Hersh, 1993, p. 398) and in the middle school environment the middle school students would take on the role of justifying and judging (as competent judges). Another way of looking at justification may be "the process employed by an individual to remove or create doubts about the truth of an observation" (Harel & Sowder, 1998, p. 241). Both these definitions talk about proof (or justification) as convincing and/or removing doubt. In this paper we turn to middle school teachers and examine their concepts of justification and what they see as the purpose of using justification in their classrooms.

Purposes

In recent years several organizations have called for justification to be a part of the mathematics education of students at all levels (i.e. NCTM, 2000). The NCTM Principles and Standards state explicitly that all students K-12 should recognize reasoning and proof as fundamental aspects of mathematics, make and investigate mathematical conjectures; develop and evaluate mathematical arguments and proofs; select and use various types of reasoning and methods of proof (p. 56).

In addition the NCTM Standards note, “reasoning mathematically is a habit of mind, and like all habits, it must be developed through consistent use in many contexts” (p. 56) and “should be a natural, ongoing part of classrooms discussions” (p. 342). With justification permeating all grades, many contexts, and classroom discussions, the question of how teachers think about justification arises. If teachers are expected to leverage and promote student justification, the teachers need to have an understanding of justification themselves as well as an idea of how to use it in their classrooms. As a field, we know relatively little about teachers’ views and practice with respect to justification (Knuth, 2002a, 2002b).

In this paper we report on the first part of a three-year project designed to investigate how teachers’ understanding of justification develops and how this understanding impacts, and is impacted by, their teaching. To begin this work, we documented, via interviews, teachers’ conceptions of justification and its role in their classrooms, including how that manifests itself when they consider specific student responses.

Perspectives

Two major types of understanding have been identified in the literature, one focusing on “how” to do something the other on “why” it works. Hiebert & Lefèvre (1986), for example, distinguish between conceptual and procedural knowledge. Conceptual knowledge “can be thought of as a connected web of knowledge, a network in which the linking relationships are as prominent as the discrete pieces of information” (pp. 3-4). By contrast, procedural knowledge focuses on “rules or procedures for solving mathematical problems” (p. 7). Teaching with justification honors children’s thinking and centralizes their sense making through a focus on conceptual knowledge. However, in many classrooms the focus lies on developing procedural rather than conceptual knowledge.
In many school mathematics classrooms, students often are encouraged to use results and methods based on the authority of the teacher, rather than on a mathematical argument that the method produces the desired result (Chazan & Lueke, 2009, p. 28). Justification plays a crucial role in classrooms that do not follow what Chazan and Lueke describe as typical practice. In such classrooms, teachers expect their students to build their own understanding and explain why things work. For teachers to be able to enact classrooms that allow students to develop conceptual understanding and take on some of the mathematical authority through justification, the teachers need to explicate their own understanding of justification and need to be explicitly aware of how and why they use it. This will allow the teachers to work with their students to establish what counts as a justification and allows the teachers to give feedback to their students on the process of justification.

Few studies have sought to understand teachers’ conceptions of justification and its role in the classroom. Knuth (2002a, 2002b) argued that teachers’ conceptions of the nature and role of proof would shape their classroom practice with respect to proof. He found that High School teachers saw as the role of proof developing logical thinking skills, communicating, displaying student thinking, and explaining why, which seemed to be akin to showing a derivation (and not promoting insight, as in the case of an explanatory proof). Knuth (2002b) remarked that he was surprised that teachers did not talk about the role of proof in supporting student learning. Knuth noted that most teachers were also not committed to the idea that all students should encounter proof, and generally felt it was more appropriate for their higher-level classes. It is possible then that teachers see proof as more of a topic to be taught than as a core mathematical process.

In this paper, we examine how a group of middle school teachers who value communication and conceptual knowledge building in their classrooms define justification and describe its role in their classrooms.

Methods

Participants

Participants in the study are 12 middle school mathematics teachers. Half of them had previously participated in intense professional development geared towards promoting student discourse in mathematics classrooms. The participants were recruited for the study based on (a) previous involvement in professional development, (b) through connections to other teachers who had been involved in professional development, or (c) through connection to the research faculty. The participants were selected in this manner because this study aims to examine how teachers’ conceptions of justification (and its role in the classroom) develop and thus it is essential that the teachers already expect their students to participate in classroom discourse; however, this discourse may not focus on justification yet. As part of the project the teachers participate in a two-year extended professional development that involves meeting with researchers for one week each summer and for three work sessions throughout the year. In addition the researchers collect data in their classrooms four times each year.

Data

The data examined in this study come from two 20 – 70 minute interviews conducted with the teachers at the beginning of this three-year project. The interviews were audio taped and transcribed for data analysis. Interview questions aimed to find out how teachers define justification and its role in their classrooms. Sample questions can be seen in Figure 2.
What is justification?
- When you talk about justification [proof], what do you mean by that term?
- Is either of Claire or Ahmed’s response an example of what you consider to be justification? Why?
- What makes a good justification? Can you try to put this in words?

Why use justification?
- Can you tell me a bit about justification in your classroom?
- What are your goals with respect to justification in your classroom?
- What do you think you can expect from your students at the beginning of the year with respect to justification?

Figure 2. Sample Interview Questions

Analysis
Data analysis began by reading all transcripts carefully and examining all answers teachers gave (across questions) for how they thought about justification and its role in the middle school classroom. Because little is known about teachers’ conceptions of justification we followed the methodology of grounded theory with open coding (Strauss & Corbin, 1990), thus keeping an eye open for categories to emerge from the data and then refining those categories with further data analysis. Several members of the research team then composed summaries for each teacher focusing on what the teachers thought justification was and how they said they would use it in their classroom. These summaries were then used to develop initial categories for each of the two questions:

(1) What do the middle school teachers think justification is?
(2) Why do they use justification?

After developing the initial categories, each transcript was carefully coded using those categories, but keeping an eye out for new or more refined versions of the categories to emerge. Each coded statement was read by at least two members of the research team to ensure agreement on classifications and the development of new categories. In this paper we report on the initial categories that emerged from this data.

Results

What is justification?
Three themes emerged in the teachers’ responses to the questions probing for a definition of justification (See Table 1 for the distribution of the teachers’ answers as well as a summary):

1. A justification explains why something works (mathematically). This category focuses on the mathematical reasons for why something works. Sample answers were “I think that justification has more of the why behind it.” [T5] and “justifying doesn’t mean just being detailed … showing your procedures, but it meant being able to get to the crux of it.” [T12] or “why does it work … why does it work mathematically?” [T3]

2. A justification explains student thinking or how the student knows. This category is more personal than the first category in that the focus is on the student rather than on the mathematics. Sample answers were: “Justification… okay, like reasoning? As to why… your reasoning as to why you think your answer is correct. Looking at your process to justify why you think something is true. Not because, because ‘I know it’s true,’ but your reasoning.” [T2]. A typical question teachers want to ask in this category is: “how did you come up with that?” [T4]
3. A justification explains what a student did. This category focuses on what the students did in comparison to the first two that focused on student or mathematical reasoning. Sample answers to what justification is in this category were “being able to explain what you did” [T10] or “showing what they did to get there” [T5].

| Table 1. Categorization of Teachers’ Responses to Questions Probing what Justification is |
|-----------------------------------------------|---|---|---|---|---|---|---|---|---|---|---|---|
| What is justification? | T5 | T4 | T8 | T12 | T3 | T7 | T1 | T6 | T11 | T2 | T9 | T10 | # of teachers |
| 1. explains why something works (mathematically) | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 7 |
| 2. explains student thinking or how the student knows | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 10 |
| 3. explains what a student did | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 4 |

As we categorized the teachers’ responses individually teachers could be categorized as holding any combination of the conceptions listed above. From the data in Table 1 we see that 7 of the 12, more than half the teachers, thought justification explains why something works (mathematically) and except for one case (T1) this was always coupled with justification is explaining student thinking or how the student knows. Another observation to make from the data is that 10 of the 12 teachers included the second category (a justification explains student thinking of how the student knows) in their definition of justification. A third observation is that there were only 4 instances of justification as explaining what a student did. The first three (T5, T4, and T9) coupled with other categories, thus only one sole occurrence. We are unsure whether the views of justification of the teachers selected for this study are representative of the larger population as many of them had sustained professional development regarding discourse in the classroom and most of them are teaching from reform curricula that include justification.

Why use justification?

Various themes emerged from our analysis of this question. One important dimension was the different constituents the teachers saw as benefitting from justification: the individual student, the group, or the teacher/assessor.

1. Justification is for individual students to help them learn the mathematics or gain a deeper understanding of the mathematics for themselves. This category emphasizes that the focus of the learning is on the individual student. Students are asked to justify so they understand the concept better. Sample answers in this category are “I think you further understand things when you can explain them to someone else.” [T5] or “[justification] makes for a deeper understanding of the mathematics” [T12]

2. Justification is for the other students in the classroom to learn from each other. This category emphasizes the shared authority in the classroom. Justification can be used as a way for students to learn from each other. Sample answers in this category include “I am just trying to get them to press each other a little bit more” [T1] and “make connections to other people’s thinking and learning, … listening to understand others and trying to make those connections.” [T1]

3. Justification is for the teacher or external examiners. Justification is used in the classroom to allow the teacher to see what the students are doing for both formative and summative assessment. This category also includes external examiners such as state tests. Sample answers in...
this category include “you know, seeing, and being able to follow – as the facilitator – how they [the students] got there.” [T2] or “so I can see what you [the student] are talking about” [T11] and later this same teacher stated “and how I know they learned.”

Table 2 shows the distribution of the teachers’ answers among the various categories. As we categorized the teachers’ responses individually teachers could be categorized as holding any combination of the conceptions listed above. Table 2 indicates that 11 of the 12 teachers saw justification as a way to help students learn mathematics for themselves or from each other. The second category (helping students learn from each other) was always coupled with the first (helping students learn for themselves), however, not all teachers coupled the two.

Interaction between the definition and the role of justification

Comparing the data in Tables 1 and 2 reveals that almost all of the 11 teachers who viewed the role of justification as helping the students learn (for themselves or from each other) also thought justifications explain student thinking and/or how the student knows (the exceptions are T1 and T10). This connection makes sense: for a student to learn from justification, the student must explicate his or her current thinking/understanding to be able to build on it. This aligns with an emphasis on conceptual (rather than procedural) understanding. However, one teacher (T9) who defined justification as including an explanation of student thinking or how the student knows did not state that the role of justification was to help students learn (for themselves or from each other). This teacher (indicated the role of justification was for the teacher to assess the student. The conjunction of these two categories – justification explains student thinking and the role of justification is assessment– shows a link of assessment to student thinking (rather than a focus on the correct answers) thus connecting to the students’ conceptual understanding rather than accepting procedurally determined answers.

How do the teachers categorize Claire’s and Ahmed’s solutions?

The teachers as a group considered Claire’s solution a justification. Ten of the 12 teachers said so explicitly and 2 said probably (see Table 3). Sample reasons for a yes response were “Claire’s response is [a justification], um, mainly because of her drawing. I think that that representation helps.” [T1] or “Well, she's explaining... I mean, she's basically explaining what she's doing … and the picture really brings it together. I mean, this would work.” [T4] A sample response coded as probably was “This [Claire’s solution], I think from what I am seeing, this has more internal meaning to students [as opposed to Ahmed’s solution].” [T3]

Ahmed’s solution elicited a much more varied set of responses from the teachers. Four of the 12 teachers considered it a justification, 3 teachers did not consider it a justification, and 3 teachers stated that it depends on either what else the student knows or what the class had done.
before. The responses of 2 teachers were not detailed enough to make a definitive determination of their view. (See Table 3.) A sample response for 

yes (Ahmed’s solution is a justification) was “But, yeah, this [Ahmed’s] is kind of a little bit more sophisticated mathematically [than Claire’s] … [but both solutions] are showing their steps. They’re showing the process they went through and they’re coming up with an answer” [T4]. A sample response for 

no (Ahmed’s solution is not a justification) “because he is thinking of his rules and he is following it and unless he was thinking that, unless he said something that a common denominator means that, this, that I, right now there is no justification in it so he’s just, so if I were to look at this without talking to him I would say, no, he is not justifying anything.” [T11] Teachers whose responses were coded 

depends indicated that Ahmed’s response might or might not be a justification depending on what they had done previously in the classroom, e.g., “it depends on where are we in the year in terms of fractions” [T10], or what level the students were at: “for an 8th grader that’s pretty given, but for a 6th grader, I want to make sure he knows why it’s working” [T8].

Note: (Y=yes a justification, N=not a justification, D=depends (on student background knowledge), ND=not determinable)

In general we notice that Ahmed’s more algorithmic/procedural response elicited a much wider variety of response from the teachers than Claire. While all the teachers classified Claire’s as a justification (or probably one) only 4 teachers did so for Ahmed. The variation seems to stem from the fact that teachers thought Ahmed’s solution could represent a range of levels of understanding of the fraction concepts, from no understanding (a mere application of a learned procedure) to a thorough understanding of the underlying relationships, most notably why finding a common denominator of 4 is useful, and why 2/4 is the same as 1/2. For example, one teacher responded that is was not clear “whether he knows it because it’s just a common denominator, or if he knows, like, ‘cause I think it’s the same rationale that Claire’s using, one half equals two quarters” [T6]. Some teachers indicated that further information may lead to a clearer determination of what Ahmed knows, thus teachers in the “no” category may change their categorizations with additional information about the students’ thinking. The stance of those indicating “depends” was that some light might be shed on Ahmed’s understanding if one knew what had been established in his classroom community before he produced this solution. If this method was established in his class then it may stand as a justification.

**Discussion**

As evidenced across the teachers’ conceptions of justification, its role in the classroom, and their particular analysis of Claire’s and Ahmed’s responses, this group of middle school teachers was strongly committed to justification as revealing student thinking and showing why something works and to the role of justification in both promoting and assessing student understanding. Their responses, and in particular, the teachers’ discussions of Ahmed’s justification, reveal high valuing of conceptual understanding – something that they, as teachers, could promote and assess by engaging students in the practice of justification. Indeed, this is at the heart of the variation in responses to Ahmed’s response, as many teachers deliberated on

---

whether the response offered evidence the student understood the fraction concept and/or the conceptual underpinnings of the algorithm to add fractions with unlike denominators.

These results contrast with prior results by Knuth (Knuth, 2002a). Unlike Knuth’s secondary teachers, this group of teachers felt justification was appropriate for all their students and saw a close connection with justification and promoting student learning. A reason for these differences might be the teachers’ extensive previous professional development (which may render them somewhat unrepresentative). Both studies, however, found that teachers thought a purpose of justification was displaying student thinking.

Conclusions

Teachers (and teacher educators) struggle to explicate what a justification is and why they use it. While teachers seem to agree that justification is a valuable practice to use in the classroom; they hold mostly implicit and intuitive notions of what a justification is and what makes a justification good. To be in a position to teach in a way that incorporates justification in the classroom, teachers need to move beyond intuitive notions of what makes a good justification and explicate what they are looking for and why. This would in turn support the development of students’ conceptual understanding and teachers’ ability to give feedback to students.

The results reported in this study are the first step in understanding how a group of middle-grades mathematics teachers think about justification and why they use it. This study provides a little insight into how teachers view justification. By understanding how teachers think about justification and why they use it, teachers can lay the foundation for discussions on how to capitalize from justification in their own classrooms. In our work with the teachers we have found that the teachers are beginning to move from simply having students share justifications in their classrooms to utilizing them more purposefully and are thinking more deeply about what to do with a justification once it has been shared.

Endnotes

1. The preparation of this paper was supported by a grant from the National Science Foundation (NSF). The views expressed are those of the authors and do not necessarily reflect the views of the NSF.
2. While we recognize that distinctions are made in the literature between the terms justification, reasoning, argumentation, and proof we are not examining the differences between those and will use them interchangeably in this paper.
3. The teacher pseudonyms were given for the initial ordering of the data. The data were then reordered to allow patterns to emerge. The ordering of the teachers stays constant throughout the paper.

VIRTUAL OTHERS: ONE LEARNER’S MATHEMATICAL ARGUMENTS IN RESPONSE TO AN ANIMATED EPISODE OF GEOMETRY INSTRUCTION

Wendy Aaron
University of Michigan
wendyaar@umich.edu

Patricio Herbst
University of Michigan
herbstp@umich.edu

This study looks at one mathematically inclined learner’s interactions with an animated episode from a high school geometry classroom. The learner being observed worked on the same geometric task as the students in the animated episode and alternated working the mathematics and watching the video. We conceive the animated characters as virtual classmates for the learner to react to, thereby locating the learner’s activity in their zone of proximal development (Vygotsky, 1978). The research questions are aimed at understanding the mathematical work done by the learner and how the positions of the animated characters supported the learner’s mathematical work.

Introduction

Vygotsky (1978) described the zone of proximal development as the difference between what a child can do with the help of others and what they can do alone. In mathematics, this construct helps us understand that students may be able to solve problems and learn in groups in ways that might not be possible alone. When students work on mathematical tasks with others, teachers or fellow students, they have more resources available to them and their opportunities to learn increase by being exposed to others’ thinking. The study described in this paper looks at one mathematically inclined learner’s interactions with an animated episode from a high school geometry classroom. The learner being observed worked on the same geometric task as the students in the animated episode and she alternated working the mathematics and watching the video. We conceive the animated characters in the episode as virtual classmates for the learner to react to, thereby locating the learner’s activity in their zone of proximal development. The research questions are aimed at understanding the resulting mathematical work done by the learner and how the positions put forth by the characters in the animation supported the learner’s mathematical work.

This study (1) is primarily concerned with they ways that students learn how to do proofs. Students in schools learn how to do proofs inside the instructional situations of ‘doing proofs’ (Herbst & Brach, 2006). The instantiations of ‘doing proofs’ in the geometry classroom are not necessarily the same as the instantiation of proving outside of a classroom. A fundamental difference between doing proofs in the realm of mathematics and in the geometry classroom is that in the latter the claims to be proven by students are assigned by the teacher and often times are inconsequential; the work is done not so much for the sake of the claim proved but for the purpose of claiming that the class has learned how to prove. This is different than the realm of mathematics where proofs are done to justify claims and to expand the knowledge of the field (Hanna, 1983). In the realm of mathematics the claims to be proven might evolve over the course of the proof (Lakatos, 1976).

In the current study, learners were shown an animated classroom episode in which students are asked to make conjectures and prove claims about the angle bisectors of a quadrilateral. We recorded each learner’s arguments and analyzed the structure and content of the arguments. By
understanding how the learners interacted with the animation we can hypothesize how interactions with animated classroom episodes could expand students’ opportunities to learn.

We ask following research questions:

- How does the learner make sense of the discussion being presented in the animation?
- What role do the animated characters’ arguments play in the arguments of the learner?

Data

The data to be used in this study was collected in individual meetings with a middle school student, Sonia, for ten, one-hour sessions each. In these sessions Sonia watched animations with the first author, and both participant and researcher would pause the animation to ask a question or give a reaction. Often the animation would be paused for many minutes while Sonia worked on mathematical questions inspired by the animation. At the time of this study, Sonia was about to enter the ninth grade. She would be taking geometry for the first time in ninth grade. These sessions were audio recorded and then transcribed and indexed for analysis.

These case study data could be framed in several ways, but we are looking at them as cases of a learner making sense of a classroom discussion about an open-ended task. In the case we can see the learner making sense of the discussion by interpreting the arguments in the discussion and creating her own arguments, perhaps drawing on the discussion in the animation.

The animation used in this study is an animated episode of geometry instruction entitled The Square (2). The Square is an eight-minute episode that shows a particular case of a teacher and her students interacting around the angle bisectors problem. After reminding students that the angle bisectors of a triangle meet at a point, the animated teacher gives her students several minutes to work on making conjectures about angle bisectors in a quadrilateral, which she says they will later try to prove. When time is up, the teacher calls Alpha to the board to share his conjecture. Alpha draws a square and its diagonals on the board and states the conjecture that “they bisect each other.” The teacher dismisses Alpha’s conjecture on the grounds that the problem is about angle bisectors, not about diagonals. Some students come to Alpha’s defense, saying that angle bisectors and diagonals are the same thing. In response to this Gamma comes to the board to show that in rectangles angle bisectors and diagonals are not the same thing. Alpha then restates his conjecture as “In a square the angle bisectors meet at a point because they are the diagonals.” Now that the conjecture has been refined, the teacher asks for volunteers to prove the statement. Lambda begins to prove the statement from his seat. In the following minutes the teacher and Lambda struggle to understand each other. Their communication is hindered by the fact that Lambda would like the teacher to erase one of the diagonals from the square and the teacher resists this action. Finally, the teacher erases one diagonal and Lambda completes his argument. The episode ends with the teacher calling for a two-column proof of Lambda’s argument.

Method and Analysis

The conversations with the learner were analyzed to reveal the argument that she made in reaction to the animation. The arguments were modeled using Toulmin’s arguments scheme (Toulmin, 1958). Toulmin’s method of modeling arguments is a tool for describing the connections that an arguer could make between a set of data (hypothesis) and a conclusion. Importantly, connecting these two are a warrant, or reason to believe that the conclusion follows from the data, a backing, or further support for the warrant, a qualifier that conveys the arguer’s confidence in the argument, and a rebuttal, or a counter argument that the arguer acknowledges

(see Figure 1). Every argument may not make use of all these components, but Toulmin claims that all arguments can be fit into this form. Toulmin’s scheme was designed as an alternative to formal logical argument models, so unlike standard mathematical proof, the warrant for an argument need not be logical connectives and the qualifier is not always “necessarily”. This freedom from formal logic makes Toulmin’s model useful for recording arguments that rely on inductive logic or intuition.

Figure 1. Toulmin’s model of arguments
(Note: The model can be read as “D implies C with probability Q, on the basis of W, supported by B, unless R.”)

Once Sonia’s arguments had been mapped from the conversations they could be compared in terms of their structure. Below we showcase the argument made by animated characters in The Square and compare it with an argument made by Sonia.

**Sonia**

To begin I will present the map of the argument presented in the first few moments of the discussion in The Square. I will then present Sonia’s argument that she produced in response to this argument, highlighting her interpretation of the animated characters’ argument and describing the form and flow of her argument.

As stated above, the animation begins with the teacher posing the question, “what can one say about the angle bisectors of a quadrilateral?” The teacher calls Alpha to the board and he makes the claim that in a square the diagonals bisect each other. This is mapped below in the top three boxes of Figure 2, representing the data, “A square”, and the conclusion, “In a square the diagonals bisect each other.” This conclusion is warranted by the exploration that Alpha did independently after the teacher posed the problem.

After Alpha makes his initial argument Beta begins a second argument by asserting the conclusion that “Diagonals are angle bisectors.” This is represented in the box at the far right of Figure 2. She bases this conclusion on Alpha’s choice to look at a square and the warrant, provided by Alpha, that “The diagonals of a square cut it in half.” This second argument, seen in the bottom half of Figure 2, and ending in Beta’s conclusion, is the argument that Sonia uses to build her own argument. We now describe the argument that Sonia made in response to the arguments of the animated characters.
From the transcript of the discussion we map Sonia’s sense making of the animated students’ comments. The result of this mapping is shown in Figure 3. In the figure, boxes that are filled and thin arrows represent comments made by characters in the animation. Boxes that are not filled and thick arrows represent comments made by Sonia. The goal of this mapping is to show the interaction between Sonia’s thought process and the discussion in the animation as well as highlight the mathematical actions that Sonia employs while making sense of the discussion in the animation.

On the second day of the case study Sonia interprets Alpha’s statement “Well, I just thought that the diagonals cut the square in half” (excerpt of the case study transcript can be seen in Appendix A). The conversation between Sonia and the researcher begins with the researcher asking Sonia what Alpha means by this and then asking her how this relates to the question the animated teacher asked, “what can one say about the angle bisectors of a quadrilateral?” Sonia goes on to interpret Alpha’s claim that the diagonals of a square cut it in half and provide an argument in response to the teacher’s question.

Sonia interprets Alpha’s statement, “the diagonals cut the square in half” as meaning that the diagonal cuts the quadrilateral into two triangles of equal area. This is represented by the node at the bottom left of Figure 3 that reads, “The diagonal cuts the square into two triangles with equal area” that is set equal to filled node that reads, “The diagonals of a square cut it in half.” Sonia says, the diagonal “cuts it in half triangle wise…like this side is the same as this side, the area.” Sonia does not mention the area again after this and it is reasonable to think that she means that the two triangles are congruent, not that they have equal area. To support this, as examples she gives the rectangle and parallelogram as quadrilaterals that have diagonals that cut the shape in half and she gives the kite and its minor diagonal as a counter-example. These warrants are shown in the very bottom left of Figure 3 in the node that reads, “This is true in a quadrilateral where the opposite sides are the same length [like parallelograms and rectangles].” The counter-example of the kite is represented in the rebuttal node above which reads “Not in the case of a kite.”
Sonia’s use of “the diagonals cut the square in half” does not match with Alpha’s. The different between the two uses can be seen when the phrase is extended to rectangles. For Sonia, the diagonals of a rectangle do cut it in half (by creating two congruent triangles), and for Alpha, it is likely that he means that the diagonals of a rectangle do not cut it in half (because the diagonals do not bisect their vertex angles).

One way to interpret Alpha’s use of this phrase that is consistent with his actions in The Square is that in a square the diagonal is a line of symmetry. Using this interpretation, the diagonals of a rhombus also cut it in half, and the main diagonal of a kite cuts it in half. Sonia’s interpretation encompasses Alpha’s definition, but we see that Alpha’s meaning accepts fewer quadrilaterals than Sonia’s (specifically rectangles and parallelograms).

In The Square, Alpha uses the claim that the diagonals of a square cut it in half to support the inference that in a square the diagonals are the angle bisectors. This argument is represented in Figure 3 by the thin arrows connecting the filled nodes, “A square,” “The diagonals are angle bisectors,” and “The diagonals of a square cut it in half.” Because Sonia interprets this claim differently than Alpha, she does not use this to support that inference. Rather, she uses the conclusion of Alpha’s argument, that in a square the diagonals are the angle bisectors, to justify Alpha’s response as an appropriate answer to the question, what can one say about the angle bisectors of a unfilled. This argument is represented in Figure 3 by the thick arrows connecting the unfilled nodes, “The diagonals of a square cut it in half,” “The angle bisectors of a square cut it in half,” and “The diagonals are angle bisectors.” The first unfilled node is the data, followed by the conclusion and warrant of Sonia’s argument. By using this claim she can transform the
statement the diagonals of a square cut it in half into the claim that the angle bisectors of a square cut it in half. This statement now says something about the angle bisectors of a quadrilateral so it is a reasonable answer to the teacher’s question.

Overall, from this analysis we can see the complicated nature of Sonia’s sense making. Although the argument that she builds is not the same as the one presented in the animation it reflects flexible thinking and the ability to build and justify a mathematical argument. It also shows her ability to link the pieces of an argument to the question that the argument aims to answer. We hypothesize that Sonia’s interaction with the animation was critical in her ability to involve in this type of argumentation despite the fact that she had not been exposed to deductive geometry.

**Conclusion**

In conclusion, this analysis shows how animated episodes of geometry instruction can be used as a basis on which learners can build mathematical arguments. The animations provide prompts for students to react to and claims for students to prove, refute, and expand upon. In dynamic and unpredictable classroom interactions animations can lay the foundation for productive mathematical discussions. The use of animations as prompts does not take away work from students but rather increases the amount of mathematical resources and operations that are available while they are working on a task and gives them virtual partners to think with.

<tr>
<td>437.</td>
<td>[Animation: Alpha: “Well, I just thought the diagonals cut the square in half. Teacher: “Alpha just said that the diagonals cut the square in half. Somebody elaborate on that.”] Animation is paused.</td>
<td></td>
</tr>
<tr>
<td>438.</td>
<td>Interviewer</td>
<td>So what do you think that means? what do you think he might mean by that, “Diagonals cut the square in half.”?</td>
</tr>
<tr>
<td>439.</td>
<td>Sonia</td>
<td>Like it cuts it in half triangle wise.</td>
</tr>
<tr>
<td>440.</td>
<td>Interviewer</td>
<td>So what…</td>
</tr>
<tr>
<td>441.</td>
<td>Sonia</td>
<td>Like this side [Interviewer: Uh-huh.] is the same as this side [Interviewer: Mm-hmm.] – the area.</td>
</tr>
<tr>
<td>442.</td>
<td>Interviewer</td>
<td>And how does that relate to the question about angle bisectors?</td>
</tr>
<tr>
<td>443.</td>
<td>Sonia</td>
<td>Well she asked for conjectures about what angle bisectors do and in the quadrilateral --</td>
</tr>
<tr>
<td>444.</td>
<td>Interviewer</td>
<td>Uh-huh, but when didn’t she – but when he said, “The diagonals cut the square in half” --</td>
</tr>
<tr>
<td>445.</td>
<td>Sonia</td>
<td>Oh the diagonals are the same thing. Diagonals don’t necessarily divide – they don’t necessary bisect the angle.</td>
</tr>
<tr>
<td>446.</td>
<td>Interviewer</td>
<td>Yeah. So – so is…</td>
</tr>
<tr>
<td>447.</td>
<td>Sonia</td>
<td>But he’s not wrong if it’s a square.</td>
</tr>
<tr>
<td>448.</td>
<td>Interviewer</td>
<td>Why not?</td>
</tr>
<tr>
<td>449.</td>
<td>Sonia</td>
<td>Because they’re at 90˚ angles at – on the side – on the shape that has the same length [Interviewer: Uh-huh.] on all sides, so the diagonals and the angle bisectors are the same thing – or they go through the same path [Interviewer: Yeah.] on the -- square.</td>
</tr>
<tr>
<td>450.</td>
<td>Interviewer</td>
<td>How do you think you would prove that?</td>
</tr>
<tr>
<td>451.</td>
<td>Sonia</td>
<td>Well diagonals divide the shape cleanly in half and so --</td>
</tr>
<tr>
<td>452.</td>
<td>Interviewer</td>
<td>That’s what he just said though right?</td>
</tr>
<tr>
<td>453.</td>
<td>Sonia</td>
<td>Yeah [laughing] I was getting to the point – ok, so – and then --</td>
</tr>
<tr>
<td>454.</td>
<td>Interviewer</td>
<td>Do diagonals always cut the – cut the shape in half?</td>
</tr>
<tr>
<td>455.</td>
<td>Sonia</td>
<td>Oh I guess not.</td>
</tr>
<tr>
<td>456.</td>
<td>Interviewer</td>
<td>Well like what do [inaudible] where it does, and where it doesn’t?</td>
</tr>
<tr>
<td>457.</td>
<td>Sonia</td>
<td>Well here you would have this small little kite things that doesn’t divide the shape into --</td>
</tr>
<tr>
<td>458.</td>
<td>Interviewer</td>
<td>Right that’ not cut in half --</td>
</tr>
<tr>
<td>459.</td>
<td>Sonia</td>
<td>No. But…in a shape where the opposite sides are the same length, and then they have to cut the shape in half.</td>
</tr>
<tr>
<td>460.</td>
<td>Interviewer</td>
<td>So what’s another example, besides the square?</td>
</tr>
<tr>
<td>461.</td>
<td>Sonia</td>
<td>A rectangle. ‘Cause that cuts the shape in half.</td>
</tr>
<tr>
<td>462.</td>
<td>Interviewer</td>
<td>Oh yeah.</td>
</tr>
<tr>
<td>463.</td>
<td>Sonia</td>
<td>And this cuts the shape in half. [Interviewer: Yeah.] And on a parallelogram let’s pretend – that’s better – that’s in half too.</td>
</tr>
<tr>

FACTORS INFLUENCING STUDENTS’ PREFERENCES ON EMPIRICAL AND DEDUCTIVE PROOFS IN GEOMETRY

The purpose of this study is to investigate what influences students’ preferences on empirical and deductive proofs and find their relations. Although empirical and deductive proofs have been seen as a significant aspect of school mathematics, literatures have indicated that students tend to have a preference for empirical proof when they are convinced a mathematical statement (Porteous, 1991; Martin & Harel, 1989). Several studies highlighted students’ views about empirical and deductive proof (for example, Chazan, 1993). However, there are few attempts to find the relations of their views about these two proofs. The study was conducted to 47 students in 7~9 grades in the transition from empirical proof to deductive proof according to their mathematics curriculum. The data was collected on the written questionnaire asking students to choose one between empirical and deductive proofs in verifying that the sum of angles in any triangle is 180°. Further, they were asked to provide explanations for their preferences. Students’ responses were coded and these codes were categorized to find the relations.

As a result, students’ responses could be categorized by 3 factors: accuracy of measurement, representativeness of triangles, and mathematics principles. First, the preferences on empirical proof were derived from considering the measurement as an accurate method, while conceiving the possibility of errors in measurement derived the preferences on deductive proof. Second, a number of students thought that verifying the statement for three different types of triangles - acute, right, obtuse triangles - in empirical proof was enough to convince the statement, while other students regarded these different types of triangles merely as partial examples of triangles and so they preferred deductive proof. Finally, students preferring empirical proof thought that using mathematical principles such as the properties of alternate or corresponding angles made proof more difficult to understand. Students preferring deductive proof, on the other hand, explained roles of these mathematical principles as verification, explanation, and application to other problems. The results indicated that students’ preferences were due to their different perceptions of these common factors.

JUSTIFICATION IN MIDDLE SCHOOL CLASSROOMS: AN ANALYSIS OF STUDENT RESPONSES TO TWO JUSTIFICATION TASKS

Llancyllius Williams  
University of Connecticut  
lance.williams@uconn.edu

Megan Staples  
University of Connecticut  
megan.staples@uconn.edu

Justification has been put forward as an important mathematical practice that should be present in K-12 classrooms (NCTM, 2000; Stylianou et al., 2009). Yet, research evidence shows that this practice is often absent from classrooms, notably those in the middle grades (Jacobs et al., 2006). For teachers to teach in a manner that centralizes justification, they must anticipate, elicit and build on students' thinking. To support this, it is helpful for teachers to have ways to think about potential student responses and important dimensions along which those responses might vary. The purpose of this study was to document the range of student responses on two justification tasks implemented in middle grades classes. In reporting the results, we use an analytic framework developed by our research team, which may be useful for categorizing student responses for justification tasks.

The data used for this poster is part of a larger NSF-funded project, JAGUAR (Justification and Argumentation: Growing Understanding of Algebraic Reasoning). Data has been collected from twelve participating (JAGUAR) teachers. For the purposes of this poster, we report findings from analyses of student work on two justification tasks, namely, the Hexagon task and the Number Trick task. The data reviewed included student work samples from both justification tasks; the objective here was to capture a wide range of student responses that could be categorized under our given framework of student forms of reasoning.

Our analysis revealed a broad range of student responses. We classified this range of student responses by its mathematical form of reasoning. For the Hexagon task, students provided justifications using verbal reasoning (describing the process), model-based reasoning—through the use of pictorial, algebraic and graphical representations, as well as empirical reasoning. For the case of the Number Trick task the responses showed elements of empirical, pattern-based, model-based as well as spatial-geometric reasoning.

These findings can support middle-school teachers in gaining a richer understanding of how students engage in justification-tasks while they develop their mathematical thinking and reasoning. The analytic framework may also be a valuable tool for both generating and analyzing student thinking.

MAKING SENSE OF RATE OF CHANGE: EXAMINING STUDENTS’ REASONING ABOUT CHANGING QUANTITIES

Heather L. Johnson
The University of Colorado, Denver
heather.johnson@ucdenver.edu

In this qualitative study I examined how six high school students who have not taken calculus reasoned about changing quantities when interacting with mathematical tasks involving multiple representations of constant and varying rates of change. Employing a cognitive perspective on mathematical reasoning, I conducted a series of five individual, task-based interviews with each student. Using a three-phase data analysis process, I identified episodes where students attended to changing quantities, traced students’ reasoning from their statements, written work and gestures to develop characterizations of their reasoning, and examined how students combined covariational, transformational, and proportional reasoning when reasoning about changing quantities. Students tended to reason in ways that remained consistent across the tasks, even though the tasks involved different contexts and different types of representations of mathematical quantities and relationships between quantities. Empirical evidence from this study supports that students without formal instruction in rate of change do combine covariational, transformational, and/or proportional reasoning when reasoning quantitatively about specific and non-specific amounts of change. I use a tool that I developed to summarize different combinations of reasoning and highlight affordances of combining different forms of reasoning.

PROOF IS IN THE EYE OF THE BEHOLDER: MIDDLE SCHOOL STUDENTS’ CONCEPTIONS OF CONVINCING JUSTIFICATIONS

Kristen N. Bieda  Michigan State University  kbieda@msu.edu
Justin Drwencke  Michigan State University  drwencke@msu.edu
Andrew Picardan  Michigan State University  picardan@msu.edu

Some mathematics educators have defined proof as the process one undertakes to remove doubt, or convince oneself and others that a statement is true (Harel & Sowder, 1998). Thus, learning to do mathematical proof involves adopting the belief of what is mathematically convincing – namely, justifying by using arguments based on general premises in a logically deductive fashion. However, middle school students have yet to learn the norms of the proving in mathematics, norms that are often learned observing proofs as completed by their instructor and generalizing features of those proofs deemed to be “correct” by a mathematical authority. Understanding what features of justifications students find convincing, such as the use of examples or the use of general statements, can support instructional interventions that highlight important distinctions between proofs and non-proofs. Weber (2009) acknowledges: “The lack of research on how students do read mathematical arguments, as well as how they should read them, represents an important void (p.2)”. This study addresses the need for research on students’ reading and evaluating of mathematical proof by investigating: In what ways does the mathematical context of the statement influence students’ choice as to which type of justification is more convincing?

Interviws were conducted with 21 seventh grade students. The students were asked to evaluate two kinds of justifications, an examples-based (EB) justification and a general, deductive (G) justification, for true statements about number theory and geometry. Of these 21 students, 16 chose the EB justification as more convincing than the G justification for the number theory task. In contrast, only 9 students found the EB justification more convincing for the geometry task. Analysis of students’ explanations for their choice revealed that while students tended to value examples as a way to “show” what the statement was trying to prove, they mentioned features related to the justification’s explanatory power only when evaluating justifications for the geometry task (n=7). However, despite context of the task, only two students mentioned choosing a general argument because examples do not prove the truth of a general statement. While the sample size limits the statistical significance of these findings, the results suggest that while middle school students tend to favor EB justifications as more convincing, they value the use of examples and explanatory statements differently across various mathematical contexts.

THE CONTRIBUTIONS OF STORYTELLING TO MATH LEARNING, TEACHING AND MATH EDUCATION RESEARCH

Tina Rapke
University of Calgary
tkrapke@ucalgary.ca

This poster presentation draws on personal experiences of completing an interdisciplinary degree in the area of education and mathematics and previous works dealing with story, learning and research (Reason & Hawkins, 1988). Story and storytelling is mentioned and used in various areas of math and math education. The Alberta Outcomes with Assessment (2002) talks about students being able to tell a story that could describe the shape of a function. Ian Stuart (2006) sums up proof writing as being able to tell a good convincing story. Some have used story to describe teacher practices (LoPresto & Drake, 2005). Others have used story to describe the field of math education research (Lerman & Tsatsaroni, 2003). Story seems to have a deep entangled role in math education research and the learning of math. The poster will explore the potential of storytelling and relationships between it and math learning, teaching and education research. I will share the story of completing a dissertation that is a joint expression of both mathematics and education. Storytelling was chosen as a mode to present the research because it allows me to express the “liveliness, the involvement and even the passion of [my] experiences” (Reason & Hawkins, 1988, p. 79). I am developing a dialogue between a fictional math graduate student and her education supervisor. The dialogic storytelling style is emerging in the math education literature (Nardi, 2008). In my poster I will explore how storytelling can be used to exhibit Lockhart’s (2009) notion of mathematics being a creative journey of the imagination. Examples of storytelling are included to illuminate the role of intuition and struggle in math learning. Further research questions concerning math, math education, math learning and storytelling are included.

VALID OR INVALID PROOFS AND COUNTEREXAMPLES: PRE-SERVICE SECONDARY MATHEMATICS TEACHERS’ PRODUCTIONS AND EVALUATIONS

Yi-Yin Ko
University of Wisconsin-Madison
yko2@wisc.edu

To implement current reforms regarding proof and counterexample in secondary school mathematics successfully, pre-service secondary mathematics teachers are expected to be able to produce proofs and counterexamples as well as to determine what arguments are acceptable in the mathematics community. Notably, what counts as a valid proof or counterexample really depends on an individual proof scheme (Harel & Sowder, 2007), and a way to better understand individuals’ conceptions of proof and counterexample is by having individuals evaluate their own work (Stylianides & Stylianides, 2009). Drawing on research on proof and counterexample (e.g., Knuth, 1999), the aim of this study is to examine how pre-service secondary mathematics teachers evaluated their own proof and counterexample productions based on beliefs they and their mathematics professors held. The primary sources of data were the pre-service secondary mathematics teachers’ semi-structured interviews. During the interview, eight pre-service secondary mathematics teachers met with the researcher individually and were asked (1) to rate the level of their confidence in terms of the validity of their production using a four-point scale, and (2) to indicate whether or not their mathematics professors would accept their productions as valid. Pre-service teachers’ proof and counterexample justifications were categorized according to Harel and Sowder’s (2007) and Knuth’s (1999) taxonomies of proof. This qualitative analysis shows the distinction between what per-service teachers and their professors believed constituted proof and counterexample. The findings suggest that more attention should be paid to teaching and learning proof and counterexample, as participants showed difficulty writing proofs and counterexamples as well as held different perspectives on evaluating their own productions.

ASSOCIATION BETWEEN SECONDARY MATHEMATICS TEACHERS’ BELIEFS, BACKGROUND CHARACTERISTICS, AND DIMENSIONS OF CURRICULUM IMPLEMENTATION
Ruthmae Sears, Rukiye Didem Taylan, James Tarr ................................................................. 965
This study examines the extent to which pre-service teacher beliefs about learning mathematics are impacted by studying videos of children’s learning. Elementary pre-service teachers from three universities participated and studied videos of children’s learning stored at the Video Mosaic Repository of Rutgers University as an intervention unit in a required mathematics education course. A pre and post beliefs assessment was administered to participants as well as to comparison groups. A statistical analysis of beliefs data showed that across all sites there was a significantly greater change in experimental pre-service teacher beliefs about student learning as compared to the comparison groups.

Introduction

This study was premised on the notion that studying well-chosen videos of children engaged in learning mathematics can serve as a seminal resource for teachers to understand how students represent mathematical ideas and reason about them (Maher, 2008). Since videos are able to capture aspects of the emerging processes of learning, they can serve to engage pre-service and practicing teachers in new strategies for effectively teaching mathematical concepts to a range of students. Videos can be stopped and started again, as well as viewed multiple times, and thus provide a medium that supports reflection and consideration of beliefs and assumptions that underlie educational practice. Evidence in support of this notion comes from researchers who examined the effects of using video clips as an alternative to classroom-based field experience for prospective elementary teachers and found significant positive growth in beliefs scores among participants in the course sections that studied children’s mathematical behavior on video (Philipp, et al., 2007).

Objectives of Study

Certain views about learning and teaching, and what it means to do mathematics, give rise to particular conditions that can be examined (Davis & Maher, 1990; Maher, 1988). The objective of this study was to investigate whether studying videos of children’s learning under conditions that invited exploration, collaboration, and building meaning of mathematical ideas while working on strands of similar problems could affect pre-service teacher beliefs about how students learn. The study was part of a multifaceted research and development project aimed at preserving and making more accessible videos from the collection amassed by the Robert B. Davis Institute for Learning through more than two decades of research.

The collection contains unique and valuable video data and meta data (i.e., data about data, such as transcripts of video, coding schemes, students’ work, observational and research notes, analytic commentaries) on how students build mathematical ideas and ways of reasoning over...
time in a variety of diverse school settings and across all grade levels, in several content domains (Agnew, Mills & Maher, 2010). Drawing from the longitudinal and parallel cross-sectional studies in urban and suburban contexts, a collection of videos has evolved that captures the development of children’s reasoning, early proof making, and students’ building of isomorphisms between and among problems of the same structure (Maher, 2005; Maher & Martino, 1996; Maher, Davis & Alston, 1992).

Videos from the collection were leveraged to conduct research in the context of pre-service teacher education through comparison of experimental instruction that incorporated the studying of video clips with instruction that did not. Instructors of courses for prospective elementary teachers selected videos from the collection that featured elementary and middle school aged children [Note 2]. The video clips from classroom research illustrated children doing mathematics, talking in pairs or small groups about their mathematical ideas, sharing those ideas with the classroom community, and offering justifications for their solutions. Interviews of children sharing their solutions strategies were also included. It should be noted that the broader context for research was attentive to the use of studying videos to raise teachers’ awareness of the complexity of learning (Spiro, Collins, Ramchandran, 2007) by attending to the process through which mathematical reasoning unfolds rather than just the final outcome, and to the development of adaptive expertise (Bransford, Derry, Berliner, & Hammerness, 2006) to help teachers prepare to recognize and build upon instances of mathematical thinking in children’s problem solving, including written work and problem-solving discourse. The focal point of the study presented here was video-based instructional invention for prospective teachers aimed at development of teacher beliefs consistent with current norms and standards of mathematics education.

**Perspectives**

Pre-service teachers form beliefs about learning from their own experiences as math learners and their observations from field experiences, and their assignment to field sites may be made on factors of convenience rather than course goals. While classroom observations and reflections on observations through keeping journals and/or engaging in discussion groups are often a component of teacher education programs, the process is not without its limitations. As other researchers have noted (e.g., Philipp et al., 2007), education faculty may find themselves unable to make much input on the assignments of pre-service teachers to classrooms for observation, such as to select sites more likely to exhibit reform-oriented mathematics instruction. Moreover, in classrooms where traditional, direct-instruction teaching practices are common in local schools, pre-service teachers who are exposed to theories and research evidence that support reform-oriented instruction as part of their teacher education programs may find themselves observing practices that are at odds with what they have been learning from their professors. Research suggests that, under those circumstances, pre-service teachers will not exhibit change toward reform-oriented beliefs about mathematics learning and teaching and their belief scores may actually decrease instead (Philipp, et al., 2007).

The opportunity to study videos of children doing and talking about mathematics can give pre-service teachers access to knowledge that might otherwise be unavailable. For example, children who are hesitant to engage in large group exchanges common in the traditional classrooms can be observed in videos of their learning in small group settings, where they may be more comfortable communicating and expressing their ideas with peers. Similarly, through video analysis pre-service teachers can study and carefully evaluate the contributions of students...
who are culturally and linguistically diverse and whose ideas when expressed may not be readily recognizable to teachers because of cultural and language differences. Another valuable feature in the use of videos for improving teacher practice is that videos make possible the study of teacher moves that play an important role in influencing learning outcomes. Teacher educators working with prospective teachers can use videos as tools for studying how students build new knowledge and how teacher actions influence student learning (Maher, 2008). As has been noted, for teachers to be able to teach mathematics as a conceptually oriented sense-making activity, teachers need to shift their beliefs about mathematics away from an idea of math as a set of facts and procedures that children find difficult, towards beliefs of children as sense-makers capable of developing sophisticated mathematical thinking (e.g., Philipp et al., 2007). A Beliefs Inventory was developed and implemented as an assessment for measuring the impact of studying videos featuring children’s mathematical reasoning on pre-service teachers’ beliefs about learning and teaching math. To this end, the following research question was posed:

What effect does studying well-chosen videos of children engaged in learning mathematics have on the beliefs held by prospective elementary and middle school teachers?

Methods of Inquiry

Participants in the study were undergraduate students enrolled in an elementary mathematics education course for pre-service teachers. One section consisted of students enrolled in a mathematics course who expressed interest in elementary school teaching. Participants came from three different universities in New Jersey. At each site, all participants from these courses were given the same Beliefs Inventory at the beginning and end of the course as pre and post-measurements. The instructional intervention for experimental groups included studying of selected video clips from the Rutgers Repository. Comparison groups of similar classes were given the same pre and post Belief Inventories; however, the comparison groups did not have access to the video-based instructional intervention.

The Beliefs Inventory included items that assessed beliefs about how mathematics is learned and how teachers influence (or not) children’s learning. For this report, we discuss the subset of belief items directly related to the theme of children’s learning mathematics that the intervention of studying videos might influence (See Table 1).

The pre and post-test Beliefs Inventory scores of the experimental groups and comparison groups were compared, first for all of the items and then for the subset of eleven of the thirty-three items that addressed children’s mathematical learning. We report, here, on the eleven items in the Beliefs Inventory that align more closely to the themes contained in video episodes. These are given in Table 1 below.

The pre and post-test Beliefs Inventory averages were calculated based upon the following coding scheme: 1=strongly agree, 2=agree, 3=uncertain, 4=disagree, and 5=strongly disagree. Inverse Beliefs question items were considered negative beliefs and coded as: 1=strongly disagree, 2=disagree, 3=uncertain, 4=agree, and 5=strongly agree. The rationale for the reverse coding of negative beliefs question items is to achieve consistency for all eleven Beliefs Inventory items in that a student’s post-test score being smaller than the student’s pre-test score is interpreted as growth in Beliefs concerning children’s learning of mathematics.

Results

Table 1 shows post-test Beliefs growth for both the experimental and comparison groups of students on each of the eleven items in the Beliefs Inventory; however, the Beliefs growth of the
experimental students is consistently greater than that of the comparison students for each of the eleven Inventory questions. The probability of this occurring due to chance alone is (0.5).

Figure 1. Predicted Beliefs Inventory post-test growth for the average of eleven Beliefs

The results of a regression model for prediction of a student’s post-test Beliefs growth mean as a function of the student’s mean pre-test score, experimental or comparison group participation, and educational institution are given. The analysis provides evidence that all these factors are statistically significant; however, the trend is consistent: (1) students with higher pre-

test Beliefs mean scores (i.e. significant number of coded undecided and disagree item scores) tend to have higher post-test Beliefs growth and (2) student’s with a significant number of coded undecided and disagree beliefs tend to have higher expected levels of growth in the experimental as compared to the comparison groups.

Figure 1 is a graph of the student’s predicted post-test growth versus the student’s pre-test mean score for the experimental (EX ----) and comparison groups (CO ----) of each of the three participating education institutions.

Inventory items versus a student’s corresponding pretest inventory score

Table 4 below examines the individual questions in the Beliefs Inventory and tabulates the nature of the student’s post-test score as an improvement in beliefs, a lowering in beliefs or no change. Table 4 shows that of all the student beliefs responses in the experimental group that were coded as disagree, a total of 60.6% of the post-test responses indicated a post-test gain for the experimental students versus 37.6% for the comparison group students. Similarly, Table 4 reports that of all the question items that were scored as undecided in the pre-test, the post-test scoring indicated a 69.7% beliefs gain for the experimental students versus a 49.7% gain for the control group students. It is useful to note that a student pre-test score of agree to an inverse belief question item is a negative belief and is tabulated in Table 4 in the disagree category of the positive beliefs question items.

Discussion
The significant changes in pre-service teacher beliefs in this study supports previous research that suggests that studying videotape data of students engaged in mathematics leads to positive growth in beliefs scores of pre-service teachers (Philipp, et al., 2007). It also extends the findings to include a larger elementary teacher population. In addition, the videos from previous studies featured early grade students working with number ideas while the videos for this study involved elementary to middle school students attending to open-ended fraction and counting problems.

It is important to note that of the thirty-three belief questions, only the eleven that specifically focused on student learning emerged as different between the experimental and comparison groups. The eleven belief questions included in the growth analysis of this report are those that were aligned with the content of the intervention videos and associated student activities. These included questions dealing with the ability of students to solve complex problems in novel ways in a group problem-solving setting, the value of student interaction and communication, the benefits of students offering multiple representations of ideas and approaches to solutions, as well as the importance of students learning concepts through problem solving prior to being introduced to procedures. The twenty-two belief questions that were excluded from the growth analysis presented in this report were those that were not aligned with the videos of children doing mathematics. An analysis of these non-aligned belief items revealed that there was

significant pre-service teacher growth in these areas; however, the growth was comparable for both the experimental and comparison groups.

The findings, while encouraging, raise important questions for further study. For example, it would be useful to know in more detail how instructors made use of the videos at the various sites while working with the pre-service teachers. Were videos studied individually by pre-service teachers as homework assignments? Were they discussed in small groups, or viewed as a whole class activity led by the instructor? Did instructors focus on the pre-service teachers’ reflections about how children learn? Additional considerations might be whether (or not) the treatment provided opportunities for multiple viewings and engaged participants in discussion of children’s mathematical behavior. Analyses of workflow data, which document the specifics of which videos were used and how they were used, might provide insight into the process of teacher belief change. In addition, for those pre-service teachers who were asked to respond to reflection prompts after viewing the videos, an examination of their responses can give insight into how the changes in beliefs evolved.

Other research questions also arise from the study of teacher beliefs and changes in those beliefs. For example, accompanying a change in beliefs, is there a change in pre-service teacher content knowledge? Does a change in beliefs influence what a teacher notices on the videos that are being studied? Does what a teacher notice change over time? Perhaps how an instructor decides to use the videos is not as critical in changing beliefs as is having access to the video collection so that teachers can become more aware of the details in children’s learning.

PLACE-BASED PRACTICES IN RURAL MATHEMATICS INSTRUCTION: A SELECT CROSS-CASE COMPARISON STUDY

howley@ohio.edu

This project studied efforts to connect mathematics instruction to community and place. Data came from interviews, observations, document analysis, and student work samples from seven sites across the United States. Analysis of the data suggested that such efforts usually result from the initiative of a particular teacher. These teachers build connections in order to sustain local practices, values, and in some cases, the community itself. A number of common affordances and constraints to place-based education emerged from the data. These reflected place-specific conditions as well as the extensiveness of various forms of support (e.g., personnel, money).

Introduction

The study from which this paper arises sought to understand the struggle to make connections between school mathematics and rural communities. The two primary research questions were: (R1) How do rural schools connect mathematics education to local communities and places? and (R2) What conditions enable and constrain such efforts? Rather than identify a set of “best practices,” a term that usually focuses too narrowly on curriculum, this study adopted a more sociological perspective by striving to understand the complex set of human exchanges and practices involved in attempts to connect mathematics instruction of rural schoolchildren to the people, land, and cultures of their communities. Many times, such practices reflected the deeply personal passions of an individual or group of educators or local community members. They always required intense creative efforts on the part of the educators—far beyond what is required to follow the inherited curriculum. As such, cases meriting study are not common, and studies of these phenomena even less so, though some examples of such work demonstrate the potential of place-based approaches (Green, 2008; Howley, Howley, & Perko, 2009).

Educational interventions that connect instruction to local people, land, and cultures are one route to authentic assessment and instruction (Sarkar & Frazier, 2008). They draw on existing knowledge at individual, school, and community levels, reflecting consistency with (social) constructivist models of learning (Smith, 2002). While forging connections between instruction and community is no less applicable to non-rural schooling, place-based practices are seen as an especially promising approach for rural schools given the primacy of community, family, and the land in rural areas (Theobald, 1997). This perspective motivated the focus of this study on rural places. One measure of the fit of “place” to “rural” is suggested by a count of the number of ERIC documents tagged with the descriptor “Place Based Education.” As of this writing, 191 documents bear the descriptor and nearly all also carry a rural descriptor or display strong rural connections. The study is therefore simultaneously an interrogation of the compatibility of place-based approaches and rural education.

A focus on mathematics education stems not only from an interest in improving mathematics instruction in rural schools, but also from the recognition that quality mathematics instruction is essential to the success of both rural schoolchildren and rural communities. In the emerging green economies, the place of rural communities figures significantly. Alternative energy

production seems tied to corn, soy, and other rural products. The skilled implementation of new technologies will necessitate all levels of expertise in math, agriculture, science, and engineering.

Focusing on the struggle to make connections as described above is not to ignore issues of pedagogy and psychology, but rather to see them within a broader set of affordances and constraints that structure educational practice. Pedagogy generally results from the struggle and stands as a reflection of an educator’s prior negotiations—of resources, of values, and of risks. If Otto Von Bismarck’s saying about politics being the art of the possible is to be believed, then the classroom may be its premier gallery. Inherited curricula come packaged in the prior approval of some authority (editors, departments, parents, administrators). Place-based approaches studied here were not off-the-shelf curricula, so bringing these approaches to the classroom involved negotiating issues of time, curriculum coverage, accountability, and support. The cases profiled in this study are examples of creativity, risk, and craftsmanship at work in classrooms across rural America.

**Background and Relevant Literature**

Mathematics education in rural schools is often considered from a deficiency perspective (Howley, Howley, & Huber, 2005). Alternative perspectives, however, recognize the affordances (Gibson, 1977) that structure opportunities within a given social setting, or the “funds of knowledge” (González, Moll, & Amanti, 2005) that similarly reside within the community and reflect the resources, skills, and knowledge available for action toward some end. This study shared the belief that everyday rural life contains important resources that can improve mathematics instruction. These alternative perspectives both structured and motivated the investigation. Further examinations of the obstacles and affordances may be found in Klein (2007, 2008, 2010).

In defining the central substantive interest as “connections between school mathematics and rural communities,” the study draws from literature on “place-based education.” Though reported instances of place-based education are comparatively common in social studies, literature, and science classes, they are almost non-existent in mathematics classes and even less common than empirical research about mathematics education in rural schools (Silver, 2003). Place-based education is itself a work in progress (Gruenewald, 2003), and is simply defined as learning wherein local “place” is an essential feature. A number of writers in rural education conceive place as the interaction of community and land—land that influences community and vice-versa; in other words, a “land ethic” (Haas & Nachtigal, 1998). To focus curriculum on these interactions, particularly in face of efforts to standardize curricula around so-called national interests—reflects what Klueb (2004) described as “curriculum struggle.”

Earlier studies of such curriculum dynamics are comparatively rare. One of the first relevant empirical studies examined the work of teachers and community members in five districts to design place-based activities and infuse them into their schools’ curricula (Wither, 2001). The study examined the development of the activities as well as the challenges faced during implementation. For example, teachers not involved with the planning valued place-based education less highly than the need to address the more self-evidently pressing school problems (e.g., test scores, AYP). Principals also offered only limited support, according to Wither. Green (2008) further showed how difficult place-based education is to sustain absent continued funding and third-party assistance. These difficulties were acknowledged as possible constraints to be aware of in the present study.
Methodology

This paper is grounded in the broader work of an NSF-supported center for teaching and learning focused on improving the teaching, learning, and understanding of mathematics education in rural America. The researchers on this project are affiliated with this center and have inherited from it an extensive collection of research that directly supports all aspects of this study. From this center’s network of rural education contacts, members of the research team contacted 58 nominators who were familiar with local practices. They were asked to nominate sites that were engaged in connecting community and place to mathematics instruction. The nomination process resulted in 61 sites, from which the team used purposeful sampling techniques to select seven representing variety in geographic location, grade level, and extensiveness of community and place engagement.

The team developed data collection protocols for interviews, focus groups, observations, and document acquisition. A member from the team spent one week at each site conducting classroom and community observations as well as focus group and individual interviews with teachers, parents, students, administrators, and community members. Data for the seven sites included 85 interviews, 27 classroom observations, and 30 sets of field notes. Individual and focus-group interviews were audio recorded, transcribed, and coded initially using qualitative software to produce a draft coding scheme. A subsequent review generated codes that were best suited to the cross-case comparison and organized into conceptually distinct categories (Strauss & Corbin, 1998).

Next, a set of cross-case themes emerged based on clusters of coded data and draft case analyses. A second researcher reviewed data and determined the extent to which they confirmed or disconfirmed the proposed themes. Secondary analysis revealed that the challenges of integrating place and community into mathematics instruction were more pronounced than initial analysis suggested. The final case studies reflect a cross-case “conversation” that depicts, in broad terms, the character of the work undertaken at each site to integrate place and community into mathematics instruction. These are organized into a forthcoming monograph.

Analysis

*South Valley Elementary School (SV) (all names given are pseudonyms).* South Valley Local School District is a small district located in rural Ohio. Ms. Ball, graduated from South Valley High School and now teaches six grade mathematics at South Valley Elementary. She engages students in a range of community-inspired mathematics projects throughout the year, including St. Jude’s math-athon, Relay for Life, Pi Day, and a stained-glass project that focuses on geometry and measurement in creating artwork. For the Relay for Life project, students collect and track money, time laps, and graph results.

*Magnolia City Schools (MC).* Magnolia City School District is located in a rural southern Alabama county where 55.65% of students receive free or reduced lunches. Magnolia City students participate in an aquaculture program and actively maintain the fish environments (monitoring pH, population size, health), track and foster fish growth, and eventually sell the fish at a community fish fry that generates funds to sustain the program.

*Meriwether Lewis Junior-Senior High School (ML).* Located in the a mountainous region of Washington, the school had just over 250 students in grades 7-12 in 2007-2008. Ms. Jay is the only middle school mathematics teacher and invites community members to her classes to describe the mathematics they use in their daily work. This has included a local fiber artist, a...
bicycle shop owner, and a video game designer. For “Math Communities,” parents lead small
groups of students through multi-step word problems every 2-3 weeks.

Eastcove Community School (EC). The school has a student body (pre-K to 12) of just 71
students and is located on a small island off of the coast of Maine (so small that the town’s
website lists the name of every baby that lives in the community). The principal and some
teachers have instituted several place-based initiatives including the design and construction of
pea-pod boats and an all-electric vehicle that was demonstrated in Washington, DC.

Green Mountain School (GM). This is the only non-profit private school in the study. The
school enrolled 127 students in grades preK-8 in 2007-2008. The school is located on a wooded
campus in rural Vermont. Students engage in “tree plot math:” a six-week project related to the
local industry of timbering. They are given tracts of land, shaped sometimes as triangles, circles,
or other shapes and they gather data about the trees in their plot, graph the results, calculate the
worth of their trees, visit the mills, and occasionally present their findings to the schools’ board
of trustees (to decide whether or not to log the tract).

Confluence District Collaborative (CD). Located in a Great Plains state, the collaborative
brings four school districts into one administrative unit with one superintendent and central
office staff. The schools in the district have poverty rates at or below the national average of 17.4%
and educate students from a wide geographic region. Moreover, survival of the individual
schools and districts involves significant sharing of resources, including teachers travelling
between schools to teach classes. Unlike other sites where place-based efforts were establishing
themselves, CD exemplified the decline of a nationally-renowned site for place-based work. The
research team found that, at CD, most informants there viewed place-based approaches as
appropriate only for lower-level students or not as possible given the distance-learning
technologies being used to solve the teacher travel problems. Studying this decline is important
in understanding what sustains or inhibits such work.

Lafayette County High School (LC). This school is a comparatively large school (over 1,000
students in grades 9-12) in rural Kentucky. Because of the initiative of a math teacher and an ag
teacher, the school operates a lutherie class in which students craft ukuleles from raw lumber
over the course of the year. Each student makes two ukuleles: one to keep and one to sell at a
community show for funds to sustain the program. Measurement, scale geometry, and
trigonometry are emphasized connections.

Results

The authors reported first findings of the study in 2009. At that time, the first round of case
analyses did not include Lafayette (LC) even though the data had been collected. In addressing
RQ1, how connections were made, and RQ2, what supported and inhibited these practices, the
following pre-LC themes emerged: (1) the influence of place-specific conditions, (2) initiative
and support, and (3) “the praxis of the real.” These themes structured our answers to both
research questions and inform a deep, cross-case analysis currently underway.

The influence of place-specific conditions characterizes significant evidence of how the
place-based work is both supported and limited according to the particularities of the place in
which that work is being done. This theme was further subdivided based on review of the data.
Economic priorities and strengths of the area was an oft-cited theme, such as at Eastcove where
the importance of fishing to the island led to students’ use of scaling, proportional reasoning, and
representation in the design of “pea-pod boats.” At Magnolia City, aquaculture and a school
program involving turf production and maintenance reflected community dependence on tourists

American Chapter of the International Group for the Psychology of Mathematics Education. Columbus, OH: The
Ohio State University.
who frequent area resorts. *Isolation and population density* limited teacher-to-teacher collaboration and student-parent access to school grounds to support these initiatives, and members of the research team perceived this theme inconsistently. Though it arose frequently at ML, a secondary analysis of the data didn’t offer significant cross-case support for “isolation” as a substantial sub-theme. Finally, *community networks* were often mobilized to support instruction, such as at ML where the teacher depended on parents and community members to share with her classes the ways that they use mathematics at work or as part of a hobby.

“Initiative and support” recognized how dependent many of the cases were on a particular teacher or educator (e.g., people, time, money). At ML, Ms. Jay was a wellspring of initiative, but indicated that collegial or administrative support was largely rhetorical. She told the research team that motivating parents to volunteer was a time-intensive and frustrating process that usually engaged the same set of parents repeatedly. That said, she continued to fight to keep the program going, reflecting her initiative and considerable skill at recruiting support. Moreover, she received grants from the local educational foundation (made up of area parents and businesses), which allowed her to compensate classroom guests for the time they took off work. This creative solution grew from her knowledge of the particular local economic realities that might prevent community participation.

The politics behind the Confluence District Collaborative left many teachers unwilling or unable to support place-based instruction, either as an act of resistance, or for want of will or means. Programs at several sites were driven by the commitment and passions of one or two educators with other teachers’ and administrators’ non-participatory approval.

Finally, the “praxis of the real” refers to the frequent comment in interviews at all sites studied, that “connecting mathematics to community and place” meant identically, “connecting mathematics to the ‘real world’.” Moreover, study participants frequently commented how challenging it was to forge these connections, and how some mathematics content and some mathematics students were not fit for the challenge. This paper focuses on this theme and how Lafayette’s case analysis has nuanced the research team’s understanding of this theme.

Inherent to the challenge of making connections to “the real” is deciding “whose real?” A seventh grade student’s reality may have to be expanded to include the considerations involved in logging a tract of land if Tree Plot Math at GM is going to be considered meaningfully “real.” At LC, the vocational agriculture teacher confessed that his greatest surprise in teaching the lutherie class was discovering that most students couldn’t read a tape measure—it simply wasn’t part of their reality to that point. Evidence from the interviews reveals a tension in this kind of work between enforcing and evoking reality. When an activity becomes curriculum, it becomes part of an enforced school reality rather than a student’s reality. Math Communities at ML engaged students in problems where their behavior was monitored as part of a prescribed path to a closed-ended solution. It should be no surprise that, since the introduction of Math Communities at ML, student scores on the problem-solving portion of the state WASL test have increased. High-stakes assessments measure connections between school realities. Evocation of a reality, on the other hand, may lead to more memorable experiences, but its open-endedness can make it difficult to prescribe outcomes as is currently the practice of modern lesson planning. As LC shows, the crafting of a stringed instrument takes two hours per day, five days a week for the entire academic year. “Evocational training” apparently takes time—a precious commodity given the pressures of accountability. This tension suggests that the praxis is as difficult to nail down as the meaningful reality. In the words of a Green Mountain teacher:

Some specific skills they may not retain better from working, or learning, in the woods or learning out of working in a textbook. However, their understanding of how they can use those skills to be in their environment and have it make sense, and actually get something out of it... and the other things they learn about... their environment, affecting the economy... those things they all remember... the woods aren't just there but there is actually something in them [emphasis added].

This passage also highlights the ties between “the memorable” and “the real” for students of a given age. Mathematical objects, it would seem, are not as memorable as a tract of woods. One must remember, though, that Tree Plot Math, like many of the projects studied here, are episodic, and that traditional classroom learning likely predominates.

A second question that arose from more careful consideration of this theme is analogous to “whose reality?” It asks, “whose praxis?” Many teachers at CD felt like the calculus teacher at one of the high schools:

I teach upper math, so I don’t know. I teach trig and calculus. So I doubt if we do any calculus in local places around here. I don’t know how we have time to do that. I am not sure that the upper math classes—maybe a lower income average are going to need that—but not my upper math class...Because my kids that I teach now are interested ‘in the math,’ I don’t have to make it flowery, I don’t have to make it enjoyable, I don’t have to make it fun, they just want to know, what’s the math, the theory behind it.

In the case of Eastcove, the fishing life of the island and the seasonal tourism was an ever-present reality that the principal of the school connected directly to the survival of the community: “Of all the islands in [the state], there are only three left...and, so, we feel like we've got to work hard to keep this community going, and part of it is connecting the kids with the community all the time in whatever ways we can.” The question of “whose praxis?” therefore is one that questions ownership of (relatedly, “buy-in to”) the purposes and practices of learning.

The Real, A Place Revisited

When the Lafayette (LC) case study was complete, the team realized that the “praxis of the real” failed to capture important nuance present in the data. What emerged from LC was evidence of the recognition that considerable fear surrounds getting local, everyday mathematics into the open. Whereas math indeed may be everywhere, it remains largely unrecognized—what we consider “locally immanent” (indwelling). Few seem willing to take on the project of “revealing” the everyday-ness of mathematics. This irony is captured well by “immanence” which is defined both as “remaining or operating within a domain of reality or realm of discourse” and “inherent...having existence or effect only within the mind” (both from Mish, 1984, p. 601). The first meaning captures the confinement of everyday mathematics to the unrecognized obscurities of daily life, while the second captures the Platonic sense of ideal mathematical objects existing only in the mind. Yet while immanent in both senses, it is also imminent, or “ready to take place; esp: hanging threateningly over one’s head” (Mish, 1984, p. 602). Despite math’s utility, it nonetheless seemed to “hang threateningly over study participant’s heads” including adult informants in schools and in the community. The reality to which school mathematics might connect is one in which mathematics is both immanent and imminent. Examples of this were found in abundance on re-inspection of data from other sites.
While the need to make mathematics fun was not a universal feature of the sites studied here, the place-based approaches were described as “memorable” and “relevant” by students, teachers, parents, and community members. Adults at all sites made familiar confessions. At Lafayette:

*Cabinetmaker* (father of former student): I wish I could say...I loved school, but math?...Geometry I was into, but when it came to algebra, it was over my head, you know?
*Teacher*: Around the country [nation] students really have a hard time with mathematics and just seeing the relevance of mathematics.
*Superintendent*: And for some reason in this area is a very feared subject by—by many kids. They’re—they have a—a fear of mathematics and, you know, they—they’re kind of turned off to math.

These same adults who confess a fear (imminence) of mathematics also report using it in their work (immanence). This sentiment was echoed by adult participants at nearly every site. As such, it seems an appropriate and more encompassing thematic frame for understanding the praxis of the real. This insight is confirmed repeatedly in the transcripts. Perhaps its best formulation was by a former student of the lutherie program at Lafayette: “The side of math you don’t see every day is the everyday math.” Her statement is rich with irony. Nevertheless, it suggests that the real challenge is in the “seeing,” rather than the “connecting.” Ongoing cross-case analysis will further bear out the appropriateness of this new thematic frame for each case.

Three cautions seem warranted in understanding the portion of results presented above. First, examples of rural schools connecting mathematics to education are promising but rare, so generalizability is not appropriate. Second, math-place or math-community connections happen (R1) because of and despite the affordances and constraints (R2) found there, so these questions can’t be considered independently. Conditions that enable and constrain place-based approaches, as evidenced by the themes of *initiative and support* and *place-specific conditions*, were far easier to see than the intricacies of *how* such connections are made. Nevertheless, evidence of how they were made yet bore the scars of their negotiated creation. Third, “connection” was a difficult concept to probe as it begged so many other questions: Of what? To what? In what way? A deeper level of cross-case comparison is underway to address these issues. It suffers from the same problems of defining context as do studies of transfer of knowledge (from what to what?).

Ongoing analysis is motivated by acknowledged limitations in the first and second passes of data. These limitations reflect the difficulties inherent to understanding community practice and are well noted in methodological literature (e.g., Geertz, 1973). For instance, members of the study team kept asking one another for each site, what the “case” was. At four sites (GM, SV, LC, ML), the presenting “case” seemed defined by the practices of a particular teacher. At CD, the collaboration itself seemed to be the case. Eastcove (EC) had the broadest scope and invoked place-based education explicitly, though even there the project was sustained by a group of teachers trained in place-based pedagogy. Making connections rested in nearly every case on the insights and passions of particular educators. Moreover, these passions seem to result from an inspirational antecedent experience or contact. The founder of the lutherie program at LC was inspired by a neighboring school’s raptor rescue program. Similar stories surfaced at GM and ML. Further analysis and team discussion will involve clearly defining the research case.

Regarding the purposes for engaging in place-based projects, place-based and rural education literature suggests “sustaining rural communities” is the primary purpose. Eastcove demonstrated this most strongly, as noted in the principal’s comments. The Confluence Collaborative, despite...
mathematics not being implicated to the same degree there, also reflected this to some degree in that the purpose of the collaborative is to provide an administrative unit that allows schools in these areas to continue operation, thus sustaining one of the anchors of rural communities (DeYoung, 1995). Projects at LC, GM, MC, and ML connected mathematics instruction to local values and practices, thus promoting sustainability of the lifeways that predominate there. The purpose of these projects is an important factor that seems connected to both R1 and R2. Ongoing analysis and further review of the extant literature will help to clarify this connection.

Quantitative literacy is a way of thinking and understanding that combines an individuals’ mathematical content knowledge, beliefs about the nature and utility of mathematics, and mathematical disposition. Since quantitative literacy skills are usually developed within mathematics courses, this study seeks to discover the quantitative literacies of future mathematics teachers. Seven preservice teachers, both elementary and secondary, were interviewed about their mathematical knowledge, beliefs, and dispositions. Participants were also asked their opinions on the notion of quantitative literacy, and how they will approach these topics in their future classrooms. The preservice teachers possess strong content knowledge of and positive attitudes and beliefs toward mathematics.

Introduction

Wilkins (2010) describes quantitative literacy as “a habit of mind that is characterized by the interrelationship among a person’s everyday understanding of mathematics, his or her beliefs about mathematics, and his or her disposition toward mathematics.” We use this conception of quantitative literacy to frame our study of the level of quantitative literacy of preservice teachers.

Cognition. Cognition, or knowledge, describes more than the mastery of school mathematics. Although skills needed for quantitative literacy are appropriate topics for elementary and middle school coursework, quantitative literacy topics are often deemphasized or skipped entirely in favor of other content (Steen, 1990). A quantitatively literate person has the skills required for a productive life, including the ability to count, tell time, use money, measure, read tables and graphs, estimate, and understand statistics as they are presented in society and media (Cockcroft, 1982; Steen, 1990).

Beliefs. Beliefs play an important role in a person’s quantitative literacy (Author, in press, 2000). De Corte, Op’t Eynde, & Verschaffel (2002) consider three categories of beliefs: beliefs about mathematics, beliefs about mathematical learning and problem solving, and beliefs about mathematics teaching. For example, one belief consistent with the notion of quantitative literacy is that mathematics is a dynamic field in which new ideas emerge, rather than a collection of absolute facts and formulas. Other beliefs about mathematics learning and problem solving that are not consistent with quantitative literacy include the idea that memorization is necessary for success in mathematics, or that the teacher is the final authority on mathematics and will always have the correct answer to a problem.

Disposition. Disposition refers to an “at-homeness with numbers” (Cockcroft, 1982, p. 11), in which people are comfortable with using mathematics. “Being quantitatively literate does not necessarily imply that one must enjoy the study of mathematics, but instead implies that one possess a willingness to engage in situations that require a functional level of quantitative reasoning” (Wilkins, 2000, p. 408). Further, disposition also refers to a person’s understanding of the value of mathematics (Wilkins, 2010).
Quantitative Literacy and Teaching

In order for teachers to effectively promote quantitative literacy among students, they themselves must also be quantitatively literate. While there is little research that analyzes all three components of teachers’ quantitative literacy, many studies singularly or dually focus on cognition, beliefs, and/or disposition.

Various studies have examined preservice teachers’ cognition, or content knowledge (e.g., Ball, 1990). While there are significant differences in content knowledge between elementary and secondary preservice teachers (Ball, 1990), both groups lack conceptual knowledge in many areas (Ball, 1990; Thanheiser, 2009). Ball (1990) found that despite the procedural adeptness of both elementary and secondary preservice teachers, their understanding of mathematical ideas was rule based, and they did not connect procedures with mathematical principles. Even though secondary education students had majored in mathematics, and scored higher on content knowledge, they showed no difference from elementary students in explaining and connecting mathematical meanings and ideas.

There are also many studies that have focused on teacher or preservice teacher beliefs and dispositions (Ball, 1990; Thompson, 1984; Wilkins, 2008). In general, secondary preservice teachers enjoy mathematics and have positive attitudes towards teaching mathematics (Latterell, 2008; Ball, 1990). Elementary teachers have more varied opinions; some greatly enjoy mathematics while others dislike it, or even fear mathematics (Ball, 1990; Liu, 2008).

Another belief shared by many preservice teachers is that mathematics is a collection of rules, and memorization is necessary for understanding mathematics (Ball, 1990; Liu, 2008). This limited view of the nature of mathematics held by some preservice teachers is unfortunate, because it has been found that teachers’ beliefs about mathematics and teaching shape instruction (Thompson, 1984). For example, Thompson found that teachers who believed that mathematics was a set of facts and procedures tended to teach in a manner that projected that belief. Another teacher, who viewed mathematics as a set of interrelated topics, used classroom activities that allowed students to explore and make connections among mathematical ideas (Thompson, 1984). Author (2008) also found a relationship between teachers’ beliefs and instruction. In this study, teachers with positive attitudes towards mathematics were more likely to use inquiry-based instruction in their classes. These findings are encouraging in that other studies have found that mathematics methods courses can positively influence preservice teachers’ beliefs and attitudes (e.g., Wilkins, 2004). The purpose of our study was to explore the quantitative literacy of preservice teachers by considering two specific questions:

1. What are elementary and secondary preservice mathematics teachers’ opinions of quantitative literacy?
2. In what ways are preservice teachers quantitatively literate (as related to their mathematical knowledge, beliefs and disposition)?

Methods

A phenomenological design was implemented to explore and describe the beliefs and knowledge of preservice teachers related to quantitative literacy. A phenomenological design was implemented because it suited the purpose of the research study; to examine the experiences and perspectives of preservice teachers, and how those experiences and perspectives were articulated by the participants (Rossman & Rallis, 2003). Seven preservice teachers in their fifth year of a teacher preparation program were interviewed. All of the preservice teachers were
enrolled in a university degree program that leads to teacher licensure and a master’s degree in education during five years of study. Four of the preservice teachers (Alicia, Bess, Julie, and Meghan) were students in an elementary program. Two of the elementary preservice teachers (Alicia and Meghan) had undergraduate degrees in English while the other two (Bess and Julie) had undergraduate degrees in Interdisciplinary Studies. The remaining three preservice teachers (Briana, Mike, and Victoria) were students in a secondary mathematics program. All three of the secondary mathematics preservice teachers had undergraduate degrees in mathematics. At the time of the interviews, all of the preservice teachers were enrolled in a methods course for elementary and middle school mathematics.

One limitation of the study is the dual relationship that the researchers had with the participants in the study. The researchers personally knew all but one of the participants due to the fact that the researchers had taken a class with the participants in a previous semester. However, the researchers and the participants had never before discussed the matter of quantitative literacy. Therefore, it was believed that the dual relationship would not adversely hinder the current study.

Data were collected through standardized open-format interviews. The researchers developed preliminary interview questions and then sought advice from other scholars and researchers about the effectiveness and clarity of the research questions. Once the interview questions were finalized, the researchers matched up each interview question with a research question to make sure that the interview suited the purpose of the study. Table 1 synthesizes the link between research questions and interview questions.

The standardized interviews consisted of questions on the subject’s mathematical background, beliefs, and attitudes. The preservice teachers were asked to describe their experiences as a mathematics student in elementary, middle, and high school as well as college (P1, P2)? To determine some of the preservice teacher’s beliefs and views about mathematics, we asked: Is math unchanging (M1)? What math skills are important for everyone to have (M2)? Why should people learn math (M3)? How does your view about why people should learn math affect what you will do as a math teacher (M4)? After the researchers presented the preservice teachers with a definition of quantitative literacy (Wilkins, 2010), the participants were asked to comment on the following questions: What do you think of this definition (O1)? Based on this definition, what level of school mathematics do you think is essential to be quantitatively literate (O2)? What is the importance of being quantitatively literate (O3)? Assuming we need to develop quantitative literacy in students, what is the role of a math teacher (O4)? Do you think people besides math teachers have a role in helping people become quantitatively literate (O5)?
The participants were also asked to perform two quantitative tasks, which highlighted both the cognitive and dispositional aspects of each participant’s quantitative literacy. One task involved calculating a tip at a restaurant, and the other task involved understanding averages based on a story from a fictional news report (T3, T4). After each task, participants described how the problem made them feel (T1, T5), and whether they thought the task required skills important for all citizens to have (T2, T6, T7).

The interviews were videotaped and transcribed. The transcriptions were then coded in order to organize, analyze, and interpret the interview data. Themes and categories of responses were organized using constant comparative analysis and code mapping (Anfara, Brown, & Mangione, 2002). First, the first two authors individually coded interviews. Next, the researchers discussed emerging themes and exchanged and recoded interviews in order to help ensure the credibility and dependability of the study. Initial codes and memos were then further categorized into themes and patterns that were relevant to the purpose of the study and that would help address the research questions.

**Results**

*Participants’ Cognition*

Certainly, using only two tasks made it difficult to assess the participants’ cognition during the interviews. However, all preservice teachers seemed to possess strong mathematical content knowledge relevant to tasks used in the study. The skills they demonstrated included performing basic computations, understanding averages, analyzing data given in paragraph and table formats, and discussing mathematical ideas as they apply to real-life situations.

When asked what mathematics skills were important for everyone to have, the preservice secondary teachers mentioned high school math courses as well as everyday quantitative skills. Elementary preservice teachers also cited rounding as an important skill. All participants felt that problem solving (or critical thinking) were essential mathematical skills for all citizens. Below are representative quotes from two of the preservice teachers.

Certainly, using only two tasks made it difficult to assess the participants’ cognition during the interviews. However, all preservice teachers seemed to possess strong mathematical content knowledge relevant to tasks used in the study. The skills they demonstrated included performing basic computations, understanding averages, analyzing data given in paragraph and table formats, and discussing mathematical ideas as they apply to real-life situations.

When asked what mathematics skills were important for everyone to have, the preservice secondary teachers mentioned high school math courses as well as everyday quantitative skills. Elementary preservice teachers also cited rounding as an important skill. All participants felt that problem solving (or critical thinking) were essential mathematical skills for all citizens. Below are representative quotes from two of the preservice teachers.

```
Definitely algebra skills, into Algebra II, just knowing how to manipulate equations…People have to have a good concept of fractions and percentages and decimals… [in order] to be a responsible citizen, which includes things like going to the grocery store or reading facts from a newspaper…People need to know how to interpret what's going on, and they need to know how to take information they receive, and sort of understand what's being said. (Briana, secondary)
```

```
Adding, subtracting, multiplying, dividing. Being able to find out percentages without having to use a calculator, for things like going to restaurants and tipping or figuring out sales. (Alicia, elementary)
```

*Participants’ Beliefs*

Of the three components of quantitative literacy, the preservice teachers elaborated the most on their beliefs about the nature of mathematics and about the teaching and learning of mathematics. Although the preservice teachers were not directly asked about their perceived ability in mathematics, many of them commented on their beliefs about mathematics ability. They believed individuals have an innate ability or disability for mathematics. Bess (elementary) described this belief well when she said, “I think that’s just the way my brain is. You know,
some people are math people, some people are not.” Coupled with this belief, the preservice teachers did not demonstrate that success (as measured by grades) affected their belief about whether or not they had natural mathematics ability. Meghan (elementary) explained that her grades in mathematics classes were typically A’s or B’s, but that she had to work incredibly hard in order to earn those grades. Even though she was successful (as measured by grades) in mathematics classes, she still considered herself terrible at mathematics. Both high and low-achieving preservice teachers related being ‘good at math’ with not having to work hard at it.

To further understand their mathematical beliefs, subjects were asked questions dealing with the certainty, simplicity, and sources of mathematical knowledge. To discover if the participants viewed mathematics in a static or dynamic manner, we asked if they thought mathematics was unchanging. One preservice teacher, Mike (secondary), explained that mathematics was constant, that the principles and concepts of mathematics were unchanging. However, the discovery of new principles and concepts also changes mathematics. By using the word *discover*, he seems to imply that mathematics itself does not change. He gave the example of discrete mathematics not existing twenty years ago, but the mathematics underlying the field has always been true, whether or not humans had ‘discovered’ it. Briana (secondary), Bess (elementary), and Alicia (elementary) felt similarly in that mathematics is always changing because of new developments, but that properties were always true, and thereby did not change. Bess (elementary) said that “two plus two will always equal four, so…basic things are unchanging.” Alicia (elementary), Julie (elementary), and Victoria (secondary) commented on how mathematics changes depending on how it is used.

An important belief about the nature of mathematics that was conveyed by participants was the presence of more than one valid method to solve a problem. The preservice teachers were asked what their response would be to two students in their classroom who were arguing because they used different methods to solve a problem. All of the preservice teachers, either implicitly or explicitly, responded that they believed more than one method to solve a problem. All seven participants believed that students should use the most meaningful and sensible to them, even if the chosen method differed from another students’. In addition, some of the preservice teachers believed that students could even use a method that they developed on their own. Meghan’s (elementary) response to the interview question was “I always say ‘use the method that works best for you’…as long as it works consistently and as long as I can understand it…and it’s not just a fluke, they are more than welcome to use it.” Alicia (elementary) mentioned multiplication as an example. She said that when she learned how to multiply two-digit numbers, there was only one way to do it. However, since taking her mathematics methods course, she realized that there were many different methods and was able to list at least five different techniques for teaching multiplication during the interview.

Closely related to the belief that there is more than one valid method to solve a mathematics problem is the belief that the reason or justification for a problem is more important than the actual answer. According to the participants, students could use different methods to solve a problem as long as they understood the reasons for using those methods. Many of the preservice teachers stressed the significance of *process* over *solutions*. Below are quotes from two of the preservice teachers expressing this idea.

*You got the answer, but that’s not the important part...The important part in math is how you came to understand it and the method you used.* (Julie, elementary)

---

The processes that are involved in stepping logically through an equation are just as important as the right answer- no, more important than the right answer. Because all throughout life, people are making decisions. And good decisions are made when people can step logically through what's going on. (Briana, secondary)

An encouraging belief that emerged from the interviews was that the preservice teachers valued conceptual understanding over memorization. Instead of placing importance on procedures and skills, the preservice teachers thought that it was important for students to develop conceptual understanding of mathematical ideas.

Another belief about the nature of mathematics, especially related to the utility of the subject in real life, was that mathematics is useful and important. All seven of the participants expressed the belief that mathematics is used every day life and essential for thriving in society. Julie (elementary) commented: “It [math] is everywhere! You can’t do anything in the world, you can’t really do anything without math!” Because math is so useful in everyday life, the preservice teachers believed that it was important to show students just how useful and relevant mathematics really is. Briana (secondary) thought that this involved more than just telling students that you need mathematics in any job. She thought students had heard that argument plenty of times and that it didn’t really mean much to students; instead, students needed to be shown examples.

Disposition

When asked if they enjoyed math, all of the secondary preservice teachers, and two of the elementary preservice teachers responded enthusiastically. However, the two elementary preservice teachers who expressed a dislike for mathematics, Alicia and Meghan, both said they appreciated mathematics more since taking their mathematics methods course. Both positive and negative views towards mathematics were attributed to their past successes or failures in mathematics coursework.

Another important finding related to disposition is that these elementary preservice teachers were not apprehensive about teaching mathematics. Bess and Julie were both extremely excited about the opportunity to teach mathematics, a subject that they both greatly enjoy. Despite their dislike of mathematics, both Alicia and Meghan were confident that they could teach mathematics in an elementary classroom due to low levels of mathematics addressed in elementary school curriculum. Alicia was excited to teach using strategies she learned in her mathematics methods course. Meghan was assured because she felt elementary mathematics was easy to understand. “I feel it’s a little easier so I’m not afraid of it. The hardest thing I’ll probably have to teach would be basic algebra, multiplication, or long division and I can do all those things well.”

Conclusions

The preservice teacher participants in this study were generally quantitatively literate and possessed strong content knowledge and positive beliefs and dispositions. Participants considered quantitative literacy to be of importance, and stated that they planned to promote quantitative literacy in their classrooms. All participants showed some awareness of quantitative literacy, whether or not they recognized it by that name. They held several beliefs consistent with the goals of quantitative literacy, in particular, those about the nature of mathematics and its value and utility in society. In addition, the preservice teachers believed that mathematics should
be taught conceptually and not just procedurally. Further, teachers seemed to possess a positive disposition toward mathematics and a willingness to engage in mathematics teaching (cf. “Curriculum”, 1989; Wilkins, 2010).

In contrast with the findings of previous research (e.g., Ball, 1990; Liu, 2008), in our study we found that preservice teachers viewed mathematics as more than a set of procedures and facts. In accordance with that belief, all participants stated that they planned to stress conceptual understanding over memorization in their instruction. They also expressed that they would try to motivate their students by showing them the usefulness of mathematics.

The participating preservice teachers were excited about teaching mathematics. For a majority of the participants, this excitement seemed to be due to their positive dispositions; even those who seemingly did not enjoy the subject. In this case, this change in attitude and beliefs was attributed to their experiences in a mathematics methods course.

Future research on the significance of quantitative literacy in teacher education programs would be valuable to better understand how to promote preservice teachers’ skills in the area of quantitative literacy and their potential to promote quantitative literacy in their future classrooms. There is little we do in America that is more important than teaching. Effective teaching of mathematics requires appropriate pedagogical and mathematical foundations, but thrives only in an environment of trust which encourages leadership and innovation (National Research Council, 1989, p. 57). Such an environment would most certainly also develop students’ quantitative literacy – their knowledge, beliefs and disposition in relation to mathematics.

UNDERSTANDING OBSTACLES TO TEACHER EDUCATION FOR POST-SECONDARY TEACHERS OF MATHEMATICS

Mary Beisiegel
Harvard University
mary_beisiegel@gse.harvard.edu

In an effort to inform teacher education for future post-secondary teachers of mathematics, a dialogue with mathematics graduate students was established in order to explore their experiences and perspectives of mathematics teaching. Using hermeneutic inquiry and thematic analysis, a series of conversations was analyzed and interpreted with attention to themes and experiences that had the potential to influence the mathematics graduate students’ ideas about and approaches to teaching. The structure of their graduate work, their views of mathematics and themselves as mathematicians, along with expectations of behavior in their department, had implications for how the graduate students formed their identities as teachers. Themes that are explored in this report are teacher versus professor, replication, and resignation in the participants’ views of who and how they could be as post-secondary teachers of mathematics.

Introduction

Mathematics departments constitute one of the largest service departments within institutions of higher education, providing prerequisite courses for students in diverse disciplines such as engineering, physics, chemistry, business, medicine, psychology, and education. As a result, the teaching of mathematics at the university level is quite important in undergraduate education and professors, instructors, and graduate teaching assistants in mathematics have a wide-reaching influence on the education of future researchers, teachers, and mathematicians (Golde & Walker, 2006). While there has been an increased focus on undergraduate mathematics education, the format and style of post-secondary mathematics teaching has remained problematic for undergraduates (Alsina, 2005; Kyle, 1997; NSF, 1996).

In the effort to improve university mathematics teaching, mathematics graduate students have recently become subjects of investigation. The most recent research into mathematics graduate students’ teaching has examined their classroom practices and possible connections between their practices and beliefs about teaching and learning. Researchers concluded that newly acquired positive attitudes and beliefs about teaching mathematics did not produce hoped for changes to graduate students’ teaching practices (Belnap, 2005; Speer, 2001). When graduate students in mathematics could speak of teaching using reform-oriented terminology, these students also reported that they maintained a traditional, lecture-style form of instruction (Belnap, 2005). Other research has shown that enrollment in a course in pedagogy did not produce expected changes to mathematics graduate students’ teaching practices.

In light of these conclusions, it appears that the experiences of mathematics graduate students and the development of their teaching practices are not yet well understood. Such an understanding is important in the field of mathematics teacher education as almost seventy-five percent of mathematics PhDs will become professors at post-secondary institutions dedicated to undergraduate education rather than research (Kirkam et al., 2006). Moreover, because professors of mathematics and mathematics graduate students often represent the last models of mathematics instruction for future elementary, secondary, and post-secondary mathematics teachers, university mathematics teaching has a far-reaching influence on teaching at all levels.

As previous studies have found that informing mathematics graduate students of different approaches to teaching, student learning, and curriculum reform did not alter classroom practices, something remains to be explored.

**Orientation of the Research**

Within the graduate students’ lives in mathematics exists a complex and intricate interplay among the structures that mathematics graduate students encounter, their feelings about mathematics and themselves, their interpretations of the nature of mathematics, and their sense of their new role as teachers. Through their involvement in their graduate programs and the routines of a department of mathematics, graduate students’ views of the discipline and its teaching are shaped. Exposure to new contexts of mathematics teaching, learning, and research have the potential to be interpreted as having implications for how they should be and convey their work as mathematicians (Austin, 2002). Further, their own ideas and beliefs also appear to have an influence on mathematics graduate students’ teaching (Speer at al., 2005).

In thinking about the idea of mathematics graduate students becoming future academics, professors, researchers, or mathematicians, where do they look for who they are supposed to become? For indications of how they should be, of how they attend to their work, their students, their discipline, and themselves? How might the graduate school experience shape the identity of these future mathematicians as teachers of mathematics? What has meaning for them in how they present themselves within their disciplines and in the classroom? What is it that mathematics graduate students interpret or understand their lives to be like in mathematics? What might they interpret as having significance for who and how they should be as mathematicians and as post-secondary teachers of mathematics?

In raising such questions, this research project is an exploration of the lives of mathematics graduate students and is concerned with how mathematics graduate students become mathematicians, the experiences they go through, and what has meaning for them as they become mathematicians and post-secondary teachers of mathematics. In order to explore the answers to these questions, hermeneutic inquiry was chosen as a way to seek an understanding of these phenomena. Hermeneutic inquiry is important for this project as “it is the interpretive study of the expressions and objectifications of lived experience in the attempt to determine the meaning embodied in them” (van Manen, 1997, p. 38). Hermeneutic inquiry helps one to unearth the ways and the whys in which we understand life and lived existence, and how we can create and find meaning through experience, language, and social engagement (Brown, 2001; Gallagher, 1992; Smith, 2006).

Mathematics graduate students’ experiences, their professors’ teaching, departmental expectations, and their teaching assistantships all have interpretive implications for what mathematics graduate students make important in their lives. As graduate students’ knowledge of their future worlds develop “as a consequence of their encounter with the department: semi-automatic, barely conscious interpretations of what teachers say and do” (Gerholm, 1990, p. 264), hermeneutic inquiry opens up a space for understanding interpretations within these different encounters. For this research project, hermeneutic inquiry affords attentiveness to the questions: What variety of experiences do mathematics graduate students encounter as they progress through their graduate programs? Among their experiences, what in particular is taken as having meaning for who and how they should be as mathematicians and as teachers of mathematics? How are these experiences interpreted to have meaning for how one lives a life in mathematics? Finding answers to these questions will help to deepen the understanding of teaching and

---

learning in post-secondary mathematics and provide guidance in structuring post-secondary teacher education in mathematics.

The Research Study

Graduate students in mathematics from an urban, doctorate-granting university were approached to be participants in this study. Six students agreed to participate. The group was fairly diverse in their backgrounds: three were master’s students, three were doctoral students, and they ranged from a first semester master’s student through a final year doctoral student; four were men, two were women; their ages ranged from 22 to 33 years; and there were four nationalities among them. While each of their paths to graduate study in mathematics was distinct, all but one of the participants expected to work in academia once they completed their degrees. During their graduate programs in mathematics, each of the participants had been assigned to teaching assistantship duties such as tutoring workshops where they helped students one-on-one with homework exercises, grading homework and exam papers, or leading one-hour tutorial sessions during which they presented mathematical topics similar to those in the affiliated lecture section of the course.

Carson (1986) and Van Manen (1997) propose conversation as a mode of doing research within hermeneutic inquiry to explore and uncover one’s own and others’ interpretations and understandings of experience. In consideration of this, over a period of six months, a series of five audio-recorded conversations were conducted with the research participants. The first two meetings and the final meeting were conducted with each participant individually, where each meeting lasted approximately one hour. The third and fourth meetings were conducted with all participants present, each lasting just under three hours. A recursive process was used in which the topic of subsequent conversations was based upon themes from previous conversations. Throughout the project, the research participants had the opportunity to review the analyses in a collaborative effort to refine, augment, and improve the reporting of their experiences.

Each conversation was transcribed by the researcher, who listened for the topics of conversation and the language used by each of the research participants. Notes were made of the congruence among the research participants. These similarities were not limited to broad categories of their lives, such as how they each had to attend to their teaching assistantship duties or their graduate level course work. Rather, it was opinions and perspectives about various aspects of their experiences that appeared to be in common. These similarities were grouped into themes using the guidelines of thematic analysis described by Braun and Clarke (2006). The themes and the participants’ comments within each theme were then assembled and analyzed using a hermeneutic, interpretive lens to understand what facets of their lives in graduate school were taken as having meaning for their identities as mathematicians and post-secondary teachers of mathematics.

Findings

For the mathematics graduate students who participated in this study, what did it mean to become a mathematician and a professor of mathematics? How did they understand their roles as mathematics teaching assistants and possible future professors of mathematics? How did they experience and make meaning of the various suggestions they encountered about teaching? What was important for success in their programs? What did the participants interpret as having meaning for who and how they should be as mathematicians and as professors of mathematics?
The concept of legitimate peripheral participation offers an interesting lens through which to interpret, understand, and describe what was happening for the mathematics graduate students. Lave and Wenger (1991) wrote “Communities of practice have histories and developmental cycles, and reproduce themselves in such a way that the transformation of newcomers into old-timers becomes remarkably integral to the practice” (p. 122). Further, Lave and Wenger (1991) claimed that “even in cases where a fixed doctrine is transmitted, the ability of the community of practice to reproduce itself through the training process derives not from the doctrine, but from the maintenance of certain modes of co-participation in which it is embedded” (p. 16, emphasis added). The “reproduction of the community” and “maintenance of certain modes of co-participation” are seen in the following themes and quotes from different participants: teacher versus professor, replication, and resignation, which were heard throughout the conversations with the participants.

**Teacher Versus Professor**

“It is difficult to ask a professor to teach”

“The first thing we need to get across is that professors and teachers are two completely different things”

“Professors are demanded to teach”

“This idea that they [the professors] need to explain it enough or well enough in order for us to understand it is absurd”

What became clear in this project is that the participants were on a path to becoming mathematicians, not post-secondary teachers of mathematics. They learned about the discipline of mathematics through their coursework and about mathematical research through undertaking their theses and dissertations. To be successful in their programs, they were compelled to become skilled in mathematics by mastering their coursework through earning high marks and undertaking a research project. In contrast to the mathematics they were required to become skilled in, the mathematics graduate students were not required to demonstrate competence in teaching, in how they interacted with students, how they presented material to a class, or how they assessed students’ learning. There was no point in their programs where they were evaluated on their teaching, even though teaching had the potential to be a significant part of their future profession. The research work that they had to focus on, in a way, became the sole indicator of what would be expected of them in their careers.

As such, their identities became tied to becoming a professor, rather than a teacher, where the research work of a professor was more important and more esteemed than that of a teacher. The research participants marked out what they observed as the separate territory of professors and teachers. They insisted that teaching was not a part of a professor’s role. They described a professor’s role in the classroom as solely presenting mathematical material, with absolutely no requirements to assist students in their understanding of the mathematics. Gaining such an understanding was the sole responsibility of the students. It is interesting to note, however, that the participants had expressed enthusiasm for and interest in helping undergraduates to learn and understand mathematics. Yet, while observing what occurred in their department, in an act of “maintaining certain modes of coparticipation,” they declared that, as professors, they would not be required to teach, nor should they be expected to, as seen in the final quote above.
Replication

“It’s easy to keep teaching calculus like this. We’ve been doing it forever”
“You just do examples. In 50 minutes, it’s over”
“How many ways can you skin a calculus class?”
“They are pretty different sections, but you pretty much do the same thing”
“You could teach a little bit better, but I don’t know how much variety you can actually put in. How much different is professor A from professor B?”

The reproduction of the community resonates in above quotes from the research participants, which illustrate the theme of replication of both mathematics teaching and of mathematicians. Similar to Lave and Wenger’s (1991) idea that communities “reproduce themselves” (p. 121), the post-secondary teaching of mathematics, as viewed by the participants, appeared to be a practice of replication, a reproducing of others’ teaching and the material in mathematics textbooks. Specifically, one participant spoke of the structure of all mathematics courses as “definition, theory, example,” where replicating the fixed structures of mathematics texts and courses was a sufficient, even sanctioned, way of being in the classroom. Further, Jardine (2006) has written that in mathematics there exists a “mood of detached inevitability: anyone could be here in my place and things would proceed identically” (p. 187), signaling the replication of identity amongst mathematics teachers. This view echoes in the language of “professor A and professor B” used by one of the participants, which spoke to an interchangeability between professors, as though their identities might be so alike or the differences so insignificant that it would not matter who was in the classroom.

Another participant’s experience of being told that she was prohibited from saying “I don’t know” in response to an undergraduate’s question represented a disclosure that certain forms of behavior were considered illegitimate within the department of mathematics. In her peripheral role as a teaching assistant, she had to abide by this prohibition in order to become similar to those in the department on her way to becoming a mathematician. With regard to his own teaching, one participant spoke of how he could not work “outside of a certain box” in the department. As a result, he no longer appeared to have a concern for his teaching, saying, “I would not be able to change things even if I wanted to.” When this participant spoke of his hopes for his future career as an academic, teaching was no longer of consequence to his success as a mathematician and future professor. In the final year of his doctoral program, this participant was an illustration of what Lave and Wenger refer to as the “transformation of newcomers into old-timers” (p. 121) and how “an extended period of legitimate peripherality provides learners with opportunities to make the culture of practice theirs” (p. 95).

The structures of the participants’ programs, their teaching assistant work, and the suggestions that were put forth by the department either through direct communication or the lack of it seemed to point to a particular, sanctioned way of being and becoming a mathematician, a way of being which implied not only that teaching was unimportant, but also that it would be determined solely by what had been observed in texts and other professors’ classrooms. Throughout the analysis of the recordings and transcripts, it became apparent that the participants began to make certain tasks more important than others through what they were and were not allowed to do as newcomers in the department. In this regard, it seemed that the participants were being primed for a particular way of being.
Resignation

“That’s never going to happen in math”
“There’s nothing I can do about it”
“No one is going to listen to me.”
“I hope I’ll be different, but I don’t think I will be”
“I guess the system just drew the love out of it”

Unfortunately, the act of replication of mathematics teaching and the thought of taking on a particular identity in mathematics evolved into feelings of resignation among the participants. With regard to his current role as a graduate student, one participant said, “You can’t have an opinion, you can’t have anything except the fact that ‘yeah, this is true.’” Here it seemed that this participant was resigned to a passive position with respect to his own learning, and that he must accept the facts not only of mathematics, but also of how he could engage in the department. Further, when speaking about the possibilities for his future teaching practice and, in particular, about the use of discussion in a mathematics classroom, he said, “that’s never going to happen in math,” a statement that expressed a resigned view that there are no alternative possibilities for what can occur in mathematics classrooms. Concerning his own observations of the ways in which the undergraduates were being taught by professors in the department, another participant remarked “I might have the same complaints, but there’s nothing I can do about it,” signaling a resignation to being unable to change the way mathematics courses are taught or structured.

Many of the participants described how they had entered their graduate programs interested in and excited about teaching. However, each of them expressed uncertainty and even frustration about this part of their current and future roles in mathematics. As a teaching assistant, one participant spoke about losing his optimism as a teacher, saying, “I’ve seen it [his optimism] just completely smothered here” and that his experience in helping students had been “completely disappointing” in the context of his teaching assistant work, in wanting to provide more meaningful experiences for undergraduates. When one participant spoke of his future role as a mathematics professor, he expressed an interest in being different from his own professors, but then followed this interest with “I don’t think I will be,” resigning himself to a particular way of being.

As a graduate student still enrolled in courses, another participant spoke about how “we’re both [professor and students] going through the motions. And maybe that’s the point, then, of why be enthusiastic [about teaching] because we’re just going through the motions.” Finally, one participant, in speaking of her love for mathematics and love for teaching, said, “the system [graduate program in mathematics] just drew the love out of it.” Without guidance or encouragement, the participants’ hopes for who they could be and what they could do as teachers of mathematics were diminished. Without a forum to discuss their views and explore different ideas for teaching, they were left to find meaning in their experiences and each participant had become resigned to a notion that there was only one way to teach mathematics and one way to be as a professor of mathematics.

Conclusion

Through their experiences as graduate students, the participants had observed that post-secondary mathematics teaching takes on a particular form and that mathematicians seem to take on particular identities. As graduate teaching assistants, they encountered rules and structures...
that did not allow or support them to diverge from a particular form of interaction with undergraduates. Their interpretations of mathematics curricula, such as calculus, as emblematic of mathematics also seemed to bind them to a specific way of presenting mathematics. It appeared that the participants were not just learning mathematics, but also how to be in mathematics.

As the graduate students moved to the next step on the ladder toward the completion of their programs, none of the steps seemed to address how they interacted with students or what their teaching practices might be like. In other words, the itinerary of progress through the department did not explicitly address their teaching, other than to suggest that it take on a particular form. It is interesting to note that as the three doctoral students got closer to earning their degrees and formally being mathematicians, teaching became less important as their supervisors and the department worked to find them other sources funding so that they would not have to teach, as though, as they became more central to the community of mathematicians, teaching itself was no longer seen as a legitimate task. The resignation that is described here seemed to develop from the participants having to give up their hopes and expectations in order to be considered legitimate within the department. But, in attending to what was legitimate in the department, there seemed to be a considerable cost. What they had to produce as mathematicians was, in a way, how they seemed to present themselves as mathematicians and as mathematics teachers – restricted and disconnected from the creative and active processes that inspired mathematics, including the mathematics they were most interested in and passionate about.

Framed by the idea of legitimate peripheral participation, through their process of becoming mathematicians, the participants in this study seemed to move from a peripheral position to a slightly more central standing in the community as their identities became closer to that of the mathematicians in their department. As they learned of the relative importance or unimportance of different aspects in the life of a mathematician, they grew into the community of mathematicians and reproduced the community. This transition was not overt, nor was it explicitly stated anywhere. The participants did not report a public statement or even an acknowledgement that they had to abandon their own ideas about teaching, that they should no longer consider teaching important and, by maintaining “certain modes of coparticipation,” they would move toward a more central position in the department. Rather, it seemed that the set-up, the structure of the department, the behaviors that deemed were legitimate, and the progression to becoming a mathematician rendered it so.

The goal of this project was to understand what the obstacles might be for post-secondary mathematics teacher education. What was true for the participants in this study is that mathematics graduate students seldom learn explicitly about what it means to be an instructor or professor of mathematics, and they are left to create meaning and develop proficiency amongst themselves. Indeed, in order to earn a graduate degree in mathematics, they must become proficient in high-level mathematics and little attention is paid to their development as teachers, to who they are, who they want to be, or will be as teachers of mathematics. The participants in this study interpreted their success and their lives in mathematics to be restricted to a particular way of being and of presenting mathematics. As a final point, then, if the current structures and suggestions of what is important to graduate study in mathematics remain in place, it is unlikely that new teacher education programs that are established for mathematics graduate students will produce hoped for changes to teaching in post-secondary mathematics.
References

Determining and changing teacher beliefs and exploring their influence on instruction have been a focus for educational researchers over the past few decades. This study investigates a group of prospective secondary mathematics teachers following attempts to facilitate change through specific pedagogical tasks in field experiences. The participants’ responses to these tasks formed three categories: affirmation of beliefs, superficial belief and practice change, and substantive belief and practice change. This paper illustrates participants’ development through accounts of three individuals. Results suggest possibilities for teacher preparation for reform-oriented instruction; yet also reveal the complexity of changing beliefs and instructional practices.

Introduction

Current mathematics education reform is built around the idea that the study of mathematics should focus on five mathematical processes: problem solving, reasoning and proof, communication, making connections, and representational flexibility (NCTM, 2000). This view differs greatly from the traditional study of mathematics as a set list of rules and procedures to be memorized and routinely manipulated (Romberg, 1992). Since the perspective of the study of mathematics has changed, this challenges how mathematics is taught in classrooms (NCTM, 1991). If mathematics should be explored and investigated in the classroom, the traditional view of the mathematics teacher as an impartor of all knowledge no longer holds up. To meet the demands of mathematics education reform, mathematics teachers must take a fundamentally different approach to the teaching of mathematics. According to Thompson (1992), reform-oriented mathematics instruction should be characterized by students engaging in “purposeful activities that grow out of problem situations, requiring reasoning and creative thinking, gathering and applying information, discovering, inventing, and communicating ideas, and testing those ideas through critical reflection and argumentation” (p. 128).

After twenty years of reform efforts, widespread changes in the teaching and learning of mathematics have not been observed (Hiebert et al., 2005; Stigler & Hiebert, 1999). One reason for this perpetuation of traditional teaching methods is the close relationship between beliefs about mathematics and practice (Raymond, 1997). These beliefs are built from prospective teachers’ apprenticeship of observation as students in classrooms where the traditional view of mathematics persists (Lortie, 1975). Mathematics education research has found that beliefs are difficult to change (Grootenboer, 2008), do not necessarily match practice (Grant, Hiebert, & Wearne, 1998), and are resistant to change (Philipp, 2007; Thompson, 1992).

Theoretical Framework

Differing models for initiating change in teachers’ beliefs have been suggested and investigated to varying degrees. Guskey (1986) cited the ineffectiveness of presuming that changing teacher beliefs, attitudes, and perceptions would have to precede any change in classroom practice. He suggested a model (Figure 1) proposing the necessity of change in
classroom practice leading to change in teacher beliefs once teachers observed positive change in student learning outcomes (Guskey, 1986, p. 7). This model was supported by von Glasersfeld (1993) who suggested, “If one succeeds in getting teachers to make a serious effort to apply some of the constructivist methodology, even if they don’t believe in it, they become enthralled after five or six weeks” (p. 37).

![Figure 1. A model of the process of teacher change (Guskey, 1986, p. 7)](image)

Implicit in a discussion of teacher beliefs and practice is a teacher’s sense of efficacy. Teacher efficacy is characterized by Tschannen-Moran, Woolfolk Hoy, and Hoy (1998) as “the teacher's belief in his or her capability to organize and execute courses of action required to successfully accomplish a specific teaching task in a particular context” (p. 233). Labone (2004) suggested prospective teachers’ efficacy beliefs had not yet developed and were more malleable than in-service teachers’ efficacy beliefs. However, prospective teachers enter teacher preparation programs with well-established beliefs about teaching (Weinstein, 1989) and efficacy beliefs related to traditional approaches to teaching built during their apprenticeship of observation could have already been formed. Therefore, it is important to consider the possibility of initiating changes in prospective teachers’ efficacy beliefs. Wheatley (2002) found that eliciting such a change might require challenging existing beliefs in a way that would cause teachers to doubt their beliefs.

Using Guskey’s model for the process of teacher change as well as the influence of prospective teachers’ sense of efficacy, the purpose of this research project is to explore the influence of specific, required, research-based strategies on prospective secondary mathematics teachers’ existing beliefs and practices regarding the teaching and learning of mathematics. The following research question guided our investigation: How does emphasis on specific pedagogical strategies to elicit student thinking in field experiences impact prospective secondary mathematics teacher beliefs and practice?

### Methodology

Participants in this study were four graduate students in a Master of Education program working to obtain a 7-12 integrated mathematics teaching license. The prospective secondary mathematics teachers in this program achieve the equivalent of a Bachelor of Science degree in mathematics in order to enroll. The program is a five-quarter program, starting in the summer.
with courses focused on mathematics methods and learning theory. Throughout the fall, winter, and spring quarters, the prospective teachers are in progressively more teaching intensive field experiences while taking methods, multicultural education, and research courses in the evening. During each 10-week quarter the prospective teachers are in the field for 12 hours per week in the fall, 15 hours per week in the winter, and full-time student teaching in the spring. Field experiences consist of a combination of middle or high school in an urban or suburban setting. The final summer quarter is devoted to finishing an individual action research report. The investigators in this study gained access to the participants as university field supervisors. The university program manager randomly assigned the participants to each supervisor. This research project focuses on data collected in relation to field experiences during the fall, winter, and spring quarter of the 2009-2010 school year.

**Pedagogical Tasks**

The participants were required to implement specific, research-based, pedagogical tasks in their field experience sites. The design and motivation for each pedagogical task was to provide participants with opportunities to elicit student thinking in their classrooms. One task was called *the lesson in teacher silence* and was designed to prevent participants from the traditional approach to teaching typically characterized by a teacher explaining his/her thinking for the majority of the lesson. The participants were supported in the development of a lesson focused on posing an engaging, open-ended problem for students to work on collaboratively followed by a student-led discussion of their thinking about the problem. In this lesson, participants were required to hold back their desire to interject their thoughts into the students’ solution strategies and record evidence of student thinking on a clipboard as they circulated the classroom. Other examples of pedagogical tasks included: questioning strategies, one-on-one interviews with students, and problem posing.

**Data Sources**

This paper presents preliminary results from the first 5 months (September – January) of a 9-month research project. Data collected and considered for this research include: 1) beliefs survey, 2) field experience artifacts, 3) classroom observations, and 3) semi-structured interviews.

The beliefs instrument used was the Mathematics Beliefs Instrument (MBI) developed by Hart (2002). It is a 30-item Likert scale instrument designed to determine respondents’ beliefs consistent with NCTM standards, beliefs about teaching and learning mathematics, and teacher efficacy. Participants completed the survey before the beginning of their field experience (September) and at the conclusion of their field experience (December). They will also complete the surveys at the end of their winter field experience (March) and student teaching (June).

Field experience artifacts consist of any documents created by the participants in relation to field experience. This includes lesson plans developed and implemented by the interns, reflections on participant observations and teaching experiences, and electronic correspondences from participants in relation to field experiences.

Classroom observations occur throughout each of the three 10-week field experiences. Participants were observed for three of eight instructional periods during their initial field experience in fall quarter. At least three additional classroom observations will take place for each remaining quarter in the project. During observations, extensive field notes are taken.

Concurrent to each classroom observation, participants participate in a semi-structured interview before and after the observation for approximately 30 minutes each time. Each
interview is audio taped and subsequently transcribed for analysis. Participants are also involved in weekly group meetings with their supervisor to discuss field experiences. These meetings are approximately 60 minutes and are also audio taped and transcribed.

Analysis
From an interpretive case study approach, analysis is ongoing, recursive, dynamic, and emergent (Merriam, 1988). All data sources collected by this point in the research project were read, re-read, and independently coded by the researchers. Emerging themes were reviewed and incorporated into a preliminary adapted model for the process of prospective teacher change. Validity and trustworthiness issues suggested by Lincoln and Guba (1985) are addressed through triangulation of data across multiple sources and independent coding by two researchers, which allows for cross-validation of results.

Results
Through data analysis three broad categories of belief and practice change were identified: affirmation of beliefs, superficial belief and practice change, and substantive belief and practice change. Although there were three broad categories that emerged in the analysis, participants were not bound to a single category but often exhibited behaviors consistent with a single category. Brief, preliminary case studies for three participants exhibiting behaviors in each category are shared. The fourth participant is not explicitly discussed in this paper because her story is similar to others.

Participants in the affirmation of beliefs category did not attempt to engage in required instructional change or reflect upon the new learning opportunities and consequently demonstrated no change in practice or beliefs about the roles of teacher and students. This category is largely defined by a discomfort with operating in novel mathematical discourse patterns or a disinterest in instructional change.

Episode 1: Sara’s Story
Sara initially measured slightly above average relative to her peers on the MBI, but planned traditional teacher-centered lessons that often focused on procedural competency. Sara was very reluctant to implement a student-centered, activity driven lesson and viewed the planning of such a lesson as a burden. In spite of her reluctance, she planned an activity requiring group problem solving on a geometric proof task involving angle measures. Although student engagement was not problematic and groups actively worked towards understanding the problem, Sara disengaged during group work time and chose to sit at her desk and grade papers. Following the lesson, Sara was very concerned about whether or not she had successfully implemented a novel teaching strategy, but made limited mention of what she perceived as different about the student thinking and learning opportunities that occurred during the lesson. Reflecting on the lesson, she voiced a discomfort and lack of confidence in facilitating small group classroom interactions. Sara showed almost no change on the MBI following her initial field experience, and approached lesson planning and instruction in a traditional, teacher-centered way throughout her field experiences.

Those demonstrating superficial changes in beliefs and practice struggled with the implementation of the required tasks and reflective discussions, but showed an awareness of a need for change. Participants in this category showed the greatest questioning of beliefs, but beliefs change did not coincide with a change in instructional planning or practice.
Episode 2: Jim’s Story
Jim initially measured well below average relative to his peers on the MBI, and planned very teacher-centered lessons. Jim initially had low efficacy for teaching, focused almost exclusively on classroom discipline, and viewed mathematics as a field of study that was best learned through practice and mental discipline. Jim was uneasy changing his instructional approaches, but planned lessons built around implementing questioning strategies to elicit student thinking. Implementing these lessons was a challenge for Jim as he struggled to recognize opportunities to expose student thinking. Following his initial field placement, Jim’s MBI scores demonstrated substantial variation from the first to the second administration and he exhibited an increased desire to try new instructional strategies (even though his instruction remained static). In his second field experience, Jim was placed with a mentor who implemented more student-centered instructional strategies, and has continued to voice an interest in trying similar strategies.

Prospective teachers participating in the study demonstrating substantive belief and practice change successfully implemented the required pedagogical tasks and engaged in deep reflective discussion following the tasks. These participants expressed substantive change in beliefs related to the roles of teacher and students, which coincided with substantive change in instructional practice.

Episode 3: Michelle’s Story
Michelle initially measured above average relative to her peers on the MBI, and voiced a desire to teach towards conceptual understanding for her students. Michelle planned and executed several lessons emphasizing student-centered activities. She demonstrated a confidence in facilitating student-centered discussions. Following these lessons, Michelle often reflected on how she viewed learning as complex and that without challenging activities and assessments it is difficult to know if students truly understand the material. After planning and implementing a lesson emphasizing what she feared would be learned as a “rote procedure”, Michelle interviewed one of her students to better understand what was learned. Following this interview, Michelle voiced a concern with her teaching approach and expressed limitations to the quality of learning that took place. Michelle showed an increase on the MBI and also has been very consistent in attempting to implement student-centered instructional approaches.

Discussion
Although the results are preliminary, they appear to support Guskey’s model for changing teacher beliefs. All participants were required to enact some form of change in classroom practices, placing emphasis on student-centered activities. Those who engaged with new modes of student learning and thinking showed different degrees of belief and instructional change, while those who did not engage with the new modes of student learning and thinking showed no evidence of change. Results suggest possibilities for effective teacher preparation reinforcing reform-oriented instruction; yet also reveal the complex intricacies of changing beliefs and instructional practices.

Based on the preliminary results of this study, an adapted model (Figure 2) of Guskey’s process of teacher change is proposed for prospective teacher education. Replacing the component of staff development is university-based experiences. These experiences include teacher preparation coursework and interactions with university field supervisors where prospective teachers are exposed to issues related to the teaching and learning of mathematics. The next component of the model that was adapted was the observed change in student learning.
outcomes. Due to the structure of field experiences, prospective teachers often have a limited frame of reference with respect to analyzing student learning outcomes and have difficulty observing substantive changes in this area. Considering prospective teachers’ limited conceptions of student thinking, the purpose of instructional changes was to increase opportunities to elicit student thinking. Preliminary data analysis suggests that teacher efficacy in dealing with novel mathematical discourse as well as teacher engagement with novel mathematical learning opportunities plays a role in the type of belief and instructional practice change. The variety of prospective teachers’ efficacy and attentiveness to student thinking influences the nature of prospective teacher belief change. Unlike Guskey’s proposed model that culminates with teacher belief change, the adapted model suggests a more complex range of prospective teacher belief change.

---

**Figure 2. A model of the process of prospective teacher change**

**Conclusion and Implications**

Prospective teachers often have a limited experience set to draw upon when planning, and rely heavily upon their experiences as students to inform their instructional practices (Lortie, 1975). Therefore, part of the role of a prospective education program is to encourage prospective teachers to engage in a variety of pedagogical strategies. Findings from this study indicate that requiring prospective teachers to plan and execute a lesson or learning experience that differs from their traditional teaching practices leads to a variety of types of teacher belief and practice change. Participants who seemed to demonstrate high levels of efficacy and engagement with student thinking showed significant and substantive changes in beliefs and instructional practices, while participants who did not seem to have high teacher efficacy and engagement with student thinking showed no change in beliefs. Participants who seemed to
demonstrate moderate levels of teacher efficacy and engagement with student thinking showed high levels of questioning of beliefs, but struggled to enact change in instructional approaches.

Guskey’s proposed model for teacher change emphasizes a change in instruction and student outcomes prior to a change in teacher beliefs. An adapted model for prospective teacher education has been proposed; emphasizing the fact that university based experiences can play a significant role in changing instruction. This change in instruction opens up new opportunities for teacher learning and exposure to new modes of mathematical discourse. Instructional change, filtered by teacher efficacy and engagement with these new student-learning opportunities, leads to a range of belief reactions. In light of the findings of this study suggesting that prospective teachers with moderate efficacy and engagement with new student learning opportunities encounter substantial questioning of beliefs and Wheatley’s (2002) finding that belief change may require teachers to doubt their beliefs, this adapted model is potentially fruitful for prospective teacher education.

MEASURING BELIEFS ABOUT CONCEPTUAL PROGRESSION AMONG PRE-SERVICE SPECIAL EDUCATION TEACHERS

Theodore Chao  
The University of Texas at Austin  
theodorechao@austin.utexas.edu

Carmen Petrick  
The University of Texas at Austin  
carmenpetrick@gmail.com

In this study, we attempt to measure whether an elementary mathematics teaching methods course can affect the beliefs of a group of 14 pre-service special education teachers, and how those changes correlate with what the course instructor notices. Using various metrics, including the IMAP instrument and classroom observations, we find that a reform-oriented course can indeed move teachers to believe that mathematics teaching should start with conceptual understanding before procedural fluency.

Introduction

*Principles and Standards for School Mathematics* states that, “Equity requires high expectation and worthwhile opportunities for all. . . . Expectations must be raised—mathematics can and must be learned by all students.” (2000, pp. 12-13). Following the publication of PSSM, a year later, the National Research Council published *Adding It Up*, reinforcing this same idea of equity through research, and specifically addressing the need to teach students with special needs, “It has long been assumed that children with moderate, mild, and borderline mental retardation or learning disabilities are not capable of meaningful or conceptual mathematical learning and, thus, unlike other children have to be taught by rote” (2001, p. 341). This dismissal of special education practices as rote and procedural added friction between the mathematics education and special education communities, stoking the fire of the ongoing ‘math wars’ and drawing lines in the sand between traditional and reform-oriented mathematics educators (Schoenfeld, 2004). Five years later, NCTM published the *Curriculum Focal Points* (2006) to pinpoint specific mathematical topics, skills, and curricular strands for each grade level (Schoenfeld, 2007), shedding more light on the idea that perhaps the two feuding sides of the ‘math wars’ were not as far apart as previously imagined.

One area in which these theoretical battles between constructivists and embedded skills proponents are especially fierce occurs in our preparation of special education teachers (Woodward & Montague, 2002). According to Allsopp and colleagues (2003), current special education pre-service programs do a minimal job preparing teachers to teach mathematics to children with special needs. And while Brownell, Ross, Colón, and McCallum write, that “research in special education teacher education is almost nonexistent” (2005, p. 248), one thing we do know is that particularly effective instruction strategies for teachers of students with special needs should “ensure that the sequence of instruction moves from the concrete, to the representational, to the abstract” (Allsopp, et al., 2003, p. 4). These statements can seem like attacks from the mathematics education community dismissing the ways in which special education teacher educators prepare their teachers.

But fortunately, some special education researchers such as Woodward & Montague have found specific teaching techniques supported by both research in mathematics education as well as special education. One particular teacher belief that pre-service teachers are expected to embrace involves a conceptually guided approach to mathematics understanding; conceptual understanding must come before learning procedural algorithms and “problem solving and
analysis [must] replace drill and practice” (2002, p. 96). Research into how pre-service special education teachers embrace this belief is also minimal (Allsopp, et al., 2003; Brownell, et al., 2005).

In this paper, we will describe how a pre-service elementary mathematics methods course might help pre-service teachers build beliefs about mathematics teaching that align both with research from the fields of mathematics education and special education–specifically looking at the belief that students must build conceptual understanding of a mathematical computation before learning the procedural algorithm. Additionally, we will explore how pre-service teachers’ actual beliefs about this conceptual progression, when measured using validated instruments, might align with issues the course instructor notices.

Perspectives

Pre-service Teacher Development

The Cognitively Guided Instruction (CGI) body of work is a professional development elementary mathematics teacher framework that comes directly from the mathematics education research community (Carpenter, Fennema, Franke, Levi, & Empson, 1999; Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Fennema, et al., 1996; Franke, Carpenter, Levi, & Fennema, 2001). A solid companion to a CGI-based pre-service program includes Ginsburg’s clinical interview framework (1997) along with textbooks that support this approach to teaching (e.g. Elementary and Middle School Mathematics: Teaching Developmentally, 2010).

Understanding how these perspectives and teaching ideas might be taken up by special education teachers is exactly the type of research in need of undertaking in order to better understand how to prepare teachers as they try to navigate between traditional and reform-oriented strategies (Bottge, Rueda, LaRoque, Serlin, & Kwon, 2007; Brownell, et al., 2005; National Council of Supervisors of Mathematics, 2008; Woodward & Montague, 2002).

Specifically, one teaching belief that bridges both the special education and the math education areas concerns the idea that students should build conceptual understanding of a mathematical idea before learning the procedural algorithm (Woodward & Montague, 2002). For instance, this means that students understand conceptually what it means to add triple-digit numbers to each other through exploration of pictures, manipulatives, or other models before learning the traditional algorithm. This might play out as a student using base-ten manipulative blocks to model a problem like “149 + 286” before learning the traditional algorithm that involves lining up each number according to place-value and then moving right-to-left through each digit, making sure to carry over extra digits into the next place value.

Measuring pre-service teacher beliefs

Measuring and understanding specific pre-service math teacher beliefs is somewhat problematic (Philipp, 2007; Thompson, 1992). Often, a Likert-scale survey question is used to measure beliefs by asking teachers to rate their level of agreement to statements like, “Students need to build an understanding of a mathematical concept before learning the algorithm”. This is tricky because capturing how a respondent interprets the statement is difficult, respondents are not given an opportunity to explain the importance of how they respond, and items on a Likert-scale are not situated within a specific context (Ambrose, Clement, Philipp, & Chauvot, 2004).

The Integrating Mathematics and Pedagogy (IMAP) instrument moves beyond traditional Likert-scale questions to elicit authentic understandings of pre-service teacher beliefs through the use of respondents impressions to student work samples and videos of teacher-student interactions.
interactions (Ambrose, et al., 2004; Philipp, 2007). Not only is the IMAP instrument a validated belief measurement tool specifically targeted to pre-service Elementary teachers, it also reflects much of the CGI conceptual framework for helping pre-service teachers listen closely to children’s thinking (Philipp, 2007).

Further study of teacher beliefs requires structured classroom observation as well. Simon and Tzur’s (1999) suggest the use of a set as the unit of analysis for studying an account of practice for a teacher. The use of a set becomes a robust analytical tool for comparing and analyzing specific pieces of a teacher’s classroom practice. According to authors, a set should consist of “at least two consecutive related mathematics lessons and interviews before, between, and after the lessons” (1999, p. 258).

In this study, we attempt to respond to the call voiced within the special education research community for the need to conceptualize how to build understanding among preservice teachers through “carefully scaffolded activities using authentic tasks” (Woodward & Montague, 2002, p. 96). Simultaneously, we aimed to respond to the goal of moving pre-service teachers away from the idea that good math teaching involves a lot of “telling” (Philipp, 2007), as proposed within the mathematics education community. Using the IMAP instrument to measure teacher beliefs and Simon and Tzur’s notion of a classroom analysis set, we explore the belief that students must learn mathematical concepts before they learn procedures, or else risk never building full conceptual understanding.

**Methods**

**Data**

The participants in this study were 14 elementary pre-service teachers within a special education cohort at a large, public university in the Southwestern United States. They were in their second-to-last semester of their professional development sequence and just about to enter their student teaching semester. The course instructor was the first author of this study. The second author also taught a similar general education elementary math methods course that is separate from this study.

In the same semester that the pre-service teachers were enrolled in this course, they were also taking another course that heavily emphasized a direct-teach model of math lesson planning. So during this study, the pre-service teachers were in classrooms using direct-teach style lesson plans, while exploring reform-based mathematics learning in their methods course. One interesting note about this cohort of teachers is that they were the first class mandated to pass the state-wide high-stakes exam in order to advance to the next grade within their K-12 careers—the first students in this particular state to experience a full K-12 of high-stakes testing culture.

Data for this study consists of four specific pieces. First, baseline teacher beliefs were taken from teacher journal entries at the beginning of the semester asking teachers to reflect upon this question, which relates to Chapters 2 and 3 of the Van de Walle, et al. textbook (2010):

*Not everyone believes in the constructivist-oriented approach to teaching mathematics. Some of their reasons include the following: There is not enough time to let kids discover everything. Basic facts and ideas are better taught through quality explanations. Students should not have to "reinvent the wheel." How would you respond to these arguments?*
The second unit of data was the course instructor’s comments and analysis on each teacher’s final project, which reflected the course instructor’s understanding of each teacher’s belief that students need to learn mathematics concepts before being introduced to the traditional algorithms.

The third unit of data involved teacher responses to the IMAP instrument, which teachers completed during the final class period of the semester. Teachers were informed that their responses to the IMAP instrument would have no bearing onto their final grade for the course. For the purpose of this study, we concentrate only on two sections of the IMAP instrument.

In the first IMAP section, teachers looked at five student responses to the problem “149+286” and responded to the prompt “Consider just the strategies on which you would focus in a unit on multi-digit addition. Over a several-weeks unit, in which order would you focus on these strategies?” One of the student responses is the traditional algorithm, another uses base-10 block manipulatives, and the other three represent various created strategies.

In the second IMAP section, teachers watch two video clips of a teacher working with a student on dividing whole numbers by fractions. In the first clip, the teacher guides the student through the traditional algorithm of changing the division sign to a multiplication sign and flipping the second fraction, without explaining why this is necessary. Using this algorithm, the student is able to solve several additional problems involving fraction division. Teachers are asked to respond to this clip as well as comment on the prompt, “Would you expect this child to be able to solve a similar problem on her own 3 days after this session took place?” Teachers then watch the second clip, which takes place three days later, in which the student is asked to solve, “6 ÷ 1/3”. The student is unable to remember the algorithm, incorrectly changing the division sign into an addition sign, and struggling to figure out what to do. Teachers were again asked to respond to the clip, as well as answer the prompt, “Provide suggestions about what the teacher might do so that more children would be able to solve a similar problem in the future.

The last unit of analysis involved a case study of a student, Christin (a pseudonym), in an attempt to utilize Simon and Tzur’s (1999) concept of a set for analyzing classroom practice. Christin was selected because she happened to be sitting near the front of the classroom on the first day of class. The course instructor observed three specific sets: at the beginning, at the midpoint, and at the end of the semester. Each set consisted of an analysis of Christin’s lesson plan for the day, a pre-observation interview, a classroom observation, and a post-observation interview. Christin's post-observation interview was conducted the day after she taught, in an attempt to allow time to self-reflect. Christin’s classroom was a special education resource room consisting of eight 3rd to 5th grade students with varying special needs. Unfortunately, the logistics of this particular student’s classroom placement did not allow us to observe consecutive math lessons to fully follow the set framework.

Analysis

Analysis of this data took four steps. First, we analyzed the student reflection assignment from the first day of class to look at the belief system that teachers were starting at before they entered the course. Second, we coded the IMAP instrument results for Belief 4, sections 3.3 and 9 using the IMAP rubric. We started by completing the IMAP coding training exercises until we both achieved a 100% match with the rubric codes. Then, each author of this paper coded anonymous teacher responses individually before convening to compare our scores. The inter-rater agreement between both authors was 92.9%, which represents a strong agreement. Third, the classroom instructor looked through the graded final reflections for each teacher, categorizing the evidence to support each teacher’s beliefs using a similar 4-point scale as the IMAP rubric for comparability. Finally, we looked deeper into sets, including classroom
observation notes, interview notes, and classroom video of Christin’s teacher practice to gain a deeper understanding and connection with how our results might correlate with actual classroom practice.

**Results**

The results of our analysis are presented in Table 1, in which pre-service teachers are categorized as showing ‘No evidence’, ‘Weak Evidence’, ‘Evidence’, or ‘Strong Evidence’ of the belief, “If students learn mathematical concepts before they learn procedures, they are more likely to understand the procedures when they learn them. If they learn the procedures first, they are less likely ever to learn the concepts.” (Ambrose, et al., 2004)

At the beginning of the course, eight of the fourteen teachers showed no evidence or weak evidence of the belief that teachers should learn mathematical concepts before they learn procedures. At the end of the course, according to the course instructors’ impression of the teachers on the final project, eleven of the fourteen teachers now showed either evidence or strong evidence of this belief. This shows substantial change in the beliefs of the teachers through their experiences in this semester. However, from the course instructor’s impression, only two teachers displayed strong evidence of this belief.

Data from the IMAP instrument shows almost the same results as the course instructor’s impressions. Again, zero teachers showed no evidence of the belief and three teachers showed weak evidence of the belief. However, the results from the IMAP instrument show substantial change in the number of teachers who showed strong evidence of this belief rather than just evidence. While the instructor’s impression was that only two teachers showed strong evidence of this belief, the IMAP instrument shows that six teachers showed strong evidence of this belief. Since the IMAP instrument is a validated tool for measuring teacher beliefs, we conclude that the number of teachers displaying strong evidence of this belief is actually much more than the course instructor originally thought. Furthermore, since the number of participants in this dataset was so small (N=14), we did not perform further statistical analysis.

The specific results for our case-study teacher, Christin, found that there was no change in the amount of evidence she displayed for this specific belief. Only one other teacher showed no change in the three measures, displaying evidence of the belief at all three metrics. However, Christin showed weak evidence of the belief on all three metrics. We can conclude that Christin did not change much in her beliefs through the course.

This result is consistent with the classroom analysis sets we observed from Christin’s classroom. In the three sets collected throughout the semester, she continually emphasized a
belief that teaching students procedural steps was just as, if not more, important than conceptual understanding.

During the pre-observation interview of her last set at the end of the semester, Christin explained that she was still struggling with letting go of control for students to struggle and come up with the conceptual understanding on their own. She started a lesson involving multi-digit subtraction word problems with an overhead transparency of the six steps for problem solving and had students in her classroom read through each step out loud as a whole group. At one point during the lesson, when most of the students seemed to be struggling with one particular problem, Christin simplified the problem situation into a numerical subtraction problem, placing one digit on top of another to show students that they should use the traditional algorithm for subtraction, and instructed students to, “solve it.” Our observation notes for this lesson expressed frustration at Christin’s continued belief in emphasizing procedural step-by-step thinking when working with her students and wondered why she continued to allow this to permeate her classroom practice. During the post-observation interview, we used non-evaluative language to tell Christin we noticed that she started breaking the problems down into specific steps. She acknowledged that this was something she is working on moving away from, but also responded, “I want them to succeed. I want them to feel good at doing what they’re doing and not feel like, “I’m so frustrated I’m going to shut down”.

Collectively, these three sets of Christin’s classroom practice reveal a continued belief that procedural steps should come before conceptual understanding, a deep belief that mathematics involves following steps. This shows an alignment with her classroom practice to the beliefs that she evidenced through our three metrics. While Christin’s set was not an ideal case to test if our metrics from the IMAP instrument and the final project would correlate with classroom practice, we can at least conclude that these metrics are accurate when measuring no change and weak evidence of the belief that conceptual understanding must come before learning a procedural solution.

**Discussion and Conclusion**

This study reveals that the IMAP instrument seems more finely tuned to elicit the precise differences between just showing evidence and showing strong evidence of specific teaching beliefs, ones that the course instructor was not able to see. Perhaps our view of our own teachers through the lens of instructor does not allow us to see the fine-grain belief changes in our pre-service teachers. We were able to pinpoint a specific teacher’s beliefs when observing their classroom practice through the framework of a set and accurately predict their beliefs. But perhaps, just reading teachers reflections, lessons plans, and other assignments does not reveal to us deep level understandings of our pre-service teachers’ beliefs.

In the end, we found that our reform-oriented methods course did indeed create substantial change in special education pre-service teachers thinking about math teaching. This answers a need in the literature to show that special education teachers can indeed embrace reform mathematical ideas as their own through a pre-service math methods course. We can conclude that it is possible to help empower special education pre-service teachers to embrace reform styles of mathematics teaching that emphasize conceptual understanding before procedural fluency, something that both special educators and math educators agree on (Woodward & Montague, 2002). And even in the midst of continually writing and implementing direct-teach style math lessons in their field placements, the pre-service teachers moved towards a belief in mathematics teaching that emphasizes conceptual progression.

However, three potential issues for drawing conclusions from these results should be taken into account. First, the primary author was also the instructor for the course. And, the IMAP instrument requires teachers to write their first and last names, so it was not taken anonymously. So even though the teachers were told that their responses would have no bearing on their final grade, teachers still knew that the course instructor would be reading their responses and therefore they could have responded thinking that their responses might affect their final course grade. The responses were not read until after the final grades for the course had been submitted. Second, while we measured teacher beliefs at the beginning and the end of the semester, we did not use the same measures. We did not have a formal pre/post measure in place to properly measure changes in belief. Third, we find it hard to draw an accurate conclusion from Christin’s classroom observation sets. Since she did not evidence any change in her beliefs, we cannot formally conclude that our metrics will always match a teacher’s classroom practice. Perhaps our metrics only work when a teacher evidences no change. We further wonder if Christin might not be an anomaly at all. If we had the time and resources to deeply observe every one of our special education pre-service teachers, would we have seen the same reliance on procedure and emphasis on a ‘follow-the-steps’ approach to mathematical learning?

Through this analysis, we learned that using a trusted mechanism to measure teacher beliefs, such as the IMAP instrument, took an incredibly long time to properly code and analyze. It took two researchers two weeks to code, discuss, and ultimately agree on the codes for just one of the seven beliefs that the IMAP instrument measures. Our original intention was to use the IMAP instrument as a formative assessment tool to elicit the shifting beliefs of our pre-service teachers. However, the lengthy coding and analysis mechanism of the IMAP instrument make that an incredibly time-intensive task.

We have a hard time concluding that these beliefs will directly affect a teacher’s classroom practice. Perhaps this link from special education teacher beliefs to actual practice is another venue for continued research into special education mathematics education. We were able to observe what happens when a teacher shows weak evidence of a belief, but what about the classroom practice of a teacher who shows strong evidence?

ON RESPONSIBILITY: THE CORRELATION BETWEEN EFFICACY AND SENSE OF RESPONSIBILITY TOWARDS TEACHING ALL CHILDREN IN MIDDLE GRADES MATHEMATICS CLASSROOMS

Lisa Poling
Appalachian State University
polingll@appstate.edu

Based on the novel framework of Academic Agency, this study explored how teacher’s sense of efficacy influenced overall sense of responsibility in instructing all children in the nature of mathematics. Survey instruments utilized to collect individual data included a modified version of the Teaching Efficacy survey, Mathematics Teaching Efficacy Belief Instrument and Teachers’ Belief Form I. Pearson Correlation was employed as an analysis tool to identify relationships existing between variables. The noteworthy finding signified that a positive relationship exists between a teacher’s sense of efficacy and overall sense of responsibility in assuring that all children have the opportunity to advance.

Introduction

Historically, educational practices have failed to provide access to quality educational experiences for children who fall outside of what may be considered the majority. National and international assessments of student progress indicate that there are disproportionate numbers of underrepresented students based upon multiple subgroups who consistently fall below the level of achievement of majority students. The No Child Left Behind (NCLB) Act was developed to illuminate these discrepancies and mandate that something be done to correct this inequitable situation. In response to this Federal mandate, multiple initiatives have been funded, as of yet, little or no impact on the mathematics achievement of underrepresented students. Knowing that the greatest factor determining success in the classroom is the teacher, taking a careful look at what level of responsibility teachers have toward the goal of teaching all children becomes not only reasonable but also essential for the success of all children.

To address what is meant by a teachers’ sense of responsibility the micro-political context in which it exists must be acknowledged. Teachers’ sense of students’ ability (Roscigno & Ainsworth-Darnell, 1999) and teachers’ sense of responsibility for students’ learning both individually and collectively (Lee & Smith, 2001; Lee & Loeb, 2000; Diamond, Randolph & Spillane, 2004) define the micro-political context. Daily interactions provide the individual sense making mechanisms for how educators value and address differences that influence student outcomes (Diamond, Randolph & Spillane, 2004; Lareau & Horvat, 1999; Roscigno & Ainsworth-Darnell, 1999). This is what is frequently referred to as collective sense of responsibility in the classroom.

A collective sense of responsibility is established by organizationally defined indicators for student outcomes (Lee & Smith, 2001). Lee and Smith (2001) identified three components to measure a sense of collective responsibility: 1) teachers’ innate sense of responsibility for student learning, 2) a teacher’s willingness to modify teaching strategies to address students’ needs and 3) a teacher’s sense of efficacy in their teaching practices. Therefore, collective responsibility exists on a continuum; on one end are schools where teachers acknowledge their success and failures in the classroom and accept responsibility for student success and at the other extreme, teachers who take little responsibility for student success and blame the failure of...
Chapter 12: Teacher Beliefs

students advancement on conditions such as student ability, socio-economic level, or lack of motivation of the student (Lee & Loeb, 2000; Lee & Smith, 1996).

Focusing attention on responsibility, two conjectures exist concerning the attribute of responsibility. Responsibility can be defined as either virtuous or accountable. Silverman (2009) posits that a responsible and virtuous person will engage in those areas that are driven by morality and how the choices that they make regulate their behavior. A responsible and accountable person on the other hand is driven by rules, outcomes, and punishment such as high stakes testing. For an individual that adheres to accountability, state mandates and political forces influence the manner in which teachers base educational decisions. Therefore, constructs that are imposed from external forces may diminish a teacher’s sense of responsibility in a classroom setting.

Previous research studies have shown that the avoidance of responsibility may serve as a means of dissonance reduction (Brock & Buss, 1962; Cooper, 1971; Lerner & Mathews, 1967). Dissonance reduction is the cognitive state where an individual fails to accept responsibility for behavior or the consequence of behavior based upon their level of investment (Cooper, 1971). Cooper (1971) identifies two processes by which an individual may avert responsibility: 1) the environment, individuals’ claim they were forced to behave in an irresponsible manner, 2) consequences of their attitude-discrepant behavior was unforeseeable.

Teachers act and react to daily occurrences based upon their own previous life experiences. According to Thompson (1992), a “teacher’s beliefs appear to act as filters through which teachers interpret and ascribe meanings to their experiences as they interact with children and the subject matter” (p.139). Good and Brophy (1990) state, a teacher who believes all students can excel in school will change their behavior to make sure that success is attainable for all learners. In many ways a teacher’s expectations become a self-fulfilling prophecy in the classroom. If a teacher expects more, they will receive more from the students in the classroom.

Ross (1998) proposed that reflection on the results of one’s teaching is the most important contributor to teaching efficacy. Self-reflection is difficult. Individuals do not want to be faced with their weaknesses, but to improve classroom practices reflection upon action becomes essential. When comparing the level of efficacy and reflection, a person with a high sense of efficacy would tend to reflect on classroom practices, identify areas for improvement, change their behaviors, and adapt a new plan to address their goals, whereas a person with lower self-efficacy may acknowledge that their practices could be improved but fail to implement any type of significant change because they feel the goal is unattainable.

In a study conducted by Ashton and Webb (1986) they found that teacher expectations and commitment to responsibility were altered by student characteristics such as socioeconomic class, race, or classroom behavior. Thus, a teacher that demonstrated a low sense of efficacy failed to accept any responsibility for student achievement. Teachers with high efficacious feelings cited more positive relationships with students and took a greater responsibility in reaching children. Although personal influences such as efficacy are not seen as a direct link to a sense of responsibility, the importance of individual belief systems are central to a learning environment.

For the purpose of this study, efficacy was identified as what individuals believe they can accomplish in a specific situation. Therefore, taking control of situations and knowing how to proceed becomes paramount to an individual’s sense of efficacy. The notion of efficacy can be seen through two aspects of control. First, the strength of the efficacious beliefs becomes a determinant of how the individual chooses to use their personal capabilities and resources to achieve a goal. The second factor of control is how individuals see themselves in relation to the

environment and how are they able to change the situation to aid in addressing the challenge at hand (Bandura, 1993).

Research conducted by Hoy and Woolfolk (1990) established that teachers with a low sense of instructional efficacy tend to possess a more custodial orientation. Their study looked at individuals either entering student teaching, taking teaching methods courses, or students taking developmental psychology classes. Through various measurement instruments, three of the four major hypotheses stated for the study were confirmed: pupil-control ideology of student teachers became more custodial, the social problem-solving orientation of the student teacher became more controlling, and the general sense of teaching efficacy for the student teachers also declined. Custodial orientation, because of limited student involvement, does not allow for motivation from within the student to drive instruction. Teachers that identify with a custodial orientation tend to believe that education is incapable of overcoming the students’ limitations. These limitations may be both internal and external. Student ability would be identified as an internal limitation, whereas living environment would be considered an external limitation.

In an educational setting where the objective is procedural, students fail to take ownership of the learning process and struggle to move forward. Ross, Hogaboam-Gray, and Gray (2004) reported that teachers with a high sense of efficacy try harder, encourage student autonomy, focus on needs of low-ability students, and help to transform students’ perception of their ability.

**Purpose**

The intention of this study was to identify how efficacy may influence a teachers’ sense of responsibility to improve the outcome of students who fail to flourish in mathematics. The question guiding this inquiry was, Do relationships exist between a teacher’s senses of efficacy, both general teaching efficacy and mathematics teaching efficacy, and their overall responsibility that will assist us in learning more about how to teach all children in middle grades mathematics classrooms? Annual educational statistics illustrate that each year millions of children fail to make adequate progress in personal mathematical understanding so the focus on teaching becomes: who is responsible and how is that responsibility defined so that underrepresented children who fall into a myriad of demographic categories such as socio-economic status or gender, receive adequate mathematics instruction? One would assume that a classroom teacher should hold a significant level of responsibility but, this assumption is neither straightforward nor clearly defined.

**Theoretical Framework**

For this study, only a small portion of the Academic Agency framework was studied. The complete framework of Academic Agency consists of three categories: efficacy, commitment, and knowledge. Each individual construct addresses components of the educational setting that tend to influence student learning. The classification of efficacy encompasses three forms of efficacy: self-efficacy, teaching efficacy, and mathematics teaching efficacy. The second division, commitment focuses on the instructional and academic emphasis of an academic setting. Knowledge, the final piece of the triad, brings attention to not only content specific knowledge but also pedagogical content knowledge (see Shulman, 1987 for additional information regarding PCK) and mathematics knowledge for teaching (see Ball & Bass, 2003; Ball, Hill, & Bass, 2005; Ball, Thames, and Phelps, 2008; Bass & Lewis, 2005 for additional information regarding MKT).

As depicted in Figure 1, the premise of Academic Agency states that only when an educator has taken the responsibility to act and react, based upon efficacy, commitment, and knowledge,
to the needs of the student they become agents of change. The purpose of this study was to identify the influence that efficacy has on an individual’s sense of responsibility within the classroom. In future publications, data will be analyzed to attend to the remaining two subsections of commitment and knowledge.

Figure 1. Theoretical Framework of Academic Agency

Methods of Inquiry

To explore whether a relationship exists between efficacy and responsibility three quantitative survey instruments were used. Survey instruments were presented to consenting middle grades (grades five through eight) mathematics teachers in three school districts: one rural, one suburban, and one urban, in central Ohio. Participants in the study included individuals who have taught one to thirty years, with the majority of participants being female. A total of forty-nine usable survey instruments were analyzed for this study.

Participant survey included, a modified version of Gibson and Dembo’s (1984) Teacher Efficacy survey measuring overall teaching efficacy, The Mathematics Teaching Efficacy Beliefs Instrument (MTEBI-A) to look at content specific efficacy, and a modified version of Silverman’s (2009) Teachers’ Beliefs Form I to address responsibility. A Likert scale was employed to record individual responses. The range of the Likert scale was from 1 to 6 with 1 representing strongly disagree and 6 corresponding to strongly agree.

Teacher Efficacy

Woolfolk and Hoy (1990), using Gibson and Dembo’s original scale, constructed a 22-item Teacher Efficacy Scale to examine the meaning of efficacy for prospective teachers. This modified version is the instrument I chose for this study. Woolfolk and Hoy’s efficacy instrument encompasses 16 items from the Gibson and Dembo (1984) Teacher Efficacy Scale that produced adequate reliability and 4 others that address the adequacy of the teacher’s preservice preparation. The two additional survey questions include two original RAND items, item one: “When it comes right down to it, a teacher really can’t do much because most of a student’s motivation and performance depends on his or her home environment” and item two:

---

“If I try really hard, I can get through to even the most difficult or unmotivated students.” Item one of the RAND items focuses attention on teaching efficacy while item two looks at personal teaching efficacy. Through previous studies using the RAND items, results have indicated that teaching efficacy and personal teaching efficacy are independent. Hoy and Woolfolk (1990) reported a Cronbach’s alpha coefficient of $\alpha=.74$ for the teaching efficacy (TE) scale and $\alpha=.82$ for the personal efficacy (PE) scale.

Mathematics teaching efficacy.

The Mathematics Teaching Efficacy Beliefs Instrument (MTEBI-A) (Enochs, Smith & Huinker, 2000) for in-service teachers, was used to measure mathematics teaching efficacy. The MTEBI-A is comprised of 13 personal mathematics teaching efficacy (PMTE) items and 8 mathematics teaching outcome expectancy items (MTOE). The MTEBI-A was developed based on the STEBI-A, a science efficacy belief instrument created by Riggs and Enochs (1990). Enochs, Smith and Huinker (2000) reported a Cronbach’s alpha coefficient of $\alpha=.88$ for the PMTE scale and $\alpha=.77$ for the MTOE scale. A sample question is: “Even if I try very hard, I will not teach mathematics as well as I teach most subjects.

Teacher responsibility.

To explore teachers’ sense of responsibility, the Teachers’ Beliefs Form I, developed by Silverman (2009) was utilized. An abbreviated 23-item version of Silverman (2009) Teachers’ Beliefs measured specific aspects of teacher beliefs regarding specific aspects of responsibility in the classroom setting. Silverman in her original study reported a Cronbach’s alpha of $\alpha=.505$ for items that addressed overall responsibility. A sample responsibility question is: “Teachers are professionally responsible for reaching all of their students”.

For this study, the following reliability statistics were reported; Teacher Efficacy $\alpha=.807$, Teaching Efficacy-Teaching $\alpha=.633$, Teaching Efficacy-Personal $\alpha=.791$, MTEBI $\alpha=.792$, MTEBI-MTOE $\alpha=.711$, MTEBI-PMTE $\alpha=.737$, and Overall Responsibility $\alpha=.604$.

To recruit participants, site visits were conducted. At each setting participants were presented with a detailed description of the study, a consent form which they were asked to complete at that time, and the survey instrument. The consenting document allowed individuals to indicate either they consented or did not consent to participate in the study. Teachers at the rural setting completed the survey the same day as the site visit. At the remaining research sites, participants completed the questionnaire individually.

As data was received individuals were given unique identifying numbers and all data was de-identified. Individual responses were then recorded in SPSS. To prepare for the initial analysis, the mean of each main variable (teaching efficacy, mathematics teaching efficacy, and overall responsibility) was computed. To prepare for the second correlation study, the summated score of each subscale within teaching efficacy and mathematics teaching efficacy were calculated.

Analysis of the data consisted of identifying any significant correlations that existed between variables and the level and direction of their relationship. The statistical measure Pearson Correlation was utilized to identify the degree and direction of existing relationships. The first level of analysis looked at the interactions of overall responsibility, teacher efficacy and mathematics teaching efficacy. The second correlation study addressed how the sub divisions of each instrument influenced one another as well as overall responsibility and assessed the association between variables.
Results

The results from the study, shown in Table 1, show a connection between a teacher’s sense of overall responsibility and their sense of efficacy, as well as a corresponding relationship between teaching efficacy and mathematics teaching efficacy. In the initial correlation analysis, as overall sense of responsibility increased, a teacher’s sense of teaching efficacy also increased and showed significance at the p-value of .05, N=43.

| Table 1. Pearson Correlation for Overall Responsibility, Teaching Efficacy, & Mathematics Teaching Efficacy |
|--------------------------------------------------|--------------------------------------------------|----------------------------------|
| MEAN TEACHING RESPONSIBILITY | MEAN TEACHING EFFICACY | MEAN MATH TEACHING EFFICACY |
| MEAN TEACHING RESPONSIBILITY | 1 | |
| MEAN TEACHING EFFICACY | .393* | 1 |
| MEAN MATH TEACHING EFFICACY | .212 | .630* | 1 |

Note. * Correlation is significant at the 0.05 level (2-tailed).

For the second phase of this study, the correlation between the subscales of teacher efficacy, mathematics teaching efficacy and the overall sense of responsibility once again showed evidence of a positive relationship between variables (See Table 2). As the subscales for teacher efficacy increased the overall sense of responsibility increased and was significant at a p-value of .05. Teacher efficacy also responded positively to the measure of mathematics teaching efficacy and outcome expectancy measured by the MTEBI-A.

| Table 2. Pearson Correlation for Overall Responsibility, Mean Teaching Efficacy, Mean Personal Efficacy, Mathematics Teaching Efficacy-Outcome Expectancy and Mathematics Teaching Efficacy-Personal Efficacy |
|--------------------------------------------------|--------------------------------------------------|----------------------------------|----------------------------------|----------------------------------|
| MEAN TEACHING RESPONSIBILITY | MEAN TEACHING EFFICACY | MEAN PERSONAL EFFICACY | MTEBI-OUTCOME EXPECTANCY | MTEBI-PERSONAL EFFICACY |
| MEAN TEACHING RESPONSIBILITY | 1 | | | |
| MEAN TEACHING EFFICACY | .345* | 1 | | |
| MEAN PERSONAL EFFICACY | .311* | .474* | 1 | |
| MTEBI-OUTCOME EXPECTANCY | .311* | .596* | .660* | 1 |
| MTEBI PERSONAL EFFICACY | .242 | .212 | .419* | .345* | 1 |

Note. * Correlation is significant at the 0.05 level (2-tailed)
The results of this study provide an entry point for further research. Analysis of the survey responses identified compelling evidence that as teachers’ sense of teaching efficacy increases an individual embraces more responsibility in their professional role. Further research is needed to delve into the more complex and challenging discovery regarding why this phenomenon exists.

**Conclusion**

The findings from this study begin to identify a gap that exists in current research. Ongoing research on teaching can contribute to our understanding of the role of teaching efficacy and its extended influence on overall responsibility. To promote the advancement of mathematics education, educators must focus attention on how they define their responsibility in the classroom and the steps that are taken to enhance the classroom experience so that all children begin to find success in the middle grades mathematics classroom.

Efficacy is only a piece of the entire Academic Agency model; therefore, a more comprehensive view of responsibility will be acknowledged once all components (efficacy, commitment, and knowledge) are analyzed and their influence is established in future publications.

The analysis described in this study involves clear limitations, including a small sample size and limited research sites. Because the sample size is limited, I am hesitant to make any type of generalization based upon the evidence collected. To more completely address the influence of efficacy on an individual’s overall sense of responsibility, a larger sample will need to be collected and multiple research sites will need to be included. As previously stated, this preliminary study provides an entry point for a much larger and necessary study.

---

Quantifying Uncertainty and Analyzing Numerical Trends (QUANT) is a yearlong professional development program to expand secondary school mathematics teachers’ statistical proficiency for teaching. This study investigated the perspectives of the 2009–2010 participants regarding their implementation of high-level tasks and the obstacles they encountered when attempting to apply them in their classrooms. The findings indicate that the program helped the participants gain confidence in their teaching and that the participants found the program to be valuable for exchanging ideas and experiences. However, the participants indicated that instructional time and class duration critically support or inhibit implementation of high-level tasks.

Introduction

According to Boston and Smith (2009), teachers are more likely to implement high-level tasks if they are exposed to professional development (PD) programs that support the implementation of such tasks. The goal of PD programs is to improve student learning, and student performance will not improve unless teacher performance improves (Loucks-Horsley et al., 2003). To be effective, technology-intensive PD programs need a clear content focus that is relevant to the participants (Foley, 2002). In a research study conducted at three Boston schools, students whose teachers received need-based PD performed significantly higher on a normed achievement test than students whose teachers did not receive PD (National Research Council, 2004). PD programs are especially crucial when teachers are required to apply new technologies and approaches in their classrooms (NRC, 2004). However, applying high-level cognitively demanding tasks inside the classroom is not straightforward for teachers, even with PD experience and support.

Mishra and Koehler (2006) argue that developing proficiency for teaching requires a thoughtful interweaving of technology, pedagogy, and content knowledge: A teacher who has deep pedagogical knowledge understands how students construct knowledge and acquire skills, and develop a positive disposition toward learning mathematics and statistics using technological support. Kynigos and Argyris (2004) show that teachers’ beliefs and practices are established over time while they are “engaged in an innovative ‘mathematical investigations’ school program, based on the use of exploratory software” (p. 247). Their research results show that “teachers refer to a variety of aspects of the learning situation in which they intervene rather than just the mathematical concepts and ideas” (p. 247).

The QUANT PD program is intended to improve teachers’ technological pedagogical content knowledge (TPACK) in the areas of data analysis, probability and statistics (Reed, 2009). The first QUANT institute took place at Ohio University in Athens in June 2008. The second and third QUANT institutes took place at Ohio Resource Center in Columbus in August 2008 and in...
June 2009, respectively. The key aims of the QUANT program are (a) to deepen participants’ understanding of content and pedagogy, (b) to develop participants’ knowledge of the mathematical tasks framework (Stein, Smith, Henningsen, & Silver, 2009), (c) to deepen participants’ working knowledge of instructional technology, and (d) to encourage participants’ use of high-level tasks during instruction of data analysis, probability, and statistics in their classrooms.

In keeping with the National Research Council (NRC, 2001), the QUANT program promotes the five major components for developing mathematical proficiency—conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive disposition. These components apply to the teaching and learning of statistics just as they do to the teaching and learning of mathematics. The QUANT materials development and program implementation are based on this premise (Foley, et al. 2010). The QUANT development team defines statistical proficiency for teaching as “teachers’ knowledge that is useful in promoting the statistical proficiency of their students” (Foley, Strayer, & Regan, 2010, p. 4).

### The Intervention

Eight high school mathematics teachers participated in the June 2009 QUANT institute held at Ohio Resource Center in Columbus. The program explored rich and inquiry-based activities in mathematics and statistics using manipulatives and enhanced technology such as the TI-nspire CAS software and TI-nspire CAS handheld computer (Wagner, 2009). Pedagogically, the participants used the mathematical tasks framework (MTF) and the task analysis guide (TAG) as presented in Stein et al. (2009). The purpose of introducing the participants to MTF and TAG was to enhance their ability to identify the two categories of mathematical tasks associated with high-level cognitive demands—doing mathematics and procedures with connections—as well as with two categories of mathematical tasks associated with low-level cognitive demands—memorization and procedures without connections. The participating teachers were then expected to select or create tasks based on their overall goals for student learning. A key aim of the QUANT program was to help teachers set up, enact, and maintain high-level tasks.

A follow-through workshop was held four months later at the Ohio Resource Center. To address the importance of Stein et al.’s (2009) TAG and to emphasize the productive disposition component of statistical proficiency, participants were asked to prepare and present lessons that reflected their capacity to teach statistical concepts using high-level tasks. These lessons gave the participants the opportunity to practice the new skills they had learned.

### The Study

This study explored participants’ perceptions of the effectiveness of the 2009–2010 QUANT program and identified perceived obstacles that prevent teachers from enacting high-level cognitively demanding tasks when teaching mathematics. Because the QUANT program specified that the participants would be able to present high-level tasks in their classroom following the program, the research team investigated the degree to which participants actually applied, or were intentionally willing to apply, what they had experienced in the QUANT program. The study examined whether the QUANT program’s activities aligned with the participants’ teaching goals. Specifically, the investigation evaluated the extent to which the participants, subsequent to the intervention, used high-level tasks when teaching mathematics.
Research Questions

- How and to what extent did the QUANT participants intend to apply high-level tasks in teaching mathematics?
- What, if any, changes did the QUANT participants make to their teaching methods as a result of following the TAG and using the TI-nspire handheld?
- What did the QUANT participants identify as obstacles that prevented their implementation of the TAG?

Methodology

This study collected data through face-to-face interviews with 5 of 8 participants, using a question protocol designed by the researchers, consisting of 11 specific, open-ended questions. Follow-up questions were used when appropriate.

Each interview lasted 60 min. The participants were asked to reflect on negative or positive experiences when they applied what they had learned in the QUANT program and ways in which this affected their daily practice. Additionally, they were encouraged to comment on the classroom environment that could support such implementation. Other specific questions addressed the usefulness of the QUANT materials and resources that were given to participants to help them in applying the updated teaching strategies.

Meetings with 2 of the interviewees took place in their classrooms, which provided insight into their teaching environment. In order to gain the most accurate self-reported answers, researchers assured the interviewees that the purpose of the study was not to evaluate their teaching ability or their mathematical knowledge, but to further understand the effectiveness of QUANT program, based on practitioners’ own input.

All interviews were recorded in their entirety, transcribed, and analyzed by the team of researchers. Common themes and differences among the interviewees’ responses were identified. Initially 3 core codes teachers’ perceptions regarding participating in PD program, implementing high-level tasks, and obstacles that may prevent any change were used in analysis.

Findings

Teachers’ perceptions regarding participating in PD program

The analysis of the interview transcripts indicated that 4 of the 5 participants reported improved attitudes about their teaching as a result of exposure to the QUANT program. The participants were mathematics teachers who also taught statistics. Some of them had begun to teach statistics recently. They all reported that they felt more comfortable when they taught statistics and tried to apply higher-level tasks after participating in the QUANT program. Participating teachers indicated that they were doing a better job compared to previous years. They claimed they were trying to change their teaching methods as a result of attending the QUANT program. The QUANT program helped them gain confidence in their job. Additionally, some of the teachers reported that it was praiseworthy to participate in QUANT program because they had been feeling isolated due to absence of other statistics teachers in their school. QUANT program was the opportunity for them to meet other mathematics teachers who taught statistics and it gave them opportunity to connect with each other, discuss some activities or share ideas. Following is typical of comments shared by this group.

I really enjoyed meeting other teachers who are teaching the same subject and are interested in the same topics ... I thought lots of the activities we did were interesting and valuable. (Participant A, interview transcript, October 2009)

On the other hand, one widely mentioned issue was that attendance of a PD program was entirely self-motivated. Several participants reported that mathematics teachers felt so comfortable and secure in their jobs that they did not appreciate PD programs and did not see the value in the support provided by such programs. They were unwilling to sacrifice their time to attend a PD program.

You know the teachers who have been there for a long time are not interested in doing your thing. A lot of them will become comfortable, and asking them to do something new is just increasing their work and there is some resistance to that. I do not think that it is a coincidence that attendance of the QUANT was not good. Even though they pay for the hotel, breakfast, and dinner, and lots of giveaway materials, [they] still could not get people to give up two weeks of their summer because people are just not interested in having to do more work. (Participant B, interview transcript, October 2009)

Thus, the participants in the study considered themselves highly self-motivated.

Teachers’ perceptions regarding implementing high-level tasks

Four participants indicated that their level of comfort and confidence had improved as a result of realizing the impact of implementing high-level tasks on students’ learning of mathematics. One such individual was Participant C a high school mathematics teacher who had been teaching statistics for more than 4 years. Participant C discussed how students had become more actively engaged in meaningful discussions about learning in the classroom because of the implementation of high-level tasks. Participant C stated that her students were showing improvement in their ways of solving mathematical problems and they were asking deeper questions as a result of shifting her teaching style towards the implementation of high-level tasks, as depicted below:

My students are asking questions more deeply than I am used to, and they begin to ask about the special cases that we never talked about it in the class. (Participant C, interview transcript, October, 2009)

Because participants spent a great deal of time engaging in solving rich problems during the QUANT program, Participant C was the one of the participants who spent time to think about questions, restate questions in a test and ask challenging questions during the discussion so as to lead the students to think.

During the interview, participants’ comments demonstrate an improved level of implementation of high-level tasks in their classrooms as a result of attending the workshop. They claimed thing real-life data from sport or business to capture students’ interest and to help them model their mathematical knowledge. Specifically, 4 out of 5 participants referred to particular tasks from the QUANT materials that they had implemented to enrich students’ experience and to increase their mathematical thinking.
Chapter 12: Teacher Beliefs

All of the participants also expressed that the QUANT program helped them break from traditional methods of teaching mathematics, resulting in greater student learning. Participant D stated he had changed his teaching methods as a direct result of the QUANT program. He had changed the sequence of tasks in his lessons. Instead of teaching all the traditional techniques and procedures from the beginning of the lesson, he opened with a higher-level task first, leading to the main topic of the lesson plan. If necessary, Participant D would reteach or apply scaffolding.

Teachers’ perspectives regarding the obstacles that may prevent change

One of the main goals of this study was to understand why applying high-level tasks and rich activities using technology in the classroom may be difficult to implement. The transcripts from the interviews showed that all participants identified time as the main constraint. With specific content to be covered in a limited time frame, the participants expressed concern that they had to sacrifice quality teaching to achieve the meet of all objectives. The 5 participants in this study were currently teaching in various school districts, with different teaching experiences, and were engaged with students from a wide range of academic proficiency. Even though there was no direct question that examined the effect of time on applying high-level tasks in the classrooms, 4 of the participants commented that time alone could influence their decision of applying high-level tasks in the classroom. Interestingly, the only teacher who did not count time as the main obstacle when enacting rich activity was the only one who taught in a 90-min class period. The results indicated that class-period duration could support or inhibit implementing high-level activity while teaching mathematics.

Another critical point raised by one participant was that time in outlines was limiting factors to a shift from traditional teaching to using high-level tasks was the level of the cognitive abilities of students accordingly. Students with high cognitive abilities and more motivation to learn do not need to experience high-level tasks because they could find them on their own.

The upper level students have lots of materials, so they have to go wide, but I think with students with lower level ability, deeper is better for them. They are expected to know lots of materials and if you go wide, but not deep, then they will not understand. I think different approach depend on the ability of the students. (Participant B, interview transcript, October 2009)

A more significant point reflected in the same participant’s response was that she did not see the importance of all the mathematical concepts in students’ lives; she saw mathematics as a preparation for college only.

According to the participants, students’ attitude and their willingness was another obstacle regarding implementation high-level tasks. Three participants stressed that students did not want to think on questions or problems deeply. One of the most experienced participants mentioned that forcing the students on high-level thinking caused frustrations for many students because the students had been conditioned to solve low-level tasks. According to one of the participants, it was more enjoyable to teach students who are curious than students who are taking the course for credit only. Because it is more pleasant to teach AP classes, they deserve high-level activities; for other student, their goal is to pass the course with a grade that is shown in their transcript, and her job is to help them achieve this goal. She indicated that subtle changes can occur only with motivated, high-ability students.

Chapter 12: Teacher Beliefs

The QUANT program emphasized the development of mathematics teachers’ TPACK. Nevertheless, some participants indicated that the unavailability of the TI-nspire in their schools would inhibit their ability to apply what they had been experiencing in the workshop. Further, because such technology requires continuous practice, the fact that teachers were not currently able to use it in the classrooms affect their ability to use later even when it became available.

Conclusion

Most of the time, teachers do not use high-level tasks or technology when teaching mathematics (Stigler & Hiebert, 1999; Tarr, Grouws, McNaul, & Sutter, 2008). On the other hand, according to Boston and Smith (2009) and NRC (2004), attending PD programs can support teachers’ implementation of new approaches and technologies such as high-level cognitively demanding tasks and the TI-nspire. The 2009–2010 QUANT program was developed to meet these criteria.

This article reported on the ways that the QUANT program potentially impacted teachers’ practices. Through face-to-face interviews, the research team was able to gain insight into the participants’ perspectives to see how the teachers themselves evaluated their experience. These data presented the participants’ point of view regarding the most valuable benefits from attending the workshop.

While the results show that the QUANT program convinced the 5 interviewees about the importance of engaging students in high-level tasks, most of them expressed concern that they would not be able to do so because of the pressure to cover specific content in limited time, because of the attitudes and willingness of their students, and because of the limited availability of the technology.

The results suggest that when designing PD programs to improve teaching, time management should be addressed as a critical issue that teachers need to consider. Class duration and the syllabus to be covered are two factors that cause an unspoken pressure on teachers. As a result, teachers face the dilemma of privileging the inclusion of high-level cognitively demanding tasks over covering the required materials.

Regarding the technology implementation, teachers may not use technology in their classroom after attending PD programs because of the lack of its availability. As a result, PD developers should consider means for providing participants with technology for their classrooms.

TEACHERS’ DISCUSSION OF MATHEMATICS AND PERCEPTION OF LEARNING

Margaret Dickey-Kurdziolek  Deborah Tatar
Virginia Tech  Virginia Tech
mdickey@vt.edu  tatar@vt.edu

In semi-structured interviews conducted with Scaling-Up SimCalc participants, treatment teachers discussed more mathematic topics they described as “newly introduced” than “basic”, while control teachers discussed more “basic” than “newly introduced.” Despite their presence in classrooms where students achieved significant learning gains on both “basic” and “newly introduced” topics, and their own testament on the conceptually difficult mathematics the SimCalc unit presented, treatment teachers still expressed that the SimCalc materials may be too advanced for their students. Teacher perceptions of student ability need to be addressed if we hope to encourage the exploration of more conceptually difficult mathematics in K-12 education.

Introduction

SimCalc MathWorlds® is a piece of educational software that facilitates students’ exploration of mathematical ideas related to rate and proportionality by supporting dynamic graph creation and manipulation, in which graphical representations are tightly coupled with representations in a simulation “world”. By linking measurable experiences and events to formalized mathematic expressions, SimCalc MathWorlds enables more students to learn the mathematics of change and variation (Kaput, 1994). Over the past 15 years, SimCalc MathWorlds has been utilized in a number of small-scale studies with great success. More recently the Scaling-Up SimCalc study has shown that the use of SimCalc MathWorlds in combination with corresponding teacher professional development and curriculum can be used with success in a wide-range of classrooms with a wide-range of students (Roschelle et al., in press; Tatar, 2008).

But finding significant outcomes for learning with SimCalc is just the beginning of the discussion. How can we ensure that SimCalc MathWorlds will not just work for a variety of teachers participating in the study, but that the teachers perceive the benefits of using the SimCalc resources and will actually choose to use it in the future? To answer this question, we turn to the corpus of phone interviews conducted with participating teachers, in which the teachers discussed their assessment of the conceptual difficulty of the SimCalc unit and articulated a wide-range of beliefs on students’ mathematical abilities. We argue that teachers are the gatekeepers of resources used in their classrooms, and that if we hope to influence their choice of resources to use in the future (such as SimCalc MathWorlds) then we must first understand teacher perceptions and goals.

Our phone interviews with teachers in the SimCalc study reveal that the positive learning outcomes may not always be apparent to teachers, even when they articulate the benefits of the curriculum themselves. In this paper, we illustrate how treatment teachers participating in the study discussed the mathematics content of the Scaling-Up SimCalc unit as compared to similar discussion on curriculum content with control teachers. Also, we demonstrate how the treatment teachers’ felt about the SimCalc unit’s conceptual complexity in relation to their beliefs on 7th grade students’ abilities and their state-mandated standards and assessment. We demonstrate by example that when we consider we empirical success of interventions such as Scaling-Up
SimCalc, we must also consider teacher perception on conceptually difficult topics and its relation to their teaching objectives and perception on student abilities.

**Context Of The Study**

SimCalc MathWorlds® software supports dynamic graph creation and manipulation, in which graphical representations are tightly coupled with representations in a simulation “world”. Students can step through the motion graph, observe characters in the world, and examine tables with corresponding values. The graphs can be directly edited with the mouse, and the simulation world and tables will immediately reflect these edits. The image above (Figure 3) is a screen-shot from a SimCalc MathWorlds activity used by the participants in Scaling-Up SimCalc study. In the image, the world shows two vehicles going on a road trip where the lower line (usually displayed in red) represents a van and the upper line (usually displayed in yellow) represents a bus. With this particular MathWorlds graph and simulation, the two vehicles would start at position 0 at time 0, and when the student presses play the bus and van will move in correspondence with the graph, arriving at their final destination 180 miles away after 2 hours for the bus and 3 hours for the van. There are several worlds the students can interact with, such as elevators in motion, ducks swimming across a pond, and clowns marching across the screen. Definition and direct manipulation of graphically editable functions, hot links between graphically editable functions and their derivatives or integrals, and connections between representations and simulations are thought to be crucial components of making the mathematics of change and variation accessible to a wide range of students (Hegedus & Kaput, 2004; Roschelle & Kaput, 1996).
The SimCalc MathWorlds approach presents mathematical ideas graphically rather than algebraically, which allows for the student to first understand the concepts dynamically and then move to numeric and algebraic functions later. Students can play the simulation to watch the characters move in correspondence to the position graph they created, therefore experiencing the mathematical constructs of algebra and calculus as dynamic, motion-based events (Kaput, 1994).

Over the past 15 years, SimCalc MathWorlds has been evaluated in numerous small-scale design-research and quasi-experimental studies showing positive and promising results (Hegedus & Kaput, 2004; Nickerson et al., 2000; Roschelle & Kaput, 1996; Stroup, 2005; Tatar, 2008). However, policy makers at the local, state, and federal levels, school administrators and legislators wanted what they would call a systematic demonstration of value. They wanted “proof” that SimCalc worked in a wide variety of classrooms. To do this, the researchers conducted a series of randomized, controlled experiments replicating and extending the hypothesis that a wide variety of students from a wide variety of settings could benefit from the use of SimCalc MathWorlds (Roschelle et al., in press; Tatar, 2008).

**Scaling-Up SimCalc Study Setting and Procedures**

Since rate and proportionality is a central topic of 7th grade, 7th grade math classes and teachers were chosen to be participants in the first and most extensive study (Roschelle et al., in press; Tatar, 2008). The researchers implemented a delayed treatment design with two conditions to test their hypothesis. Teachers were assigned to condition randomly by school (that is, teachers in the same school were in the same condition). The experimental, or treatment group, was assigned to use SimCalc during year one, while the delayed treatment, or control group, was assigned to use SimCalc during year two. In year one, the control teachers were asked to teach their normal rate and proportionality unit. Students from both conditions were given a pre-test before their unit on rate and proportionality, as well as an identical post-test once the unit was completed. Full presentations of the experiments and their results are published in (Roschelle et al., in press; Tatar, 2008).

From an experimental point of view, study location has implications for how the study is conducted and for the generalizability of results. Diversity in teachers, students, and settings was necessary, but availability was also a consideration. The researchers chose to base the Scaling Up SimCalc study in Texas for three reasons:

1) The Charles A. Dana Center, which is a leader in math and science teacher professional development in Texas, and has an ongoing relationship with teachers and schools, was willing to participate.

2) The State of Texas gathers comprehensive yearly data about schools and teachers that helped characterize the sample.

3) State standards and testing had been in place in Texas for longer than other states, and were more stable.

The exact pedagogical goals of the experiment were influenced by this choice. 7th grade math classrooms in Texas typically focus on a formula-based approach to rate and proportionality (\(a/b = c/d\)) that has its foundations in elementary school mathematical, fractions. A typical problem requires the student to solve for a single unknown value when given three numbers in a proportional relationship. An alternative approach to rate and proportionality is to emphasize its relationship to algebra by formulating problems as function-based (\(y=kx\)). A function-based approach requires students to find a multiplicative constant that maps a set of inputs to a set of outputs. To show that the intervention was successful, students in the treatment...
condition needed to (1) learn standard mathematics to the same degree or better than their peers and (2) learn mathematics beyond what is normally taught (Tatar, 2008). Pre and post-tests were developed to evaluate the students on standards for their grade level, as well as more advanced topics. To develop the pre and post-tests, the researchers used questions from the “TAKS”, or Texas standards exam, to evaluate requirement number one. The TAKS (Texas Assessment of Knowledge and Skills) mathematics exam for 7th grade focuses on formula-based questions. To test requirement number two, the researchers developed additional function-based questions on rate and proportionality.

Scaling-Up SimCalc Study Results

Year one of the study was completed with 95 teachers and 1621 students in 7th grade math classes throughout Texas. Students in the treatment condition had a higher mean difference score, or gain score, compared to their peers in the control condition, t(93)=9.1, p < .0001, e.s. 0.84, using a two-level hierarchical linear model with students nested within teachers. This indicates that students from the treatment group learned more, as measured by the test, than students in the control group (Tatar, 2008). Furthermore, students in the treatment condition did even better than students in the control condition on the complex, or function-based, portion of the test as opposed to the simple, standards-focused, formula-oriented portion (t(93)=10, p < .0001, e.s. 1.22) (Tatar, 2008).

The Meaning of the Experimental Findings

Based on these experimental findings, the Scaling Up SimCalc study was a great success. Especially when combined with replicated experimental findings, it suggests a clear causal association between SimCalc and student mathematics learning. However, data from the year one teacher phone interviews suggested that the relationships between the teachers, students, and SimCalc content were complex. The teachers’ did not seem to perceive the substantial learning gains taking place in their own classrooms; however, they expressed opinions on the SimCalc unit’s difficulty and their students’ abilities that may have serious implications for their future use of SimCalc resources.

Post-Unit Teacher Phone Interviews

Each teacher phone interview was scheduled within 10 days of his or her administration of the post-test. We used a semi-structured interview protocol, and the interviews always started with the questions “what went well?” and “what went poorly?” From that point the interview continued with questions divided into the following six topics: Teaching Experience, Mathematical Content, Technology, Students, Collaboration, Support, and Research. After each teacher response the interviewer would ask follow-up questions to gain further description from the teachers. There were also additional “wrap-up” questions at the end of the interview. In both years of the Scaling-Up SimCalc study we conducted phone interviews with every participating teacher, however, for the purpose of this report we will focus on interviews conducted during the first year of the study.

During the first year of the Scaling-Up SimCalc study we conducted 95 interviews in total, which amounted to 5163 minutes of audio data. 48 of those interviews were with delayed treatment (control) teachers, while the remaining 47 were with immediate treatment teachers. The corpus of interviews were transcribed and analyzed using a Grounded Theory perspective through an iterative coding process. The analysis resulted in codes such as teaching philosophy,
school environment, technology concerns, administration support, collegial support, and mathematic topics discussed. For the purpose of this report we are reflecting solely on the “mathematic topics discussed” code (or “Math Topics” for short), but a complete description of the codes and analysis can be found in Kurdziolek, 2007.

Teacher Discussion of Math Topics

During the interview, the teachers were asked to describe math topics that went well or were difficult for their students either while using the SimCalc materials (immediate treatment teachers) or using their usual curriculum on rate and proportionality (delayed treatment/control teachers). The responses to these questions were coded and categorized as “difficult” or “went well”. Also, while responding to these questions, the teachers would often characterize the math topic as either a “basic” skills that the teacher felt students should have mastered before this point in time, or as topics that were being “newly introduced” in the SimCalc unit or their usual curriculum on rate and proportionality. The following two quotes are examples of typical teacher responses to these questions:

- “Well, the kids got really confused when you had - when there was a graph where the scale wasn't by 1's. And so they are thinking, 'well, I'm moving up one' but really they are moving up 20 spaces because it is a scale of 20 and so that was really confusing. And then, trying to get them when they are drawing the triangles to, you know, go all the way on the line and where it's an intersection point - an easy to read point - because sometimes they would go over to the line on the graph and it wouldn't be an easy to read point and so their estimating and dividing the slope wouldn't, you know, come out right.”
  – Treatment teacher description of mathematical topics that were difficult

- “The graphing was great and it really - what's the word here - they've gone over it in science and stuff before but "slope?" They had never heard of it. They understood it. The constant - the constant speed - just that that was a straight line. That went well. They understood that no slope was an object standing at rest or, you know, not moving. So, that all went well. The graphing was great. The technology, you know - they wouldn't have gotten it as well as they did without the software and that went really well.”
  – Treatment teacher description of mathematical topics that went well

Figure 2. Number of teacher (treatment and control) comments on “basic” or “newly introduced” topics going well for their students (left) and being difficult for their students (right)

After all the year one, teacher phone interviews had undergone the coding process, we counted the number of teacher responses for the math topics that “went well” or “were difficult” and characterized by the teachers as “basic” or “newly introduced”. Teachers could have discussed multiple math topics throughout the course of the interviews, and each separate math topic discussed was included in the count. The maximum number of separate math topics discussed in any one interview was 12, and the minimum 2. The graphs above (Figure 4) show the results of this simple count between the treatment and control conditions. Overall, the teachers talked about more topics that went well than topics that were difficult. For both math topics that “went well” or “went difficult”, control teachers talked about more topics they described as “basic” than treatment teachers, and treatment teachers talked about more “newly introduced” topics than the control. This can be seen in Table 1.

**Table 1. Number of treatment and control teacher comments on basic or newly introduced math topics**

<table>
<thead>
<tr>
<th></th>
<th>Basic Topics</th>
<th>Newly Introduced topics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Treatment</td>
<td>36</td>
<td>268</td>
</tr>
<tr>
<td>Control</td>
<td>75</td>
<td>219</td>
</tr>
</tbody>
</table>

By running a chi-square analysis on this table we get the value of $\chi^2(1) = 18.47$ ($p < 0.001$), which means that treatment teachers routinely discussed more newly introduced topics than control teachers during the interviews, and that control teachers discussed more basic topics than treatment teachers. This result suggests that the SimCalc materials influenced the type of math topics treatment teachers discussed with us in the interviews, and presumably presented to their students as suggested by our experimental results. Also, since the treatment teachers did not discuss “basic” topics as much as control teachers, they presumably spent less time with their students on math topics that they would describe as basic while teaching the SimCalc unit.

**Teacher Discussion on SimCalc Unit Difficulty**

While the teachers were discussing the mathematical topics in their usual rate and proportionality unit or the SimCalc unit, they would often provide characterizations of the students’ capacities in their school/class, characterizations of the rate and proportionality unit’s difficulty level, and characterizations of their students’ ability in relation to the unit’s difficulty. In the case of the immediate treatment teachers, several (31 out of 47 – need to change these numbers) commented on how they and their students coped with using the SimCalc unit for the first time, and (24 out of 47) on how the SimCalc unit compared to their state-wide mathematics standards and assessment (TEKS/TAKS). Below are comments from four immediate treatment teachers on the SimCalc unit’s difficulty and their students’ abilities.

- “For my students, that’s just my opinion. I felt like it was a little difficult for them. Especially, not knowing - they’ve been so conditioned to choose these multiple choice questions that when they’re faced with something that shows them to think and to give an answer themselves, it was a little complicated. I would venture to say, if they were to have math maybe like this for maybe two years consecutively, you’d see a big change.”
- “I saw the whole unit as being pretty pre-algebra unit, not a pre pre-algebra unit. It struck me as a regular 8th grade, advanced 7th grade type curriculum, even towards the beginning part. And, I feel pretty good that we’re teaching aligned with what the Essential Knowledge and Skills are for the 7th grade, as far as 7th graders. But, I love
the stretch. I don't want to say I don't want to do that. It's just that I might do the more
required earlier because we've got to make sure their solid in all their standard skills
first.”

- “Yeah. Neither I nor my teammate, we didn't try this with any of our regular classes. And
she said, I wouldn't even try it with a regular class. Now, next year, I'm not going to
have 7th pre-AP, I'm going to have 6th pre-AP and 7th regular, so I'll be doing it with a
regular class but I will be doing it differently. To the extent that resource doesn't exist,
I'll be trying to think of a way - because if a regular kid misses a day of this - the most
likely ones to miss are the ones that are most likely to get a huge hole that they won't be
engaged and then they'll be totally off track.”

- “I would have liked to have been able to go more in depth with the graph as in slope and
things like that but I just did not feel like my students were ready for that yet. But, I wish
- my goal would be that they would be ready for that so then when they go into algebra,
or pre-algebra, they will have heard those terms before and understand what it means so
they can connect it all.”

The four teachers quoted above expressed that the SimCalc unit was a stretch for their
regular 7th grade students. In the first two quotes, we see that the teachers assessed the SimCalc
unit difficulty in relation to their students’ abilities and background, as well as their state
standards and assessments. In the case of the last two quotes, both teachers felt that the SimCalc
unit was more appropriate for advanced 7th grade or 8th grade students, and they may not use
SimCalc with regular 7th grade classrooms in the future.

Out of all the immediate treatment interviews, only one teacher described the SimCalc unit as
being more conceptually difficult than their usual unit on rate and proportionality and within the
realm of regular 7th grade students’ abilities.

“In 7th grade. Because they are doing those linear equations and you might as well. I
mean, you are doing unit rate - you might as well. So, it gave me a new experience as to
whether they had the ability to do slope or not and, although we didn't go over it a lot, you
know, I had to, you know, do one or two of the problems and then go on to the next thing. It
did let me see that they could/would be able to slope in 7th grade.”

While the teacher quoted above was teaching the SimCalc unit, (s)he realized that 7th grade
students had the ability to understand the concept of slope. Perhaps in the future this teacher will
present slope, a conceptually more difficult math topic, to his/her students even though slope is
not a topic on the annual 7th grade TAKS. Unfortunately, this teacher is an exception to the
general trend of comments on the SimCalc unit difficulty in the post-unit teacher interviews.
Overwhelmingly, when treatment teachers discussed the conceptual difficulty of the SimCalc
unit they also describe topics or parts of the unit they would not cover in the future.

Conclusions
The Scaling-Up SimCalc study provides a compelling example of an intervention being used
in a wide variety of classrooms with a high degree of success. After the first year of the Scaling-
Up SimCalc study, researchers obtained statistically significant results indicating that students in
the treatment condition had higher learning gains than their peers in control condition classrooms.
This could be seen as a treatment (SimCalc) having a direct effect on outcome measures (student
gains). However, this description of the intervention is deceptively simple. Students’ relationship

American Chapter of the International Group for the Psychology of Mathematics Education. Columbus, OH: The
Ohio State University.
to much of the material and content SimCalc provided is filtered through teachers, in the sense that teachers received the SimCalc materials and were ultimately the ones who decided how and when the students accessed those resources. As Eugene Judson (2006, p. 583) put it, “When establishing any classroom innovation, it is the teacher who is the key determinant of implementation.”

The SimCalc researchers who developed the replacement unit intended for the curriculum to be more advanced than the usual 7th grade curriculum and focus on function-based proportionality, yet still on par with an average 7th graders ability. While treatment teachers recognized and described the SimCalc unit as being more conceptually difficult than their usual curriculum, they did not perceive their students’ learning gains on both the “simple” and “complex” mathematics. This perception of the SimCalc unit certainly affects the potential use of SimCalc resources in the future, but more importantly, represents a challenge to be addressed in the future. How can we increase teacher awareness of student learning gains? This is an issue to be addressed if we hope to encourage the exploration of more conceptually difficult mathematics in K-12 education.

Teachers’ interactions with algebra content are shaped by varied and complex factors such as her/his knowledge and beliefs as well as by the representation of the algebra content. This study examines two separate groups of teachers who explained multiple algebra problems as requiring students to “translate from English to math”. Interviews revealed conflicting beliefs about whether the act of “translation” is mathematical. The teachers also expressed concerns that the wording of the problems was an obstacle to the mathematics. The findings broaden the discussion of how teachers’ beliefs about mathematics may impact their interactions with curricular materials.

Introduction

In its communication standard, the National Council of Teachers of Mathematics (NCTM, 2000) notes that “because mathematics is so often conveyed in symbols, oral and written communication about mathematical ideas is not always recognized as an important part of mathematics education” (p. 59). The preceding quote acknowledges a relationship between symbol use in mathematics and perceptions of what constitutes mathematics education. In the following pages, I will present research and perspectives which complexify teachers’ perceptions of the relationship between symbolic and verbal representations in mathematics. Specifically, I investigate groups of teachers’ categorizations of algebra problems as about “translating from English to math” and how their interpretations of this phrase may reflect particular views of mathematics.

The sites for the present study were two 3-day workshops (2006 and 2008) at a large university in the southwestern United States. The participants were teams of mathematicians, mathematics educators, and teachers from geographically diverse locations. The teachers were middle and high school teachers of algebra; the mathematicians and mathematics educators were university professors (See Table 1). A focal point of the workshop was a set of 12 algebra problems spanning content from pre-Algebra to Algebra II. The problems were compiled by the workshop organizer Chris Norris, a mathematician, and administered in the participating teachers’ classrooms. The problem set was the same for both workshops. Most of each workshop was devoted to discussing the workshop problems and analyzing student work. My data is primarily drawn from a particular task in which the workshop participants, within their professional groups, analyzed and categorized the 12 algebra problems. This categorization task required each professional group to negotiate and justify categories for the set of 12 problems; the instructions for the task were summed up by Norris in 2006 as “So what do you think is the sort of mathematical content of the problems and do they fall naturally into different groups?”

The results reported herein are from a larger study of these two workshops which investigated the ways in which the participants made sense of the workshop algebra problems. Herein, I focus on a surprising theme which emerged in these workshops; in both 2006 and 2008, the groups of teachers (which shared no common members) categorized a large portion of the workshop problems as being about translating from English to mathematics. In 2006, five out of the 12 problems were categorized as such and in 2008 six problems were categorized as such. For example, number eight (Figure 1) was categorized as being about “translating” by the teachers in both workshops. The questions which I investigate are: (1) How did the workshop participants interpret the phrase “translating from English to math”? and (2) What insight does this provide about participants’ interactions with the algebra problems?

To convert from miles to kilometers, Abby takes the number of miles, \( m \), doubles it, then subtracts 20% of the result. Renato first divides the number of miles by 5, and then multiplies the result by 8.

\begin{itemize}
  \item[a.] Write an algebraic expression for each method.
  \item[b.] Use your answer from part (a) to decide if the two methods give the same answer.
\end{itemize}

\textbf{Figure 1. Problem Number 8}

**Perspective**

My primary focus was on the problem categorization tasks at the workshops: I conceptualized this task as mathematicians, mathematics educators, and mathematics teachers interacting with the workshop algebra problems. As such, there are three overlapping categories of research which make up the theoretical framework: (1) research on the learning and teaching of school algebra, (2) research on interactions with curricula, and (3) research on the beliefs, knowledge, and dispositions of the three professional groups. The inclusion of research on school algebra in the theoretical framework provides structure in which to situate not just Norris' algebra problems but also the interpretations of and interactions with these problems by all participants in the workshop. Indeed, a view of school algebra was influencing the workshop participants' interactions with these problems.

Kieran (2007) describes the content of school algebra as ranging between reform-oriented and traditional. Reform-minded algebra often is characterized by an emphasis on functions, real-world problems, and a value on multiplicity of techniques (such as the use of technology). Included in this the view of algebra are the multiple ways of representing functions including graphical, tabular, and symbolic representations. A traditional view conceptualizes algebra as generalized arithmetic and often focuses on symbolic manipulations, recognition of forms, simplification of expressions, solving equations, and factoring polynomials. The traditional view puts an emphasis on letter-symbolic aspects of algebra, reformed algebra emphasizes a combination of mathematical representations.

Analysis of these interactions with the algebra problems is also framed by research on interactions with curricular materials in general (the workshop problems being considered curricular materials). The present study is, in part, framed by Remillard's (2005) description of curriculum use as a participatory relationship between teacher and curriculum. Her framework acknowledges that teachers construct their understanding of curricular materials yet are also influenced by these materials. Of particular interest are the characteristics of curriculum, including the more “subtle and often unintended” components, which affect the teacher-curriculum relationship.

There are surely many factors which influenced the interactions of the workshop participants with the problem set. These factors include the presentation and content of the problems. They also include less tangible characteristics of the workshop participants who are interpreting these problems. For this reason, the theoretical framework also includes research on these disciplinary groups' beliefs about and dispositions toward mathematics in general and algebra in particular. The few studies about mathematicians’ and mathematics educators’ beliefs about mathematics indicate a diversity of views (Mura, 1993, 1995; Burton, 1999).

Of the research on teachers’ beliefs, the work of Nathan and Koedinger (2000a, 2000b) is particularly relevant. They investigated how 67 secondary school mathematics teachers and 35 mathematics education researchers predicted student difficulties with a set of arithmetic and algebra problems. Most of the researchers and teachers predicted greater difficulty with word-problems and algebra than with symbolic problems and arithmetic thus endorsing a view which Nathan and Koedinger referred to as the Symbolic-Precedence Model; students' symbolic reasoning strictly precedes verbal problem solving and arithmetic skills precede algebraic skills. This view is similar to that commonly portrayed in textbooks. However, analysis of student problem-solving strategies on these problems indicated that a Verbal-Precedence Model prevailed; that is, “contrary to teachers' expectations, students experienced greater difficulties when solving symbolic-equation problems than when solving verbally presented problems” (p. 179). In the follow-up study, 107 K-12 teachers were asked to rank-order (by difficulty) the mathematics problems from the previous study and to complete a Likert-scale assessment about the teachers' beliefs. They found that, across grade levels, teachers’ responses tended to reflect reform-oriented views of math. Elementary teachers were the most likely to agree with reform-oriented views and high-school teachers were the least likely. Middle school teachers did best at ranking the difficulty of the problems (as measured by comparison to student responses) whereas teachers from other levels displayed a Symbolic-Precedence Model.

Methods

Data included audio and video recordings from the 2006 and 2008 workshops and observational data/field notes from the 2008 workshop. The recordings from the problem categorization tasks were transcribed and coded, as were other relevant parts of the workshop (e.g., Norris’ description of the categorization task). There were three rounds of coding based both on the theoretical framework and emergent themes.

Interviews lasting from 24 to 60 minutes were conducted with all but one participant in 2008 (other than Norris, no 2006 participants were interviewed). Each interview was transcribed and coded. The open-ended interviews included questions about participants’ understanding and use of the phrase “translating from English to math” within the workshop. In general, I collected multiple data sources and subjected them to methodical, iterative analyses while simultaneously documenting my reflections and decisions. After analysis was complete, I conducted member checks with three of the participants (one from each professional group).

Results

On one level, “translating” refers to converting from a verbal representation to a symbolic representation. However, I was intrigued by the communication of this idea through the phrase “translating between English and math”. Is there an idea of algebra or mathematics which might
be underlying the use of this phrase? What idea of algebra might be inspired in a student who hears this phrase? Is the act of translating, itself, a part of mathematics?

**Figure 2. Problem Number 5**

The following dialog from the teachers' 2008 categorization activity is exemplary of the way in which they spoke about “translating.” Judith Hardy (a middle school teacher) and Nadya King (a high school teacher) are referencing problem number five (Figure 2) which both the 2006 and the 2008 groups of teachers categorized as “translating.”

Judith: And I think it goes back to what you were saying about converting the language of English to the language of math too. That you have to have, I think, a pretty decent grasp of English and then be able to convert that.

Nadya: Yeah, because we were portraying equivalent expressions again. But before we can even get to that comparison we have to dig through all those words.

In the group discussions in both 2006 and 2008, the phrase “translating from English to math” was picked up upon and used by members of all disciplinary groups. During the problem categorization tasks in 2006, the mathematicians brought up translating twice (numbers 5 and 8) and the mathematics educators mentioned this sort of “translating” once (number 7). The phrase itself was never explicitly discussed during the workshop. However, in 2008, I asked about “translating from English to mathematics” in the interviews. The mathematicians all agreed that the phrase is potentially misleading since they believed that this sort of translation is in itself a mathematical activity. The responses amongst the teachers were a bit more mixed (no mathematics educators were interviewed).

Keith Young (high school teacher, 2008) spoke about translation in a way that perhaps evoked an image of a boundary between mathematics and English where the mathematical activity happens on just one side of the boundary.

Interviewer: But you could argue that the math is doing that translation. It's not like it becomes [math] as a process of it, but the math is the process.

Keith: Mmmm, you see I understand what you're saying there but the main reason for doing that translation is so you can easily do the mathematical manipulations that you need to do. But then once you've manipulated it, whatever form you've manipulated it in, you've got to be able to take that and put it back… into English terms.
Greg Davis (high school teacher, 2008), after a similar prompt, more explicitly expressed a sentiment that the mathematics begins after the verbal representation has been translated: “I see what you're saying but I don't think necessarily mathematics is being able to translate, I think a skill you need in order to do mathematics well is to be able to translate.”

The phrase “translating between English and math” may indicate a range of underlying views of mathematics. Users of this phrase may think that the mathematical activities begin after the translating has been completed or may feel that the translation is a mathematical activity. The mathematicians in 2008 all agreed with the latter analysis though the 2008 group of teachers expressed more varied opinions.

The Wording of the Problems

In Remillard's (2005) conceptualization of the participatory relationship between teacher and curricular materials she highlights the roles of both the teacher and the curricular materials. The preceding discussion suggests that teachers’ beliefs about “where the mathematics begins” may have influenced their interpretations of the problems. But, conversely, the interactions between the workshop participants and the set of 12 algebra problems were also influenced by the problems themselves.

During the 2006 problem categorization task, the teachers described the wording as problematic for their students on seven out of the 11 problems which they discussed for more than one minute. The group of teachers in 2008 discussed the wording on 10 of the 12 problems as a source of difficulty for students. There were a variety of reasons cited when the wording was criticized. For example, Ursa Harper (MS teacher, 2006) spoke about unfamiliar wording as an obstacle on number 9 (Figure 3):

And I didn't like exactly the way D [the correct answer] was worded: “The number of people of people who decide not to go if the price is raised by a dollar.” And I teach them it's the “change per” and the word “per” wasn't in there.

The wording of problems with regard to symbol use was also seen as an obstacle at times. For example, several teachers perceived the symbols “$p$” ($p$ dollars) in number 9 to be confusing for their students. Other problems presented difficulty because of their structure. For example, on number 5 (Figure 2), teachers from both workshops referenced students interpreting “In [parts] (a)-(c)” as “variable a minus variable c”.

If the tickets for a concert cost $p$ each, the number of people who will attend is $2500 - 80p$. Which of the following best describes the meaning of the 80 in this expression?

A. The price of an individual ticket.
B. The slope of the graph of attendance against ticket price.
C. The price at which no-one will go to the concert.
D. The number of people who will decide not to go if the price is raised by one dollar.

Explain how you chose your answer.

Figure 3. Problem Number 9
During the teachers’ categorization task in 2006, Tom Luft (middle school teacher) summed up some of the teachers’ concerns:

I think that could be a general comment overall. I thought the directions on several problems the kids are like, “What am I supposed to do on this thing?” And, you know, and I would clarify the directions because we wanted to get, we wanted to get data on the problems not on their ability to interpret the directions on the problems.

But to what extent does “clarifying” the problem change the problem? Luft’s quote seems to imply that changing the wording of a problem does not change the problem.

Discussion

Throughout the workshops I observed interactions which served to complexify the relationship between the written and the understood. It was the wording of the problems which was often cited, especially amongst the teachers, as a source of confusion and difficulty for the students. In parallel to this, the teachers from both workshops categorized about half of the problems as being about “translating from English to Math”. At times, the remaining computational tasks (after the “translation”) were described as “doing the math”.

As discovered in the 2008 interviews, there were two prominent ways to conceptualize the act of “translating”: (1) it is what a student needs to do in order to get to the mathematics (i.e., the translation is not mathematics), or (2) it is, in itself, a mathematical activity. The second of these perspectives was endorsed by all of the mathematicians yet there was variation within the group of teachers. Cutting across these two perspectives is the student activity of converting from a verbal representation to a symbolic representation; the difference is in how this activity relates to and fits in with ideas about mathematics. As Kieran (2007) reported, a focus on multiple mathematical representations is associated with a reformed view of algebra and the representation itself can serve as a source of meaning for an algebra problem.

The wording of the workshop problems was, at times, described as an obstacle to students' success. Indeed, this perception is consistent with Nathan and Koedinger's (2000b) finding that (7th through 12th grade) teachers and mathematics educators perceived verbally presented problems to be more difficult than symbolically presented problems. Perhaps their description of this “symbolic-precedence” is related to a particular view of mathematics or of algebra. Within the workshops, one manifestation of the criticism of the problems' wording was Tom Luft's (Middle School teacher 2006) clarification of the problems for his students. Luft was perhaps communicating an opinion that the wording of a problem is largely separate from the mathematics of the problem. This may correspond to the view that mathematics begins after the translation from English.

Certainly, a student who solves the “clarified” problem has engaged in a different task than a student who solves the originally-worded problem. The question, however, is whether or not the student has engaged in a different mathematical task. The answer is perhaps, among other things, dependent on an individual's view of mathematics. If the wording of a problem is an obstacle then, for some, the problem may be about the wording; that is, the problem may be about “translating from English to math”.

It is possible that the teachers’ concerns about the wording of the workshop problems were, at least in part, byproducts of the unusual circumstances through which the workshop problems were introduced to their classrooms. For example, the problem set was distributed to teachers

with no specific instructions for implementation; they were free to do what they pleased with the
problems. So Tom Luft’s “clarification” of the problems may not have reflected a particular view
of algebra. Rather, it may have been nothing more than a practical means through which to
produce materials for the workshop; he may or may not have believed that he was changing the
mathematics of the problems by clarifying them. Nonetheless, the interviews with teachers from
2008 (Luft was in the 2006 group which was not interviewed) did reveal varying opinions about
the relationship of “translating” to mathematics.

But if we accept the view that “translating” is a part of doing mathematics, then any sort of
clarification (regardless of the motivation) needs to be done with care. Hiebert and Grouws
(2007), in their survey of literature on teaching for conceptual understanding, cited as a key
feature “the engagement of students in struggling or wrestling with important mathematical
concepts” (p. 387). Is “translating from English to math” an “important mathematical concept”
with which students should be allowed to struggle?

The phrase “translating from English to math” may, in itself, communicate a viewpoint that
mathematics begins after the translation is complete. During the workshop teachers'
presentations about their students' work on the problems, there were instances where the
workshop participants would look at a student's work and say something like, “This student
understood the mathematics but just couldn't put it in writing.” For example, during the teachers'
presentations in 2006, Tom Luft commented: “I have those kids that know how to do stuff but
they can't explain it. They're not verbal and they're not linguistic but they are so mathematical,
they can just do stuff.” Is this a description of students' difficulties “translating from math to
English”? Regardless of the view of mathematics held by a teacher, mathematician, or
mathematics educator who says phrases such as “translating from English to math” or “the
student understood the mathematics but couldn't write it”, these phrases may imply a divide
between the written and the understood in mathematics, between the wording of a problem (as
not being mathematics) and the computations required by the problem (as mathematics).

But what is the appropriate way to discuss “translating”? Is it a skill or ability which is
subsumed by the concept of transformational fluency? Is it a component of mathematical
knowledge that needs to be labeled and made explicit? If we accept the view that “translation” is
a part of algebra and mathematics, then what is an appropriate way to describe a students' ability
to take a mathematical approach to a verbally described situation? If a teacher holds a view that
mathematics does not include “translating” then how does that affect her/his pedagogical
decisions? For instance, how do teachers working with English language learners make use of
English word problems? And do the decisions they make reflect or endorse the particular views
of mathematics just described? As Drouhard (2004) noted, “the way you teach algebra depends
dramatically on what you believe algebra is; therefore this question is worth addressing” (p. 44).

At the very least, the present research has shown that the use of the phrase “translating
between English and math” can correspond to varying views about which parts of a word
problem are mathematical. Furthermore, the wording of a problem may be perceived as an
obstacle to student engagement with mathematics rather than as a part of the mathematics.
However, it would be useful to unpack and to characterize the ways in which wording may
present obstacles. For instance, if a problem is difficult because the wording is unfamiliar then
that has different consequences than if the wording is plainly inaccurate. Indeed, interpreting
problems which use unfamiliar wording or symbols is an activity which many students are often
required to do on standardized assessments. The ability to flexibly translate from verbal to
symbolic representations may be undermined if students are not given opportunity to

---

Ohio State University.
constructively struggle with unfamiliar wording or if they have a view of mathematics which does not include “translation” as mathematical skill or knowledge.

Beliefs represent a determinant of behavior and a cluster of relationships among systems of beliefs (Green, 1971). Teachers’ beliefs about the teaching and learning of mathematics significantly influence not only how the subject is taught but also how students are expected to learn (Leder, Pehkonen, & Törner, 2002). As a result, it is imperative that researchers examine the extent to which beliefs influence the process of teaching and the product of learning within classrooms (Philipp, 2007). Therefore, we present correlations between teachers’ beliefs, background characteristics, and dimensions of curriculum implementation.

We collected data from 151 mathematics teachers who participated in the Comparing Options in Secondary Mathematics: Investigating Curriculum (COSMIC) project, a 3-year quasi-experimental longitudinal study of the impact of two types of curriculum on student learning, a subject-specific approach (Algebra 1, Geometry, Algebra 2, Pre-Calculus) and an integrated approach (Integrated 1, Integrated 2, Integrated 3). The participating teachers completed an Initial Teacher Survey (ITS) to provide information on background characteristics and beliefs about the teaching and learning of mathematics. Additionally, we conducted 326 classroom observations, generated opportunity-to-learn indices, and documented teachers’ fidelity of implementation. We analyzed data using factor analysis, a comparison of group means, and bivariate correlations. Findings suggest that teachers’ beliefs clustered around three factors: reform practices, didactic approaches, and self-efficacy (Tarr et. al, 2010). Furthermore, reform practices correlated positively with the classroom learning environment, technology use, and teachers’ alignment with NCTM Standards. Alternatively, the belief factor, didactic approaches, was negatively associated with attributes that correlated positively with reform practices. Self-efficacy correlated negatively with teaching experience. None of the beliefs were significantly correlated with fidelity of implementation and opportunity-to-learn indices.

In this article, we claim that reducing certain problems to consideration of the sample space, which consists of equiprobable outcomes, may not be in accord with learners’ initial ways of reasoning. We suggest a “desirable pedagogical approach” in which solving the problem builds on the set of outcomes identified by learners and acts as a bridge towards mathematical convention. Through detailing prospective high school mathematics teachers’ engagement with a famous probabilistic problem, which they had not encountered previously, we discuss the participants’ mathematical solutions and demonstrate the convincing power of the suggested pedagogical approach.

Introduction

The purpose of this article, in general, is to contribute to research on the probabilistic knowledge of teachers. According to Jones, Langrall, and Mooney (2007), with respect to probability, “research on teachers’ mathematical content knowledge, pedagogical content knowledge, and knowledge of student learning [i.e., probabilistic knowledge] is limited” (p. 933). Specifically, our intent is to inform future developments associated with teaching and successful student learning about the sample space.

In order to start our discussion, consider the following problem: In a family of three children, what is the probability that there are two boys and a girl? Individuals well versed in probability, or experienced readers, will determine that the probability is 3/8. However, many novice learners, including prospective elementary school teachers, claim initially that this probability is 1/4, considering that ‘two boys and a girl’ is one out of four possible options (the other three being all boys, all girls, two girls and a boy). Claiming that the sought probability is 1/4 is quite common and similar examples (e.g., Speiser & Walter, 1998) are found throughout probability education literature.

Literature Review

Although there is an abundance of sample space literature found in mathematics education (e.g., Fischbein, 1975; Green, 1983; Nilsson, 2009), there are “conflicting results in this research” (Jones et al., 2007, p. 920). Despite the conflicting results, sample space research is categorized into different domains, which, in a broad sense, include sample space generation, incomplete generation leading to multiple sample spaces, and the assignment of probabilities based on sample space.

The majority of existing sample space research is focused on the generation of outcomes of the sample space and these studies indicate that students have difficulty in determining all possible outcomes that could occur in a variety of tasks and situations. Researchers use combinatorics (e.g., English, 2005), symmetry (e.g., Borovcnik & Bentz, 1991), and levels (e.g., Jones, Langrall, Thornton & Mogill, 1997) to account for students’ abilities or inabilities to list the set of all possible outcomes, i.e., the sample space. Building upon the notion of incomplete generation of the sample space, certain researchers discuss the existence of more than one sample space for particular students. For example, “to justify the probabilities for the outcomes

of dice games, learners construct informal sample spaces” (Speiser & Walter, 1998, p. 61). The inferred structure of these informal or personal sample spaces has been used to demonstrate particular anomalies found in probability education research. Speiser & Walter demonstrated that certain individuals found, for example, the outcome (4,5) for the experiment of rolling two identical dice to be indistinguishable from the outcome (5,4). The researchers extrapolated the lack of discernment between pairs to all of outcomes (e.g., (3,4) and (4,3)). Consequently, the researchers hypothesized and subsequently concluded that the sample space employed by certain individuals answering their question consisted of 21 possible outcomes and not 36 outcomes, because individuals treated the outcomes (4,5) and (5,4) as one outcome. Alternatively stated, the inability to generate all possible outcomes of the sample space led to multiple sample spaces and, consequently, to various probabilities.

“Although the concept of sample space appears to be a relatively straightforward aspect of the mathematics of random phenomena, it is more subtle and elusive than it appears” (Jones, Langrall, & Mooney, 2007, p. 920). In line with the aforementioned statement, and recognizing the lack of research on teachers’ probabilistic knowledge related to the sample space presented earlier, we draw upon a famous probabilistic task as our medium for investigation. To aid our investigation and in an attempt to synthesize and rectify conflicts in sample space research, we first introduce our theoretical constructs.

**Theoretical Constructs**

In this section we introduce a working definition for two constructs: the sample set and a desirable pedagogical approach. We start by providing a rationale for our notion of ‘sample set’, which is based, in part, upon lack of common terminology used in sample space research and our analysis of the possible ways for listing outcomes.

**The Sample Set**

While the notion of sample space plays a critical role in many probabilistic considerations, it has been described in literature (e.g., Konold, 1989) that individuals’ ideas of sample space may be inconsistent with normative mathematical understanding. As presented in the previous section, researchers use different expressions to refer to unconventional sample space descriptions identified by students; for example, they refer to informal sample spaces, or multiple sample spaces. The lack of common terminology to describe student-generated lists of outcomes – that are not in accord with the conventional sample space – can be confusing. Further, research does little to distinguish between an erroneous or incomplete listing of outcomes from an unconventional listing. To overcome this confusion we introduce the notion of a sample set (to be defined below), and in what follows we provide further motivation for this construct.

Determining the probability that two heads and a tail result from three flips of a fair coin – a task isomorphic to the one presented in our prelude – requires listing the set of all the possible outcomes, i.e., the sample space. However, as Chernoff (2009) demonstrated, subtleties associated with what is meant by the term “outcome” (i.e., an element of the sample space) can lead to more than one sample space listing for a particular experiment. For example, one potential listing of the set of all possible outcomes is: 3 heads and 0 tails (i.e., HHH), 2 heads and 1 tail (i.e., HHT, HTH, THH), 1 head and 2 tails (i.e., TTH, THT, HTT), and 0 heads and 3 tails (i.e., TTT). As such, we define a sample set as any set of all possible outcomes, where the elements of this set do not need to be equiprobable. In other words, \{3 heads and 0 tails, 2 heads and 1 tail, 1 head and 2 tails, 0 heads and 3 tails\} is a sample set for three flips of a coin because
all possible outcomes are listed as a set, but the outcomes are not equiprobable. For this example, the outcome *2 heads and 1 tail* (i.e., HHT, HTH, THH) is three times as likely as the outcome *3 heads and 0 tails* (i.e., HHH). In general, a sample set is a set of all possible outcomes, that is to say the sample space, which is not listed in conventional form.

**Desirable Pedagogical Approach**

We consider a *desirable pedagogical approach* (for the purposes of this discussion) as one that uses the learner’s ideas as a starting point. From this point, where possible, building on initial ideas can develop conventional mathematical solutions. We consider this approach more desirable than attempting to impose mathematical convention, while ignoring the learner’s (initial) interpretation. This approach is in accord with ample research in mathematics education that advocates for building on students’ knowledge (e.g., Mack, 1990).

Our claim, in this instance, is that consideration of equiprobable outcomes, while correct mathematically and foundational to the theory of probability, may not be a desirable pedagogical choice in certain situations. We contend, consideration of the alternative descriptions of the sample space, that is the sample set, made by students is a desirable initial idea to embrace. Our research is seeking pedagogy that, without compromising mathematical rigor, acknowledges the learner and serves as a bridge between personal (sometimes naïve) and conventional knowledge.

**Task & Participants**

Participants in our study were 30 prospective high school mathematics teachers enrolled in a problem-solving course. This course is a “companion” to the traditional methods course for teaching high school mathematics, and is usually taken in the last semester of studies before teaching certification. In this course the students are expected to enhance their personal problem solving skills through a variety of problem solving experiences and to examine pedagogical approaches for making problem solving an integral part of their future classrooms. The research we present here is based upon responses to a probability task and the classroom discussions that followed the task.

The “classical” problem described in this section, known as the Problem of Points, has developed into many variations and is presented in a number of sources (e.g., Davis & Hersh, 1986; Devlin, 2008) as the problem that started the development of the field of probability. In several particular instantiations of this problem, the two players are named Pascal and Fermat. While it is unlikely that these prominent mathematicians entertained themselves in this way, we use their characters to exemplify and honour the problem.

Pascal and Fermat play a game that involves flipping a coin. If the coin comes up Heads, Fermat gets a point. If it comes up Tails, Pascal gets a point. A stake of 100 francs is put up and the first player to get 10 points wins the whole stake. However, the game is interrupted (with no possibility to resume and finish) when Fermat has 8 points and Pascal has 7. How should the 100 francs be divided?

**Results & Analysis**

Responses from the 30 individuals who completed the Problem of Points fell into five different categories, which are presented below according to how participants divvied up the 100 francs between Pascal and Fermat.
Solution 1: 50 to 50, or 100 to 0

Three participants chose to either split the stakes between Pascal and Fermat each getting 50 francs or give the leading player all 100 of the francs.

Olivia: Fermat is in the lead and the game is over so according to most sporting events, if the game is 50% complete then the winner is whoever is in the lead.

Peter: Although it would seem that probability should influence the answer, given the limited number of trials, really anything can happen. This means that there is really no sure winner. Hence it should be all or nothing to the winner. In this case, there is no winner, hence the money should be divided equally.

Two individuals (one of which was Olivia) decided to give all the francs to the leading player because, as they mentioned, one cannot predict the future and, as such, the game is, in essence, over once it is interrupted. In a similar fashion Peter, who decided to split the francs evenly, also made reference to the unpredictability of the future. However, given this unpredictability, and because of the slim lead in the game, the francs according to Peter should split evenly between the two players, as there is no certain winner.

Solution 2: $\frac{46}{3}$ to $\frac{53}{3}$

Unlike the focus on the future in the previous section, a large number of individuals, 9 in total, decided to split the pot between Pascal and Fermat based on events that had occurred, i.e., the past.

Quince: So far there have been 15 coin flips and Pascal has won 7 of 15 and Fermat won 8 of 15...The remaining flips are chance. Therefore, their outcomes are unknown. The division is based on flips already won.

In a simple and straightforward arithmetic calculation presented for this solution, Fermat has obtained 8 wins and Pascal 7, bringing the total number of wins to 15. For Fermat, he has achieved 8 of the 15 possible wins, which is $\frac{53}{3}$%; therefore, he deserves $\frac{53}{3}$ of the 100 total francs. Similarly, Pascal has achieved 7 out of a possible 15 wins, which is $\frac{46}{3}$%; therefore, he deserved $\frac{46}{3}$ of the 100 total francs.

Solution 3: 47.50 to 52.50

Three individuals, in their responses, combined elements of the first two responses presented above.

Robert: Fermat had 80% of the required wins (goal was 10) and Pascal had 70% of the required wins (goal was 10). So, Fermat gets 80% of 1/2 the pot, Pascal gets 70% of 1/2 the pot and of the 25 left, they each get half.
Those who decided to split the pot 47.50 to 52.50 argued that Fermat had achieved 8 out of the 10 required wins and, thus, deserved 80% of half of the pot, or 40 francs. Similarly for Pascal, who had achieved 7 out of the 10 required and, thus, deserved 70% of half of the pot, or 35 francs. This approach is similar to the $46 \frac{2}{3}$ to $53 \frac{1}{3}$ solution above; however, when adding the numbers together, the total only comes to 75 francs. Given there are 25 francs remaining, it was subsequently determined that the remaining 25 francs should be split evenly between the two individuals – which has similar elements to the 50-50 solution presented above – so that they each receive an extra 12.50 francs, bringing to the totals to 47.50 and 52.50 francs each.

Solution 4: 60 to 40

In an attempt to cope with the unpredictability of the future, the majority of individuals, 11 in total, decided to divide the francs in a 60 to 40 split. Sonya’s answer, presented below, accurately represents the approach for 9 of the 11 individuals who answered with a 60 to 40 split.

Sonya: Because Fermat has 6 possibilities and Pascal only has 4 possibilities to win so it should be divided 60% to 40% and therefore Pascal should get 40 francs and Fermat should get 60 francs.

Given Fermat had eight wins, he only required two more wins in order to achieve his goal of ten wins. Similarly for Pascal: with seven wins under his belt, Pascal only required three wins to achieve his goal of ten wins. At this point, many individuals demonstrated the same approach; they listed all of the possible ways that Pascal could obtain three heads and all of the possible ways that Fermat could achieved two heads. Each participant found four possible ways that Pascal could win (i.e., TTT, THTT, TTHT, and HTTT) and six possible ways that Fermat could win (i.e., HH, HTH, THH, TTHH, THTH, and HTTH). As such, Fermat would have 6 possibilities to win, Pascal would have 4 possibilities to win and, therefore, the pot should be split 60 francs to 40 francs. As mentioned above, this was the most frequent solution.

Interestingly, two of the 11 individuals who responded with a 60 to 40 split arrived at their answer in a different fashion than discussed above.

Ursula: Pascal has two ways to win: 10-8 or 10-9. Fermat has three ways to win: 7-10 or 8-10 or 9-10. Since there are 5 ways to win Pascal should get 2/5 of the pot and Fermat should get 3/5 of the pot.

Timothy: Because Fermat had one more point than Pascal, Fermat should take 60 francs and Pascal should take 40.

While Ursula’s division of the francs is the same as the other 9 individuals who responded with a 60 to 40 split, her reasons for the 60 to 40 split are quite different. Ursula’s 3 to 2 ratio happens to be an equivalent ratio for the possibilities of Pascal and Fermat winning in the other nine individuals’ responses. Timothy’s reasoning was not elaborated upon further and remains unclear to us; however, we suspect that the “one more point than Pascal” changes the split in francs from 50:50 to 60:40.
Solution 5: 31.25 to 68.75

Only responses from 4 out of 30 participants (approximately 13%) were in accord with the conventionally correct probabilistic solution. Amongst the correct responses, all four individuals utilized a similar tree diagram to answer the task. In utilizing a tree diagram, all four individuals’ calculations were similar in fashion, as represented with Vincent’s response below:

As shown with the recreation of the tree diagram in Figure 1, the solution considered the game in progress and the branch terminates when there is a winner. The 10 endpoints correspond to the 10 options identified below. However, the probabilities assigned to each option are different. The total chances of Fermat (Heads) winning is given by $1/4 + 1/8 + 1/16 + 1/8 + 1/16 + 1/16) = 11/16$, attending to the black endpoints (seen in the tree diagram). Similarly, the chances of Pascal (Tails) winning are given by $1/16 + 1/16 + 1/16 + 1/8 = 5/16$, attending to the white endpoints (also seen in the tree diagram).

![Figure 1. Tree diagram utilized in correct responses](image)

We note that this solution is similar to the one presented in previous section (see, for example, Sonya’s excerpt) in identifying 10 possible outcomes. However, the crucial difference is that that Sonya and others mistakenly considered the 10 outcomes as equiprobable, while Vincent and others assigned appropriate probabilities to each of the outcomes. It may be the case that mathematical symmetry (and along with it the solution’s simplicity) is lost by considering outcomes that are not equiprobable, i.e., considering the sample set. However, what is gained, and what we intended to discuss with the group, is the principle of starting with learners’ ideas and developing from those ideas, rather than rejecting them and imposing a different frame of thought.

Discussion

We started our debrief the next class by presenting all 5 possible solutions and asked participants whether they wanted to abandon their solution and accept a different one. Most participants who initially presented Solutions 1, 2 or 3 switched their preference towards Solution 4, finding it “more reasonable” and “more probabilistic”. Participants who initially suggested Solutions 4 or 5 appeared to keep their initial preferences.
Ignoring the notion that the players would normally stop once the game is finished is, arguably, counterintuitive, yet concurrently a key component to detailing the conventional sample space for the Problem of Points. Presenting, or trying to elicit from the participants, the approach of listing all \((2^4=)\ 16\) outcomes resulted in considerable resentment. Participants’ solutions were based upon the game stopping once somebody had won. Even though four flips would assure that the game ends, in most cases four flips were not necessary; the game can end within two or three steps. Consequently, our listing all approach was deemed not only as inconsistent with “common sense,” but also inconsistent with the rules of the game. The students insisted that the game must stop once there is a winner and suggested a different set of possible scenarios. They insisted that the listing of possible outcomes should stop once there are two heads or three tails on the list. This consideration results in the ten options, where Fermat (Heads) is the winner for six options and Pascal (Tails) is the winner for four options as seen in Solution 4, and not the 16 outcomes we had presented.

With us using 16 outcomes for the Problem of Points and the participants using 10, we implemented what we consider a desirable pedagogical approach. To begin, we focused our attention on the 60 to 40 responses to the Problem of Points. The 10 possible ways that the game could finish – the four possible ways that Pascal could win (i.e., TTT, THTT, TTHT, and HTTT) and six possible ways that Fermat could win (i.e., HH, HHTH, THH, TTHH, THTH, and HTTH) – were presented on the board. Next we employed an alternative representation of the tree diagram that certain individuals had used in their correct responses to the Problem of Points. We connected the diagram, similar to that on Figure 1, to the 10 outcomes listed by participants, as shown in Figure 2.

![Figure 2. Placing 10 outcomes on a tree diagram](image)

At first, drawing the tree diagram did not help. After all, the 10 outcomes featured in the 60 to 40 decision remained listed, but in a different visual representation. The time came for us as a group to focus on whether or not each of the 10 outcomes was equally likely. As such, participants’ attention was drawn to the “length” of each of the branches, which indicated that all 10 of the outcomes presented were not equally likely. Resultantly, the appropriate probabilities of each branch were easily calculated, which led to the conventional solution. Having dealt with the correct mathematical solution to the Problem of Points, the conversation shifted back to the 10 outcomes that were still listed on the board. Having recognized that the 10 outcomes were not equally likely, it soon became apparent what they represented: the sample set. As such, the student-generated sample set was employed to bridge the participants’ answers from the 60 to 40, where equiprobability was incorrectly assumed, to the 31.25 to 68.75 response in which

---

different correct probabilities of each scenario are acknowledged. Accompanying our discussion with the participants of, what we now call, the sample set were conversations about the treatment of the sample set, from both a pedagogical and mathematical perspective, as either correct or incorrect.

Conclusion

There is no denying the probabilistic and historical significance of the Problem of Points, in paving the path of the development of theoretical probability; however, we have also demonstrated its pedagogical significance, in having a considerable number of prospective teachers to “fall into the pit” of popular mistakes and assisting them on their way out. It is a common experience of those working in teacher education that guiding prospective teachers through experiences similar to those of their future students enhances both their mathematical understanding and their pedagogical sensitivity. However, in assuming that teachers’ knowledge of the subject matter significantly extends beyond that of their students, such experiences may be not easily designed. We attempted to provide such an experience with the probabilistic task and the notion of sample space, being aware that “teachers may make pedagogical decisions based on their own understanding of the task rather than their students’ current understandings” (Stohl, 2005, p. 358). Further, we have presented and detailed particular constructs to aid in our contention that probabilistic reasoning is not detached from subjective considerations. Instruction often asks students to abandon initial/naïve ideas and buy into conventional ones. We suggest that, where possible, learner’s naïve incomplete or erroneous ideas can be adjusted and bridged towards the correct conventional ones, rather than rejected and abandoned. Our assessment as well as reaction of prospective teachers experiencing this approach is very positive. As Stohl (2005) contends, “teachers must develop their own understanding of the complexities of probability concepts” (p. 362). Alternatively stated, “what is good for the geese is good for the gander.” However, further research will determine to what degree our constructs will be beneficial for the learning and understanding of probability.

Twenty-four seventh-grade teachers participating in a research project focused on formative assessment in a networked classroom were given pre-and post-assessments of content knowledge for teaching. This paper examines several interesting differences in content knowledge for teaching between and among the two groups and suggests possible links between the differences and the content of the two models of professional development in which the participants were engaged.

Background

This paper reports on a three-year research project funded by the National Science Foundation that is investigating feasible models of implementing formative assessment in mathematics classrooms using networked technology. Although proven to be effective, formative assessment has been challenging for teachers to implement in their classrooms (Ruiz-Primo & Furtak, 2006; Shavelson, R. J., Yin, Y., Furtak, E. M., Ruiz-Primo, M. A., Ayala, C. C., Young, D. B., et al., 2006; Yin, 2005). Similarly, using technology to implement formative assessment practices has also been a challenge for teachers (Owens, Pape, Irving, Sanalan, Boscardin, & Abrahamson, 2008). There are different points of view regarding how to assist teachers in developing facility in implementing formative assessment strategies using networked technology, and our group’s research was designed to compare the efficacy of training in both formative assessment and technology simultaneously with training in formative assessment strategies prior to implementing networked technologies. The project was designed to examine differences resulting from two different professional development models over a two-year period of time. Input from the eight Advisory Board members along with numerous articles on professional development, formative assessment, technology and related topics (Ayala & Brandon, 2008; Black & Wiliam, 1998a; Black & Wiliam, 1998b; Black & Wiliam, 2005a; Black & Wiliam, 2005b; Gearhart, & Saxe, 2004; Guskey, 2007/2008; Stiggins, 2002, 1997; Stiggins, Arter, Cahappuis and Chappuis, 2004; Wiliam, Lee, Harrison, & Black, 2004; Wiliam. 1999) were taken into consideration. A thorough discussion of the design considerations for formative assessment and technology in a networked classroom is discussed elsewhere (Olson, Im, Slovin, Olson, Gilbert, Brandon, Yin, 2010). The research reported in this paper reflects data on teacher content knowledge for teaching collected during the first year of participant involvement.

Methodology

Thirty-two teachers were assigned to two groups, which for purposes of this paper will be referred to as FA and NAV. During the first summer of the project, teachers in FA participated in
five days of professional development on the use of classroom formative assessment. During the same time, teachers assigned to NAV participated in professional development on the use of classroom formative assessment using the TI-Navigator™ networked classroom system\(^2\). Project facilitators planned the agendas together with the goal of providing as similar an experience with strategies for formative assessment as possible. In all cases where practicable, the same or very similar mathematics tasks were included. The formative assessment professional development in both groups was based on the same framework. Targeted content (i.e., mathematics content addressing several Hawaii content standards) that teachers were expected to teach during the third quarter of the school year was selected as a focus.

**Formative Assessment**

The formative assessment portion of the professional development was based on the Stiggins (1997) model and also drew from the Ayala & Brandon (2008) emphasis on the ongoing communication aimed at understanding student thinking (and misunderstandings) within the process. Throughout, the project staff emphasized the interplay between teacher and student as the centerpiece of the construct. Figure 1 lists the seven strategies of the Stiggins model for formative assessment. A teacher’s ability to effectively implement formative assessment requires facilitating the shift in student’s initial understanding towards where she needs to be. The aspect of formative assessment where teachers focus on how students are understanding (or misunderstanding) relies on the teacher’s knowledge of the mathematics used in teaching, and led us to the examination of teacher content knowledge reported in this paper.

**Where am I going?**

1. Provide a clear and understandable vision of the learning target.
2. Use examples and models of strong and weak work.

**Where am I now?**

3. Offer regular descriptive feedback.
4. Teach students to self-assess and set goals.

**How can I close the gap?**

5. Design lessons to focus on one aspect of quality at a time.
6. Teach students focused revision.
7. Engage students in self-reflection, and let them keep track of and share their learning.

![Figure 1. Seven Strategies of Assessment for Learning](image)

**Teacher content knowledge**

It is widely established that teachers need to possess a deep and fundamental understanding of the mathematics they teach. For example, when teachers differentiate problems (responding to individual variance) to challenge and/or provide additional scaffolds for students, they use their mathematical understanding to: (1) listen to students’ explanations of unconventional solution strategies to determine whether or not they are likely to lead to generalizable approaches, (2) press student thinking through appropriate questioning, and (3) create or select formative and summative assessment problems that are mathematically similar to the work done in class.
Studies in classrooms have found that improving teachers’ mathematical knowledge for teaching significantly affects students’ learning of mathematics (e.g. Hill, Rowan, & Ball, 2005). While teachers’ undergraduate mathematics courses support their learning up to a point, Monk (1994) found that beyond five mathematics courses, the number of mathematics courses teachers had taken less significantly affected students’ learning. In fact, Adler and Davis (2006) suggest that advanced courses may encourage teachers’ compression and abbreviation of mathematical knowledge. This is problematic, since unpacking mathematical knowledge can provide entry points for students to understand, and therefore is necessary for teaching. This unpacking has begun to focus research into teachers’ mathematical knowledge as it concerns the depth, connectedness, and explicit articulation of the mathematics of teaching (Ball, 2003; Ma, 1999). Knowing how to respond appropriately to students’ questions and developing the ability to choose or create questions and problems targeting specific mathematical concepts is at the center of the content knowledge needed for teaching (Ball, 2003). Studies involving teachers of elementary students have found that improving their mathematical knowledge for teaching significantly affects students’ learning of mathematics (e.g. Hill, Rowan, & Ball, 2005).

To measure the growth of participants’ content knowledge for teaching (CKT), the University of Michigan’s Learning Mathematics for Teaching (LMT) instrument was administered at the beginning of the summer institute in year one, and then again after one year of participation. The LMT measures have been shown to be a significant predictor of student achievement (Hill, Rowan, & Ball, 2005). The results of these test administrations are reported in the next section of this paper, with our purpose being to examine the aggregated teacher scores as well as the results between the two groups. We will examine the aggregate scores, and will also take a closer look into the differences in pre-and post-test responses for both groups and for the individual teachers.

The items on the LMT test are not released, and so we will describe the mathematical content of the tasks only in general terms, and will not directly refer to any specific calculations or tasks. A similar task could be the Staircase Problem shown in Figure 2. There are multiple ways that this problem could be represented using diagrams. Two representations are shown in Figure 3. Suppose that the task was to identify the correct expression that should accompany the diagram in Method f. Three possible choices are seen in Figure 4.

In Method f, the area is the sum of the area of the large grey triangle plus the area of the smaller triangles. This can be seen as (1/2) times $n^2$ plus $n$ times (1/2), since the area of the smaller triangles is 1/2 the area of the $n$ smaller squares. In this case, the correct response would be...
be A. It needs to be emphasized that even though all of the expressions are mathematically equivalent, response B corresponds to Method g, and neither response C or B clearly demonstrate the effect that dividing by 2 as shown by the diagonal would have on the diagram.

Findings

The results reported here are for the twenty-four teachers (twelve each from the FA and NAV groups) who fully completed the pre-assessment and post-assessment of the LMT instrument. The specific LMT test chosen was *Middle School Patterns Function and Algebra – Content Knowledge*. All items on the assessment are constructed to highlight the content knowledge that is involved in teaching. The content strands of this test include items intended to assess teacher’s fluency with determining and interpreting patterns, functions, expressions, equations, and representations. The instrument consisted of 29 responses in the form of multiple-choice questions. The pre-test was given at the beginning of June 2008, prior to any professional development activity, and the post-test was given at the beginning of May 2009 at the final follow-up session for the school year. At this point in the project teachers had participated in five days of full-cohort professional development in June 2008, five half-day follow up sessions during the school year, and at least three coaching visits from project staff. It needs to be noted that not all participants were able to attend every professional development session, although a large majority of participants were in attendance at every session.

Descriptive data for the pre-test and post-test is given in Table 1. The overall score for the aggregated group on the post-test was a respectable 73%, but the overall scores mask some significant differences. For example, on several items, virtually all of the teachers answered correctly.

</tbody>
</table>

Across both groups, we found that the participants experienced the greatest difficulty on items involving functions, with a particular challenge on characterizing and identifying the

different types of functions. This paper will first report on the overall data findings, and then examine the results on the tasks by content strand.

A student pre- and post-test in algebra was also administered, and the teacher’s CKT scores proved to be a significant predictor. For each one point gain on a teacher’s post-test score, their students achieved 0.448 higher points on the student post-test after accounting for the influence from the other teacher variables (Olson, Im, Slovin, Olson, Gilbert, Brandon, & Yin, 2010).

The mean number of correct responses for the NAV group increased by over 2 points, about 7%, and the mean for the FA group increased by one-third of a point, about 2%. No individual successfully answered all questions correctly on either test. Three FA and two NAV teachers had fewer correct answers on the post-test than on the pre-test. The largest individual gain from pre-test to post-test was 8 and the greatest decline was 6. The mean scores on the tests give an indication that the questions were of sufficient complexity for the teachers.

A look inside the responses by task

It is interesting to portray the differences between the two groups by considering the variation of responses on the individual items. For each group, the sum of the total number of correct responses by item on the pretest was subtracted from the sum of post-test correct answers. Table 2 shows that the sum of the differences of correct answers by item from the pre-test to the post-test was 4 for the FA group and 23 for the NAV group. These large discrepancies can be explained by further disaggregating the data by task.

<table>

<th>Table 2. Comparisons of Gain by Task</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Group</strong></td>
</tr>
<tr>
<td>FA</td>
</tr>
<tr>
<td>NAV</td>
</tr>
</tbody>
</table>

For the FA group, there were 12 items where the number of correct answers increased on the post-test and 11 items where there were more incorrect responses. No change occurred on 6 items. On the individual test items, the largest gain on the post-test was 5 more correct answers, and the largest loss on an individual item was 4 more incorrect answers. This data is shown in Table 3.

<table>
<thead>
<tr>
<th>Table 3. Comparison of number of changed answers</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Group</strong></td>
</tr>
<tr>
<td>FA</td>
</tr>
<tr>
<td>NAV</td>
</tr>
</tbody>
</table>

For the NAV group, there were 14 items where the number of correct answers increased on the post-test, and 7 items where there were more incorrect items. No change occurred on 8 items. The largest loss on the individual test items for the NAV group post-test was 2, which occurred on two items, and on one of the items this group had 5 more correct answers.
It is interesting to note the items yielding the largest changes in correct/incorrect answers from pre- to post-test occurred on different items for each of the groups. The largest gains for the FA group were seen on two items that asked for the teachers to select the linear relationship from a list of expressions. There were nine more correct responses, which increased the percentage on the two items from 46 to 84%. For comparison, on the same post-test, the NAV group’s scores on these same two items increased by four percent, from 84 to 88%.

The largest post-test gain for the NAV group came on a task that asked if there were no solutions, exactly one, or more than one solution to a compound inequality (there were no solutions). Five more teachers answered the question correctly on the post-test, with the result that nine of the twelve NAV group answered successfully. For this item, the most popular incorrect answer for the NAV group on both tests was to say that there were multiple solutions. Only on this inequality task were there more than three additional correct answers from the pre-to the post-test for the NAV group. The result on this item for the FA group was one correct answer on the pre-test, and three correct responses on the post-test. Of the incorrect answers for the FA group on both tests, all responses were “more than one solution” with the exception of one “not sure” response on both the pre-and post-test.

### Analysis of changed responses

Also of interest was the number of answers that were changed from the pre-test to the post-test. These results are reported in Table 4 below. In the FA group, 8 teachers changed over 10 answers from pre-test to post-test while only 3 teachers did so in the NAV group. It also should be noted that not all of those answers were changed from incorrect to correct. In fact, in the FA group, on average, less than half of the answers changed resulted in correct solutions. While the NAV group scored higher, still less than 60% of the changes resulted in correct solutions. It should be noted that both administrations of the test involved the same items.

### Item Analysis

There were several individual items of particular interest, which serve to highlight the differences on the pre-test and post-test data between the two groups. Two of the tasks required teachers to differentiate between linear, quadratic, and exponential functions. The first of the tasks asked teachers to identify a growing sequence depicted with square tiles. Table 5 can demonstrate this pattern, although the table representation does not show the pictorial pattern of growth of the function. On the pre-test, the FA group had four correct responses, and three on the
post-test, a lower overall score. All four of the correct responses to this item on the pre-test were changed to incorrect responses on the post-test. The three correct responses for this item on the post-test had been incorrect responses on the pre-test. The NAV group had seven correct responses on both the pre- and post-tests. Of the seven correct responses, one teacher changed from incorrect to correct on the post-test, and one switched from correct to incorrect.

The second task asked teachers to identify the growth of a function given a contextual example. In this two-part task, one section featured linear growth and the other was exponential. On the linear part, the FA group had seven correct answers on both the pre- and post-test, and the NAV group had seven correct answers on the pre- and six on the post-test. On the second task section, the FA group had six correct answers on the pre-test, but only 2 on the post. The NAV group had five correct responses on the pre-test and six on the post-test.

On another task, teachers were asked to identify an approach to solving an equation that involved dividing both sides of the equation by the variable \( x \) and thus division by zero must be considered. On the post-test, the number of correct responses from the FA group decreased from four to one. The NAV group’s scores improved from four to six.

The lowest overall number of correct responses for both groups on both tests came on an item similar to The Staircase Task in Figure 2 above that asked teachers to identify which expression on a list that matches a visual representation such as what is seen in Figure 3. This item asked teachers to identify expressions that matched an area diagram where one of the dimensions was the variable \( x \). An incorrect response on such an item is a nice way to distinguish between simple mathematical content knowledge and CKT. The content knowledge used in teaching is about trying to understand student thinking and having thought about the differences among approaches to solving the problem (all components of CKT). In teaching, this knowledge highlights the differences between the mathematical knowledge used in teaching and common content knowledge, the mathematical knowledge and skills used in settings other than teaching (Ball, Thames, & Phelps, 2008).

The FA group’s scores on the pre- and post-test were five and three correct responses respectively. Only one member of the NAV group correctly answered this item on the pre-test, although four correctly answered on the post-test. The salient feature of this task is that the expressions shown were mathematically equivalent, but did not represent the situation shown in the diagram.

Discussion

The findings are interesting in light of the content of the professional development that included the summer professional development, follow up, and coaching. While we attempted to maintain consistency in the formative assessment strategies and most of the mathematical tasks provided for participants, these results give cause to consider how the two models of professional development affected the resulting differences in the results on the teacher content knowledge assessment. Certainly, the use of the graphing features using the TI-Navigator system highlighted the tabular and graphical representations of functions and easily allowed for an examination of a variety of linear functions and expressions. The teachers in the FA group did not have any experiences with TI-Navigator, and perhaps that is why there was a decrease of 4 correct answers when asked to identify functions for a growing sequence and a decrease of 4 for identifying an exponential function, yet this did not happen for identifying a linear sequence.

As the professional development spent significant effort to discuss equivalent expressions, it was surprising when the teachers in both the FA and NAV group were not able to successfully answer that question.

Teachers’ overall averages on the post-test were respectable. While there were a large number of answers changed from pre-test to post-test, less than 60% of those changes resulted in changing an answer from incorrect to correct. In the FA group, on 12 of the 29 items there was an increase in average correct, while on 11 of the 29 items the average declined from pre-to post-test. For the NAV group, these numbers were 14 and 7 respectively. While teacher content knowledge has an impact on student achievement, less is known about organizing professional development to expand teacher knowledge. It appears that the NAV model was more useful in improving overall teacher knowledge and also resulted in fewer teachers changing answers from correct to incorrect. Further work is needed to determine what parts of the professional development were helpful so that teachers made changes from incorrect to correct as well as examining what might have impacted those teachers who changed from correct to incorrect. Perhaps the emphasis on different reasoning strategies and solutions might have hindered the FA group while multiple representations might have helped the NAV group.

EXPLORING TEACHERS’ MEASUREMENT DIVISION KNOWLEDGE

Soo Jin Lee

Chandra Hawley Orrill
University of Massachusetts Dartmouth
corrill@umassd.edu

This study provides fine-grained analysis of teachers’ reasoning as they engage with quotative division tasks. We consider teacher knowledge at a fine grain in an effort to examine the content knowledge teachers have that may be important for student learning. This qualitative analysis considers the mathematical knowledge that six middle-grade teachers used in a professional development program and during interviews. In all of the items, fraction division situations were approaches through linear or area models. Our analysis focused on three knowledge components critical for reasoning about measurement fraction division situations: partitioning operations, flexibility with referent units, and interpretations of the measurement division model.

Introduction

In this study, we examined the knowledge components that teachers use as they engage in measurement division tasks that involve fractions. Our interest is in examining teacher knowledge and the ways teacher understanding develops over time. Specifically, we consider three knowledge components teachers use in approaching measurement division situations.

Over the past few years, researchers have built from Shulman’s (1986) proposition about different kinds of knowledge teachers need to be successful in their practice. Shulman’s concept of pedagogical content knowledge (PCK), specifically, has led to ongoing discussion about the unique knowledge teachers need in order to support student learning. In last two decades, researchers have expanded the notion of PCK through the development of fine-grained conceptualizations of this knowledge for teaching mathematics. Ball and her colleagues (e.g., Ball, Thames, & Phelps, 2008) have sought to define the specialized knowledge teachers need that the ‘man on the street’ does not. They have named this body of knowledge mathematical knowledge for teaching (MKT). While we recognize there are multiple ways to frame this specific body of knowledge, our interest in this paper is confined only to a sliver of the work. We are specifically interested in the specialized content knowledge teachers have related to quotative fraction division and the affordances and limitations of that knowledge in terms of its potential for supporting student learning.

Previous research on teacher understanding of fractions has been somewhat limited. We know from research focused on preservice and inservice teachers, that their conceptions of fraction division are lacking (e.g. Ball, 1990; Simon, 1993; Ma, 1999; Tirosh, 2000; Li & Kulm, 2008). Specifically, we know that teachers, both preservice and inservice, struggle to provide appropriate word problems for division situations, instead they provide word problems that focus on multiplication by a fraction. For example, in an example such as 2 ÷ ½, teachers suggest examples involving making half a batch of a recipe rather than focusing on questions about how many groups of one-half are in two (Ball, 1990; Simon, 1993; Ma, 1999). These shortcomings are important as demonstrated in one case study by Borko et al. (1992). In that case, a preservice teacher was unable to answer basic questions from students about why the invert-and-multiply algorithm works resulting in an explanation that actually focused on fraction multiplication. Ma (1999) argued that teachers need a profound understanding of fraction division and found that one or more pieces of knowledge necessary to teach fraction divisions were missing in her
sample of US teachers. In short, prior research has uncovered that teachers have significant gaps in their understanding of fraction division, however, fine-grained work has not yet been undertaken to understand how teachers reason about division with fractions. Since teachers’ MKT enables or constrains their ability to orchestrate mathematical discussions that provide students with opportunities to develop meaningful understanding it is important for teacher educators and professional developers to understand how teachers know mathematics (Silverman & Thompson, 2008). With this regard, we tried not only to understand the teachers’ constraints but also to determine the basis for their constraints.

For our analysis, we drew from the ideas that emerged from the Fractions project (see below), which focused on children’s knowledge of fractions and their operations. The analysis framework from the fractions project allowed us to consider the kinds of compartmentalized knowledge focused on various stable operations that had been seen in children. In our analysis, we also saw some aspects of this knowledge in our teachers.

Using this model, we previously considered teachers’ reorganization of their measurement division (MD) knowledge by refining their partitioning operations and units through the sequence of problem situations in which the relationship between the dividend and the divisor becomes more complex (Lee & Orrill, 2009). This study extends that work by focusing on six teachers participating in a professional development course (PD). While it is beyond the scope of the article to describe Steffe’s fraction schemes in detail, we offer a brief description of a few schemes that we observed from our teachers under the following framework.

**Theoretical Framework**

The perspective of knowledge we use in this research draws on literature on cognition in mathematical and scientific domains (e.g., DiSessa, 1993; Izsák, 2008). The perspective of knowledge suggests that developing accounts of knowledge used by learners requires inferring diverse, fine-grained knowledge elements that they activate and how those elements function together as the learner tries to accomplish particular goals. In this study, the analysis led to three categories that serve to highlight the diversity of knowledge elements that our participants used – partitioning operations, flexibility with referent units, and interpretation of measurement division situations (how many groups of divisors in dividend versus using repeated subtraction).

The ideas of iterating and partitioning have been determined to be fundamental for children’s fraction knowledge development (Piaget, Inhelder, & Szeminska, 1960), and Kieren (1976) provided a logical analysis of the foundations of rational numbers that considered the notions of unit and partitioning as mechanisms for developing knowledge of fractions. Building on the frameworks of Piaget et al. and Kieren, scholars in mathematics education have explored the relationship between partitioning and units with fractions (e.g., Behr, Harel, Post, & Lesh, 1992, 1994; Confrey, 1994; Mack, 1990, 2001; Steffe & Olive, 2010). They have provided insights into how students draw on their knowledge of partitioning to reconceptualize and partition different types of units to solve problems involving multiplication of fractions. In particular, students’ use of partitioning was influenced by their ability to view fractional parts in relation to the referent, or unit, whole. We consider this ability keeping track of *referent unit (or whole)* in this study. In fraction multiplication, viewing fractional parts in such a manner helped students to consider a referent unit and to partition that unit by forming iterable units or splitting quantities in ways that reflected the multiplicative nature of the problem (Steffe & Olive, 2010).

By adopting a view of fractions as *measurement units*, teachers are able to reason about fraction division situations in meaningful ways. For example, teachers can think of a problem...
like $2/9 \div 1/3$ as asking, “How many thirds are in two-ninths?” In our previous work, we found teachers needed to attend to both the correct referent unit and they needed to develop flexibility with it as the relationship between the dividend and the divisor got complex (Lee & Orrill, 2009). One focus of the PD was on developing this kind of flexibility with referent units. For example, focusing on a teacher’s ability to keep track of the unit to which a fraction refers (e.g., in a problem such as $1/5 \times 1/4 = 1/20$, the $1/4$ refers to a whole, but the $1/5$ refers to a portion of the $1/4$) and to shift their relative understanding of the quantities as the referent unit changes. We observed that when teachers did not explicitly attend to the referent units, they were unable to identify diagrams that best modeled the problem. Based on our analysis, however, we assert that having this flexibility is necessary but insufficient for quotative division. Rather, it needs to be paired with refined partitioning operations.

*Common partitioning* is defined as an operation used to re-partition a partitioned bar until a common number is found (Steffe & Olive, 2010). It accompanies children’s explicit attention to the *co-measurement unit*, which is a measurement unit for commensurable segments, which are segments that can be divided by a common unit without a remainder. In our study, teachers used this operation when the divisor could not clearly measure out the dividend (i.e. denominators are relatively prime). For instance, they could coordinate and compare two composite units, such as $3$s and $5$s for $1/3 \div 1/5$, to determine a common multiple, $15$. Steffe and Olive described *cross partitioning* when they observed children solving the problem $\frac{1}{3} \times \frac{1}{5}$ by partitioning a bar vertically into three parts and horizontally into five parts and get $15$ of one-fifteenth automatically. In order for children to calculate the correct answer to the problem, they needed to know that the quantities of the resulting fractional part was in reference to one whole not one fifth. Steffe (2004) stated that the use of a cross partitioning operation in a fraction multiplication context differed from the common partitioning operation in that the former provides a simultaneous repartitioning of each part of an existing partition without having to insert a partition into each of the individual parts. Even though cross partitioning is the fundamental operation for producing *fraction composition scheme*, which is a multiplying scheme for fractions, we observed some interesting consequences in applying it to our teachers’ reasoning about division. Two mediating factors seemed to shape their approach. First, we observed that cross partitioning in division is inherently different from in multiplication because of the different roles referent units play in the two operations. Second, our teachers had already mastered ‘invert and multiply’ algorithm, which shaped their relationship to the operations.

**Methods**

This study is part of a larger project, Does it Work (DiW), which is concerned with what teachers learn in a professional development experience and how that learning translates into classroom practice.

In this analysis, we focused on six teachers, three sixth grade and three seventh grade, who participated in PD that met three hours one evening per week for 14 weeks. Of the fourteen teachers in the courses, eight were selected to participate in in-depth interviews about three assessments given as part of the research effort. Of those teachers, the six who demonstrated sophisticated reasoning about fraction division were considered for this study. The other two teachers relied strategies such as finding the drawing that matches to numerical calculation or identifying requisite features that were not grounded in quantitative reasoning.
The PD focused on fraction and decimal operations as well as proportional relationships. Each class meeting was videotaped using two cameras and the resulting video was combined into a restored view (Hall, 2000) using picture in picture technology. For this analysis, we focused on the two class meetings concerned with measurement (quotative) fraction division. In these two sessions, the teachers engaged with several tasks that relied on number line and area model representations and participated in discussions about using representations for fraction division.

Our analysis also considered participants’ responses to two division items on the written assessments that were administered as part of the larger project. One of the items focused on using an area model to illustrate quotative division of fractions while the other was a number line item that implied partitive division (e.g., answering the question, ‘what number is $\frac{1}{2}$ one-fifth of’), but that our six participants approached quotatively (e.g., answering the question, ‘how many $\frac{1}{2}$s are in $\frac{1}{5}$’). Because our assessment items are secure, all descriptions depict similar items to those actually used. In the interviews about these assessments, we asked teachers to discuss their reasoning for the choices they made on each item. In this way, we were able to gain insight into the mathematics that teachers used to analyze the tasks. Each interview was videotaped using two cameras as with the professional development sessions. Additionally, the interviews were all transcribed verbatim. As part of the data analysis, lesson graphs of the interviews were also created to allow easy reconstruction of the interviews.

Data analysis occurred in stages. The first stage was ongoing analysis throughout the implementation of the professional development course. Both researchers and the PD facilitator debriefed at the end of each session. Our discussion focused on how the participating teachers were making sense of the content and planning for future sessions. Immediately after each session, the facilitator (who was also a member of the research team) created annotated timelines of each session. These summaries provided written description of teachers’ mathematical activities and interactions with the instructor as well as emerging key points in teachers’ reasoning that were taken into account for the next session. The second stage of analysis was retrospective analysis. We worked from our initial lesson graphs that outlined the key incidents of the class meeting to identify key episodes. Then, we memoed (Strauss & Corbin, 1998) teachers’ mathematical reasoning to determine which categories of fraction reasoning were important for teachers working in measurement division contexts. The three emergent categories that were at play in the teachers’ reasoning were: (1) partitioning operations, (2) flexibility with referent units, and (3) the interpretations of measurement division model. In the third stage of analysis, we categorized our six teachers’ reasoning in terms of the categories, and generated hypotheses that were then united into comprehensive accounts. We then compared the generated accounts of our hypotheses of teachers’ reasoning with each of the interview lesson graphs. Specifically, we noted every time a teacher showed indications of each of the three categories, and took notes on lesson graphs of our inferences. Finally, we generated inferences about teachers’ reasoning under the three categories of knowledge components.

**Results**

To summarize our main findings, while only two teachers used measurement models for division at the outset (Claire and Donna), all six used quotative interpretations by the end of the professional development. The six teachers’ approaches to measurement division differed in terms of partitioning operations, ability to keep track of the referent unit in a flexible manner, and ways of interpreting quotative division problems. Also while children used cross partitioning...
To highlight teachers’ thinking in relation to cross partitioning and keeping track of the referent unit, we consider Walt and Claire. Both were able to interpret the area model item on the assessment, which showed the case where they could measure the dividend by the divisor such as $1/3 \div 1/9$. However, when asked to determine a number line model that relied on a partitive interpretation to show $3/4 \div 1/3$, both experienced difficulties and changed to a quotative division model. Claire drew an area model and cross partitioned the bar into four columns by three row pieces. Then she shaded three columns to represent $3/4$, and shaded in four pieces of $1/12$ much darker than the three fourths (Figure 1a). After she reminded herself to find the number of one thirds in three fourths, she measured out the number of four twelfths ($=1/3$ of 1) from three fourths, and told us that 2 and $1/4$ groups of $1/3$ could fit into $3/4$. She correctly chose the referent unit of one third as one and she recognized that the $1/12$ remaining after she counted two sets of $4/12$, was $1/4$ of $1/3$. When teachers confound the referent units in this case, often they would consider one third in reference to three fourths (Figure 1b & 2b), as in multiplication where the goal is to identify parts of parts (e.g., $1/3$ of $3/4$), and then count the number of three twelfths ($=1/3$ of $3/4$) inside three fourths, and get 3 as a quotient for $3/4 \div 1/3$ (Figure 1b).

As described above, Claire was able to appropriately reason with an area model. However, in the post-assessment interview, she demonstrated constraints in her common partitioning operation. She was able to break the number line into four parts and identify the length of three fourths, and then she repartitioned the same number line into three parts without considering the four parts that were already divided (Figure 3). We suggest that this indicates that she was unable to coordinate three-fourths and one-third simultaneously on the number line using common partitioning. She was not able to replicate the common partition from the area model in the number line situation. This was particularly interesting given that she had been able to do this in the first post-assessment interview.

In contrast to Claire, Walt was able to generate a number line using a common partitioning operation but failed to apply referent unit reasoning to his interpretation of the quotient. Actually, he first showed us the drawing similar to Claire’s, but when we asked him how he would
determine the answer to $\frac{3}{4} \div \frac{1}{3}$ with the model, he told us that he needed to find the common denominator, 12, of $\frac{3}{4}$ and $\frac{1}{3}$. He then drew a second number line (Figure 4), divided it into twelve parts, and marked every fourth and every third using a curved line. Then, he counted the number of one-thirds that fit into $\frac{3}{4}$. Once he counted the two $\frac{1}{3}$s, he struggled with the remaining part, which was $\frac{1}{3}$ of $\frac{1}{4}$ of the whole. The remaining part would be referred to as $\frac{1}{4}$ in the quotient because it is $\frac{1}{4}$ of another $\frac{1}{3}$ piece that would fit into the original quantity $\frac{3}{4}$. When asked about the common partitioning, which was not adequately supporting his reasoning, Walt explained that he had calculated the common denominator to determine how to partition the line. Walt was able to generate a correct response to this item, however, his reasoning was not sophisticated compared to an approach that reasoned through the common partitioning and demonstrated the ability to keep track of the referent unit.

The cases of Walt and Claire highlight the necessity for common partitions and their reliance on drawing from what they already know. Specifically, we Claire used area models and Walt relied on common denominators. These pre-existing understandings were insufficient for generating appropriate answers. In Claire’s case, the area model did not allow her to apply an understanding of common partitions to a number line model, whereas Walt’s common denominators did not support him in readily making sense of the number line.

Carrie and Donna demonstrated models other than measurement division in their work. Both Carrie and Donna relied on a repeated subtraction model of division in the posttest interview and Donna demonstrated that understanding in the course and in other interviews as well. This led to limitations in interpreting situations where the divisor was smaller than the dividend. Carrie’s understanding was further limited by her inflexibility in interpreting referent units. In fact, Carrie often discarded referent units to simplify the problem. She had no sophisticated way to reason about the quotient in a division problem because she would not consider the whole, only the parts of the problem.

In summary, we saw that simply developing a measurement model for division was insufficient for this professional development work. The teachers were all able to move toward measurement division models, yet most experienced significant limitations in their abilities to reason about the division situations. Particularly important in this work is the realization that, unlike children, the teachers relied on the algorithm to identify a common denominator to re-partition the number line before they attempted to reason with the drawn quantities. In fact, some teachers were unable to identify the common partition leading them to fail at operating on the number line. This pre-existing procedural knowledge suggests that teachers’ knowledge development trajectory might be different from children’s.

Conclusions and Implications

Conceptual analysis of teachers’ knowledge at this grain size allows us to develop an understanding of teachers’ capacities to reason about fraction division. While this report offers only a glimpse into teachers’ reasoning, it raises important issues. We note that the categories from research on students are valid lenses for considering teacher knowledge. However, there are limitations in relying on research about children’s reasoning to make sense of teacher knowledge. In this case, the teachers had strong procedural knowledge that helped them work around some operations, such as common partitioning. This is an issue because, as noted by Steffe and Olive (2010), common partitioning is a key operation for constructing more advanced operations. Thus, students need opportunities to engage in activities that support the development of this operation, however, teachers who cannot reason with it are unlikely to incorporate common partitioning into their students’ classroom experiences.

Most studies have not looked at teachers’ knowledge any closer than simply saying that teachers’ reasoning about fraction measurement division is insufficient. While the studies have provided the pioneering work in identifying knowledge teachers lacked (in this case, fraction division), more studies are needed to uncover how teachers can reason about fractions and how we support them in developing their knowledge for teaching. That is, teachers need to have opportunities to learn mathematics, to understand how key understandings can empower their students’ learning, and the actions they, as teachers, need to take to support students’ development of understanding (Silverman & Thompson, 2008).

By building on understanding of teachers’ mathematical concepts and operations in the ways illustrated here, we propose that a richer understanding of teachers’ understandings was identified, which could be used as the foundation for developing stronger professional learning opportunities for teachers.

INFORMING INSTRUCTIONAL DESIGN: EXAMINING ELEMENTARY PRESERVICE TEACHERS’ STRATEGIES IN A PARTITIVE QUOTIENT PROBLEM

Alison Castro Superfine
University of Illinois at Chicago
amcastro@uic.edu

Wenjuan Li
University of Illinois at Chicago
Wli26@uic.edu

In order to demonstrate a thorough understanding of rational number, learners need to understand each of the subconstructs of fractions, including the partitive quotient. This paper explores elementary preservice teachers’ understanding of the partitive quotient subconstruct of fractions by examining their strategies presented in whole group and the discussions that ensued. Based on the analysis, we reveal some blind spots in terms of PSTs’ understanding of the partitive quotient subconstruct, and propose implications for the design of instruction.

Introduction

Researchers generally agree that teachers need a robust understanding of the mathematics content they teach (RAND Mathematics Study Panel, 2003). Although there is less agreement about the precise nature of the mathematics knowledge teachers need to possess (e.g., Ponte & Chapman, 2002), researchers have increasingly emphasized that teachers need to know how and when to use procedures, the concepts underlying different procedures, and how various concepts are related to each other (Kilpatrick, Swafford, & Findell, 2001; Ma, 1999). Specifically in the domain of rational numbers, however, much of the extant research highlights limitations in preservice teachers’ (PSTs) understanding of rational number concepts and procedures (e.g., Newton, 2008; Tirosh, 2000; Ball, 1990; Li & Kulm, 2008; Behr, Khoury, Harel, Post, & Lesh, 1997). Despite this growing body of research, little is known about PSTs’ understanding of what some researchers argue is the foundational rational number subconstruct - namely the partitive quotient subconstruct.

Defined generally as fraction division, Kieren (1976) and Freudenthal (1973) argue that the partitive quotient subconstruct is foundational to a more holistic understanding of rational number. As fraction division is an important topic in elementary mathematics, albeit conceptually challenging to understand (Ma, 1999), it is important to determine the extent to which PSTs are mathematically prepared for some of the instructional tasks they will encounter as classroom teachers (Eisenhart et al., 1993). Teaching mathematics for understanding requires considerable knowledge and skill on the part of the teacher (Even & Ball, 2009). Building on previous work focused on young children’s partitioning strategies used in partitive quotient (PQ) problem situations (Charles & Nason, 2001; Lamon, 1996), the authors examine four typical PSTs’ PQ problem strategies presented in class and the follow-up discussion that ensued around those strategies, and discuss how the ways in which they partitioned, quantified, and ultimately discussed the strategies reveals the extent of their ability to build and understand the PQ subconstruct from the problem situation. Our aim in this paper is to inform the design of instructional tasks related to the PQ subconstruct to be used with PSTs, thus illustrating the process by which a math teacher educator may go through as they enact a task and examine PSTs’ work on the task in order to inform subsequent instructional decisions.
Framework

Building the PQ Subconstruct

Within the domain of rational numbers, researchers have identified five subconstructs that constitute the rational number construct: part-whole, operator, decimal fraction, PQ, and measure (Kieren, 1976; Post, Behr, & Lesh, 1982). See Behr, Lesh, Post, & Silver (1983) for a discussion of the relationship between these different subconstructs. The PQ subconstruct of rational number is defined as the quotient resulting from partitive division such that given a quantity $x$ (the dividend) and a quantity $y$ (the divisor), when $x$ is divided into $y$ shares, the resulting amounts to be shared are of size $x/y$ (Kieren, 1976). In other words, the idea underlying this procedure is to consider a PQ problem situation in terms of partitive division and to then consider the results of the division as a fraction. The PQ subconstruct also allows for quantification of the amount resulting from dividing a quantity into a given number of parts (Kieren, 1980).

Indeed, researchers argue that, for children, the major cognitive structure underlying the PQ subconstruct is partitioning, which is the ability to divide an object(s) into a given number of equal parts (Kieren, 1976). Charles & Nason (2001) argue that partitioning strategies have to generate equal shares and the equal shares need to be quantifiable. That is, partitioning should facilitate two conceptual mappings: (1) mapping the number of people ($y$) to the fraction name ($y$ths), and (2) mapping between the number of objects to be shared ($x$) and the fraction name ($y$ths). If these conditions are not met as part of the partitioning component, then learners do not abstract the PQ subconstruct even if they are able to complete the task, thus solving the task procedurally without demonstrating a more conceptual understanding of the underlying subconstruct.

Beyond partitioning, quantification is a centrally important component that helps build up the PQ subconstruct. Quantification generally involves the aforementioned conceptual mappings that are often implicit in partitioning. Thus, a strategy that facilitates building of the PQ subconstruct must fulfill the following requirements: the outcome of the partitioning component needs to facilitate the aforementioned conceptual mappings (i.e., mapping the number of people ($y$) to the fraction name ($y$ths), and mapping between the number of objects to be shared ($x$) and the fraction name ($y$ths)); the outcome of the quantification component should reflect these two mappings.

However, as compared to children’s dependence on partitioning in order to solve PQ tasks, (e.g., Charles & Nason, 2001; Lamon, 1996) we argue that PSTs employ quite diverse strategies, not necessarily partitioning, and rely on their prior knowledge of other fraction subconstructs and fraction operations in order to solve a PQ task. For example, PSTs may be able to employ a partitioning strategy that facilitates the two aforementioned conditions, but are unable to generate the correct fractional answer because of their limited understanding of fraction operations (Li & Kulm, 2008; Ball, 1990). Given PSTs’ prior knowledge of fraction concepts and operations, we hypothesize that PSTs will not rely solely on partitioning strategies or their understanding of fractions, but also on their prior knowledge of fraction operations.

Given the centrality of rational numbers and operations to the elementary school curriculum, it is important for teachers to have a thorough understanding of the concepts and operations within this domain of mathematics. Although much of the extant research explicitly involving the PQ subconstruct focuses on children’s strategies employed in such problem situations, this body of research provides a foundation for understanding the nature of PSTs’ knowledge in this domain given their often limited knowledge of such concepts as documented in past research.
(e.g., Ball, 1990; Newton, 2008; Tirosh, 2000). The authors hypothesize that while some of strategies employed by PSTs will be similar to those employed by young children, other strategies will also be employed given PSTs’ prior knowledge of rational number concepts and operations.

**Methodology**

This study took place in the context of a required mathematics content course for elementary PSTs at a large public university in the Midwestern United States. The content course is designed around developing PSTs’ mathematics knowledge needed for teaching (see Ball, Thames, & Phelps, 2008). The content of the course includes place value and number operations, rational number concepts, and aspects of number theory, and provides PSTs with opportunities to develop their abilities to engage in mathematical tasks central to teaching. The learning environment in the content course is largely collaborative in nature, where PSTs are encouraged to pose questions, share their ideas, as well as understand and discuss other people’s strategies. The classroom excerpts used in this analysis were selected from two sections of the content course that were offered in the Fall 2008 semester. The task used as part of this study was specifically designed to deepen PSTs’ understanding of the PQ subconstruct in a way that PSTs could engage with the more conceptual aspects of this subconstruct as opposed to simply solving naked fraction division problems (e.g., \( \frac{1}{2} \div \frac{3}{4} \)). Called the Cake Problem, the task reads as follows:

*Roger has 3 cakes that he wants to share equally among 5 friends. How much cake can he give to each friend?*

An important aspect of the task design was to create a potentially unfamiliar context for PSTs, one that would highlight for the instructor where PSTs were in their ability to build the PQ subconstruct. Thus, the task was worded in such a way so as to not trigger for PSTs that a fractional answer was required. PSTs were asked to solve this problem first individually, then discuss their work on the task in small groups, and finally discuss their strategies with the whole group. As they worked on the task, instructor feedback was limited to probing PSTs to explain their thinking for purposes of making their thinking about the task explicit.

**Results**

PSTs’ work on the task is taken from transcripts of videotapes of small and whole group discussions, chalkboard pictures of their strategies, as well as from their written solutions. The aim of this analysis is not to draw conclusions about individual PSTs’ understanding, but rather to examine the strategies employed and discussions around these strategies for purposes of informing the design of instructional tasks involving the PQ subconstruct.

Various strategies were identified in the analysis. For example, distribute partitioning strategy (Lamon, 1996), chunking partitioning strategy, preservation of pieces partitioning strategy (Lamon, 1996), and proceduralized partitive quotient strategy (Charles & Nason, 2001). Based on the data, the authors found that some PSTs were able to solve the problem using their own strategies, but became easily confused by other strategies, were unable to make connections between different strategies, and were unsure why other strategies were valid. The four most common strategies and PSTs’ discussions around these strategies are analyzed in the following excerpts:

---

Chapter 13: Teaching Knowledge

Excerpt 1: $\frac{1}{5} + \frac{1}{5} + \frac{1}{5} = \frac{3}{15}?$

In her explanation of the distribute partitioning strategy (Figure 1) during the whole group discussion, one PST drew three circular objects, then divided each object into five pieces, “...because there are 5 people.” She then shaded one part from the first object, another part from the second object, and another part from the third object, totaling three parts. She stated, “Okay, so that’s one person [share].” She proceeded to number each part in each whole object in order that each person received three parts (i.e., one part from each object). This is illustrative of the distribution partitioning strategy whereby PSTs share out one part from each object to each person, and is similar to Lamon’s (1996) distribution strategy. The PST stated, “Each person gets $\frac{1}{5}$ of each cake.” Another PST interprets the same picture differently. She stated that this is the same thing that she did. What is different is that she counts how much cake each person received by considering 3 pieces out of 15 pieces.

Following this discussion, one PST (Student 1) proposed a connection between these two explanations. However, her classmates largely reject it:

Student 1: Well if each cake is broken up into fifths...like so, like each person gets one fifth. It's just one fifth plus one fifth plus one fifth, which you know would be like three fifths. So if you think about...
Students: It should be three fifths.
Student 2: You don't add the denominator because they have common denominators.

The two explanations presented here are evidence of building of the PQ construct, as it facilitates the two mappings. However, Student 1’s failure to connect these two strategies shows limited understanding of the PQ subconstruct. She did not see the two different units that are used to represent the fractions, which is the critical point underlying the connection that is implicit in Student 1’s strategy. That is, to understand the relationship between these two explanations, PSTs need to realize a reunitizing process that was implicit for most of them. Additional evidence to support this claim can be found from other students and Student 2, who refuted Student 1 by pointing out the answer is wrong: $\frac{1}{5} + \frac{1}{5} + \frac{1}{5}$ is $\frac{3}{5}$, not $\frac{1}{5}$, without paying attention to the units involved in these two different strategies and the reunitizing process that connected them.

Excerpt 2: Some people got $\frac{3}{5}$ of a cake, and some people got $\frac{3}{5}$ of two cakes?

PSTs who utilized the chunking partitioning strategy (Figure 2) partitioned each object into five parts first. However, instead of distributing a single part from each whole object to each person, PSTs who utilized this strategy denoted three consecutive parts from each object as each person’s share. Then, they determined that each person’s share consists of $\frac{3}{5}$ of a cake.

The partitioning of the cake in the chunking strategy is different from the distribution strategy. The difference resulted in a confusion with the quantification of these two different partitionings. After the presentation, one PST showed her confusion when she asked how each person’s share from different cakes is the same as taking each person’s share from the same cake.
Student 3: Um, I don't know what we were talking about over here we can't have three fifths of a cake because we would have some left over like.

Student 3: Like you can't get three fifths of a pie (cake) because there's going to be two pieces left over and you have to borrow a piece from the other pie (cake).

Teacher: So you're saying some people are going to have to get cake from two different pieces from two different cakes.

Student 3: Yeah everyone can't get three fifths of a pie (cake).

Student 4: Unless you do it that way. (Referring to the distribute partitioning strategy.)

Student 3: Yeah like that. ((3 sec pause)) I don't know cause they can say that three fifths is three fifths of a pie (cake) and that's not of a pie (cake).

Student 3: Because everyone can't get three fifths of each of the cakes. I mean they can because there's like two they are going to have to borrow one from the other cake so it is like two cakes.

There are two ways to quantify the chunking partitioning strategy. The strategy represented on the board quantified by dividing a unit into fifths and designating 3 (3/5), which is the same as the quantification involved in the distributing partitioning strategy. Another way is dividing 3 units into 5 parts (5 different chunks). These two quantifications result in the same quantity. However, according to Kiren (1980), this presents different problems for the learner, which is also illustrated by Student 3’s confusion.

Excerpt 3: I don’t know, but I feel like visually this is cool.

The PST (Student 5) who presented this preservation of pieces partitioning strategy (Figure 3) drew three whole objects, divided each object in half, which resulted in six half objects. She then distributed the six halves to each person with one half-object remaining. This partitioning shares many common features with Lamon’s (1996) preservation of pieces partitioning strategy in that PSTs attempted to make the fewest number of cuts possible. She continued the partitioning by subdividing the remaining half object into five pieces, and then sharing each fifth to each person, as indicated by their numbering or shading of each fifth. When she quantified the remaining half object that was sub-divided into five parts. For example, in order to determine the size of the five small parts in relation to the whole object, the PST
multiplied 1/5 by 1/2, which resulted in 1/10. Finally, in order to quantify each person’s share, she added the 1/2 cake and the 1/10 together using fraction addition, which resulted in an interpretation of the answer as 3/5 of a cake in each person’s share.

Although the PST who utilized this strategy came up with the correct answer in the context of the problem, she did not complete the necessary conceptual mappings as part of their partitioning and quantification components.

Student 5: Okay so everyone got half a cake and then we had one half of a cake left over so we divided that by five people also. So everyone’s going to get half a cake and then whatever they get from here, which is one piece. So we want to know how much is each piece so we did half divided by five people and which is like half times one over fifth. So each one gets one tenth of that (remaining) half.

As illustrated above, when she was representing, she explained that each one gets one tenth of that (remaining) half. Then she added 1/2 of a cake and 1/10 of a half together (Figure 3 was the final manifestation of her work and different from what she originally wrote down). Obviously, the quantification does not reflect the partitioning.

Moreover, due to the complicated partitioning, PSTs were not able to explain whether this strategy is valid. As Student 6 commented below:

Student 6: I feel like visually this is cool. This is kind of interesting but with numbers it's hard to explain I feel.

Again, as with the chunking partitioning strategy, the essential quantification that dividing 3 units into 5 parts is implicit. Each of the 5 parts are made of 1/2 of a cake and 1/10 of a cake. PSTs were able to do the addition without recognizing what the addition really means in the context of the strategy.

Excerpt 4: I don’t know which to divide first.

In this strategy, PSTs obtained the fraction by dividing 3 by 5. This strategy is the same as Charles & Nason’s (2001) proceduralized PQ strategy, which is a high-level strategy that indicates the abstraction of the PQ subconstruct. However, we found that the proceduralized strategy might lead to building of the PQ subconstruct, but also might leave the understanding of PQ construct at procedural understanding level. As Student 7 stated in her presentation:

Student 7: Um. I did, well at first I did five divided by three and I realized this was wrong. So, um, I finally figured it out that it's three divided by five.

Student 7: Well at first I didn't. I did five divided by three and then I… So this is what I did before I did this. So then I got. I realized that three does go into five once and then I did minus three and then have two so two

---

thirds and then that one is wrong. So then I did it this way and then I got zero minus zero equals three and I wanted it in a fraction so then I got three fifths.

Teacher: Everybody convinced? Okay, just cause the other one was wrong can this one be wrong too?

Students: Yeah.

Teacher: Can they both be wrong?

Teacher: Why is this really the right thing to do?

No response.

Students are able to figure out the answers to the PQ problem, but are unable to explain why the different strategies are valid. Moreover, they rely on the long division algorithm to obtain the answer rather than producing the fraction directly. This might be due to the disconnection between fraction as division and division as fractions. PSTs may not see the PQ problem as a partitive division problem.

Discussion

The authors examined the strategies presented by PSTs with a PQ task and the follow-up discussion involving those strategies. As discussed previously, we posited that PSTs would employ diverse strategies, not necessarily partitioning, and rely on their prior knowledge of fractions and fraction operations in order to solve the PQ task. Based on our strategy analysis, we argue that, given PSTs’ prior knowledge of fraction concepts and operations, they are able to build the PQ subconstruct. As evidenced in the class discussion, however, the building of the PQ subconstruct resulted from a largely procedural understanding of partitioning and quantification processes, with limited conceptual understanding of those processes. For example, PSTs were unable to make connections between different strategies (Excerpt 1), became easily confused by some strategies (Excerpt 2), and were unsure why some strategies were valid (Excerpt 3 & 4).

Though not part of this analysis, we have designed additional follow-up tasks to help facilitate PSTs’ conceptual understanding of the PQ subconstruct.

Based on our analysis, the knowledge PSTs needed to develop a conceptual understanding of the PQ construct are reunitizing, two fundamental ways of quantifying a partitioning, as well as partitive division in the PQ context. For PSTs, these three features of fractions are dramatically different from whole number contexts. For example, when using whole numbers to represent quantities, they do not consider the unit and reunitizing because the unit is always “1.” However, whole numbers, a subset of rational numbers, cannot be considered as a different and isolated number system from rational numbers. Thus, we propose that in order to facilitate a thorough understanding of the PQ construct, teacher educators need to reveal the implicit connections between whole numbers and fractions as the following:

- For whole number problems, no reunitizing is involved due to the consistency of the unit; for fraction problems, reunitizing is involved because the referent unit varies, as in the Cake Problem where the unit could be 1 cake, 3 cakes or half of a cake.
- For whole number problems, there is only one way to quantify: divide all the units into a certain number of parts because it does not involve dividing a unit. Using this way to think about fraction problems is valid because all of the units are divided into a certain number of parts in both situations. However, the answer usually cannot be
obtained directly. For example, in excerpt 3, to quantify each part (i.e., 1/2 of a cake and 1/5 of half a cake), fraction addition and multiplication are employed.

- For whole number problems, the quotient of the division can be represented using fractions, which is similar to the PQ problem used in this study. For example, 6 cakes shared with 3 people can be represented as $6 \div 3 = 6/3 = 2$, while 3 cakes shared with 5 people could be represented $3 \div 5 = 3/5$.

Following the discussion of the uniformity of whole numbers and fractions in terms of these three features, the variance of the features of fractions should be emphasized. The following is the work that mathematics teacher educators can do to emphasize a more conceptual understanding of the PQ subconstruct: as to reunitizing, we propose to emphasize the importance of unit in representing a quantity using fractions. In their previous learning, only two elements of fraction are emphasized, denominator and numerator. Unit as an essential component of fractions is usually ignored. As to two fundamental ways of quantifying a partitioning, first, the properties of partitioning as Lamon (2000) discussed should be made explicit to PSTs. Second, PSTs should be encouraged to explain different partitioning using the two quantifying processes.

MATHEMATICAL KNOWLEDGE FOR TEACHING IN ACTION: SUPPORTING ARGUMENTATION IN THE CLASSROOM

Nicole Shechtman

This study examines how middle school math teachers’ mathematical knowledge for teaching (MKT) can support their teaching. This post-hoc analysis examines data collected around a teacher professional development program designed to help teachers learn to facilitate mathematical argumentation in their classrooms. Findings show a range of MKT across the teacher sample and that the amount of argumentative talk in teachers’ classrooms is strongly related to teachers’ MKT. Contrasting illustrations of classroom discourse of a high-MKT/high-talk teacher and a low-MKT/low-talk teacher illustrate important ways MKT can be used in the actions of teaching. Implications for research and professional development are discussed.

Introduction

The purpose of this study is to examine the claim from commonsense wisdom, recent education policy discussions, and emerging research that teachers’ mathematical knowledge for teaching (MKT) plays an important role in their teaching of mathematics. In particular, we investigate how teachers use MKT moment-by-moment in the teaching moves that they enact to support classroom discussion, specifically mathematical argumentation.

Hill et al. (2008) began an important line of inquiry examining the relationships between teachers’ MKT and their instructional practices. They reported a series of case studies investigating elementary mathematics instruction. These studies traced connections between teachers’ MKT and what they call “Mathematical Quality of Instruction” (MQI) observed in classroom teaching. Mix’s categories characterize the rigor and richness of the mathematics of the lesson, including teachers’ mathematical errors, the appropriateness of teachers’ responses to their students’ ideas, and precision of mathematical language. Across the case studies, they found positive and strong associations between MKT and MQI, as well as a number of mediating factors that support or hinder the teachers’ use of their knowledge in practice.

The present study builds on this literature with a post-hoc analysis of data collected in the context of the Bridging Professional Development Project, a teacher professional development program designed to both improve teachers’ MKT and develop their skills to facilitate mathematical argumentation in the classroom. The program targets middle school mathematics teachers teaching in underserved urban districts. We examine how teachers’ MKT relates to the argumentative discourse that occurs in their classrooms when they teach a 2- to 4-day replacement unit designed to foster argumentation around important middle school mathematics. Although the Bridging Project was not planned specifically to investigate links from MKT to classroom discourse, the research design entailed a rich and relatively controlled context for systematic exploration of this relationship. The design included both direct assessment of specific MKT (using a test modeled on Hill and colleagues’ work) and a systematic analysis of transcripts of classroom discourse. The design provides several methodological affordances that have not been present in prior research: (1) the content of the classroom instruction is held relatively constant, as all participating teachers (within a year) teach with the same instructional unit; (2) the content of the MKT assessed is highly aligned with the content of the mathematics
lessons taught and observed; and (3) the sample size is large enough to afford statistical inferences. Furthermore, while most prior research on MKT has focused on elementary school, this study examines middle school teaching and learning.

In this post-hoc analysis, we characterize the distribution of MKT across the middle school math teacher sample and analyze possible relationships between teachers’ level of MKT and characteristics of their classroom discourse. We look for MKT in action—how teacher’s knowledge of mathematics is used—or not—in the moment of instruction.

**Theoretical Framework**

**Mathematical Argumentation**

Mathematics educators, mathematicians, and philosophers agree that mathematical argumentation is essential for learning mathematics. It can provide students with opportunities that enable them to construct conceptually rich understandings and develop a sense of ownership in the construction of knowledge. It can also be empowering to students, enabling them to develop intellectual autonomy and confidence as they become active co-constructors of mathematical arguments, formulating and determining the validity of their own justifications. Indeed, mathematical argumentation is highlighted in national math education policy documents as part of the development of essential mathematical proficiencies.

In deciding how to frame to teachers the mathematical practice of argumentation, we began by examining Toulmin’s oft-cited structure of argumentation (2003). In this scheme, an argument in any discipline consists of core elements, such as a claim about something in the world, data used as evidence to support the claim, and warrants that explain the relationship of the data to the claim. To that make this scheme practical for teachers’ use in the classroom, we define conjecturing as a process of “conscious guessing” to create mathematical statements of as-of-yet undetermined mathematical validity and justifying as a process of explicating one’s reasoning to establish the mathematical validity of a conjecture. Finally, we also emphasize concluding as coming to agreement about the validity of an argument.

Conjecturing, justifying, and concluding, then, are the elements of our framework for argumentation, in our work with teachers. Teachers learn to make language-based mathematical arguments to justify solutions, compare and contrast alternative solutions, and establish generalized claims. Specialized forms of these categories of knowledge are needed in different aspects of teaching—planning, responding flexibly to students, connecting content to students’ future studies, exploiting connections among mathematics topics, and more.

**Mathematical Knowledge for Teaching**

Foundational to teaching with argumentation is deep knowledge of both the mathematical content that is the object of the argument and the mathematical practice of argumentation. We conceptualize these understandings in terms of the construct of MKT, which Ball, Hill, and others use to characterize the specialized mathematical knowledge, skills, and practices that are grounded in, but not confined to, use in the classroom, at an appropriately higher level than what students are expected to learn (e.g., Ball, Lubiensky, & Mewborn, 2001; Hill et al., 2005) Our project focused on the mathematics of proportionality in geometry as well as properties of geometric shapes in coordinate geometry.
The Bridging Teacher Professional Development Model

The Bridging PD has been implemented as a 2-week summer workshop designed to foster intensive teacher learning. The training in week 1 focuses on deepening MKT, while the training in week 2 builds on this knowledge to develop the pedagogical aspects of facilitating mathematical argumentation. The pedagogical approach, which is described in detail elsewhere (see Shechtman & Knudsen, in press), draws on methods from improvisational theater and emphasizes the development of a repertoire of teaching moves—discrete units of instructional practice that teachers use to scaffold classroom mathematical argumentation. The workshop is designed to help teachers, within a two week timeframe, develop a repertoire of teaching moves that they can use flexibly, responsively, and appropriately given the moment-by-moment needs of the students as they engage in mathematical argumentation. Summer workshops activities include:

- **Building mathematical knowledge for teaching.** Using adult versions of a classroom unit for teaching proportionality, teachers learn to make mathematical arguments for themselves, while deepening their proportionality MKT. They analyze brief classroom scenarios focusing on students’ mathematical thinking. Teachers learn to make their whole-group arguments in terms of conjecturing, justifying and concluding.

- **Script read-throughs.** Teachers take on parts in fictionalized transcripts of classroom discourse. Images of argumentation take on a first version of reality through these read-alouds. This builds teachers’ awareness of new tools and practices particularly as compared to their own current practices, without requiring independent use of them.

- **Teacher improv games.** These activities provide an experience of teaching that shares the improvisational nature of “the real thing”—classroom teaching. The games have rules that constrain teachers’ actions, enabling them to consider the use and purposes of teaching moves. The games advance teachers’ understanding and use of new practices, including the affective component of doing something new.

- **Writing the script: lesson planning.** Teachers use “think alouds” with the prompt, “what are you actually going to do for this lesson?” to compose detailed lesson plans with step-by-step anticipation of classroom action when they teach with the Bridging curriculum unit.

- **Rehearsal.** Teachers choose a portion of their lesson to rehearse improvisationally, with the whole group acting as the class. Lesson segments are chosen to highlight potentially difficult places in the flow of the lesson: for example, orchestrating getting agreement about the validity of a justification. In the rehearsals, teachers apply new moves and tools to potential classroom interactions.

**Methods**

**Research Design**

In this early design phase of the Bridging Project, we implemented the PD within the structure of a small-scale 2-year randomized experiment impact study with complementary case studies. Teachers were recruited from high-poverty urban districts in the San Francisco Bay Area. A total of 35 teachers attended the workshops across the two years. Teachers were randomly assigned to either a Treatment or Control group. Each year, teachers in the Treatment group received the full 2-week Bridging intervention. Teachers in the Control group received only the week 1 MKT training but not the week 2 training addressing pedagogy (during that week, they received a different but equally valuable workshop focused on vertical coordination.
across grade levels). We implemented two iterations of this workshop in the summers of 2006 and 2007. During the school year, teachers were asked to teach a 2- to 4-day instructional unit using curriculum materials from week 1 of the summer workshop. To examine classroom discourse during these lessons, classes were videotaped using a set of microphones with the capacity to capture all student and teacher talk in the classroom. All whole-class discussion was transcribed verbatim for analysis.

The main hypothesis of the experiment was that the classroom discourse of Treatment group teachers (compared to that of Control group teachers) will have more and longer episodes of mathematical argumentation. In our first-year iteration, Treatment classrooms had significantly more episodes of argumentation (effect size 1.22), while in the second-year iteration there was no significant difference between groups. In both years, there were trends, though not significant, that argumentation episodes were longer in the Treatment group. In the present post-hoc analyses of the data from this experiment, we focus on examining relationships between teachers’ MKT and classroom discourse.

**Measures**

Each year, teachers were given an assessment of their MKT before and after their 2-week PD program. The assessment was developed in alignment with the content of the PD. The research team followed a sequence of steps to rigorously develop and validate assessment: (1) establish a mathematically-precise conceptual framework to underlie both the curriculum and assessment, (2) work with a panel of experts to develop a pool of potential items, (3) conduct cognitive think-alouds, and (4) field test the items with about 20 teachers to establish item and test characteristics. The year 1 assessment focused on similarity across the strands of geometry, algebra, and number; it had 23 items and a Cronbach’s alpha of .84. The year 2 assessment focused on coordinate geometry; it had 30 items and a Cronbach’s alpha of .94. Both assessments contained a mixed of multiple choice questions assessing conceptual knowledge and items requiring the construction of mathematical definitions and justifications.

To examine argumentation in classroom discourse, we developed the Mathematical Argumentation as Joint Activity in the Classroom (MAJAC) coding protocol to locate and analyze episodes of mathematical argumentation in transcripts of whole-class discussion (Shechtman, Knudsen & Kim, 2008). It is implemented by coders who have extensive experience in the mathematics classroom, either through teaching or research. Two independent coders read through the transcript and record the line numbers on which they observe entry and exit points for episodes of classroom mathematical argumentation. Consensus is then sought through discussion.

**Results**

**Distribution of MKT in the Teacher Sample**

Teachers came into the workshop with a wide range of MKT as measured by the Bridging assessments. In both years, teachers’ pretest scores were distributed across the range from 10-20% correct to about 90% correct. This affords an analysis of how varying degrees of MKT impact practice. Also, teachers’ mathematics learning in the MKT workshops was significant, though modest. From pre- to post-workshop, MKT grew a mean of 0.5 SD \( t(23) = 4.2, p < .001 \) and 0.3 SD \( t(20) = 4.5, p < .0001 \) in years 1 and 2, respectively.
**Discourse Patterns Across the Sample**

Figure 1 shows an important pattern we observed in examining the relationship between MKT and the amount of talk teachers’ classrooms spent in argumentation. Overall, there was a robust relationship across years that the higher the teacher’s MKT the more argumentative talk occurred in their classroom. Note that the correlations are almost identical for pretest scores.

![Year 1 (Similarity Across Strands) vs. Year 2 (Coordinate Geometry)](chart.png)

**Figure 1. In the treatment groups, correlations between teacher MKT and total student turns justifying in whole-class discussion during 2- to 4-day instructional units**

**Illustrations of MKT in Action**

To begin to unpack how teachers use MKT in action, here we examine excerpts from the classroom discourse of two year 2 teachers. Ms. Shanna was the highest-scoring teacher on the MKT post-test in the year 2 workshop and had the highest amount of classroom argumentative talk, while Ms. June was one of the lowest-scoring teachers and had relatively little classroom argumentative talk. In this limited space, rather than focus directly on the amount of argumentative talk, we have chosen to focus on an activity toward the beginning of the Bridging curriculum that lays the conceptual foundation for the argumentation to follow. In this activity, teachers facilitate a whole-class discussion in which the class co-constructs the mathematical definition of a rectangle. This in itself is argumentative, as posing a definition requires both making conjectures that particular statements capture all the appropriate cases of a rectangle and justifying these conjectures. At the heart of these illustrations, drilling down into the teachers’ actual assessments reveals significantly different conceptual understandings (or misunderstandings or confusions) that the two teachers held. When asked to write a precise definition of “rectangle” in terms of what a rectangle would be on a coordinate plane, the two teachers wrote the following:

**Ms. Shanna:** A rectangle consists of 4 line segments intersecting at 4 vertices. Each vertex consists of 2 lines whose slopes are negative reciprocals of each other.

**Ms. June:** A rectangle’s 2 vertical line segments share the same x value and the 2 horizontal segments share the same y value. The 2 line segments are parallel to the x and y axes, and the points of intersection of these line segments are perpendicular. 4 right angles are formed at the vertices.

Ms. Shanna. An excerpt of classroom dialogue from Ms. Shanna’s class is as follows:
Ms. S: What’s, what’s your definition of a rectangle?

Students: Sides. Squares. Two sets of parallel lines.

Ms. S: I will take a quiet hand… Okay, John?

John: A shape with four sides. Four pairs of parallel sides… I mean, not four parallel sides. Two parallels.

Ms. S: So, it’s a shape. [Writes “A shape…” on the board.]

Students: Two parallel sides. The length is uneven of the width. A stretched square.

Ms. S: It’s a shape with two parallel sides. [Writes this on the board] What else?

Student: A longer square.

Ms. S: A longer square?

Student: A stretched--

Ms. S: Stretched? Is that what you mean?

Student: The width is stretched out.

Ms. S: The stretched

Student: A stretched square, huh? [laughter]

Ms. S: Okay. Larry.

Larry: The width is longer than the length.

Ms. S: Okay. I like that… the width is longer than the length. [Writes this on the board] And how do you know FOR SURE, how do you know for sure that what you drew is a rectangle? I have a question for you. Here’s two short sides. And here’s two long sides. Is that a rectangle? [Draws a trapezoid on the board]

Students: [simultaneously] No. That’s a <inaudible>. Is that a heptagon?

Ms. S: Well, we know it’s not a rectangle.

Students: <inaudible>

Ms. S: It’s a trapezoid, ok? Right?

Student: Four 90-degree angles with two sets of parallel lines.

Ms. S: Oh okay, I like that. [Writes this on the board] Okay, four 90-degree angles with-

Student: Two sets of parallel lines.

Ms. S: Two sets of parallel lines.

Ms Shanna’s MKT seems to have supported many of the moves that she makes here. She starts by collecting conjectures from students about the key aspects of the definition of a rectangle. In general, she is able to pick and choose from among the many statements that students make in order to highlight important mathematics. She keeps the focus on the mathematical properties of rectangles, such as lengths of sides and angles, which could help move students to a more mature view of geometric shapes as more than the colloquial understanding as holistic images. By line 17, she is poised to make an important argumentative move: she provides students with a counterexample. In the context of defining a rectangle, a counterexample is a shape that should fit the definitions students have given, but that is clearly not a rectangle. This counterexample “breaks” the incorrect definition students had made and helps them to see what aspects of a shape are necessary and sufficient to define a rectangle. The definition also, of course, includes squares, but Ms Shanna had, perhaps wisely, not taken that on. A discussion of whether or not squares are rectangles can become more of a debate than an argument, unless students are specifically equipped with the ideas to take it on.
Ms. June. In Ms June’s class, defining a rectangle was spread over two days. The discussion was a lengthy one, summarized through these two excerpts.

1 Bruce A rectangle…its vertical lines are longer than its horizontal lines.
2 Ms. J Uh, okay. Write that down… He said the vertical line is longer than the horizontal. So this is an assumption he is putting out there. He’s making a conjecture that, to be a rectangle, the vertical line must be longer than the horizontal… What’s another property of a rectangle that you can know? And we’re just putting them up here. Some of these may, we may decide are not good definitions, and we might want to, um, modify.

<several minutes of talk>

3 James Uh, I was going to say two lines are…horizontal and two lines are vertical…The two, uh, the two lines that are horizontal are, um, equal, and the two lines that are vertical are equal, too.
4 Jason What about, about parallelogram?
5 Ms. J It’s a parallelogram? Jacob, Jacob.
6 Jacob Uh, there are four right angles.
7 Ms. J There are four right angles, okay? Is there anything else you want to add to the definition?
8 Student Yes, please.
9 Joan Oh! <raises hand>
10 Ms. J Yes.
11 Joan It’s like a square, but longer.

As in Ms. Shanna’s class, students start from their basic colloquial understanding of rectangles as holistic images that are qualitatively different than squares. Ms June responds by naming Bruce’s statement as conjecture, by asking for another property of rectangles, and warning that some of the statements that were on public display would not be true in the end. By asking for a definition, then calling a proposed definition a conjecture and then asking for properties, Ms June leaves the difference between these terms unclear. Note also the parallel to her written definition on the assessment that lacks mathematical precision with the omission of the basic premise that the object is a quadrilateral. It is important to note in this classroom, it is a student who offers a counterexample, but while Ms. Shanna was able to leverage her counterexample to lead the students to clarify their thinking, Ms. June does not explicitly disambiguate the counterexample from other properties. In the end, it is not clear what was left “standing” as a definition of rectangle.

On the second day of our observations, Ms June begins with a review:

12 Ms. J Who knows a definition for a rectangle? Who has a definition for a rectangle? Jill?
13 Jill It’s like a square but the base...
14 Ms. J It’s like a square.
15 Jill The width and the length are the same and the height is the same too but if you add them all up.
16 Ms. J Okay, you’re saying the length and the width are the same?
17 Jill Which one is the length and which one is the width?
Ms. J: Um, Jill I appreciate what you’ve done. Hold on. Andy, can you add on?

Andy: Yeah. She’s right. It’s like a square. But the width of it is a little bit longer and so that’s what makes it a rectangle.

Ms. J: Okay. The length and the width are two different dimensions. And traditionally we would say the length is longer, but using what property does it, that we can change the length and width around. What property allows us to change them?

Myra: Commutative.

Ms. J: Commutative property of addition. Okay. Now, what is the quadrant plane?

Ms. J’s moves still do not lead students to a mathematically precise definition of a rectangle. Instead, she gets sidetracked into talking about labeling conventions. Furthermore, she goes on to incorrectly invoke the commutative property of addition as the reason “we can change the length and width around.” This is much in line with Hill and colleagues’ finding that low MKT was associated with teacher errors.

**Discussion and Conclusion**

This post-hoc analysis of data from a teacher professional program examined MKT in the action of teachers’ facilitation of mathematical argumentation in their middle school classrooms. We found that teachers in the program represented a broad range of MKT backgrounds and that teachers’ MKT strongly predicted the amount of argumentative talk in their classrooms. We examined the discussions of a high-MKT/high-talk classroom and a low-MKT/low-talk classroom, which reveal how teachers may leverage their knowledge to focus classroom discussion, select appropriate mathematical threads to follow in the discussion, provide mathematical precision, and avoid confusing errors. Future analyses will examine other ways that MKT is used in action to explain the finding that MKT supports greater argumentative talk.

These findings have important implications for research and practice in teacher professional development. While it is an intuitively appealing notion that teachers’ MKT is important for classroom practice, several studies have failed to find strong direct correlations between teacher knowledge and student achievement; it is therefore important for the field to examine the ways in which MKT helps, is irrelevant to, or even hinders student learning in the context of the full system of classroom instructional resources (Shechtman, Roschelle, Haertel & Knudsen, in press). In the MQI tradition, this study helps to illuminate where and how MKT is important specifically in moment-by-moment practice. Future research will need to continue to unpack how MKT is used in the action of teaching, the impacts this may or may not actually have on student achievement, and how these findings can be used to improve teacher training.

---

As part of a larger study, which defined mathematical knowledge as participation in mathematical processes, we investigated the mathematical knowledge of a prospective secondary mathematics teacher and how he used mathematical processes in his teaching, both as a preservice teacher and later in his first year of teaching. His personal mathematics was characterized by a tendency not to place primary emphasis on mathematical processes. His stated core beliefs about mathematics teaching might have been expected to spur a more intensive use of mathematical processes but, as he envisioned these beliefs, did not conflict with the role of mathematical processes in his mathematics. The result was classroom mathematics that echoed personal mathematics and made little use of mathematical processes.

Introduction

Of growing importance in the area of mathematics teacher education are the connections among what teachers know, what they do in the classroom, and what students learn. Current research has made progress in assessing relationships between what elementary teachers know and their students’ mathematics achievement (Hill, Rowan, & Ball, 2005). Other studies (e.g., Eisenberg, 1977; Monk, 1994) examined the relationship of secondary mathematics teachers’ knowledge to students’ achievement through proxies of courses, GPAs, years of experience, and degrees. Researchers have also attempted to measure secondary mathematics teacher knowledge through tests of content knowledge (e.g., Eisenberg, 1977; KAT, 2005). This study investigated the relationship between the mathematical knowledge of teachers and how they draw on that knowledge in their teaching.

Researchers have conceived mathematical knowledge in various ways including knowledge of school mathematics, knowledge of mathematics for teaching, and knowledge of collegiate mathematics. Often mathematical knowledge is represented as sets of procedural skills and conceptual understandings, but for both theoretical and pragmatic reasons, we follow Zbiek, Peters, and Conner (2008) and cast mathematical knowledge as the ability to participate in mathematical processes. Doing so allowed us to look at mathematical knowledge across different subject matter in a generalized form. We selected processes that are essential to mathematical thinking: defining, justifying, generalizing, and representing. We distinguish these processes from their products: definition, justification, generalization, and representation. The goal of our research was to characterize novice secondary mathematics teachers’ use of these processes and products in their personal problem solving and in their classrooms and to characterize the relationship between them. We chose to focus on novice secondary mathematics teachers because it allowed us to observe the challenges that novice teachers face in using their own mathematical knowledge in their teaching practice. We observed their use of mathematical processes.
processes over an extended period of time, affording us the opportunity to characterize the enduring features of their mathematical knowledge.

The influence of mathematical knowledge on what happens in the novice teacher’s classroom may be overshadowed by their focus on survival. Research and theory have suggested that novice teachers usually focus first on classroom management, then on teaching concerns and student concerns (Fuller & Brown, 1975; Fuller, 1969; Berliner, 1989, as cited in Berliner, 1991; Kremer-Hayon & Ben-Peretz, 1986). Studies of novice teachers show that issues of student behavior and classroom management are in the top three concerns of novice teachers (Adams & Krackover, 1997; Pigge & Marso, 1992; Veenman, 1984; Westerman, 1990). The need to attend to survival issues may account for research findings that novice teachers are often less attentive to monitoring student learning and adjusting instruction to meet student needs (Artzt & Armour-Thomas, 1997; Westerman, 1990) than to concerns about their actions in their role as teachers. However, Levin, Hammer, and Coffey (2009) observed that some novice teachers do attend to student thinking even before resolving classroom management issues. They suggest that attention to how a novice teacher is framing what is occurring in the classroom may account for why some novice teachers seem to attend to student thinking and some do not.

One factor that would seem to impact the way teachers frame what is occurring in the classroom is their set of beliefs about mathematics and its teaching. The relationship between teachers’ beliefs about the nature of mathematics and the nature of teaching mathematics and their instructional practice is complex (Thompson, 1984, 1992). Other research implies that teachers’ beliefs influence their instructional practice (Pajares, 1992; Thompson, 1984, 1992). For instance, Thompson (1984) found a consistency between the practices of three junior high mathematics teachers and their beliefs about the nature of mathematics and their instructional practice. Thompson concluded that “[m]any factors appear to interact with the teachers’ conceptions of mathematics and its teaching in affecting their decisions and behavior, including beliefs about teaching that are not specific to mathematics” (p. 124). Likewise, in a study of six elementary teachers, Raymond (1997) found some inconsistencies between teachers’ professed beliefs and their instructional practice, and she identified several categories of factors that influenced these teachers’ practices. These studies are illustrative of research suggesting that teachers’ beliefs play an important role in their instructional practice but that these beliefs are just one of many factors that influence practice.

Green’s (1971) metaphor for belief systems provides a lens for examining the relationship between beliefs and instructional practice. Green identified three dimensions of belief systems that deal with how beliefs are held including the psychological strength of beliefs. Central or core beliefs are strongly held beliefs that are resistant to change. The centrality of beliefs can be used to examine the relationship between teachers’ beliefs and their instructional practice (see Beswick, 2007).

**Methodology**

This study is one of several case studies we conducted with prospective secondary mathematics teachers documenting how prospective/novice teachers use mathematical processes and act on the products of those processes in their personal mathematics and in their teaching. Each teacher who participated in the study engaged in task-based interviews and several series of teaching observations spread over a span of four to five semesters. Each observation included pre-observation and post-observation interviews focused on clarifying participants’ use of processes. This paper reports on the case of Russ (a pseudonym). At the close of data collection,
Russ was a full-time first-year teacher of mathematics at a middle school in an Eastern state. Over the 2.5 years of involvement in the study, Russ participated in five 1.5 to 2 hour task-based interviews, and 13 observation cycles. These cycles included asking Russ about the extent of his agreement with several statements about the nature of mathematics and mathematics teaching.

¹ An observation cycle consists of a pre-observation interview, an observation, and a post-observation interview. For observation cycles on consecutive days, the post-observation interview for day n occurred at the same time as the pre-observation interview for day n + 1.

Interviews were focused on clarifying Russ’s use of processes in his personal mathematics and his teaching. All task-based interviews were videorecorded, transcribed, and annotated. The pre- and post-interviews and the classroom observations were audiorecorded, transcribed, and annotated with two observers’ notes and still photos. Transcriptions were coded for instances of Russ’s use of the processes and/or products. After initial coding, the coded instances across all transcripts were elaborated and then categorized into the four process categories. These categories were then analyzed for emerging patterns of use of the processes and products, for Russ’s personal mathematics and separately for his teaching. The patterns were then checked for consistency across his personal mathematics and teaching.

### Results

We observed Russ in two preservice settings in the context of second-year algebra courses and during his first year of teaching. At the time we observed his first year of teaching, Russ was teaching an introductory algebra course in a full-year block schedule (double period) to middle school students. Throughout our observations, Russ displayed refined skills in classroom management that are atypical for novice teachers. Russ was remarkably comfortable in front of his class, commanding the attention and respect of his students naturally. In the rare instances in which students were not behaving as Russ would have preferred, he was quick and effective in addressing the issue and proceeding with his lesson. Russ was reflective of his own role as a teacher and revealed strong stances regarding this role.

**Russ’s use of mathematical processes**

Our analysis of data revealed consistencies in Russ’s mathematical processes across the 2.5 years of data gathering. Following are illustrative examples of our observations.

Russ’s use of processes in personal mathematics. Russ’s generalizing and justifying are illustrative of his use of processes in his personal mathematics. Russ’s personal mathematics is often informal. When Russ justifies his claims, he typically does so by reasoning from a limited number of cases: checking algebraic results by substituting a few numerical values and verifying the generality of a geometric observation by checking a few instances. Once he has checked a few instances, he makes no attempt to reason formally to a general result. For example, when Russ is asked to relate a given formula for the area of a given equilateral triangle to a geometric problem on which he is working, he justifies that \( \frac{(x-d)^2\sqrt{3}}{4} \) represents the area of a particular triangle by substituting 1 for \( x \) and 2 for \( d \) and verifying that the result makes sense for the related diagram. He engages in no further verification of the formula.

Russ’s pattern in generalizing is that he generalizes to a set of mathematical cases based on examining a small subset of those cases. Although Russ is confident in generalizing and stating generalizations, he makes no attempts to justify those generalizations unless prompted to do so, and even though his explanations are usually in the ballpark, they are typically not sufficient mathematically. For Russ, generalizing seems to be about pattern recognition, both when he is generalizing (looking for patterns) and when he applies generalizations (extending the form of a generalization to a new situation without examining the applicability of the generalization). Russ does not prove his generalizations for a global applicability; rather he tests a few cases for consistency. In the context of a task-based interview (see Figure 2), upon observing the graph associated with the square diagram in Figure 2a, Russ interprets the shape of the graphs as reflecting the fact that the rates are increasing faster in some places, but he does not seem to recognize that this shape is related to the positioning of sides of the square in relation to line \( l \). He immediately generalizes the curved graph for the square example (see Figure 2a and Figure 2c) to the triangular example (see Figure 2b and Figure 2d) without accounting for the effect on rates of change of differences in orientation of the sides.

Russ’s use of processes in classroom mathematics. In class, it is not uncommon for Russ to ask students to make generalizations based on an insufficient set of cases. For example, one generalization that Russ aims to teach is that the vertex of a function of the form \( f(x) = |x - b| + c \) is the point \((b, c)\). Having identified the vertex of only one example, \( y = |x| \), Russ asks students to guess the identity of the vertex of \( y = |x-1|+3 \) without previously exposing them to functions that have a vertex that is not at the origin.

Although Russ is confident in stating generalizations in his classes, he does little generalizing and makes no attempts to justify generalizations unless specifically prompted by students to do so, and even though his explanations are usually in the ballpark, they are typically not sufficient mathematically. For example, following up on Russ’s generalizations, the interviewer asks, “how do you know that the absolute value function is V-shaped and how do you know that a parabola is U-shaped?” Russ explains that the graph of the absolute value function consists of two lines with the same constant rate of change, and that the parabola is not V-shaped because “the rate of change from point to point is different.” Later he adds to his argument that a parabola is U-shaped stating that “I know they’re not straight and so if they’re somewhat curved then they have to be that U.” Russ presents the pieces of an argument, relying (not unexpectedly) on what is visible, but he does not structure his argument into a coherent whole.

Consistency in Russ’s processes. In his personal mathematics, Russ’s informal reasoning can be strong but is not infrequently less than accurate, and it seldom relies on formal mathematics. Without verifying his claims with formal mathematics, these inaccuracies at times go unrecognized. These same features also seem to characterize his classroom mathematics.
Russ’s Beliefs

Our observations of Russ’s problem solving showed that most of the time he did not engage in mathematical processes as we defined them but at other times he showed the capacity to do so. We viewed his lack of engagement in processes as a preference or tendency and thought it possible that his beliefs about processes or about teaching were dominant in his problem-solving strategies.

Figure 2. Given the diagram and a description in Figure 2a the interviewee was asked to generate a function rule for the shortest distance from the point P to the line l as a function of u. A similar question and set of directions accompanied the diagram in Figure 2b. Russ is provided with the computer-generated graph in Figure 2c for the square and he generalizes and generates the graph for the triangle (Figure 2d)

Russ’s beliefs about processes. Russ seldom chooses to prove, generalize, or define mathematically in his personal mathematics or in his classroom mathematics. We looked through the data for evidence of how Russ viewed these processes, and found that he referenced them very little unless we directly solicited his views on the processes. When asked, Russ expressed views that seemed to suggest an appreciation for the importance of proof, although he did not make statements recognizing the processes of proving and defining as important to his mathematics or that of his students. Although much of his personal and classroom mathematics

seemed to be based on reasoning from examples, he strongly disagreed with the statement that “It is not important to check the validity of the procedure if you have used it before and it has always worked,” and he stated that, “I would strongly disagree with that cause um it could be coincidence that it’s always worked.” Regarding proof, he stated: “I think proofs are always necessary” and “Proofs generally helped me to agree with mathematics … with things that are presented to me.” He expressed a view that mathematics was about much more than symbols and calculations: “It’s understanding the importance of the symbols and calculations and how, and why, you know, why do I do these calculations.”

Russ’s core beliefs. Russ’s use of processes in his teaching did not reflect the statements he made in interviews related to the use of the processes. We wondered whether, perhaps, Russ’s beliefs about teaching could account for these discrepancies. In order to explore this hypothesis, we examined our data to investigate Russ’s core beliefs—beliefs that seemed to guide his instruction and that endured throughout our data-gathering.

Russ’s most dominant core belief related to his teaching was that his role as a teacher was to support the development of the whole person in his students. This commitment was strong and seemed to regularly underpin his instructional decisions. Russ invariably gave his students positive reinforcement when they responded in class discussions. When those responses were not correct or not on target, Russ would typically respond with something like “I see what you mean.” He expressed his reason for one such interchange, saying: “I didn’t want to quell their thinking.” He elaborated on this perspective:

And that’s, I guess that’s too kind of what I’m trying to do is that there’s a baaaad, bad connotation when you say mathematics. You either love it or you hate it. And I, I want a lot of loving. I want a lot of loving going on in this math class. So I, I try and push that and maybe sometimes it’s by not talking about math. Talking about maybe how math helps me understand the world better. ... You know and so it just, it kind of helped them see that um, help them be better decision makers, be better people.

Russ’s commitment to the personal development of his students was also exhibited in his resolve to help his students see that mathematics is useful in their lives. A second core belief was that mathematics should be relevant to his students. He declared: “… what they learn in any class has no meaning unless you can somehow see a connection maybe to life.” He carries out this resolution by selecting tasks that are embedded in situations that have real-world features. During our observations of his first year of teaching, every lesson was somehow connected to one such situation: Aunt Edna’s Gourmet Cookies set up a business situation in which Russ engaged his students in thinking about x-intercepts and y-intercepts; Turtle Race, to set up talk about slopes of linear functions, drew on the vision of turtles racing each other positioned on their hind legs; and Leaky Faucet involved a data-gathering experiment that provided students with a real-life based function.

A third core belief for Russ was that students should have a “deeper understanding” of the mathematics they encounter. He does not define what he means by “deeper understanding” but offers an example: “But what I’m hoping to do is to get them to understand you know um just, just a little bit deeper you know the three comma four in parenthesis means that on the x-axis it goes over three.” This example and our observations of his classes suggested to us that his meaning for “deeper understanding” is different from what we might have expected.
Relationship of Beliefs to Mathematical Processes

We identified what we did as Russ’s core beliefs about goals for teaching mathematics both because of what he said and because they seemed to guide what he did in the classroom. We hoped to see a relationship between these beliefs and how Russ used the targeted mathematical processes in his classroom mathematics. His overarching goal of helping his students become better people, his commitment to real-world connections, and his resolve to develop deeper understanding could have led to the need for intense use of mathematical processes. This was not the case, however. Instead, we found that his use of the targeted processes in his classroom conformed closely to the way that he engaged these processes in his personal mathematics. Justifying, generalizing, and defining seems to us to be at the heart of deeper understanding of mathematics, and they were not present as processes in much of Russ’s classroom mathematics.

Russ has a relaxed view of mathematics. He does not seem to feel a need to pin down every bit of mathematics; he is content to leave loose ends. This view of mathematics and Russ’s way of engaging with the targeted mathematical processes did not conflict with his core beliefs about mathematics teaching. One reason for this lack of conflict is that both his goal of developing the whole person and his goal of having students see that mathematics is useful in their lives are, as interpreted by Russ, not tied specifically to mathematics. For Russ, these goals are focused on student affect rather than on mathematical goals. Russ’s view of what it meant to help his students become better people centered on helping them learn to interact appropriately with others—a behavior he expertly modeled. His commitment to real-world connections, which could have engaged students in substantial justifying why a real-world situation could be modeled as he suggested, used real-world settings as incidental backdrops instead of situations that necessitated the mathematics. The lack of conflict for him between his goal of students gaining a “deeper understanding” of mathematics and his ways of engaging in processes becomes understandable only when we consider Russ’s limited vision of “deeper understanding.” His resolve to develop deeper understanding, which could have required consistent justifying, generalizing, and defining, instead manifested itself in his simply asking the question “Why?” without probing students’ responses. Russ’s beliefs about teaching did not conflict with the ways in which he used processes. If one’s use of mathematical processes does not conflict with his or her beliefs related to teaching mathematics, it is natural that we would see the processes play out in the classroom as they do in one’s personal mathematics. This was the case for Russ.

Even though there is no evidence of conflict between the three core beliefs held by Russ and his use of processes in his personal mathematics, as well in his classroom mathematics, we posit that he may be on the verge of discovering a conflict between these two constructs. Even in his first semester of teaching, Russ was already aware of a possible lack of understanding of the mathematical content by his students. He stated that he was not happy with his students’ grades and he interpreted this poor performance as evidence of a lack of the type of understanding he hoped to see in his students. He further elaborated, “So I would look at a test and it wasn’t that there were a lot of silly mistakes it was a lot of no clue what to do. And so I thought okay maybe I need to start pushing there them to really justify what they tell me in class and not just take their guesses.” Russ’s solution for this lack of understanding was to ask the question “Why?” to his students in the classroom. However, he did not seem to have a clear plan to deal with the myriad of responses to his queries. He was observed to solicit multiple responses from his students, but then, as a rule, he did not ask his students to clarify their answers. As a result, it is possible that this perceived lack of understanding may persist for his students and may evidence itself in continued poor performance by the students on quizzes and exams. In the future, if Russ

continues his pattern of being reflective of the students’ performance, then he may notice that the student performance is not improving. This may prompt him to question the sufficiency of his strategy of just asking the question “Why?” Doing so would likely create a conflict between his use of the processes and his belief that students should have deeper understanding of the mathematical content.

A CASE STUDY OF CHINESE ELEMENTARY TEACHERS’ KNOWLEDGE OF CURRICULUM FOR MATHEMATICS TEACHING

Tingting Ma
Texas A&M University, College Station
ting@tamu.edu

Gerald Kulm
Texas A&M University, College Station
gkulm@tamu.edu

This study investigated Chinese elementary teachers’ knowledge of curriculum for mathematics teaching (KCMT). Through qualitative interviews, we identified strands of KCMT: orientations, implementation, connections, and resources. The results show the importance of the sequence of topics in mathematics curriculum for different grades and contents of mathematics curriculum materials at a certain grade and at the previous and following grades. Findings suggest that professional community activities and the alignment of written curriculum with intended curriculum contribute to curriculum implementation. We also formed insights for the connections between KCMT and other components of mathematical knowledge for teaching and resources for obtaining KCMT.

Introduction

Chinese students have repeatedly demonstrated relatively superior performance than their U.S. counterparts on international tests (e.g., Lapointe, Mead, & Askew, 1992). Among numerous explanations, Chinese teachers’ profound understanding of subject matter knowledge and markedly different pedagogical content knowledge from the U.S. teachers may account for Chinese students’ superior mathematics performance (An, Kulm, & Wu, 2004; Ma, 1999).

Teachers’ subject matter knowledge and pedagogical content knowledge as mathematical knowledge required for effective teaching, has been a research focus (e.g., Ball & Bass, 2000; Fennema & Franke, 1992; Hill, Rowan, & Ball, 2005). In studies on mathematical knowledge for teaching, however, knowledge of curriculum for mathematics teaching (KCMT), lacks substantial research.

In this study, we examined Chinese elementary teachers’ KCMT, focusing on their perspectives on KCMT, the connections between KCMT and knowledge of content and teaching and between KCMT and knowledge of content and students, and their ways of obtaining KCMT. The following research questions guided this study: 1) What are the perspectives on KCMT from Chinese elementary teachers? 2) How are KCMT and knowledge of content and teaching and knowledge of content and students connected in the cases of Chinese elementary teachers? 3) How can Chinese elementary teachers obtain KCMT?

Theoretical Perspectives

Our theoretical perspectives were derived from frameworks on curricular knowledge (Shulman, 1986) and mathematical knowledge for teaching (Ball, Hill, & Bass, 2005; Ball, Thames, & Phelps, 2008).

According to Shulman (1986), curricular knowledge is composed of three components: alternative curriculum knowledge, lateral curriculum knowledge, and vertical curriculum knowledge. Alternative curriculum knowledge means knowledge of alternative available curriculum materials for instructing a specific subject or content within a grade; lateral curriculum knowledge indicates a teacher’s ability to connect the content of a specific subject or content with other subjects or content being studied simultaneously by students; and vertical
curriculum knowledge, which means “familiarity with the topics and issues that have been and will be taught in the same subject area during the preceding and later years in school, and the materials that embody them” (p. 10). With KCMT, teachers are able to discriminate and give priority to mathematical goals and topics (Kilpatrick, Swafford, & Findell, 2001).

In characterizing categories of teacher knowledge base, Shulman (1987) claimed that “curriculum knowledge, with particular grasp of the materials and programs that serve as ‘tool of the trade’ for teachers” (p. 8). Specifically, curriculum knowledge indicates knowledge about “the full range of programs designed for the teaching of particular subjects and topics at a given level, the variety of instructional materials available in relation to those programs, and the set of characteristics that serve as both the indications and contraindications for the use of particular curriculum or program materials in particular circumstances” (Shulman, 1986, p. 10).

In the most recent efforts to provide a map of mathematical knowledge for teaching, Ball and her colleagues (2005, 2008) developed Shulman’s ideas of CK and PCK. In the domain of pedagogical content knowledge, three components were included: knowledge of content and teaching, knowledge of content and students, and knowledge of curriculum (Ball et al. 2005). However, Ball and her colleagues further raised questions about the nature of KCMT:

We have provisionally placed Shulman’s third category, curricular knowledge, within pedagogical content knowledge …. We are not yet sure whether this may be a part of our category of knowledge of content and teaching or whether it may run across the several categories or be a category in its own right (pp. 402-403).

**Methods**

**Participants**

Four Chinese teachers participated in the study. They came from two elementary schools in urban and suburban school districts of East China, teaching children with various socio-economic backgrounds. The four participants were recruited according to the following criteria: first, teaching mathematics at an elementary school; second, having at least ten years of teaching experiences.

**Procedures**

Prior to the interviews, we adapted a list of open-ended questions (English version) from the interview protocol employed by Kaffuman (2002) and examples of grounded theory interview questions (Charmaz, 2000). During the interviews, the participants were also asked additional relevant questions which aimed to get more details from their answers.

**Data Analysis**

The interviews were transcribed and translated by the first author into English within one week of the interviews. The transcripts were coded and analyzed using grounded theory (Strauss & Corbin, 1990). From a grounded theory perspective, the transcripts were coded in two steps: first, initial or open coding, which helped us discover views of participants and decide how to analyze the transcripts; second, selective or focused coding, in which the most frequently occurred initial codes were used to sort, synthesize, and conceptualize all the transcripts (Charmaz, 2002).

Through examining the transcripts closely through line-by-line coding, the emergence of themes were pursued and conceptual categories began to be constructed to explain and...
synthesize the data. After the transcripts of the first two participants were coded and categorized, the categories were compared with each other to synthesize the overall patterns of the interviews. During the coding of the next two participants’ transcripts, the categories were refined through comparative processes. When the coding of transcripts and construction of conceptual categories were completed, the categories were integrated into a theoretical framework (Charmaz, 2000; Glaser, 1992; Glaser & Strauss, 1967).

Results

This section describes four central themes emerged from data analysis: orientations, implementation, connections, and resources. These central themes characterize the participating Chinese elementary teachers’ KCMT.

Orientations

Remillard and Bryans (2004) found that teachers’ orientations toward curriculum materials influenced how they used the curriculum. Orientations toward curriculum refers to “a set of perspectives and dispositions about mathematics, teaching, learning, and curriculum that together influence how a teacher engages and interacts with a particular set of curriculum materials and consequently the curriculum enacted in the classroom and the subsequent opportunities for student and teacher learning” (Remillard & Bryans, p. 364). In this study, “orientations” was used to indicate elementary teachers’ stance towards KCMT, composed of their perspectives about mathematics, mathematics teaching and learning, and mathematics curriculum. The results show that participants’ orientations centered on three major categories: connotations, implications, and levels.

Connotations. Participants described the connotations of KCMT, composed of principles of mathematics teaching, content areas, methods, techniques, and transition. T1 responded by stating principles of mathematics teaching. T4 also asserted, “We have a national-wide adopted Compulsory Education: Mathematics Curriculum Standards (italics added and abbreviated hereafter as the Standards)”. T1 stated, “I think of content areas in elementary math such as number and algebra, space and graphs … and statistics and probability”. T2 mentioned the arrangement of topics in curriculum materials. T1 responded, “Teaching methods and techniques, like, problem posing, practice, communications and discussions … including teacher-student and student-student [discussions]”. Participants also made references to transition as an important connotation of KCMT. For example, T1 reported the transition from elementary mathematics curriculum to middle school mathematics curriculum. Similarly, T3 mentioned the transition from kindergarten mathematics curriculum to elementary mathematics curriculum and the transition from elementary mathematics curriculum to middle school mathematics curriculum.

Implications. Participants shared their orientations in terms of implications of KCMT. Positive implications included a bridge between teaching and learning, a foundation for encouraging students’ thinking, and the premise for achieving teaching and learning objectives of the lesson. T1 regarded KCMT as “a medium for the interactions between teacher and students”. However, more responses focused on negative implications. For instance, T2 reported an implication of “memorization,” and structured ways of teaching with teacher dominance of the class. Similarly, T3 stated an implication of “duck feeding,” the outdated teacher-centered style. T4 echoed this point by stating “fixed without flexibility,” serving for passing examinations and “not helpful for student development”.

Levels. Two levels of KCMT were reported by participants, including KCMT at the macro level and KCMT at the micro level. KCMT at the macro level refers to the sequence of topics in mathematics curriculum. KCMT at the micro level indicates the content of curriculum materials. The most important approaches mentioned by the participants to achieve macro-level KCMT included reading textbooks and teacher manuals for different grades and gaining experience from teaching all grades in an elementary school. Professional community activities in a school or district were also reported helpful.

Major approaches to get micro-level KCMT consisted of familiarity of textbooks at a certain grade and also at the previous and following grades, gaining experience from teaching one grade and participating in teaching and research activities at the grade level. In those activities, as T4 reported, teachers “focus on one copy of the curriculum materials we [teachers] are using and discuss the overall framework and lesson plans for each unit”.

Implementation

Implementation of intended curriculum to mathematics classrooms is a key dimension in the participating Chinese elementary teachers’ KCMT. Only through implementing the intended curriculum to actual teaching can teachers apply their KCMT.

According to the participants, there is not a direct link between intended curriculum and implemented curriculum. All participants agreed that the intended curriculum or the Standards provides a general guidance or blueprint with basic requirements and objectives. The main ideas offered by the intended curriculum serve as orientations for teachers. However, the question is, as T2 said, “how to teach?” T4 also held a similar view: “[The intended curriculum is] not a detailed instruction on how to teach”.

In order to transform from intended curriculum to implemented curriculum, participants reported several key factors. Two categories emerged from the interviews: professional community activities and the alignment of written curriculum with intended curriculum.

Professional community activities. Professional community activities include teaching and research activities at the grade, school, or district level. According to T1, professional community activities at the district level are more general than activities at the grade level. T3 also stated that grade-level activities are more practice-oriented: “Teachers in the teaching and research group [at our grade] discuss the content together. For instance, in the treatment of examples, some issues emerged after … [our] discussion, which I ignored or did not realize the importance before”.

As stated by T4, the grade-level professional community activities usually last for “half an hour from Monday to Thursday”. T1 reported that school-level professional community activities are held “every Tuesday,” and the district-level activities occur once “for every semester”. It is clear that the most frequent professional community activities are grade-level teaching and research group activities, and the least frequent are district-level activities.

Alignment between written curriculum and intended curriculum. A key emergent issue in curriculum implementation was that teachers can understand intended curriculum by reading textbooks and teacher manuals due to the alignment of written curriculum with intended curriculum. T3 reported, “I do not read the intended curriculum. The textbooks provide objectives for teaching each unit. The objectives of each unit in textbooks represent the objectives of the intended curriculum”. T4 also stated, “Aligned with the Standards, teacher manuals describe the requirements for each unit. In my teaching, I followed teacher manuals closely to ensure the achievement of the requirements in the Standards”.

Because of the alignment between written curriculum and intended curriculum, these Chinese elementary teachers were not faced with any challenge in the transformation from intended curriculum to implemented curriculum at the stage of understanding intended curriculum. As reported by the participants, Chinese elementary teachers do not have to read and understand the intended curriculum as much as they read textbooks and teacher manuals. Instead, they read the intended curriculum as a reference book when teachers, as T3 illustrated, “unsure about some points or teachers show disagreements about some issues”.

**Connections**

Participations described connections between KCTM and knowledge of content and teaching and between KCTM and knowledge of content and students.

*Connections between KCTM and knowledge of content and teaching.* Two categories emerged from the interviews: knowledge as continuous development, and flexible treatment of curriculum materials. According to the participants, an important influence of their KCMT on knowledge of content and teaching is viewing mathematics knowledge as continuous development in teaching. For example, T3 stated:

*If you know what needs to be taught in the following classes, you know where you are leading the students .... Let’s say we have beads. If you have knowledge of elementary math curriculum, you will know how to make a string of beads other than separated beads. In that way, you will have a better idea about how to teach in class.*

Furthermore, T1 reported how KCMT is connected with their knowledge of content and teaching: “I learned what prior knowledge is connected to new knowledge. When I teach a new topic, usually I introduce new knowledge by reviewing the prior knowledge”. It can be seen that instead of focusing on isolated bits of mathematics knowledge, these Chinese teachers locate each piece of knowledge in the whole picture of elementary mathematics and view mathematics knowledge as continuous development.

Participants described that their treatment of curriculum materials in teaching mathematics has also been impacted by KCMT. As T3 shared:

*Since I have knowledge of elementary math curriculum, I will delete some parts and add some other parts as adjustments [in mathematics teaching]. At the sixth grade, we will teach problem solving on fraction and equation solving .... The textbook compilers lowered the learning requirement for computation. Only one-step computation is required in the fifth-grade textbook, such as 2x=10 or 2+x=10. Since I am familiar with the math curriculum, I know that problem solving skills and equation solving are important for student learning of algebra such as variables in the future. Therefore I will provide more challenging problems in teaching [at the fifth grade], such as 2x+5=10.*

Also, T3 “intend[ed] to informally introduce some topics at lower grades”. It is shown that due to the impact of KCMT, participants treat curriculum materials in a more flexible way.

*Connections between KCTM and knowledge of content and students.* Connections between KCMT and knowledge of content and students were reported in the interviews. According to the participants, understanding problems and difficult points presented in teacher manuals and

---

preparing lesson plans for students help them anticipate common errors and difficulties of students.

T2 shared the experience of preparing lesson plans for students:

*Now we should be able to, according to the principles of the Standards, prepare lesson plans for students. Lesson plans should consider how students are likely to understand the topic and anticipate their answers to questions. [When preparing lesson plans,] teacher should take into account student thinking, and their possible answers and approaches. Also, teacher may think about the balance between the amount of time for questioning and for students to think about and answer questions. So I think knowing elementary math curriculum helps to understand student learning.*

However, connections between KCMT and knowledge of content and students are not as strong as connections between KCMT and knowledge of content and teaching. Three participants reported that their knowledge of content and students mainly come from their former students at the same grade they taught before. T3 added that asking for suggestions from teachers who already taught the same topic impacts their knowledge of content and students.

**Resources**

Participants reported resources to obtain KCMT. The most frequently reported resources included textbooks and teacher manuals. All the four participants emphasized the importance of reading textbooks and teacher manuals. T4 stated, “[Elementary teachers should] spend a lot of time reading textbooks and teacher manuals”. T4 suggested, “Read textbooks and teacher manuals everyday”. Besides time and frequency of reading textbooks and teacher manuals, participants also emphasized the expected goal of reading. As T3 reported, “[Elementary teachers should] read all twelve copies of elementary math textbooks and study the connections between and among mathematical topics, the extent [of teaching] and learning objectives”. Furthermore, T2 pointed out the necessity of reading textbooks over and over again:

*I will read the fifth-grade textbooks again even if I read the fifth grade textbooks before or I already taught the fifth grade. Every time you read the textbooks, you will have different reflections and learn new knowledge. As Confucius said, if you can gain new insights through restudying old material, you are qualified to be a teacher.*

The second most frequently reported resources were videos of mathematics teaching and open classes. Both T3 and T4 said that watching videos of mathematics teaching and attending open classes help teachers gain KCMT, especially new teachers or pre-service teachers. T2 reported reflective journals as another resource, and explained as follows,

*When I write down my reflections, I will analyze the classes I taught and find theoretical support for the success or deficiency of a class. Every elementary math teacher has to write lesson plans, but it is better to write something more like reflective journals of classes and analyses of open classes. Writing will motivate elementary math teachers to learn and develop knowledge. It is a process of accumulation. Also, teachers may have chances to participate in writing competitions and even publish their reflective journals.*
Other resources mentioned by participants included the *Standards*, teaching and research activities, online resources, books, lectures, colleagues, experienced teachers, courses in teacher preparation programs, other subjects such as reading and science, exemplary lesson plans, and teaching classes while inviting other teachers to attend and provide comments and suggestions.

**Discussion**

Through qualitative analysis of interviews with four Chinese elementary teachers, we generated a description of KCMT, and identified its strands, including orientations, implementation, connections and resources. As an exploratory study, it serves to broaden our understanding of KCMT.

Conceptually, this case study contributes to deepen our understanding of the role of KCMT in the map of mathematical knowledge for teaching with some evidence that KCMT is connected with other components of mathematical knowledge for teaching. More importantly, it highlights the importance of KCMT and serves as a starting point for studying KCMT.

In addition, the findings from this study may be helpful for professional development of elementary teachers by illustrating important resources for obtaining KCMT. It offers insights for elementary teachers to improve their KCMT by such means as reading textbooks and teacher manuals, watching videos of mathematics teaching, and keeping reflective journals on their teaching.

Limitations were noted in this study. For example, the small number of participants may not represent the population of Chinese elementary teachers. In addition, different from their U.S. peers, Chinese elementary teachers use the national-wide adopted curriculum materials. In fact, some researchers suggested that the lack of a common and coherent curriculum hampers mathematics teaching and learning in the U.S. (e.g., Schmidt, Houang, & Cogan, 2002). Even with the limitations, however, this exploratory study provides an opportunity to get a look into KCMT.

ASSESSING HOW PRE-SERVICE TEACHERS UNDERSTAND BALANCE THROUGH
CLINICAL INTERVIEWS AND A VIRTUAL TOOL

Jennifer Wilhelm  Shirley Matteson  Xiaobo She
University of Kentucky  Texas Tech University  Texas Tech University
jennifer.wilhelm@uky.edu  shirley.matteson@ttu.edu  xiaobo.she@ttu.edu

Our study was enacted in mathematics education classes with pre-service teachers (PSTs). This research focused on videotaped PSTs’ interview responses used to assess their understanding of balance when challenged with tasks involving virtual manipulatives. PSTs relied on visual cues to implement procedures that were often inappropriate for the task at hand. When confronted with missing-value balance tasks, 47% of the PSTs attempted an incorrect procedure using direct proportions while others employed an incorrect fractional method. Only one PST systematically solved the tasks, where he invented an inverse proportions model. Most interviewees relied on intuition and qualitative guess and check reasoning.

Introduction

This study investigated pre-service teachers’ understanding of the “big idea” (Wiggins & McTighe, 2005) of balance, an idea that transcends the isolated worlds of pure mathematics and science. Our research paper concerns using the context and big idea of balance to assess pre-service teachers’ understandings of concepts related to equilibrium. We claim that one cannot understand “balance” without understanding the physical conditions of equilibrium and the mathematical conditions of equality. We argue that studying balance situates mathematics in physical contexts (forces, torque, and center of gravity) and mixes the physics of balancing weights within mathematical realms of systematic reasoning, inverse proportions, vectors, equalities, and product summations.

Literature Review

The Principles and Standards for School Mathematics (NCTM, 2000) advocate the need to integrate the mathematics and science disciplines. NCTM argues that students need to experience contextualized mathematics in order to aid understanding of fundamental concepts. Certain topics lend themselves to natural integration such as sound waves and superposition of sinusoidal functions, or motion and rate of change concepts. Some topics are often indistinguishable to classify as “math” or “science” and demand integration. For example, density (mainly taught in the science classroom) could easily be viewed as a mathematics concept with an emphasis on volume and measurement of mass; or velocity and speed concepts taught in the physical sciences are often taught in mathematics as rate problems. For this paper we focus on the topic—balance, which is much more than a topic that is difficult to classify and is, in fact, a big idea. What is a “big idea”? Wiggins and McTighe (2005) defined a big idea as “a concept, theme, or issue that gives meaning and connection to discrete facts and skills” (p. 5). The ideas of balance are found in such things as: mathematical equivalency; general algebraic equations to chemical and physical equations; the center of gravity of an object; and the creation of stability through distribution of weight on each side of a vertical axis.

According to the National Council of Teachers of Mathematics in Curriculum Focal Points, students should be able to a) use symbolic algebra to represent situations to solve problems, b)
recognize and generate equivalent forms for simple algebraic expressions, and c) model and solve contextualized problems using various representations (NCTM, 2006, p. 36). Problems or tasks involving balance fashion a scenario where learners must: consider the system’s center of gravity and conditions for equilibrium; visualize possible rotations; recognize equivalent situations that will create stability; and algebraically represent and model the proposed physical situation. In addition, learners must be able to reason systematically as they problem solve, thus requiring them to “act in the mathematical moment” (Mason & Spence, 1999) as they engage in the big idea of balance.

For this paper, we describe pre-service teachers’ ways of thinking and methods of problem solving as they engage in tasks involving balance using a virtual applet. Examples of a balanced beam are illustrated in Figures 1 and 2. Previous research on children’s thinking about balance have shown generally four stages of cognitive development regarding rules for distinguishing states of balanced equilibrium (Siegler, 1976; Klahr & Siegler, 1978). The most primitive rule (Rule 1) used by children to determine if a beam is balanced involves consideration of the weight on each side of the fulcrum; if the weight on both sides is equal, the beam is balanced and if not, the heavier side dips down. The second rule (Rule 2) is slightly more advanced than the first rule and considers the weight’s distance from the fulcrum. In general, if the weight is the same on each side, then the weight with the greatest distance from the fulcrum goes down; however, if distances are equal then the beam is balanced. The third rule (Rule 3) incorporates both the first and second rules, but also considers situations where the weights on both sides may not be the same and may not be the same distance from the fulcrum. Rule 3 does not assist with those situations where the greater weight is not on the same side as the greater distance from the fulcrum. When this conflict arises, children usually use the “muddle through” or guess and check process as described by Siegler (1976). Finally, the fourth rule (Rule 4), considered by Siegler as the most sophisticated rule, displays the learner systematically realizing the composition rule of summing the products of weight and distance on each side of the fulcrum.

Other methods, but similar to Siegler’s Rule 4, of solving the problem of balancing a beam or determining if a beam is balanced often includes application of the more traditionally taught summation of torque rule. That is, if the sums of the total torque, \( \sum F_i d_i \) (where \( F \) is the perpendicular force on the beam and \( d \) is the distance between the applied force and the fulcrum) on each side of the fulcrum are equal and the summation of forces on the beam are equal to zero, then the beam is balanced. Yet another balancing rule, explained by Inhelder and Piaget (1958), involves a double inverse proportion resulting from the amounts of work needed to move two weights, \( W \) and \( W' \) (on opposite sides of the beam’s fulcrum) to heights \( H \) and \( H' \).

“When two unequal weights \( W \) and \( W' \) are balanced at unequal distances from an axis \( L \) and \( L' \), the amounts of work \( WH \) and \( WH' \) needed to move them to heights \( H \) and \( H' \) corresponding to these distances are equal. Thus, we have the double (inverse) proportion: \( W/W' = L'/L = H'/H \)” (Inhelder & Piaget, p. 164).

Shen (2006), conducted a study on the topic of balance with in-service K-8 science teachers and found that the teachers tended to generate only a limited additive rule (Rules 1 or 2), when determining whether a beam was balanced or not, and failed to incorporate the more general multiplicative rule when considering balance (Rule 4).

University students often only “experience” mathematics in abstract uncontextualized settings. Because of this, they have difficulties knowing how to solve contextualized...
mathematical tasks. Mason and Spence (1999) described varying degrees of knowing mathematics: Knowing something is true, knowing how to carry out a procedure, knowing why something is true, and knowing to act in the moment when given a novel problem. Wilhelm, Sherrod, and Walters (2008) examined students’ mathematical and scientific thinking as they engaged in project work. Wilhelm et al. found that students had difficulty applying basic mathematics (scaling, ratios, sinusoidal curves) within their project tasks. One piece of the project work necessitated the need for a calculation of an object’s velocity as it moved in a circular path. Students seemed to only know that distance and time were involved in this velocity calculation and were unsure whether distance and time should be multiplied or divided. Students had difficulty reasoning systematically about the velocity situation even though all should have been able to relate it to everyday experiences of driving a car and maintaining speed limits of 55 miles/hour or 65 miles/hour. Many also claimed that the distance around a circular path was \( \pi r^2 \) instead of \( 2\pi r \) and missed an opportunity to reason dimensionally.

Often when novel tasks are posed to students, instead of thinking systematically, they simply rely on visual cues or practiced mathematical procedures that are inappropriate for the task at hand. Davis (1984) as cited in Kirshner and Avery (2004), described how learners used visually triggered sequences to solve problems, “visual cue V₁ which elicits a procedure P₁ whose execution produces a new visual cue V₂ which elicits a procedure P₂,...and so on” (p. 227). Other research has documented that when a task is posed as a missing value word problem, students used a proportional method to problem solve, even when this method did not yield a correct result (Van Dooren, De Bock, Evers, and Verschaffel, 2009). We follow with our research study where participants were given opportunities to apply their background knowledge and experiences to a novel situation using a virtual balance applet.

**Participants and Methods**

The 17 subjects (13 female, 4 male) in this study were pre-service teachers (PSTs) of junior ranking enrolled in a middle level mathematics methods class taught by the second author in a state university in the southwestern United States. This paper focused on videotaped and transcribed PST responses during a clinical interview assessing PSTs’ understanding of balance as they were challenged with tasks involving a virtual manipulative. The first author conducted the interviews with all 17 subjects. The virtual balance applet (Rensselaer Polytechnic Institute, 1998) allowed for the subject to place various weights at different locations on a uniform beam that had a fulcrum located at its center (see Figure 1). No PST had any experience with this balance applet prior to their interview; however, all participants had experiences with physical balances within their math methods class work. In their math methods class, PSTs had built a physical balance and practiced leveling it. Of the 17 interviewed PSTs, 13 had previously taken a physics class (ten college physics, three high school physics). Of these 13, seven had been physics students in Author 1’s Introductory Physics class at some point during their middle level certification program but were not her current students during the time of data collection.

The interview protocol consisted of three main tasks that were inspired by Duckworth’s (1996) chapter pertaining to “Figuring out My Own Ideas” (p. 122-124). The first task had an unbalanced beam with one weight located a set distance to the right of the fulcrum. Each PST was asked to predict, test, and check where a second weight would need to be located in order for the beam to be balanced. The second task had the PST observe the weight arrangement shown in Figure 1, and asked the PST to consider how one would have to move either the red or the yellow object in order to maintain balance if the blue object were moved 30 units to the right.
The third task asked the PST to consider the arrangement shown in Figure 2. The posed question was “If we were to move the blue weight 100 units to the left, how would we need to move one of the other three weights to maintain balance?” The research questions directing this study concern: A) How do pre-service middle level teachers think about balance and what prior knowledge will they use as they determine ways to achieve or maintain a balanced system? B) How will pre-service teachers translate virtual explorations towards a more abstract understanding of equivalence and equilibrium? Siegler’s rules were used in analyzing the PSTs’ responses to the balance problems to help determine each PST’s level of abstraction achieved regarding balance, equilibrium, or equivalence. Methods of problem solving were coded into categories of proportional, fractional, guess and check, and inverse proportional.

![Figure 1. Balanced beam for task 2 of the clinical interview. Rensselaer Polytechnic Institute (1998) ![Figure 2. Balanced beam for task 3 of the clinical interview](attachment:image.png)

**Data & Analysis**

We highlighted representative examples of each of the methods employed by the PSTs to illustrate how they considered their balance tasks, problem solved, and utilized prior knowledge. We also categorized their methods according to Siegler’s Rules when appropriate in order to ascertain each PST’s level of abstraction as it pertains to balance and equivalence.

Nearly 60% of the participants in the study had previously taken their university physics course, thus giving them prior exposure to balance concepts and conditions for equilibrium. During their interviews, none of the 17 PSTs mentioned the words torque or conditions for equilibrium even though 10 had taken physics within the last two years of their program. Prior to the interviews, all participants had conducted an activity in their mathematics methods class involving the exploration of balance with a physical apparatus (created out of thin cardboard for the balance beam, a pin for the fulcrum, and paper clips for weights).

Each interview began with PSTs’ considering an unbalanced beam with one weight (50 units) located a distance of 120 units to the right of the fulcrum. Each PST was asked to predict, test, and check where a second weight would need to be located in order for the beam to be balanced. PSTs chose a weight equal to 50 units placed at a position 120 units left of the fulcrum.
which did create a balanced system. This confirmed that all participants had succeeded in correctly utilizing Siegler’s most primitive Rule 1.

During each of the posed tasks, follow-up questions were asked regarding placement of a second weight that was not equivalent to the weight on the opposite side of the fulcrum. Doing such questioning allowed access into PSTs’ level of abstract understanding for those situations where weights and distances were unequal (Siegler’s Rules 2 and 3). For example with task 1, each PST was asked: Where would you place a second weight that was not the same weight as the 50 unit weight in order to balance the beam? Many interviewees chose a lighter second weight to be placed left of the fulcrum. Most (82%) knew that a second weight lighter than the weight on the opposite side would need to be placed farther out from the fulcrum than the heavier weight in order for balance to be achieved. This demonstrated that 15 of the 17 PSTs were within Siegler’s Rule 3 classification level. Many verbally linked their reasoning with prior experiences such as, their math methods balance activity (2 PSTs), a physics course (3 PSTs), seesaw riding (2 PSTs), and daily life (2 PSTs). The following excerpts from the transcribed interviews (names are pseudonyms, R is the researcher) illustrate such previous experiences:

**Eva:** Maybe if you went a little lighter and put it out a little farther out.
**R:** Okay, so you think a little farther out if it (the second weight) were a little lighter?
**Eva:** Yeah, we just see-sawed all weekend….for our sorority to raise money….we have like really light people and heavy people.
**R:** So the heavier person has to go where (to balance the seesaw)?
**Eva:** The heavier person, the farther up (towards the fulcrum), and the lighter person back (away from the fulcrum).

Another PST, Lisa, also correctly stated that a second weight, heavier than the existing 50 unit weight, would have to move farther in, while a lighter weight would have to move farther out. She claimed she knew this would work because of her math methods exploration where she had been “doing the whole balancing thing. I was exploring with the different paper clips.”

When not relying on a guess and check method, eight of the 17 (47%) attempted a ratio and proportion method to solve for the location of a second weight. For these PSTs, the visual cue was the missing value, x, for the position of the second weight. For example, one PST’s method involved setting up the following proportion: $50/40 = 120/x$ where 50 was the weight located 120 units to the right of the fulcrum and 40 was the added weight left of the fulcrum. This proportion was equivalent to $W/W' = L/L'$, a direct proportion as opposed to the correct inverse proportion. When solving for x, this PST (Amy) arrived at a distance of 96 units; however, she knew instantly that this answer could not be correct since it was not larger than 120 units. She then reasoned that she should add 96 units to 120 units and move the second mass to a position 216 units left of the fulcrum, which also did not balance the beam. The following is an excerpt of Amy’s next approach.

**Amy:** If it is lighter, it needs to be farther away I am going to start at 150 and sees what that does? (Moving the 40 unit weight to 150 units left of the fulcrum balanced the beam.) I wonder why that works.
**R:** Yeah, Why do you think that works?
**Amy:** I changed the weight by a variable of 10 and then had to move it 30 away. Well, let’s see what 1/5 of 120 is Oh! Fractions (Amy became excited because she thought she had
figured it out.) So, we take away 1/5 of the distance so 1/5 of the distance from 120 is 30. So it is fractional….The mass is proportional, the distance isn’t proportional. It is a fractional thing….So we have 40/50, 4/5ths. Need to find 4/5ths of 120. No, we take away 1/5 from the weight of the block. 1/5 of 120 so you get 5x=120 (calculating answer). So it is still not exactly right. In theory it is kind of right, you get closer to the idea.

R: So how do you know it is not exactly right?
Amy: Because you need a change of 30
R: And you got a change of 24.

Amy considered how the 40 unit weight needed to move 30 units farther left of the 120 unit position for the system to balance (to position 150 left of the fulcrum). She claimed that in order to solve the problem, one needed to proportionally think of the masses (W/ W'), but use a “fractional thing” to discover the distance needed to move the 40 unit block. After doing the calculation of 1/5 of 120, she arrived at a “change of 24,” which was not the needed change of 30.

Like Amy, others chose to pursue a “fractional method” to discover a missing value position while solving the second balance task (35%). This second task involved the balanced arrangement shown in Figure 1. PSTs were asked if the 25 unit (blue) block on the right were moved 30 units to the right, how would one need to move the yellow (30 unit) block in order to maintain balance. We follow with two representative examples of the fractional method utilized by PSTs.

Jill: I am going to move the yellow over, we will try 15 (15 units left).
R: Why are you thinking 15?
Jill: I just move it half. I know that yellow is bigger so I don’t think it is going to take as much movement.

Similar to Jill, another PST used fractions beginning with a leftward movement of 1/5 of the 30 unit distance that the blue block had been moved. “Okay, since trying 1/5 of distance didn’t work let’s try ½, so 15. So that is -65. Still made blue heavier”. This fractional method mixed with trial and error was continued until the correct 75 unit position (left of the fulcrum) was found for the yellow block. Once this correct position was realized, the PST pondered, “Now why is that? Trying to think of my physics and that has been so long”.

When another PST, Chris, solved the second task, he came up with an interesting and sophisticated procedure. He made a ratio of the two weights W and W' (25/30) and multiplied that ratio by the 30 unit distance (moved by the blue weight). He arrived at 25 units which he explained to mean was the distance that the yellow weight would have to move to the left for balance to occur. Looking at Chris’ method more closely—we find that he was the only PST out of 17 to arrive at Siegler’s Rule 4 level of abstraction. Chris applied the following method: (W/W’)*(ΔL) = ΔL’. He was thinking more in terms of displacement vectors. One could also equate his method to the following, where we begin with the traditional summation of torque rule or product-moment rule. We apply this to the situation in task 2 where we have two objects on the left and one object on the right (subscripts stand for object’s color). Summing the torques on the left and right where the beam is initially in balance, we get $W_1L_x + W_2L_y = W_3L_b$. Now subtracting the new summation of torques where only the yellow object is moved to a new
position $L'_y$ and the blue object is moved to a new position $L'_b$, we arrive at the following equation:

\[
W_r L_r + W_y L_y = W_b L_b \\
-(W_r L_r + W_y L'_y = W_b L'_b) \\
W_y (L_y - L'_y) = W_b (L_b - L'_b) \\
W_y \Delta L_y = W_b \Delta L_b, \\
\Delta L_y = (W_b/ W_y) \Delta L_b
\]

Those that ultimately solved task 2’s positioning of the yellow weight arrived at the correct answer through guess and check methods except for Chris who employed a systematic approach utilizing displacement vectors and inverse proportions.

Task 3 used the scenario shown in figure 2, a balanced beam with three weights left of the fulcrum and one weight to the right of the fulcrum. Each PST was asked how one of the weights (located left of fulcrum) would need to be moved if the 25 unit weight (right of fulcrum) were moved 100 units left. This question required displacement of one of the weights across the fulcrum in order to maintain balance. The easiest weight to move would be the red block since it was of equal weight to that of the blue block. However, it still needed to move a total distance of 100 units to the right resulting in a crossover to the other side of the fulcrum, landing it at position 60 units to the right of the fulcrum. Of the 17 PSTs, 7 (41%) correctly positioned the red block at the 60 unit location. Although solving this task in this manner did not require a Rule 4 abstraction level, it did hone in on ideas of equality as well as displacement vectors. For example, one PST asked permission to cross this imaginary boundary of the fulcrum and was successful at balancing the beam when she placed the red (25 unit) weight 100 units to the right of its original position. She claimed this worked because of “equal and opposite reactions, just like balancing equations…whatever you do to this side, you have to do to other side…so you wouldn’t do something to this side that you wouldn’t do to this side because it is not fair.” Where this PST described this balance situation “like balancing equations,” others made reference to both distance moved and direction, “So I was correct in wanting to move the red one in the same amount as the blue one; I just need to move it in the opposite direction.”

While many (41%) were able to solve this task with a simple movement of the red block, albeit across the fulcrum, others (35%) seemed to revert back to a Rule 1 level of thinking. PST, Samantha, chose to move the red block to position -69 (69 units left of fulcrum) since the blue block was moved to position +69. She seemed to think the system would balance even though there were two additional weights left of the fulcrum besides the red block. Similarly, two other PSTs were unsuccessful as their balance efforts contained a 100 unit leftward movement of the red block instead of the correct vector displacement of 100 units to the right.

As with the other two tasks, a follow-up question required the PST to consider movement of one of the other two weights (yellow or green) that were not of the same weight as the blue 25 unit weight. All PSTs that made this attempt at balance with the other weights made use of the guess and check method except for Chris. He applied the same approach he invented during task 2 for each individual movement. However, when using the technique for the green and yellow weights, he did not arrive at a whole number. His correctly calculated result for the green weight was to displace it 71.4 units to the right. The applet did not allow decimal values, so he first tried a movement of 71 units (which tilted the beam to the left) and then a movement of 72 units (which tilted the beam to the right). He was confident that his technique worked and if the applet permitted decimal answers instead of only whole numbers, the beam would have balanced.
Conclusion and Implications

During the interviews, PSTs vocalized that the “balance” tasks were similar to previous math methods activities, riding a seesaw, physics course lessons, or daily life experiences. Assessing PSTs understanding of concepts related to the big idea of balance showed mainly qualitative levels of sophistication where 82% of the PSTs displayed comprehension within the Rule 3 stage of Siegler’s analysis. Of these 82% only one PST could quantitatively solve all balance tasks and achieve Rule 4 abstract mastery.

When posed with three balance tasks during the clinical interviews, most PSTs struggled; none applied the “traditional” rules for establishing equilibrium, but instead relied on intuition and qualitative guess and check reasoning (more than 70%). When other methods were pursued, PSTs relied on visual cues to implement mathematical procedures that were inappropriate for the task (similar to Van Dooren, De Bock, Evers, & Verschaffel, 2009). When confronted with what appeared to be a “missing-value” balance task, 47% of the PSTs attempted an incorrect procedure using direct proportions while 35% made use of an incorrect fractional method. Only one PST systematically solved the tasks, where he invented an innovative model using inverse proportions and displacement vectors.

Our study included 13 PSTs who had taken either a college or a high school physics class, where the presumption was that all had been exposed to concepts concerning conditions for equilibrium (\(\sum F_d = 0\), and \(\sum F_i = 0\)). However, only three PSTs related the balance tasks to their previous physics experiences and only one systematically solved all problems. This suggests that although the teacher education candidates had taken courses in physics as well as other advanced mathematics, they did not fully understand the concept of balance from either the mathematics or physics perspective.

The implications of this study advise that more purposeful experiences should be crafted within teacher education programs that lead to better connections across the disciplines of big ideas such as balance. These experiences should prompt future teachers to act in the mathematical moment and move their mathematical reasoning beyond qualitative connection making towards higher levels of abstraction that can be applied to new and novel situations.

BEYOND NOTHING: TEACHERS’ CONCEPTIONS OF ZERO

Gale Russell  
University of Saskatchewan  
glr127@mail.usask.ca

Egan J Chernoff  
University of Saskatchewan  
egan.chernoff@usask.ca

This qualitative study engaged two elementary teachers in a hermeneutic dialogue about how they understood zero and when and why zero became a part of teaching and learning in their classrooms. The data collected revealed two ways in which the teachers understood and worked with the concept of zero: as a set of techniques and procedures and as a philosophical and theoretical concept. The results of this study revealed many potential areas of interest regarding teachers’ and students’ number sense and understanding of zero.

Introduction

Zero is a foundational, complex, and multi-functional concept in modern mathematics (Seife, 2000; Barrow, 2000; Kaplan, 1999), yet research has shown that pre-service teachers struggle with many of the understandings of zero within elementary mathematics (Wheeler & Feghali, 1983). Ma’s (1999) research comparing the mathematical knowledge and understandings of elementary teachers in Singapore and the United States also revealed that teachers from the United States misconceptions related to zero. Furthermore, research involving students demonstrates that they have the same misunderstandings of zero as identified for pre-service and in-service teachers (Piaget, 1964; Pasternack, 2003; Wilkinson Evans, 1983; Baroody, Gannon, Berent, & Ginsburg, 1983; Reys and Grouws, 1975; Kamii, 1981; Allinger, 1980; Whitelaw, 1984; Anthony & Walshaw, 2004). These parallel results suggest that the development of misconceptions about zero may be supported through classroom interactions. Leeb-Lundburg (1977) however, has demonstrated that through engagement in activities that involve exploring quantity and place value, elementary students are able to come to understand many of the roles of zero within mathematics.

Given the importance of zero in mathematics, the lack of understanding by both teachers and students warrants further investigation into the situation. As a starting point for this investigation, this paper details the methodology and results of a new research project that investigated the response of elementary teachers to the questions: “How do you understand zero,” and “When and why does zero become a part of teaching and learning in your classroom”.

Literature Review

Wheeler & Feghali (1983) investigated many different facets of pre-service teachers’ understanding of zero. Paralleling research into students’ understanding of zero (Inhelder & Piaget, 1964; Neurwirth Beal, 1983; Pasternack, 2003; Wilkinson Evans, 1983; Baroody et. al., 1983; Wheeler, 1987), 15% of the pre-service teachers Wheeler & Feghali (1983) interviewed said that zero was not a number, explaining that zero is ‘nothing’, and that numbers must represent ‘something’. More than half of the pre-service teachers habitually said ‘oh’ instead of ‘zero’ when reading phone numbers and the digits of license plates out loud which is another common finding in the research related to students’ understanding of zero (Baroody et. al., 1983; Allinger, 1980; Whitelaw, 1984). Even in replicating some of the tasks that Inhelder& Piaget (1964) used with children, Wheeler & Feghali (1983) obtained results for the pre-service teachers that were reminiscent of those produced by the children. Wheeler & Feghali’s (1983)...
results demonstrated that the pre-service teachers only considered partitions of numbers involving zero if the problem being solved was set in a real world context, such as fishing. The pre-service teachers also struggled with the idea of using zero, or the null set, as a possible classification within a sorting task.

Ma’s (1999) research, involving the comparison of mathematical knowledge of teachers from the United States and Singapore, also gave insights into the teachers’ understanding of zero within the contexts of subtraction and multiplication. In the case of both operations, the teachers from the United States demonstrated misunderstandings related to zero in terms of place value and the decomposition of numbers, which echoed the results of Neurwirth Beal’s (1983) research involving students. The teachers from Singapore, however, demonstrated greater understanding of zero in both contexts (place value and number decomposition).

In response to this literature, this study embarked on further exploring how teachers understand zero and how those understandings are brought to the mathematics classroom. By choosing to use a qualitative approach, I hoped to uncover what specifically teachers believe and know about zero, and to engage the participants and myself in a process of learning as well.

Methodology

The intent of the research questions required an approach that would engage participants in revealing and constructing personal meaning and understanding of zero, leading to the selection of a hermeneutic approach based on Gadamer’s philosophy. Three features of Gadamer’s philosophy played an important role in the defining of the methods of data collection and analysis in this research: horizons of understanding, dialogue, and the meaning of words.

Gadamer (1989) defined two inter-related horizons of understanding that each person has for every concept or idea. The historical horizon is defined by the past and traditions that come from the generations before. The present horizon is a composite of all that a person believes, has experienced, and has learned about a concept. The historical horizon is an influence, often unrecognized by the individual, on his/her present horizon. Using dialogue, Gadamer (1989) contends that individuals can explore and come to know both their own present horizons of understanding as well as the present horizons of those that are involved in the dialogue. In a Gadamerian hermeneutic dialogue, the “Dialectic consists not in trying to discover weakness in what is said, but bringing out its real strength” (Gadamer, 1989, p. 367), and thus provides everyone involved in the dialogue with the opportunity to clarify their understandings of others’ horizons, while also validating, modifying, and expanding their own. This negotiation of one’s horizon is important because of a dichotomy related to words that Gadamer (1989) identifies. Gadamer (1989) presents that a word names an object and everything that object is, however; when a person speaks or hears that particular word he/she is only using that word in the context of a small portion of his/her present horizon. Gadamer (1989) argues that through hermeneutic dialogue both speaker and listeners come to greater understanding as they reveal, explore, validate, and expand the portion of their present horizons being accessed.

Participants

This research involved Nora and Elaine, pseudonyms for the two teachers, who taught in different schools in the same urban school division in central Canada. Nora was teaching a class of 22 students aged seven to ten in a public elementary school in a mostly mid-lower socioeconomic area. Elaine was teaching a class eight to twelve year olds in a mostly lower socioeconomic area with a number of her students requiring additional learning assistance.
Chapter 13: Teaching Knowledge

Research Methods

Data was collected through three group meetings, an in-class teaching session in each of the participating teachers’ classrooms, and an interview with the teacher following one of the in-class teaching sessions. The three group meetings were each three hours in duration and audio recordings of the meetings were transcribed and then verified by the teachers. Through dialogue directed by questioning, the three group meetings focused on the teachers’ recollections of learning and teaching about zero, exploring and assessing the teachers’ revealed understandings of zero, creating new understandings of zero, and discussing when and how zero enters into, or should enter into, mathematics instruction.

Results and Analysis

The data collected through the group meetings, in-class teaching session, and interview was explored for emerging patterns and themes. These ideas were compared to those found in the literature review, looking for similarities, as well as departures and new perspectives. The insights and ideas of the two teachers were codified according to the broad themes, which form the organizational structure and content of the results.

Starting To Know Zero

At the beginning of our dialogues, Nora and Elaine reflected on their memories of learning and knowing about zero. Elaine commented that she “couldn’t come up with a concrete time period when [she] actually [remembered] spending any time talking about [zero]”. Nora agreed, but gradually, three themes of knowing zero emerged: zero as a number, zero within procedures, and zero outside the classroom. All three of these themes highlighted how their experiences and knowledge of zero as students were fragmented and dominantly procedural and technical aspects of understanding.

Zero as a number. In elementary school, Elaine learned that zero was the starting point of numbers, but not that it was a number itself. Then in middle school, Elaine was told that zero was the “middle of the integers”, like a type of physical divider. With only technical knowledge of zero, these two meanings were irresolvable for Elaine. Without knowing of the social construction and evolution of zero and the integers, as well as not knowing that zero is theoretically a quantity, Elaine’s learning about zero, as well as the whole numbers and integers, was relegated to points of trivia to be remembered, but not understood. Elaine’s view of zero as not being a number correlates with findings from Wheeler & Feghali’s (1983) study of pre-service teachers and with research involving students (Wilkinson Evans, 1983; Anthony & Walshaw, 2004; Wheeler, 1987).

Nora recalled learning that “zero is nothing”. Like the pre-service teachers in Wheeler & Feghali’s (1983) research, and the students involved in the studies of Baroody et. al. (1983), and Whitelaw (1984), Nora said that defining zero as ‘nothing’ caused her to believe that zero was not important and that it made sense that it could be ignored. Throughout our discussions, Nora regularly returned to this definition and trying to rectify it was a major motivation for her seeking of a philosophical and theoretical understanding of the concept of zero. Eventually, Nora refined her definition to ‘nothing of something’. This modification parallels the conclusion by the students in Leeb-Luneburg’s (1977) research: “Zero is nothing – of something!” (p. 25). By modifying the definition she had been given, Nora was able to create a philosophical understanding of zero that made sense of the technical roles of zero that she had learned.

The students in both teachers’ classes also perceived zero as ‘nothing’ and said it could be ignored. This concerned both Nora and Elaine, and Nora was particularly troubled to hear her students tell the primary researcher that zero was not a number. The students reasoned that if it was a number, then they would have been taught it when they were taught about one to ten and that it would be said in number names (for example, if zero is a number we would say twenty-zero just like we say twenty-one). Although some research had demonstrated students’ confusion over the naming of numbers containing zeros (Kamii, 1981; Baroody et. al., 1983), none of the research had provided evidence that students were making assumptions about zero based upon their recognition of what hadn’t been said or done by the teacher.

Nora and I were also surprised to find that her students believed that zero, rather than being a number, was in fact a shape. When asked what they had zero of, the students gave replies that pointed out objects in their possession or in the classroom that were circular in shape. Allinger’s (1980) research with students, and Wheeler & Feghali’s (1983) research with pre-service teachers both noted the equating of the number ‘0’ and the letter ‘O’, however; none of the research mentioned the equating of zero with a circle.

**Zero within procedures.** Many of Elaine and Nora’s memories of zero related to mathematical procedures they had memorized. Nora recalled learning to “carry the 1” when adding two digit quantities, but noted that it was not until she was an adult that she realized that the ‘1’ actually represented ‘10’. As a student she had not understood where the ‘1’ came from and that because the zero was not shown, it confirmed her belief that zero could be ignored. Similarly, Elaine spoke of learning to divide questions such as $20 \div 340$ and being told to “just knock off the zeros”. She did not know why she could do this – just that ignoring the zeros made things easier. These limited and misconstrued understandings are reminiscent of those identified by Ma (1999) with the teachers from the United States’ understandings of subtraction and multiplication and of those identified in Neurwirth Beal’s (1983), Wilkinson Evans’ (1983), Anthony & Walshaw’s (2004), and Wheeler’s (1987) research involving students.

Both teachers had learned to do computations involving zero as procedures without any basis of understanding. Over time, they had come to theoretically understand some of the computational procedures they had been taught, but many had remained unquestioned until our meetings.

**Zero outside the classroom.** Elaine and Nora both spoke of how much of their understanding of zero developed outside the classroom. Elaine recalled having an aunt who used the word ‘aught’ in place of zero, and both teachers spoke of how ‘oh’ was frequently used when saying the number zero in different contexts such as postal codes which has also been noted in other research (Wheeler & Feghali, 1983; Allinger, 1980; Baroody et. al., 1983; Whitelaw, 1984). This avoidance of the word zero reinforced many of their mathematically incorrect beliefs about zero, including that it can be ignored.

Nora and Elaine also talked about how zero was frequently used in non-numerical contexts. Elaine reflected about zero being associated with people in ways that indicated they were defective or substandard, and Nora provided the example of the novel *Holes* and its central character, Zero, as verification. Both teachers agreed that these experiences gave them the understanding that zero somehow indicated a deficiency or disapproval and that they did not have such a pessimistic (or emotional) attitude towards other individual numbers. Although Allinger (1980) mentions this type of use of the word zero, Nora and Elaine demonstrated that this non-mathematical contextualization of zero had influenced how they view and think about the mathematical concept of zero.
Marginalization And Legitimatization Of Zero

As we moved deeper into the dialogue, both teachers became concerned about what they perceived to be the marginalization of zero and ways to legitimatize it. They identified a number of contexts for the marginalization of zero, some of which are presented below.

**Computations.** Elaine and Nora both spoke of the need to change the ways of teaching and learning related to computations involving zero. Elaine commented that one problem was that zero was being presented to students in ways that made it seem less significant than other numbers. The result of this was that students either learned to ignore zero, or to memorize procedures to deal with zero when it did occur. Both teachers also spoke of the practice of rote teaching and learning, with memorization and not understanding, being a problem for students’ development of computational skill.

Nora and Elaine spoke of the marginalization of students’ understanding of zero as being a result of teachers’ lack of understanding themselves and of teaching traditions. Both felt that it was crucial that teachers learn to understand zero themselves so that the tradition of teaching for doing and not for understanding could be changed. The processes of teaching and learning about zero were only explored in the research by Leeb-Lundberg (1977), which demonstrated that changes of the type proposed by Elaine and Nora made significant changes in students’ understandings of zero.

Nora and Elaine’s discussions about teaching and learning demonstrated their ongoing struggle with recognizing and developing theoretical understandings of zero that would either explain or debunk the technical and procedural pieces that made up the majority of their present horizon of understanding.

**Language.** Elaine and Nora also argued for a change in the way language was being used, both in and out of the classroom. Nora compared society’s acceptance of saying ‘oh’ for ‘zero’ to how, “when kids are starting to read they get confused with ‘1’ and ‘L’... but it’s not viewed as acceptable to confuse them”. Nora spoke of how zero was not getting the same level of distinction or respect as other numbers do. Both Nora and Elaine felt the practice of replacing zero by ‘oh’, ‘none’, or ‘nothing’ was sending the incorrect message that zero means the same as those three words and is not a quantity. Both teachers called for a stop to the practice of replacing zero with other words. Throughout their discussions, they emphasized specifying zero of ‘something’, thus strengthening their theoretical perception of zero as a quantity.

**Other attempts to legitimatize zero.** Nora was concerned that zero was not always included in our world where it could have been. In this regard, she commented: “you have First Avenue, Second Avenue, Third Avenue, but no Zero Avenue”. She was also concerned because there was no year ‘zero’ in our calendar system. Nora was not aware of the use of zero in the Mayan calendar.

Elaine, on the other hand, was more concerned with obtaining a single perspective for zero that made everything work. She found a possibility in her initial knowledge of zero as a starting point. She argued that every context of zero could be related to a starting point. For the integers Elaine explained that zero is actually the starting point of both the positive numbers and negative numbers and that even zero gravity is the starting point of gravity. This then moved the conversation to changes that would need to occur to make zero the starting point, such as making all timers count up from zero, creating a temperature system that starts at zero (she was not aware of Absolute Zero), and the renaming of ‘home base’ to ‘zeroth base’.

These attempts at legitimatizing zero are evidence of both teachers’ lack of understanding of the social evolution of zero and of the complexity of its meanings and ongoing development.
**Representation Of Zero**

Nora and Elaine considered how students might be asked to represent and talk about their understandings of zero. Nora suggested three possible ways in which students could be asked to physically, concretely, or pictorially represent zero: through the absence of objects, as the quantity before one, and through subtraction. In the first case, Nora felt that students could understand zero as the absence of particular objects, such as considering a picture of a farm that showed zero birds. Alternatively, if the picture had one bird in it, the students could be asked how many birds were there before it arrived and then be asked to draw the situation. Finally, Nora addressed students representing and understanding zero through subtraction by having the students remove objects from a given context or picture to lead to the quantity of zero.

Elaine, although appreciative of these ideas, struggled with the notion of students representing zero because of its abstractness. She questioned what would be the concrete aspect (what the students could see or physically touch) of Nora’s suggested ways to represent zero. Thus, while Nora became convinced that students are capable of representing and theoretical understanding zero, Elaine was still unsure about whether young students had the ability to develop an abstract and theoretical understanding. Like the two teachers, the research is polarized on this matter. Leeb-Lundburg’s (1977) research demonstrated how grade two students were able to construct the types of understandings that Nora proposed, while Piaget & Inhelder’s (1964) research demonstrated that children did not understand zero.

**Zero Within Numbers**

The final theme that emerged from Nora and Elaine’s dialogues focused on the role of zero in place value and number composition. Both teachers argued, based on their experiences as students and as teachers, that students did not understand the full role of zero in our place value system. Elaine spoke of how many of her students ‘just lose [the zero]” when they are naming numbers such as in the case where 204 would be read as “twenty-four”. This error in understanding was also cited in Baroody et. al. (1983).

Through their dialogues, Elaine and Nora developed an understanding of zero which defined two roles for zero within numbers: as helping to define the magnitude of the numbers (for example two hundred four rather than twenty four), and as defining the quantity of that particular place value position (there are zero tens in 204). Nora and Elaine’s concern with what their students understood about zero served as a major impetus for their seeking and proposing theoretical underpinnings for what they technically and procedurally knew with respect to zero.

**Discussion**

Regardless of the theme, the understandings of zero that Nora and Elaine demonstrated can be classified in two distinct, categories: procedural and technical, and philosophical and theoretical. At the start of our dialogues, there was no interplay between the two categories and most of the understandings that Nora and Elaine revealed and explored were procedural or technical. As Elaine and Nora tried to explain and justify those understandings, they began to recognize their deficiencies related to the philosophical and theoretical aspects of zero and began to construct new understandings to justify or make sense of their procedural and technical knowledge. Through this process, the two teachers explored both determining the axioms and theories that allowed for the mathematics they already knew as well as exploring and trying to guess about the social evolution of zero. Figure 1 below illustrates the relationships that emerged between these two facets of understanding zero.

---

In some instances, Nora and Elaine were able to successfully construct philosophical and theoretical understandings that parallel those that developed historically and exist in modern mathematics (Barrows, 2000; Seife, 2000; Kaplan, 1999). There were other cases, however, in which their attempts ended up creating conceptions of zero that do not reflect those of the historical or modern understandings and uses of zero.

**Conclusion**

This study found that for Nora and Elaine, the answer to the question “How do you understand zero,” was a limited set of procedural and technical facts, some right and some wrong, with virtually no philosophical or theoretical understandings to support what those facts. Moreover, as the two teachers attempted to determine and/or define such philosophical and theoretical understandings, they increased their confidence in their knowledge while also creating some theory that “made things work,” but was mathematically or socially incorrect. In relation to the second question “When and why does zero become a part of teaching and learning in your classroom,” both teachers recognized that zero had never been a consideration in their planning for mathematics instruction. As the study progressed, Elaine and Nora both expressed concern about their prior omissions related to zero, and discussed ways to bring more focus to the roles of zero within the mathematics that they were engaging their students in. As their own personal understandings of zero expanded, so did their desire to bring zero into their classrooms in meaningful ways.

By using a hermeneutic approach in this study, the primary researcher also noted an expansion of her horizons of understanding zero. She came to realize that the history of zero, especially in terms of socially accepted norms such as not having a year zero in our calendar, is much more than a bit of interesting trivia in one’s understanding of zero within modern mathematics. Without knowledge of these socially constructed and arbitrary features of zero, confusion and misunderstandings can abound.

This research demonstrates how the lack of understandings and misunderstandings held by teachers about zero that were reported in the 1980s still exists today. Through carefully planned activities and discussions, however, Nora and Elaine were able to construct richer understandings of zero, just as the students in Leeb-Lundberg’s (1977) research did, suggesting that the situation can be changed. It is also notable that my study revealed a misunderstanding of zero held by...
some students, which has not been noted before, namely the confusion of the number zero with the shape of a circle.

There is still much need for further research into the understandings of zero for both teachers and students, including the procedural and technical understandings and the supporting philosophical and theoretical understandings. Strategies for deliberately and effectively engaging teachers and students in learning about all aspects of zero, including the evolution of zero related to different societies, need to be explored and developed further.

This study examined how Chinese teachers develop students’ procedural fluency and conceptual understanding simultaneously when teaching fraction division. Twelve videotaped lessons and corresponding lesson plans from three elementary school teachers in China composed the data of this study. A theoretical framework of teaching with variations was adopted for analyzing the data, which assumes that creating dimensions of variations on critical aspects of learning objects for students to experience is a necessary learning condition. It was found that systematic variations of mathematics problems were assigned to students for generating, clarifying and consolidating their learning of concepts and computational rules. Discussing and solving problems with multiple methods over the consecutive lessons is another essential characteristic in teaching with variations.

Introduction

In school mathematics, it is commonly recognized that students’ learning of mathematics knowledge should go beyond procedural acquisition and skill fluency (e.g., National Council of Teachers of Mathematics [NCTM], 2000). The emphasis placed on empowering students mathematically has inevitably led to not only on-going discussions about the relationship between conceptual and procedural knowledge (e.g., Rittle-Johnson & Alibali, 1999; Star, 2005), but also the quest for high-quality instructional practice that can develop students’ mathematics knowledge with understanding and fluency. Many investigations of Chinese mathematics classroom instruction suggest that instructional practices in China contain some unique features that may assist our thinking in developing alternative practices (e.g. Huang & Leung, 2004). Mathematics education practices in China have a long tradition of emphasizing “basic knowledge and skills” (Zhang, Tang, & Li, 2004). It is further believed in China that creativity and higher-order thinking abilities can only be grounded on the “basics” (Wong, 2008), and the key to pursue a high-quality mathematics education is to bridge “basics” and “higher-order thinking abilities” (Zhang et al.). Some researchers argued that a teaching method, called teaching with variations, could possibly lead to meaningful learning in large-size classes (Gu, Huang, & Marton, 2004), and further serve as a bridge from “basics” to “higher-order thinking abilities” (Wong). Huang and Leung (2004) examined how teachers teach the topic of Pythagoras theorem from the perspective of teaching with variations. They found that through teaching with variations, students were actively involved in learning mathematics content, solving mathematics problems under teachers’ skillful guidance. Recently, based on an experiment about the effect of a mathematics curriculum guided by a spiral variation (bianshi) on students’ learning, Wong, Lam, Sun, and Chan (2009) revealed that students using spiral teaching materials performed significantly better than their peers using standard textbooks.

Although the previous studies demonstrated a positive potential in improving mathematics teaching by adopting the notion of variations in mathematics teaching and learning, we are not clear about what really happens in classrooms when teachers teach specific content topics over a series of consecutive lessons. In this study, we aimed to examine three Chinese elementary
mathematics teachers who taught the same topic of fraction division over a sequence of four lessons. In particular, we focused on these teachers’ practices in carrying out their teaching of fraction division with variations over four consecutive lessons.

Theoretical Consideration

To identify and interpret classroom characteristics that are conducive to student learning, we selected a theory of variations espoused by Marton and Booth (1997), which has demonstrated the potential to reveal salient features of classroom instruction (Marton & Tsui, 2004; Watson & Mason, 2006). According to Marton and Tsui, learning is a process in which learners develop a certain capability or way of seeing or experiencing. In order to see something in a certain way, the learner must discern certain features of the object. Experiencing variations is essential for discernment and significant for learning. Marton and Tsui further argued that it is important to attend to what varies and what is invariant to a learning situation. The intended object of learning designed by lesson plans, does not affect the learning of the students in itself, but the way in which it is implemented does. What varies and what is invariant constrain learning and make the learning possible. *Enacted object of learning* is described through necessary conditions for the appropriation of the object of learning (Marton & Pang, 2006). Pedagogically, Gu, Huang and Marton (2004) described the fundamental features of teaching with variations which has been around in China for several decades. This theory of teaching emphasizes building essential connections between new knowledge and previously learned knowledge through guiding students to experience certain variations on critical features of the object of learning. Two types of variations were suggested to help students learn mathematics meaningfully: “conceptual variation” and “procedural variation”. Conceptual variation consists of two parts. One is composed of varying embodiments or representations of a concept to form the connotation of the concept. The other means highlighting the substantial features of the concept by providing counterexamples as a contrast. Conceptual variation is meant to provide learners with multiple experiences from different perspectives. Procedural variation refers to the process of forming a concept logically (scaffolding or transformation), arriving at solutions to problems and forming knowledge structure. The function of procedural variation is to help learners acquire knowledge step by step, enrich learners’ experience in problem solving progressively, and finally obtain well-structured knowledge.

Recently, Wong et al. (2009) further developed a framework to describe different variations in terms of the functions of a problem. This mode includes four types of bianshi (variation): *inductive, broadening, deepening, and applying*. By use of ‘*inductive bianshi,*’ rules and concepts are derived through the inspection of a number of everyday situations. These rules are consolidated by a systematic introduction of variations in mathematical tasks. Yet, in the case of ‘*broadening bianshi,*’ no new rules and concepts are introduced, and learners broaden their scope through exploring a variety of problems. At a certain point, by further varying the types of mathematical tasks, learners are opened up to more deep mathematics concepts and skills. This is called ‘*deepening bianshi*’. Mathematics knowledge is then applied to a variety of daily life problems, which can be called ‘*applying bianshi*’.

Essentially, classifications by Gu et al. (2004) and Wong et al. (2009) are closely related. The *inductive* and *broadening bianshi* could be roughly grouped into conceptual variation, while *deepening* and *applying bianshi* basically fit in procedural variation. However, since knowledge development is spiral and connected, all these categories are not static and exclusive, rather they...
depend on the situation under study. Thus, we regard Wong et al.’s classification as an extension of Gu et al.’s model in this study (hereafter, variation will replace bianshi).

In this study, knowledge generation and development will be examined from two levels. At the macro level, we examined the lesson structure over consecutive lessons to see how the intended objects of learning were constructed as a whole. At the micro level, we examined how a particular concept or procedure was developed within or across lessons from the lens of teaching with variations. Taken together, we aimed to answer three research questions:

- What are the intended objects of students’ learning over consecutive lessons?
- What are the enacted objects of students’ learning through teaching with variations?
- What are similarities and differences in the enacted objects of learning among these teachers?

**Methods**

**Data Resource**

The data of this study taken from a larger project, mainly consisted of four consecutive videotaped lessons of each of the three teachers from three different elementary schools in East China, with a total of 12 videotaped lessons. All the teachers adopted the same unified textbook. In addition, lesson plans of the teaching content were used as supplementary and triangulation documents.

**Data Analysis**

The data analysis is mainly based on lesson plans, videotaped lessons and their transcripts in Chinese. First, we read through the lesson plans which include similar components such as topics, instructional objectives, important and difficult content points, teaching methods and techniques, and post-lesson reflections. It helped us identify the main contents, instructional objectives, and procedures of the lessons. Then, we watched the video-taped lessons carefully, paying particular attention to the content taught, instructional objectives addressed and the procedures of lessons unfolded. Through examining the lesson plans and transcripts, we assured that our understanding was accurate. Thus, we identified the main instructional objectives for Teacher A and Teacher C (see Table 1). After that, we classified all the problems used in the lessons into four categories, with a focus on the ways of solving and discussing these problems (See Table 2 for the case of Teacher A). Finally, we summarized all the dimensions of variations in teaching to identify the necessary learning conditions provided for students’ learning. In particular, we focused on the following two aspects:

*Intended objects of learning.* The lesson plans and lesson structures were examined to describe the intended objects of learning and the pedagogical flow to achieve their instructional objectives. Then, the similarities and differences can be compared with regard to the intended objects of learning.

*Enacted objects of learning.* At the second level, the analysis focuses on how teachers use different types of problems to introduce, broaden, deepen and apply knowledge progressively. The types of problems were categorized and the ways of implementing these problems were analyzed qualitatively.

**Results**

The findings are organized into two parts. First, the instructional objectives set in lesson plans (e.g., intended objects of learning) are summarized, and relevant instructional procedures...
are described. Then, the enacted objects of learning created in lessons through problems solving are illustrated in detail.

**Intended Objects of Learning and Lesson Structure**

With regard to instructional objectives, Teacher A and Teacher B had essentially the same objectives; yet Teacher C set slightly different aims as showed in Table 1.

<table>

<td>Understanding and mastering the computation rules of fraction divided by fraction (F/F)</td>
<td>Mastering the methods of solving word problems by fraction division; Understanding comparing fractions</td>
</tr>
</tbody>
</table>

Thus, basically, all the teachers set the following objects of learning over the consecutive lessons: (1) understanding the meaning of fraction division, and the relationship between multiplication and division; understanding and mastering the computation rules of fraction divided by whole number (F/WN) (in Lesson 1); (2) understanding and mastering the computation rules of whole number divided by fraction (WN/F) (in Lesson 2); (3) understanding and mastering the computation rules of fraction divided by fraction (F/F) (in Lesson 3); and (4) mastering the methods of solving word problems of fraction division; understanding the size of fraction divided by fraction, compared with original fraction (in Lesson 4). In addition, Teacher C emphasized the methods to learn a new computation rule including meaning, rules and sequence in Lesson 1 (See Table 1). As far as the instructional procedure is concerned, all three teachers followed the similar patterns: (1) reviewing the previous lesson content or relevant knowledge before learning the new topic; (2) introducing new topic through solving mathematical problems in everyday life; (3) practicing with a variety of interconnected problems and summarizing relevant key points or contents in the lesson; and (4) assigning homework. There are slight differences across lessons: Lesson 3 and 4 include several times of practice and summary.
Enacted Object of Learning through Solving Problems

Through examining the features of problems used over the consecutive lessons, and ways of implementing these problems, we can map the routes of how each teacher enacted the object of learning over lessons, and the similarities and differences between different teachers. One case of Teacher A was displayed in Table 2.

| **Applying variation** | Variation of problems in terms of formats and functions of the expressions. | Variation of problems from the textbook. | Variation of problems. | Variations of word problems, and comparing values of arithmetic expressions. |
Teacher A demonstrated the following features when selecting and implementing problems over lessons: (1) All the concepts or computation rules were introduced through solving and discussing varying word problems; (2) problems were explored through group activities, and multiple solutions were explored and discussed by using multiple representations; and (3) systematic variations of exercise were assigned to students for them to clarify and consolidate the learned concepts and computation rules.

Through exploring these variations of problems, students were expected to develop understanding of the concepts and computations rules (inductive problems and broadening problems), and further consolidating them by applying problems in Lesson 1 and 2. Moreover, in Lesson 3 and 4, after introducing some new concepts through inductive problem solving, the focus was given to the application (applying problems) of all the learned knowledge in the consecutive lessons.

Through these processes, we concluded that Teacher A produced some enacted objects of learning and provided possible learning conditions through creating certain dimensions of variations for students to explore (See Table 3). The dimensions of variations provide possible conditions for students to achieve the enacted objects of learning.

</tbody>
</table>

Let us illustrate how the Teacher A initiated student understanding of the rationale of computation rules of F/WN through constructing several dimensions of variations. First of all, the teacher presented a question: If we evenly separate a rope of 4/5 meter into two parts, how long can we get for each part? By solving this problem, one dimension of variation of multiple
solutions to the problem was presented: pictorial explanations for $\frac{4}{5} \div 2 = \frac{4}{2} \times \frac{1}{2}$; meaning of a number divided by 2; $\frac{4}{5} \div 2 = \frac{4}{5} \times \frac{1}{2}$; and converting fraction into decimals. Then, a second dimension of variation of changing divisors (from 2 to 3) was created by presenting a variation of the previous problem: If we evenly separate a rope of $\frac{4}{5}$ meter into three parts, how long can we get for each part? By comparing three methods in the new situation, the advantages of the computation rule (one of the multiple methods) were highlighted. Thus, students developed understanding and justified the computation rule.

Similarities and Differences in the Enacted Objects of Learning among Teachers

When comparing the enacted objects of learning of the three teachers, although each of them aimed to create a similar enacted object of learning as showed in Table 2, we identified subtle but essential differences. Teacher A created broad dimensions of variations to help students understand why the computation rules work or do not work under different conditions. However, Teacher B always directly focused on some dimensions of variations which help students understand why relevant computation rules work under some particular conditions as stated in the textbook. As a contrast, Teacher C, not only made efforts to create similar enacted objects of learning as Teacher A, but also aimed to create a dimension of variation to help students realize how to learn fraction computation rules by analogizing relevant rules performing on whole numbers. This learning object has a long-term overarching effect on students’ learning because it provides a thinking method of extending numerical system and relevant computation rules (i.e., extending operation rules from whole numbers to fractions). Thus, although all three teachers enacted learning objects as displayed in Table 3, they still pursue with some subtle different learning objects that may result in differences of student achievement.

Conclusion and Discussion

The findings of this study suggest that these Chinese teachers had quite similar instructional objectives including developing students’ understanding of relevant concepts and computation rules through inductive and broadening problem solving step by step, improving their computation skills through systematic exercises (i.e., applying problems), and summarizing key points over consecutive classes. Classes were organized in a consistent model, including reviewing relevant knowledge, introducing new topics, applying new knowledge and summarizing key points, and assigning homework. Thus, over these consecutive lessons, the teachers may provide students the condition of developing coherent and interconnected knowledge (Leung, 2001). It was argued that through well-designed task sequences, students can learn knowledge, enhance their abilities, and benefit from interactions in the class (Simon et al., 2010). In addition, these three teachers tended to enact the objects of learning to achieve their instructional objectives through creating relevant dimensions of variation focusing on objects of learning. These dimensions of varying problems help students make sense of concepts, understand why computation rules work or do not work under particular conditions, and further deepen and consolidate students’ understanding of relevant concepts and computation rules. Based on our framework, developing conceptual understanding and computation skills were enacted simultaneously in these classes.

Theoretically, this study demonstrates that the framework of teaching with variations could be a powerful tool to identify the features of classroom instruction that are conducive to high-quality teaching. It is echoed by the claim that “if the teacher offers data that systematically expose mathematical structure, the empiricism of modeling can give way to the dance of exemplification, generalization, and conceptualization that characterizes formal mathematics” (Watson & Mason, 2006, p.94). This analysis also provides some strategies for enhancing classroom instruction.

TEACHERS' UNDERSTANDING OF PROPORTIONAL REASONING

Kate J. Riley
California Polytechnic State University
kriley@calpoly.edu

This report provides empirical evidence of pre-service teachers’ understanding of proportional reasoning. Eighty elementary pre-service mathematics teachers were given proportional reasoning problems. This paper analyzes their responses to those items. Proficiency in proportional reasoning is considered as one of the critical foundations of algebra. While past research shows the difficulty students have understanding proportional reasoning, results of this study show a concern of a recycling effect where teachers themselves lack a robust, conceptual understanding of proportional reasoning.

Introduction

The purpose of this report is to establish evidence of pre-service teachers’ understanding of proportional reasoning, especially reasoning beyond traditional missing-value type problems. In testimony before the Committee on Labor and Education in May 2008, Francis (Skip) Fennell, past president of the National Council of Teachers of Mathematics (NCTM) gave a report of “Foundations for Success”, which was work completed in March 2008 by the National Mathematics Advisory Panel. In his testimony, Fennell stated that Algebra is the gateway to higher level mathematics. He also added that research shows that students who complete Algebra II are more than twice as likely to graduate from college as compared to students with less mathematics background.

In the Foundations for Success report, the National Mathematics Advisory Panel noted that a major goal for K – 8 mathematics education should be to develop proficiency in the area of fractions, decimals, percent, ratio and proportions and deemed this area as one of the “Critical Foundations of Algebra” (2008). For this same reason, the NCTM noted in their Curriculum and Evaluation Standards (1989), that proportional reasoning “is of such great importance that it merits whatever time and effort must be expended to assure its careful development” (p. 82). In 1988 Lesh, Post, and Behr went as far as to state that proportional reasoning is the capstone of the elementary school curriculum and the cornerstone of high school mathematics and science.

Our youths’ understanding of proportional and algebraic reasoning is paramount to our sustenance as a nation to develop the next generation of science, technology, engineering, and mathematical (STEM) careers. In the NCTM’s Second Handbook of Research on Mathematics Teaching, Lamon stated “my own estimate is that more than 90% of adults do not reason proportionally – compelling evidence that this reasoning process entails more than developmental processes and that instruction must plan an active role in its emergence” (2007, p. 637). Lamon noted the lack of research within the last 15 years and coupled with the fact that “teachers are not prepared to teach content other than part-whole fractions” goes on to state a critical call for more research in the area of rational numbers and proportional reasoning (2007, p. 632). Therefore, given that many in the mathematics education community note that knowledge of proportional reasoning is essential as a foundation for algebraic thinking, research on understanding of proportional reasoning is essential to understand just where we stand.

Theoretical Perspective

Even though there are relatively few studies aimed specifically at teachers’ understanding of proportional reasoning, there have been a substantial number of past research studies on children’s understanding of rational numbers, ratio, and proportion as outlined by Lamon (2007). According to Lamon, much of the research from 1970 to 1985 produced an extensive inventory of factors that influence the difficulty children have in understanding proportion problems (2007). Students’ difficulty understanding and using ratios, rates, and percents, is largely because they have not acquired a capacity for proportional reasoning. For example, Hart (1981, 1988) and Karplus, Pulos, and Stage (1983) noted children frequently use additive strategies when they should have use multiplicative comparisons.

A research study by Canada, Gilbert, and Adolphson examined pre-service teachers’ conceptions of proportional reasoning. Their results revealed pre-service teachers’ difficulties with a problem that was posed in three different ways and they concluded that some pre-service teachers had a very limited understanding of proportional reasoning (2008). Another study of pre-service teachers' understanding of fraction problems showed that U.S. pre-service teachers were out-performed by their Taiwanese counterparts and tended to use more intuitive and visual reasoning rather than formal and symbolic reasoning on open-ended problems (Luo, Lo, & Leu, 2009). A study by Lee and Orrill (2009) of twelve middle grades mathematics teachers understanding of fraction division concepts revealed that teachers can reorganize and generalize operations and concepts of fractions.

Since 1988, Susan Lamon has been a leader within the mathematics education community on her work with the analysis of proportional reasoning. She defined proportional reasoning as “the ability to scale up and down in appropriate situations and to supply justifications for assertions made about relationships in situations involving simple direct proportions and inverse proportions” (2005, p. 3). She noted seven core ideas or structures that must be addressed to help children develop a deep understanding of rational numbers and proportional reasoning. Lamon’s interrelated concepts, contexts, representations, operations and ways of thinking are shown in the following diagram (2005, p. 9).

This report will briefly touch on a few of Lamon’s core ideas. According to Lamon, central to the understanding of the unit in working with fractions is the role of composite units (units of numerosity greater than one) and the idea that ratios and rates can be viewed as complex types of units. Lamon (1993, 1994) suggested that unit building is an important mechanism in

---

Chapter 13: Teaching Knowledge

sophisticated mathematical ideas. She noted that when this happens, “a part-whole schema comes into play and the individual is able to think about both the aggregate and the individual parts that compose it” (2007, p. 243). Being able to compose and decompose a unit is central to one’s reasoning that is needed in the field of rational numbers.

In addition, proportional reasoning is “reasoning up and down” (Lamon, 2007). Classic reasoning up and down problems are those where you are given the situation such as “if 6 individuals can paint a room in 4 days, how long will it take 8 people to paint the room”. Students can complete problems like this without using the form \( \frac{a}{b} = \frac{c}{d} \).

The mathematical model for proportional relationships is the linear function \( y = kx \), where \( k \) is called the constant of proportionality. You can think of this as \( y \) is a constant multiple of \( x \) or that two quantities are proportional when they maintain the constant ratio: \( \frac{y}{x} = k \). The constant \( k \) plays an essential role in understanding proportionality. According to Lamon (2005), one of the most useful ways of understanding mathematics requires the transformation of quantities or equations in such a way that some underlying structure remains unchanged (invariant).

Method

The participants in this research study were 80 pre-service elementary teachers in their third course of a sequence of three quarter (year-long) courses of mathematics for elementary teachers. All 80 participants were liberal studies majors (elementary education) that had completed the two prerequisite courses. The study was conducted two weeks prior to the end of the quarter. This course represented the last mathematics course that was required for their major.

A questionnaire with 8 open-ended items was used to collect data. The first two items were multiple choice problems and the last six items were open-ended problems that asked participants to complete different proportional reasoning word problems. This report will focus on the results of the six open-ended items in the area of proportional reasoning. Items were adapted from various sources and are noted per item below. The problems were:

#4.) Glenn mixed 6 ounces of cherry syrup with 53 ounces of water to make a cherry-flavored drink. Ardis mixed 5 ounces of the same cherry syrup with 42 ounces of water. Who made the drink with the stronger cherry flavor? (Kastberg, S., D’Ambrosio, B., & Lynch-Davis, K., 2010).

#5.) Brent and Roger decide to start a landscaping business together. Most of the homes in their neighborhood have similarly-sized lawns. Typically, Brent can mow a lawn in 3 hours. Roger usually needs 2 hours to do the same job. They decide to work together on 5 lawns. How long does it take them to finish? (Sinn, R., Spence, D., & Poitevint, M., 2010).

#7.) A crew of 8 people can build a concrete wall in 6 days. If four more people join the group from the beginning, how many days will it take to build the same wall? (Kastberg, S.,

D’Ambrosio, B., & Lynch-Davis, K., 2010).

#8.) *Hannah and Adele are decorating the gym with helium-filled balloons for the graduation. Hannah can inflate and tie off 7 balloons every 6 minutes. Adele requires 3 minutes to finish 4 balloons. Working together, how long will it take for them to have 25 balloons ready?* (Sinn, R., Spence, D., & Poitevint, M., 2010).

Item #3 can be correctly solved using the cross-multiplication algorithmic approach to set up the proportion and solve for the missing-value. Item #4 was a mixture problem that could be solved by finding the ounces of cherry syrup per ounce of water. This item asks students to compare ratios. Lamon (2005) noted that such items ask students go beyond setting up the proportion and asks students to engage in justification to determine the drink with the more cherry flavor. Item #5, #7, and #8 represent problems in which one quantity is related in an inversely proportional way to another quantity. According to Lamon (2005), items such as this should be understood by students in 7th or 8th grade. To complete this problem, participants needed to understand that as one quantity varies with the other, but in opposite directions. The two scale factors are inverses of each other (Lamon, 2005). Item #6 asked participants to understand the difference between multiplicative and additive thinking where the change in one quantity might be proportional to the change in the other quantity. These items are typical of the upper elementary or middle school curriculum and also are similar to items on the proportional reasoning part of the state’s high school exit exam.

**Results**

The results of the 80 pre-service teachers’ responses for the six open-ended items are noted below in table 1 by examining the number of correct responses.

<table>

<td>46%</td>
<td>39%</td>
<td>39%</td>
</tr>
</tbody>
</table>

In addition to analyzing the results by means of accuracy of the solution, the solution strategy that the participants used to complete the task was noted. For item #3, the problem that asked participants how long to cook a turkey, it is noted that 90% of the pre-service teachers correctly answered this item. This item is a typical missing-value problem that can be solved by setting up the proportion and cross-multiplying. Item #6 that asked participants to solve an open-ended question on additive thinking, only 46% of the pre-service teachers correctly solved this item. In an item analysis of participants’ solution strategy used, of the 43 participants that incorrectly solved this item, 38 of the 43 pre-service teachers (48 % of all 80 participants) solved the

---

problem by using a cross-multiplication strategy arriving at an incorrect solution of 45 laps. Below is a one of the responses from a pre-service teacher that was typical of these 38 participants:

#6.) Lorri and Cole are running equally fast around a track. Lorri started first. When she had run 9 laps, Cole had run 3 laps. When Cole completed 15 laps, how many laps had Lorri run?

\[
\frac{L}{C} = \frac{9}{3} \times \frac{x}{15} \quad x = 45
\]

\[
\frac{15}{3} = \frac{45}{x}
\]

\[
9 \times 15 = 3x
\]

\[
Lori \quad would \quad have \quad completed \quad 45 \quad laps.
\]

Figure 2. Student C8 Response

For the more difficult items on inverse proportions, some of the pre-service teachers tried solving by the cross product algorithm. In an item analysis of participants’ solution strategy used for item #7, of the 49 participants that incorrectly solved this item, 19 of the 49 pre-service teachers (24% of all 80 participants) solved the problem by using a cross-multiplication strategy arriving at an incorrect solution of 9 days. Below is a one of the responses from a pre-service teacher that was typical of these 19 participants:

#7.) A crew of 8 people can build a concrete wall in 6 days. If four more people join the group from the beginning, how many days will it take to build the same wall?

\[
\frac{8 \text{ people}}{12 \text{ people}} = \frac{6 \text{ days}}{x \text{ days}}
\]

\[
\frac{8}{12} = \frac{6}{x}
\]

\[
2 = \frac{3x}{x}
\]

Figure 3. Student C11 Response

Conclusions

An understanding in ratio and proportional reasoning is imperative for our students to

develop a solid foundation before they enter Algebra. Given this, in-service and pre-service teachers themselves must have a profound and deep understanding of proportional reasoning that goes beyond applying the cross product algorithm. The main purpose of this report was to provide a snapshot of pre-service teachers’ conceptual understanding of proportional reasoning, especially when asked to complete problems beyond the traditional missing-value problems.

The data results from the pre-service teachers' responses is concerning and certainly notes the need for more in depth studies that will inform us of teachers’ conceptual understanding of proportional reasoning. Results support that pre-service teachers had difficulty with the more difficult inverse proportional problems. It was surprising to note the number of participants that completed the additive thinking problem (item #5) incorrectly. The item analysis of this problem showed that 48% of the participants had difficulty differentiating between additive and multiplicative thinking. This problem is traditionally part of the upper level elementary curriculum and is a good problem to test whether participants can go beyond thinking of the traditional cross product algorithm. For the inverse proportion problems, some of the students relied on a cross product algorithm to solve. These results support the idea that we need to develop students’ conceptual understanding of strategies of proportional reasoning before exposing them to the cross product algorithm.

Results from this study indicate that some of the teachers do not have a full understanding of proportional reasoning. There is concern that pre-service teachers have difficulty discerning when to use or not use cross-multiplication to solve proportional problems. Given that the content of the problems in this study are very similar to the elementary or middle school curriculum that the pre-service teachers will soon be teaching, it is concerning that a recycling effect will happen because teachers themselves lack a robust, conceptual understanding of proportional reasoning. This is in line with Lamon’s statement, “teachers are not prepared to teach content other than part-whole fractions” (2007, p. 632).

Certainly more research studies are needed in this area that will inform us of pre-service and in-service teachers’ conceptual understanding, especially research that delves into individuals’ understanding of proportional reasoning beyond the basic algorithmic approach of cross multiplying. It is noted that an understanding of proportional reasoning is a critical foundation of algebra and the importance of success in algebra is crucial to understand higher level mathematics. Given this, it is imperative that we address the lack of understanding of proportional reasoning with our pre-service and in-service teachers.

Introduction

In order to reach national goals of improved algebraic instruction and enhanced student learning, it is important to continue to examine teachers’ knowledge about algebraic instruction regarding equivalence (National Mathematics Advisory Panel, 2008; RAND, 2003). Subject matter knowledge is not sufficient for effective teaching. Prior studies show that teachers’ knowledge for teaching mathematics impacts student learning (Hill, Rowan, & Ball, 2005; Ma, 1999). However, there is a dearth of knowledge related to teachers’ knowledge about algebraic instruction (Kieran, 2006) and recent studies have identified the need to better understand how such teachers’ knowledge develops (Doerr, 2004). Since reformed-based teaching methodology in a mathematics methods class positively influences preservice teachers’ knowledge and attitudes (Leonard, Newton, & Evans, 2009), we approached the development of teachers’ knowledge of algebraic vocabulary though a meaning making or semiotic perspective. The goal of mathematics instruction using this perspective is “to make and give meaning” (Thompson, Kersaint, Richards, & Hunsader, 2008, p. 4), as signs and representations comprise the essence of mathematics (Hoffmann, 2006).

Given that the goal of mathematics instruction is to construct meaning, middle school mathematics teachers need a robust understanding of key algebraic vocabulary, including the term equivalent expressions. Therefore, we propose that the development of teachers’ knowledge of equivalent expressions can be represented through the use of concept mapping, which might afford us the opportunity to see how teachers integrate elements of semiotics and the mathematical processes of communication, connections and representations which are essential to effective instruction (NCTM, 2000). There has been little research on the use of concept mapping as a tool to help promote middle school teachers’ knowledge about equivalence. This led us to the following research question: How do middle school teachers develop mathematical, semiotic, and language constructs of the term equivalent expressions through concept mapping?

Theoretical Perspectives

The background in this study draws upon two areas, teachers’ knowledge for teaching algebra and concept mapping. Teachers’ knowledge, or pedagogical content knowledge, refers to “the ways of representing and formulating the subject that make it comprehensible to others” (Shulman, 1986, p. 9). Shulman also distinguished between two kinds of understanding, knowing “that” and knowing “why”:

We expect that the subject-matter content understanding of the teacher be at least equal to that of his or her lay colleague, the mere subject-matter major. The teacher need not only understand that something is so; the teacher must further understand why it is so. (p. 9)

Teachers who can distinguish the “why” have a robust understanding of pedagogical content knowledge. Insufficient pedagogical content knowledge can impede the teaching and learning
processes in algebra. Algebraic instruction is becoming integrated into the elementary grades (Kaput, Carraher, & Blanton, 2007) and is also a central focus of the middle school curriculum (NCTM, 2000). As algebraic thinking is integrated into the grades K-8 curriculum, it becomes increasingly important to understand how to develop teachers’ knowledge so that they can help students bridge the gap between arithmetic and algebra. The research base on teachers’ knowledge for teaching algebra is limited (Asquith, Stephens, Knuth, & Alibali, 2007; Doerr, 2004). Extant studies report that the transition from arithmetic to algebra is difficult (Kieran, 1992). In studies about lessons on equivalent expressions, novice teachers did not make connections between lessons, nor did teachers use spatial reasoning to show that expressions were equivalent (Even, Tirosh, & Robinson, 1993). Nathan and Koedinger (2000) suggested teachers hold a symbol-precedence view of student mathematical development and concluded that mathematics teachers should become aware of the “range, flexibility, and efficacy of students’ alternative mathematical problem-solving strategies and the difficulties students have developing their symbolic-reasoning abilities” (p. 231). Finally, teachers’ knowledge about the concepts of equivalence and variable are central to successful algebraic instruction, yet teachers rarely identify student misconceptions as an obstacle to student learning (Asquith et al., 2007).

Concept mapping is commonly used to both illustrate and assess existing knowledge, and can be used to develop deeper understandings about key mathematical ideas (Thompson et al., 2008). Concept maps diagram, classify, and organize relationships between concepts, words, and other elements of knowledge. Concept mapping (also called semantic mapping) is relational in that it integrates prior knowledge, experiences, and beliefs with new information. Research supports the effectiveness of concept maps for reinforcing vocabulary knowledge for a variety of learners (Horton, Lovitt, & Bergerud, 1990), and in many content areas such as mathematics (Monroe & Pendergrass, 1997) and literacy (Levin et al., 1984).

In teaching students new concepts, relating semantic features through the use of mapping approaches has been shown to have positive effects on the comprehension of new material (Baumann, Kame’enui, & Ash, 2003). In studying the vocabulary of junior high students, Margosein, Pascarella, & Pflaum (1982) found significant main effects for using semantic mapping over a more traditional vocabulary instruction approach on both weekly test scores and a standardized vocabulary knowledge measure. Rekrut (1996) described semantic mapping as an effective method for teaching high school students because it makes use of students’ prior knowledge and experiences, and it engages them in the learning process. Similarly, an intervention study featuring learning-disabled junior high students performed by Bos & Anders (1990) revealed that those who participated in interactive strategies including semantic mapping outperformed those receiving direct vocabulary instruction on measures of vocabulary and comprehension. They hypothesized that this was because concept mapping strategies emphasize the activation of prior knowledge and also encourage students to share and elaborate on what they already know. Perhaps it is this the fact that the learner often becomes an active participant using prior knowledge to construct meaning that makes concept mapping an effective method for increasing vocabulary knowledge and leading to deeper comprehension of new constructs.

Methods

This qualitative study draws upon a models and modeling perspective of teacher development (Doerr & Lesh, 2003). The development of teachers’ knowledge is a complex process where “the essence of the development of teachers' knowledge... is in the creation and continued refinement of sophisticated models or ways of interpreting the situations of teaching,
learning and problem solving" (p. 126). Events that foster such model development include a multi-stage process of eliciting new ways of thinking, resolving the mismatches, and finally sharing and sustaining the model. This study is aimed at the initial stages of this model development in an effort to assess whether concept mapping can account for and promote the development of teachers’ knowledge.

All participants were enrolled in a six-week summer online graduate course called Literacy Strategies for the Middle Grades (5-9) Mathematics Classroom. The textbook used for the course was written by Thompson et al. (2008) entitled *Mathematical Literacy: Helping Students Make Meaning in the Middle Grades*. Teachers were asked to create a concept map of the term equivalent expressions. They were given two days to post this concept map and asked to create it before beginning the course materials. Midway through the course in Week Four, teachers were directed to solve the Pool Border Problem (Annenberg, 2010), also sometimes called the Tiling Pools Problem (Phillips & Lappan, 1998).

Explain to the class that they will be working in groups of four to investigate the number of tiles needed for pools of various sizes. (Annenberg, 2010)

![Figure 1. The Pool Border Problem](image)

Week 4 assignments included reading a section on concept mapping and creating a concept map of the term area. During Week 4, the course instructor gave each student feedback consistent with semiotic models of concept maps in the textbook. In the final week, teachers were asked to create a final concept map of the term equivalent expressions, and to answer this question: “Compare/contrast your first concept map done in the Icebreaker [first] Module with your new concept map by answering these questions: What changed? Why? How did doing the Pool Border problem influence your new concept map, if at all?”

Data analysis was conducted after the course was completed. Each teacher's concept map was examined for correct mathematical content, and then examined for growth and the use of the
many suggestions related to semiotics from the textbook including: illustrate relationships between concepts, show special examples, use the term in various examples, give the definition, show examples and non examples, and define relationships (Thompson et al., 2008). Seventeen inservice teachers participated in the course taught by one of the researchers. A summary of the participants’ teacher certification appears in Table 1.

**Results**

Our analysis of the development of the concept maps from the first module to the last showed that the concept maps fell into a continuum between two categories: (a) conceptually well developed, and (b) little to no growth in conceptual understanding. None of the initial concept maps were consistent with what might be considered a rich concept map with multiple nodes. Robust concept maps that demonstrated development included multiple nodes consistent with those modeled in the Thompson et al. (2008) textbook. These maps included nodes for definitions, use of the equals sign, and examples or non-examples. These concept maps integrated examples that referred to the Pool Border problem presented in the middle of the course. These robust concept maps also included nodes related to a semiotic perspective of teaching mathematics. Concept maps with little or no growth and that were in need of further development omitted most of these features and tended to be based in arithmetic.

In Figure 2 and 3, we examine the concept maps from Teacher A, a grades 7-12 mathematics teacher with a B. A. in mathematics education. This example represents the most dynamic growth of any student in the course. This initial concept map does include three different mathematical representations. However, it does not contain a definition, connections to arithmetic, examples of where the term is used, or non-examples. The exit concept map does include most of these elements.

![Figure 2. Teacher A: Initial Concept Map](image)

This teacher commented,

My first concept map only includes examples of equivalent expressions. This does not show that I have an understanding of the term equivalent expressions… My second concept map provides more insight… This change occurred after reading the section in chapter eight about concept maps. I was able to see how concept maps can be more useful than just listing examples. Providing more information such as definitions, properties, and non-examples can
(1) help students to develop meaning and a better understanding of a concept or term and (2) allow teachers to evaluate where their students’ abilities lie with a particular concept. When concept maps are done this way, they can be a very useful tool in the classroom; one that I see myself using to benefit my students’ learning.

Teacher A appears to appreciate that the use of concept mapping may result in enhanced student learning and may provide insight into her students’ conceptual understanding. It is also interesting to note that her arithmetic example of a false sentence $2 + 5 = 10$ appears as a non-example. It is possible that this teacher still needs to think about the transition from arithmetic to algebraic thinking.

Figure 3. Teacher A: Exit Concept Map

Figure 4 shows a concept map with limited conceptual growth. Teacher B, a childhood science concentrate, began her concept map using examples based in arithmetic and moved to an algebraic interpretation. Her initial definition was based in arithmetic, and she misused the term “Equations” where she should have used “Expressions.”

Her exit concept map included a better definition for the term and examples based in algebra. In explaining the difference between her two maps, she stated that “After completing the tiling problem, I realized that equivalent expressions involve the distributive property... [and] Seeing concept maps in the book also helped me.” However, many features related to a semiotic perspective are missing including algebraic terminology such as variable, algebraic properties, arithmetic-based examples, and non-examples. Her hierarchical style limited her ability to show connections between nodes. Similar to the concept map of teacher A above, it is possible that Teacher B needs to think more about the transition from arithmetic in the early elementary grades to algebraic thinking in the middle grades.

In Figure 5, we examine the exit map of Teacher C. This student was a childhood mathematics concentrate with an extension to teach grades 7-9 mathematics. He has worked the last five years in a tutoring center for grades K-9. His concept map omits many of the elements we expected, particularly after completing the Pool Border problem. Concerning his exit concept map, he wrote:

I took the symbols used in algebraic expressions and linked them to the words that are found in the problems. There is a similarity in the fact that it is like a web where the words in each

---

**Figure 4. Teacher B: Initial and Exit Concept Maps**

bubble are related to each other in one way or another. The tiling pool problem influenced this because the students had to come up with an algebraic expression equivalent to the word problem given to them.

We believe that this student did not develop an appropriately conceptual or semiotic understanding of the term equivalent expressions. We are concerned that the most basic elements covered in the textbook are absent. His map completely missed any mention of the equals sign or equivalence. Student D’s comments about his concept map reflect little understanding of the course objectives or the place of equivalent expressions in the middle grades curriculum. In fact, his definitions of key vocabulary are more congruent with instruction in the early elementary grades on the meaning of operations. The Pool Border problem was more about different representations for equivalent expressions than having students find one expression for a given word problem. Though the student referenced the Pool Border problem in his comments, he did not offer any examples related to the problem in his concept map, nor did he allude to the possibility of different interpretations of the given signs.

![Figure 5. Teacher C: Exit Concept Map](image)

**Conclusion**

If we want middle school teachers to teach reform-based curriculum where conceptual and procedural knowledge are valued, teachers themselves need a deep understanding of algebraic terminology. We found that iterative cycles of concept maps (Doerr & Lesh, 2003) taught within a reform-based graduate level methods course provided in-service teachers with opportunities to connect mathematical ideas related to equivalence. Consistent with the semiotic perspective

---

advocated by Thompson et al. (2008), concept maps have the potential to pinpoint students’ misconceptions. The online course as structured helped some of these inservice teachers develop their model of equivalent expressions. We were able to make very tentative conclusions that inservice teachers with a content concentration in mathematics or science often created multifaceted concept maps. In order to meet national goals of improved algebraic instruction, we believe the use of concept mapping has the potential to immerse all inservice teachers in the language of mathematics. Further research should be conducted in two areas. We believe that these concept maps should be shared by students in the course to further develop their ideas about teaching equivalence. And finally, more attention should be devoted to the development of teachers’ understanding about equivalent expressions and the transition from arithmetic to algebraic thinking.

RECONCILING TWO PERSPECTIVES ON MATHEMATICS KNOWLEDGE FOR TEACHING

Ellen L. Clay  Jason Silverman  David Fischer
Drexel University  Drexel University  Drexel University
elc37@drexel.edu  silverman@drexel.edu  df49@drexel.edu

Despite the fact that there is widespread agreement as to the importance of teachers’ mathematics knowledge, there is little consensus as to the particular content and structure of that knowledge. In this paper, we expand on our earlier work highlighting the importance of teachers’ developing powerful, generative understandings from which an understanding of a body of mathematical ideas and its relation to other bodies can emerge. We will highlight the differences between this perspective and the other primary conceptualization of MKT found in the literature. The paper includes analysis of teachers’ work from both perspectives, identifies differences between the two perspectives, and proposes a unified perspective on MKT that capitalizes on the strengths of each.

Introduction

The importance of teachers’ mathematical knowledge has been well documented in the literature (Ball, 1993; Ma, 1999; Shulman, 1986). While there is widespread agreement as to the importance of teachers’ mathematics knowledge, historically there is little consensus as to the particular content and structure of that knowledge and researchers continue to develop and study more fine-grained conceptualizations of the mathematical knowledge needed for teaching mathematics. In recent years the notion that teaching mathematics for understanding requires special mathematical knowledge for teaching (MKT) has gotten a great deal of traction and has become a major research focus in mathematics teacher education.

There are at least two perspectives on MKT present in the mathematics education literature. Ball, Hill and their colleagues have spent almost two decades studying the work that teachers do in teaching mathematics and have identified particularly useful practices, representations and “unpacked” mathematical understandings that allow teachers to interact productively with students in the context of teaching mathematics (Ball, 1993; Ball & Bass, 2003; Ball, Hill, & Bass, 2005). Alternatively, Silverman, Thompson and Clay approach the question of MKT from a different perspective (Silverman & Clay, 2009; Silverman & Thompson, 2008; P.W. Thompson & Thompson, 1994) that places teachers’ mathematical understandings—the web of connections developed by individuals that allows them to act and enact within situations he or she encounters—at the center of research on MKT.

In this paper, we will analyze a sample of students’ work from both the Ball-Hill and Silverman-Thompson-Clay perspective, identify differences between the two perspectives, and propose a unified perspective on MKT that capitalizes on the strengths of each.

Theoretical Perspective

Ball, Hill and their colleagues have identified practices, particularly useful representations and “unpacked” mathematical understandings that can support teachers as they attempt teaching mathematics to support students learning with understanding. Their pioneering work has succeeded in empirically identifying mathematical reasoning, insight, understanding and skill needed in teaching mathematics for understanding and has developed, tested and validated
instruments for measuring MKT (Ball, 1993; Ball, et al., 2005; Ball & McDiarmid, 1990). Further, they have succeeded in identifying a positive relationship between mathematical knowledge for teaching and student achievement (H.C. Hill, Rowan, & Ball, 2005; H. C. Hill, Schilling, & Ball, 2004).

As an example of MKT from the Ball-Hill perspective, consider the incorrect application of the algorithm for multiplying two multi-digit numbers shown in Figure 1. In the example, we see a student who forgot to “move the 70 over.” Ball, Hill and Bass (2005) argue that while the ability to do the multiplication is essential for teachers, teachers need additional knowledge — in this case they would need to recognize that the student was simply multiplying 2 (from 25) times 35 without acknowledging or realizing that the “2” actually represents 2 tens. This MKT provides teachers a starting point for engaging productively with students about mathematical understandings as opposed to a focus on teaching students to implement the rule appropriately.

![Figure 1: Incorrect Application of Multiplication Algorithm](image)

In our work, we approach the question of MKT from a different perspective. Rather than focusing on identifying particular mathematical insight, understanding and skill needed in teaching mathematics, we focus on mathematical understandings “that carry through an instructional sequence, that are foundational for learning other ideas, and that play into a network of ideas that does significant work in students’ reasoning” (Thompson, 2008). We refer to these understandings as coherent understandings: powerful, generative “big ideas” from which an understanding of a body of mathematical ideas and its relation to other bodies can emerge. As an example of our perspective, consider the case of algebra. Even a cursory glance over a pre-algebra, algebra, or pre-calculus text yields two broad categories of content: (1) those focusing on sets, operations, and their properties (including a set theoretic conception of functions and equation solving) and (2) those focusing on variables as varying quantities and relationships between those varying quantities (including rates of change, maxima and minima, and a graphical perspective of functions and equation solving). Further, within each category, students learn a variety of disconnected techniques and procedures for dealing with the variety of problem types that occur. Rarely, if ever, do students have an opportunity to look across problem types, reason with significant mathematical ideas, and ask questions such as “In what ways are \( y = x^3 \) and \( y = \sin x \) the same? How can what we know about \( y = x^3 \) help us understand \( y = \sin x \)?”

It has been argued elsewhere that the development of covariational perspective, which involves a focus on coordinating changes in one varying quantity with corresponding changes in a second varying quantity (Confrey & Smith, 1994) can support students with engaging productively with a variety of seemingly disconnected functional relationships from category #2 (Silverman & Thompson, 2008; Thompson, 1994; 2008). In this paper, we draw upon the mathematical field of algebra to describe a scheme of understandings within which much of the variety of school algebra content is seen as small variations of the same theme (bringing coherence to the content from category #1). As opposed to learning and remembering when to apply particular techniques for particular problem types, a focus on algebraic structure provides a
general framework that allows learners to engage with a variety of mathematical tasks from the 7-16 school curriculum in a consistent and sensible way. Further “new” content is then experienced as an extension of this structure (for example, the inverse of the sine function allows students to answer the question “How do I undo the sine function?”). We argue that this is a coherent understanding of school algebra.

This algebraic perspective places primary emphasis on understanding the algebraic structure of the various sets (integers, real numbers, functions) and operations (addition, multiplication, composition) encountered throughout the school algebra curriculum. Within this context, particular attention is paid to algebraic properties such as the existence of identities and inverses and commutivity. In traditional classes and texts, students are often asked to spend time memorizing each of these properties and matching a particular application of these properties with the name of the property during the first days of each academic year. This surface-level approach diminishes the centrality of algebraic structure within school algebra and mathematics in general. It is these algebraic properties that allow us to perform the actions we want to perform (add), that forces us to narrow the places in which we perform them (one-to-one functions), to create new sets to perform them in (complex numbers), and/or the reason we can not do many the things we would like to do (solve matrix equations with non-invertible coefficients).

Practically every string of symbols in algebra texts (expressions, equations, functions, etc.) is made of quantities from sets and operations acting on those quantities. When viewed this way, these quantities and operations can be seen as emerging organically from students’ understanding of arithmetic. For example, consider the following “algebraic” explanations:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Algebraic explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>2x + 5</td>
<td>the quantity x is being multiplied by 2 then 5 is being added to the result</td>
</tr>
<tr>
<td>-(\frac{1}{2} x + 2)</td>
<td>the quantity x is being multiplied by -(\frac{1}{2}), negated, then 2 is being added</td>
</tr>
<tr>
<td>2(x - 7)^2 - 8</td>
<td>the quantity x is having 7 subtracted from it, being squared, multiplied by 2, then 8 is subtracted</td>
</tr>
</tbody>
</table>

The advantage to the algebraic approach is that once students recognize the algebra in each string, it provides them with a point of entry to topics such as evaluating expressions, solving equations, or finding inverse functions. While evaluating an expression for a particular value of \(x\) seems like a trivial step from the algebraic explanation above (perform the operations on a particular value of the quantity, \(x\)), solving an equation in which the expression is equal to a particular value or finding an inverse might seem like a stretch for the algebraic perspective. Through our experience working with teachers, we have found that teachers routinely read an equation from left to right and then begin to “work it,” saying “add -5 to both sides” or a similar action, giving no mathematical or logical reason for the action. In this way, traditional instruction has a tendency to develop understandings similar to those described by Erlwanger more than three decades ago: (1) students believing there are rules for each type of problem and the challenger of learning mathematics is to figure out which rule to apply to which problem and (2) applications of these rules are not rational and logical and not subject to sense making (Erlwanger, 1973).

In contrast, from the algebraic perspective, solving equations is all about recognizing the quantities, operations, and properties of those operations that can be applied to the quantities, including “undoing” these operations by applying inverse operations and generating identity elements. As an example, the following table demonstrates an algebraic way of thinking about operations being applied to \(x\) and applying the corresponding inverse operations to zero to solve

---

the equation $2(x - 7) - 8 = 0$:

<table>
<thead>
<tr>
<th>Operations</th>
<th>Expression</th>
<th>Inverse operations</th>
<th>Inverse operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>subtract 7</td>
<td>$x - 7$</td>
<td>add seven</td>
<td>$\pm 2 + 7 = 9$ or $5$</td>
</tr>
<tr>
<td>square</td>
<td>$(x - 7)^2$</td>
<td>“un-square”</td>
<td>$\sqrt{4} = \pm 2$</td>
</tr>
<tr>
<td>multiply by two</td>
<td>$2(x - 7)^2$</td>
<td>multiply by $\frac{1}{2}$</td>
<td>$8 \cdot \frac{1}{2} = 4$</td>
</tr>
<tr>
<td>subtract 8</td>
<td>$2(x - 7)^2 - 8$</td>
<td>add 8</td>
<td>$(0 + 8) = 8$</td>
</tr>
</tbody>
</table>

While on the surface this activity may seem virtually identical to the equation solving that goes on in schools, there are two significant affordances to the algebraic perspective. First, it gives students a means of engaging with any algebraic task in the school mathematic curriculum. Rather than seeking (or asking the teacher for) the rule or procedure for each new problem, algebraic situations can be approached by students focusing on and asking the questions, “What are the quantities in this problem?” and “What’s happening to these quantities?” Second, this approach allows students to see coherence in the school mathematics curriculum. For example, students can engage in a similar manner as described above with any of the following equations:

- $2(x - 7) - 8 = 0$
- $2\ln(x - 7) - 8 = 0$
- $2 + x - 7 dx / dx = 8 = 0$

As a result, the key challenge for students shifts from learning what to do for each type of problem to engaging sensibly with a given problem and analyzing and utilizing the algebraic structure: “OK, I know how to solve this. First I figure out what the quantities are, what’s being applied to them, and what properties can I use to answer the question.” When students encounter an operation they are unfamiliar with, several highly mathematical questions arise: “What properties hold? Is there an identity? Does an inverse exist? Can I find it?” It is this algebraic focus in early algebra experiences that can support students as they encounter new and diverse sets like functions, matrices, and differentials and related expressions and equations.

### Setting and Participants

In this paper, we will present our analysis of a small slice of a course titled Algebraic Reasoning in which we look at solving equations. This online graduate course is a content-based course required for the master’s degree program in mathematics education at a university in the Mid-Atlantic region of the United States. The course was designed by the second author and has gone through multiple iterations of testing and revision by all authors. The course is designed to support participants in developing an understanding of algebraic structure and to use this structure to support teachers in developing coherent understandings of algebra. Initial learning activities focused on supporting teachers in unpacking the algebraic structure of the integers under addition and the rational numbers under multiplication, with particular attention being paid to the language of algebraic properties especially the existence of identities and inverses. These activities were then used as a springboard for thinking about solving equations. This transition from operations on numbers to solving equations began with the task of using the language of algebraic structures to read algebraic expressions focusing on an unknown quantity and
operations being applied to that quantity, then asked teachers to use the properties they had learned when thinking about solving equations. In the second half of the course participants explore increasingly complex sets including functions, complex numbers, matrices, and finite sets, along with equations with quantities and coefficients from these sets.

**Data and Analysis**

In the following section, we present two teacher responses to a task that was developed as a starting point for teachers making the transition from studying algebraic properties of various sets and operations to using algebraic properties in a variety of “solving equations” tasks. Prior to working on the task, the teachers viewed a video podcast highlighting the “big ideas” of this transition. Then, the teachers were assigned the task of creating an audio-visual podcast responding to the following task: “Using the big ideas and language you used in our previous work, demonstrate and discuss how you would solve equations. Be sure to demonstrate making zeros and ones, the use of zero-pairs and one-pairs, and to practice using the language of identities and inverses in these problems. Don’t forget to read each problem with algebraic meaning.” A set of eight linear equations was provided for the students on which to focus their podcasts.

Initial analysis involved reviewing a set of responses to the given task and identifying patterns in the responses. A number of exemplars of each category were transcribed and analyzed in further detail. The responses included below represent two distinct categories of the initial student responses. While throughout the remainder of the course these responses were the focus of small group discussions, individual feedback from the instructor and teaching assistant, and revision, we limit our attention in this paper to the teachers’ initial responses.

**Category 1: Focus on Coefficients and Canceling with Added Language of Algebraic Properties**

As an example of the first category of solutions and explanations, we consider the work of John (all individuals are identified by a pseudonym). In the following excerpt, we see John’s discussion of solving the equation \(-2x – 1 = -9\):

"Our first problem is \(-2x – 1 = -9\). Now, we’re going to try to solve this equation. What we want to do is get \(x\) by itself. ... We have \(-2x – 1\) and we want to get that \(x\) to be by itself so we’re going to clear out that \(-2\) and that \(-1\) and this is how we’re going to do it. We’re going to think about “negative one”... we’re going to think about “minus one” as being a “negative one” and we’re going to think about the additive inverse of “negative one.” ... So the positive one that we added cancels with the negative one on the left hand side, because remember positive one and negative one are inverses. They’re additive inverses. So when you add them you get the identity. And, of course, the additive identity is zero. ..."

We argue in this example that John is expanding on a “typical” explanation that involves “getting \(x\) by itself” by examining the coefficients and constants on the left hand side of the equation and canceling each out in an order loosely determined by commonly established order of operations. John does go beyond a typical explanation in that he is incorporating more detailed algebraic language in his explanation. For example, he justifies the step of “adding one to both sides” and provides additional details on “canceling” through clear references to the relevant algebraic properties. While we see these advances as significant both mathematically and
pedagogically, we believe they are not evidence of a transition to a more coherent understanding of school algebra. This claim will be highlighted by the contrast between John and the second category of solution and explanation discussed below.

**Category 2: Focus on Operations on a Quantity and Properties of the Operations**

The second category of solutions and explanations, exemplified by Sarah’s below, involves a more substantial shift towards developing an algebraic perspective and using the language of algebra. In the excerpt below, we see Sarah discussing the solution to the equation $3x + 7 = 2$:

The first equation I selected was “three $x$ plus seven is equal to two.” This is telling us that we have some quantity and then we multiply that by three and add seven and the result is two. ... So we have to find out for what value of $x$ will give us $3x + 7$ equal to two. There are some operations which are being applied here. The first one we see is that we are multiplying $x$ by three ... The second operation is to add seven, so we first multiply by three and then we add seven. ... In order to solve this equation, we want to find the inverses so that we can use the multiplicative and the additive identity and other properties that we have learned about. Now for three, the multiplicative identity is “one over three.” And we know that three multiplied by one over three, its inverse or its reciprocal, is equal to one – the multiplicative identity or the “do nothing” element. Similarly, for our plus seven, its inverse is negative seven and we know that seven plus negative seven is equal to zero, the additive identity. That means it does nothing. With these – seven plus negative seven, that forms a zero pair. And three multiplied by one-third gives me a one-pair. Now let’s ... solve this equation. We have $3x + 7 = 2$. The first thing I will do is to form a zero pair by adding the additive identity of seven, which we have identified already. And it is an equation so what I’m doing on one side, I have to do on the other. This gives me $3x$ plus seven plus a negative seven being equal to two minus seven [the right hand side of the equation]. ... From here we have the additive identity zero, so we have $3x$ plus zero is equal to five and that tells me that $3x$ is equal to negative five. Now we want to get the single unit of $x$, so what am I going to do here? I’m going to multiply by its multiplicative inverse, which is one over three. One over three multiplied by $3x$ is equal to -5 multiplied by one over three. ... What I am doing here on the left hand side – I have one over three times $3x$ and I’m creating a one-pair and we know that they are multiplicative inverses and they form one. And one multiplied by any number gives me itself, so we have the solution $x$ is equal to five over three or five thirds.

In this excerpt, we see Sarah using a perspective that we argue is fundamentally different from the typical discussion of solving equations. Rather than focusing on getting $x$ by itself by performing actions on the coefficients based on pre-established rules for solving equations, Sarah is reasoning through the algebraic structure by (1) analyzing the operations being applied to the quantity $x$, (2) identifying the inverse operations, and (3) applying those inverse operations in an order determined solely by the operations being applied to $x$. While Sarah’s discussion does have room for improvement, most notably, clearly explaining that we’re creating zero pairs for a particular purpose and not just “forming them,” it does demonstrate a way of thinking that generalizes past the particular task. Whereas John’s explanation could be described as telling a
reader (or a student) how to solve a particular mathematical task, Sarah’s explanation was embedded within a way of thinking that can easily generalize to other problem types. For example, it is easy to imagine Sarah engaging with \( \cos x + 7 = 2 \) in a similar way, only (possibly) wondering what the inverse of \( \cos x \) is.

**Discussion**

While the distinction between the two categories above is interesting from the perspective of student learning, we wish to close by returning to the previous discussion of the two perspectives on MKT. John and other teachers in this category, who enriched their explanation of their solution method by adding mathematical explanations for the various steps of the solution and connecting it with other mathematical ideas, were drawing on (and possibly developing) MKT. We argue that this “enriched explanation” is analogous to the MKT discussed by Ball and her colleagues: it is mathematical knowledge that can support teachers as they attempt to teach particular mathematical content for understanding. In contrast, consider teachers like Sarah in the second category: they did not simply add mathematical explanations and justifications, but rather capitalized on the algebraic structure to present a solution that is ripe for generalization. While we acknowledge that they are likely not aware of the generalizibility of their explanation, making that evident is a focus for the remainder of the course. Regardless, we believe that without coming to understand particular algebraic scenarios in a way that can be generalized, there is little chance of coming to see the inherent coherence of mathematics or to support it in one’s students.

In some ways, this is similar to what Ball and her colleagues refer to as *Horizon Content Knowledge* (HCK), or “knowledge of how mathematical topics are related of the span of mathematics included in the curriculum” (Ball, Thames, & Phelps, 2008, p. 404) or related to mathematics beyond the scope of the K-12 curriculum. While it is similar, we find it necessary to make one clarification: in most cases, teachers are aware of the algebraic properties discussed in this paper and secondary teachers, who have taken abstract algebra are (or were) aware of the connections between the first few sections of their 10th grade algebra text and their university abstract algebra text. What they have not developed is a conceptualization of mathematics that uses the lens of algebraic structure to provide coherence to a variety of related mathematical ideas and content. This, too, is a mathematical understanding, but one of a much bigger grain size than most other perspectives of MKT.

We wish to close this paper by highlighting the synergy between the two conceptualizations of MKT. We see the work of Ball and her colleagues as focusing on language, representations and “unpacked” mathematical understandings of particular mathematical ideas as indispensable. But we also believe that a more global view, one that highlights a teachers’ connected web of understandings of which this language and these representations and understandings are a part, is also essential. We believe that a more refined theory of MKT will only emerge if its emphasis is both on the local and global perspectives.

**Endnotes**

It is important to note that while the mathematics itself is not disconnected, students are offered little opportunity to experience this connectedness. Instead, they experience a disconnected set of facts and procedures.

TEACHER DIFFERENCES IN MATHEMATICS KNOWLEDGE, ATTITUDES TOWARD MATHEMATICS, AND SELF-EFFICACY AMONG NYC TEACHING FELLOWS

Brian R. Evans
Pace University
bevans@pace.edu

Supplying urban settings with quality teachers is important for student achievement. We examined the differences in content knowledge, attitudes toward mathematics, and levels of self-efficacy among teachers in the NYC Teaching Fellows program. Findings revealed that high school teachers had significantly higher content knowledge than middle school teachers, and Mathematics Teaching Fellows had significantly higher content knowledge than Mathematics Immersion Teaching Fellows. Lastly, mathematics and science majors had significantly higher content knowledge than other majors.

Introduction

The purpose of this study was to determine differences in content knowledge, attitudes toward mathematics, and concepts of teaching self-efficacy among different categories of alternative certification teachers in New York City. Determining these differences is critical for two reasons. First, it is important for teacher recruitment. If policy makers, administrators, and teacher educators know which teacher characteristics lead to the highest levels of content knowledge, attitudes, and self-efficacy, recruitment can be better focused to yield the best results for students. Second, in teacher preparation, knowing which teachers need the most support, and in what areas, can lead to increased teacher quality through better preparation and focused professional development. This study is a continuation of a previous study that found high positive attitudes and high concepts of teaching self-efficacy among the teachers sampled.

The teacher participants in this study come from two mathematics methods sections of New York City Teaching Fellows (NYCTF) teachers. The NYCTF program was developed in 2000 in conjunction with The New Teacher Project and the New York City Department of Education (NYCTF, 2008; Boyd, Lankford, Loeb, Rockoff, & Wyckoff, 2007). The program goal was to recruit professionals from other fields to supply the large teacher shortages in New York City’s public schools with quality teachers. A shortage of 7000 teachers was predicated for 2000, with a possible shortage of 25,000 teachers over the next several years (Stein, 2002). Prior to September 2003, New York State allowed teachers to obtain temporary teaching licenses in order to meet the schools’ staffing needs.

Mathematics Teaching Fellows begin graduate coursework at one of several New York universities and student teach in the summer before they start teaching in September. Teaching Fellows receive subsidized tuition and are given a stipend in the summer, and receive full teacher salaries when they begin teaching in September. Over the next several years Teaching Fellows continue taking coursework in education while teaching in their classrooms with a Transitional B license from the New York State Education Department (NYSED) that allows them to teach for three years before earning Initial Certification. Before they begin teaching in September, Teaching Fellows must pass the Liberal Arts and Sciences Test (LAST) and the Content Specialty Test (CST) in mathematics required by the New York State. Those who lack the required 30 mathematics course credits are labeled as “Mathematics Immersion,” and those with
the minimum required 30 credit hours are considered “Mathematics Teaching Fellows.” Mathematics Immersion Teaching Fellows must complete the required credits within three years. Teaching Fellows generally teach in high needs schools throughout the city (Boyd et al., 2006).

**Literature Review and Theoretical Framework**

Recently there has been an interest in studying the effects of alternative teacher certification programs in U.S. classrooms with a particular interest in teacher quality issues (Darling-Hammond, 1994, 1997; Darling-Hammond et al., 2005; Evans, 2009, in press). Further, there has been specific interest in Teaching Fellows in New York schools (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006; Boyd, Lankford, Loeb, Rockoff, & Wyckoff, 2007; Stein, 2002). A majority of these studies investigated teacher retention and student achievement as variables that determine success. These are two of the most important variables, but there is a need to investigate other variables related to success, such as teacher content knowledge, attitudes toward mathematics, and teacher self-efficacy. Suell and Piotrowski (2007) called for a strong academic coursework component for alternative certification teachers. According to them this specialized body of coursework is the key determinant of quality teacher preparation. Previous studies also found that teachers prepared in alternative certification programs, such as the Teaching Fellows program, manage to secure higher scores on tests of content than other teachers (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006; Boyd, Lankford, Loeb, Rockoff, & Wyckoff, 2007). However, details about the quality of content knowledge have been sparse. Indeed, there has been a lack of concentrated focus on mathematics teachers specifically.

Aiken (1970) was an early pioneer in researching the relationship between mathematical achievement and attitudes toward mathematics. Similar to Aiken’s work, Ma and Kishor (1997) found a small but positive significant relationship between achievement and attitudes through meta-analysis. This reported relationship between achievement and attitudes, along with Ball, Hill, & Bass’ (2005) emphasis on the importance of content knowledge for teachers, formed the framework of this study. Three research questions guided data collection and analysis as listed below:

1. Are there differences in mathematical content knowledge, attitudes toward mathematics, and concepts of teacher self-efficacy between middle and high school Teaching Fellows?
2. Are there differences in mathematical content knowledge, attitudes toward mathematics, and concepts of teacher self-efficacy between Mathematics and Mathematics Immersion Teaching Fellows?
3. Are there differences in mathematical content knowledge, attitudes toward mathematics, and concepts of teacher self-efficacy between undergraduate college majors among the Teaching Fellows?

Bandura’s (1986) construct of self-efficacy theory framed the study’s focus on self-efficacy of Teacher Fellows. Bandura divided teacher self-efficacy according to a teacher’s belief in his or her ability to teach well, and his or her belief in a student’s capacity to learn well from the teacher. Teachers who feel that they cannot effectively teach mathematics and affect student learning are more likely to avoid teaching from an inquiry and student-centered approach with real understanding (Swars, Daane, & Giesen, 2006).

---

Methodology

The study utilized quantitative methods. The sample consisted of 42 new teachers enrolled in the Teaching Fellows program. Approximately one third of participants were male. The Teaching Fellows in this study were enrolled in two sections of mathematics methods that involved a combination of both pedagogical and content instruction. The course focused on constructivist methods with an emphasis on problem solving and real-world connections.

Teaching Fellows were given a mathematics content test and two questionnaires at the beginning and at end of the semester. The mathematics content test consisted of 25 free response items ranging from algebra to calculus. The mathematics content test taken at the end of the semester was similar in form and content to the one taken at the beginning. Additionally, mathematics Content Specialty Test (CST) scores for the New York State certification were recorded as another measure of mathematical content knowledge.

The first questionnaire was created by Tapia (1996) and has 40 items that measured attitudes toward mathematics including self-confidence, value, enjoyment, and motivation in mathematics. The instrument uses a 5-point Likert scale ranging from strongly agree, agree, neutral, disagree, to strongly disagree. The second questionnaire was adapted from the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI) developed by Enochs, Smith, and Huinker (2000). This survey measures concepts of self-efficacy. The MTEBI is a 21-item 5-point Likert scale instrument with the same choices as the attitudinal questionnaire, and is grounded in the theoretical framework of Bandura’s self-efficacy theory (1986). Based on the Science Teaching Efficacy Belief Instrument (STEBI-B) developed by Enochs and Riggs (1990), the MTEBI contains two subscales: Personal Mathematics Teaching Efficacy (PMTE) and Mathematics Teaching Outcome Expectancy (MTOE) with 13 and 8 items, respectively. Possible scores range from 13 to 65 on the PMTE, and 8 to 40 on the MTOE. The PMTE specifically measures a teacher’s self-concept of his or her ability to effectively teach mathematics. The MTOE specifically measures a teacher’s belief in his or her ability to directly affect student learning outcomes. Enochs et al. (2000) found the PMTE and MTOE had Cronbach alpha coefficients of 0.88 and 0.77, respectively.

Research question one and two were answered using independent samples t-tests on data collected from the 25-item mathematics content test, 40-item attitudinal test, and 21-item MTEBI with two subscales using both pre and posttest scores. Research question three was answered using one-way ANOVA on data also collected from the same instruments. For the third research question Teaching Fellows were divided into three categories based upon their undergraduate college majors: liberal arts, business, and mathematics and science majors. Liberal arts majors consisted of majors such as English, history, Italian, philosophy, political science, psychology, sociology, Spanish, and women studies. Business majors consisted of those studying accounting, business administration and management, commerce, economics, and finance. Mathematics and science majors included those studying mathematics, engineering, and the sciences (biology and chemistry). All significance levels in this study were at the 0.05 level.

Results

The first research question was answered using independent samples t-tests comparing middle and high school teacher data using the 25-item mathematics content test, 40-item attitudinal test, and 21-item MTEBI with two subscales: PMTE and MTOE. The results of the independent samples t-test for the first part of research question one revealed a statistically significant difference between middle school teacher scores ($M = 68.42$, $SD = 15.600$, $N = 26$).
and high school teacher scores \((M = 85.13, SD = 16.041, N = 16)\) for the mathematics content pretest with \(t(40) = -3.334, p = 0.002, d = 1.056\). This means high school teachers had higher content test scores than middle school teachers on the pretest. Additionally, there was a large effect size. The results of the independent samples \(t\)-test for the first part of research question one also revealed a statistically significant difference between middle school teacher scores \((M = 79.46, SD = 15.402, N = 26)\) and high school teacher scores \((M = 92.63, SD = 6.582, N = 16)\) for the mathematics content posttest with \(t(40) = -3.230, p = 0.002, d = 1.112\). This means high school teachers had higher content test scores than middle school teachers on the posttest as well. Additionally, there was a large effect size. For attitudes toward mathematics and concepts of self-efficacy there were no statistically significant differences found between middle and high school teachers on both pre and posttests.

The second research question was answered using independent samples \(t\)-tests comparing Mathematics Immersion and Mathematics Teaching Fellows data also using the 25-item mathematics content test, 40-item attitudinal test, and 21-item MTEBI with two subscales: PMTE and MTOE. The results of the independent samples \(t\)-test for the first part of research question two also revealed a statistically significant difference between Mathematics Immersion Teaching Fellows’ scores \((M = 68.90, SD = 17.008, N = 30)\) and Mathematics Teaching Fellows’ scores \((M = 89.50, SD = 7.868, N = 12)\) for the mathematics content pretest with \(t(40) = -4.005, p = 0.000, d = 1.555\). This means Mathematics Teaching Fellows had higher content test scores than Mathematics Immersion Teaching Fellows on the pretest. Additionally, there was a large effect size. The results of the independent samples \(t\)-test for the first part of research question two also revealed a statistically significant difference between Mathematics Immersion Teaching Fellows’ scores \((M = 80.53, SD = 14.600, N = 30)\) and Mathematics Teaching Fellows’ scores \((M = 94.33, SD = 7.390, N = 12)\) for the mathematics content posttest with \(t(40) = -3.130, p = 0.003, d = 1.202\). This means Mathematics Teaching Fellows had higher content test scores than Mathematics Immersion Teaching Fellows on the posttest as well. Additionally, there was a large effect size. For attitudes toward mathematics and concepts of self-efficacy there were no statistically significant differences found between Mathematics and Mathematics Immersion Teaching Fellows on both pre and posttests.

The third research question was answered using one-way ANOVA comparing different undergraduate college majors using the 25-item mathematics content test, 40-item attitudinal test, and 21-item MTEBI with two subscales: PMTE and MTOE. Teaching Fellows were grouped according to their undergraduate college major along three categories: liberal arts \((N = 16)\), business \((N = 11)\), and mathematics and science \((N = 15)\) majors. The results of the one-way ANOVA for the first part of research question three revealed a statistically significant difference, \(F(2, 39) = 8.582, p = 0.001\) (see Table 1) on the pretest. A post hoc test (Tukey HSD) was performed to determine exactly where the means differed. The post hoc test revealed that mathematics and science majors had significantly higher content knowledge on the pretest than business majors, \(p = 0.001\) and liberal arts majors, \(p = 0.008\). There were no other statistically significant differences. The results of the one-way ANOVA for the first part of research question three also revealed a statistically significant difference, \(F(2, 39) = 6.469, p = 0.004\) (see Table 1) on the posttest. Again, a post hoc test (Tukey HSD) was performed to determine exactly where the means differed. The post hoc test revealed that mathematics and science majors had significantly higher content knowledge on the posttest than business majors, \(p = 0.005\) and liberal arts majors, \(p = 0.025\). There were no other statistically significant differences. It was concluded that mathematics and science majors had statistically significant differences.
higher content knowledge scores on both pre and posttests than non-mathematics and non-science majors. For attitudes toward mathematics and concepts of self-efficacy there were no statistically significant differences found between the undergraduate college majors on both pre and posttests.

Since significant differences were only found for content knowledge, as measured by the 25-item mathematics content test, it was decided that a focus on content knowledge differences would be appropriate using another content instrument. The first part of each research question was addressed again by using scores on the CST. It was found using an independent samples t-test that high school teachers (M = 269.25, SD = 17.133, N = 16) had statistically significant higher content knowledge than middle school teachers (M = 255.31, SD = 20.372, N = 26) with t(40) = -2.283, p = 0.028, d = 0.741 as measured by CST scores. Additionally, there was a moderate effect size. This means mathematics high school teachers had higher content test scores than middle school teachers on the CST, just as was found using the 25-item mathematics content test.

Further, it was found using an independent samples t-test that Mathematics Teaching Fellows (M = 276.33, SD = 16.104, N = 12) had statistically significant higher content knowledge than Mathematics Immersion Teaching Fellows (M = 254.33, SD = 18.291, N = 30) with t(40) = -3.636, p = 0.001, d = 1.277 as measured by CST scores. Additionally, there was a large effect size. This means Mathematics Teaching Fellows had higher content test scores than Mathematics Immersion Teaching Fellows on the CST, just as was found using the 25-item mathematics content test.

Teaching Fellows were again grouped according to their undergraduate college majors: liberal arts (N = 16), business (N = 11), and mathematics and science (N = 15) majors. The results of the one-way ANOVA revealed a statistically significant difference, F(2, 39) = 6.765, p = 0.003 for the CST scores (see Table 1). A post hoc test (Tukey HSD) was performed to determine exactly where the means differed. The post hoc test revealed that mathematics and science majors had significantly higher content knowledge, as measured by the CST, than...
business majors, $p = 0.004$ and liberal arts majors, $p = 0.021$. Again, it can be concluded that mathematics and science majors had statistically significant higher content knowledge scores than non-mathematics and non-science majors, as measured by the CST. There were no other statistically significant differences.

**Discussion**

Results indicated that high school teachers had higher mathematics content knowledge than middle school teachers. Further, it was found that Mathematics Teaching Fellows had higher mathematics content knowledge than Mathematics Immersion Teaching Fellows. Finally, it was established that mathematics and science majors had higher mathematics content knowledge than non-mathematics and non-science majors. However, no differences were found between middle and high school teachers, Mathematics and Mathematics Immersion Teaching Fellows, and liberal arts, business, and mathematics and science majors in regards to their attitudes toward mathematics and concepts of teacher self-efficacy.

In the first study it was found that teachers had positive attitudes toward mathematics and high concepts of self-efficacy. Combining the results of the first study with the findings of the present work, an interesting outcome emerged. Teachers had the same high positive attitudes toward mathematics and same high concepts of self-efficacy regardless of content ability. Thus, teachers believed they were just as effective at teaching mathematics, despite not having the high level of content knowledge that some of their colleagues possessed. This is significant since high content knowledge is assumed a necessary condition for quality teaching (Ball et al., 2005). This finding contrasts sharply with reports of research conducted on the relationship between content knowledge and attitudes (Aiken, 1970, 1974, 1976; Ma & Kishor, 1999).

It was not surprising that high school teachers had higher content knowledge than middle school teachers. However, New York State requires a minimum of 30 mathematics credits for both middle and high school teachers. It would be expected that high school teachers may have higher content knowledge due to their experience working with higher level mathematics students. However, this does not explain why high school teachers scored better on the CST and content pretest instruments since this study began at the beginning of their teaching careers, and the teachers did not yet have significant classroom experience. It is speculated that teachers with stronger content knowledge may be drawn more to high school teaching, rather than middle school teaching, and the more rigorous content that comes with teaching high school mathematics.

It is imperative that future research address whether or not there are differences in actual teaching ability among the Mathematics and Mathematics Immersion Teaching Fellows and different college majors held by the teachers. One way to determine this would be to measure student performance in the schools to determine differences in student achievement among students with varying teacher content knowledge, mathematics immersion status, and teacher college majors.

Considering that many alternative certification teachers, such as Teaching Fellows, teach in high needs urban schools in New York City (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006), and throughout the United States, it is imperative that policy makers, administrators, and teacher educators continually evaluate the teacher quality in alternative certification programs. NCTM says, “Every student has the right to be taught mathematics by a highly qualified teacher—a teacher who knows mathematics well and who can guide students’ understanding and learning” (NCTM, 2005). This study informs teacher education since it was found that high school...
teachers, Mathematics Teaching Fellows, and those who majored in mathematics and science had higher mathematics content knowledge on several measures. Since New York State holds the same high standards for both high school and middle teachers alike, strategies to better middle school teachers’ content knowledge should be investigated and implemented. It is recommended that middle school teachers be given the professional development they need in mathematics content knowledge by both the schools in which they teach and the schools of education in which they are enrolled. Many professional development activities focus on pedagogical knowledge. However, middle school teachers need an emphasis on strengthening content knowledge as well.

Better preparation for Mathematics Immersion Teaching Fellows and non-mathematics and non-science majors is needed. Based upon the results of this study, it is recommended that before teachers from non-mathematics backgrounds are placed in mathematics classrooms, they first be required to earn a minimum of 30 mathematics credits. Further, the 30 mathematics credits should be a prerequisite to enrollment in an alternative teacher preparation program. It is clear from the results of this study that even after a semester in a mathematics methods course teachers from non-mathematics backgrounds are not as knowledgeable as teachers who have stronger mathematics backgrounds. Teacher educators must consider that with today’s shortage of highly qualified mathematics teachers and current economic climate, more people are attracted to the profession even if they do not have a strong mathematics or science background. The best ways to prepare career-changers in mathematics content need to be further investigated in future research.

In order to make well informed decisions about teacher recruitment and development, more research is necessary on the growing alternative certification segment of the teaching population. Teaching Fellows currently account for one-fourth of all New York mathematics teachers (NYCTF, 2008). Also, Teaching Fellows grew from around one percent of all newly hired teachers from its beginning in 2000 to 33 percent of all new teachers by 2005 (Boyd, Loeb, Lankford, Rockoff, & Wyckoff, 2007). Unless something is done to better prepare teachers with the rigorous content they need, having teachers who had not majored in mathematics and science related areas teach mathematics could be a disservice to our students. For the sake of urban students who have teachers in alternative certification programs, the certification of high quality teachers must continually be a high priority for policy makers, administrators, and teacher educators. Considering the call for high quality teachers, high stakes examinations, and accountability, now more than ever we need to ensure that the teachers we certify are fully prepared in both content and pedagogical knowledge to best teach our highest needs students.

References

This study extends research on teachers’ difficulties with fraction division by examining underlying difficulties they can have coordinating levels of units. Research on students has demonstrated that coordinating 3 levels of units is central to multiplicative reasoning, including reasoning about fractions, but similar attention to levels of units is rare in research on teachers. The present study uses data from a 40-hour professional development course for in-service middle grades teachers to demonstrate that reasoning with 3 levels of units was a central obstacle for some teachers when using drawings to understand fraction division. The results suggest that the capacity to coordinate two 3 levels structures is necessary for teachers to use word problems and drawings to model fraction division effectively for their students.

Introduction

Research on teacher knowledge has expanded from studies of teachers’ subject-matter knowledge of various content areas to the organization of teachers’ knowledge for teaching particular content to students (e.g., Ball, Lubienski, & Mewborn, 2001; Ball, Thames, & Phelps, 2008; Shulman, 1986). This expansion reflects increasing awareness that teachers need not only content knowledge that many educated adults have, but also knowledge specialized for teaching particular topics to students. Ma (1999) described several examples of mathematical knowledge specialized for teaching, and elaborating such knowledge remains a central challenge for the field.

The present study uses data from a professional development course to examine knowledge necessary for using drawn models to explain measurement division with fractions—knowledge important for supporting reform-oriented teaching practices. Research reviewed below has demonstrated that teachers often struggle to produce coherent conceptual explanations for the product or quotient of two rational numbers. We extend previously reported results by demonstrating that teachers’ capacities to coordinate three levels of units is essential if they are to use drawn models to explain measurement division with fractions. Our results shed new light on what teachers must accomplish if they are to explain fraction division using drawings and suggest important topics on which teacher educators and professional developers should focus.

Introduction

Teachers’ Understanding of Multiplication and Division with Rational Numbers

Research on preservice and in-service teachers’ understanding of fractions has demonstrated that, beyond knowledge of computation procedures, teachers’ understandings of multiplication and division with rational numbers is limited. A main result reported across studies is that teachers can confuse situations that call for dividing by a fraction with ones that call for dividing by a whole number or multiplying by a fraction (Ball, 1990; Borko et al., 1992; Ma, 1999; Sowder, Philipp, Armstrong, & Schappelle, 1998). This confusion is often evident when teachers
generate word problems to illustrate fraction division (e.g., Ball, 1990; Ma, 1999). Teachers can similarly mistake division for multiplication by a decimal number less than one (e.g., Graeber & Tirosh, 1988; Harel & Behr, 1995).

Only a small number of studies have reported directly on teachers’ capacities to use drawn models to multiply or divide fractions or decimals. Borko et al. (1992), Eisenhart et al. (1993), and Sowder et al. (1998) have all reported that teachers’ difficulties with basic meanings for multiplication and division can be revealed when they attempt to generate and interpret drawn models. The present study examines an additional underlying difficulty—teachers’ capacities to coordinate levels of units.

**Unit Structures in Multiplicative Reasoning**

Research on multiplicative reasoning has emphasized the central role played by units of various types. For the present study, we focus on two main results. First, conceptual analyses of multiplicative reasoning (e.g., Greer, 1992) have emphasized that when numbers are embedded in multiplication or division situations, each number has a different referent unit. To see this, consider the following two word problems:

1. Carrie has run 1/2 mile. If she walks another 1/3 mile, how far has she traveled?
2. John has run 2/3 of a mile on a track. If one lap is 3/4 mile long, how much of one lap has he run?

In the first problem, 1/2, 1/3, and the answer, 5/6, all refer to the same unit—one mile. In the second problem, 2/3 refers to the distance John has run, 3/4 refers to the miles per lap, and the answer, 8/9, refers to the portion of one lap that John has run. In contrast to Problem 1, each number in Problem 2 refers to a different unit. Some teachers in the present study struggled to identify appropriate referent units in fraction division situations.

Second, further studies of multiplicative reasoning (e.g., Behr, Harel, Post, & Lesh, 1992; Steffe, 1994, 2001, 2003) have highlighted the importance of multi-level unit structures. (We explain multi-level unit structures in the next section.) Nearly all of the empirical research on the role of forming and transforming multi-level unit structures in multiplicative reasoning has concentrated on students. Two studies that have examined teachers are those by Behr, Khoury, Harel, Post, and Lesh (1997) and by Izsák (2008). Both studies have reported significant constraints in preservice and in-service teachers’ capacities to form and transform multi-level unit structures when reasoning about situations that call for multiplication of fractions. The present study contributes to this line of research by examining in-service teachers’ capacities to form and transform multi-level unit structures in situations that call for division of fractions.

**Theoretical Framework**

Our theoretical perspective emphasizes cognitive operations for forming and transforming multi-level unit structures. In particular, we make direct use of Steffe’s distinction between two levels and three levels of units. Steffe (1994, 2001, 2003) has argued that the capacity to form three levels of units is necessary for students to construct multiplicative schemes and schemes for operating with fractions. We apply a similar perspective to the study of teachers. The discussion below demonstrates that the capacity to form and transform 3-level structures is necessary for using drawn models to make sense of fraction division.

The following analysis of the statement $a/b \div c/d$ focuses on the measurement division question: “How many times (or what part of) $c/d$ is $a/b$?” We begin with the example $2/3 \div 1/6$. To determine the answer using length quantities, one might start by drawing a unit interval
subdivided into three equal parts as shown in Figure 1a. This requires attention to just two levels of units, the whole and the thirds. To determine how many 1/6 are in 2/3, one could further subdivide the thirds into sixths as shown in Figure 1b. Answering the division question requires interpreting the bold line segment simultaneously as 1/6 of the whole and as 1/4 of 2/3. Thus, understanding that the answer is 4 requires attending simultaneously to three levels of units—the whole, the 2/3, and the 1/6.

(a) A 2-level structure for 2/3.  
(b) A 3-level structure for determining how many 1/6 is 2/3

Figure 1. Determining 2/3 ÷ 1/6

Now consider the more complicated example, 2/3 ÷ 3/4. Here, using length quantities to determine the answer requires coordinating two 3-level structures. One can start again by constructing a 2-level structure for 2/3. The new challenge is that fourths do not subdivide thirds evenly. Thus, one needs to anticipate a finer partition that simultaneously subdivides thirds and fourths. One way to accomplish this is to use knowledge of whole-number factor-product combinations: 3 and 4 are factors of 12. Figure 2a shows 2/3 as 8 one-twelfths, and Figure 2b shows 3/4 as 9 one-twelfths. One now has constructed two 3-level structures that allow multiplicative comparisons between 2/3 and 3/4. Answering the question “How many times (or what part of) 3/4 is 2/3?” requires interpreting the one-twelfth segment shown in Figure 2a and Figure 2b simultaneously as 1/8 of 2/3 and as 1/9 of 3/4. This implies that 8/9 of 3/4 is 2/3.

Methodology

The Does it Work? Professional Development Course

The present study is part of an ongoing NSF-funded research project called Does it Work?: Building Methods for Understanding Effects of Professional Development (DiW). The data came from a 40-hour professional development course on fractions, decimals, and proportions offered in Fall 2008. The participants came from an urban district in the Southeast. Thirteen were in-service mathematics teachers and one came from the district’s central office. Of the teachers, one taught in Grade 5, and the others taught in Grade 6 or Grade 7.

We designed the course to prepare teachers for new curriculum standards in their state. Similar to standards developed by the National Council of Teachers of Mathematics (2000), the state standards address content areas, such as number and operations, and processes of mathematical thinking, such as representing and solving problems. The new state standards require teachers not only to compute efficiently and accurately with fractions, decimals, and proportions, but also to reason about fractions, decimals, and proportions embedded in problem situations. We recruited teachers by offering a small stipend and by explaining that the professional development would help prepare them for the new state standards.

A member of the DiW research team facilitated the course, which met for 3 hours one night per week for 14 weeks. Each class focused on a set of tasks that addressed a particular topic. Topics included multiplication and division with fractions, multiplication and division with decimals, and proportional reasoning. Many of the problems created opportunities to reason with...
multi-level unit structures by requiring teachers to generate and interpret drawn models for multiplication and division of fractions and decimals. Teachers constructed drawn models using either paper and pencil or software called Fraction Bars (Orrill, n.d.) that allowed them to draw and partition rectangles accurately. The instructor moved back and forth between whole-class discussions and group work. The whole-class discussions were lively, and the teachers directed many of their comments and questions toward each other, not the instructor. At the end of most classes, the teachers completed reflections that consisted of short written tasks related to the focal topic for that particular class.

**Data and Analysis**

We videotaped all class sessions using two cameras. One researcher used the first camera to record the entire class, and a second researcher used the second camera to record written work on the whiteboard during whole-class discussion and on teachers’ papers and computer screens during group work. We also administered a multiple-choice pre-test and post-test that we developed (Izsák, Orrill, Cohen, & Brown, 2010) by modifying (with permission) the middle grades Learning Mathematics for Teaching measure of Mathematical Knowledge for Teaching (Hill, 2007). To gather information on how teachers reasoned on the pre-test and post-test, we conducted videotaped interviews with seven. We selected these teachers to represent a range of performance on the pre-test from high to low. (When collecting classroom data, we prioritized these seven teachers.) Finally, we collected all of the teachers’ written work.

We began our analysis by examining teachers’ answer choices on the pre-test and post-test. We hoped to see clear gains in teachers’ performance, but about half the teachers had low scores on the pre-test and post-test, about one third of the teachers had high scores on the pre-test and post-test, and the remaining teachers were in the middle. On closer inspection, we found cases where teachers’ answers to particular items moved from incorrect on the pre-test to correct on the post-test, but we also found cases where teachers’ answers moved from correct on the pre-test to incorrect on the post-test and cases where teachers’ answers moved from one incorrect answer to a different incorrect answer. To understand these results, we turned next to the pre-test and post-test interviews conducted with seven teachers. These interviews revealed aspects of growth and change to which the multiple-choice tests were insensitive—for instance, some teachers appeared more confident in their reasoning on the post-test than on the pre-test—but they also confirmed a high degree of stability from pre-test to post-test for some teachers. This stability was particularly evident on fraction division items. Surprisingly, some of these stable teachers were among the most active participants during the course.

We were puzzled that we did not see more definitive evidence of teacher learning from pre-test to post-test, especially since some teachers gave lucid, correct explanations for measurement division with fractions during whole-class discussions and because fraction division was treated twice, once in the first half and once in the second half of the course. This led us to analyze the video-recordings of the class sessions. Our initial pass through these data, revealed that teachers often struggled with meanings for division, referent units for numbers, and strategies for partitioning lengths and areas in drawn models. We then retraced all of the class sessions a second time to create a more detailed chronological list of problems on which the teachers worked, the strategies they used to solve those problems, and comments and questions they had about their own solutions and solutions generated by other teachers. We looked specifically for data on teachers’ meanings for division, referent units for numbers, and strategies for partitioning lengths and areas in drawn models. It was here we noticed that some teachers appeared to reason

---

with just two levels of units, while others appeared to reason with three levels of units. We took one final pass through our data to develop cases for each of the seven interview teachers that focused on their capacities to reason with multi-level unit structures.

**Results**

Our main result is that some teachers appeared to coordinate only two levels of units, while others coordinated three levels of units, and this distinction played a central role in most teachers’ stable performance from pre-test to post-test. In particular, teachers who coordinated only two levels of units had difficulty understanding their colleagues’ lucid explanations for measurement division that made use of three levels of units (similar to the explanation summarized in Figure 2). Other teachers could form three levels of units but were still learning to coordinate more than one 3-level structure. Finally, one teacher began the professional development course able to form 3-level structures and to explain measurement division for fractions correctly during the pre-test interview. We illustrate the central role played by multi-level unit structures with cases of two teachers who were among the seven we interviewed and who made regular contributions to whole-class discussions. These teachers were among those for whom we had the largest amount of data. We keep each case brief but emphasize that for both teachers we examined all of our data before making claims about whether they coordinated two levels or three levels of units.

**Carrie Reasoned with Two Levels of Units**

Initial evidence that Carrie reasoned with two levels of units came from her solution to the Candy Bar problem: *Share two candy bars equally among five people. How much of one candy bar does one person get?* In whole-class discussion, Carrie disagreed with teachers who explained that the answer was 2/5. She used a diagram to argue that getting 1/5 of each bar was the same as getting 2/10 of the two bars; therefore, the answer should be 1/5. Her explanation suggested that she conceived of each bar separately divided into 5 parts (one 2-level structure) and two bars together divided into 10 parts (a second 2-level structure), but not a 3-level structure that coordinated the entire amount of candy (one level), the two separate candy bars inside the total amount (a second level), and the fifths inside each candy bar (a third level).

When the class began to work on fraction division, Carrie reported that she just computed answers to fraction division problems and that she did not have a particular division question that she asked herself. As the class proceeded, however, she did begin to ask the measurement division question. On one reflection that asked teachers to write a story problem for 5 ÷ 1/3, Carrie responded with the following: If I have 5 inches of ribbon, and it takes 1/3 of an inch for a ring, how many rings can I make? Although Carrie was developing meaning for dividing by a fraction, she struggled to coordinate three levels of units one week later. The facilitator had observed Carrie struggle to draw appropriate models for fraction division during the class and so worked with her again at the end of class. They used the problem 2/3 ÷ 1/4. Carrie interpreted the division statement appropriately as asking how many fourths are in 2/3, but she could not use drawings to answer this question correctly. Looking at a diagram that showed a whole divided vertically into thirds and then into 12ths (Figure 3a), Carrie stated that each of the smallest squares were fourths of the whole, when in fact they were fourths of 1/3. She then concluded that there were 8 fourths in 2/3. When the facilitator pointed out that three of the smallest squares made one fourth of the whole and showed Carrie what one fourth in one third looked like (Figure 3b), Carrie interpreted the diagram as showing “three fourths in two thirds.” Similar to her

---

interpretation of the Candy Bar problem, Carrie appeared able to think of a whole divided into three parts (one 2-level structure) or a third divided into fourths (a second 2-level structure), but not a 3-level structure that coordinated 12ths, 3rds, and the whole. Thus, articulating the measurement division question is necessary but not sufficient for use drawings.

Donna Reasoned with Three Levels of Units But Still Struggled with Division

Unlike Carrie, Donna began the professional development course with an explicit meaning for division. She stated that division meant repeated subtraction during her pre-test interview, several times during the professional development course, and again in the post-test interview. Donna was able to use her repeated subtraction interpretation to explain problems like 2 ÷ 1/4 for which the answer is a whole number, but she had difficulty explaining problems like 2/3 ÷ 3/4 for which the answer contained a fraction. Donna could construct three levels of units, but she struggled to coordinate two 3-level structures.

The first evidence that Donna could construct three levels of units came on the same Candy Bar problem: *Share two candy bars equally among five people. How much of one candy bar does one person get?* In contrast to Carrie, Donna explained to her fellow teachers that taking 1/5 from each bar was the same as taking 2/5 from one bar. By equating one fifth of total amount of candy with two fifths of one bar, Donna appeared to attend simultaneously to the total amount of candy (one level), the two separate candy bars inside the entire amount (a second level), and the fifths inside each candy bar (a third level).

Further evidence that Donna could construct three levels of units came two weeks after the discussion of the Candy Bar problem. The teachers were working on a task that asked them to examine similarities, differences, patterns in the following set of division problems: 2 ÷ 3, 2 ÷ 1/4, 2 ÷ 3/4, and 2/3 ÷ 3/4. After teachers had worked in pairs, the facilitator convened a whole-class discussion around 2/3 ÷ 3/4. Keith was the first to present, and his solution used a number line similar to Figure 2b. He explained that you cannot “get 3/4 into 2/3” but, if you divide the 3/4 into nine parts, you can get 8/9 of 3/4 into 2/3. Carrie responded, “I am so lost, it is unreal,” but Donna seemed to understand Keith when she connected his solution to her thinking “How many times can I subtract 3/4 from 2/3? Not quite one time, 8/9 of one time.” Donna then demonstrated to the class how she used two rectangles to approach the problem. She began by drawing two rectangles, dividing the top rectangle into thirds, and dividing the bottom rectangle into fourths. After Donna subdivided the first fourth into three parts, the facilitator interrupted and asked her to explain her thinking. Donna explained, “What I am looking for is a way to name this point right here (see Figure 4). So I realized that right then I had to split these pieces (the fourths) into smaller pieces.” Donna’s explanation demonstrates the intention to construct three
levels of units using the whole rectangle (one level) and the fourths (a second level). As Donna continued, however, she confessed that she did not know how to construct the third level for this problem until she saw another teacher use 12ths.

Figure 4. Donna intends to name 2/3 in terms of fourths

Discussion

The present study contributes to research on teachers’ knowledge of fraction division by demonstrating that the ability to form multi-level unit structures can play a central role in their capacity to use drawn representations. The case of Carrie demonstrates that teachers who only construct two levels of units can find it very difficult to understand lucid explanations for fraction division, let alone construct their own solutions. In particular, Carrie could not understand explanations offered by the facilitator and by Keith. This limited opportunities for her performance to change from the pre-test to the post-test. At the same time, the case of Donna demonstrates that the capacity to form 3-level structures is necessary but not sufficient for using drawn representations to explain fraction division. Teachers need to be able to coordinate two 3-level structures, and teachers need to understand division in terms of multiplicative comparisons (see Figure 2). Finally, our results suggest that teacher educators and professional developers should give explicit attention to reasoning with three levels of units so that teachers can be confident using drawn models for fraction division with their students.

This study documents teachers’ productions in professional development (PD) of algebraic generalizations and justification that draws on specialized content knowledge (SCK) for teaching. Images of the entailments of teachers’ productions that draw on SCK are essential to advance the field’s understanding of teacher knowledge. Twenty teachers’ written and verbal productions of two tasks were analyzed. Results show that teachers’ productions elaborated on key mathematical work such as correspondences across representations, construction and connection of multiple solutions, and productive interplay of empirical and generic examples that contributed to developing SCK. Implications of this research are ways of working mathematically in PD to advance teachers’ SCK.

Introduction

In order to create classroom experiences where students reason and justify mathematics, teachers need to understand mathematical proof1 and know how to apply it in practice (Stylianides & Stylianides, 2006). Research on teachers’ knowledge uncovers that it is the form of proof, rather then the nature of proof and student learning that teachers notice (Knuth, 2002). Similarly, research on teachers’ knowledge of algebraic reasoning shows a number of weaknesses in understanding (Kieran, 2007). Yet, teachers’ knowledge of mathematics and their instruction impacts students’ learning (Hill, Rowan & Ball, 2005). In order to advance teachers’ knowledge of justification and its role in algebraic reasoning teachers need opportunities to construct justifications (Elliott, Lesseig, & Kazemi, 2009; Lo, Grant & Flowers, 2008).

Research on mathematical knowledge for teaching (MKT) suggests that the aim of professional development (PD) programs should advance teachers’ specialized content knowledge (SCK) of mathematics that is unique to the work of teaching (Elliott et al., 2009; Suzuka et al., 2009). Although this seems like a logical argument -- teachers should learn the mathematics unique to their work -- researchers have documented competing purposes of mathematics PD where teachers’ learning migrates to topics other then mathematics (Wilson, 2003). Confounding the finding that teachers’ mathematical learning is often negotiated away, is the fact that there is not an agreed upon knowledge base of the mathematics teachers need to know (Ball, Sleep, Boerst, & Bass, 2009) nor portraits of teachers’ deep understanding of algebraic reasoning (Doerr, 2004). Such images could serve professional educators learning how to facilitate PD oriented to SCK and researchers who are trying to build a knowledge base on teacher learning.

This report offers images of teachers’ productions of algebraic generalizations and justification as they invoke and develop SCK and suggests ways of working mathematically in PD. In doing so, we address two research questions:

How do teachers’ justifications of generalizations orient them to SCK?

What ways can mathematics PD take up teachers’ productions with the purpose of supporting SCK?

This study examines the mathematical productions of teachers who had a long-term commitment to work on mathematics with one another. Analysis of their mathematical work provided insights on critical elements of justification that orients teachers to SCK in PD.

**Theoretical Considerations**

This study draws from three research areas, (i) justification and proof, (ii) justification for algebraic generalization, and (iii) mathematical knowledge for teaching.

Research on teachers’ knowledge of justification and proof has provided insights on their limited understanding of the construct and the need to for enhanced teacher learning opportunities (Knuth, 2002; Martin & Harel, 1989). Teachers’ work asks them to: (i) explain why something is correct by revealing mathematical concepts underlying a proof, (ii) argue and communicate with others within a community (i.e., classroom), (iii) learn and support the learning of new mathematical ideas, and (iv) establish truths based on a deductive system, their work demands that they understand proof beyond verification (Knuth, 2002; Simon & Blume, 1996).

Although teachers may need this knowledge for their work, further investigation of research on teachers’ use of justification suggests limited teacher knowledge of the construct in professional education (Lo, et al., 2008; Simon & Blume, 1996). Most research examines preservice and practicing teachers’ conceptions of proof or proof schemes given various forms of proofs and non-proofs (Knuth, 2002; Martin & Harel, 1989; Stylianides, Stylianides & Philippou, 2007). There remains a need to understand teachers’ productions of justification because these are intellectual resources and practices that teachers draw on when teaching.

Research investigating teachers’ use of justification in their work associated within algebraic reasoning is very limited in scope. What research does exist documents a number of deficiencies in teacher understanding of functions, representational use, and the role of generalization (Doerr, 2004; Kieran, 2007). Progress has been made to understand aspects of teacher knowledge in algebraic reasoning, however the field “does not yet have a rich set of portrayals of expertise…” of teachers from a range of settings (Doerr, 2004, p. 285). There remains a need for further teacher development and research on teachers’ algebraic reasoning productions.

From a discipline perspective, Carraher and Schlieman’s (2007) review of research on algebraic reasoning highlights mathematical representations and the role of generalization. Mathematical representations included pictures, words tables, graphs, and symbols to represent algebraic reasoning. Similarly, Kaput’s (2008) research positions generalization as a key strand of algebra. Studies investigating teachers’ knowledge in these areas, although mostly focused on teacher beliefs, have found teachers’ orientations to algebra inadequate to support the teaching of mathematics called for from research (Kieran, 2007).

Drilling down further into algebraic reasoning, we see a serious lack of research on teachers’ understanding of justification for algebraic generalization. Fortunately research on students’ understandings in this area provides insights on the import of considering the coordination of justification and generalization and the examination of varying levels of justification (e.g., appealing to authority, empirical arguments, deductive justification) to support generalizations (Ellis, 2007; Healy & Hoyles, 2000; Knuth, Choppin, & Bieda, 2009; Lannin, 2005). In particular, Lannin’s work (2005) highlights that justifications provide a view of learners’ use and coordination of underlying mathematical relationships, representations, and structure to construct a generalization. By examining the level of justification used to generalize researchers are able to consider learners’ reasoning – how the range of evidence available from empirical to deductive is

used. It is through the interplay of empirical and deductive justification students gain greater awareness of the limitations of previous levels as new understandings become taken-as-shared, easing the transition to deductive justification (Ellis, 2007; Healy & Hoyles, 2000; Knuth & Elliott, 1998). Research on students’ learning has identified the powerful connection between justification and generalization for student learning and the role empirical arguments play in development. We advance justification is an essential element for generalizing especially for teachers who need to understand the underlying mathematical relationships, representations, and structures. Further, they must be able to distinguish empirical from deductive arguments to advance student learning. This study considers how teachers justify their generalizations and the levels of justification utilized in productions constructed during PD.

In previous work researchers have argued that the purpose for doing mathematics in PD is to advance teachers’ SCK (Elliott et al., 2009; Kazemi, Elliott, Mumme, Carroll, Lesseig, & Kelley-Petersen, in press; Suzuka et al., 2009). Because SCK is a fairly new idea in the field, researchers and professional educators need images of particular mathematical content oriented to SCK. Ball and colleagues’ work on SCK (Ball, Thames, & Phelps, 2008) has helped us theorize what might be entailed in SCK oriented teacher productions for justification of algebraic generalizations. Teachers’ work demands that they not only construct justifications to verify solutions, similar to the work of other professionals who use mathematics, call common content knowledge, it requires a repertoire of ways to generalize coordinating ideas across representations, understanding the interplay between empirical and deductive arguments, and knowing what are key connections across generalizations. This is mathematical work that draws on knowledge unique to the work of teaching, SCK. Our current research allows us to examine images of SCK oriented mathematical practice, justification, and specific content, algebraic generalizations.

**Project Background**

Participants for the study (n = 20) were volunteers participating in *Researching Mathematics Leader Learning (RMLL) seminars* drawn from a pre-existing three-year Mathematics Initiative working on mathematics and developing leadership skills. RMLL prepared leaders to facilitate mathematics PD and took place during the second year of the Initiative. Teachers in the seminars were becoming, or already were, leaders in their schools, districts, and regions charged with facilitating mathematics PD. All of the participants were current or past full-time classroom K-12 teachers (five high school, seven middle school, eight elementary). Teachers in the study were forthright in suggesting that they had developed particular ways of doing mathematics prior to attending RMLL seminars and saw the mathematical work in RMLL similar to the ways of engaging in the Initiative. Teachers brought with them particular conceptual tools – mathematical knowledge and ways of engaging in mathematical work – that were cultivated over the two summers of the Initiative.

Data for the study were participants’ mathematical productions on two tasks (Figure 1) focused on algebraic reasoning with an emphasis on constructing generalized solutions. During seminars, teachers shared solutions with one another and reasoned to develop collective understandings discussed in whole group. During small and whole group discussions, teachers were asked why a solution worked (justification based on mathematical argument) and how solutions work in all cases (generalization). Teachers commented that they knew they “needed” a justification for their generalization especially when trying to explain solutions to one another (see Elliott et al., 2009b).

The *Staircase* and *Candles* tasks were completed by teachers as homework to prepare for small and whole group discussion in RMLL seminars. Nineteen *Staircase* teacher productions (one teacher did not have a written solution) and 20 *Candles* teacher productions were analyzed.

**Tasks One – Staircase**
Adapted from Shell Center Materials

1. Build the next two staircases.
2. Describe the 10th staircase.
3. What is the relationship between the staircase number and the number of cubes it takes to build the staircase? See if you can find a rule to represent that relationship.

**Task Two -- Candles Task**
This task is excerpted from Driscoll (1999).

1. Maria lights two 18 cm long candles at the same time. One candle takes six hours to burn out, and the second takes three. After one hour of burning, what do the candles look like? How much time will pass until one of the candles is exactly twice as long as the other? Explain your answer.
2. Maria lights two 36 cm long candles at the same time. One candle takes three hours to burn out and the other takes six. How much time will pass until the slower-burning candle is exactly twice as long as the faster-burning one? Explain your answer.
3. Maria lights two candles of equal length at the same time. One candle takes six hours to burn out and the other takes nine. How much time will pass until the slower-burning candle is exactly twice as long as the faster-burning one? Explain your answer.

**Methods**

Data used in this study were fieldnotes based on video and audio-taped sessions of small and whole group mathematical discussions including pictures of teachers’ work. In addition, teacher journals with recorded mathematical work were analyzed. The first two authors conducted a series of analyses together and separately to come to agreement on the nature of productions. Analysis inventoried teachers’ written productions focusing on what representations were used in solutions, brief notes on the ways representations were used, and the number of different models or solution strategies completed. The inventory process captured the broad spectrum of approaches teachers constructed on the two tasks. Fieldnotes and transcripts of video were reviewed, writing memos about teachers’ productions shared in small and whole group discussion. Because two cameras were used, two sets of four to five teachers’ productions were captured in more detail during small group work. Here analysis focused on the nature of solutions constructed with attention given to: (i) the types of representations used, (ii) the correspondences of ideas across representations, and (iii) the number of solutions constructed. At
the same time teachers’ journals were examined more closely for productions and to follow the progression of how a production unfolded as teachers’ verbalized their reasoning. Finally, we examined the nature of teachers’ justification provided in verbal and written form considering the level of justification utilized. Findings are based on the patterns identified in the teachers’ written work and discussions of mathematical solutions.

Results & Discussion

Three findings were central in teachers’ productions. Because of limited space, data are summarized for our findings. Our presentation will share additional data to support patterns and claims.

*Use Multiple Representations To Examine Relationships & Confirm Generalizations Beyond Reproach*

One of the most striking themes that emerged across twenty teachers’ productions from each task was the use of multiple representations to build justifications for generalizations (recursive and explicit in symbols and words). Most teachers were individually able to construct generalizations, *Staircase* (n = 18), *Candles* (n = 15). Yet, teachers’ productions did not conclude as soon as a generalization was found. Teachers used a number of representations, orally and in writing, to either confirm a generalization or help build it. For example, many productions of *Staircase* used a rectangle model, with many constructing more than one visual model, relating it to the expression \( n(n+1)/2 \) and other equivalent expressions. Examining correspondences within each task, teachers considered mathematical relationships in the tasks to reason and justify a generalization (either recursive or explicit) as Lannin (2005) suggests is necessary for a deductive argument. Heeding the calls of mathematics reform, teachers showed that they could construct and connect representations (NCTM, 2000). However, teachers went beyond what students might do, teachers’ productions, as shown in Table 1, used numerous representations in their individual productions. [The top row shows the number of teachers using the various types of representations.] Although the table does not provide the nature of the representations used and connections, it is notable that a majority of teachers used at least three representations in their solutions and each was means to further their production.

We came to understand teachers’ use of multiple representations as a means of exploring mathematical relationships in order to construct justifications of generalizations beyond mathematical reproach in the community. In teachers’ verbal productions for *Staircase* and *Candles* there was clear intent to support any symbolic generalization with connections to other representations. Although, teachers knew that for a solution to be a generalization it had to
always work, they were not satisfied until they had constructed a justification that made sense to
themselves and colleagues examining correspondences across representations. It was through the
skilled and strategic use of and correspondences among representations that teachers drew on
and develop mathematical knowledge.

Construct Multiple Solutions to Uncover Mathematical Characteristics & Build Justification that
Explain Why

Striking in teachers’ productions was the volume of solution methods constructed with more
then half of the teachers’ journals containing two or more unique productions and oral
productions sharing numerous methods. Teachers’ productions were not “serial sharing” one
after another, but allowed teachers to examine relationships among solutions, attend to the nature
of change in tasks, and ultimately develop justifications that explained why. Productions of the
Staircase task illustrated different interpretations of the quadratic pattern manifesting in unique,
but equivalent expressions. Discussions centered on how change occurred across cases in the
pattern relating to different definitions of variables symbolical represented. Similarly, the
Candles task illustrated multiple pathways (using tables, pictures, equations) to reason about
indirect variation. Here discussions focused on considerations of how solutions were developed,
why mathematically they worked, and how solutions provide insights on one another to construct
more robust justification.

Elaborate Stumbles With Reasoning to Examine Structures and Validate

In our data there were points in both small and whole group that teachers stumbled in their
productions when elaborating challenging generalizations. During these elaborations, teachers
returned to empirical cases (a specific Staircase or concrete numbers in Candles) to reason and
elaborate on the nature of the generalization. Examining specific cases allowed teachers to
consider underlying key mathematical structures of tasks and ultimately move to deductive
arguments that they suggested were essential. For example, it was in searching for the
underlying pattern in a unique visual model with a specific case in Staircase, and pressing on the
relationship of variables and structure of the pattern, that teachers were able to produce a
deductive justification using a generic visual model for a generalization. Similarly, in elaborating
why a generalization was valid for the indirect relationship in Candles teachers worked
collaboratively to construct a deductive argument and understand the underlying structure of the
task represented in visual models, tables and the more typical system of equations.

We claim that the dance from specific to generic arguments taken up when faced with
conceptual stumbles allowed teachers to investigate key mathematical ideas in tasks and verify
generalizations. Although researchers suggest that teachers’ reliance on empirical justification is
evidence of weak understanding (Martin & Harel, 1989; Simon & Bloom, 1996), this dance was

American Chapter of the International Group for the Psychology of Mathematics Education. Columbus, OH: The
Ohio State University.
productive for teachers to elaborate the mathematical underpinnings of tasks. Furthermore, the less mature (empirical) forms of justification supported the deductive reasoning teachers suggested was needed to validate a generalization. Teachers’ work with justification pressed them to distinguish and develop ways of validating justifications dependent on understanding underlying mathematical structures.

**Conclusions**

Teachers’ elaborations of justification, while doing mathematics in PD, have helped us better understand the role that justification and algebraic generalization can play in teacher learning. Because justifications for generalizations needed to convince beyond reproach, explain, and verify, teachers’ productions opened up conversations about underlying relationships characteristics, and structures. Teachers developed keen skills of identifying correspondences across multiple representations, exploring connections across solutions, and using and distinguishing levels of justification that serve to explain, communicate, and verify new understanding. Teachers’ productions of justifications for generalizations were both useful for the work of teaching and embodied the enhanced notions of justification called for by researchers (Knuth, 2002). This research illustrates how teachers’ productions of justification for algebraic generalization support the development of specialized content knowledge (SCK) needed in teaching (Ball et al., 2008). Our work contributes to the limited body of work on specific forms of teachers’ SCK. Further research is needed on teachers’ justification productions across other groups and tasks to explore the range of potential benefits and drawbacks for developing SCK in PD.

**Endnotes**

1. The term justification is used to note verbal and written mathematical arguments to verify a solution. When referencing others’ work their term is used.
2. Project funded by granting agent. Opinions expressed are the authors and do not necessarily reflect the views of the granting agent.
3. Seminar descriptions are in other publications, see author.
4. Teachers’ participation was examined to better understand justification in PD. No causal claims are made about the impact of leader seminars.

**References**

This study used video data to explore how mathematics teachers conceptualize the partitioning of regions by axes in a three-dimensional geometric space. In collaborative settings, teachers approached the problem using both combinatorial and graphical methods, the latter being laden with gestures. For some teachers difficulties arose in the transition from two-dimensional to three-dimensional space. For others interpreting three-dimensional models was difficult. While all groups solved the problem posed, many failed to verbalize connections between the multiple representations introduced during their discussions.

**Introduction**

Teachers need a robust, unified, flexible understanding of fundamental mathematical concepts (Ma, 1999; Ball, Thames, and Phelps 2008) that allows them to “mediate students’ ideas, make choices about representations of content, modify curriculum materials, and the like” (Ball and Bass 2000, p. 97). One of the most fundamental mathematical ideas is that of graphing. Graphing usually involves the use of the $xy$-plane and ordered pairs to locate points in two dimensions. The National Council of Teachers of Mathematics (2000, 2006) has advocated the use of graphing starting as early as the upper elementary grades to study patterns and extending through the later high school years to “investigate conjectures and solve problems involving two- and three-dimensional objects represented with Cartesian coordinates” (NCTM, 2000, p. 308).

Despite students’ experience with number lines when learning arithmetic, the use of the Cartesian coordinate system is so integrated in the culture of mathematics that it is often introduced as a single, static two-dimensional tool with a particular orientation rather than a blending of two orthogonal one-dimensional spaces. Instead of building on students’ foundational knowledge and making transparent the longitudinal coherence of mathematics, teachers place emphasis on conventions, such as the use of Roman numerals and counterclockwise numbering, rather than on actual fundamental concepts. While this is not misleading, it does not convey a deep understanding of the use of two perpendicular number lines intersecting at their origins to form four distinct regions called quadrants.

**Purpose of the Study**

Teachers routinely share the idea of the four quadrants, but do they understand what these regions, named quadrants, represent or how they are formed? When asked to determine the number of regions formed by the $x$-, $y$- and $z$-axes in three-space, what types of responses and problem solving techniques are elicited from teachers? What does the teachers’ reasoning about the regions formed in three-dimensional space reveal about how they conceptualize them? Do teachers realize how the two-dimensional example is related and connected to its three-dimensional counterpart?

The purpose of this work is to take a first look at how teachers conceptualize the partitioning of regions by axes in a geometric space. In particular, in what ways do they respond to the
question: If the axes of the xy-plane divide it into four regions (called quadrants), how many regions do the axes of the xyz-space divide it into?

**Mode of Inquiry**

Video and observation data were gathered from groups of preservice and inservice teachers over three years in two different settings. In the first setting, four groups of four to five members worked collaboratively on the question above as part of a mathematics education graduate course at a research university in the northeastern United States. These groups were comprised of a mixture of inservice and preservice teachers. The inservice teachers were all certified, had less than three years teaching experience, and held undergraduate degrees in either Mathematics or Mathematics Education. The preservice teachers all had either a Bachelor’s degree in Mathematics or at least 30 credits in undergraduate mathematics courses. In the second setting, two college mathematics instructors (each with over three years of experience), seven secondary mathematics teachers (two with 20 years experience and the rest with three years or less), and four preservice teachers worked collaboratively in three groups on the same question. These participants were attendees of a spatial reasoning workshop at an annual state mathematics teacher conference.

In the tradition of multimodal analysis (Jewitt, 2008) and its inclusion of gesturing, tool use, tone of voice, facial expression, and direction of gaze, the research team used the data from the teachers’ collaborative problem solving of the question in both settings to capture the essence of the episodes. The video data were analyzed by all members of the research team who discussed their findings until consensus was reached. During the analysis, the data from each group was first observed solving the problem in its entirety, then the problem solving episode was repeatedly watched, often in slow motion or frame-to-frame to determine the exact gestures used by each group member. Patterns began to emerge rather quickly in the teachers’ responses and how they engaged with the mathematics problem presented.

A coding schema was employed to unravel the interplay of content and multimodal discourse by classifying gesture and tool use as well as teacher interaction. Coding details are left for future publication. This paper will instead focus on the more general framework that emerged to describe the tendencies of the teachers as they engaged in the mathematical problem that was posed. It will report on how the findings help form a theoretical perspective adopted by the research team related to the domains of mathematical engagement which emerged as they considered teachers’ understanding of axes and regions in three dimensions.

**Video Episode: Teachers’ Collaborative Problem Solving**

At some point in the collaborative problem solving activity, all of the groups used gestures and tools to support or supplement the following: their communication, their individual and collaborative reasoning, and their visualization. A more detailed description regarding each group will now be related. Information that was not pertinent to the problem solving episode is omitted.

**First Setting: Collaborative Groups in a Mathematics Education Graduate Course**

Group 1 consisted of five members. When the question was posed, one of the inservice teachers, Sam, immediately answered the problem. His initial justification was that there had to be eight regions since “two times two times two is eight.” Sam received verbal confirmation from only one group member, Barb, who began gesturing as soon as the problem was posed and
completed the gesture before responding to Sam. He then immediately launched into a second explanation that relied on counting the ordered triples that were possible. The other three group members showed more response to this explanation; however, confusion arose when one of them discovered she had missed one of the possible permutations. At this point, Sam offered a third explanation that involved extensive gesturing of a three-dimensional box to show how the box’s edges could extend to represent three intersecting planes. While Sam was a predominant influence in the discussion, others did contribute and used gestures to consider his ideas. Even though Sam seemed to understand the concept, he failed to verbalize connections between the three different explanations he offered for the problem. While two of his group mates seemed to grasp the visualization approach, two others clung to the ordered triples.

Group 2 also consisted of five members. When the question was posed, the group collaboratively explored a more visual approach. Two inservice teacher members of the group, Matt and Fred, collaborated by using sheets of paper to create a figure that representing the three intersecting planes. Matt understood that there were eight regions and was attempting to explain this to the others. Fred, however, admitted that he was having a difficult time visualizing the situation even with the figure. Two of the other members of the group, inservice teacher Jane and preservice teacher Wendy, studied the figure that Matt and Fred created while joining in the discussion. A fifth member of the group, preservice teacher Ann, also joined in the discussion, but she used two sheets of paper as planes and was focused on her figure rather than Matt and Fred’s figure when discussing the problem. While Wendy and Ann seemed comfortable with Matt’s eight regions answer, Jane and Fred were still struggling to come to grips with the problem. Even though all the members believed there were eight regions, they were not sure how to write up a justification for this (as was required for the assignment). At that point, Matt then proposed that they consider ordered triples. All group members seemed satisfied with this development although Matt never made an explicit connection between the ordered triples and the more visual exploration of the problem that had been discussed originally. During their discussion the issue was raised, as to whether these regions should be called quadrants or not.

Group 3 consisted of four members. When the question was posed, inservice teacher Lisa, immediately offered that there were eight regions. This received verbal affirmation from one group mate, but the other two offered only confused expressions. Lisa then used a sheet of paper as a plane (holding it vertically) and moved the ruler to represent a line horizontally intersecting the plane. She indicated that four regions would fall on the left hand side of the plane and four regions would fall on the right hand side of the plane, hence there should be eight regions in total. Her group mates agreed with this demonstration. This group spent the least amount of time (just under two minutes) on the problem that was posed.

Group 4 also consisted of four members, three preservice teachers and one inservice teacher, Sonya. Once the problem was posed, Sonya asked Pete to physically represent the situation. He modeled the $xy$-plane with both the $x$- and $y$-axes as well as an intersecting orthogonal $z$-axis. While staring at Pete’s figure, Sonya stated there should be four “big” regions. Jen used Pete’s model to indicate that there would be eight regions, four where the $z$-coordinate was negative and four where it was positive. Rather than using Pete’s figure, Emily used a drawing of the three axes and tried to explain this to Sonya. Sonya, however, referred back to Pete’s model later indicating she could not use a drawing to visualize the situation. Sonya continued to discuss the problem referring to Pete’s model. Jen spoke up after a while and offered the suggestion that the regions could be thought of in terms of combinations where the $x$, $y$, and $z$-values were either negative or positive. The others agreed and proceeded to write all ordered triples. The group also

discussed their unease having eight “quadrants” deciding instead to use the word “regions” even though at one point Jen tentatively formed the word “octants.” Sonya revisited Pete’s model to ensure that all regions were listed, pointing out where each coordinate value was negative or positive. At this point Emily made reference to her drawing again. Emily later mentioned her reluctance to use Pete’s figure stemmed from how the others were labeling the axes contrary to the manner to which she was accustomed. This group spent the longest time on the problem, about 11 minutes.

_second setting:_ Collaborative Groups at Mathematics Teachers Conference

Group A consisted of four members. In this group the college instructor, Bob, lead the discussion. Bob immediately solved the problem and then discussed it with the other three members of the group. During this discussion none of the group members made use of gesture. While two of the members indicated that they followed his explanation, the third, preservice teacher Cindy, did not. Bob reworded his explanation using hand gestures to indicate the eight regions that would be formed. Cindy still did not follow and starting using index cards as planes to investigate the situation on her own, eventually asking one of the workshop presenters to confirm her results.

Group B consisted of three inservice teachers and one preservice teacher, Ned. Two of the inservice teachers were sisters, Sally and Sarah. The group did not have a leader but worked collaboratively to solve the problem. Mary (the third inservice teacher) stated there would be six regions; Sally and Sarah agreed. Ned spent this time gesturing to himself and later vocalized that he thought the answer would be eight. The group members individually speculated whether the answer would be six or eight each using different gestures to represent the intersecting planes. They came to the common consensus that the answer was eight only after collaboratively building a model using paper to represent three intersecting planes. At that point Sally pondered, “I wonder why we came up with six?” Mary explained that she was “seeing it flat” using gestures to explain that her mental image was a flat, two-dimensional drawing of the three axes as is typically shown in textbooks (see Figure 1). In their attempt to read the two-dimensional representation in their minds, they confused the properties of this “flat” drawing to the object itself. Sally responded, “Your brain knows its three-space, but your eyes see it in two-space.”

Figure 1. Misconception: Six Regions in Three-Space

Group C consisted of three inservice teachers and one college instructor, Claude. When the problem was initially posed, Claude began using index cards to form two intersecting planes; Theresa, a veteran teacher, did the same using her hands. Nancy first drew the group’s attention to Claude’s figure then Theresa leaned forward to place a piece of paper on it as the third intersecting plane. Claude proposed that there were eight regions. Henry pointed to the regions formed by the figure and counted them. He and Claude began discussing the problem. Meanwhile, Nancy was still confused so Theresa used her fingers to represent two intersecting axes to explain the situation. When Nancy started to count the regions she hesitated. Theresa then picked up three pens and formed the axes with them. Henry, who still seemed to be mulling the problem over, noticed what Theresa had done and imitated her use of three pens to represent the three axes. Theresa then made connections between her pen figure that represented the intersecting axes and Claude’s index card figure that represented the intersecting planes. Claude and Henry also discussed the planes and axes using Henry’s figure. Henry struggled to determine the regions since he saw four regions on top, four on the bottom, four on the left, four on the right, four in front, and four in back. The group discusses the problem trying to help Henry see that he was counting the same regions more than once. Theresa started to discuss the sign of the axes leading the group to think about the ordered triples; this convinced Henry that there were only eight regions.

**Discussion: Modeling, Terminology, and Connections**

*Need to Model the Situation*

Gestures and tools were often employed by the teachers to help them communicate, visualize, and reason about the number of regions formed in the problem. The teachers most often used their hands or other easy-access materials, like sheets of paper, index cards, and rulers to model intersecting planes. While Groups 3 used a plane and a single axis during their exploration of the problem, Sam in Group 1 hinted at axes in his reference to the edges of a box. Group C represented the situation by modeling the three specific axes alone without any planes. Group 4 represented the situation using all three axes as well as the $x_2y_3$-plane. Only Groups 4 and C explicitly labeled the axes in their exploration of the problem.

In Group 4, Sonya had a definite preference for three-dimensional models over two-dimensional figures indicating that she had difficulty visualizing the situation with a drawing. Group B came to the consensus that there were eight regions only after they used a three-dimensional model. Prior to that, misconceptions arose in this group as they attempted to interpret the two-dimensional drawing of a three-dimensional situation. Both cases model what Parzysz (1988) is talking about with regard to the loss of information the more distant the representation is from the actual geometric object. For the three-dimensional situation posed in the problem, a three-dimensional figure was a closer (and hence better) representation than a two-dimensional drawing.

*Tie to Terminology: Quadrants*

Groups 2 and 4 considered whether it was appropriate to call the regions formed “quadrants” after they determined that there would be eight regions. Sarah and other members of Group B referred to the “quadrants” that would be formed in both three and four dimensions. In general, some of the teachers seemed very tied to this label, even though they recognized that the prefix quad- indicated four. Of all the participants only Jen used the word octants; nobody else made any reference to the prefix oct- when discussing labels for the regions.

Multiple Perspectives, Lack of Connections

As noted earlier, only Groups 3, 4, and C explicitly represented at least one axis when modeling the problem. Sonya in Group 4 and Theresa, along with other members of Group C, were careful to make clear connections between the labeling of the axes, the ordered triples, and the corresponding three-dimensional regions.

Groups 3 and A solved the problem using visual models alone. Other groups also incorporated more combinatorial approaches to solving the problem. While Sam in Group 1, Pete and Jen in Group 4, and Sarah and Ned in Group B mentioned either $2 \times 2 \times 2$ or $2^3$ in their combinatorial approaches, none of them verbalized how this idea was connected to the visual models they were also using in their explanations. Similarly, Sam in Group 1 and Matt in Group 2 made no explicit connections between the signs for the coordinates in the ordered triples and the visual models. It is immediately apparent that some of the teachers had multiple perspectives on how to solve the problem, but few communicated to their group mates the connections between these perspectives. These results make one wonder if the teachers really understand and are able to communicate to their students the connection between ordered pairs, axes, and the two-dimensional regions called quadrants that form the Cartesian coordinate system.

Lisa in Group 3 demonstrated a fluid understanding of the connections between two- and three-space in her spontaneous use of dynamic gesture to model the outgrowth of eight three-dimensional regions from a two-dimensional plane. Likewise, Theresa in Group C, demonstrated a deep understanding in her flexible modeling, her fluid transition between models, and the explicit connections she made between graphical and combinatorial approaches to solving the problem. In contrast, Nancy in Group C struggled to understand how the two-dimensional plane could be extended into three-space to determine the number of regions there. Emily in Group 4 seemed to envision three-space as a single, static entity with a particular orientation and was resistant to her group’s use of a different arrangement of the axes. Nancy’s and Emily’s responses to the problem seem to indicate that some teachers lack a deep understanding of the Cartesian coordinate system’s natural extension into three-space.

Discussion: Mathematical Engagement Domains

During review of the video data, response patterns revealed that engaging with the problem involved three overlapping domains: visualization, reasoning, and communication. These domains are characteristic of mathematical problem solving in general, and geometric problem solving in particular. They underpin the essence of the teachers’ engagement with the given problem. Figure 2 models the three-part conceptualization of these domains. A description of each follows.

Visualization independent of reasoning and communication is the act of calling up a mental image without employing it in any way. Visualization alone prohibits the act of communicating ideas to others and does not involve performing any operations on the mental image. Reasoning without communication refers to an individual’s internal analyses and interpretations for personal understanding. While these processes may involve symbolic representations (i.e. algebraic manipulations), they preclude the use of mental images. Communication by itself is the act of conveying predetermined or factual information and evoking understanding through the use of linguistic or symbolic means that do not employ the use of mental imagery.
Intersection of the Visualization and Reasoning Domains

The intersection of the visualization and reasoning domains (VR) occurs when an individual uses imagery while analyzing or interpreting within a given context. Although it is possible to reason about geometric figures without visualization, they are commonly considered in conjunction with mental images (Fischbein, 1993). Teachers in each setting used gestures while making no attempt to communicate with their group members as they reasoned through different aspects of the problem. In Group 1, Barb’s immediate response to the problem was to engage in “self talk” in which she was gesturing to herself before she chose to join in the group discussion. Before Nancy directed Group C’s attention to Claude’s figure, both he and Theresa were engaging in self talk that involved the use of gesturing (implying visualization). In Group A, Cindy disengaged from the conversation that was occurring and initiated self talk using the index cards to help her visualize the problem. In Group B, Ned’s self talk as he considered his group mates’ assertion that the solution to the problem was six regions, eventually helped him come to the conclusion that the answer was in fact eight regions.

Intersection of the Visualization and Communication Domains

Visualization and communication (VC) intersect when individuals use imagery to share the knowledge (or perceived knowledge) that they possess, in an attempt to elicit understanding from others. Gestures, drawings, and tool usage augment discourse and objectify the internal imagery that the individuals possess. In many instances teachers within a group would attempt to communicate information that they had already reasoned through. The VC overlap manifested as teachers used gestures, tools, and drawings to explain the problem to their group mates. In Group 2, Matt employed Fred’s help to create a model of three-space to illustrate his solution to his group mates. At first Lisa and Bob, from Groups 3 and A respectively, gave only verbal explanation for their solutions. When some of their group mates did not seem to follow the verbal explanations, they each spontaneously implemented gestures as a means to better convey their ideas. The inclusion of gestures in the explanation was successful for all of Lisa’s group mates, but not for Bob’s.

Intersection of the Communication and Reasoning Domains

When participants used discourse, non-iconic gesture (McNeill 1992), written symbols, etc. to share mathematical ideas without employing mental images, they are performing in the...
Intersection of communication and reasoning (CR). While most groups began immediately to gesture or use tools to visualize the problem posed, Sam in Group 1 initially conceived of the solution using a more combinatorial approach. This resulted in members of his group using symbolic notation to solve the problem as they considered the possible permutations of ordered triples. Contrastingly, Group 2 began with a visual approach, but then Matt offered the ordered triple representation of the solution. No gestures, tools, or drawings were used for visualization in either group when they discussed the ordered triples.

Intersection of the Visualization, Reasoning, and Communication Domains

The overlap of visualization, reasoning, and communication (VRC) occurred when participants worked together as they actively explored problems, and communicated with each other via external representations of mental imagery. The VRC overlap was present in all groups. One example occurred in Group 4 when Jen introduced the ordered triples to help Sonya better understand the problem. In an attempt to reason through and connect the visual and symbolic explanations, Sonya reached over to Pete’s model using it to indicate the locations of each permutation of the ordered triples. While engaged in the gesturing, Sonya worked to solve the problem, verbalizing her reasoning to Jen. Another example was found with Group B when they worked together to construct a model of the problem as they collaboratively explored and discussed how many regions would be formed.

This study examined the relationships among teaching experience, professional ranks, number of courses taken, and knowledge for teaching algebra (KTA). Three hundred and thirty-eight in-service secondary mathematics teachers completed a questionnaire of KTA. Multiple comparisons and a structural equation model were used to examine their relationships. It was found that school algebra knowledge (SAK) has a significant and positive effect on teaching algebra knowledge (TAK), but does not have a significant effect on advanced algebra knowledge (AAK). Professional rank and the number of courses taken were found to have a significantly positive effect on SAK while teaching experience was found to have a significantly negative effect on AAK. Teachers’ AAK presents negative correlations with their teaching experience and their professional rank. The implications of this study for teacher professional development are discussed.

Introduction

Algebra is an important content topic in school mathematics (e.g., National Council of Teachers of Mathematics [NCTM], 2000; National Mathematics Advisory Panel [NMAP], 2008). Efforts to improve the quality of teaching and learning of school algebra have led to ever-increasing interest in examining and changing educational policy and practice related to school algebra (e.g., RAND Mathematics Study Panel [RAND MSP], 2003). Among many different factors that contribute to the quality of algebra teaching and learning, it is commonly recognized that teachers’ knowledge needed for teaching is crucial for developing and carrying out high-quality instruction that can eventually result in student learning outcome (Hill, Rowan, & Ball, 2005; NMAP, 2008). Yet, much remains unclear about the nature of teachers’ knowledge needed for teaching mathematics in general, algebra in particular.

What knowledge teachers need to have for teaching algebra is not a question restricted to any single education system. In fact, learning what pre-service and in-service teachers know and are able to do in different education systems has become an important approach to help teacher educators and researchers understand better about the nature of such knowledge that teachers need to have for teaching (e.g., Li, Huang, & Shin, 2008; Ma, 1999; Schmidt et al., 2007). For instance, Ma’s study (1999) revealed what elementary mathematics teachers can and should know in mathematics for teaching, shed insight into what we can learn from Chinese practice. By focusing on teachers’ knowledge for teaching algebra (KTA), this study is also designed to focus on the case of China where policy and practices in teaching and learning algebra have been promising for students learning (e.g., Li, 2007). In particular, we aimed to examine the
characteristics of KTA and possible factors contributing to the growth of teachers’ KTA in China that are outlined as the following two questions:

1. What are the characteristics of in-service mathematics teachers’ KTA?
2. What are the relationships between in-service mathematics teachers’ KTA and their highest education degree, professional rank, teaching experience, and number of courses taken?

Theoretical Consideration

Mathematics Knowledge for Teaching Algebra

Drawing on Shulman’s (1986) framework of teacher’s knowledge, content knowledge, curriculum knowledge and pedagogical knowledge, Ball and her colleagues (Ball, Hill, & Bass, 2005) have developed a refined framework defining mathematics knowledge for teaching. This model highlights the kind of mathematical content knowledge that is specific to teachers, and recognizes that knowledge of mathematics for teaching is partially the product of content knowledge interacting with students in their learning processes and with teachers in their teaching practices. Since algebra is the main body of school mathematics and is challenging for students to learn (NCTM, 2000; NMAP, 2008), several researchers have proposed ways of describing teachers’ knowledge for teaching algebra (e.g., Even, 1990; Ferrini-Mundy, McCrory, & Senk, 2006). Recently, Floden and McCrory (2007) have developed a three dimensional construct to guide the development of a measure of teachers’ knowledge for teaching algebra. According to this model, the knowledge for teaching algebra includes three types of algebra knowledge for teaching: school algebra knowledge, advanced algebra knowledge, and teaching algebra knowledge. School algebra knowledge (SAK) refers to the algebra covered in the K-12 curriculum. Advanced algebra knowledge (AAK) includes calculus and abstract algebra that are related to the school algebra; and teaching algebra knowledge (TAK) refers to typical errors, canonical uses of school mathematics, and topic trajectories in curriculum and so on. The content consists of two major themes in school algebra: (1) expressions, equations/inequalities, and (2) functions and their properties.

Factors Influencing Teachers’ Knowledge Growth

Traditionally, education degree earned and years of teaching have been used as main indicators for measuring teachers’ knowledge and competence. However, both of these measures are either unrelated or negatively related to improvements in pupil performance (Wilson, Floden, & Ferrini-Mundy, 2002). Some researchers (e.g., Monk, 1994) used the number of courses as one of major indicators for gauging mathematics teachers’ knowledge, and found it is positively related to how much mathematics students learn at the secondary school level. Moreover, it was found that teachers’ undergraduate mathematics education coursework contributed more to their students gains than did courses in undergraduate mathematics.

In China, there is also a promotion and ranking system through which teachers’ professional knowledge has been developed progressively and continuously (Huang, Peng, Wang, & Li, 2010). For example, the professional ranks of secondary teacher include senior (Gaojie) teacher, intermediate (Zhongjie) teacher, and primary (Chujie) teacher. For each level of teacher position, there are specific requirements in political, moral, and academic aspects. For example, the requirements for being a teacher at the senior rank include five or more years’ experience as a
secondary school teacher at intermediate level or with a Ph.D. degree. Thus, it is reasonable to assume that teacher professional rank reflects the level of teacher knowledge for teaching.

In this study, we considered the background variables including teachers’ highest education degree, teaching experience, professional rank, and number of courses taken, as major factors associated with teachers’ knowledge for teaching. Thus, we aimed to examine the relationships among these background variables and three components of KTA.

**Research Method**

**Participants**

The participants were convenience samples from three different summer teacher education programs. In total, we collected completed questionnaires from 398 in-service mathematics teachers in China. One group of teachers was the participants of a summer course for their master’s degree in mathematics education (more than 170 teachers at both middle and high schools) in East China. Another group of teachers was the participants of a training program for using middle school mathematics textbooks (around 100 participants) organized by the textbook publisher in North China. The third group of teachers was the participants of a training program for using a high school mathematics textbook (more than 130 participants) organized by the textbook publisher in South China. Due to blank answers, we discarded 60 incomplete questionnaires. Thus, we have 338 valid completed questionnaires. About 80% of participants held a bachelor degree, 11% of them held a master degree, and the remaining 9% had a secondary school diploma. About half of the participants had an intermediate professional rank (48%), and one third of them held a primary rank (35%), and the rest had a senior rank (15%). 84% of the participants had more than 5 years of teaching experience.

**Measure**

An instrument was developed based on an existing instrument for measuring mathematics teachers’ knowledge for teaching algebra (Floden & McCrory, 2007). The survey consisted of three parts: Background information, multiple-choice items, and open-ended items. Background information includes grades (1=middle, 2=high schools), gender (1=male, 2=female), highest education degree (1=diploma, 2=B.S., 3=M.A.), professional ranks (1=primary, 2=intermediate, 3=senior and exceptional), years of teaching experience (1=less than 4 years, 2=from 5 to 9 years, 3=10 years and above), and number of math and mathematics education courses taken. With respect to the course taking, we provided a list of 22 courses based on literature review (Li et al., 2008), and also asked teachers to add relevant course if necessary (the value of this variable is the total number of the courses taken). The second part included 17 multiple-choice items which were translated from the original instrument of KTA in English. The third part consisted of 5 open-ended questions. Three of them were translated from the original KTA (items 18-20), while the other two questions were developed by the authors based on our literature review and study of Chinese mathematics curriculum. The instrument in English was translated into Chinese by the first author and a Ph.D candidate in mathematics education in the Chinese Mainland independently. A bilingual mathematics educator in the US was then invited to compare the two Chinese versions for deciding a final reversion. The final instrument included seven items (1, 3, 6, 14, 17, 19, & 21) in school algebra knowledge, eight items (4, 8, 9, 12, 13, 16, 20, & 22) in advanced algebra knowledge, and seven items (2, 5, 7, 10, 11, 15, & 18) in teaching algebra knowledge. The following are two sample items:

---

Multiple choice item (School algebra). Which of the following situations can be modeled using an exponential function?

i. The height \( h \) of a ball \( t \) seconds after it is thrown into the air.
ii. The population \( P \) of a community after \( t \) years with an increase of \( n \) people annually.
iii. The value \( V \) of a car after \( t \) years if it depreciates \( d\% \) per year.

A. i only; B. ii only; C. iii only; D. i and ii only; E. ii and iii only

Open-ended item (Teaching algebra). On a test a student marked both of the following as non-functions

(i) \( f: \mathbb{R} \rightarrow \mathbb{R}, \quad f(x) = 4 \), where \( \mathbb{R} \) is the set of all the real numbers.
(ii) \( g(x) = x \) if \( x \) is a rational number, and \( g(x) = 0 \) if \( x \) is an irrational number.

(a) For each of (i) and (ii) above, decide whether the relation is a function; (b) If you think the student was wrong to mark (i) or (ii) as a non-function, decide what he or she might have been thinking that could cause the mistake(s). Write your answer in the Answer Booklet

Data Collection

Two university professors who took charge of the teachers’ summer programs administered this survey within one lesson duration (45 minutes). Participating teachers were told that this survey is a component of their summer course for researchers to understand teachers’ knowledge for teaching algebra. Similarly, two experts from textbook publishing house conducted the summary workshop for training teachers how to use their textbooks. The participants were invited to complete the questionnaire within one section of the workshop (around 45 minutes) as a part of the training program. All the participants returned their completed questionnaires on site. The collected answer booklets were then sent to a coordinator in Shanghai by express mail. The coordinator scanned all the completed questionnaires into PDF files, and sent the files to the researchers.

Data Analysis

Regarding the multiple-choice items, a correct answer was rated as 1 while a wrong answer was rated as 0. With regard to the open-ended items, the rubrics for the first three open-ended items were adapted from the U.S. ones, while the rubrics for the two newly added open-ended items were developed by the researchers. Two coders worked together to code 100 copies from participants of master education program. After that, one coder who was a middle and high school mathematics teacher for many years coded the entire remaining questionnaire (238 copies). Then, the first author cross-checked the coding for 133 participants who attended the workshop of using the textbook at high school level. The agreements for the five open-items are as follows: 89% for item 18, 98% for item 19, 100% for item 20, 96% for item 21 and 91% for item 22. The disagreements were resolved through discussion. Then, the coder rechecked all the remaining questionnaires and made necessary corrections.

Results

We used two approaches to analyze the data. First, we examined the means of different components of KTA in terms of background variables by using SPSS16. Second, we estimated a model of teachers’ contextual variables and KTA using AMOS16 (Byrne, 2010).
Descriptive Statistics

The reliability (Cronbach’s Alpha) of the instrument is .57. The mean of all variables are reported in Table 1 for the 338 participants, as well as by the professional ranks and years of teaching experience.

Note. *p<.05; Asterisks in the column of years of teaching experience represent significant differences between years of teaching experience 2 and 3

With regard to the relationship between teaching experience and KTA, advanced algebra knowledge (AAK) decreases as teaching experience increases. In particular, the decrease from experience 2 (5-9 years) to experience 3 (10 years and above) (mean difference (MD) =0.84, p<0.05) is significant. The SAK and TAK increase as teaching experience increases from experience 1 (i.e., less than 5 years) to experience 2. However, after five years of teaching experience, TAK continues increasing as teaching experience increases while SAK decreases slightly.

Overall, the higher rank a teacher had the higher mean score of KTA the teacher achieved. With regard to AAK, the mean scores decrease continuously with the promotion of professional ranks although there is no statistically significant difference. It is interesting to notice that TAK increases steadily while SAK decreases slightly from primary rank (rank 1) to intermediate rank (rank 2). However, TAK decreases slightly while SAK increases steadily from intermediate to senior rank (rank 3).

Estimating a Model of Background Variables and KTA

The relationships among highest education degree, professional position ranks, years of teaching experience, number of courses taken, school algebra knowledge, advanced algebra knowledge and teaching algebra knowledge were modeled by a series of path models (e.g., Figure 1). We assumed that SAK and AAK interact with each other and both of them impact TAK. Furthermore, KTA (including SAK, AAK and TAK) is hypothesized to be a function of background variables. SAK, AAK and TAK are considered as endogenous variables in the model. The aim of the path analysis is to include the entire set of variables which may contribute to the explanation of the variance in the endogenous variables (components of KTA). As it is impossible to include everything that may impact these variables, an error term is included in the
model to be estimated for each endogenous variable (e.g., es1, ea1, and et 1 are the error terms for SAK, AAK, and TAK respectively, see Figure 1). The errors reflect all those unobserved predictors that were not measured in this study nor included in this model.

In addition, these variables of KTA were hypothesized to be influenced by background variables including teachers’ highest degree earned, professional rank held, years of teaching experience, and a total number of courses taken. These variables were considered to be exogenous, which are hypothesized to influence KTA.

Initially, all the parameters for the background variables on the endogenous variables were estimated. Subsequently, the path coefficients that were relatively small or not statistically significant were deleted for the model and the model was then re-estimated. The final model is presented in Figure 1.

The Chi-square value for this model was not significant, $\chi^2(3)=1.6, p=0.67$. This indicates a good fit of the model. The comparative fit index (CFI)) was equal to 1.00. This index can take value from 0 to 1 with value close to 1 showing a better fit, and value greater than .95 usually indicating a relatively good fit. The root mean square error of approximation (RMSEA) was equal to 0.000. This index takes into account the complexity of the model, that is, the number of parameters being estimated. This index can range from 0 to 1 with a value less than .05 representing good fit (Byrne, 2010). Thus, the indexes suggest that the data fit the model very well.

According to the parameter estimates in the final model showed in Figure 1, teachers’ years of teaching experience was found to have a negative, direct and significant effect on their advanced algebra knowledge ($\beta=-0.67, p<.05$). It suggests that teachers with more years of experience tend to have less advanced algebra knowledge. Professional rank was found to have a positive, direct and significant effect on school algebra knowledge ($\beta=0.32, p<.05$). The number of courses taken was found to have a positive, direct and significant effect on school algebra knowledge ($\beta=0.40, p<.05$).

---

algebra knowledge ($\beta=0.10$, $p<.05$). Moreover, teachers’ school algebra knowledge was found to have a positive and significant effect on their teaching algebra knowledge ($\beta=0.12$, $p<.05$). Teachers’ highest education degree was not found to have a significant effect on their KTA.

## Conclusion

Teachers with more teaching experience seem to have more Teaching algebra knowledge (TAK). However, their school algebra knowledge increases with less than 10 years of teaching, then it presents a decreasing trend after 10 years of teaching. Overall, the higher rank a teacher had the higher mean score of knowledge for teaching algebra the teacher achieved. The promotion from primary rank to intermediate rank is mainly associated with the increase of teaching algebra knowledge while the promotion from intermediate rank to senior rank is mainly associated to the increase of school algebra knowledge. Path analysis also showed that teachers’ professional rank has a significant and direct effect on their school algebra knowledge.

It was found that advanced algebra knowledge has a negative correlation with the increase of teachers’ teaching experience. The path analysis further confirmed that teaching experience has a negative and significant direct effect on advanced algebra knowledge. Moreover, there is a negative correlation between teachers’ advanced algebra knowledge and their professional rank. In addition, the number of courses taken was found to have a positive, direct and significant effect on school algebra knowledge, and school algebra knowledge was found to have a positive and significant effect on teaching algebra knowledge. The highest education degree was not found to have any significant effect on KTA.

## Discussion

The findings suggest that the number of courses taken (mathematics and mathematics education) has a significant effect on school algebra knowledge; the school algebra knowledge has a significant effect on teaching algebra knowledge. Consequently, the number of courses taken may be related to students’ performance (Monk, 1994). This highlights the importance of providing adequate number of mathematics and mathematics education courses in pre-service teacher preparation. However, school mathematics knowledge and advanced mathematics are not closely related to each other, and advanced algebra knowledge does not have a significant effect on teaching algebra knowledge. These call for developing high quality courses for teacher preparation programs so as to enhance the interconnection of different types of knowledge. Because teaching experience has mixed effects on teachers’ knowledge for teaching, one should be cautious about how to maximize the positive effects of teaching experience. The advanced algebra knowledge decreases continuously as teaching experience increase, probably due to the amount of time elapsed since taking mathematics courses. Although the teaching algebra knowledge increases continuously with teaching experience, the increase of school algebra knowledge is only associated the cases with lesson than 10 years of teaching experience. Thus, how to maintain or update advanced algebra knowledge, and continuously develop school algebra knowledge is a challenging task for in-service teacher professional development.

The professional rank system is perceived as a powerful mechanism for facilitating in-service teacher professional development in China. It is interesting to notice the pattern that the promotion from primary to intermediate rank is mainly associated with the increase of TAK while the promotion from intermediate rank to senior rank is mainly associated with the increase of SAK. This may reflect the emphases of teacher professional development at different stages.
in China. At the primary rank stage, the focuses of teacher learning are on studying teaching materials/textbooks and mastering basic teaching routines through participating in mentoring schema and teaching research activities. These activities may contribute to the development of teaching knowledge (Huang et al., 2010; Ma, 1999). At intermediate rank, teachers further develop their deep understanding of teaching materials and acquire various teaching strategies through participating in various teaching research activities. Since they have already formed certain teaching styles, they may broaden and deepen the understanding of school mathematics. Thus, promotion from intermediate to senior rank is mainly associated with the increase of SAK. However, teachers advanced algebra knowledge weakens although their professional rank advances. This is a serious issue that calls for further research and action. Moreover, the finding that senior teachers do not demonstrate their superiority in teaching algebra knowledge leads to some theoretical considerations. Studies show that expert teachers have a much more interconnected and accessible knowledge structure (Borko & Livingston, 1989) that may not be easy to gauge by a limited number of items.

Although this study produced some interesting findings, the limitation of sampling should be considered. This was a convenience sample, and the cohorts of different groups were not controlled. Thus, any generalization of these findings should be made cautiously.

Endnote
Thanks go to Dr. R. E. Floden for allowing the use of their KTA and sharing his expertise. We appreciate Dr. Jiansheng, Bao, Mr. Wenge Wang, Dr. Jianyue Zhang, and Dr. Weizhong Zhang for their valuable help in collecting data.

DETERMINING TEACHER QUALITY IN TEACH FOR AMERICA ALTERNATIVE CERTIFICATION

Brian R. Evans  
Pace University  
bevans@pace.edu

The purpose of this study was to understand the level of teacher self-efficacy and differences between content knowledge and self-efficacy among teachers of different undergraduate majors in the Teach for America (TFA) program. This present study revisited a cohort of TFA teachers in their second year of teaching and taking graduate education courses at a partnering university in New York. Most studies conducted with TFA teachers have focused primarily on student achievement and teacher retention (Darling-Hammond, 1994, 1997), two of the most important variables. However, examining only these variables is not sufficient if the goal is to increase teacher quality. The following questions guided the current research project:

1. What level of self-efficacy did TFA teachers possess?
2. Was there a difference in mathematical knowledge between undergraduate majors for TFA teachers?
3. Was there a difference in perceptions of self-efficacy between undergraduate majors for TFA teachers?

Undergraduate majors for teachers consisted of liberal arts ($N = 8$), business ($N = 9$), and mathematics related majors ($N = 5$). TFA teachers took the New York State Content Specialty Test (CST) and were given a self-efficacy survey called the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI) with two subscales: Personal Mathematics Teaching Efficacy (PMTE) and Mathematics Teaching Outcome Expectancy (MTOE) (Enochs, Smith, & Huinker, 2000). Findings revealed that teachers had high levels of self-efficacy. Mathematics related majors had higher mathematical content knowledge than business majors, but similar self-efficacy levels. Liberal arts majors had similar content knowledge and levels of self-efficacy as mathematics related majors.

DETERMINING THE LEVEL OF MATHEMATICAL KNOWLEDGE FOR TEACHING OF GEOMETRY OF TWO COHORTS OF SECONDARY MATHEMATICS TEACHERS

Sarah Gilchrist  
The Ohio State University  
gilchrist.42@buckeyemail.osu.edu

Ravi Somayajulu  
The Ohio State University  
somayajulu.1@buckeyemail.osu.edu

The purpose of our research project was to examine the mathematical knowledge for teaching of geometry at the secondary school level. This project was based on an adaptation of the Knowledge of Algebra for Teaching framework (KAT) developed by Ferrini-Mundy et al. (2008). The participants of this study were preservice teachers enrolled in the one year STEM M.Ed. program 2009-2010 cohort and those enrolled in the 2010-2011 cohort. In particular, we analyzed the preservice teachers’ knowledge of content trajectory in geometry when analyzing school children’ work. Four questions guided data collection and analysis: (1) what were the levels of the preservice teachers’ knowledge of the trajectory of mathematical concepts presumed as central to the study of geometry? (2) What were the levels of the preservice teachers’ knowledge of the trajectory of mathematical concepts presumed as central to the study of geometry as it pertains to analyzing and assessing high school students’ mathematical work in a geometry context?, (3) How did the specific content knowledge defined in (1) and (2) impact pedagogical knowledge?, and (4) How did the performance of preservice teachers of the 2009-2010 cohort at the end of the program on (1), (2) and (3) differ from that of incoming preservice teachers of the 2010-2011 cohort?

Surveys were administered to the preservice teachers. Based on the responses to those surveys, participants were chosen for an interview. The data from the surveys and the interviews were scored using both qualitative and quantitative methods in order to determine the level of mathematical knowledge for teaching of geometry with respect to the four research questions. Although there has been much research conducted on elementary teachers’ mathematical knowledge for teaching of mathematics (Ball et al., 2005), at the high school level much is still unknown about teachers’ mathematical knowledge for teaching. This study was a significant attempt toward instrument development for measuring knowledge of teaching of geometry.

DEVELOP CONTENT KNOWLEDGE FOR TEACHING THROUGH DYNAMIC COURSE CONTENT

Wei-Chi Yang
Radford University
wyang@radford.edu

Agida Gabil Manizade
Radford University
amanizade@radford.edu

In this paper, we propose that dynamic course content has an essential role in developing teacher’s content knowledge for teaching mathematics. We are presenting technology-based mathematical conceptual activities designed to improve teachers’ content knowledge for teaching of abstract algebraic topics including but not limited to the mean value theorem, the Cauchy mean value theorem, and the global minimum of total squared distances among non-intersecting curves (Ball, Thames, & Phelps, 2008). These activities can help to develop teachers’ representational fluency of aforementioned topics and deepen their conceptual understanding of these mathematical constructs. Therefore these activities can influence development of teachers’ content knowledge for teaching. As mathematics educators in any part of the world we would like to see mathematics teachers who are: a) competent; b) have conceptual understanding of mathematics; c) have strong mathematical content knowledge for teaching; and d) are able and willing to use a curriculum that promotes mathematical reasoning, allows students to develop deep conceptual understanding of mathematics, and gives opportunity to develop students’ representational fluency. We believe these goals can be archived through use of dynamic technology, such as GeoGebra, in teachers’ training as well as in school mathematics. One of our main goals in this paper is to create technology-based activities (using free open source software Geogebra) as part of the dynamic course content that helps to develop teachers’ conceptual knowledge. More mathematics concepts, as well as more challenging mathematics can be explored in depth by using technological tools in a mathematics classroom. These conceptual activities can also affect teachers’ content knowledge for teaching and influence students learning of mathematics (Zbiek, Heid, Blume, & Dick, 2007). The activities presented at this poster are designed to assist teachers to develop representational fluency in order to further improve their content knowledge for teaching of the aforementioned mathematical topics (Becker & Rivera, 2006; Zbiek, Heid, Blume, & Dick, 2007).

LEADERSHIP CONTENT KNOWLEDGE: A CASE OF PRINCIPAL LEARNING IN ALGEBRA

Michael D. Steele

Stein and Nelson (2003) argue that to support systemic change, administrators need knowledge of teaching and learning of subject matter at the classroom level (about the subject and how students learn it), at the school level (how teachers learn), and at the district level. This study focuses on the first two categories, examining administrator learning in the context of a content-focused year-long professional development (PD) initiative developed as a joint project between a university and a county with districts spanning from small city to distant rural. Nine secondary administrators from six districts participated in the voluntary PD focused on algebra (conceptualized as the study of patterns and functions). Specifically, we explore the question: what did administrators learn as the result of engagement in the study group about algebra teaching and learning?

The administrators’ pre- and post-assessments, transcripts from interviews at the end of the study groups, and content of the local algebra improvement initiatives designed by the principals and teachers for implementation in the following year were analyzed for this report. We examined changes in principal knowledge about algebra (content knowledge at the classroom level) and of algebra teaching (content knowledge at the school level). With respect to content, we focus on defining, representing, and providing examples of function. The results show that principals deepened their knowledge of function - being able to define function, provide examples, and make conceptual connections in a contextual patterning task. For example, on the pre-test, none of the principals were able to construct a definition of function, two principals were able to give an example of function and none were able to provide a non-example. On the post-test, however, five of the eight responses contained a definition that included univalence and did not rule out arbitrary functions, six responses successfully provided an example (and one ambiguous response) and six responses provided a non-example. This change in content knowledge is likely to impact instructional leadership in two ways, giving principals confidence in a core area of the secondary mathematics curriculum and providing a mechanism for principals to continue to enhance their content knowledge through the study of teaching practice. With respect to knowledge about algebra teaching, the analysis suggests that exploring the teaching and learning of algebra supported principals in specifically identifying mathematical practices that supported student-centered learning.

How does environmental context help reveal preservice teachers’ thinking about mathematics? To what extent are preservice teachers’ beliefs regarding teaching and learning mathematics revealed in visual snapshots of mathematical connections? Do students take pictures related to the mathematics they know or are their insights beyond their formal mathematics? Can a hierarchy be, developed depending on the amount of mathematics a person knows?

This study involved forty-six preservice mathematics teachers and data collection included questionnaires and mathematical snapshots (a two-part Mathematical Pictures activity as part of the coursework in their elementary mathematics methods course). In both the first and second part of Mathematical Pictures, the students were to each independently take ten photographs of mathematics embedded in everyday life and write at least two sentences explaining the mathematical concept in the snapshot. After the preservice teachers submitted the first set of pictures, the researchers introduced the Conceptions Questionnaire, a four point Likert scale questions based on promoting a constructivist approach that focuses on the role of the student, the role of the teacher, and the nature of mathematics. In addition, the preservice teachers encountered creative ways to present and think about elementary mathematics in a methods course before they worked on the second set of pictures.

A rubric was, used to evaluate both set of pictures. Pictures were, rated as “flexible” meaning containing many different categories; “fluent”, meaning containing many different ideas within a single category; “elaborative”, meaning an in depth view of one category; or “original”. The findings from the rubric analysis and questionnaire are, shared in our poster session. The mini study found that the more constructivist the preservice teacher beliefs, the more elaborate and original the mathematical connections made, as seen in their illustrations of the snapshot visuals and captions.

UNDERSTANDING VARIATION IN MAINTENANCE OF THE COGNITIVE DEMAND OF MATHEMATICAL TASKS ACROSS SCHOOL DISTRICTS

Anne Garrison
Vanderbilt University
anne.l.garrison@vanderbilt.edu

This poster examines the cognitive demand of written tasks and the extent to which the demand of the task is maintained within a mathematics lesson in middle school classrooms in three, large urban school districts. The nature and cognitive demand of classroom tasks, as well as the implications for student learning have been studied for nearly 30 years. Stein, Grover, and Henningsen (1996) focused specifically on the initial cognitive demand of mathematical tasks and examined how the demand increased or declined across different stages of a math lesson (e.g., the task as set up and the task as implemented). They found that tasks with the potential for high levels of cognitive demand often decreased in cognitive demand as they were implemented. I extend this work by exploring teacher characteristics and district factors to explain why the cognitive demand of tasks might initially be low or decline as they are implemented in the classroom.

This analysis uses data collected for a four-year study in which we are collaborating with four, large urban districts that are attempting ambitious, instructional reform in middle-school mathematics. Three of the four districts are using the Connected Mathematics Project 2 (CMP2) curriculum, and those districts are the foci of this analysis. Each year, we document the classroom practices of approximately 30 teachers in each district by video-recording two successive lessons. These video-recordings are coded using the Instructional Quality Assessment (IQA) (Boston & Wolf, 2006). In addition, we conduct semi-structured interviews with teachers that focus on key aspects of the school and district settings in which they work and also assess the teachers’ mathematical knowledge for teaching by administering the Learning Mathematics for Teaching (LMT) assessment (Hill et al., 2004).

Our analyses showed a significant variation between school districts with regard to the potential of the task as written ($F(2, 95) = 5.95, p < .01$). We also found that the higher the cognitive demand of the task, the more likely it was to decline over the course of the lesson. Furthermore, there was statistically significant variation in the decline of high-level tasks between the districts ($F(2, 95) = 3.24, p < .05$).

“WHAT’S WRONG WITH THIS PICTURE?” COMPLEXITY IN REPRESENTATIONS OF MATH TEACHER KNOWLEDGE

Tony Pascuzzo
University of Calgary
tmspascu@ucalgary.ca

Research in mathematics teacher knowledge has adopted increasingly sophisticated conceptualizations of its object of study. The research programs espoused by Deborah Ball (e.g. Hill, Ball, & Schilling, 2008) and Brent Davis (e.g. Davis & Simmt, 2006) are used here as characteristic of the current field. Both of these approaches rely on particular modes of representing teacher knowledge, and these modes have their respective and concomitant limitations. In accepting the nature of mathematical understanding for teachers and learners to be a complex phenomenon situated in a dynamic environment this poster uses selected works from a painter and a composer to re-examine some realities and possibilities in addressing complex qualities within representations of math teacher knowledge.

The surrealist painter, René Magritte, produced many paintings explicitly addressing themes of representation. Three of Magritte’s earlier works, entitled: ‘The Treachery of Images,’ ‘The Human Condition,’ and ‘Not to be Reproduced,’ each speak to some of the profound challenges and limitations in the human endeavor of representation. These images are used to illustrate some fundamental difficulties that are encountered when attempting to represent teacher knowledge in mathematics.

Composer Igor Stravinsky is perhaps most famous for having written the musical score for a ballet whose 1913 premiere performance instigated a riot among the more typically sedate attendees. The score and music of this same ballet, The Rite of Spring (Le Sacre du Printemps), is used to explore the possibilities of representing complex phenomena within a relatively rich medium of expression (i.e. music). This particular piece of music was written as a description of a human response to the organic process of the spring season, and is a qualified success as a representation of a complex phenomenon. Passages of music excerpted from the full score are selected on the basis of their musical characteristics, which include dissonance, recursion, and parallel asymmetries.

This study examines the work of preservice teachers (PSTs) on fraction word problems for which drawing a model would be a beneficial strategy. We report on a set of four problems posed to three groups: secondary PSTs in a mathematics methods course; elementary PSTs in a beginning mathematics for teachers course; and elementary PSTs in an upper level mathematics for teachers course. We report the success of those in each group in solving the problems and the degree to which they provided explanations. We also discuss their solution strategies and some of the difficulties PSTs encountered when solving these problems.

Introduction

The importance of fraction concepts and computation in preservice teachers’ mathematical understandings across the K-12 curriculum is widely recognized. Although this area of mathematics learning and teaching has been extensively examined, we argue that further articulation regarding the facility of preservice teachers’ to navigate fraction word problems is critical in informing preservice elementary, middle, and secondary teacher education programs. Specifically, at all grade levels, K-12, the ability to negotiate fraction word problems by explicitly connecting computational understandings to models and actions elicited by wording in fraction word problems is critical to a teacher’s ability to effectively engage students in similar conceptually and computationally engaging fraction problems.

As mathematics teacher educators who work with preservice teachers (PSTs), we view this issue as one of high importance. As such, in our study, we examine the computational strategies used by PSTs in solving worded fraction problems to determine whether they can provide explanations and representations that make sense mathematically, rather than just procedurally. Specifically, in this study we address the following research question: To what extent and mathematical depth do PSTs provide conceptual explanations and representations related to the implied fraction computations in worded fraction worded problems?

Theoretical Perspectives

From Ball (1990) to Newton (2008) there has been an extensive analysis of understanding of fraction concepts by prospective elementary teachers. Understanding of the arithmetic of fractions, especially multiplication and division, is difficult for students. In summarizing past work and setting the focus for future work on rational numbers and proportional reasoning, Lamon (2007) writes:

Of all the topics in the school curriculum, fractions, ratios, and proportions arguably hold the distinction of being the most protracted in terms of development, the most difficult to teach, the most mathematically complex, the most cognitively challenging, the most essential...
to success in higher mathematics and science and one of the most compelling research sites. In the last decade or more, researchers have made little progress in unraveling the complexities of teaching and learning these topics (p. 629).

In describing the importance of fractions, Wu (2009) states, “Because fractions are students’ first serious excursions into abstraction, understanding fractions is the most critical step in understanding rational numbers and in preparing for algebra” (p. 8). Keiran (2007) describes the difficulty students have connecting word problems and algebraic equations. In prior explorations with middle grades students, one group of researchers (Olson, Zenigami, and Slovin, 2008; Olson, Slovin, & Zengiami, 2009) found that 5th grade students with no formal instruction in multiplication and division of fractions could solve worded problems involving those concepts. In doing so, however, the students made use of the models and actions implied in the wording of the problems. Importantly, these methods for solving the problems were the primary vehicles for computationally and conceptually addressing fractions available at the students’ disposal.

Ma (1999) observed that teachers in the United States tend to be procedurally focused, and that even when they can solve problems they often cannot explain well. For the most part, U. S. teachers in her study felt it was sufficient to justify the steps of the algorithm used, rather than to conceptually examine and explain why the algorithm makes sense mathematically. Green, Piel, and Flowers (2008) observed that reliance on algorithms potentially allows for misconceptions to become more resilient. In fact, it may be that the use of algorithms can act as a shield to avoid further mathematical reasoning and exploration.

Methods

Participants

Participants in the study were all PSTs in licensure programs. Twelve secondary PSTs, seeking licensure for grades 7-12, were enrolled in a secondary mathematics methods course (SMM) designed to develop their pedagogical knowledge and skill for teaching mathematics, and were near the end of their program of study. The elementary PSTs, who sought licensure for grades K-6, were enrolled in Mathematics for Teachers courses and most were in their first two years of study; eleven PSTs were enrolled in the first course (MA1) of the sequence, while sixteen were taking the second course (MA2). Several of the latter students had, during the first course of the sequence, investigated fractions using a variety of models, including Cuisenaire rods. Most of the elementary PSTs had not taken any other mathematics at the college level.

Procedures

PSTs were given about 45 minutes to work on four problems (described below). Due to differences in the nature of the two courses, slightly different directions were given. Directions were given orally as well as in written form. Because the secondary PSTs were enrolled in a secondary methods class they were directed to try to solve the problem “according to how it is written” by using models and sense making rather than direct computations, and to show how to explain to a student who does not understand, or is having difficulty understanding, how to solve it algebraically. The PSTs in the Mathematics for Teachers classes were simply asked to solve the problems and to show their work and explain their thinking.

For each problem the work of the PSTs was examined for correctness of answer using the following coding scheme: 0-no response or simply a restatement of the problem; 1-incorrect solution; 2-correct solution. Explanations for each problem for the elementary PSTs were coded.
using the following scheme: 0-no explanation; 1-explanation with major flaw; 2-explanation with minor flaw; and 3-correctly justified explanation. Explanations for each problem of the secondary PSTs was coded on a five-point rubric, briefly stated as: 0- no explanation; 1-minimal explanation failing to explain what was done or why it was done; 2-addresses only one of what was done or why it was done; 3-addresses what was done but not fully why; and 4-explained both what was done and why it was done (Olson & Olson, 2010).

Problems Investigated

Four problems were developed to assess the ability of the prospective teachers to solve word problems involving fractions and proportional reasoning. The problems are given below, followed by a discussion of the ideas that guided the development of the problems. “Explain your reasoning and support your answer” was stated at the end of each problem.

1. It takes 3/4 liter of paint to cover 3/5 m². How much paint is needed to paint 1 m²? Explain your reasoning and support your answer.

2. Macy had a distance to swim during practice. When she had gone two-thirds of what she was supposed to swim she had traveled one-half kilometer. What was the total distance Macy was to swim during practice? Explain your reasoning and support your answer.

3. It took Brooke 2/3 of her advertising budget to buy 3/5 of a newspaper column. What part of the advertising budget is needed to buy a whole column? Explain your reasoning and support your answer.

4. Jonnine had a board. She cut and used 2/5 of the board for bracing. She measured the piece used for bracing and found it to be 3/4 foot long. How long was the original board? Explain your reasoning and support your answer.

The following specific ideas guided the creation of the four fraction problems:

1. Problem 1 is referred to as a “common numerator” problem. We maintain that if a student understands the inherent 1:1 correspondence between the numerators, the problem can be reconciled simply by examining the numerators. It is known that common denominators are useful in solving problem but problems where the use of common numerators is helpful to determine a solution are not often investigated. Furthermore, each of the remaining problems could also be solved with a common numerator strategy. For example, in Problem 4 if the fractions 2/5 and 3/4 were replaced by the equivalent fractions 6/15 and 6/8 then Problem 4 has a structure similar to Problem 1.

2. Problems 2, 3, and 4 are similar in structure in two important ways. First, they each can be modeled algebraically as \( a \cdot x = b \), where \( a \) and \( b \) are known values. Second, the first fraction mentioned in each problem has 2 as a numerator. We were deliberate in using fractions with a numerator of 2 because children appear to use models to reach a solution more effectively when division by 2 is involved. We were interested if the prospective teachers would be able to effectively model their solutions and felt these problems might be easiest to model. However, while Problem 3 is similar in structure to Problems 2 and 4, the way the question is asked changes the thinking needed to find a solution.

3. The structure of Problems 2 and 4 suggest that a linear model would match the actions of the words. If a number line is an effective way to understand fractions, then perhaps PSTs would be able to use a linear model to answer these questions.

4. Explanations of models used to solve problems 2, 3, and 4 often use the idea that the first thing to be done is to divide by the numerator of one of the fractions and then multiply by the denominator of the same fraction. Effective modeling of solutions to these problems can help explain why “invert and multiply” makes sense when dividing fractions.

Results

The data collected from the PSTs are summarized in Table 1, organized by group (SMM, MA1, MA2) and by problem. The number of PSTs who scored 0, 1 or 2 for correct solution is reported for each problem. It should be noted that the majority of PSTs in MA1, who had not received instruction in fractions in this course, responded in ways that simply restated the information given, or indicated confusion (“I don’t know where to begin”). Several expressed general confusion and misapprehension regarding fraction problems (for example, “I don’t understand fractions at all”). PSTs in the other two groups had greater success.

It was expected that the common numerators in Problem 1 would lead students to use the 1:1 ratio between fourth-liters of paint and fifth-square meters of wall; yet only one of the MA1s and only about 75% of each of the other groups answered it correctly. Though Problems 2 and 4 are similar in structure, only Problem 2 was answered correctly by all SMMs and most MA2s; fewer in both groups answered Problem 4 correctly. Furthermore, while the structure of Problem 3 is similar to Problems 2 and 4 it was answered correctly by half of the SMMs and less of MA2s.

Table 2 below presents data showing the number of PSTs in each group who solved the problem correctly and whose explanation was scored at the highest level of justification. While the columns cannot be directly compared because the SMMs were expected to explain with a model and justification that went beyond getting the correct answer, it is of interest that both the MA2s and SMMs solved Problems 2 and 4 with the highest explanation more than Problems 1 and 3. In the discussion we only share student work on Problems 1 and 2 as the work on Problems 3 & 4 is similar to that of Problem 2.

Discussion of Work Samples: Problem 1

In problem 1 the common numerators led some easily to see a 1:1 ratio. One MA2 explained, “Since 3/4 L of paint covers 3/5 sq. m. of wall, 1/4 of a liter of paint covers 1/5 m² of wall. One will need 2 more 1/4 L to cover the remaining two 1/5 m² of wall that needs paint.” A SMM used a diagram, symbolic representations and a written explanation (Figure 1) to describe this use of a 1:1 ratio. Another MA2 used two number lines (Figure 2) very effectively to solve this problem.

![Figure 1. SMM Diagram and explanation](image1)

![Figure 2. MA2 Simultaneous number lines](image2)
A variety of algorithms were also used to solve Problem 1, as shown in Figures 3-5. PSTs who solved the problem algorithmically provided no explanation, though some of the SMMs included a diagram. This seems to support the claim by Lesh, Post and Behr (1988) that students use algorithms, or procedural thinking, to avoid reasoning. However, the single MA1 who correctly solved the problem provided a detailed explanation of her work: “To do this problem, I divided 3/4 by 3 because it paints 3/5 of the whole wall. I then realized that 3/4 of a liter paints 1/5 of a wall. This is how I reached 1 1/4 liters to paint a whole wall…”

One difficulty with procedural thinking is that if there is not true understanding, algorithms can be applied incorrectly. A few SMMs and several MA2s seemed to choose operations randomly, often beginning with finding common denominators for the two fractions. A MA2 tried several operations (Figure 6), stating that she tried adding the fractions, using “cross multiply” and “straight multiply”. No justification was given for any of these operations, nor did she explain why she chose the answer to the addition problem as the solution to the problem.

Discussion of Work Samples: Problem 2

The majority of SMMs and MA2s were able to solve Problem 2 and justify their solutions. For the SMMs and MA2s who successfully solved this problem, drawing a diagram as shown in Figure 7 was an effective approach. As they had been directed, SMMs explained the models in
more depth; one wrote “If we divide the distance into 3 equal lengths, we can label the total distance of the first two lengths segments as 1/2 km. We split/divide this into the 2 equal segments to be 1/4 km each. Since the last (3rd) segment is the same length, we label it as 1/4 km as well. We add the 3 segments up to equal 3/4 km.”

![Figure 7. MA2 Diagram and solution](image)

A few relied on an algorithm to solve this problem, and provided no justification (Figure 8). One SMM used a series of operations (Figure 9), similar to the work of the MA2 in Figure 6; there appear to be several “solutions” (1/4, 1/3, and the correct answer, 3/4). Two MA2s also appeared to choose operations at random, for example adding 2/3 and 1/2. This indicates no understanding of the relationship; 2/3 is the portion of the total distance and 1/2 km is the amount of that portion. Like others in each group who solved the problems incorrectly, these two PSTs arrived at an answer that could not possibly be right (1 1/6 km is more than double the portion already swum), but did not question their thinking.

Only one MA1 was able to solve this problem; two others made attempts that might have led to a solution. Eight were unable to even make an attempt, expressing confusion over the use of metric units (“I am having problems with understanding what type of distance she was swimming”), or requesting a formula.

![Figure 9. SMM Correct and incorrect “solutions”](image)

**Conclusions**

It was discouraging to find that a large number of PSTs in this study had difficulty solving these fraction word problems. Most SMMs were successful, but given the fact that all have minors in mathematics, we expected all to be able to correctly solve the problems. About half of the MA2s experienced success, but only one of the MA1s even made an attempt at solving the problems. While it is true that this last group has not had any college mathematics prior to this semester (most are in their first year of college), all successfully completed mathematics up to

---

and including high school algebra. Yet earlier research had found that fifth graders with no formal instruction in fraction arithmetic use the context of the worded problems to find solutions. Most of the PSTs in this study did not use models to solve the problems. While some drew diagrams or pictures, as directed, many of these simply represent the words of the problem, and are not useful components of the solution. There are exceptions: The simultaneous number lines in Figure 2 represent an excellent model that leads to a solution and demonstrates conceptual understanding of the relationship between the units. However, most chose to solve the problems using algorithms such as equations or cross-multiplying to solve proportions. Some of those who were unsuccessful chose incorrect algorithms, and two (Figures 6 and 9), applied multiple algorithms to obtain multiple solutions; no rationale was offered. Most of the MA1s who did not even attempt to solve the problems stated that they required a formula, or that they just could not solve problems with fractions.

While SMMs were specifically directed to use models and sense making to show how they would help students understand, the explanations related to these problems involving fraction concepts and computations were not at the level we expected of students seeking a mathematics degree with certification to teach secondary mathematics. Many simply wrote and solved an algebraic equation; it is possible that they, like the U. S. teachers in Ma’s (1999) study, felt this was sufficient justification.

Several of the MA2s and the single MA1 who successfully solved the first two problems provided models and/or explanations that demonstrated some conceptual understanding, rather than only reliance on algorithms. The second of two mathematics courses emphasizes representations and multiple solutions and the PSTs are required to explain and justify their work. The beneficial nature of that expectation is seen in the differences in the results reported.

Ma’s research reveals the lack of what she terms profound understanding of fundamental mathematics in U. S. teachers. Teachers need to develop mathematical knowledge that has depth and breadth, to understand the connections among mathematical concepts and procedures, to use multiple approaches in solving problems, and to provide multiple explanations and representations for their students (Ma, 1999). Only teachers who have developed this profound understanding will be able to teach for understanding. This preliminary research points to the need for further investigation into PSTs’ proportional reasoning, and to strategies that enhance their ability to solve problems and explain their thinking in ways that make sense mathematically and that use models or reasoning beyond algorithms to explain the solution to such problems.

EVALUATING TAIWANESE PRESERVICE ELEMENTARY TEACHERS’ UNDERSTANDING ABOUT THE MEANINGS OF FRACTION DIVISION

Fenqjen Luo
Montana State University-Bozeman
fluo@montana.edu

This study investigated 40 Taiwanese preservice elementary teachers’ understanding about the meanings of fraction division. This investigation was made through evaluating their performance on representing a symbolic problem of fraction division using words and reasoning how to solve the word problem using a diagram. Results indicated that a significant percentage of the preservice teachers were unable to construct an appropriate word problem for the given symbolic expression. Most word problems constructed by the preservice teachers match with the structure of equal-groups measurement. The most prevalent diagrams illustrated by the preservice teachers can be classified into the area and length models.

Introduction

This paper reported 40 Taiwanese preservice elementary teachers’ understanding about the meanings of fraction division. As the National Mathematics Advisory Panel (2008) has identified, “proficiency with fractions” serves as a major goal for K-8 mathematics education because “such proficiency is foundational for algebra and, at the present time, seems to be severely underdeveloped” (p. xvii). Although “proficiency with fractions” is our target, research (Azim, 1995; Ball, 1990a, 1990b; Tirosh, 2000; Simon, 1993) has addressed that the understanding of fractions is a problematic area for elementary teachers especially when involving operations. In fact, while working on the topic of fraction division, preservice elementary teachers often concentrated on only remembering rules and mastering standard procedures rather than demonstrating comprehensive understanding of mathematical procedures (Ball, 1990a). For example, to divide one fraction by another, they only mastered the procedure, “a/b ÷ c/d = a/b \times d/c = ad/bc.” Often, they interpreted fraction division as an opposite of fraction multiplication by turning the second factor (divisor) upside down and then multiplying.

To expand our knowledge on this problematic area from a broader perspective, we summarized Taiwanese preservice elementary teachers’ understanding about fraction division in this paper. As suggested by mathematics educators (Barlow & Cates, 2007; English, 1998; National Council of Teachers of Mathematics [NCTM], 2000), Taiwanese preservice elementary teachers’ understanding level about this challenging topic can be recognized by assessing their performance on word-problem writing and reasoning. The results gained from this assessment can be used to determine what teacher educators still need to know in order to effectively develop and provide better-quality teacher preparation to the preservice teachers.

Theoretical Framework

The theoretical framework for this research is grounded by the discussions of specialized content knowledge by Ball, Thames, and Phelps (2008) and paradigmatic knowledge by Bruner (1985). Specialized content knowledge refers to mathematical knowledge and skills needed uniquely by teachers. Examples of such knowledge include determining the validity and potential of nonstandard solution methods, and knowing the affordances and limitations of different types of diagrams in communicating mathematical ideas. In this study, it refers to

---

preservice elementary teachers’ knowledge in determining the most valid word problem to represent a symbolic problem and the most potential diagram to reason this word problem’s solution. Paradigmatic knowledge focuses on “mathematical models or mathematical structures that are universal and context-free” (Chapman, 2006. p. 216). In relation to word problems, preservice elementary teachers’ paradigmatic knowledge can be assessed through analyzing the semantic structure of word problems, the mathematical structures or models that are evoked in a word problem and its solutions.

As suggested by Ma (1999), a deep conceptual understanding of fraction division is built upon a network of prior knowledge. To categorize the developed word problems and their solutions of fraction division into structures and models, we should first conceptualize the meanings of fractions, whole number division, and its inverse operation – multiplication. For the operations of multiplication and division, Greer (1992) has identified four different structures of word problems: (1) equal groups, (2) multiplicative comparisons, (3) area and other product-of-measures, and (4) combinations structures. Of these, the structure of equal groups is the most prevalent one. Multiplication and division problems embedded in the structure of equal groups deal with certain number of groups, all equal size. Multiplicative comparisons problems deal with the situations that one set involves multiple copies of the other. In area and other product-of-measures problems, the multiplication product consists of a two-dimensional unit, such as a two-lengths (length × width) unit for the product of area. The structure of combination problems involves counting the number of possible pairings that can be made between two sets, but rarely involve the need to use the division operation to solve them.

Each of the equal-group and multiplicative comparison structures consist of three models of word problems: multiplication, measurement division, and partition division (Van De Walle, 2007). Of these, the measurement and partition models identified by Fishbein, Deri, Nello, and Marino (1985) must be considered when exploring division situations. For measurement division, one tries to determine how many groups of the intended quantity are contained in the given quantity (object or collection of objects). For partition division, the given quantity (an object or collection of objects) is divided into a given number of equal groups, and the goal is to determine the intended quantity (or size) in each group.

To make sense of fractions, three types of pictorial models are often adopted to represent the concepts of fractions: area or region, length, and set (Reys, Lindquist, Lambdin, & Smith, 2009; Van De Walle, 2007). In an area or region model, the fractions are based on parts of an area or region. Although the versions of area models can be various, Reys and his colleagues think that circular “pie” models are by far the most commonly used area model. It is interesting to know whether this version of area models is more prevalent than others from this study. With length models, lengths are referred instead of areas. Among various versions of length models, the number line has been treated as a more sophisticated length model (Bright, Behr, Post, & Wachsmuch, 1988). In set models, the whole is understood to be a set of objects, and subsets of the whole make up fractional parts.

In this study, through assessing Taiwanese preservice elementary teachers’ performance on writing a word problem and reasoning out of a solution to this word problem using a diagram, their specialized content knowledge and paradigmatic knowledge of fraction division were investigated. Their word problems can be categorized but not limited to the following structures: (1) equal-groups multiplication, (2) equal-groups measurement, (3) equal-groups partition, (4) comparison multiplication, (5) comparison measurement, (6) comparison partition, and (7) areas.
Furthermore, their diagrams can be categorized but not limited to the following models: (a) area, (b) length, (c) set.

**Methods**

The data analyzed in this paper came from a research study on preservice elementary teachers’ fraction knowledge. Due to absences, 41 preservice teachers answered the first-stage study and 40 preservice teachers answered the second stage. These participants were from a traditional teacher education university in Taiwan. All preservice elementary teachers in Taiwan have either a content concentration (e.g., mathematics, science, language arts, and social studies) or specialization (e.g., special education, elementary, and counseling education). The participants in this study are all non-mathematics and science concentration majors. They were juniors taking their 2-credit mathematics method course. This is the only required mathematics education related course for non-mathematics and science concentration majors of the teacher education program. The study was conducted at the beginning of this course.

The study in the first stage focuses on preservice elementary teachers’ fundamental fraction concepts, and the study in the second stage focuses on their understanding of the meanings of fraction operations. This paper only focused on preservice elementary teachers’ understanding about the meanings of fraction division. The data was based on the 40 preservice teachers’ performance on a fraction division problem given in the second stage. These preservice teachers were invited to represent a symbolic problem of fraction division using words and reason how to solve the word problem using a diagram as follows:

Write a word problem which can be solved by using “8 2/3 ÷ 1/4 =?” and model how to solve it by drawings.

The analyses of the preservice teachers’ responses were guided by the following two clusters of research questions.

1) How successful were preservice elementary teachers in representing a symbolic problem of fraction division using words? What structures of multiplication and division did preservice elementary teachers use when constructing their representations? How successful were preservice elementary teachers in representing each structure of word problems?

2) How successful were preservice elementary teachers in reasoning how to solve the posed word problems using a diagram? What models of diagrams did preservice elementary teachers use when reasoning how to solve the posed word problems? How successful were preservice elementary teachers in reasoning solutions with respect to each adopted pictorial model?

**Results**

In this section, we report and discuss two major mathematical processes demonstrated by the Taiwanese prospective elementary teachers. The first process is representing a symbolic problem using words, and the second process is reasoning how to solve a word problem using a diagram.

Representing a Symbolic Problem Using Words

Only 26 of the participating 40 Taiwanese preservice elementary teachers (65.0%) were able to pose a word problem that is meaningful and correct for the given symbolic problem “8 2/3 ÷ 1/4 =?” Taiwanese preservice elementary teachers have been recognized to have excellent
abilities to solve fraction division problems (Luo, Lo & Leu, 2008, 2009). For example, all preservice Taiwanese elementary teachers participating in the study of Luo, Lo and Leu (2009) can solve the word problem, “Jim jogged 1 1/2 miles yesterday. This is 3/8 of his weekly goal. How many miles does he plan to run each week? Explain”. This problem can be solved by computing the fraction division “1 1/2 ÷ 3/8.” Thus, in terms of fraction division, Taiwanese preservice elementary teachers’ ability to represent a symbolic problem using words is much lower than their ability to solve a word problem. Still, the Taiwanese preservice elementary teachers in this study have demonstrated a much greater understanding about the meanings of fraction division than their U.S. counterparts in Simon’s (1993) study. Simon found that only 30% of the U.S. preservice elementary teachers were able to create an appropriate word problem for the fraction division of 3/4 divided by 1/4.

As shown in Table 1, although the constructed word problems include various structures of multiplication and division, over a half (57.5%) of the Taiwanese preservice elementary teachers constructed an equal-groups measurement problem to represent the symbolic problem, “8 2/3 ÷ 1/4=?” This percentage is much higher than that of the preservice teachers who constructed an equal-groups partition problem (57.5% versus 15.0%). Further, there is a higher accuracy for the word problems embedded in the structure of equal-groups measurement than those embedded in the structure of equal-groups partition (87.0% versus 66.7%). This finding seems contrasting with previous research in fractions and division. The concept of equal-groups partition, which involves the process of forming fair shares, has been treated as the first goal in the development of fraction concepts (Van De Walle, 2007).

It is interesting to find that the preservice teachers were more successful in using the structure of equal-groups measurement rather than the equal-groups partition to interpret the meanings of fraction division. Is it possible that their preference in constructing an equal-groups measurement problem rather than an equal-groups partition problem is because the given divisor is not a whole number? When the divisor is a whole number, it is often interpreted as the number of persons in a sharing context. This interpretation has been continually used to introduce fraction concepts in which the whole number is the denominator of a fraction and is often explained as the number of sharing persons. For example, to develop fraction concepts, the very first example provided in the book written by Van De Walle is, “Ten brownies shared with four children.” However, when the divisor is a non-whole number, the interpretation of the divisor as the number of sharing persons does not work in nature since a person is an undividable group. In this study, none of them interpreted the divisor as the number of dividable sharing groups such as “3/8 class” and tried to find the solution for the intended size of quantity for a whole group such as “a whole class.” For those who still successfully adopted the structure of equal-groups partition, rate
contexts rather than sharing contexts were applied in their word problems like the sample W.2 shown in Table 2.

Same as the structure of equal-groups partition, 15.0% of the preservice Taiwanese elementary teachers constructed a word problem embedded in the structure of equal-groups multiplication. However, although most of their equal-groups multiplication problems can be led to the intended operation of division and the same final answer like the sample W.3 shown in Table 2, the direct operation embedded in an equal-groups problem is multiplication. Based on “knowledge package for understanding the meaning of division by fractions” proposed by Ma (1999), they only achieved the layer of meaning of multiplication with fractions or meaning of multiplication with whole numbers. They have not yet achieved the understanding of division by fractions. Since the inverse number of the divisor “1/4” given in the symbolic problem is a whole number, it is unknown whether those preservice teachers who adopted this structure tried to avoid the use of a fraction as a divisor while posing a word problem.

Reasoning How to Solve a Word Problem Using a Diagram

Overall, 22 of the participating 40 Taiwanese preservice elementary teachers (55.0%) were able to reason how to solve their word problems using pictorial illustration. Since only the data from those 26 preservice teachers who constructed a correct word problem can be considered as reasonable illustrations and solutions, the overall result also means that 55.0% of the Taiwanese preservice teachers could represent a symbolic problem of fraction division using words, and reason how to solve a word problem of fraction division using pictorial models. It is worth to notice that 84.6% (22 out of 26) of the preservice teachers who had successfully represented the problem in words were also able to solve it using pictorial models. Therefore, the preservice teachers who could write a word problem could potentially model the relevant pictorial solution.

Furthermore, as shown in Table 3, the percentage of the Taiwanese preservice teachers who adopted an area model to solve and reason a word problem is approximately the same as that who adopted a length model. It means the Taiwanese preservice teachers’ ability or preference in adopting an area model is similar to a length model. This result supports the findings from prior studies by Luo, Lo, and Leu (2008, 2009) that Taiwanese preservice elementary teachers had equal abilities toward both models, which were different from U.S. preservice elementary teachers who were less prepared for the length model. They seem weaker or less preferred in applying a set model than the others.

It is interesting to notice that most of diagrams drawn by the Taiwanese preservice teachers did not fully illustrate how to solve a word problem. Those preservice teachers still substantially depended on verbal or symbolic reasoning processes to complete an exemplary solution as samples shown in Table 4. In addition, like the diagram for the problem sample W.1 shown in Table 4, a diagram in a circular “pie” version described by Reys and his colleagues (2009) is still the most commonly used area model. Eight out of the 11 area model-based diagrams (72.7%) are in this version.

Implications

Although prior studies (Luo, Lo, & Leu, 2008, 2009) show that Taiwanese preservice elementary teachers were identified to be well-prepared in their common content knowledge as proficient mathematics problem solvers, it was found that they still need to be better prepared in their specialized content addressed by Ball and her colleagues (2008). Specifically, they have to be more proficient in the following mathematical knowledge and skills needed uniquely by teachers: representing a symbolic problem of fraction division in words, and reasoning how to solve a problem by depending on drawings only. They need to increase their familiarity and flexibility with some less popular structures of fraction division such as the equal-groups partition, comparison measurement, and areas. They need to learn how to reason the solution process using a set model as well as area and length models.

Some findings from this study could serve as starting points for future research. Answers to the following questions, for example, would be helpful in the development of efficient methods for instructing preservice teachers. First, will preservice elementary teachers perform better if they have more experiences in writing and reasoning word problems for fraction division? As previously stated, the Taiwanese preservice teachers attending this study were at the beginning of their mathematics methods course. They might lack experiences in writing word problems or reasoning their solutions using drawings. Thus, the results may more reflect their limitations in writing and reasoning word problems than in understanding fraction division. A follow-up experimental study would clarify whether the performance of writing and reasoning a word problem is determined by experience or by knowledge of fraction division.

Note. No reasonable justification is led from the illustrated quantities.

Note. No reasonable justification can be led from the illustrated fan.
Second, will preservice elementary teachers choose different structures or models when the numbers given in the symbolic division problem are different? This question is raised from the finding that most word problems developed by the Taiwanese preservice teachers can be classified into the structure of equal-groups measurement. As mentioned earlier, however, in most entry level curricula for division or fractions, this structure is not as popular as the structure of equal-groups partition which can be directly connected to sharing contexts. Further research needs to be undertaken to find what kind of division problems that preservice elementary teachers prefer to construct when the divisor is a whole number. If their problem structures are determined by the characteristics of numbers given in the symbolic division, it means they may have a difficulty to make a coherent transition from whole number division to fraction division. It also means they may need an intervention emphasizing a coherent transition from whole number division to fraction division to develop sufficient abilities to facilitate future students’ understanding based on previous knowledge.

A flexible understanding of the notion of measures of central tendency is an important component of educating people in mathematics. Based upon the responses of 27 preservice teachers (PSTs) to an averaging problem, we extended the categorizations of Mokros and Russell (1995) into four different conceptions of average: pairwise balancing, average as total balance point, reasonably close, and algorithmic. Using a U-M-R cycle from the SOLO model, this study analyzes the PSTs’ ability to use alternate conceptions of average flexibly. In this study PSTs were presented with student artifacts to facilitate recognition of alternate conceptions and to reflect on which conceptions are most helpful in a particular situation.

Introduction

The notion of average, including the concepts of mean, median or mode, is an important tool in the study of statistics; it provides tools to represent data sets, and it can be especially useful in comparing data sets. A number of researchers (Mokros & Russell, 1995; Konold & Higgins, 2003; Watson & Moritz, 2000) have investigated student representations of average at varying levels of sophistication, however there has been relatively little attention paid to teacher conceptions of average (Shaughnessy, 2007). Effective teaching requires that instructors are sensitive to children’s thinking, which includes the flexibility to recognize alternative conceptions of average in others (Thompson & Thompson, 1994). Artifacts of children’s thinking can be used to both probe PSTs’ currently held conceptions and to introduce alternate conceptions while helping PSTs learn the vital skill of dealing with children’s strategies that differ from their own (Philipp, Ambrose, Lamb, Sowder, Schappelle, Sowder, et al., 2007). This study examines preservice teachers’ (PSTs) knowledge of different representations of average and their level of flexibility in recognizing and using those representations when examining student work. PSTs’ levels of flexibility are categorized using the UMR cycle of the SOLO model (Watson, Collis, Callingham & Moritz, 1995).

Theoretical Background

This study builds upon the work of Leavy and O’Loughlin (2006) that examined 263 undergraduate students enrolled in their first year of an education program in Ireland. They analyzed the PSTs’ view of mean in terms of conceptual and procedural understanding through a written think-aloud protocol. Leavy and O’Loughlin (2006) found that the majority of the PSTs had a computational grasp of the concept of mean, as indicated by the relatively high performance on construction activities in which the direct application of the standard mean algorithm could be used. However, the future teachers struggled with problems that involved non-standard applications of the mean, such as creating a data set to fit a mean or working with weighted averages. The researchers concluded that the PSTs’ relative lack of flexibility in solving nonstandard problems indicated a deficit in conceptual understanding.

Other authors have proposed multiple characterizations for the conception of average beyond conceptual and procedural. Based on the responses of 26 fourth, sixth and eighth graders, Mokros and Russell (1995) differentiated between five different types of student reasoning about
average: mode, procedure, reasonable, midpoint and point of balance. Students were classified as having modal reasoning if they focused only on the most common value when summarizing data. Students had a procedural understanding of average if they relied on the “add and divide” algorithm to find the mean. A student was placed in the reasonable category if they used their own real world experiences to inform their thinking and if they placed the mean toward the middle of the data set. Students with a midpoint conception of average insisted on putting the same number of data points above and below the middle, as would be appropriate for a median. The choice in values was usually, but not necessarily, symmetric. Student who did try to balance higher and lower values around the mean were classified as moving toward a point of balance conception. No students in the Mokros and Russell study successfully completed the point of balance approach.

A common lens in statistical research education through which to categorize understanding is the SOLO model (Shaughnessy, 2007). Originally developed by Biggs and Collins (1982) for analyzing learning in any context, it was adapted to statistics education research by Watson et al. (1995). The SOLO model is a hierarchical structure comprised of five modes of reasoning, and within each of these modes the learner engages in U-M-R (Unistructural-Multistructural-Relational) cycles. At the unistructural level, a learner only gives attention to a single aspect of a task; a multistructural response includes several relevant elements, and at the relational level, the learner recognizes the relationships between relevant components and appreciates the relative importance of each.

Several other authors, including Watson and Moritz (2000) and Groth and Bergner (2006), have studied the concept of average using the UMR framework. In this study, a U-M-R framework was used to examine the PSTs’ flexibility in their conception of mean. Given the difficulty in measuring PSTs’ conceptual/procedural understanding, the U-M-R model provided the researchers better insight into PSTs’ multiple types of conceptions of average as needed to evaluate and guide student thinking. Although each concept of average, such as fair share or pairwise balancing, may have some procedural components, our primary interest was to explore the ways in which PSTs connect the data to a measure of center and how the concepts of average relate to student thinking.

Thus, the primary research question addressed in this paper is if PSTs are able to: (a) use alternate conceptions flexibly depending on the appropriateness of a situation; (b) recognize when another student’s work indicates the presence of a particular conception; and, (c) reflect on which conceptions are most helpful in a particular situation.

**Methodology**

The participants in our study were 24 PSTs enrolled in the second term of a three-term sequence in elementary mathematics at a large public urban university. Data was gathered through an initial written survey. The surveys were analyzed and then each PST was asked follow-up questions in a 15-20 minute videotaped interview. The interviews were then transcribed and reviewed.

The goal of our research is to understand what statistical conceptions PSTs have before beginning formal instruction, and therefore the surveys and interviews were completed before the PSTs began the probability and statistics portion of their elementary mathematics course. This paper focuses on the Potato Chip Task (first appearing in Mokros & Russell, 1995, p. 23) in Figure 1. Follow-up questions to the Potato Chip Task were designed by the research team, following our analysis of the survey responses. The follow-up questions were intended first to

--

clarify which conceptions of average the PSTs were using when approaching the Chip Task. We chose to use artifacts of student thinking in order to explore PSTs’ ability to recognize and work with alternate conceptions of mean. We believe that it is important for PSTs to be able to recognize their students’ currently held conceptions of average and to purposefully decide whether to work within their students’ current conceptions or to introduce alternate conceptions. The examples of student work provided a tool to assess PSTs’ flexibility in dealing with multiple conceptions of average.

The conceptions of average used in this study were observed and categorized by a team of six researchers. Starting with the characterizations of average presented by Mokros and Russell (1995), the transcripts were reviewed independently by the researchers, and then the categorizations were compared and consensus was formed on the primary reasoning models. Several of the characterizations in the literature did not appear in this study; perhaps because of the tasks or perhaps because the subjects were PSTs and not children. For example, the PSTs in this study did not consider average as mode, perhaps because they were already aware of mode as a separate concept. After review, four primary conceptions of average emerged: pairwise balancing, average as total balance point, average as reasonably close, and algorithmic. Pairwise balancing involves picking a pair of numbers equidistant from the average value, whereas total

---

balancing takes place over more than two values, such as going 2 below for one value and 1 above for two other values. Although Mokros and Russell used only a single balancing category, we found it useful to distinguish between two types of balancing approaches, as PSTs who demonstrated pairwise balancing did not necessarily have success with total balancing. This was not an issue in the Mokros and Russell study because although there was evidence that a few students were moving toward a balancing strategy, none of the students had fully understood how to complete the balancing to create an appropriate data set for a given mean (1995, p 33).

Our interpretation of average as “reasonably close” relates to Mokros and Russell’s concept of average as “reasonable.” Mokros and Russell classified student solutions as “reasonable” if they were based on the students own experience with real world situations rather than just a number found from a mathematical process. We classify students as having the “reasonably close” conception of average if they are considering the context of the problem and an appropriate level of variability when creating the data set, rather than focusing on a particular mathematical algorithm. For example, students who disapproved of Student B’s solution because the 1 cent prices were unreasonably low were classified as having a “reasonably close” concept of average.

Our final conception of average is algorithmic understanding, which is an extension of the category used by Mokros and Russell (1995). While Mokros and Russell limited algorithmic understanding to a direct application of the “sum and divide” algorithm, we will also include a “working backward” strategy in which the correct total is partitioned into pieces. For example, in this problem the total price for all of the bags would need to be $1.89 for the average to be 27 cents for seven bags. The “working backwards” strategy involves constructing prices that total to $1.89. Mokros and Russell included this strategy as part of “point of balance;” however we do not feel that any balance conception is required to find seven unrelated values that sum to a fixed total. Instead this strategy is a short-cut in the process of the “sum and divide” algorithm, where values can simply be summed.

The flexibility of PST conceptions of mean was analyzed using a UMR framework. At the unistructural level students have a single main conception of mean, such as mean as the outcome of an algorithm. The multistructural level refers to students who have multiple conceptions of mean. At this level, students may consider mean as balancing in one context and mean as fair share or algorithm in another context. However, at the multistructural level students do not articulate an awareness of the relationships between the multiple conceptions, and they may not be able to recognize that they have multiple conceptions. At the relational level students are able to relate multiple conceptions of mean and reflect back on which conception of mean is appropriate for a given situation. We argue that the relational level is especially important for PSTs because it allows them to make purposeful decisions when they choose which conceptions of mean to share with their students. In addition, their ability to relate multiple conceptions may influence how they work with their students’ alternate conceptions of mean.

This framework differs from that used by Watson and Moritz, primarily due to the focus on the flexibility of PST conceptions needed for effective teaching. Whereas Watson and Moritz only allow colloquial usage of average to be classified as unistructural, in the present study any student that indicates only one type of usage of average is classified as unistructural. Watson and Moritz also did not consider "R" as a relational understanding, which we argue is critical for PSTs. Our model also differs from the Groth and Bergner model. While their primary concern was the depth of understanding of the definitions of mean, median and mode, we are focused on how the PSTs can respond flexibly with different conceptions of mean based on student work.
Of the 24 PSTs who participated in this study, six were chosen as case studies for discussion purposes. Since this research explores the level of flexibility that PSTs have when approaching the concept of mean, case studies were selected to emphasize these different levels. Our analysis focuses on the thinking of Kira and Ursula at the U level, Phyllis at the M level, and Joyce, Greg, and Stacie at the R level. All of the names used in this paper are pseudonyms.

**Data and Analysis**

Among the 27 PSTs interviewed, the first two authors coded five as unistructural, thirteen as multistructural, and nine as relational. Within each of the levels, the PSTs exhibit a spectrum of abilities associated with each level. The following examples illustrate the representative abilities for each level, as well as some singularities.

**Unistructural**

Of the five PSTs with unistructural concepts of mean, four relied solely on the mean algorithm and one relied exclusively on the pairwise balancing technique. Our first example, Kira, is representative of the unistructural PSTs that indicated only an algorithmic understanding of mean. To solve the chips task, as she relied on guess and check as her solution method. To check her initial guess, she summed all the numbers and divided by 7; if the resulting average was too high or low, she raised or lowered one of the chip values and tried again. During the follow-up tasks, she realized that the sum of the numbers needed to be 189, without needing to divide by 7 to see the 27 cents.

When Kira was shown the first follow-up task in which a student uses a balancing approach, Kira did not recognize that this is a different tactic than the one she was using. When asked how she could help this student, she replied “just doing a lot of guessing and checking is the way that I would probably help them, but then again I don’t know too much about like actually helping a child with probability questions ‘cause I haven’t done that before.”

In response to Student A and Student B, Kira’s first reaction was to sum each row of data and divide by seven. This led her to determine that Student A was incorrect and Student B was correct. She did not attend to notions of balance or spread, but relied exclusively on the outcome of the algorithm. When prompted to explain why some students might not like Student B’s response, she did note that the data might be unrealistic. This did not seem to contradict her understanding of mean. Kira’s conception of mean and interaction with the student responses was typical of the three other unistructural PSTs who relied on the algorithm of mean.

Ursula was unique in that she was the only PST that did not indicate knowledge of the algorithmic method for finding the mean. She stated, “I don’t remember if there’s some sort of formula to get the average.” Instead she relied exclusively on the pairwise balancing technique. Ursula struggled in her approach to question 4, because she saw that her solution did not balance. In her description of the first student’s response, her pairwise balancing technique was apparent; “I think it needs to be balanced ... it has to be under 27 and over 27, yeah under and over. I don’t know why, it just seems like that would balance it out.” When specifically working with the first student’s response she said that it balances to 27 “because 25 is two under 27, and 29 is two over. So that’s why it would be balanced.” Because her concept of average relied on balancing in terms of pairs, she did not have a solution for how to find values for an odd number of items.

Ursula recognized that Student A’s response was similar to hers, but also incorrect because it did not balance in a pairwise fashion. She did not think that Student B was correct because it did...
not balance. She states, “It seems like you could get a right answer with Student B, but not that answer….There’s 1,2,3,4,5 under and two over. But they are so low that it’s like… and these are so high!” Because Ursula only has a pairwise balancing conception of average, she not only fails to identify when students have alternate conceptions of average, but she also incorrectly identifies Student B’s solution as incorrect.

**Multistructural**

All thirteen of the multistructural PSTs included the algorithmic concept of mean. In addition to that strategy, ten included the concept of pairwise balancing, one described a general balancing technique, and four indicated the “reasonably close” concept of average.

Phyllis was chosen as an example of a multistructural PST because she indicated algorithmic and “relatively close” understandings of average, although it was unclear that she understood the relationships between them. To solve the problem where none of the bags could equal 27 cents, she used her algorithmic knowledge of average to find the total of 27 times 7, and then she found “different combinations of different amounts” that sum to 189. This might indicate a deficit understanding of average in terms of pairwise balancing, for she was unable to see that 27 was the midpoint of each pair of numbers. In addition, when asked to offer advice to the student with the incomplete pairwise balancing technique, Phyllis could not deviate from her method. She said, “I would try to rework it from the beginning, and try different amounts from 10 cents to 50 cents.” Thus she may have trouble working with a student whose only conception of average relies on pairwise balancing.

In contrast, when evaluating Student A’s and Student B’s responses Phyllis liked Student A’s better because the values was closer to 27. Although Student B gave an exact average, she did not like that the values had a “big jump from 1 cent to 84 cents,” even though her original solution gave values from 3 cents to 79 cents. Thus although Phyllis favored a more algorithmic approach in the first problem, she favored a “reasonably close” view of average for this portion of the problem. She did not articulate a clear reason for her choice. Phyllis was placed into the multistructural category and not the relational category because of her inconsistency in selecting one strategy over another without being able to articulate her rationale for her choice.

**Relational**

PSTs at the relational level demonstrate multiple conceptions of average along with the ability to relate those conceptions to one another and make purposeful decisions about which conceptions are most appropriate for specific situations. PSTs with a relational understanding of multiple conceptions of average have the flexibility to recognize a student’s currently held conception and to work within that conception if appropriate, or to help the student move beyond that conception if necessary. Nine PSTs were categorized as relational because they offered some indication that one strategy would be more important in a certain situation, however there was a spectrum of abilities in articulating the relationships between the conceptions.

Three of the relational PSTs indicated that the algorithmic conception of average was faster, easier, or more accurate than other approaches. Joyce was an example of a PST that began using a general balancing strategy, but then abandoned it because it was too difficult. She stated, “I did 25, so that’s like -2. 28, and that was plus 3. Because I was going to try and keep track of it. And then I decided that took too long.” Instead she switched to the algorithmic approach of finding values that totaled to 189. These three PSTs were categorized as relational because they...
specifically indicated understanding of multiple conceptions of average, and they evaluated the merits of those approaches.

Six of the relational PSTs recognized that the pairwise balancing technique indicated in the first sample of student work was inappropriate. Greg is an example of such a PST. He approached the potato chip task using algorithmic understanding; he found seven values that would sum to 189. When asked about the student with the missing solution, Greg instantly recognized that the student was using a pairwise balancing technique, and he evaluated that this type of strategy would not work for an odd number of bags. He states, “What they have done makes sense if you are only using six chip bags, but they need the seventh one, so I think spacing it out just won’t work when it’s an odd number like that.” Although Greg recognizes that this particular technique is inappropriate, he does not believe that the student can modify their strategy into a correct one. He states, “If you want to help them, you’d kind of have to teach them a whole different way.” Thus Greg was able to identify the pair-wise balancing technique, evaluate that it was inappropriate, but he failed to indicated that a more general total-balancing strategy was possible. Instead, he recommended that the student adopt his algorithmic approach to solve the problem.

Stacie is another example of a PST in the relational stage in her concept of average. She initially solved the chip task by finding what the total cost needed to be and worked backwards to find 7 prices that totaled to 189. When given the first student’s response, she recognized that this student was having difficulty specifically because of the pairwise balancing strategy the student had chosen. However, instead of imposing her sum and work backwards strategy as appropriate for the student, she instead recommended modifying the pairwise balancing technique, “I guess telling them that you can add on to any of them.” It is important that unlike Greg, Stacie was not only able to recognize the student’s strategy, but was able to offer advice on how to complete the solution using a strategy similar to the student’s (total balancing), rather than her preferred strategy (algorithmic). Both Stacie and Greg are relational, but because Stacie understands the total-balancing concept of average, she is able to help the student by enhancing the student’s current approach into a more appropriate general balancing strategy.

Six of the relational PSTs stated that the “reasonably close” conception of average was false or unimportant. They maintained that as long as the mean of the values was 27, the values could be anything. This conception is classified as relational because it specifically states that the algorithmic approach to average is more important than “reasonably close.” For example, when asked to give advice to Student A, Stacie offers the following solution; “I guess [I would] explain that it could be more flexible than it having to be exactly off, just like, as long as all of them together add up to 189 the numbers could be anything.” These students recognize that the conception of average as values that are “reasonably close” exists, but prioritize the algorithmic formulation of mean for this context. They distinguish that data values do not necessarily need to be tightly clustered around the mean for the algorithmic mean to hold.

Conclusions

Although having a relational concept of average is helpful when working with students’ currently held conceptions, we have found that not all PSTs operate at that level. PSTs with a unilateral understanding of average may lack the ability to interpret the understanding of others. This may inhibit their ability to communicate with those who conceive of average in alternate ways. PSTs with a multistructural concept of average are much more successful in interpreting student work, and they may also have the stepping-stone skills needed to articulate a full concept.

of average to students. However they may not have the skills needed to identify when a student is using an inappropriate strategy and be able to guide that student using terminology that still fits within that child’s cognitive model. PSTs with a relational conception have the ability to reason using multiple concepts of average, and they may also have the ability to identify and guide students successfully given a particular concept. However having relational understanding of several constructs of average does not imply full understanding of every concept of average.

Our study was limited to PSTs’ investigation of a particular task involving the average price of seven bags of potato chips. This research could be extended by examining PSTs’ conceptions of average in a variety of contexts. If a situation involves repeatedly measuring a single item, will PSTs use a different conception than for a situation that involves measuring a variety of different items? Do PSTs access different conceptions of average in situations involving sharing and fairness? What types of situations encourage PSTs to attend to variability as well as center? Given different tasks, we anticipate that some PSTs will demonstrate additional conceptions of average beyond the four outlined in our investigation.

One aspect of our research that was especially helpful in probing PSTs’ understanding of mean was the use of student responses. These tools allow us a window into whether PSTs recognized alternate conceptions and strategies. They also provided an opportunity for PSTs to demonstrate whether they could use those alternate conceptions to help a student complete the given task, or whether the PSTs would revert to their original conceptions when assisting others. The use of student responses can be very helpful in examining PSTs’ conceptions of average and it may also be a valuable tool for teacher educators to use when introducing new strategies to future teachers in their preservice mathematics courses.

While research continues to grow towards understanding pre-service teachers’ knowledge of statistics, there is still a need to fully define what constitutes strong understanding of averages. This article investigates aspects of statistical content knowledge of 27 pre-service elementary school teachers as they worked on survey and interview tasks that allowed them multiple opportunities to discuss measures of center. Analysis of the data revealed that pre-service teachers could complete tasks requiring the construction of data sets from a given mean by utilizing multiple views of mean simultaneously. A discussion of the advantages and limitations of these solution strategies is presented.

Introduction

In 1989, the National Council of Teachers of Mathematics (NCTM) released the document *Curriculum and Evaluation Standards for School Mathematics*. This document was one of the first to highlight statistics as an area of focus in the K-12 mathematics classroom. As a result, the last two decades have seen an explosion in statistics education research, much of which has concentrated on defining and observing deep understandings of topics in elementary statistics. One such topic is conceptions of average. Current research points to a number of ways in which school children think about averages and suggests further research into how children’s conceptions of average develop (Mokros & Russell, 1995; Konold & Higgins, 2003; Watson & Moritz, 2000).

In order to support students’ thinking about the representative nature of the idea of average (Mokros & Russell, 1995), it is imperative that their educators possess a rich understanding of data analysis and the roles of central tendency, variability, and distribution in analyzing such data (Shaughnessy, 2007). For this reason, Shaughnessy (2007) has called for further investigations into the statistical knowledge of pre-service teachers (PSTs); a focus of the present study.

Many statistics educators agree that simply knowing the algorithm for and finding the arithmetic mean are not sufficient for developing a rich and flexible notion of average (Watson & Moritz, 2000; Groth & Bergner, 2006). However, varying opinions exist as to what does constitute such an understanding. Several authors have taken the stance that a contextual view of measures of central tendency is one key to developing a more complete sense of average. Konold and Higgins (2003) called for young students to build knowledge through experiences with “real data”, through which they will draw connections between certain statistical concepts and their applications to context. Watson and Moritz (2000) conducted a longitudinal study with students to discover the nature of their understanding of average, and suggested that emphasizing context, in addition to cultivating an ability to utilize the algorithms for measures of center, could be one critical piece of developing higher levels of understanding. This emphasis should allow students...
the opportunity to explore connections between a “specific measure of central tendency and possible data sets that could have created it” (p. 48).

Mokros and Russell (1995) presented a categorical framework for discussing students' methods in constructing data sets from an average. They suggest five approaches to solving these problems: average as mode, algorithm, reasonable, midpoint, and point of balance. Average as mode is the inflexible use of the most often occurring value in the data in solving problems related to average. This and average as algorithm (strict adherence to the mean algorithm in solving problems) are not considered to take representativeness of the mean into account, whereas the other three methods are. The midpoint approach involves symmetrically choosing points above and below the mean, often believing that the mean and middle number are synonymous. The balance approach sees the mean as a point of balance, rather than a middle number and takes “into account the values of all the data points” (p. 25). Though the authors explicitly divide the methods by those that see average as representative and those that do not, balance and midpoint are considered the more advanced than average as reasonable. In their study, none of the students were able to construct a data set from a given mean when the mean value could not be used in the data set.

This study aims to look more in depth at the framework presented by Mokros and Russell (1995). Their work focused on young children; the goal of the current study is to determine whether their framework is appropriate for use with PSTs and to modify this framework so as to appropriately characterize PSTs’ thinking about measures of center.

**Methods**

Participants of this study included 27 PSTs enrolled in a 10-week course at a large urban university in the Pacific Northwest. The course was the second part of a 3-term sequence designed to give prospective teachers the chance to explore different mathematical topics through a hands-on, activity based approach to mathematics. The research team took advantage of an opportunity to investigate PSTs’ statistical reasoning prior to statistics instruction in this sequence. Data sources for this project consisted of written surveys and interviews.

A statistics assessment survey was administered to the entire class prior to their statistics unit. Using the framework of Mokros and Russell (1995) as an initial guide to analysis, the current study aimed to gain deeper insight into PSTs understanding of average. The Potato Chip Task shown in Figure 1 was borrowed from their study and forms the basis of the current report. The purpose of using the Potato Chip Task was to see the ways in which PSTs would reason about average and the ways in which they would construct data sets to suit a particular mean.

A) The average price of a bag of chips is 27 cents. We have seven bags of chips each of which has an empty price tag. Place prices on each of the bags so that the average price is 27 cents.

B) The average price of a bag of chips is 27 cents. We have seven bags of chips each of which has an empty price tag. Place prices on each of the bags so that the average price is 27 cents. **However, none of the bags of chips can cost 27 cents.**

**Figure 1. The “Potato Chip Task”**

After the surveys were analyzed, PSTs were invited to participate in short (20 minute) clinical interviews. The interviews were designed to further investigate PSTs' thinking about measures of center, and to provide the researchers an opportunity to follow-up on questions that were raised during the analysis of the survey data.

Some of the interview tasks included asking PSTs to further explain their responses to the survey, and some new tasks were created to further explore PST responses to the Potato Chip Task (see Figure 2). The interviews were videotaped and transcribed for further analysis.

| How would you help a student who had started number 4 as follows? |
|---|---|---|---|---|---|---|
| 25 | 25 | 26 | 28 | 29 | 29 |

**Figure 2. Sample Interview Task 1**

All 27 interviews were initially analyzed with respect to Mokros' and Russell's (1995) framework, and it was found that some modification to this framework was needed to accommodate the approaches of PSTs. A discussion of these modifications follows. All names used in this report are pseudonyms.

**Results**

The analysis of PSTs’ work on the Potato Chip Task showed statistical reasoning closely related to the framework of Mokros & Russell (1995). Although their framework was useful in building an initial image of PSTs’ statistical reasoning, many of the PSTs strategies extended beyond the scope of the originally established categories. Though Mokros and Russell (1995) observed that PSTs who viewed average as a midpoint had difficulty transitioning from a given mean to a data set when the mean could not be used, this was not usually the case in the present study. One would expect PSTs, that is, undergraduate college students, to have had experiences working with averages for twelve or more years of their lives. It seems plausible, therefore, that PSTs have multiple approaches to problems involving measures of center and most were able to successfully construct data sets given a specific mean regardless of whether or not the mean could be used as one of the data points. PSTs may, however: (1) be unaware that they hold multiple conceptions of average; (2) experience difficulty applying appropriate conceptions of average in a particular context; and/or, (3) be unable to clearly articulate their different approaches. The authors of this paper argue that PSTs need to be aware of multiple conceptions of average and be able to articulate the differences between solution strategies in order to teach ideas of measures of center coherently.

What follows is a description of the modified framework of Mokros and Russell (1995) for use with PSTs. Described in detail below (Table 1) are the different characterizations of average used by PSTs in this study and how they are similar to and different from those of Mokros and Russell (1995). Excerpts from four interviews are shared in order to clarify categories in the new framework. Modifications are italicized. Average as Backward Algorithm and Average as Cluster Balance are not found in Mokros’ and Russell’s (1995) initial framework. Average as Forward Algorithm, Average as Midpoint, and Average as (Total) Balance were modified from Mokros’ and Russell’s original framework to consider strategies utilized by PSTs. The modified Average as Midpoint addresses a tendency for PSTs to view constructing 27 as the middle number in a pair-wise fashion, often reverting to the algorithm in order to express as much (for example, the average of 26 and 28 is 27). This micro use of the mean algorithm is also seen in Average as (Total) Balance, but the overall solution approach of PSTs differs in that they appear...
to consider the data as a whole rather than just subsets of it. This transition from subsets to the overall data set is expressed in the modified (Total) Balance category.

<th>Table 1: Modified categories of PSTs’ view of averages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average as Algorithm (as previously defined by Mokros and Russell)</td>
</tr>
<tr>
<td>- View finding an average as carrying out the school-learned procedure for finding the arithmetic algorithm.</td>
</tr>
<tr>
<td>- Often exhibit a variety of useless and circular strategies that confuse total, average, and data.</td>
</tr>
<tr>
<td>- Have limited strategies for determining the reasonableness of their solutions.</td>
</tr>
<tr>
<td>- Use of algorithm in guess and check for choosing data points when creating a distribution.</td>
</tr>
<tr>
<td>Average as Backward Algorithm (developed by research team as a result of analysis)</td>
</tr>
<tr>
<td>- View finding an average as carrying out the school-learned procedure for finding the arithmetic mean.</td>
</tr>
<tr>
<td>- View finding data sets corresponding to the mean as reversing the school-learned procedure for finding the arithmetic mean. In which case they multiply the given mean by how many data points then choose numbers that sum to this product.</td>
</tr>
<tr>
<td>Average as Midpoint (modified by research team as a result of analysis)</td>
</tr>
<tr>
<td>- View average as a tool for making sense of the data;</td>
</tr>
<tr>
<td>- Choose an average that is representative of the data, both from a mathematical perspective and from a common-sense perspective.</td>
</tr>
<tr>
<td>- Look for a “middle” to represent a set of data; this middle is alternatively defined as the median, the middle of the X axis, or the middle of the range;</td>
</tr>
<tr>
<td>- Use symmetry when constructing a data distribution around the average. They show great fluency in constructing a data set where symmetry is allowed but have significant trouble constructing or interpreting nonsymmetrical distributions.</td>
</tr>
<tr>
<td>- Use the mean fluently as a way to “check” answers. Have a tendency to compare pairs of numbers, making sure the mean is the middle of the pair. May believe the mean and middle are basically equivalent measures.</td>
</tr>
<tr>
<td>Average as Cluster Balance (developed by research team as a result of analysis)</td>
</tr>
<tr>
<td>- View the mean as a tool for making sense of the data.</td>
</tr>
<tr>
<td>- Views the data in the form of subsets/clusters rather than the whole distribution.</td>
</tr>
<tr>
<td>- Use the mean with a beginning understanding of the quantitative relationships among data, total, and average; they are able to work from a given average to data, from a given average to total, from a given total to data.</td>
</tr>
<tr>
<td>- Being able to view average in the form of midpoint, but as restricted to subsets.</td>
</tr>
<tr>
<td>Average as (Total) Balance (modified by research team as a result of analysis)</td>
</tr>
<tr>
<td>- View mean as a tool for making sense of the data.</td>
</tr>
<tr>
<td>- Look for a point of balance to represent data.</td>
</tr>
<tr>
<td>- Take into account the values of all the data points.</td>
</tr>
<tr>
<td>- Use the mean with a beginning understanding of the quantitative relationships among data, total, and average; they are able to work from a given average to data, from a given average to total, from a given total to data.</td>
</tr>
<tr>
<td>- Break problems into smaller parts and find “sub-means” as a way to solve more difficult averaging problem. Besides just comparing subsets of the distribution, the PST is able to generalize from looking at 2 to 3 data to the overall distribution of data points; rather than looking at small subsets of the data, they can articulate how groups of the data relate to the overall distribution.</td>
</tr>
<tr>
<td>- View balancing through multiple subsets (i.e. 2 or more points) to generate the distribution.</td>
</tr>
</tbody>
</table>
Average as Backward Algorithm

While many PSTs were able to apply the algorithm of the mean to check their work, it was necessary to consider the knowledge required to reverse the mean algorithm. An individual had to be aware of undoing division in the mean algorithm through a multiplication and then undoing the sum through a method of repeated subtraction; this is highly algebraic and perhaps more readily used by the PSTs given their additional mathematical experiences. The reversing strategy was done by 17 of the PSTs. These took the mean of 27 that was given in the Potato Chip Task and multiplied by 7, giving 189, which they used to redistribute prices to the 7 bags of chips. One example was Lisa.

Lisa: Uh...I was doing...I know...okay...so I made the 4 bags 1 cent higher and start with that and I got 112. And that was for the four bags. And then...(mumbles)...and then I just did below the 27 cents cause I know I had to get 27 so I get 3 more bags. So I had to find what would equal umm...the 189 from the...and the 112 and 189. And ended up getting 26 and 26. And I decided to figure out um...that was 152 so I subtracted the 189 and 152 from the 189 and that was 25. I think...maybe not...kidding. 164. Yeah 164...25 remain so that was my seventh bag.

As mentioned, Lisa was aware that the total of 189 was needed in order to produce the correct mean. Her method of distributing the numbers to the different bags of chips required a repeated subtraction of numbers from 189 followed by constant checking of her values to make sure the sum remained 189. When distributing the prices of bags, some PSTs considered the idea of “reasonable” values. Lisa appeared to be staying near the value of 27 when subtracting her chosen values from 189. In the context of the Potato Chip Task, some, like Lisa, maintained that it did not make sense to select numbers too far from 27, and none chose negative values or fractions of cents. Therefore, ideas of representativeness and context may play roles in such problems for some PSTs.

Average as Midpoint

The midpoint view of balancing relies on the knowledge that data sets must focus on the mean as a center. Through this view, PSTs tended towards a strategy of looking at pairs of numbers and checking how values related to the mean. 12 PSTs had a tendency to look at how two numbers related to each other (e.g. one number is 1 above the mean and another is 1 below) and in certain cases take the average of those two numbers in order to verify its similarity to the given mean. Gene was an example of one PST who used this strategy. He responded to part B of the survey task as follows: 20, 25, 26, 28, 29, 30, 31. He described his solutions to part A and B of the survey tasks as follows:

Gene: Umm...where 27 was used. And I realized that, you know, by comparing these like 27 in the middle you know you are gonna have 26 and 28 are gonna average to 27. 25 to 29 are gonna average to 27. 30 to 24 are gonna average to 27.[...] except now we couldn't use 27 umm...as one of the price tags. I just started with 28. Umm...and then I just kind of went out from there. So then I, 26 and 29. [...] Umm...you know skipping 27. And then 25 and 30. And then umm...31 going up and then, you know, just have figure out the one last number [...] Umm...I kinda took a guess at 20 based on umm...you know the differences and
numbers there. And 31 being so much higher. Umm...I sorta took a guess at it. And I figured 20 was probably about right. And so then I plugged in and it worked out.

The strategy Gene used for part B was a midpoint approach, as he explicitly mentioned 27 being the “middle” and then symmetrically distributed his data above and below this value. He moved outwards using pairs that he observed as averaging to 27. The students in Mokros' and Russell's (1995) study using this pairing strategy were unable to complete part B; however, Gene effectively altered his approach by changing his middle number to 28, using two of the same lower values (25, 26) and pushing his upper values up by one (29, 30, 31). Gene’s way of assigning the new middle number and finding the remaining value of 20 was done through a “guess and check” utilization of the mean algorithm that he explicitly mentioned. This is consistent with Mokros and Russell’s original framework for a Midpoint View where PSTs consistently use the mean fluently to check their answers. It is important to note that his pairing strategy focused solely on looking at two data points at a time. As Gene got closer to finding the final data point, he changed his method to checking through use of the forward mean algorithm rather than simply extending his pairing strategy.

Average as Cluster Balance

While several of the PSTs were able to apply a pairing strategy when finding data points, individuals such as Gene were unable to extend the pairing strategy to the last value. J.Z., on the other hand, extended his pairing strategy differently than Gene. His solution for part B was (28, 28, 26, 26, 29, 26, 26), but he described his process differently.

**J.Z.:** So, and I had started by going with two bags that had 28 cents and two bags that had 26 cents. And since there is an odd number of bags all together I knew that I was going to have to use something other than 28 and 26 for the last three boxes, or bags. Umm. So I didn't really have a precise way to do that, so I just went with 29 and two 26's. [...] 28 and 26, you know, when you add them up together and divide by 2 you get 27, I believe. [...] I figured if I was going to use 26, then I would have, if I was going to use 26 twice, then I would have needed something substantially higher than 28 to make it 27.

J.Z. started this problem by seeing a pairing of two values of 26 with two values of 28, each of which was one cent away from the desired mean of 27 cents. J.Z. was averaging each pair using the mean algorithm. This is indicative of the Midpoint View. However, J.Z. considered three values to be his midpoint, viewing the last three boxes as the place where his strategy needed altering in order to solve the problem. J.Z.’s ability to extend beyond looking at pairs of numbers to small subsets that act as a single center indicates a more flexible strategy than the original Midpoint of Mokros and Russell (1995) and a shift towards considering the overall distribution.

Average as Total Balance

The Total Balance view is a modification of Mokros & Russell’s (1995) final category. Rather than simply calling it a balance category, we chose total balancing to indicate PSTs who are seeing the overall distribution. While we view Cluster Balance as more sophisticated than Midpoint View, Total Balance indicates an additional level of sophistication from applying a pairing strategy to smaller segments of the data. PSTs who possessed this view of average are capable of extending from individual pairs of data points to balancing subsets of data values to considering the total data set as a balanced entity. One such example is Belle who provided the solution of 26, 26, 29, 26, 28, 26, 28 part B of the Potato Chip Task.

---

Belle: Umm...I did number 3 the easy way of having if they are all 27 cents then the average is going to be 27 cents. And then for number 4, since none of them can cost 27 cents, I put them on either side. 26 and 28 cents. But because there was an odd number, I needed to balance one more of the 26. So that's why one of them was a 29. So I have 4 26s....so there's a pair of 26 and 28, there's a pair of 26 and 28, and then these three...the 29 balances the 26. The two 26s.

In her description, Belle explicitly introduced the term “balancing” as attributed to the two bags labeled with 26 cents and the single one labeled 29 cents. Belle saw a value farther away from the mean as requiring two values closer to 27 cents in order to balance the data; she had moved beyond her initial pairing method into being able to find the triple. Lastly, she was able to say in her excerpt that the four 26s balance with the three values 28, 28, 29. Her reasoning regarding her final distribution took into consideration how overall groups compared rather than small segments of the distribution.

Table 2 (below) shows the number of PSTs observed to fit into the categories as described in Table 1. Please note that some PSTs strategies fall into more than one category and are tallied as such.

Table 2. Summary of PSTs views of averages pertaining to the “Potato Chip Tasks”

</tbody>
</table>

In summary, many of the PSTs were capable of doing a Backward Algorithm. The Backward Algorithm seemed rather natural for many of the PSTs, perhaps due to more experience working with the forward algorithm or other algebraic manipulations. Twelve of the 27 PSTs were able to apply a Midpoint view of average through the use of a pairing strategy, but returned to using the Forward Algorithm to check their work. Surprisingly only a small percentage of PSTs were able to apply Cluster Balance to complete the construction tasks. Half of the participants who use a Cluster Balance approach were able to explicitly show evidence of Total Balance. The PSTs were rarely seen to relate their pairing or tripling strategies to the distribution as a whole, hence the small representation in the Total Balance category.

Discussion

It should not be surprising that many PSTs were found to have utilized more than one strategy in their work with averages, or that hybrid categories should exist for this population. PSTs have had more experiences in mathematics than grade schoolers, and draw on these experiences in completing tasks like The Potato Chip Task. The primary benefit of this extended experience is that PSTs often find unique ways of creating a solution that is also replicable. Authors such as Watson and Moritz (2000) maintain that this ability to replicate solutions is a necessary skill for a more complete understanding of average. It should be noted, however, that in most instances the PSTs were unable to completely articulate their solution process. This is seen in the above excerpts where all but Belle struggled significantly in coherently describing
their methods. This ability to articulate a solution strategy is imperative for PSTs as they plan to become future elementary school teachers, and complete and comprehensible explanations of mathematical methods will be required of them.

This study is but a jumping off point for what we hope will be a basis for further analysis of PSTs’ knowledge of measures of center. The preliminary analysis found in this article shows that many PSTs possess the flexibility to utilize different notions of average in conjunction with one another in order to persevere in solving the task. Future studies should investigate how PSTs develop the ability to articulate different strategies for solving mean problems and a recognition of different strategies in examples of student work, as these are important skills for PSTs in order to effectively teach measures of center.

Although this paper is a preliminary study that focuses on PSTs understanding of the mean, it is important to consider how new strategies of thinking of mean may affect how PSTs think of variation. If PSTs are capable of implementing a flexible strategy when solving tasks involving the mean, then this may give educators an opportunity to see how PSTs attend to variation. Therefore, we suggest subsequent studies to investigate PSTs’ responses to context-based tasks that highlight the use of these new strategies in conjunction with notions of variability. In order to accomplish this, tasks must be carefully constructed for the PSTs to construct or investigate data around given means with data that is not so artificial. ‘Messy’ data sets (Mokros & Russell, 1995) might help PSTs consider the conception of the mean as it relates to the variability of real data.

Further investigation must also study the importance of the relationship between context and measures of central tendency. Watson and Moritz (2000) presented a similar problem to the Potato Chip Task when they asked children to develop a data set for the number of children in ten families with an average of 2.3 children. A couple of striking differences are seen, the primary being that 2.3 is not a possible number of children. While the Potato Chip Task asked PSTs to construct data without a value, the value being neglected was reasonable for a bag of chips to be priced, allowing many to initially set this value as the midpoint. In this context, PSTs may find 2.3 a completely unreasonable value to work from. This leads one to question whether the techniques that have been described above are affected by context. It should also be noted that the Watson and Moritz (2000) question had pre-existing values that the students had to take into account (4 children in one family and 1 in another). The question of whether pre-existing data values limit the construction of a data set requires investigation as well.

The future of statistics education depends on discovering what PSTs know, and building on their existing knowledge of central tendency, variability, and distribution in a constructive way that allows them to articulate their ideas thoroughly.

References

In this study, we investigated the extent of knowledge in mathematics and pedagogy that 361 prospective elementary school teachers in China and 291 in South Korea have learned and what else they may need to know for developing effective classroom instruction. We focused on both prospective teachers’ (PT) confidence about their knowledge preparation and the extent of their knowledge on the topic of fraction division. The results reveal a gap between these PTs’ confidence and their knowledge in mathematics and pedagogy for teaching, as an example, fraction division. Moreover, PTs in China and South Korea shared many similarities in their knowledge and confidence but differed in other aspects. The results suggest possible connections with the training programs provided in these two education systems.

Introduction

It is generally recognized that Chinese elementary teachers have a profound understanding of the fundamental mathematics they teach (e.g., Li & Huang, 2008; Ma, 1999). The results have led to further interest in understanding how Chinese elementary teachers are prepared through their teacher education programs and whether different high-achieving education systems in East Asia share similar best practices in teacher preparation (e.g., Li, Ma, & Pang, 2008; Li, Zhao, Huang, & Ma, 2008). While recent studies suggested that high-achieving education systems in East Asia actually have developed and used different policies and practices in preparing mathematics teachers (Leung & Li, 2010; Li, Ma, & Pang, 2008), it is inevitable to question whether prospective teachers are similarly well prepared through different teacher preparation programs practiced in different high-achieving education systems. As a part of a large international research study of prospective mathematics teachers’ knowledge development in mathematics and pedagogy, this article focuses on the case of prospective elementary teachers from two high-achieving education systems in East Asia: China and South Korea. Specifically, 361 prospective elementary school teachers in the Chinese Mainland and 291 in South Korea were sampled for a survey to examine their knowledge of mathematics and pedagogy for teaching in general and on the topic of fraction division, in particular.

The selection of the content topic of fraction division is mainly based on two considerations. The first consideration is about the nature of the content topic itself. Mathematically, fraction division can be presented as an algorithmic procedure that can be easily taught and learned as “invert and multiply.” At the same time, the topic is conceptually rich and difficult, as its meaning requires explanation through connections with other mathematical knowledge, various representations, and/or real world contexts (e.g., Greer, 1992; Li, 2008). The selection of the topic of fraction division, as a special case, can thus provide a rich context for exploring possible depth and limitations in prospective teachers’ mathematics knowledge for teaching (e.g., Ball, 1990; Ma, 1999; Tirosh, 2000). The second consideration relates to some previous studies. For example, several researchers focused on the content topic of fraction division in their investigation of Chinese practicing elementary teachers’ knowledge (e.g., Li & Huang, 2008; Ma,
1999) and of U.S. prospective mathematics teachers’ knowledge (e.g., Li & Kulm, 2008). Relevant findings can thus be used to help understand possible development in Chinese teachers’ knowledge after beginning their teaching career and possible cross-national similarities and differences in prospective teachers’ knowledge between the U.S. and the two educational systems in East Asia.

**Theoretical Framework**

In a recent assessment of prospective teachers’ knowledge in mathematics and pedagogy for teaching (Li & Kulm, 2008), a conceptual framework was developed and used to capture both teachers’ confidence as well as their mathematics knowledge for teaching (MKT). Different from some other studies that focus on teachers’ beliefs and perceptions of mathematics knowledge (e.g., Schmidt et al., 2007), Li and Kulm focused on prospective teachers’ confidence of their knowledge preparation and readiness. Results from assessing both U.S. and Chinese prospective teachers’ confidence and mathematics knowledge for teaching suggested the importance of such a specification on teachers’ confidence (Li & Kulm, 2008; Li, Ma, & Pang, 2008). In particular, these investigations of both U.S. and Chinese prospective teachers’ perceptions and knowledge revealed what we did not know before – a gap between what prospective teachers perceived and what they really knew and were able to do. The success in assessing prospective teachers’ confidence of their knowledge preparation and readiness prompted us to include a similar component when examining Chinese and Korean prospective elementary teachers’ knowledge.

Another component of the framework is teachers’ mathematics knowledge for teaching (MKT). Because prospective teachers differ from practicing mathematics teachers in terms of what they can know and learn for teaching, the component is structured in a way that is consistent with others’ work (e.g., Hill, Schilling, & Ball, 2004; Shulman, 1986) but different in their specifications (Li & Kulm, 2008). In particular, specific items were selected and adapted to assess prospective teachers’ common content knowledge, specialized content knowledge, and pedagogical content knowledge on the topic of fraction division.

In this study, we plan to use the same framework (Li & Kulm, 2008) to examine Chinese and Korean prospective elementary teachers’ knowledge preparation. The use of this framework would allow us to examine Chinese and Korean prospective elementary teachers’ knowledge in mathematics and pedagogy for teaching in two aspects: confidence about their knowledge preparation, and MKT that is further specified as mathematical knowledge on specific content topics (fraction division) and the knowledge needed when carrying out the task of teaching (teaching fraction division). Moreover, the use of the same framework would also make it possible to compare Chinese practicing elementary teachers’ confidence and their mathematics knowledge for teaching (e.g., Li & Huang, 2008) with Chinese prospective teachers’ confidence and knowledge reported in this article.

**Research Questions**

By focusing on the content topic of fraction division, this article is developed to examine Chinese and Korean prospective elementary teachers’ confidence and mathematics knowledge for teaching. In particular, we aimed to address the following two research questions:

1. How do prospective elementary school teachers in China and South Korea perceive their knowledge preparation in curriculum and instruction for their future teaching career?
(2) What similarities and differences can be found between Chinese and Korean prospective elementary school teachers’ knowledge in mathematics and pedagogy for teaching fraction division?

Method

Participants and Context of the Study

The participants were prospective elementary school teachers sampled in China and South Korea. In China, the survey was given to both junior and senior prospective elementary teachers in 10 institutions. 361 responses were collected and used for data reporting, with 50.4% of the responses from junior normal colleges (with fewer years of preparations than the 4-year B.A. or B.Sc programs, see Li, Zhao, Huang, & Ma, 2008), and 49.6% from 4-year normal universities/colleges. In South Korea, the survey data was collected from 291 seniors in three universities that all offer 4-year B.A. or B.Sc. preparation programs. These 291 seniors included those with mathematics education as their focus area, and ones with their focus areas in other subjects.

Instruments and Data Collection

Two instruments developed and used in a previous study (Li & Kulm, 2008) were adopted in this study. The first instrument is a survey of prospective teachers’ confidence of their knowledge preparation. Many items were adapted from TIMSS 2003 background questionnaires (TIMSS 2003).

The second instrument is a mathematics test that focuses on prospective teachers’ content knowledge and pedagogical content knowledge of fraction division. It contains items targeted to prospective teachers’ possible difficulties in order to reveal the extent of their knowledge and understanding of fraction division. Some items were adapted from school mathematics textbooks and previous studies (e.g., Hill, Schilling, & Ball, 2004; Tirosh, 2000) and others were developed following the structure of the framework.

Both instruments were translated into Chinese and Korean by persons fluent in both English and the second language. Special attention was also given to specific problem context to ensure their familiarity with Chinese and Korean prospective teachers. The translation was cross-checked by others to ensure the accuracy and feasibility.

All soon-to-graduate prospective teachers enrolled in the selected institutes in China and South Korea were invited to participate in this study. The participants were notified that both the survey and the test were for research purposes only and should be completed anonymously. Mathematics education faculty in different institutes helped administer the survey and the test. Participants were asked to complete the survey first, then the mathematics test.

Data Analysis

All the data for this study were analyzed in the original language of Chinese and Korean. Selected data were translated to English to provide evidence needed in the later sections of this article. To address our research questions, both quantitative and qualitative methods were used in the analysis of the participants’ responses. Specifically, responses to the survey questions were directly recorded and summarized to calculate the frequencies and percentages of participants’ choices for each category. To analyze participants’ solutions to the problems in the mathematics test, specific rubrics were first developed for coding each item, and subsequently, the participants’ responses were coded and analyzed to examine their use of specific concepts and/or procedures.

---

Results and Discussion

In general, the results present a two-sided picture, along the two components specified in the framework that illustrates the importance of examining and understanding prospective teachers’ knowledge in mathematics and pedagogy for teaching.

On one side, the results from the survey indicate that (1) many prospective elementary school teachers sampled in China and South Korea were not confident in the preparation they received in mathematics and pedagogy for future teaching careers; and (2) there were more prospective teachers in China than those in South Korea who lack the confidence in their preparation needed for teaching fraction division.

On the other side, however, these sampled prospective teachers’ performance on the mathematics test reveals that their mathematics knowledge for teaching fraction division was mathematically sound but less strong in pedagogical content knowledge. The apparent inconsistent pattern in their responses suggests that prospective teachers in China and South Korea did not develop enough confidence with their strong mathematics knowledge only. Nevertheless, the gap is “favorable” as prospective teachers were not satisfied with what they already know in mathematics that is not enough for developing effective teaching. The following sections are organized to present more detailed findings corresponding to the two research questions.

Prospective Elementary Teachers’ Confidence of Their Knowledge Preparation in Mathematics and Pedagogy for Teaching

Prospective teachers’ responses to the survey show the lack of confidence. The following items are selected from the survey to illustrate prospective teachers’ confidence of their knowledge preparation needed for teaching, as related to fraction division.

For item 1: How would you rate yourself in terms of the degree of your understanding of the National Mathematics Syllabus? On a scale of four choices (High, Proficient, Limited, Low), there are only 16% of sampled prospective teachers in China and 20% of those in South Korea self-rated with either “high” or “proficient” understanding of their national mathematics syllabus. Consequently, 84% of prospective teachers sampled in China and 80% in South Korea self-rated with either “limited” or “low” understanding of their national mathematics syllabus.

For item 2-(5): Choose the response that best describes whether primary school students have been taught the topic – Multiplication and division of fractions. In a scale of five choices (Mostly taught before grade 5, Mostly taught during grades 5-6, Not yet taught or just introduced during grades 5-6, Not included in the National Mathematics Syllabus, Not sure), 67% of sampled prospective teachers in China and 61% of those in South Korea indicated correctly that the topic is “mostly taught during grades 5-6”, while the remaining sampled teachers in both China and South Korea chose other responses. This result, in conjunction with the participants’ response to question 1, suggests that the majority of prospective teachers sampled in China and South Korea gave adequate self-assessment of their own knowledge preparation. Some prospective teachers in China and South Korea might even be modest in providing their self-assessment.

For item 3-(4): Considering your training and experience in both mathematics and instruction, how ready do you feel you are to teach the topic of “Number – Representing and explaining computations with fractions using words, numbers, or models?” On a scale of three (Very ready; Ready; Not ready), 45% of sampled prospective teachers in China and 70% of those in South Korea thought they are “ready”, while 15% in China and 6% in South Korea chose “very ready”...
and the remaining 40% in China and 23% in South Korea “not ready.” The results indicate that many prospective teachers in China and South Korea were not confident in their preparation for teaching fraction computations, including fraction division. However, there were significantly more prospective teachers in South Korea than those in China who are confident about their preparation for teaching the topic ($\chi^2(2)=14.11, p=0.01$). The cross-national difference in prospective teachers’ confidence is supported by their performance differences in test items that assess prospective teachers’ pedagogical content knowledge needed for teaching, as reported in the following sub-section.

**Prospective Elementary School Teachers’ Knowledge in Mathematics and Pedagogy for Teaching Fraction Division**

Prospective teachers’ responses to the mathematics test allowed us to take a closer look at the participants’ knowledge in mathematics and pedagogy for teaching, especially on the topic of fraction division. Results indicate that prospective teachers sampled in China and South Korea did very well in computing fraction division. For example, for the problem “find the value of $\frac{5}{4} \div \frac{3}{2}$,” 93% of prospective teachers sampled in China and 97% of those in South Korea solved the problem correctly. Even when the problem was changed slightly with a conceptual requirement, their performance is still good. As an example, to find “How much $\frac{1}{2}$’s are in $\frac{1}{3}$?”, 88% of those in China and 79% in South Korea solved it correctly. In fact, this problem is a typical problem in mathematics textbooks for elementary school students. The responses of these prospective teachers in the two education systems suggest their adequate preparation in mathematics related to division and their understanding of fraction division.

Moreover, Chinese and Korean prospective teachers’ training in mathematics is also reflected in their performance of solving problems that involve fraction division, especially for a multi-step problem. In particular, 75% of sampled prospective teachers in China and 93% of those in South Korea solved the following problem correctly.

Lee’s Pizza Express sells several different flavors of pizza. One day, it sold 24 large-size pepperoni pizzas. The number of large-size plain cheese pizzas sold on that day was $\frac{3}{4}$ of the number of large-size pepperoni pizzas sold, and was $\frac{2}{3}$ of the number of large-size deluxe pizzas sold. How many large-size deluxe pizzas did the pizza express sell on that day?

At the same time, Chinese and Korean prospective teachers were also asked to explain given computations of fraction division. In particular, the problem of “How would you explain to your students why $\frac{2}{3} \div 2 = \frac{1}{3}$? Why $\frac{2}{3} \div \frac{1}{6} = 4$?” (adapted from Tirosh, 2000) was included in the test. It is found that about 88% of sampled Chinese prospective teachers provided valid explanations for dividing a fraction by a natural number (82% for the second computation). However, the majority (64% for the first computation and 73% for the second) explained with “flip and multiply” that is not recommended for this problem. The remaining valid explanation was dominated by explaining the division procedure (e.g., “dividing a whole into six equal parts, each part is 1/6, four parts should be 4/6. In other words, 4/6 contains four 1/6. Thus, 4/6 ÷ 1/6 = 4.”

Because 4/6 equals 2/3, so 2/3 ÷ 1/6 = 4.”). Few students tried to draw a picture such as a circle to help with their explanations.

In contrast, more prospective teachers in South Korea were able to provide valid explanations about fraction division (98% for the first computation, and 88% for the second computation). Moreover, they came up with various methods such as drawing (45% for the first computation, 33% for the second computation), using manipulative materials (10%, 5% respectively), using the meaning of division and/or fractions (8%, 4%), finding the common denominator (6%, 23%), number lines (6%, 5%), and using word problems (5%, 1%). In addition, quite many respondents (about 15%) actually provided explanations in two or more ways. Only a limited number of respondents (3% for the first computation, and 10% for the second computation) used the algorithm of “flip and multiply” to explain the computation.

The difference between Korean and Chinese prospective teachers’ performance in their pedagogical content knowledge becomes even more dramatic when the fraction division was presented in a way that prevented prospective teachers to use the “flip and multiply” explanation. For example, in solving the following problem:

During the lesson when you teach the algorithm for “division of fractions” (i.e., \( \frac{a}{b} ÷ \frac{c}{d} = \frac{a}{b} × \frac{d}{c} \)), students asked why you change from ‘division’ to ‘multiplication’ and flip the second fraction. How would you explain to students?

About 64% of prospective teachers sampled in South Korea and 30% of those in China provided valid explanations. Moreover, among those who provided valid explanations, a higher percentage of Korean prospective teachers (73% of those with a valid explanation in Korea versus 59% of those in China) proved why the algorithm is correct (e.g.,
\[
\frac{a}{b} ÷ \frac{c}{d} = \frac{a}{b} ÷ (1 ÷ \frac{d}{c}) = \frac{a}{b} × \frac{d}{c}
\]
while a higher percentage of Chinese prospective teachers (24% of those with a valid explanation in South Korea and 36% of those in China) used specific numbers to verify the correctness of the algorithm. The results suggest that although both Chinese and Korean prospective teachers’ pedagogy content knowledge was relatively less strong than their mathematical knowledge on the topic of fraction division, Korean prospective elementary teachers had much better performance in pedagogical content knowledge than their Chinese counterparts.

Chinese and Korean prospective elementary teachers’ performances on the mathematics test reveal their strength in mathematical content preparation but relatively less strong in pedagogical content training. This situation is understandable as prospective teachers can be expected to further develop their pedagogical content knowledge once getting into the teaching profession. In fact, existing studies already documented that Chinese in-service elementary teachers have a profound understanding of mathematics they teach, for example on the topic of fraction division (e.g., Li & Huang, 2008; Ma, 1999).

It is important to point out the sampling differences in selecting prospective elementary teachers from China and South Korea in this study. While Korean prospective elementary teachers were all sampled from 4-year B.A. and B.Sc. teacher preparation programs, about 50% of those sampled in China were from junior normal colleges that offered fewer than four years’ teacher preparation programs. A recent analysis of Chinese data suggests that these two groups of prospective elementary teachers in China share many similarities in their confidence and

---

performance, with exceptions on a few items that contain complex or abstract mathematics (Zhao, Ma, Li, & Xie, 2010). Thus, further analyses are needed to help us understand better how different types of preparation programs in China may prepare prospective teachers differently in comparison with their counterparts in South Korea.

**Conclusion**

The findings from this study present two different and seemingly inconsistent sides of prospective teachers’ knowledge in mathematics and pedagogy for teaching. The positive side is revealed by the prospective teachers’ performance on the mathematics test. Sampled prospective elementary teachers in China and South Korea showed their solid preparation in mathematics content they will teach. At the same time, however, mathematics training that Chinese and Korean prospective teachers received may not be enough to build a strong confidence in their preparation for teaching. While prospective teachers’ lack of confidence may partially relate to the influence of Chinese culture in the region (e.g., Bond, 1996; Wong, 2004), the ‘gap’ itself becomes ‘favorable’ as prospective teachers were likely cautious for what they may think is enough preparation for teaching. In fact, both Chinese and Korean prospective teachers’ performance suggests that their pedagogical content knowledge on fraction division can be improved. As prospective teachers sampled in Korea had higher confidence with better performance on items that assess teachers’ pedagogical content knowledge than their Chinese counterparts, it can be assumed that prospective teachers with better preparations in pedagogical content knowledge should become more confident about their readiness for teaching.

Although the discrepancies in Chinese and Korean prospective teachers’ performance in pedagogical content knowledge need to be examined further due to sampling differences, the cross-national difference itself suggests possible connections with different training provided to prospective elementary teachers through teacher education programs in these two education systems. Further efforts are needed to investigate what may help Chinese and Korean prospective elementary teachers to develop their pedagogical content knowledge differently through their program studies.

Finally, the results also provide an opposite picture to the case of the U.S. when a group of prospective middle school mathematics teachers were investigated about their confidence and knowledge in mathematics for teaching fraction division (Li & Kulm, 2008). The previous study revealed that sampled U.S. prospective teachers are very confident with their preparation needed for teaching, while their knowledge in mathematics and pedagogy for teaching fraction division is procedurally sound but conceptually weak. The different patterns presented in prospective teachers’ confidence and their mathematics performance between the U.S. and the two education systems in East Asia suggest possible influence of the culture in addition to teacher preparation programs and practices. Similar to what we now know about teaching as a cultural activity (Stigler & Hiebert, 1999), caution needs to be taken when learning about teacher preparation practices cross-culturally.

tjland@iastate.edu

Despite the prevalence of mathematics curriculum materials in elementary classrooms, most current mathematics methods courses and texts spend little or no time helping pre-service teachers learn to use curriculum materials. To meet this need, we have designed and studied several activities intended to provide pre-service teachers with opportunities to learn about and from the use of curriculum materials. In this paper, we describe our research related to one of these activities – Addition Starter Sentences. In particular, we focus on the ways in which the activity both supported and constrained pre-service teachers in identifying the goals of the curriculum materials and enacting the materials in ways consistent with those goals. We conclude with implications for mathematics teacher education research and practice.

Introduction

Using curriculum materials is a practice that, for many teachers, is at the core of their classroom mathematics instruction (Remillard, 2005). Nonetheless, despite the prevalence of mathematics curriculum materials in elementary classrooms, most current mathematics methods courses and texts spend little or no time helping pre-service teachers (PSTs) learn to use curriculum materials (Drake, in progress). We believe that a need exists to design research-based activities for the elementary mathematics methods course that allow PSTs to learn about - and from - the use of curriculum materials. We have chosen to focus on the use of Standards-based curriculum materials in particular because of 1) their increasing use in districts across the country (Stein & Kim, 2009), 2) their descriptions of mathematics teaching and learning activities that are often quite different from those experienced by PSTs in their own experiences as elementary students, and 3) their explicit attention to opportunities for teacher, as well as student, learning within the curriculum materials (Collopy, 2003; Lloyd, 2009). We have designed these course activities to provide PSTs with opportunities to engage with the educative features (Davis & Krajcik, 2005) of curriculum materials.

In this paper, we present an in-depth look at one of the activities we have designed and our findings related to that activity. We first situate our project in existing literature related to PSTs and curriculum materials, followed by detailed descriptions of the initial design of the activity, findings from the first implementation of the activity, revisions to the activity, and findings from a subsequent implementation. We conclude with implications of our study for mathematics education researchers and teacher educators and a brief description of next steps for this work.

PSTs and Curriculum Materials

We acknowledge that PSTs will not learn to be expert curriculum users in a single-semester methods course. However, it is our goal to position PSTs on a trajectory that will allow them to continue to learn from and about curriculum materials as practicing teachers. In fact, we claim that learning to read and use curriculum materials in particular ways during a methods class can equip PSTs with a generative practice (Franke et al., 2001) that will support them in continuing to learn – about teaching and about children’s mathematics – as novice teachers.

Twenty-five years ago, Shulman (1986) suggested the construct of curricular knowledge was an important, but neglected, aspect of teacher education stating that, “If we are regularly remiss in not teaching pedagogical knowledge to our students in teacher education programs, we are even more delinquent with respect to the third category of content knowledge, curricular knowledge” (p. 10). Shulman described this curricular knowledge as, in part, about, “the set of characteristics that serve as both the indications and contraindications for the use of particular curriculum or program materials in particular circumstances” (p. 10). Two years later, Ball & Feiman-Nemser (1988) described two teacher education programs that discouraged the use of textbooks and, as a result, did not prepare pre-service teachers to use textbooks in effective, flexible ways that supported both student and teacher learning. They suggested, “Perhaps beginning teachers can be oriented toward learning from teacher’s guides and other curriculum materials in a way that allows them to move toward building their own units of study, units that are responsible to subject matter goals and responsive to students” (p. 421).

More recent work related to PSTs and curriculum materials has focused on PSTs’ capacities to evaluate, or critique, curriculum materials. Nicol and Crespo (2006) asked PSTs to critique mathematics curriculum materials. The researchers found that PSTs were able to critique materials, but PSTs differed “in terms of: (1) the types of problems selected; (2) how problems were adapted; (3) whether or not problems were developed; and (4) how the participants considered using textbooks in their future teaching” (Nicol & Crespo, 2006, p. 337). Lloyd & Behm (2005) investigated the ways in which PSTs compared and contrasted two textbook lessons (one traditional and one reform-oriented). The researchers found that PSTs looked for aspects of the lessons that were familiar to them. Furthermore, PSTs’ fondness for traditional lessons led to misinterpretations of the two lessons:

The influence of preservice teachers’ familiarity with more traditional instructional material components was, at times, so strong that it led them to inaccurately describe the two sets of instructional materials or to arrive at questionable conclusions about the materials (Lloyd & Behm, 2005, p. 54).

Methods

In this study, we employed a design research methodology, as described by Cobb et al. (2003). We began with a conjectured trajectory for PST learning from and about curriculum materials and then designed activities to help PSTs advance along that trajectory. Each activity has been implemented multiple times – often by different instructors and at different university sites. In all, six instructors from two universities have participated in implementing one or more of the activities. This variety is a purposeful aspect of our research design as it allows us not only to learn from one another, but also to disentangle the contributions of context, instructor, and activity in advancing PST learning.

Data collected for the study include PSTs’ work from the activities and PSTs’ reflections on the activities, PSTs’ responses to survey items related to their intended use of curriculum materials, instructor reflections on the activities, videotapes of methods classes, and instructor field notes. These data were analyzed through a process of open and emergent coding (Strauss & Corbin, 1998). Using the conjectured learning trajectory and our goals for each activity as an initial framework, data were analyzed independently at the two university sites. As themes emerged and were shared across sites, they contributed not only to the on-going data analysis at each site, but also to subsequent iterations of activity design and data collection. This process is
developed in greater detail in the remainder of the paper – specifically related to the Addition Starter Sentences (TERC, 2008) activity.

**Developing the Starter Sentences Activity**

In addition to having a course goal of helping PSTs learn about and from curriculum materials, we have several other course goals (e.g. teaching through problem solving and attention to children’s mathematical thinking). Because of limited time in the methods course, we want to accomplish multiple course goals within a single course activity. Therefore, in designing new course activities, we sought out lessons or units from Standards-based materials that could address multiple course goals. The Unit 3 Addition Starter Sentences lesson from the 3rd grade *Investigations* (TERC, 2008) series stood out to us because it followed the teaching through problem solving lesson model, provided information about alternate addition strategies, and afforded us a context to discuss children’s mathematical thinking.

Addition Starter Sentences (TERC, 2008) begins by asking students to decide which of the following “addition starter problems” is easier for them to solve and why: 100 + 200 = ______, 136 + 200 = ______, 136 + 4 = ______. Next, students are asked to choose a starter sentence to solve 136 + 227 and explain why that would be a good start. After students solve 136 + 227, they share their solution paths. Students then complete a worksheet with five more “sets” of tasks, which consist of three starter problems matched to a final problem.

In the methods course, we enact the lesson as written with PSTs participating as students. We then ask PSTs to read the curriculum materials and discuss the educative features (Davis & Krajcik, 2005). One educative feature we focus on is the information about alternate addition strategies that align with the starter problems: breaking apart by place; adding one number in parts; and changing a number, then adjusting (TERC, 2008). Next, we examine a later lesson in *Investigations* that revisits starter sentences (from Unit 8) focusing on how it builds on the Unit 3 lesson. Finally, we ask PSTs to categorize examples of children’s mathematical thinking according to the three strategies and discuss how teachers can support students in using them.

Our hope with the Starter Sentences activity is that PSTs will notice that the curriculum materials provide valuable information about the use of alternate strategies (TERC, 2008). Furthermore, we conjecture that because many teachers view textbooks as authorities (Herbel-Eisenmann, 2009; NCTM, 1991), engaging in a textbook-based lesson about alternate strategies might change how some PSTs value and interpret the role of alternate strategies.

**Findings from the First Implementation**

*Starter Sentences in the Methods Class*

Over the course of a semester, Tyminski’s methods course met on campus 21 times for 75-minute sessions and nine times at a local elementary school for a field experience. During the field experience, the PSTs had an opportunity to teach three lessons from Standards-based curricula. The class consisted of 22 students, all female. Although he regularly included exposure to children’s alternative strategies for addition in previous methods courses, this was the first time he did so through the use of curriculum materials. In past iterations of his course, he introduced alternative strategies through the course textbook and its examples of student work (Van de Walle, 2009), and gave PSTs opportunities to solve new tasks using these strategies. Instruction largely focused on the PSTs’ abilities to make sense of and use the mathematics of the children’s solutions, as well as the types of tasks and teaching approaches useful for generating these strategies. These continued to be his goals for the activity involving the

---

In addition, he also had goals aligned with the project goals above: for his students to become familiar with curriculum materials designed to support and elicit alternative thinking strategies, and for students to see how ideas are developed in the *Investigations* curriculum. At the time the activity was taught, it was not known (and upon reflection, not even considered) that any of the PSTs would teach this lesson during their field experience.

During the enactment of the Starter Sentences activity in the methods class, it was clear that the PSTs were able to mentally solve the starter sentences and were able to find multiple ways to use the starter sentences to continue solving $136 + 227$. When asked which starter problem was easiest to solve, every PST chose $100 + 200$. They gave reasons such as “There is nothing on the end” and “You don’t have to carry”. When asked which starter problem would be a good first step to solving $136 + 227$, most PST chose $136 + 200$ as the starter problem they would use. One PST reasoned, “Its [136 + 200] just basically the same without the 27”. When another PST suggested there were reasons why a child might choose $100 + 200$ as a first step, Tyminski asked the class to discuss what the child’s next steps might be. With this prompt the PST suggested a child might add the 10’s together, add the 1’s together, and then add all of the partial sums to find the total. Another PST suggested a way she could use $136 + 4$ as a first step in a compensation strategy, using $136 + 4$ to change $136 + 227$ into $140 + 223$. The students then selected one of the starter problems and finished solving for the sum. Next, Tyminski introduced the five sets of starter problems for PSTs to solve. In the course of doing so, he was explicit on four different occasions that the PST did not have to use the starter problems and it was okay if they did not. All PSTs however, seemed to use the starter problems and were able to use them in a variety of ways and record keep their ideas, which they shared on the board.

The next stage of the lesson involved the PSTs reading the lesson materials from Unit 3 and Unit 8 and discussing what they noticed about the materials and/or their enactment. Tyminski had asked his PSTs to read the materials prior to class, knowing he would not have time to spend reading in class. The students had little to say about the features of the materials or the lesson enactment. The class then discussed and named the three strategies evident in the starter sentences. As the students summarized the Starter Sentences lesson from Unit 8, Tyminski briefly listened to their ideas and summarized what he believed to be the three big additions in Unit 8: asking students to estimate before solving using starter sentences, including problems that would “spill over” into the next place value, and at the end, encouraging students to write their own starter sentences. The rest of the class was spent by the PSTs identifying and making sense of student addition strategies.

As we examined Tyminski’s lesson video we realized something important and interesting. Namely, it seemed that his goals and focus in his previous lessons on this topic influenced his enactment of the activity. In spite of his stated goals for his students to become familiar with curriculum materials designed to support and elicit alternative thinking strategies, and for students to see how ideas are developed in the *Investigations* curriculum, he appeared to gloss over the opportunities built into the plan to address these goals. Rather, the majority of the class time was spent either on PSTs making sense of and using the alternative addition strategies presented in the curricular materials or using these experiences to interpret students’ work. When his time was limited, he made choices to focus on goals related to the mathematics of children and the mathematics of the PSTs. In and of itself, this did not strike us as problematic. After all, teachers make choices and judgments all the time in the process of teaching. And, the PSTs had been asked to read the materials for two related units and worked through tasks from both. Perhaps, even though explicit attention was not paid to them, the goals of the individual lessons

and the big ideas of *Investigations* were as evident to the PSTs as they were to the authors. As we later realized, this was not the case; at least not in the case of Cathy.

*Using Starter Sentences in the Field: The Case of Cathy*

For the field experience component of the course, Cathy (pseudonym) was placed in a third grade classroom. As a course requirement, Cathy was to negotiate a mathematical topic with her cooperating teacher and teach a lesson on that topic from a Standards-based curriculum. Her teacher asked her to teach a lesson on adding three digit numbers whose sum was greater than 1000. Cathy chose to implement the lesson from Unit 8 involving starter sentences.

*I knew that the students had been learning and practicing adding three digit numbers this semester based on what Mr. “Y” told me. He said that the students were having a lot of trouble with adding four digit numbers and the one-thousandths [sic] place, so I thought that this lesson would be a great way for students to learn how to use simpler ways to add while practicing with the three digit numbers they had been learning to add. My goals were for the students to be able to pick one starter problem and use it to solve the addition problems I wrote on the board and that were in their worksheets that were passed out as an assessment.* (Reflection)

As she enacted the lesson, she began with the lesson’s estimation task for 379 + 412, which her students solved by finding exact answers. Then she presented the students with the three starter sentences for this addition problem; 379 + 400 = _____, 300 + 400 = _____, and 379 + 1 = ___. The curriculum directed the teacher to remind students they had used starter sentences earlier in the year, and to ask them “Which one of these makes it easiest for you to solve the problem? Choose one of these starter problems, and think about how you would finish the problem. Write your strategy to keep track of it,” (TERC, 2008, p. 73). Cathy introduced them by telling her students that the number sentences “were starter problems and they would help them while adding” (Cathy, Reflection). She set the students to work on the task and walked around the room, interacting with the students. Cathy described what she saw in her reflection,

*While walking around the room to see who [sic] to call on to give me their starter problem, I noticed that all but two students used the standard one number on top of the other way of adding. This is where I felt a bit of panic because students were not doing what I intended or even trying to use the starter problems. I noticed that almost all of the students solved the starter problems and the real question that were on the board instead of picking one starter problem to help them solve the real problem. During this discussion time I called on the students who used starter problems and wrote their methods on the board. (Reflection)*

As she described, the majority of the students used the standard algorithm to solve the problem. One of her students however, used 379 + 400 = ____ to solve the problem by adding the left over 12 to 779. A second student was able to use 379 + 1 = ___ by rewriting 379 + 412 as 380 + 411. Cathy explained these two solution strategies and pointed out how the starter problems helped each student solve the problem. She also had a student explain how they solved the problem using the standard algorithm. “I quickly learned that students who learned how to add the standard way, stuck with that method because it was what they knew and it worked for them” (Cathy, Reflection). Next the students worked on the six sets of starter problems from the Unit 8

lesson. As Cathy walked around to talk with students she noticed that students had solved all of the starter problems as well as the original problem. Only two students, but only one of the same as before, used the starter sentences. In her final discussion, she had the students who used starter sentences share their thinking along with students who used the standard algorithm.

Cathy’s goal for the lesson was for students to solve addition problems using starter sentences. However, despite the fact that her students successfully solved the problems posed, she viewed her lesson as a failure because they did not solve them the way she wanted them to.

 Based on my objectives of each student using a starter problem to solve the real problem, the lesson was a complete failure because that did not happen. I feel negatively about this because I feel that I did not do my job as a teacher since they did not do what I intended. (Reflection)

Investigations pose tasks for students to explore the process of doing mathematics and supports teachers in interpreting and developing student thinking. Implicit to this notion involves the teacher meeting the student where she is, working from what students are doing, and not “forcing” strategies on students. As evidenced by this excerpt, this idea was not clear to Cathy.

 I found it very difficult to teach students new concepts especially if what they already do is working for them…Overall I think that my intentions were good, but the execution did not happen. I needed to put more emphasis on why we were using these problems and how they would help students add. (Reflection)

This is an example of our activity’s failure to develop Cathy’s curriculum vision (Drake & Sherin, 2009). Cathy clearly focused on implementing the individual lesson’s ideas in a literal manner and paid little attention to the bigger ideas and goals of the curriculum. Due to this serendipitous event however, were able to see from her enactment and reflection the message Cathy constructed from the methods class activity. We believe it is reasonable to assume her experiences with the activity in the methods classroom influenced her goals for the lesson and her sense of how the materials should be used. As we realized the message Cathy constructed was not our intended message, we realized we were missing answers to important questions: What message did the other PSTs take away from the methods course activity? What goals would they have had in using this lesson?

Findings from the Next Implementation

Based on the findings described above, as well as our own experiences with implementing the starter sentences activity, Drake and Land made multiple pedagogical changes to the activity in their next enactment. They also made methodological changes in the data collected from PSTs about the activity. They were particularly interested in collecting data related to their PSTs’ understandings of the goals of the lesson and the relationship of these goals to children’s thinking about and strategies for multi-digit addition.

The major pedagogical change was the addition of a task at the end of the activity. PSTs were asked to construct the “curriculum storyline” by using the curriculum materials to identify the overall goal of the lesson, the key lesson steps (Brown et al., 2009), and the relationship between each of those steps and the lesson goal. The intent of this new activity was to 1) provide greater support for PSTs in identifying and reflecting on the overall goal of the starter sentences lesson,
as well as the elements of the lesson and curriculum materials that contributed to this goal and 2) introduce the concept of a curriculum storyline as a strategy, or tool, for PSTs to use in purposefully reading curriculum materials and developing curriculum vision.

Drake and Land also added two reflection questions for PSTs to answer, providing us with insight into PSTs’ thinking about their learning about children’s strategies for multi-digit addition and the goals of the lesson. Here we share the findings from the question that most directly addressed our findings from the first implementation:

Depending on your purpose, you might have the following goals for students:

1. Choose just one strategy and practice it
2. Use more than one strategy to solve each problem
3. Use more than one strategy across the problem set (i.e., use one strategy for one number combination and a different strategy for a different number combination)
4. Learn and master all of the strategies

If you were teaching the Addition Starter Sentences lesson, which of these goals would you have? Why? (You can use evidence from the materials or from your own experiences to support your choice).

Half of the PSTs chose the goal of having children use more than one strategy to solve each problem. The remaining PSTs were evenly split across the other three choices. Most interesting to us, however, was that the PSTs who chose the second, third, or fourth goals above all provided similar justifications for their choices, even though they selected different goals. They all wanted children to develop flexibility in their strategies while still identifying a strategy that worked best for them. Thus, while 15 out of 18 PSTs seemed to hold a consistent understanding of the overall purpose of the lesson – and of the use of alternate strategies more generally – they differed in their interpretations of how they would enact the materials to support this purpose.

Implications and Next Steps

It is our intent to have PSTs learn about and from curriculum materials. Since instructors’ future pedagogical choices depend on knowledge of PSTs’ current conceptions it is important for instructors to know what ideas PSTs take away from their experiences with curriculum materials. To accomplish this it is crucial to ask them to explicitly reflect on what they have learned from the activities and to see them enact what they have learned in practice. The next steps to this project are reflected in the case presented. We believe we can structure future activities to better examine what PSTs learn from interactions with these types of materials. However, we need opportunities to see PSTs teach with these materials to see the relationship between their intended goals for implementation and their enactment of the lesson.

This paper examines the impact of pre-service mathematics methods courses aimed at integrating a focus on children’s mathematical thinking and community/cultural funds of knowledge in mathematics instruction. Analysis revealed that many pre-service teachers entered methods courses with the belief that connecting mathematical funds of knowledge was a valued teaching practice. Prospective teachers found their engagement with students’ communities to be a positive and meaningful experience that helped them develop mathematics curriculum. However, pre-service teachers also faced challenges, remaining vague about what they might actually do to draw on children’s funds of knowledge and at times reifying stereotypes.

Introduction

The field of mathematics education currently lacks a deep understanding of how mathematics instruction might integrate children’s mathematical thinking with cultural, linguistic, and community-based knowledge that children bring to classrooms in ways that support learning. On the one hand, research supports the effectiveness of instruction centered on children’s mathematical thinking and documents that teachers’ knowledge of children’s mathematical thinking leads to productive changes in teachers’ knowledge and beliefs, classroom practices, and student learning (Carpenter, Franke, Jacobs & Fennema, 1998; Fennema, Carpenter, Franke, Levi, Jacobs, & Empson, 1996). On the other hand, research documents that historically underrepresented groups benefit from instruction that draws upon their cultural, linguistic, and community-based knowledge (Ladson-Billings, 1994; Turner, Celedón-Pattichis & Marshall, 2008). This research argues that teachers need to understand how students’ home and community-based funds of knowledge – the knowledge, skills and experiences found in students’ homes and communities - can support their mathematical learning (Civil, 2002; Moll, Amanti, Neff & Gonzalez, 1992).

At the same time, as our nation’s public schools have become increasingly diverse, the pre-service teacher (PST) population steadily consists of White, middle-class, monolingual females typically underprepared to address such diversity (Hollins & Guzman, 2005). While there is significant research related to preparing teachers to work in diverse classrooms, little of it addresses the specific challenges and resources of learning to teach mathematics to diverse learners. We contend that experiences that help PSTs understand the mathematical knowledge and practices of students’ communities can enhance their ability to provide effective mathematics instruction for diverse learners.

This research investigated preK-8 pre-service mathematics teachers’ work in mathematics methods courses around instructional modules aimed to prepare them to design and implement effective instruction for diverse student populations that builds on and integrates children’s
multiple knowledge bases. In particular, this study investigated the following research question: What changes do we notice in PSTs’ knowledge, beliefs, dispositions, and practices related to integrating children’s mathematical thinking and their home and community-based funds of knowledge in mathematics instruction? This paper presents selected results from this research.

**Theoretical Perspectives**

This work draws upon situated, socio-cultural perspectives of teacher learning (Lave & Wenger, 1991) that frame teacher learning as situated social practice. This study conceptualizes PST learning as a process of identity development (Wenger, 1998); as PSTs engage with the mathematical practices and identities of children and families as children move across contexts and spaces, PSTs move along a trajectory toward becoming mathematics teachers - analyzing, reflecting, and acting on their own practices and identities. In considering potential learning trajectories for PSTs, we draw on Mason’s (2008) constructs of attention, awareness, and attitude for examining PSTs’ reflections and discussions. In particular, we hypothesize that by participating in modules designed to focus on mathematics and children’s multiple knowledge bases, pre-service teachers enter a learning trajectory in which they begin to attend to children’s mathematical thinking and their cultural, linguistic, and community-based knowledge and experiences. This attention in turn supports PSTs’ awareness of and attitudes toward students’ competencies and knowledge relevant to mathematics. This combination of attention and awareness prepares PSTs to participate in more complex, field-based tasks in which they work with children in schools and the community. PSTs begin to make emergent, and then meaningful connections as their understanding of children’s multiple mathematical knowledge bases progresses from considering the knowledge bases as separate, to understanding how they might work together to support mathematical learning. As PSTs make meaningful connections, these connections then facilitate incorporating multiple knowledge bases in instruction, where PSTs plan problem-solving tasks that incorporate what they know about how children develop understanding of these concepts with what they know about the mathematics used in this community setting.

**Methods**

**Participants**

Approximately 200 pre-service elementary and middle school mathematics teachers enrolled in mathematics methods courses at six university sites that represent a diverse range of teaching contexts (i.e., urban, a mixture of urban, suburban, and rural, suburban, and borderlands) participated both in the instructional modules examined in this research and in pre- and post-course surveys.

**Survey**

Pre- and post-course surveys were administered to participants to gauge PSTs beliefs about the teaching and learning of mathematics and children’s cultural, linguistic, and community-based funds of knowledge as resources for teaching. The surveys included 18 Likert-type items, six short answer responses, between two and four instructional scenarios (pre-survey only), and nine questions related to effectiveness of course activities (post-survey only).
Instructional Modules Overview

Instructional modules were created and implemented in elementary and middle school mathematics methods courses with study participants. These modules were informed by research and professional development materials on Cognitively Guided Instruction (Carpenter et al., 1999), community-based funds of knowledge for teaching mathematics (Civil, 2002), and Villegas and Lucas’s (2002) six-strand framework for preparing culturally responsive teachers. More specifically, we designed the modules to include opportunities for PSTs to a) identify and build on children’s mathematical thinking and funds of knowledge, b) recognize and describe instructional and community practices that support preK-8 students’ mathematical learning, and c) adapt curriculum materials and lesson plans to incorporate rich mathematical content, children’s mathematical thinking and funds of knowledge.

Focus Module: Community Mathematics Exploration

This paper focuses on one module in particular, Community Mathematics Exploration, which required PSTs to engage with the local community (e.g., visit community locations, observe and interact with community members, conduct a community walk) and consider how knowledge gained through that interaction could inform their teaching. The goal was for PSTs to identify mathematical practices and mathematical funds of knowledge in students’ communities and build on them in a standards-based mathematics lesson or mathematics problem. In the methods courses, pre-service teachers read articles about what it means to build on children’s community funds of knowledge in mathematics classes (e.g., Civil & Kahn, 2001). How PSTs engaged with the community varied somewhat with each site. Regardless, all PSTs engaged with the community in some way, and then designed either a mathematics problem or standards-based mathematics lesson that built on what they learned about children’s community and cultural funds of knowledge. In the example discussed in this paper, two PSTs enlisted the expertise of a Latina parent as they engaged in a walking tour of the community. The PSTs then created a third-grade mathematics lesson inspired by what they learned on their community walk. Finally, PSTs reflected on the experience in terms of what they learned about themselves, their students, and their teaching.

Data Analysis

The data analyzed for this paper included artifacts from the methods classes around the module: recordings of class discussions, individual reflective writing, and PSTs’ lesson plans or mathematics tasks designed to integrate multiple knowledge bases. Data also included surveys from 194 pre-semester respondents and 130 post-semester respondents.

We examined artifacts from the methods course using analytic induction (Bogdan & Biklin, 1992) with open coding (Corbin & Strauss, 2008). In the analytic process, initial conjectures were made from the existing data record then continually revisited and revised in subsequent analyses. Particular attention was paid to PSTs’ developing understandings of the integration of children’s mathematical thinking and children’s cultural, linguistic, and community-based funds of knowledge. Further, drawing from Mason’s (2008) work, we identified patterns of similarity and differences in PSTs’ attention, awareness, and attitude with regard to building instruction on children’s mathematical thinking and cultural, linguistic, and community-based knowledge.

Survey responses were analyzed both overall and by campus. Particular attention was paid to establishing PSTs’ beginning and end-of-course knowledge and beliefs related to connecting
children’s mathematical funds of knowledge. Analysis of this data was then used to inform the development of initial learning trajectories for PSTs’ engagement in this instructional module.

**Results**

**Survey**

Across all six campuses, analysis revealed that many pre-service teachers entered methods courses with the belief that connecting mathematical funds of knowledge was a valued teaching practice. More than 90 percent of PSTs agreed or strongly agreed on the pre- and post-surveys with statements such as, “The teacher can better support students’ development in math if s/he draws on their home/community resources,” and “Home and community activities are good contexts for posing and solving mathematical problems.” Despite this agreement, we were able to see movement on these items across the semester, with substantial percentages of PSTs moving from “agree” to “strongly agree.”

At the same time, analyses of instructor reflections and PSTs’ written work suggest that while PSTs are very supportive of these ideas in the abstract, they tended to be very vague, particularly at the beginning of the courses, about what teachers might actually do to draw on these home and community resources. For example, when asked about the role that children’s families and communities play as they are planning mathematics lessons, the majority of PSTs alluded to “making lessons students could relate to” without any specification of how one might learn about students’ communities and their out-of-school experiences, or how one might use that knowledge to plan a lesson. Reponses such as “If you’re familiar with your students families and communities, you can then incorporate it into your lessons” or “it’s important to put math in a context that your students can relate to” were quite common. We conjecture that, through their participation in this and other instructional modules, PSTs acquired specific knowledge about mathematical resources available in children’s homes and communities as well as specific ideas for using these resources in instruction. The opportunity to “try out” these ideas may have supported PSTs in beginning to incorporate them into their practices and identities, and in moving along our hypothesized trajectory toward making emergent connections.

**Community Mathematics Exploration**

The following example serves to illustrate how the Community Mathematics Exploration module supported some PSTs in identifying mathematical contexts for mathematics lesson development that builds on children’s multiple funds of knowledge and in confronting stereotypical assumptions about children. In this example, two PSTs enlisted the expertise of a Latina parent as they engaged in a walking tour of the community. The PSTs then created a third-grade mathematics lesson inspired by what they learned on their community walk and grounded in the mathematical practices and skills used in a familiar “hub” for the local Latino community – a Lavandería/Laundromat. Specifically, the PSTs used information obtained by visiting the Lavandería, such as washer/drier prices, detergent prices, estimation of number of loads, and family budget constraints, to design high cognitive demand mathematical tasks that incorporated problem-solving and computational fluency with whole numbers and fractions.

For example, there were three washer prices: La máquina de una carga / Single load washer: $1.75/load; Las máquinas de dos cargas / Double load washer: $3.00/load; Las máquinas de tres cargas / Triple load washer: $4.00/load. Mathematics tasks were situated in a familial context asking students to help “your mother” determine the cost to wash and dry 10 loads of dirty clothes, including the “maximum and minimum that one might pay.” The lesson also included an...
extension problem incorporating fractions and rates, asking students to use their own family situation to determine the maximum and minimum cost given the parameter that each family member “makes 1 ½ loads of dirty laundry.”

While not all PSTs were this successful in developing math lessons that built on children’s community funds of knowledge, as will be delineated in the sections below, the example does illustrate the potential of this instructional module to support PSTs’ practices related to integrating children’s mathematical thinking and their home and community-based funds of knowledge in mathematics instruction. The following paragraphs highlight the learning opportunities and challenges this instructional module holds for developing PSTs’ knowledge, beliefs, dispositions, and practices in this way. Specifically, analysis of the artifacts from the Community Mathematics Exploration module revealed that PSTs were initially wary and nervous about the activity, but that the module supported them in strengthening relationships with students, feeling more comfortable about engaging with students’ communities, identifying mathematical contexts as a resource, and, in some cases, it helped PSTs confront stereotypical assumptions about students.

**Learning Opportunities and Challenges for PSTs**

**Initial skepticism.** One challenge for PSTs at the outset of the module was that to engage fully, they first had to acknowledge personal discomfort about the usefulness of such an activity. PSTs expressed initial discomfort, saying things like “Before I engaged in this activity, I was a little nervous. I was concerned that the people I interviewed would be apprehensive and not want to answer my questions fully. I also felt like I would be intruding by asking certain questions…thus, I was unsure of what to expect.” Other students expressed their fears about the assignment itself, asking, “Are there specific places we should go?” or “Should what we find be strictly linked only to math?” Still others were explicit about their skepticism, asking, “How is this going to help us teach math?” and reflecting, “Before engaging in this activity, I was not sure if it was going to be relevant or helpful to me.”

**Strengthening relationships.** Once PSTs were able to move beyond their initial discomfort and skepticism, our analysis suggests that the module supported them in a number of ways. First, PSTs saw the activity as a means to strengthen their relationships with their students and the community, reflecting that “The mathematical activity occurring in the community may not intend to shorten the distance between teacher and the students; however, I believe it does.” Many PSTs reflected that they appreciated the opportunity to get to know one or more of their students better and argued that this, in and of itself, was a valuable aspect of the experience, noting things like, “Getting to know your students on a personal level is just as important as knowing them on an intellectual level.”

PSTs reported seeing mathematics “everywhere” in the community, extending the idea that both mathematical activities and resources extended beyond the classroom walls. PSTs reported being “surprised” at the many ways they could mathematize the students’ environments, “We came up with at least twenty promising math explorations that could [get] kids to analyze relationships in mathematical ways.” For one PST, a former community activist, this activity allowed her to see her community in multiple “perspectives:” mathematics, kids, and mathematics as a tool for social justice.

*I actively looked for numbers in places that I normally would not. It was easy to spot numbers in the café or the corner store: prices and money. But in addition, it was fun to

---

think about the angles of the crooked fencing near the school, or the garbage-to-receptacle ratios in People’s Park... In my past, I have spent a lot of time highlighting the gentrification of the [Neighborhood] to City officials, and espousing the positive qualities of the neighborhood and its residents. However, this time, with the “math” and “kid” lenses also in focus, I saw new places for justice. The corner store, with its miles of candy and its spoiled meat from [Big Store Chain], struck me, in particular. It seems to be a place preying upon kids, under the guise of convenience...I’m sure an interesting math lesson exists there.

In addition, the community mathematics explorations allowed more nuanced views of the communities their schools served. Some PSTs reported previously “avoiding” certain communities because of negative reputation (e.g. violence, pawnshops, few grocery stores and parks). By explicitly investigating these communities, some PSTs found evidence that challenged the one-dimensional negative view of specific communities noting new parks, restaurants, building rehab projects, “ornamental additions” to streets/sidewalks, and the presence of churches (e.g.15 in a 1 mile radius of their school). The Community Mathematics Exploration enables PSTs to recognize mathematical practices in the community and facilitate a more nuanced and mathematical view of the community that can benefit mathematical learning and teaching in the classroom.

**Comfort.** Additionally, the module shows promise in helping PSTs feel more comfortable engaging with their students’ communities. By working through their initial fears, PSTs saw both the importance and benefit of connecting with students’ families and communities. As one PST said, “This project helped build my confidence as a teacher. It helped me overcome a bit of my shyness and open up to the people that are important to my students. I learned more about my students and gained confidence about speaking to the family members of my students.” Another noted her newfound comfort, reflecting, “After completing this informal interview, I feel more comfortable exchanging words between parents of students, especially those parents who have an ESL student in my classroom.” Still others found themselves trying to see schooling from the parents’ perspective, reflecting, “Before conducting the interview I never realized how difficult it is for the parent of the student. I didn’t realize that often the parent is learning and discovering with the child.... Through this experience, I now hope to get parents more involved in my classroom.”

**Identifying mathematical contexts.** The module also supported PSTs in identifying mathematical contexts as a resource for mathematics problem and mathematics lesson development. All of the PSTs that engaged in this activity were able to create a mathematics problem or mathematics lesson that built on what they learned in their Community Mathematics Exploration. Many of these problems and lessons required rigorous mathematics and, as such, communicated high expectations for children’s learning (e.g., the Lavandería/Laundromat lesson described above).

However, other PSTs struggled with coming up with good, rigorous mathematics tasks that drew on children’s multiple funds of knowledge. For example, PSTs noted that many children enjoyed and participated in activities such as shopping and going out to eat and designed mathematics story problems such as, “Johnny was saving money for a toy he really wanted. His mom decided to bring him to the supermarket to empty his piggy bank in the coin machine. He has 75 quarters, 40 dimes, 26 nickels, and 175 pennies. How much money does he have for his toy?” Other PSTs merely described the kinds of activities they imagined doing with students.

---

without generating ideas for specific lessons. Confronting stereotypes. Finally, in some cases, the instructional module supported PSTs in confronting stereotypical assumptions about children and their communities. For example, one of the PSTs involved in the Lavandería/Laundromat exploration described above noted:

When one of the resource room teachers heard about our Community Math lesson project, she exclaimed that it was a great opportunity to “show them how to fix some of their problems. Maybe you can somehow make a lesson that will make parents care about their kids.” We felt passionately that this bias against the community was unfair – clearly, parents in the Sunny Hill (pseudonym) community care deeply about their children. As such, we wanted our lesson to be a tiny step in the opposite direction; we wanted our project to recognize (and even celebrate) students’ families and values rather than criticize them.

These PSTs are beginning to develop capacities as culturally responsive mathematics teachers that integrate understanding of mathematics, children’s mathematical thinking, and community-based funds of knowledge to promote mathematical advancement for their students.

In other cases, however, this instructional module did not fully support PSTs in moving away from stereotypes about students and their communities. For example, one PST who conducted a community walk in a rural area but did not have an opportunity to speak with any community members reflected, “These students who come from a small community may not have any idea of the problems that are being faced in the real world and teaching them through math could be beneficial. Having students explore ideas of racism, equality, socio-economic status and so forth in math would not only help them learn the relevance of math, but also introduce the students to things they might not even realize are happening.”

Discussion

Returning to Mason’s (2008) notions of attention and awareness and our hypothesized learning trajectory for PSTs, our survey results suggest that the majority of PSTs enter their mathematics methods courses pre-disposed to attend to children’s family and community-based knowledge and experiences, but lack specific practices for doing so. At the same time, fewer PSTs begin the methods class attending to children’s mathematical thinking, but gain both the knowledge and dispositions to attend to and develop awareness of children’s mathematical thinking by the end of the course.

This combination of attention and awareness and attitude toward children’s competence prepares PSTs to participate in more complex, field-based tasks in which they work with children in schools and the community. As we see from the results of the module reported above, our PSTs are also beginning to make emergent connections. This is evidenced in the fact that all PSTs were able to develop a mathematics problem that builds on children’s multiple funds of knowledge, though some struggled with the mathematics involved or with knowing how to connect what they learned about the mathematics activity of the community to instruction.

As PSTs make meaningful connections, these connections then facilitate incorporating multiple knowledge bases in instruction. As PSTs make meaningful connections they might recognize, as in the example above, that children’s family experiences at the Lavandería involve mathematical practices including estimation and reasoning about rates. Next, they incorporate multiple knowledge bases by planning problem-solving tasks that incorporate what they know
about how children develop understanding of these concepts with what they know about the mathematics used in this community setting.

These results provide an important starting point for understanding how to design instructional activities for elementary methods courses that will support PSTs in learning to connect mathematical funds of knowledge in their own classrooms. Although the Community Mathematics Exploration was just one component of the mathematics methods course, it seemed to serve as a catalyst to challenge PSTs’ negative views of mathematics and students’ communities.

Prospective elementary teachers must deeply understand fraction division to meaningfully teach this topic to their future students. This paper explores the nature of the subject content knowledge possessed by a group of Taiwanese prospective elementary teachers. The findings provide preliminary evidence that many Taiwanese elementary teachers have developed the knowledge package of fraction division as described by Ma (1989). However, the tasks of representing fraction division either through story problems or pictorial diagrams remain to be challenging. This study contributes to the continued effort to improve prospective elementary teachers’ mathematics knowledge needed for teaching.

Introduction

Elementary teachers need a deep understanding of mathematics knowledge in order to optimize their students’ opportunity to learn mathematics. One challenging mathematics topic for upper elementary and middle school students to learn is fraction division. Consider the following released item from the 2003 TIMSS as reported in Yoong, Yee, Kaur, Yee, & Fong (2009):

*A scoop holds 1/5 kg of flour. How many scoops of flour are needed to fill a bag with 6 kg of flour?*

Among all participating 8th graders, only 38% of students answered this question correctly, with the three highest performing participating Asian countries—Singapore, Hong Kong SAR, and Taiwan—ranging from 79% to 75%. Many factors contribute to the low student performance. One factor that has been suggested is the quality of mathematics knowledge held by the teachers. Research studies done in the U.S. and Australia have found that many prospective elementary teachers had difficulty carrying out the fraction division algorithm correctly, and even fewer were able to develop appropriate representations for a given fraction division problem when the divisor is a proper fraction (e.g., Ball, 1990; Li & Kulm, 2008; Ma, 1999; Rizvi & Lawson, 2007; Son & Crespo, 2009). On the other end of continuum, Ma’s account of Chinese elementary teachers’ knowledge of fraction division has provided a rich description of what deep understanding of fraction division could be expected of practicing elementary teachers. A missing piece of this line of research is what can be expected of prospective elementary teachers. In this paper, we will provide an account of the knowledge of fraction division possessed by prospective teachers from a TIMSS high-achieving country, Taiwan.

Theoretical Framework

Based on interviews with U.S. and Chinese elementary teachers, Ma (1999) proposed a “knowledge package for understanding the meaning of division by fractions” that teachers should have, as illustrated in the Figure 1 below. According to this model, a deep conceptual understanding of fraction division is built upon a network of prior knowledge. At the top layer, it includes concepts of unit, meaning of fraction with multiplication, meaning of division with
whole numbers, and the conception of inverse operation between multiplication and division. These, in turn, are built upon more fundamental knowledge such as concept of fraction and the meaning of multiplication with whole number, which is built upon the meaning of addition with whole number.

Fishbein, Deri, Nello, and Marino (1985) identified two primitive models for whole number division: a partitive model and a measurement model. For measurement division, one tries to determine how many times a given quantity is contained in another quantity. For partitive division, an object (or collection of objects) is divided into a given number of equal parts (or sub-collections), and the goal is to determine the quantity in (or size of) each part (or sub-collection). Prior studies have identified many challenges students (and prospective teachers alike) face when attempting the above two meanings of division to fraction division, especially when the divisor is a fraction. For example, many find the idea of sharing among “3/4” group to be very unnatural. This observation has led to the suggestion of the introduction of fraction division through measurement context and the emphasis of division as the inverse operation of multiplication. Both were identified as main characteristics of a fraction division unit in Chinese and Japanese mathematics curricula (Li, Chen & An, 2009).

Figure 1. A knowledge package for understanding the meaning of division by fraction, p. 77 of Ma (1999)

Two unit-related concepts are critical to the development of a deep understanding of fraction multiplication and division. The first one is the idea of unitizing. Steffe (2003) defines unitizing as a mental operation that treats an object or collection of objects as a unit, or a whole. In the measurement division, when considering “How many scoops of 1/5 kg flour are needed to fill out a 6 kg bag?” students need to be able to conceptualize 1/5 kg as a unit, and use it to measure the 6 kg. The second one is the idea of referent unit. Izsák, Orrill, Lobato, Cohen, and Templin (2009) suggest that fraction tasks in the school curriculum can be separated into two categories. One includes those that conserve the referent unit, such as those that explore the relationship between the parts and the whole, compare fractions, and add or subtract fractions. For example, the answers for adding ½ cup of sugar and ¾ cup of sugar will still carry the same referent unit, “cup.” The other includes multiplication and division of fractions, where the referent units change. For example, in the above flour packing problem, the answer 30 will carry the unit...
“scoops,” which is different from the referent unit given in the problem. Teachers need to be aware of these differences and have the ability to deal with referent units appropriately across different tasks.

This study investigates prospective elementary teachers’ fraction division concepts with respect to three main areas: meanings of fraction division and multiplication, inverse relationship between multiplication and division, and the two unit-related ideas discussed above. Their solution strategies in three different tasks—number line, story problem, and representations with story problems and pictorial diagrams—are examined. The first two fall under what Ball, Thames, and Phelps (2008) refer to as common content knowledge (CCK). CCK refers to the knowledge needed to solve mathematics problem that is not unique to teaching. This knowledge is distinguished from specialized content knowledge (SCK), which refers to mathematical knowledge and skills uniquely needed by teachers, such as posing story problems and utilizing pictorial diagrams to facilitate student reasoning.

Methodology

The data analyzed in this paper came from a research study on prospective elementary teachers’ fraction knowledge. Participants included 45 prospective elementary teachers from a traditional teacher education university in Taiwan. All prospective elementary teachers in Taiwan have either a content concentration (e.g., language arts, math, social studies) or a specialization area (e.g., special education, counseling education). The participants in this study included 28 special education majors, 7 art education majors, and 10 counseling education majors.

A 16-item instrument was administered in two separate sections at the beginning of the mathematics methods course. This methods course is the only required math education-related course for non-math majors in the teacher education program at this university. The first section of the instrument contains 12 items that focus on CCK, including basic fraction concepts (e.g., part-whole, unitizing, ordering, meanings of operations, etc.) and story problems (one-step and multiple steps). The second section contains 4 items that focus on SCK, such as explaining a fraction problem in multiple ways, posing story problems for given computations, and using diagrams to model the solutions of given computations. Because of student absences, 41 students answered the first part and 40 students answered the second part.

The focus of this paper is on prospective elementary teachers’ solutions to three fraction division-related items. The first two focus on CCK and the third one on SCK. The three items are listed below.

<table>
<thead>
<tr>
<th>#1.</th>
<th>What is the value of x?</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a)</td>
<td>7/12</td>
</tr>
<tr>
<td>(b)</td>
<td>3/5</td>
</tr>
<tr>
<td>(c)</td>
<td>7/10</td>
</tr>
<tr>

#2. Jim jogged 1 ½ miles yesterday. This is 3/8 of his weekly goal. How many miles does he plan to run each week? Explain your solution.

#3. Write a story problem which can be solved by using “8 2/3 ÷ ¼=?” and model how to solve it by drawings.
The analyses of the prospective elementary teachers’ responses were guided by the following two main research questions:

3) How solid was Taiwanese prospective elementary teachers’ common fraction knowledge? What strategies did they use to solve fraction division word problems? Did their strategy reflect flexibility and connections as depicted by Ma’s model?

4) How successful were Taiwanese prospective elementary teachers in their representations of fraction division through story problems and pictorial diagrams? What meanings of division did prospective elementary teachers use when constructing their representations?

Prospective teachers’ solutions and explanations for #1 and #2 were coded individually for correctness and type of strategy. Problem #3 was analyzed separately for the story problem they posed and the types of diagrams they used, taking into consideration the correctness and reasonableness of story problems, diagrams, and final answers.

Results

Prospective Elementary Teachers’ Solution Strategies for Fraction Division Problems

Similar to the prior studies (Luo, Lo, & Leu, 2008, 2009), prospective elementary teachers in Taiwan are proficient in solving fraction division problems. All but one student answered #1 correctly, and 100% answered #2 correctly in this study. Three main strategies were used to solve #1; one student skipped this problem. These strategies are summarized below.

| Strategy 1: (Unit fraction approach: Identifying the quantity associated with the “unit-fraction” first) | 63.4% |
| 6/5 is equivalent to 12 units, so each unit is equivalent to 1/10. Since the unknown quantity is equivalent to 7 spaces, it is equivalent to 7/10. |
| Strategy 2: (Part-whole approach: Conceptualizing the part-whole relationship between the given and unknown quantity) | 26.8% |
| The unknown quantity is 7/12th of 6/5. Therefore, it is equivalent to 7/12 × 6/5 = 7/10. |
| Strategy 3: (Ratio approach: Setting up a ratio relationship between the given and unknown quantity) | 7.3% |
| The ratio between the unknown quantity and 6/5 is equivalent to 7: 12. Applying cross multiplication, the unknown quantity is equivalent to 7/10. |

Four main strategies were used to solve #2. Three of those strategies, the same as those used to solve #1 above, and one additional strategy are listed below.

| Strategy 1: (Unit fraction approach: Identifying the quantity associated with the “unit-fraction” first) | 14.6% |
| 1 ½ miles is 3/8 of the total distance, ½ mile is 1/8 of the total distance, so the total distance is ½ × 8 = 4 (miles) |
| Strategy 2: (Part-whole approach: Conceptualizing the part-whole relationship between the given and unknown quantity) | 68.4% |
| 1 ½ miles is 3/8 of the total distance. Let x equal the total distance. Set up the equation 3/8(x) = 1 ½, so x = 1 ½ × 8/3 = 4 (miles) |
| Strategy 3: (Ratio approach: Setting up a ratio relationship between the given and unknown quantity) | 7.3% |
| The ratio between the total distance and 1 ½ miles is equivalent to 1: 3/8. Applying |
Further analysis was conducted to see if prospective elementary teachers used the same or different strategies for solving these two problems. Among 40 who attempted both problems, 60% used two different strategies for the two problems. The following table shows the distribution of the strategies used for these two items.

As the data illustrate all but one prospective elementary teacher who used part-whole approach for the Number-Line problem continued to use the same strategy for the Jugging Problem. But many of those who used unit-fraction approach for the Number-Line problem switched to a different strategy when solving the Jugging problem.

**Prospective Elementary Teachers’ Representations of Fraction Division**

Similar to prior studies, prospective Taiwanese elementary teachers’ performance level for representing a fraction division problem was much lower than their ability to solve a fraction division problem. Overall, only 65.0% (n = 40) were able to pose a story problem that was meaningful and correct for the given fraction division computation “8 2/3 ÷ ¼ = ?” Of those teachers posing successful story problems, 21 out of 26, based their problem on the meaning of measurement division, 4 out of 26 based it on partitive division, and the remaining 1 student gave the following area problem: “The area of a blackboard is 8 2/3 square meters. The length of it is ¼ meter, how wide is the board?” Also, similar to the previous findings, the majority of the incorrect story problems were about the computation problems “8 2/3 ÷ 4=?” or “8 2/3 × 4=?” (e.g., Ma, 1989).

Prospective Taiwanese elementary teachers’ performance level to represent with a pictorial diagram was even lower. Fifty-five percent were able to draw a pictorial diagram that depicted the underlying meaning of fraction division with various degrees of detail. For example, some students showed only the nature of repeated subtraction for measurement division (Figure 2).

![Figure 2. Diagram accompanying the story problem “A long ribbon is 8 2/3 meters. How many pieces of ¼ meter ribbon can be cut from this long ribbon?” by ID#18](image-url)
In this case, the diagram was used to illustrate the underlying mathematical structure embedded in the problem. This provided a sufficient to justify the division operation later used to compute the answer. However, other pre-service teachers used a different type diagram that showed both the underlying mathematical structure as well as the process of reaching the correct answer. Figure 3 below shows an example of such diagram.

![Diagram](image)

**Figure 3. Diagram accompanying the story problem “There are 8 2/3 pizzas. If each person gets ¼ of a pizza, then how many people can get pizza?” by ID#9**

The goal of the first type of drawings was to illustrate the underlying meaning of the operation. This is different from the second type of pictorial diagram, where the diagram was used to identify the correct answer in addition to illustrating the underlying mathematical structure of the problem. For example, in the second diagram, one could see the 32 shares in 8 pizzas. In order to figure out how many ¼ pizza are in 2/3 pizza, this prospective elementary teacher changed 2/3 pizza to the equivalent of 8/12 pizzas and noted that there were “two” additional 3/12 pizza (= 1/4 pizza) in 8/12 pizzas, with 2/12 (= 1/6) of a pizza as left over. The majority of the Taiwanese prospective elementary teachers drew the first type of pictorial diagram.

As discussed earlier, one main challenge for solving fraction division problems was to pay attention to the referent units. In the case of measurement division, the dividend, divisor, and remainder will all have the same referent unit, but the quotient will have a different referent unit. In the case of partitive division, the dividend, quotient, and remainder will have the same referent unit, but the divisor will have a different one. Depending on the given story problems, the correct answer could be 34, 35, 34 2/3, or 34 with 1/6 left over, with the appropriate referent unit attached. A close examination of the prospective elementary teachers’ solutions indicates that, among those having correct story problems and appropriate pictorial diagrams, all but one had answers reflecting the appropriate use of referent units.
Discussion

The analysis presented above suggests the following characteristics of Taiwanese prospective teachers’ knowledge of fraction division. First, they are very proficient in solving fraction division problems commonly seen in upper elementary and middle school levels. Second, there exists preliminary evidence that many of the prospective elementary teachers in this study have developed the knowledge package of fraction division as described by Ma (1999). All three major strategies prospective teachers used to solve the Number Line problem and the Jogging problem—the unit fraction approach, the part–whole approach, and the ratio approach—are built upon multiple pieces of the knowledge package. Being able to use different strategies also demonstrates the flexibility of their reasoning. Furthermore, it is worth noting that, while many prospective teachers solved the Jogging Problem by setting up an algebraic equation, none set up an algebraic equation for solving the Number Line Problem. Rather, they approached the problem through either a unit fraction approach or a part–whole fraction approach. This shows an ability to move between the arithmetic-based reasoning and algebraic-based reasoning, which is a critical goal of mathematics curriculum transition from the elementary to middle school level. Third, similar to the prior studies of prospective elementary teachers in the U.S., the findings of this study also show that Taiwanese prospective elementary teachers were less proficient in posing story problems and using pictorial diagrams appropriately to model a solution strategy than solving fraction division problems directly. Rather than using pictorial diagrams as a tool to “find the answer” of a given story problem, the pictorial diagrams produced by the prospective teachers were used to show the underlying structure of an operation.

Implications

The findings of this study were limited by a small sample of prospective elementary teachers from Taiwan. Nevertheless, the study contributes to the continuing effort to optimize the mathematics learning for all students by focusing on the mathematic knowledge teachers needed to teach effectively. The most recent TIMSS, conducted in 2007, and the Programme for International Student Assessment (PISA), conducted in 2006, indicate that Taiwanese students had a much higher level of mathematics achievement than their American counterparts in a national representative sample of 4th graders, 8th graders, and 15-year-olds (Mullis, Martin, & Foy, 2008; Organization for Economic Co-operation and Development [OECD], 2007). The findings of this study suggest that the roots of such discrepancy in student performance might be in the mathematics knowledge possessed by prospective elementary teachers. The majority of Taiwanese prospective elementary teachers entered their teacher education program with a much deeper understanding of mathematics than their U.S. counterparts. The characteristics of Taiwanese prospective elementary teachers’ knowledge of fraction division could provide an expectation benchmark for designing the required mathematics courses for prospective elementary teachers in the U.S.

Even though elementary students in Taiwan are not required to pose story problems or use pictorial diagrams to demonstrate their proficiency with fraction divisions, it is a common practice for elementary school teachers to use both representations when engaging students in reasoning with fraction multiplication and division. This experience alone appeared to be sufficient for many prospective elementary teachers to be able to do such “teacher-tasks” without being taught directly. This seems to suggest that specialized content knowledge could be co-developed with the common content knowledge with a carefully developed mathematics curriculum and an instructional emphasis on reasoning. Nevertheless, a sizeable number of

Taiwanese prospective elementary teachers, despite their strong CCK, were unable to use story problems or pictorial diagrams appropriately. More research studies are needed to identify the conceptual challenges of developing SCK for fraction division and other important mathematics topics.

This paper considers the heuristic value of using the perspectives “mathematics,” “mathematical literacy,” and “literacy,” individually and together, in discussions of situated geometry-teaching practices with pre-service elementary teachers.

Introduction

Recently, mathematics education researchers Jon R. Star, Sharon Strickland, and Amanda Hawkins (2008) have raised the question “What is mathematical literacy?” Referencing literature in both mathematics education and literacy studies, they have distinguished between two field-specific uses of the term “content-area literacy.” According to Star, Strickland, and Hawkins, literacy educators tend to read this term as “content-area literacy,” meaning “reading and writing activities that are embedded within content courses,” such as “keeping a mathematics journal, reading newspaper articles related to mathematics, reading the mathematics textbook or other mathematics-related books, writing research papers on topics in mathematics, and writing paragraph explanations to accompany solutions to mathematics problems” (p. 106). As these authors have pointed out, such content-area-literacy tasks may be thematically related to mathematics without requiring conceptual understanding of the discipline (p. 106). In contrast, Star, Strickland, and Hawkins have observed that mathematics educators tend to read the term “content-area literacy” as “content-area literacy” or as “mathematical literacy,” which itself has been variously used to mean (1) “mathematical understanding, including knowledge of content and the ability to approach mathematical problems (such as those seen in mathematics texts) logically, analytically, and thoughtfully”; (2) “appreciation of mathematics, including the ability to recognize when and how mathematics is used in the real world”; (3) “application of mathematics to real-world problems, including calculating tips in restaurants, working with budgets, and reading graphs in newspapers”; and (4) “ability to reason mathematically, including mathematical communication” (p. 110, emphasis in original).

Speculating on potential consequences of these different uses of the term “content-area literacy,” Star, Strickland, and Hawkins have brought into focus challenges that secondary mathematics teachers may face in attempting to integrate content-area literacy and content-area literacy in their mathematics courses: “…Content-area literacy can be faulted for its disconnection with content, while content-area (mathematical) literacy is perhaps guilty of an insufficient connection to literacy” (p. 111, emphasis in original). According to these authors, current institutional demands on U.S. secondary mathematics teachers to incorporate content-area literacy instruction in their courses are especially difficult to meet, given that middle- and high-school teachers have likely had few opportunities to study and practice literacy teaching methods in their teacher-preparation programs (p. 107). But what about U.S. elementary teachers whose professional responsibilities include teaching both mathematics and literacy as content areas? (U.S. elementary teachers are currently under tremendous pressure to help students in the early grades to develop English language arts skills. Reading abilities, in particular, determine whether or not students are promoted to the next grade.) What conceptual and pedagogical
challenges related to content-area literacy might be foregrounded if we consider the particular institutional situation of elementary mathematics teachers? How might these insights resonate with the predicament of secondary mathematics teachers who teach content-area literacy? Moreover, how might the question of integrating the teaching of content-area literacy and content-area literacy in mathematics lessons be differently pursued if we think about pre-service elementary teachers’ designing and delivering mathematics lessons during their teaching internship? (Pre-service teachers in U.S. teacher preparation programs tend to study a great deal of English language arts topics, especially early literacy development.) Are mathematics and literacy always so difficult to teach together? Admiring the theoretical rigor that Star, Strickland, and Hawkins have contributed to conversations on mathematical literacy, we will continue their “explorations” in this paper, as we consider the conceptual and pedagogical challenges of distinguishing among “mathematics,” “mathematical literacy,” and “literacy” when elementary teacher candidates teach geometry to early elementary students.

Teaching Elementary Geometry

Elementary geometry teaching and learning are understudied by mathematics education researchers, who have favored studies of children’s development of arithmetic concepts and skills, a trend reflected in U.S. elementary mathematics curricula and teacher preparation programs, both of which have placed a great deal of emphasis on Number and Operations (Chapin & Johnson, 2006, p. 220; NCTM, 2000). One reason why mathematics education researchers have directed relatively little attention to elementary geometry teaching and learning is that, in contrast to other mathematical topics, U.S. geometry curricula for the elementary grades have historically demanded less mathematical rigor of students. Moreover, these units of study, especially for the early grades, have tended to focus on literacy development, particularly on students’ acquisition of geometry vocabulary. The National Council of Teachers of Mathematics (NCTM) (2000) “Geometry Standard for Grades Pre-K-2” suggests that early elementary students should learn to “recognize, name, build, draw, compare, and sort two- and three-dimensional shapes”; and to “describe attributes and parts of two- and three-dimensional shapes” (p. 96, emphasis ours). Similarly, the NCTM “Geometry Standard for Grades 3-5” recommends that upper-elementary students should learn to “identify, compare, and analyze attributes of two- and three-dimensional shapes, and develop vocabulary to describe the attributes”; and to “classify two- and three-dimensional shapes according to their properties and develop definitions of classes of shapes such as triangles and pyramids” (p. 164, emphasis ours). Put differently, NCTM has proposed that all elementary students should develop lexical and taxonomic fluency related to particular geometry topics, abilities that entail both mathematics and literacy knowledge. Whereas mathematics educators may tend to read NCTM’s elementary geometry standards as expectations for mathematical performances, these standards can also be read as criteria for evaluating students’ displays of mathematical literacy or, more broadly, mathematical rhetoric. It is this interdisciplinary potential of U.S. elementary geometry curricula that we will begin to explore in this paper.

Mathematics, Mathematical Literacy, and Literacy

Extending Star, Strickland, and Hawkins’s discussion of content-area literacy, we wish to introduce two more terms into the conversation: “Writing Across the Curriculum (WAC)” and “Writing in the Disciplines (WID).” The term “content-area literacy,” read as “content-area literacy,” is a K-12-specific articulation of the tenets of Writing Across the Curriculum, a higher-

education literacy movement whose supporters have promoted extensive writing assignments in a variety of university subject-matter courses beyond traditional first-year writing courses (Bazerman et al., 2005, pp. 9, 11, 32-34). Similarly, the notion of “content-area literacy” is associated with a higher-education literacy movement, Writing in the Disciplines, whose advocates have sought to investigate writing as it is practiced in specific disciplinary contexts and to use research on disciplinary rhetoric to inform writing instruction (Bazerman et al., 2005, pp. 9-10, 66-104). [WID researchers have tended to share purposes and methods with Writing in the Professions researchers, who have studied writing practices in law, medicine, and engineering, for example (Bazerman et al., 2005, pp. 10-11).] Put differently, both content-area literacy and content-area literacy are issues of interest to the broad literacy-studies community. Moreover, WAC and WID bear on mathematics education. For example, if mathematics educators are dissatisfied with the contributions of WAC research to the proliferation of content-area literacy tasks in mathematics courses, they may wish to draw instead on WID research as they inquire further into mathematical literacy. (Issues of disciplinary “reasoning” and “communication” like those raised by Star, Strickland, and Hawkins (p. 110) have been pursued by WID researchers.)

Distinguishing among “mathematics,” “mathematical literacy,” and “literacy” is itself a rhetorical project shaped, in part, by considerations of audience, genre, and purpose. We do not wish to suggest otherwise. Indeed, in this paper, we contend that evidence of mathematics, mathematical literacy, and literacy may be generated at any moment in a mathematics lesson. For example, imagine a situation in which a pre-service early-elementary teacher introduces the term “square” to students by drawing the four-sided figure on the classroom whiteboard and announcing, “This is a square.” From a mathematics perspective, we might observe that the teacher is inviting students to engage the initial van Hiele level of geometric reasoning, “visualization,” or shape awareness (van Hiele, 1986). If the teacher then draws a second square on the whiteboard, which, relative to the first, has been turned clockwise by ninety degrees, and declares, “This is also a square,” we might similarly note that the teacher is encouraging students to work at the next van Hiele level, “analysis,” or recognition of shape properties (van Hiele, 1986). From a literacy perspective, we might remark that the teacher is showing students that a square is not a letter or a number, that the square figure may be turned without semiotic consequence, which would not be the case for the letters b, q, d, and p, or the numbers 6 and 9. From a mathematics literacy perspective, we might think that the teacher is beginning to distinguish for students rhetorical conventions associated with mathematical uses of the term “square” from those related to everyday uses of the same term. For example, in general parlance, we might say that a “square” of chocolate retains its “squareness” even when its edges melt and become slightly rounded. In this paper, we will read pedagogical situations through the lenses of “mathematics,” “mathematical literacy,” and “literacy” not to argue that the boundaries among these terms may be, or should be, determined once and for all but, rather, to claim that these three frames may be usefully mobilized, both individually and in relationship to one another, to open conversations on the purposes, practices, and effects of mathematics teaching.

The Posing, Interpreting, and Responding (PIR) Project

The following scenarios have been informed by our ongoing, National Science Foundation-sponsored study of pre-service and practicing elementary mathematics teachers’ posing, interpreting, and responding practices. Our study comprises both cross-sectional and longitudinal study designs. In the cross-sectional study, we have collected pre-service elementary teachers’
written imaginings of their pedagogical responses to a variety of teaching scenarios, using survey-style open-response questions, at three different points in their teacher preparation program. Based on these survey responses, we have selected 16 focal participants for two concurrent longitudinal studies. We have followed one set of participants from their first to last year of teacher preparation, and the other set from their last year of teacher preparation to their second year of beginning teaching. In this paper, we focus on two participants in the first longitudinal study, both of whom, at the time of the classroom observations referenced here, were in the early months of their teaching internship in a Midwestern state, whose elementary geometry standards were consistent with those of NCTM. Both of these pre-service teachers had also taken a required course in “geometry for teaching” one-to-two-years prior to the internship.

In the course of the cross-sectional and longitudinal studies, we have gathered evidence of pre-service and practicing elementary teachers’ imagined and implemented mathematics teaching practices, a distinction which we have drawn in order to explore relationships among our cross-sectional data sources—various “What would you do?” exercises (imagined teaching)—and our longitudinal data sources—lesson plans and pre- and post-lesson interviews (imagined teaching), and videotaped lessons (implemented teaching). However, we consider our distinction between “implemented” and “imagined” teaching practices to be analytic rather than ontological: Where does text end and reading begin? In keeping with this premise, we present below imagined/observed scenarios of early-elementary geometry teaching, constructed from case studies of two of our 16 focal participants.

Teaching Geometry in Early Elementary Education

*Red-tangles, Ovals, and Other (Non-)Shapes*

Imagine a kindergarten classroom. Imagine students sitting along the edge of the classroom’s oval carpet. Imagine a pre-service elementary teacher, two months into the teaching internship, sitting on the carpet beside the students. Before the teacher are piles of colorful construction-paper cut-outs of geometric shapes. The circles are small and black, about two inches in diameter; the squares are similar in size but red. One kind of rectangle is large and red, a 5x7-inch sheet of construction paper; another is narrow, long, and gray, about six inches in length. Imagine the beginning of a geometry lesson.

Teacher (displaying a large red rectangle for the class): What shape is this?
Students (simultaneously): Red. Rectangle.
Teacher: What shape is this?
Students: Red…tangle.
Teacher: Good. How come it is not a square? Do you remember?
Student 1: A square has four ends, and a rectangle has four ends.
Teacher: They do both have four ends. But what is special about the rectangle?
Student 2: There’s two big sides and two small sides.
Teacher (displaying a square): Good, and what shape is this, then?
Students: Square.
Teacher: Square. How do we know this is a square?
Student 3: It has four ends. And it is littler.
Teacher: It doesn’t matter that it’s littler. It could be the same size. Because of why? Student 4?
Student 2 (speaking out of turn): Because they’re all the same length.
Student 4: Because they’re all the same length
Teacher: Because they’re all the same length.

From a mathematics perspective, we might read this scenario as an illustration of a pre-service teacher’s engaging students in learning geometry content consistent with the first two van Hiele levels (“visualization” and “analysis”) and endorsed by the NCTM standards (p. 96). The teacher invites students to recognize and name two-dimensional geometric shapes and to discuss their properties (“What shape is this?” “How come it is not a square?”). Students generate a sense of “squaredness” and “rectangularness” that exceeds a comparison of the particular cut-outs displayed by the teacher (“A square has four ends [corners], and a rectangle has four ends [corners]…[but a rectangle has] two big sides and two small sides”). From a literacy perspective, we might read this episode as an example of a pre-service teacher’s involving students in a demonstration of how one might conduct an oral discussion about a topic, a rhetorical practice that students would ultimately stage in their written arguments. We might focus on the situated consequences of speaking out of turn in a discussion. From a mathematical literacy perspective, we might read this exchange as a case of a pre-service teacher’s facilitating students’ emerging distinction between mathematics-specific and everyday uses of the terms “rectangle” and “square.” We might emphasize the quantity-related vocabulary voiced by students (“four,” “two,” “big,” “small,” “littler,” “length,” “same”). However, we might also merge these three frames to consider the question of the “red-tangle.” Is “redness” an essential property of a (mathematical) “rectangle,” as the metonymy of “red…tangle” in the scenario above would suggest? Is “redness” an essential property of a (mathematical) “square”? If it is possible to confuse a red rectangle and a red square, is it also possible to confuse a gray rectangle and a red square? Is a (mathematical) “square,” a (mathematical) “rectangle”? Is “red,” a shape? We think that mathematics teacher educators might productively mobilize the perspectives of “mathematics,” “mathematics literacy,” and “literacy,” individually and together, with pre-service elementary and secondary teachers in discussions of the goals and implications of contextualized pedagogical approaches.

Imagine the end of the lesson. Imagine the students sitting again along the edge of the oval carpet, which has both an inner and an outer border, yellow and red. For the past half hour, students have played a game at their work tables, resulting in their each having glued the set of construction-paper cut-outs to a blank sheet of paper to make a picture of a fire truck. Some students have drawn fire fighters and Dalmatian fire dogs in their fire trucks. Imagine the teacher again sitting beside the students on the carpet, a pile of the students’ pictures in hand.

Teacher (displaying a student’s picture for the class): What shape is this fireman’s head?
What shape is his head (points to the fire fighter’s elliptical face)?
Student 5 (softly): An oval?
Teacher: A circle. His head is a circle.
Student 6: He has hair.
Teacher: And he has hair, doesn’t he? What shape is this sun up here (points to the picture)?
What shape is this?
Student 7: A circle.
Teacher: A circle. Can you think of any other shapes you see? What shapes do you see in the classroom? What shape is our rug?
Student 8: Circle.
Student 9: Oval.

Teacher: It’s an oval. Good.
Student 10: This is a circle right here (points to the carpet’s yellow inner oval), and this is a oval (points to the carpet’s red outer oval).
Student 11: They’re both oval.
Teacher: They’re both ovals. You’re right. They’re both ovals.

This scenario is marked by certainty and confusion (“An oval?” “A circle.” “Circle.” “It’s an oval”). What is a “circle,” and what is an “oval”? Do “circle” and “oval” operate in this exchange as geometric concepts, geometric rhetoric, real-world artifacts, and/or everyday words? What might it mean to “understand,” “apply,” “appreciate,” and “reason” (Star, Strickland, & Hawkins, p. 110), both as a teacher and as a student, in this geometry situation? We think that these questions might be usefully raised with pre-service elementary and secondary teachers.

Apples, Squiggles, and Other (Non-)Shapes. Imagine a first-grade classroom. Imagine students sitting at their work tables. Imagine a pre-service elementary teacher, one month into the teaching internship, standing before the students. Imagine the beginning of a geometry lesson.

Teacher: Think of one of the shapes that we talked about this week.
Teacher (after several seconds): Who can think of a shape? Student 1?
Student 1: A Granny Smith.
Teacher: A Granny Smith? Is that a shape?
Students (laughing): No.
Teacher: That’s an apple. Raise your hand if you can think of a shape. Student 2?
Student 2: Circle.
Teacher: Circle.

We read this scenario as an illustration of the conceptual and pedagogical challenges of distinguishing among “mathematics,” “mathematical literacy,” and “literacy,” particularly when considering elementary geometry teaching. In this exchange, unlike in the sample content-area literacy activities that Star, Strickland, and Hawkins have presented, mathematics and English language arts are not easily separated and thus difficult to integrate; rather, they are entangled. After all, the questions What is a shape? and How might one teach “shape”? can be answered from mathematics, mathematical literacy, and literacy perspectives. Moreover, within each perspective, we might plausibly respond to the question Is a Granny Smith, a shape? with both Yes and No answers. In the scenario above, both the pre-service teacher and Student 1 can associate multiple meanings with the word “shape.” We can imagine that the teacher, in other rhetorical (even pedagogical) situations, might not treat an apple as never being a shape, or a circle as always being a shape. Similarly, we can surmise that Student 1, at the time of this exchange, was not utterly lost when a classmate proposed that a “circle” is a shape, though Student 1 may have been puzzled as to why both a circle and a Granny Smith must not be included in the same set of shapes. The interfluency of mathematics and English language arts in acts of geometry teaching is an issue that we think mathematics teacher educators might explore with elementary and secondary pre-service teachers. The content-area-literacy challenge is not always one of integrating mathematics and literacy; sometimes it is one of extricating mathematics from literacy, or literacy from mathematics, or mathematical literacy from mathematics and literacy, depending on one’s conceptual and pedagogical purposes at the time.

Imagine several minutes later in the geometry lesson. Imagine the students still sitting at their work tables. Imagine a flip chart, supported by an easel, poised before the students. On the flip chart, two long, horizontal, awkwardly undulating lines have been hand-drawn (perhaps with an unsteady hand). Beside these squiggles, the word “parallel” has been written. Imagine the teacher standing beside the flip chart.

Teacher: Who remembers what two lines are called if they are like this (traces the squiggly lines with two fingers), and they’re never gonna touch each other, they’re never gonna meet or cross? It starts with a puh, puh, puh (makes the aspirated sound of the letter “p” in English). Student 3, what are they called? Do you remember?

Student 3: Line.

Teacher: They’re a special kind of line. It starts with a “p.” Does anybody remember?

Student 4?

Student 4: Parallel.

Teacher: Parallel lines. And when we have parallel lines (traces the squiggly lines with two fingers), that means that these lines are gonna keep going, and they’re never gonna touch. So are these lines parallel?

Students (simultaneously): Yes. No.

In this scenario, the pre-service teacher connects for students the oral word “parallel” (“It starts with puh, puh, puh”) with the written word “parallel” (“It starts with a ‘p’”) and a visualization of the notion “parallel” (the drawing of wavy lines). Mathematics educators may recognize the written word “parallel” as a literate performance. But what about the drawing of “parallel lines”? If we regard the hand-drawn parallel lines as phenomenal objects from either a mathematics or a literacy perspective, we might agree with some of the students that these squiggles are not “parallel”: They do not meet the requirements of either general or mathematics-specific definitions of the term. Even from a mathematical literacy perspective, we might say that this visualization of “parallel lines” does not adhere to rhetorical conventions of the discipline, as would the symbol “‖” (vs. “⊥”). However, from a pedagogical mathematical literacy perspective, we might remember our own experiences with having seen mathematics teachers (perhaps even ourselves) hand-draw parallel lines in a demonstration for students, and we might speculate that the pre-service teacher in the scenario above was reiterating a convention of visual rhetoric for mathematics teachers. In other words, we might agree with some of the students that the squiggles are “parallel lines.” Of course, all of these arguments would be arguments, and we think that staging such a dialogue for pre-service elementary and secondary teachers would be generative, in that it would ask pre-service teachers “Where’s the math?” Speaking, writing, and visualizing geometry for students does not necessarily mean that one is teaching mathematics. Nor does it necessarily mean that one is not.

Imagine several minutes later in the geometry lesson. Imagine the students still sitting at their work tables. Imagine that a new page on the flip chart is visible. It is a chart with columns for the names of various geometric shapes; colorful, handmade construction-paper cut-outs of each shape; the number of sides for each shape; the number of corners for each shape; and indications whether all of the sides of each shape are equal in length. Imagine the teacher standing beside the flip chart, capped marker pen in hand.
Teacher: Let’s look at our shapes. Let’s see if we can find some shapes that have parallel lines. Let’s look at our circle. Is our circle gonna have any parallel lines?

Students: No.

Teacher: Why not? Why couldn’t our circle have any parallel lines? Student 5?

Student 5: ’Cause it’s round.

Teacher: ’Cause it’s round. Does it have any sides at all?

Students: No.

Teacher: No. How could it have parallel sides if it doesn’t have any sides? What about our triangle? Look at the sides of the triangle (traces three sides of the cut-out triangle with one finger), the straight sides. Do you see any parallel lines? Can our triangle have parallel lines? Raise your hand if you think our triangle could have parallel lines (traces three sides of the cut-out triangle with one finger), two lines that are never gonna touch each other? Do you see any on that triangle?

Students: No.

Teacher: No, because, see, this side and this side (traces two sides of the cut-out triangle with the capped marker pen, extending the line of each side so that they intersect) are gonna touch right here (points to vertex). And then this side is gonna touch with this side (traces two sides of the cut-out triangle with the capped marker pen, extending the line of each side so that they intersect) in the corners. So a triangle doesn’t have any parallel lines.

Imagine that the teacher turns over a new page on the flip chart. Imagine that, with the marker pen, now uncapped, the teacher draws a triangle on the new page. Imagine that the teacher then hand-draws lines extending the sides of each triangle, making visible in ink the intersections of these lines. The lines are squiggly, not having been drawn with a straight edge.

Teacher: Can these lines be parallel?

Students: No.

Teacher: No, because they’re crossing right here.

Student 6: ’Cause it makes an “x.”

Teacher: It does make an “x.” That’s a good way of thinking about it. If you see two lines and they make an “x,” you know that they’re not parallel, because they’re meeting.

Imagine that the teacher repeats this process for a “square” and a “rectangle,” using a ruler to draw the shapes and hand-drawing the two sets of extended parallel lines in different colors of ink. Imagine that the teacher draws a “rhombus,” using the straight edge of the ruler, then invites a student to hand-draw the extended lines. Imagine that the teacher repeats this student-assisted process for a “parallelogram.”

Teacher: Let’s look up at these purple lines. Student 7, do they look like they’re gonna touch? What do you think?

Students: No.

Teacher: Raise your hands if you think that these purple lines are parallel.

Students (raise hands)

Teacher: Interesting that this shape is called a parallel-ogram.
In this scenario, the pre-service teacher’s oral and visual rhetoric make several conceptual substitutions: Parallel lines are conflated with parallel sides; straight lines with squiggles, intersecting lines/sides with the letter “x,” and a parallelogram with a “parallel-ogram.” From mathematics, mathematical literacy, and literacy perspectives, we can ask whether such substitutions cross content-area knowledge domains and what effects such crossings might have for particular geometry lessons. In the words of the pre-service teacher in the scenario above, when are mathematics education and literacy education “parallel” projects, and when do they “touch”? When is it conceptually and pedagogically useful to consider general and mathematics-specific rhetorics together and apart? When do literacy terms impede and/or improve mathematics lessons, and vice versa? We think that these questions may be valuably posed to pre-service elementary and secondary teachers.

**Where’s the Math?**

In conversations among mathematics education researchers, the provocative question *Where’s the math?* tends to elicit simple answers, like *Nowhere* or *Everywhere*. Nevertheless, we argue that this question can generate complicated responses if pursued from the perspectives of “mathematics,” “mathematical literacy,” and “literacy,” either individually or together. Separate and apart, these three frames can bring into focus the complexity of language-based mathematics instruction, including the perhaps surprising complexity of early elementary geometry teaching.

CONCEPT-FOCUSED INQUIRY: PROGRESS TOWARDS A VIABLE THEORY FOR MATHEMATICS INSTRUCTION

Denise B. Forrest

dforrest@coastal.edu

Austin M. Hitt  
Coastal Carolina University  
amhitt@coastal.edu

Though there are theories used to organize and inform educational research, there exists a gap between theory and classroom practice. In this paper, we propose a general theory of mathematics instruction called Concept-Focused (CFI) which has been specifically designed to inform everyday educational practices in mathematics classrooms. To introduce the theory, the three core principles of CFI are presented. This is followed by an explanation justifying CFI as a viable theory of instruction, as defined by criteria established by Jerome Bruner. The paper ends with a summary of the research framework being used to further develop the theory and a presentation of the pilot year findings showing the impact of using CFI to train secondary preservice teachers.

Introduction

In mathematics education, constructivism or the idea that learning occurs through the construction and integration of new knowledge within a preexisting conceptual framework has been the central learning theory and impetus behind student-centered instruction. The consensus among math educators is that constructivist-based instruction is effective. However, math educators express a common concern that teachers frequently resist the integration of constructivist-based methods in their educational practices. Teachers seem to ignore or have a fragmented perception of the theory, and instead rely too often on their pedagogical knowledge and practical experiences to determine appropriate approaches for classroom instruction.

One approach for bridging the gap between theory and practice is to train teachers to apply an explicit theory of instruction. A theory of instruction “sets forth rules concerning the most effective way of achieving knowledge or skill” (Bruner, 1966, p. 40). This prescriptive function is what differentiates it from learning theories which explain how and why students learn. “A theory of instruction, in short, is concerned with how what one wishes to teach can best be learned, with improving rather than describing learning” (p. 40).

According to Jerome Bruner (1966), a viable theory of instruction (1) identifies the experiences that are compatible with the way students learn, (2) explains the structure of the knowledge within a discipline, (3) identifies the most effective instructional sequences, and (4) addresses appropriate pacing and motivational strategies. Others have described a similar set of principles, each focusing on the application of knowledge and guidance on how to help students learn (Reigeluth, 1999; Merrill, 2002). In summary, “Instructional theories are created as a set of principles and guidelines. They are not rigid sets of rules that must be followed at all cost but are guidelines that help the practitioner judge the value of a theory” (Defazio, 2006).

In order to improve teachers’ understanding and perceptions of constructivist-based teaching, a theory of instruction designated as Concept-Focused Inquiry (CFI) was developed. Its purpose is to offer a coherent and practical approach to teaching mathematics. In this paper, CFI is introduced by first, describing the core principles that frame the instructional theory. Second, we justify CFI as a viable theory of instruction as defined by the criteria outlined above by Bruner. Finally, we summarize an emerging research project where preliminary findings indicate
teachers trained to use CFI specifically improve in their conceptual understanding of mathematics and application of constructivist-based instruction.

**Concept-Focused Inquiry**

Concept-Focused Inquiry (CFI) is founded on three core principles. The first principle states mathematics is a process of conceptualizing and understanding mathematical objects in our world. This is consistent with the conversation in John Dossey’s chapter *The nature of mathematics, its role and its influence* (1992) where he describes Hersh’s view that mathematics arises from activity with already existing mathematical objects, and from the needs of science and daily life.” (Hersh, 1986 as cited in Dossey, 1992, p. 42). Further, Dossey concludes individuals construct mathematical ideas through experimentation, observation, and experience. The first core principle clarifies the nature of our subject because that has a strong impact on the way in which our subject is approached in the classroom (Cooney, 1985; Thompson, 1992).

The second principle of Concept-Focused Inquiry (CFI) is that in order to teach conceptually, teacher must have a conceptual understanding of the content. Conceptual understanding occurs when an individual can accurately discuss the three attributes of a mathematical concept (macroscopic, modeling and symbolic) and identify the connections between the attributes (Hitt & Townsend, 2007). For example when teachers teach *area* they need to be able to plan lessons that provide students with macroscopic experiences such as a word problem that is applies the notion of area or more elementary an experience where students cover a space to visualize an application of the concept. A macroscopic experience is one that provides a context for the concept and is an occurrence that has the student being able to visualize the concept in an applicable context. Next, students need to draw or explain the situation using their own thoughts and representations. This is where the student creates a record of his/her perception of the concepts. This could be in the form of written text, drawings, or an enactment. It is the students’ representation of the concept. Once students have devised a working model of their ideas they are ready to learn the mathematical definitions and formulas, or the more symbolic attributes of area.

Even though the three attributes presented above are described as discrete elements of a concept, the elements are connected. For individuals to engage in a conceptualizing process, they integrate these elements and can explain the relationships between them. Figure 1 depicts this relationship.

The third principle of Concept-Focused Inquiry (CFI) states when individuals explicitly reflect upon the three attributes of mathematical concepts, they achieve conceptual understanding. Commonly teachers and students use terms, definitions, and formulas in classroom conversations but do not truly understand the full meaning. This lack of conceptual understanding may explain why students must often be re-taught fundamental concepts in mathematics. When students do not have opportunities to observe and explain targeted concepts they fail to develop meaningful connections (Bransford & Donovan, 2005). As a result, students resort to the short term solution of memorizing the information for a test. In order to achieve conceptual understanding individuals need to have macroscopic observations, create, critique, and modify their own models of the concept, as well as apply the appropriate symbolic terms and formulas that explain their macroscopic observations and models. In summary, mathematics instruction focused on developing conceptual understanding provides students with opportunities to interact with the macroscopic, model, and symbolic attributes of a concept.

---

Figure 1. The three explicit and related attributes of concept(s) defined in CFI

The three principles of Concept-Focused Inquiry (CFI) describe the nature of mathematics that is consistent with current views in mathematics education (Dossey, 1992) and make explicit the types of opportunities teachers should make available to students. In general, these ideas are not new. For one, Jerome Bruner emphasized a similar idea in his work on cognitive growth (Clabaugh, 2010). In particular, Bruner states that in order for cognitive growth to occur, students must move through three stages of learning: enactive, iconic, and symbolic.

In the enactive state, students begin to develop understanding through active manipulation. Therefore, students at the enactive stage should be given the opportunity to ‘play’ with the materials in order to fully understand how it works. In the second stage, iconic, students are capable of making mental images of the material and no longer need to manipulate them directly. Here students are able to visualize concrete information. The symbolic is the final stage in which students can use abstract ideas to present the world... Students must go through all of these stages successively in order to connect new ideas and concepts if they are to generate their own understanding (Clabaugh, 2010, p. 3).

Concept-Focused Inquiry (CFI) is an extension of Bruner’s ideas. Bruner explains conceptual learning as a developmental progression where students master one stage at a time. Once a learner fully understands the concept at one stage, they move to the next and the earlier stage is no longer necessary. The three attributes macroscopic, model, and symbolic correlate to the enactive, iconic, and symbolic stages respectively, but the attributes are not viewed as independent of one another or as a stage of development. CFI emphasizes the need for every learner to experience each of the attributes to fully understand a concept. In the next section we make an argument that CFI meets the criteria for a general theory of instruction as defined by Bruner.

Concept-Focused Inquiry, a viable theory of instruction

In A Theory of Instruction (1966), Jerome Bruner identifies the criteria of an empirical and instructional theory of education. According to Bruner a viable theory of instruction meets four criteria: identifies the experiences that are compatible with the way students learn, explains the structure of the knowledge within a discipline, identifies the most effective instructional sequences, and addresses appropriate pacing and motivational strategies. In this section, we argue Concept-Focused Inquiry (CFI) is a viable theory of mathematics instruction.

Concept-Focused Inquiry is compatible with the way students learn. According to Bransford & Donovan (2005), in order for learning to occur, students must engage in metacognition, intellectual inquiry, and address prior beliefs and knowledge. These learning processes are embedded in Concept-Focused Inquiry (CFI) because when a teacher provides the opportunity for students to collectively engage with the macroscopic, model, and symbolic attributes of a concept, students share their prior beliefs and knowledge of the concept through their models of the macroscopic experience. When the teacher emphasizes the relationships between among the attributes, it naturally becomes a form of intellectual inquiry. The figure below shows explicitly where the processes are explicitly embedded in CFI.

Concept-Focused Inquiry explains the structure of knowledge in mathematics. The principles for Concept-Focused Inquiry (CFI) are grounded in the conceptual nature of mathematics. In particular, the first two core principles emphasize the nature and structure of conceptual knowledge. Besides explicitly explaining the structure of knowledge in mathematics, CFI allows educators to operationally define conceptual understanding. That is, conceptual understanding involves the ability to communicate and connect the macroscopic, model, and symbolic attributes of the concept.

Concept-Focused Inquiry identifies the most effective instructional sequences. The third core principle emphasizes an effective instructional sequence. Instruction begins with a macroscopic event. This provides the context for understanding the targeted mathematics concept. It is an event that provides students with a context and mental picture of the concept. Next the students move to the model attribute, where they are asked to explicitly communicate their models for thinking about the macroscopic experience. The teacher probes students to encourage them to make explicit their ideas about the target concept. By emphasizing the students’ model, the teacher can identify how the students currently understand the concept, what misconceptions or naïve conceptions are present in the classroom, and what to focus on in order to guide the students’ thinking toward a desired mathematical explanation. The teacher uses the students’ models to introduce or clarify the abstract, symbolic attributes of the target concept.

Concept-Focused Inquiry addresses appropriate pacing and motivational strategies. Once the learner has been engaged with the macroscopic attribute of a concept, the students create a model to display his/her current understanding of the concept. The accuracy of the models displayed by the students will determine the appropriate pacing of the instruction. That is, when the models are inaccurate or incomplete, the teacher will engage the learners in further inquiry. This is done so students have the opportunity to process the phenomena in more depth and can make adjustments to their models. A teacher using CFI will pace the instruction based on the model attribute. Once the models are developed, the unknown symbolic attributes become part of the instruction. Appropriate pacing in CFI is about not rushing to the symbolic attribute of a concept and instead allowing students to fully experience the opportunity to display a model of their thinking.

According to theories of motivation that are focused on fostering learning, motivation is enhanced when the classrooms practices include providing diverse opportunities to demonstrate mastery; adapting instruction to students’ knowledge, understanding, and personal experiences.
providing opportunities for exploration and experimentation; defining success in terms of improvement; emphasizing effort, learning, and working hard rather than performing or getting the right answer; and treating errors and mistakes as a normal part of learning (Stipek, 1996). CFI addresses these suggestions by emphasizing the students’ display of the model attribute being the focal point of an instructional sequence. Having the model attribute as the focal point puts the students’ knowledge, understanding, and personal experiences at the center of instruction. The emphasis on using metacognition, preconceptions, and inquiry to define the instructional processes further addresses the presence of these classroom practices.

**Developing Concept-Focused Inquiry as a theory of instruction**

The framework being used to guide the research in order to develop Concept-Focused Inquiry (CFI) is an interpretation of the work outlined by Defazio (2006). In summary, the agenda for developing Concept-Focused Inquiry is organized around a 4-level system. At level 1, creation of the instructional theory, the focus is on clarifying the theory and verifying its substance in existing literature. The work at level 2 is organized around testing the theory’s effectiveness. This involves a review of existing literature, particularly those conducted in practice, to verify the theory’s appropriateness and effectiveness. At level 3 the theory is tested with quantitative and qualitative data, providing real-world results use of the instructional theory in practical situations. Level 4 is replicating the study on a large scale and/or long term studies to determine further the usefulness and conditions.

At this point in time, the development of Concept-Focused Inquiry (CFI) as a theory of mathematics instruction is in the beginning stages of level 3. In other words, we are concentrating on designing and implementing studies that provide real-world data. We have three projects initiated and actively in progress. Namely, during the Fall of 2009 and again this year, CFI was used as the conceptual framework for a secondary mathematics methods course. The findings from year 1 of this project are elaborated in the next section. The second project initiated Fall 2010 uses CFI as the conceptual framework for a middle level mathematics methods undergraduate course, and finally a third project also initiated in Fall 2010 uses CFI in a year-long professional development program for middle level inservice teachers.

**Research using Concept-Focused Inquiry**

**Subjects/Design.** Concept-Focused Inquiry (CFI) has been used as the conceptual framework for a secondary mathematics methods course in a Master of the Arts of Teaching (M.A.T.) program at a mid-sized university during the past two years. Four master-level preservice teachers (1 males and 3 females) were enrolled in the methods course Fall 2009 and student teaching Spring 2010. These preservice teacher completed an undergraduate degree in mathematics, and prior to enrolling in the methods course they completed two graduate level content courses and two education courses, a foundation to education and teaching course and a course on reading in the content area. In addition, two of the four preservice teachers completed courses in educational psychology and diversity prior to enrolling in the methods course. The other two preservice teachers took the educational psychology and diversity course concurrent with the methods course.

The mathematics methods course met once a week over a 16-week fall semester. During class meetings the candidates participated in mathematical activities designed to demonstrate the principles of Concept-Focused Inquiry (CFI) and how to use CFI to design their instruction. Throughout the course the preservice teachers learned how to create lectures, demonstrations,
cooperative learning opportunities, etc that sequentially addressed the macroscopic, model, and symbolic attributes of targeted concepts. In addition to coursework, the preservice teachers were immersed in high school mathematics classes for a period of one and two weeks.

In Year 1, the impact of the Concept-Focused Inquiry (CFI) framework on preservice teachers’ perceptions of mathematics (Core principle #1) was measured qualitatively using an initial survey and exit interview. Specifically, the preservice teachers were asked to describe in their own words what mathematics means to them, what they believe are the founding principles of mathematics, what they believe students should know about mathematics, and why they believe mathematics may be difficult for some students, and how they might address these difficulties. Initial responses to these prompts were incorporated into classroom conversations, and during the exit interview the participants were further probed. Transcriptions of these selected class periods were included as part of the data set to measure the preservice teachers’ perceptions of mathematics.

Daily lesson and unit plans developed by the preservice teachers were assessed in order to determine their understanding of Concept-Focused Inquiry (CFI) core principles #2 and #3. The preservice teachers completed three daily lesson plans and one 3-4 day unit during the methods course. One of the daily lessons was ‘taught’ in our class setting to their peers, and at least one of the lessons in the unit was taught in a high school classroom during the second field experience and observed by the university instructor. In both the daily lessons and unit plans, the preservice teachers were instructed to identify specific concepts and explicitly discuss how their lesson addressed the macroscopic, modeling, and symbolic attributes of the target concepts. The plans and instruction were scored using an inquiry rubric developed by Schwab (1962) and modified by Nadelson (2009). In the context of this study the level of inquiry is an indicator of the preservice teachers’ ability to apply constructivist-based teaching strategies. The rubric consists of five levels of inquiry-based instructional practices (Table 1). Higher levels of inquiry reflect higher levels of inquiry-based instruction. For example, at the highest level, Level 4, students are required to develop a research question, devise data collection methods, interpret results, and to evaluate the plausibility of the results. In addition the different types and frequency of mathematics processes as defined by the National Council of Teachers of Mathematics (NCTM, 2000) were recorded and analyzed. The processes as defined by the five NCTM Process Standards: Communication, Reasoning & Proof, Connections, Problem Solving, and Multiple Representations.

Findings

Analysis of Concept-Focused Inquiry (CFI) core principle #1 measuring the nature of mathematics indicates the CFI-based instruction changed the preservice teachers’ perspectives. On the initial survey, every preservice teacher expressed views indicative of either a Platonist view (2 preservice teachers) where mathematics is a static but unified body of knowledge, a crystalline realm of interconnecting structures and truths, bound together by filaments of logic and meaning” (Ernest, 1988, p. 10) or the instrumentalist view (2 teachers) that mathematics is “like a bag of tools, is made up of an accumulation of facts, rules and skills to be used by the trained artisan skillfully in the pursuance of some external end (Ernest, 1988, p. 10 as cited in Thompson, 1992). During the methods course, these beliefs were challenged by the activity and discussions that took place, and by the exit interview, 3 out of the 4 preservice teachers responded with views indicating mathematics as a dynamic, problem-driven field of activity where people create or developed mathematical thought by experimentation, observation, and experience. These preservice teachers’ statements included terms such as concept(s), conceptualization, and conceptual understanding.

Concept-Focused Inquiry (CFI) Core Principles #2 and #3 – Analysis of the three daily lessons prepared early in the semester and the 3 – 4 day unit plan prepared at the end of the course reveal a general increase in the level of inquiry and the number of mathematic process skills used in the plan for instruction. Comparing the average inquiry level of the first sets of lesson designed and the average inquiry level of the lesson prepared as part of the unit showed all four preservice teachers’ improving in terms of the level of inquiry, albeit one of them minimally, and only one of the preservice teachers produced lessons using fewer mathematics processes in the unit plan than in earlier lessons.

Two factors must be considered when looking at these values. The preservice teachers selected the topics for the pre lesson plans but the post unit was based on the content they were assigned to teach during the two-week long field experience. It is probable that the cooperating teachers influenced the content of the unit plans. Conversations with the cooperating teachers indicated that they favored more teacher-centered instruction. As a result, the preservice teachers’ planning was likely influenced by this view. In light of these factors, it can still be inferred that the preservice teachers developed a relatively strong understanding of constructivist/inquiry instructional practices at the conclusion of the methods course.

After the pilot year, it was determined that Concept-Focused Inquiry (CFI) presents a potentially effective approach for training preservice teachers to plan and implement constructivist-based lessons. We found that by providing preservice mathematics teachers with a theory of instruction, CFI, their instructional decision making for planning and teaching mathematics improved. This is because CFI simplifies the instructional decision-making process. In addition, using CFI in the methods course allowed preservice teachers to “see” connections between different topics as well as instructional approaches.

Concept-Focused Inquiry (CFI) is now being used in two mathematics methods courses--both secondary and middle level--and one project with middle level practicing teachers. Additional data sources have been added to measure the effects of CFI on the teachers’ planning, teaching, and understanding of mathematical concepts. In conclusion, we recognize theory development requires multiple iterations in different contexts. In this paper, we have shared an overview of our work thus far. We have presented the core principles that define Concept-Focused Inquiry (CFI). We made an argument that CFI can be considered a theory of instruction. As the title suggests, CFI is a work in progress, and it is a potential theory of mathematics instruction.

Developing a meaningful conception for multi-digit whole numbers is important because it allows PSTs to have the knowledge necessary to help children learn place value in a meaningful way and make sense of multi-digit addition and subtraction. Many PSTs do not have such a conception. Data from a teaching experiment suggests critical events aiding one PST in developing a more meaningful conception of multi-digit whole numbers in the context of addition and subtraction. The critical events involved artifacts of children’s mathematical thinking, using manipulatives, and listening to others.

Introduction

Consider the following scenario: A preservice teacher (PST) is asked to comment on the work of a second grader (see Figure 1). The second grader is curious as to why the 1 is put above the 5. Now consider one PST’s response to interpreting that regrouped 1:

this one is part of the number seventeen, and we just carried it over because you can’t put the number seventeen here … well, the one is added here because it’s part of the seventeen, and, again, you can’t write the number seventeen here, so you have to carry it, ahm, over here.

The PST quoted here is not equipped with a conception that would allow her the ability to discuss the regrouping in a meaningful way with the child. The call to teach in a way that allows children to develop a meaningful understanding of the mathematics (including standard algorithms) has become prominent throughout the United States (Kilpatrick, Swafford, & Findell, 2001, NCTM, 2000). The PST above would be unable to help a child understand the standard algorithm with regrouping for addition.

![Figure 1. The work of a second grader.](Task_modified_from_(Philipp,_Schappelle,_Siegfried,_Jacobs,_&_Lamb,_2008,_p._32)](Task_modified_from_(Philipp,_Schappelle,_Siegfried,_Jacobs,_&_Lamb,_2008,_p._32)

The National Council of Teachers in Mathematics (NCTM) Principles and Standards state that meaningful “mathematics teaching requires understanding what students know and need to learn and then challenging and supporting them to learn it well” (NCTM, 2000, p 11). Creating an environment to promote student learning in a classroom requires a teacher’s ability to decompose mathematical content knowledge so they are able to teach in a way that allows the child to develop meaningful understanding of the mathematics (NCTM, 2000; Kilpatrick et al, 2001). In particular, mathematical content knowledge necessary for teaching multi-digit addition

---

and subtraction of whole numbers requires the ability to decompose knowledge of numbers and regrouping. In the example above the 1 should be seen as 10 ones of the 17 ones (a result of adding 8 ones and 9 ones) and as 1 ten (a result of composing 10 ones into 1 ten or decomposing 17 into 1 ten and 7 ones) which is now added to the tens in the tens’ column. Thus the 1 in 17 has to be flexibly seen as either 1 ten or 10 ones. This extends further in three-digit numbers where we have to be able to switch flexibly between seeing the 1 in 187, for example, as 1 hundred, 10 tens, and 100 ones.

Upon looking for PSTs’ current knowledge of multi-digit addition and subtraction of whole numbers, Thanheiser (2009a) found that 10 of 15 PSTs entering their first mathematics content course for teachers held a conception of multi-digit whole numbers that would be insufficient for a meaningful explanation of regrouping in the context of addition and subtraction. Therefore, mathematics educators need to work with PSTs to help them develop more sophisticated conceptions of multi-digit whole numbers. However, this is not easy (Thanheiser, 2009b).

**Theoretical Framework and Background**

Although most PSTs are able to compute using algorithms successfully, many are unable to explain the algorithms in a meaningful way (Ball, 1988; Ma, 1999; Thanheiser, 2009a). To help PSTs develop conceptions, which will allow them to work with children in a meaningful way, it is important to build on PSTs’ current conceptions and prior knowledge (Bransford, Brown, & Cocking, 1999). To help PSTs develop conceptions that would allow them to interact in a mathematically meaningful way with a child, we (mathematics educators) first need to identify their conceptions. Then we can create activities to allow them to extend their existing conceptions.

One framework developed to identify PSTs’ place value conceptions (Thanheiser, 2009a) includes four categories, two incorrect and two correct.

- **Concatenated Digits Only:** conceiving of all digits in terms of ones (e.g. 389 would be 3 ones, 8 ones, and 9 ones)
- **Concatenated Digits Plus:** viewing at least one digit in a number incorrectly in terms of ones and not in terms of its value. (e.g. 389 might be 300 ones, 8 ones, and 9 ones).
- **Groups of Ones:** conceiving of all digits in terms of groups of ones alone (e.g. 389 would be 300 ones, 80 ones, and 9 ones).
- **Reference Units:** conceiving of the reference units for each digit in the number and relating the reference units to one another (e.g. in 389, the 3 can be seen as 3 hundreds, 30 tens, or 300 ones and the 8 can be seen as 8 tens or 80 ones).

Using this categorization, Thanheiser (2009a) showed that many PSTs enter their first mathematical content course for elementary school teachers with an incorrect conception of place value (either concatenated digits only or concatenated digits plus).

Several different ways to help children develop a meaningful understanding of multidigit whole numbers and the standard algorithms for addition and subtraction successfully have surfaced. One such way is to allow children to develop their own algorithms (Kamii, 1994), another to focus students on listening for differences in explanations (McClain & Cobb, 2001). Both these approaches allowed children to build a meaningful understanding of place value. The later also improved their interaction within the classroom by emphasizing listening for what made methods different. Working with adults is different. They have practiced and used the

---

standard regrouping algorithm for years and we cannot simply expect them to abandon this method. By instead asking them to work with various manipulatives to create ways of adding and subtracting numbers, react to children’s mathematical thinking artifacts (see Philipp et al., 2007), incorporate various different strategies and relate those to the standard algorithm, an environment can be created that allows the PSTs to uncover concepts underlying the standard algorithm. In our work, we examine how these various activities affect one PST’s conception.

**Methods**

The data for this study comes from the first three days of a five-day teaching experiment with six PSTs, as well as pre, post, and delayed post interviews of one PST, Isabel. Each day of the teaching experiment consisted of one 150-minute session with six volunteer PSTs from a large, urban, comprehensive state university. Two PSTs had previously taken their education methods course and the remaining four had not. All sessions were videotaped. Field notes were created and used to identify critical events, which were then transcribed. The interviews were all 60 to 90 minutes long and conducted immediately before, immediately after, and approximately eight months after the teaching experiment respectively. All interviews were transcribed. The questions in the interviews were designed to elicit the PSTs’ conceptions and coded according to the above framework (Thanheiser 2009a).

The tasks for the teaching experiment were designed based on the pre-interviews and the intent was to address/build on the PSTs’ initial conceptions. The tasks included addition and subtraction of three-digit numbers using various manipulatives, discussion of artifacts of children’s mathematical thinking such as video clips of children solving problems, discussion of manipulatives, and an exploration of Mayan numbers.

More specifically, on the first day of the teaching experiment, students used various ways to add 389+475: (a) Montessori digit cards (see Figure 2a); (b) Base ten blocks; and (c) Any other method they could think of (mentally or using paper and pencil). Montessori digit cards provide a way to connect the symbols to their values. Students use the cards to build multidigit numbers. For example, 423 is built by layering the 400, the 20, and the 3 (Figure 2b). Base ten blocks help elicit the correspondence between place values, but as Hiebert et al (1997) point out, this meaning must be constructed and is not inherent in the blocks.

![Figure 2a. Montessori digit cards](image)

![Figure 2b. Representing 423 value with Montessori digit cards](image)

The PSTs also watched one video of a child completing a three-digit addition problem. The video showed a student adding three digit numbers (Figure 3). This child previously used the expanded addition algorithm correctly with two-digit addition (Figure 4). In the video, the student incorrectly used the expanded addition algorithm while adding three-digit numbers. She added the digits from left to right and lined up the values vertically to get that 638+476=34. The child did six plus four is ten instead of six hundred plus four hundred is one thousand; three plus seven...
is ten instead of thirty plus seventy is one hundred; and correctly did eight plus six is fourteen (Figure 3).

Figure 4. To use the expanded algorithm, one looks at each place value and adds it individually. One then adds those values. The child (referenced in figure 3) completed this problem correctly in this manner

The goal of the addition tasks was to help the students develop methods different from the standard algorithm to help explicate and develop their conceptions through explanations of these alternate methods.

In this paper, we analyze one student, Isabel, through the first three days of the teaching experiment using Thanheiser’s framework. Isabel’s conception was categorized as concatenated digits only on the pre-interview and as reference units on the post interview (Thanheiser, 2009b). We identify the development of her conceptions throughout various tasks and identify critical events that changed her attitude toward learning, demonstrated gaining knowledge, or demonstrated development of a skill (Woods, 1993).

Results and Discussion

Isabel was categorized as holding a concatenated digits only conception in the pre-interview and developed a reference units conception over the course of the teaching experiment. In the delayed post interview, Isabel demonstrated that she still had a reference units conception. A change in conception is not trivial, as mere exposure to correct conceptions was not enough to cause a change (Thanheiser, 2009b). In this section, we will trace Isabel’s development over the course of the first three days focusing on three phases. The first phase reemphasizes the findings of Thanheiser (2009b), that exposure alone is not sufficient. The second phase addresses Isabel’s changing conception and the third phase is the solidification of her reference-units conception.

Phase 1: Exposure is Not Enough

Isabel saw all digits in terms of ones, rather than in terms of their values at the beginning of the teaching experiment. During the first phase of the teaching experiment, she continued to hold this conception even when exposed to correct conceptions (Thanheiser 2009b). She was aware that her method was different from other students’ methods, but did not classify it as being better or worse. “I just think that there is no really right way, like, everyone is thinking about it

differently, but it’s not like she was wrong or I was really wrong, it’s just that everybody thinks about it differently.” Although she was hearing the other students, she may not have been paying attention to them or listening for distinct differences to evaluate what these differences might mean (McClain & Cobb, 2001).

**Phase 2: A Changing Conception**

**Part 1: Responding to video.** Isabel’s first instance of change came in response to the video at the end of day one. In response to the child’s solution (see Figure 3) Isabel stated “She didn’t even add it properly… she knows it’s a ten, but I don’t think she is understanding the concept of place values.” Upon reflecting about this video, Isabel began to show understanding that her own conception may not be enough (Thanheiser 2009b).

*She [the child] is just adding them as single digits, like six plus four, and then that’s one problem, and then three and two is another problem, and then taking those numbers and making it a third problem or a fourth problem… you need to indent to get the correct place values.*

Through this discussion, Isabel showed, for the first time, an understanding that you need to see each digit of a number as more than a digit. Even though her understanding seems to remain procedurally focused, this was the first instance of her acknowledging that not all strategies have the same validity. This event triggered her change of conception and thus, the researchers classified it as a critical event in the sense that it changed her attitude toward listening to and learning from others.

Beginning with this event Isabel began to pay attention to what others were saying. First, she paid attention to the child’s (incorrect) solution. After the video, she began to pay attention to the other students in the teaching experiment as well. One hypothesis as to why she started to listen is that the child held a conception similar to her own but did not arrive at the correct answer. Thus, this may have made Isabel aware of the fact that some additional aspects of understanding are necessary to solve this problem correctly.

**Part 2: Attention on others.** After responding to the child’s incorrect solution (see Figure 3) Isabel began listening to other students in the teaching experiment. The first task following the viewing of the video was to consider teaching multi-digit addition to a class of second graders. The PSTs were asked to react to two scenarios: (a) how they would teach the second graders and (b) how they would teach if they had no materials available. Isabel wrote in response to the first scenario that she would use the blocks because “then they [the children] can understand why we are carrying the ones… because these ones become also a ten … so you put it in the ten’s place.” This response indicates that she is now aware of the need to understand what the regrouped values mean. In the second scenario, she suggests the use of the standard algorithm because it is “easier to break up into three smaller problems than to see it as one larger problem” (Figure 5a). After some discussion, Jason (another participant in the teaching experiment) presents an expanded algorithm (Figure 5b). Isabel then decides that she would rather use Jason’s method to introduce addition because “it is a little more clear for a beginner to see… it’s like the actual, you know, that the six represents six hundred.” In her response she indicates that she now sees the value of the 6 not merely as 6 (as she did at the beginning of the TE) but as 6 hundred. She is also paying close enough attention to someone else’s method to adopt it as what she would rather use and thus the researchers classified this as a critical event in the sense that she demonstrated
acquiring knowledge (of Jason’s method). Isabel now has an alternate method available to her that she saw as easier for someone who was just learning the ideas for the first time. After the video, Isabel’s awareness allowed her to listen carefully to Jason, adopting his method as her own.

![Figure 5a. Isabel’s standard algorithm](image1)

![Figure 5b. Jason’s expanded algorithm](image2)

**Part 3: Use of materials.** While trying to connect the standard algorithm to Jason’s expanded algorithm (Figure 6b), Isabel references base ten blocks.

Well, eight plus two is ten, and then I guess, like with the blocks it would be ten, it’s going to be one ten, so you’re going to carry it over to the tens place like fifty plus ten plus you’re adding another ten value… and then five plus one plus one will give you seven, so in the problem that’s really seventy in that place value there, it’s seventy, not seven. And then four plus six is ten, but it's really one thousand seventy.

Throughout the first part, Isabel is comfortable referencing the blocks without having them in front of her and was able to explain the addition by connecting the digits in the ten’s place to their value (i.e. 70 for 7 in the ten’s place). However, as the explanation carried on, she seemed to lose track of the blocks and fell back to an explanation referring to digits. Even though she attended to placement in the final answer, she did not reference the digits along with their value to support their placement in her final answer. We are able to see that, although she still falls back to a concatenated digits conception, she is beginning to draw on correct conceptions.

**Phase 3: Solidifying a Correct Conception**

After discussing addition, the PSTs began discussing subtraction. At this point, Isabel moved beyond exclusively relying on the concatenated digits conception. As demonstrated in phase 2, Isabel previously drew on correct conceptions at various points throughout the discussions. In the context of the subtraction problems Isabel was able to draw on these conceptions immediately. For instance, when Isabel was writing an explanation for 527-135 (Figure 6), Isabel used the visual representation of the base ten blocks and stated that you should convert *one hundred to ten tens* to aid in the subtraction process (Figure 7). During the discussion, she reemphasized her thoughts: “you can explain if you cannot take away a certain number of tens then you can break one of the hundreds up.” By not falling back on her concatenated digits conception, Isabel demonstrated that she had moved beyond the concatenated digits conceptions. She was able to use her developed conception to understand and explain regrouping in the subtraction algorithm, so the researchers classified this as a critical event in the sense that she demonstrated development of her skill set.

---

Conclusion & Implications

Although helping PSTs develop conceptions that are more sophisticated is hard, there are certain events that seem to aid in developing a more sophisticated conception. Using artifacts of children’s mathematical thinking (in this paper, a video) can help a PST to understand that their conception is inadequate. Listening to other students’ explanations and solutions provides PSTs one way of developing conceptions that are more sophisticated. Listening is essential for learning mathematics, and this could involve children or fellow students. Either way, a classroom of students will involve many levels of conceptions, so purposeful sequencing of the events is critical to aid in developing these conceptions. Although manipulatives do not hold mathematical meaning on their own they can be used as a tool to communicate mathematical ideas and share mathematical understanding. Essential aspects of all these activities are that (a) they address the PSTs’ currently held conceptions (in our case the concatenated digits only conception) and (b) allow the PST to build on those to develop more sophisticated conceptions. For example, the video explicated the inadequacy of the concatenated digits conception and thus prompted the search for a more meaningful one.

Tracing Isabel’s conceptions through the teaching experiment allowed us to see while change of conceptions is possible it may not be fast or easy. We need to allow time and carefully choose activities addressing the PSTs’ currently held conceptions to allow them to develop conceptions that are more sophisticated.

EXAMINING PROSPECTIVE ELEMENTARY TEACHERS’ CONCEPTUAL UNDERSTANDING OF INTEGERS

Stacy Reeder  
University of Oklahoma  
reeder@ou.edu

Summer Bateiha  
Western Kentucky University  
summer.bateiha@wku.edu

Teachers tend to teach mathematics they are comfortable with, and if their mathematical understanding is limited or based on misconceptions, they are likely to avoid teaching mathematics as much as possible or simply focus their teaching efforts on procedural proficiency. This investigation examined the degree to which prospective elementary teachers had developed a meaningful and conceptual understanding of what integers are and explored their development of models for multiplication with integers that are related to everyday activities. Additionally, this study explored how these understandings informed prospective elementary teachers envisioning of their teaching these concepts to their future students.

Introduction

The success of the current efforts for reform in mathematics education depends largely on teachers’ conceptual knowledge and understanding of the mathematics they will teach. By the time prospective teachers begin their education or mathematics methods coursework they have spent years learning mathematics from teachers whose pedagogic practices are predominantly teacher centered and driven by the aim for algorithmic and procedural proficiency. Further, prospective teachers’ experiences with mathematics at the university level that tend to focus on college level mathematics do not do much to improve their conceptual understanding of the mathematics they will teach. It is the culmination of these experiences with school and university level mathematics that often develops limited understandings and a sense of low self-confidence with mathematics. Likewise, in prospective teachers, these experiences create difficulties envisioning mathematics teaching for understanding from a perspective that is more aligned with constructivist ideas about learning.

This study aimed to understand the degree to which prospective elementary teachers had developed a meaningful and conceptual understanding of what integers are and to explore their development of models for multiplication with integers that are related to everyday activities. Additionally, this study explored how these understandings informed prospective elementary teachers envisioning of their teaching these concepts to their future students.

Background

Research has indicated that many prospective elementary teachers have developed misunderstandings and/or limited understandings of various basic mathematics concepts (Ball, 1988; Ma, 1999). This limited understanding is often and unfortunately passed on to prospective elementary teachers’ future students thus creating a cycle of limited knowledge in mathematics and an inability to critically question the mathematics one is being taught. The National Council of Teachers of Mathematics (NCTM) stated that:

Central to the preparation for teaching mathematics is the development of a deep understanding of the mathematics of the school curriculum and how it fits within the discipline of mathematics. Too often, it is taken for granted that teachers’ knowledge of the...
content of school mathematics is in place by the time they complete their own K-12 learning experiences. Teachers need opportunities to revisit school mathematics topics in ways that will allow them to develop deeper understandings .... (1991, p. 134).

Despite this admonition from NCTM two decades ago, it remains the case today that most prospective elementary teachers are engaged in mathematics at the university level that includes topics well beyond what they will eventually teach. This common practice may be based on an underlying belief that if prospective teachers are exposed to “higher level” mathematics they will naturally make sense of and deepen their understanding of the mathematics content they will teach to their students.

Conceptual Understanding of Integers. Traditionally, students have been required to memorize rules for operations with integers thus leaving them without the fluency or flexibility to use the mathematics learned in situations different than those in which they first learned them. Students often get confused about which rule to follow and are left to rely on their instincts to solve problems dealing with integers (Bolyard & Moyer-Packenham, 2006; Ferguson, 1993).

When students first encounter negative numbers they are unable to relate them to the models they have previously made sense of with counting numbers because they cannot “see” negative numbers. According to Heibert and Carpenter (1992), the models used to teach counting numbers and fractions should make sense to students so they can remember rules that are generalized for performing the operations. However, working with models that will make sense to students is more challenging with integers because the models can only be used in abstract ways in an effort to relate integers to what students have previously learned. Students struggle with the signs used to indicate positive or negative integers since they are the same signs used for addition and subtraction operations (Stephen, 2009). Models most frequently used to teach integers include the neutralization models and the number line which are often represented by two-color counters or positive and negative charges scenarios (Reeves & Webb, 2004; Nurnberger-Haag, 2007). Further, studies indicate that even when students are introduced to integers in ways that they can relate to, they often do not develop an understanding of the “negativeness” or “positiveness” of the situation in which the integers are embedded (Hackbarth, 2000). This study explores preservice elementary teachers’ conceptual understandings of integers and multiplying them when they gain experiences with both abstract models and “real world” scenarios that depict multiplication of positive and negative whole numbers.

Methodology

Data Collection

Journal entries, participant short-answer responses, and video-taped classroom discussions constitute the data sources for this study. Three different groups of prospective elementary teachers comprised the participants for the study and data were collected over two semesters in two sections of a senior level mathematics course in the fall (N = 32) and one section of the same course (N= 29) during the spring. In both the fall and the spring, the instructor for the course collected the data as an ongoing and normal part of the coursework and assignments.

Data were collected after the prospective teachers had participated in a variety of activities focusing on what integers are and experiences aimed at developing their understanding of operations with integers in everyday contexts. Participants were asked to respond to the following questions and/or prompts:

What are integers?
Where do we encounter them or in what ways are integers used in the “real world”?
How would you teach each of the following scenarios with integers?
 (+)x(+), b. (+)x(-), c. (-)x(+), and d. (-)x(-)
Write a story or scenario for each of a through d above.
Reflecting on your own learning experiences answer the following:
- Were you taught to multiply integers by using the “rules”?
- Did you question these rules when you were taught them? Why or why not?
- How did this classroom experience make you feel?
- Do you feel like you can now teach these concepts better through an inquiry approach?

Setting
The participants involved in this study were prospective elementary teachers at a university in the Southwestern region of the United States in a teacher preparation program wherein perspective teachers take four mathematics content courses and three additional courses focused on elementary mathematics methods. A belief in the tenets of social constructivism was the underlying philosophy and theory that drove the decision to engage students in activities and experiences that supported problem centered learning approaches to teaching and learning mathematics (Wheatley, 1991; Wheatley & Abshire, 2002; Van de Wall, 2004).

The course in which this study was conducted served as the last mathematics methods course students took in their final semester prior to their student teaching internship. While the course focused on teaching mathematics in grades four through eight, an overarching goal of the course was to further develop the mathematical power (NCTM, 1989) of the prospective teachers through engaging them in continual problem solving, critical questioning of the ways in which they had been taught mathematics, and integration of social justice arts. The activities and experience designed for this course were purposively selected in order to improve the mathematics content understanding of prospective teachers, to help them make connections in and among mathematics and other content areas, to engage them in mathematics in every day contexts (specifically issues of social justice) (Gutstein & Peterson, 2006), and to provide opportunities for them to develop their ability to solve non-routine problems, with the goal of improving prospective teachers overall mathematical power (NCTM, 1989).

Data Analysis
Data were analyzed using an interpretive framework. The initial phase of data analysis was an exploratory examination of student journals and video recordings. The researchers hoped to develop an overall idea of what student perceptions of integers were. This initial exploration was followed by several subsequent readings and viewings, that were analyzed and began to form common trends and categories. After several cycles of analysis through the data and the formation of themes, the researchers began to identify answers to the following questions. (1) How did these preservice teachers describe integers? (2) What methods did they develop for teaching multiplication of integers? (3) How did their understandings inform their ideas about teaching these concepts to their future students? Data were then summarized and one final read through was conducted to verify that the questions of the study had been answered. During the final analysis cycle, examples were extracted for use in illustrating the results.

Research Results

The results of this study indicate that after having had multiple experiences with integers through discussion about where integers are encountered in the everyday activities of life, solving non-routine problems with integers, working with a variety of models typically used to teach integers and operations with integers (two-color counters, positive and negative charges, and number line models) and creating problems (stories and scenarios) with integers for each operation, the prospective teachers in this study could discuss what integers are and where they are found in the “real world.” They seemed comfortable with multiplication of two positive integers and multiplication of one positive integer with one negative integer; however, they remained hesitant in their abilities to demonstrate an understanding of multiplication of two negative integers (particularly in writing a “real world” story problem). A small minority of students seemed to be cautious about using approaches and models aimed at conceptual understanding of operations with integers and instead believed that the use of “gimmicks” or “sayings” will help their future students memorize the “rules” for multiplication of integers.

Analysis of the data collected revealed that all participants could accurately discuss what integers are and where they are likely encountered in everyday activities. Overwhelmingly participants indicated that integers can be encountered in the game of golf (above and below par), the game of football (yards lost or gained), borrowing money and/or debt with credit cards, temperature, above and below sea level, and a variety of board games. All seemed to be ways that made sense to the prospective teachers and contexts they could relate to.

The second focus in data collection asked the participants to discuss specifically how they would teach multiplication of integers to their future students. They were asked to address all possible combinations of positive and negative integers in multiplication (i.e., (+)x(+), (+)x(-), (-)x(+), and (-)x(-)). Most responses to this question included participants citing one or more of the models that had been presented in class (typically two-color counters or a line number model). Analysis of this data revealed that in all cases wherein a participant indicated a model for teaching multiplication of integers, she/he did so correctly. Additionally, many participants also indicated that they would use repeated addition or multiplication by grouping relying on the context of everyday activities with integers. However, approximately half of the participants who cited everyday activities with integers and combined it with an array, two-color counters, or number line model did so correctly across all four combinations of multiplication with positive and negative numbers. The following is an example of one participant’s response that included both models and everyday contexts. Maggie wrote:

\begin{itemize}
\item[a.)] + x + 
Arrays, two-color counters, lattice multiplication, groups of items, drawings.
Sally had 3 baskets with 5 apples in each basket. How many apples does she have in total?
\item[b.)] + x – 
Story problems. Teach – x + first and then commutative property.
4 friends have $-20 in each of their bank accounts. What is the total of their bank accounts put together?
\item[c.)] – x + 
Two-color counters, pictures.
-3 x 3
\end{itemize}
You scored -1 (1 birdie below par) on every hole on an 18-hole golf course. How far below par are you?

d.) – x –
Every time I go to the casino I lose $25. I don’t go for 3 days. How much $ did I save? (Student journal)

Although many students such as Maggie were able to create story problems for multiplication of integers (i.e., the casino problem above), during discussions that proceeded writing these scenarios, many of them expressed concern about the mathematical validity of the (-)x(-) word problems. Debates ensued about whether or not saving or maintaining money is the same as gaining money. The most common concern was some form of the idea that if you begin with $0 and don’t go to the casino for three days, you are still at $0, not at $25. Is a problem such as Maggie’s accurately portraying a negative integer times a negative integer? Many students emerged from the class believing that it does; however, for some, concerns pushed them to ponder the matter further. Although this issue seemed to cause significant dissonance for most students in class, after discussing the matter for a few minutes, all but one class seemed temporarily satisfied with the idea of “saving money” as a positive integer answer and so discussion of the matter was terminated. However, in one class, the following example was proposed:

Your friend paid for your lunch three times this week. Lunch costs $5 each time. In other words, at the end of the week, when you pay your friend back your bank account will decrease by $15, or 3 x -5 = -15. Your friend decides to take away two of those lunch charges, so she relieves you of two $5 charges, or -2 x -5 = 10. Your account will decrease by $5 instead of $15, so you have gained $10.

Participants in this particular class then began asking whether it was necessary to find a “real world” example of a negative integer times a negative integer, because it seemed to be the case that in the “real world” it would make more sense to simply use the terminology of a positive integer times a positive integer. Ultimately, one student proposed that although it may not be common to phrase “real world” multiplication problems in the way this example illustrates, the point of the example would be to portray the logic behind a negative times a negative in the “real world” (i.e., there is a “real world” scenario for negative integer multiplication). Although only one class seemed to debate the matter for a longer period of time than the others, students from all the classes continued to be uncomfortable with the idea of finding a contextual example for (-)x(-), as many of them revisited and questioned this concept periodically throughout the rest of the semester.

Unfortunately, about one-fifth of the participants indicated they would rely solely on methods of memorization to teach multiplication with integers. Shelly discusses the fact that she believes that teaching “rules” is still a necessary part of what she will need to do as an effective mathematics teacher.

I know that we should be allowing the students to explore math and come up with their own rules and definitions without actually teaching them the rules; however, sometimes
you have to teach the rules and then create opportunities to prove they are correct. I found this poem online while trying to research why a – x = +. I think this is a great tool to use when teaching negative integers.

When good things happen to bad people, that’s bad. (+ x = –)
When bad things happen to bad people, that’s good. (– x = +)
When bad things happen to good people, that’s bad. (– x + = –)
When good things happen to good people, that’s good. (+ x + = +) (Student journal)

Jennifer likewise indicates that she would not necessarily teach the “rules” but instead found a way she thinks is better for teaching multiplication with integers. She believes she will use the “Dating Game.”

The Dating Game!

a.) I like you, you like me – it’s positive.
b.) I like you, you don’t like me – it’s negative.
c.) I don’t like you, you like me – it’s negative.
d.) I don’t like you, you don’t like me – it’s positive. (Student journal)

The final focus of this research study was to examine the perceived impact of experiences in a methods course aimed at improving prospective teachers overall mathematical power on their vision of how they would teach mathematics as it pertains to multiplication of integers. Asking the prospective teachers to write about whether they feel like they can teach integers and multiplication of integers through inquiry approaches revealed in some cases the resilience of their misunderstandings and challenges with mathematics. For example, Julie discusses her own learning of the “rules” for the multiplication of integers:

As I mentioned in class, I don’t really remember being taught those rules. The only thing that really sticks out of my head is when I was taught that you take the bigger number’s sign when multiplying. I remember having a hard time learning these rules. I couldn’t understand why you would need to know this equation in real life. I believe that I was my biggest downfall in mathematics, not being able to relate math to real life experiences. (Student journal)

Brittany echoed common sentiments about frustrations with learning mathematics in her journal:

Thinking more critically about how to teach (-)x(+) and (-)x(-) and story problems that have students doing this mathematics was at first mindboggling to me. For so long I just knew the rule and it was hard for me to think about why I thought this. Doing the (+)x(+), (-)x(+), and (+)x(-) were much easier than (-)x(-). When it came to creating a problem, for (-)x(-) I was frustrated because every “everyday” situation I thought of wouldn’t work for this problem. (Student journal)

The experience of learning with the goal of conceptual understanding in mind, and being asked to reflect on their own mathematics learning, seemed to have a positive impact on most of
the participants. As they envisioned how they would eventually teach their future students, most students seemed to believe a “deeper understanding” should be a necessary component of their future classrooms. Allison wrote:

Growing up, I was always very frustrated by math and got through it purely by memorization and repetition. However, even though I was constantly confused by the many varying rules, I never once questioned them or thought to ask why they were applicable. I think this is mainly because my math was taught to me in fairly traditional manner with little social justice or authentic applications or connections looking back. I wish that I had learned differently because I feel that it would help me teach, but I’m also thankful that I leaned the way in which I did because it will help me understand the many different perspectives of my students. I do think it is better to teach integers through an inquiry approach because it allows the students to develop their own individual understanding and methods prior to being subjected to the “right” way. (Student journal)

Anne continued with this sentiment by stating;

I feel like I can teach these concepts better now that I have analyzed the meaning behind them. Having this deeper understanding will allow me to ask probing questions that will cause the students to analyze and consider these concepts. Using story problems will help the students put these concepts into a context that makes sense to them. (Student journal)

Although some participants indicated that they were unsure whether they could teach in ways that would foster more conceptual understanding due to their own frustrations with mathematics, all students revealed a belief that mathematics is better understood, better taught, in the context of everyday scenarios. Kim states “relating math to real life scenarios help everyone understand it.” The participants expressed overwhelmingly that with integers in particular, the use of everyday contexts helped them examine their own misconceptions and limited understandings of multiplication with integers.

**Discussion**

Teachers tend to teach mathematics in a way that is comfortable to them (Sowder, Phillip, Armstrong, & Schappelle; 1998). If they are only exposed to algorithmic and procedural methods and do not develop a solid understanding of mathematics, they may be left with very few options but to teach in traditional ways. When the idea of developing the mathematical power of prospective teachers is infused in a mathematics methods course it may be possible to not only improve the content knowledge of prospective elementary teachers but also provide an opportunity for them to envision teaching mathematics for conceptual understanding. The results of this study indicated that providing prospective elementary teachers the opportunity to examine their own mathematics understanding through challenging them regularly to make sense of mathematics in everyday contexts can be powerful. While some of the prospective elementary teachers who participated in this study still indicated that they would rely on memorization based methods for teaching their own students multiplication with integers, the overwhelming majority indicated the power of using everyday contexts or scenarios for teaching mathematics. They also indicated that through the use of everyday contexts and a variety of models for understanding
integers, they feel more empowered not only in their own mathematics knowledge but also in the ways they now envision teaching their future students.

THE INFLUENCE OF A REFORM-BASED MATHEMATICS METHODS COURSE ON PRESERVICE TEACHERS’ BELIEFS AND ATTITUDES

bevans@pace.edu

Kathleen Krier  
Temple University  
kkrier@21pstem.org

We report the results of two studies aimed at examining two elementary preservice teachers’ beliefs and attitudes before and after taking reform-based methods courses at an urban university in the northeastern U.S. It was learned that practices such as those modeled in reform-based mathematics methods courses lead to higher gain scores in the attitudinal survey given to one cohort of preservice teachers.

Introduction

The preparation of mathematics teachers has become an increasingly important area of interest to mathematics educators and policymakers in recent years. In the United States the National Science Foundation (2005) and the National Research Council (2000) agree that reforming teacher preparation in postsecondary institutions is a central factor in enhancing the capacity to improve mathematics education for all students. At the same time, the quality of K-16 mathematics education is a critical component to broadening the diversity of students in the undergraduate STEM pipeline. Quality mathematics education is especially needed in urban schools where there are high concentrations of minority students and underachievement is exacerbated by diminished access to highly qualified teachers of mathematics as compared to non-urban and low-concentration-minority schools (Ingersoll, 2002). The conversation about highly qualified teachers is generally focused on knowledge of content (Ball, Hill, & Bass, 2005). However, two important factors that are often overlooked in the discourse on highly qualified teachers are beliefs and attitudes about teaching mathematics and students’ ability to learn mathematics. In our work with preservice teachers who are more likely to enter the teaching profession in urban settings, these beliefs and attitudes are seminal to student success.

Purpose

Based on data collected on elementary preservice teachers’ mathematics backgrounds and attitudes toward mathematics, the first author and teacher-researcher in this study believed her primary role was to influence preservice teachers’ beliefs about teaching and learning mathematics. In 2004, she conducted a qualitative study (Study 1) to examine elementary preservice teachers’ beliefs before and after taking the reform-based methods course at an urban university in the northeastern U.S. Then in 2005, a second instructor (and co-author of this paper) conducted a mixed-methods study (Study 2) to examine teacher beliefs and attitudes before and after taking a similar reform-based methods course at the same university. Thus, the purpose of these studies is to report on changes in preservice teachers’ beliefs (Study 1 & Study 2) and attitudes (Study 2) before and after taking reform-based mathematics methods courses. The main research question that guided this study was: How do preservice teachers’ attitudes toward mathematics (ATM) compare before and after taking a reform-based mathematics course? We also examined beliefs, which were part of a larger study (Newton, Leonard, Evans, & Eastburn, under review).
Theoretical Framework

This research study is framed by sociocultural theory (Vygotsky, 1987) and self-efficacy theory (Bandura, 1997). The sociocultural perspective purports that collective and individual processes are directly related (Cobb & Yackel, 1996). In this context, an instructor guides learning and enculturation as students are taught the skills and concepts needed to function and become productive citizens in society (Vygotsky, 1987). In this perspective, learning is understood as a process of “enculturation into a community of practice” (Cobb, 1994, p. 13). As a community of practice, we developed a set of ideas to strengthen preservice teachers’ mathematics identity. Mathematics identity is one’s belief about his/her “(a) ability to do mathematics, (b) the significance of mathematical knowledge, (c) the opportunities and barriers to enter mathematics fields, and (d) the motivation and persistence needed to obtain mathematics knowledge” (Martin, 2000, p. 19). Many of the preservice teachers we taught had negative experiences with mathematics teachers and/or the content. Our premise was most of these preservice teachers did not fully understand the mathematics and were fearful of teaching it. Teacher “identity and awareness both mediate action and pedagogy” (Gonzalez, 2009, p. 23). By attending to identity, we focus on preservice teachers’ beliefs and attitudes about teaching and learning mathematics and their roles as teachers of mathematics (Gonzalez, 2009).

Beliefs, attitudes and values combine to form a person’s belief system, which influences teacher behaviors and decision-making in the classroom (Parajes, 1992). These belief systems, which we call educational beliefs, encompass beliefs about confidence to perform a specific task (self-efficacy) and confidence to impact student performance (teacher efficacy) (Parajes, 1992). Thus, self-efficacy is also an important construct in the examination of teacher beliefs. Bandura (1997) developed what is now commonly known as efficacy theory.

According to Bandura (1986), teacher efficacy beliefs consist of two substructures: personal self-efficacy and outcome expectancy. Personal self-efficacy is defined as the perceived judgment that an individual has about his or her capacity to teach, whereas outcome expectancy reveals the teacher’s perception of the students’ ability to learn from his/her teaching and is often referred to as teacher efficacy in the literature (Parajes, 1992). Bandura’s (1997) theory suggests efficacy is malleable, and he described four factors that contribute to its development: mastery experiences, vicarious experiences, verbal persuasion, and physiological and affective states. Mastery experiences are those obtained from actual practice. How one feels about a particular subject influences how one teaches it. Teachers who express poor attitudes or disaffection with mathematics are more likely to avoid planning or teaching these subjects (Trice & Ogden, 1986).

Negative emotions may contribute to low efficacy, triggering avoidance behaviors and inhibiting teaching performance (Jesky-Smith, 2002). On the other hand, teachers with high efficacy are more likely to engage students in inquiry and student-centered teaching, which have been linked to higher student achievement (Swar, 2005). Teachers need opportunities to engage in this kind of inquiry throughout the preservice stage, taking advantage of a growing set of practice-based materials (e.g., video of classroom instruction, case studies of student thinking, and student work samples) to engage in thinking about not only what they need to know, but also “an appreciation of what it takes to use it wisely in context” (Lampert & Ball, 1998, p. 36).

Methodology

In order to build a learning community, the first assignment was for preservice teachers to write about their history and past experiences with mathematics. Then she engaged preservice teachers’ in a reform-based mathematics methods course, which she believed would positively
impact preservice teachers’ beliefs about teaching and learning mathematics. Teacher educators, who are reflective of their own practice, often draw upon ethnography as the primary means of data collection (Cochran-Smith & Lytle, 1990). Ethnographies take on many forms including qualitative research, case study research, field research, or anthropological research (Erickson, 1985). Our concept of the ethnographic method is also aligned with Goodall’s (2000) notion of the new ethnography, which deals more directly with the interpersonal aspect:

writing based on interpersonal relationships gains authenticity from the quality of the personal experiences, the richness and depth of individual voices, and a balance between engagements with others and self-reflexive considerations of those engagements (p. 14).

In light of this work, we used autoethnography to engage in reflexivity and interpret our respective roles as instructors in our methods courses (Goodall, 2000).

Setting and Participants

The College of Education where the study took place is situated in an urban city in the northeastern United States. The number of students enrolled in the College is approximately 2,100 per year. In their junior year, prospective teachers who are admitted to the early childhood/elementary certification program are enrolled in practicum and methods courses. Each practicum is taken in conjunction with specific methods courses in the core curriculum (i.e. reading/language arts and social studies methods and practicum; mathematics and science methods and practicum). Practicum students are assigned to urban K-8 classrooms where they team-teach in groups of four two days a week.

Results

Due to the limitations of this paper, we are only reporting changes in preservice teachers’ attitude scores. The qualitative analysis on teacher beliefs is currently under review and was presented at a previous conference (Newton, Leonard, Evans, & Eastburn, under review).

Comparison of Pre-Post Attitude toward Mathematics Scores

Preservice teachers’ scores on the ATMI were compared (Tapia & Marsh, 1996) before and after taking the methods course. As shown in Table 1, the results of a paired samples t-test (two-tailed) reveal a statistically significant difference in attitude pretest and posttest scores for preservice teachers in Carol’s methods course.

<table>
<thead>
<tr>

<tr>
<td>Section 2 (N = 24)</td>
</tr>
<tr>
<td>Pretest</td>
</tr>
<tr>
<td>Posttest</td>
</tr>
</tbody>
</table>

* p < 0.05 (two-tailed)
For Carol’s first section, there was a statistically significant difference between pretest scores ($M = 3.16, SD = 0.663$) and posttest scores ($M = 3.54, SD = 0.632$) for the attitude test, $t(27) = -5.108, p = 0.000, d = 0.59$. Further, for Carol’s second section, there was also a statistically significant difference between pretest scores ($M = 3.56, SD = 0.670$) and posttest scores ($M = 3.77, SD = 0.702$) for the attitude test, $t(23) = -2.491, p = 0.020, d = 0.29$. Thus, in both cases, there was an increase in attitudes over the course of the semester. Effect sizes were small to medium.

![Figure 1: Results of Attitude toward Mathematics Inventory Scores by Section (Carol)](image)

Discussion

The results of this study of two teacher educators’ practices and the development of preservice teachers’ attitudes toward mathematics support several findings. Both sections of Carol’s classes experienced significant increases in positive attitude toward mathematics. Analyses of qualitative data support Skemp’s (1976) claim that attitudes in mathematics are reflective of the teaching-learning environment. It is clear from the cross sample of journal reflections that the reform-based mathematics methods course allowed preservice teachers in this study to make connections between research and practice and methods and practicum. Additional studies that examine development of preservice teachers’ attitudes in different types of learning environments are needed to increase understanding about the relationship between the cognitive and affective domains. Results from this study suggest that educational beliefs can be positively enhanced during a methods course.

Experiences reported in Bridget’s class illustrate the next finding: the microteaching of peers had a profound influence on preservice teachers’ beliefs. Microteaching was a salient part of the reform-based course. This finding is unique since it is absent from the literature on preservice teacher preparation.

teachers’ beliefs. Another element of the course that influenced preservice teachers’ efficacy was the Kay Toliver videos. These preservice teachers’ belief statements confirm that videos can provide preservice teachers with the vicarious experiences needed to change their beliefs. While the literature suggests that mastery experiences are also important they were only mentioned by one student at the beginning and end of the course. This may have more to do with the writing prompts. This finding suggests future studies should ask preservice teachers to reflect on practicum more specifically in connection to the methods course.

In summary, it was learned that practices such as those modeled in reform-based mathematics methods courses lead to higher gain scores in the attitudinal survey given to one cohort of preservice teachers. Hill, Rowan, and Ball’s (2005) claim that reform-based mathematics instruction produces high quality early childhood/elementary teachers of urban students. Thus, pedagogy in the classes in this study was changed to engage preservice teachers in inquiry-based activities in order to enhance their conceptual knowledge and understanding. Future studies should examine the relationship between increased content knowledge, attitudes toward mathematics, and concepts of teacher efficacy. Improving both the mathematics content knowledge and attitudes of beginning teachers who choose to work with diverse populations should translate into improved mathematics learning and achievement among poor and urban students if teachers are also attentive to these students’ learning styles and culture (Leonard, 2008; Martin, 2007). The results of this study are promising. However, studies are acknowledged that span practices learned in teacher education programs to practices actually performed during induction that are needed to determine whether attitudes toward mathematics learned in reformed-based mathematics methods courses are sustained across time.

DEVELOPING PRE-SERVICE ELEMENTARY TEACHERS’ UNDERSTANDING OF COMPARING FRACTIONS USING A BENCHMARK

Jennifer M. Tobias
Illinois State University
jtobias@ilstu.edu

With the *Curriculum Focal Points* (NCTM, 2006) and other standards advocating for students to compare fractions using reasoning, it is increasingly important for teachers to understand this type of reasoning as well. This is not only for teachers to foster students’ development of understanding fractions as quantities, but also “to distinguish appropriate student strategies from those based on faulty reasoning” (Lamon, 2005, p.113). Though studies have documented the importance of using reasoning strategies when comparing fractions as opposed to using procedures (Behr et. al., 1984; Lamon, 2005), research has lacked in documenting the ways in which teachers develop this knowledge for themselves.

To determine the ways in which teachers develop this knowledge a semester-long classroom teaching experiment was conducted with a class of thirty-three pre-service elementary teachers. The study was conducted in a content course focusing on mathematics for teaching elementary school. Specifically, the research question was:

In what ways do classroom mathematical practices develop related to rational number?

This poster will highlight the results from this study regarding pre-service teachers’ development of comparing fractions using a benchmark. The results indicated that there were three different solution strategies that were presented by the pre-service teachers. These included comparing fractions to 1/2, comparing with an additive within relationship, and comparing using a whole number dominance strategy by only comparing numerators. After two days of instruction, the class determined that the only valid strategy of these was the strategy of comparing the fractions to 1/2.

By exploring misconceptions in conjunction with correct strategies the class was able to develop an understanding of why the benchmark strategy was acceptable, understood when the benchmark strategy would fail, and was able to expand this to include that any fraction can be used as a benchmark. Thus, allowing pre-service teachers to explore problem situations in which their reasoning can come to the forefront of classroom conversations supported their understanding in determining which reasoning strategies were mathematically correct or incorrect.

EXPLORING MIDDLE SCHOOL PRESERVICE TEACHERS’ MATHEMATICAL PROBLEM POSING

Alma Fabiola Rangel-Chavez
Texas A&M University
fabiolarangel@neo.tamu.edu

Problem solving plays an important role in the teaching and learning of mathematics. The National Council of Teachers of Mathematics [NCTM] Principles and Standards for School Mathematics suggested that teachers integrate problem solving into the context of mathematical situations by choosing specific problems, because they are likely to prompt particular strategies and allow for the development of certain mathematical ideas. However, the activity of problem generation is typically a more challenging and creative task than obtaining the solution itself (Kilpatrick, 1987). Problem posing allows students to generate or to reformulate new problems based on a given situation or problem (Gonzales, 1994). In addition, NCTM encourages teachers to incorporate problem posing as a means of instruction to engage students with problems involving higher-order mathematical thinking. Therefore, this study analyzes the effect of “What-If-Not” (WIN) strategy (Brown & Walter, 2005) on the types of problems pre-service teachers (PTs) generate based on a give problem. In addition, using a reflective journal, this study investigates PT’s perceptions on their problem reformulation process.

An open-ended mathematical problem was presented to 39 middle school PTs at a southwestern public university. Based on the given problem, PTs posed a new problem with the same or higher level of difficulty. Later, after three sessions of problem posing interventions, PTs were asked to reformulate the original problem using the WIN approach. A classification scheme adapted from Lavy and Bershadsky (2003) was used to categorize the problem posing statements in terms of problem types. Finally, content analysis was conducted on journal entries to investigate PT’s perceptions of their problem reformulation process. Results revealed that even when a wide range of types of problems were posed, the changes made were not significant. Major emphasis was given to numerical changes. However, the overall PT’s problem posing skills improved. Also, the findings from their reflective journals enabled the researchers to study the differences in PT’s perceptions in creating their own problems. Implications for mathematics teacher education are described.

FOSTERING PROBABILISTIC INTUITION THROUGH MULTICULTURAL GAMES OF CHANCE

Nirmala Naresh  
Miami University  
nareshn2@muohio.edu

Iris DeLoach Johnson  
Miami University  
johnsoid@muohio.edu

The Principles and Standards for School Mathematics (2000) strongly emphasizes the importance of teaching probability for students at all levels. Traditional instruction is often insufficient, and even has negative effects on students’ understanding of probability (Shaughnessy, 1992). Reform-based teaching methods call for inclusion of diverse games of chance to promote an individual’s understanding of probability.

For teachers to develop a strong, coherent and intuitive background for probabilistic reasoning among their students they need to possess strong content knowledge and pedagogical knowledge in this domain; moreover they should be aware of and be able to understand, identify, and overcome their own misconceptions related to probability (Fischbein & Schnarch, 1997). However, there is a dearth in literature that concerns teachers’ understanding of probability that can inform preservice and inservice teacher education programs. We devised a research study that attempts to fill in part of this gap by investigating preservice teachers’ (PSTs) understanding of probability as they explored multicultural games of chance (e.g. Lu-Lu, Ampe, Songish).

We will refer to the probabilistic thinking framework developed by Polaki and colleagues (2000) to analyze preservice teachers’ understanding of probability and their responses to the tasks based on the games. We engaged PSTs in a 4-week probability module that exposed them to multicultural games of chance. PSTs explored these games, collected, recorded and analyzed experimental data. Data included written student work, audio / video recordings of student engaging in simulations of the games, and pre test and post test responses. PSTs completed simulations of games, collected and analyzed experimental data, and engaged in meaningful conversations related to sample space, experimental and theoretical probability, and in certain instances, the law of large numbers. Preliminary data analysis highlighted PSTs’ difficulties associated with connecting and extending their prior knowledge of probability to new real-life contexts. In our poster, we will feature descriptions of games, probability tasks, and findings related to two of these games – Lu-Lu and Ampe.

INFLUENCES OF MATH CONTENT COURSES ON ELEMENTARY PRESERVICE TEACHERS

Fabiana Cardetti  Mary P. Truxaw  Cynthia A. Bushey
University of Connecticut  University of Connecticut  University of Connecticut
fabiana.cardetti@uconn.edu  mary.truxaw@uconn.edu  cindy.bushey@gmail.com

There is a general consensus that mathematical content knowledge (M-CK) is crucial for enabling elementary school teachers to effectively teach mathematics (Ball, 2003). However, it has been suggested that M-CK is not sufficient for elementary school teachers – it must be accompanied by mathematics pedagogical content knowledge (M-PCK) (Ball, 2003). In order to identify coursework that may promote M-CK and M-PCK, this study investigates confidence of M-CK and M-PCK of elementary preservice teachers (PSTs) who have completed mathematics content coursework designed for elementary teachers. Confidence with respect to M-CK and M-PCK was explored by comparing survey responses of PSTs who completed the identified math content courses (content, C-group) with those who did not complete them (non-content, NC-group). The survey included Likert items adapted from the Fennema-Sherman Mathematics Attitude Scale (Mulhern & Rae, 1998) and open-ended content problems designed to uncover both M-CK and M-PCK. This poster focuses on 19 PSTs (9 C, 10 NC) who completed both pre- and post-surveys prior to and after completion of a required math methods course. Likert items were analyzed using standard statistical techniques. Analysis of open-ended problems and additional interview data is in progress. Analysis of the Likert items indicated that the C-group reported greater M-CK confidence both pre- and post- methods course than the NC-group, but that the NC-group showed greater increases in M-CK confidence. Further, the results suggest greater M-PCK confidence by the C-group than the NC-group both pre- and post-methods course and that the C-group showed greater increases in M-PCK confidence than the NC-group. A conjecture is that PSTs going into a math methods course with greater M-CK (C-group) may increase their M-PCK confidence, and that this increase could be greater than those going in with less M-CK (NC-group). The NC-group’s gains in M-CK confidence and relative lack of gain in M-PCK confidence from pre- to post-methods course may suggest that their attention was focused on mathematics content over teaching methods or student learning. A possible implication is that math content courses designed for elementary PSTs may enhance learning outcomes of math methods courses by providing sufficient M-CK to allow the PSTs to focus their attention, during the methods course, on the teaching methods and the student learning related to the mathematics. Without these math content courses, the PSTs’ attention toward student learning and mathematical teaching may be diluted.

INTERACTIONS BETWEEN A PRE-SERVICE ELEMENTARY SCHOOL TEACHER’S CONCEPTIONS OF DECIMAL VALUES

Krista Heim  
Portland State University  
kheim@pdx.edu

Eva Thanheiser  
Portland State University  
evat@pdx.edu

Research has shown that pre-service teachers struggle with the concepts of decimal numeration and decimal place values (e.g., Stacey et al., 2001). In order to help pre-service teachers develop a stronger conceptual understanding of decimal numbers in teacher preparation courses, we must continue to try to understand their current conceptions about decimals and how those conceptions play out in various contexts (Bransford, Brown, & Cocking, 1999).

Two incorrect conceptions have been identified in the literature: 1) associating decimal numbers with negative numbers (Stacey et al., 2001) and, 2) increasing powers of ten for each consecutive place value to the right of the decimal point (Zazkis & Khoury, 1993). Our research considered the interactions of these two conceptions.

The data analyzed for this report are drawn from a 60-minute one-on-one, task-based interview with one pre-service teacher, Sarah. The analysis focused on characterizing Sarah’s conceptual understanding. Results of this analysis suggested that Sarah holds the two incorrect conceptions described above and that these misconceptions can interact to produce correct answers on decimal value comparison tasks. For example, in her interview, she correctly indicated that .01 is less than .9. However, her reasoning was as follows: 1) both numbers are less than zero (associating them with negative numbers) and 2) that .01 is “one more” than .9 (like 10 is one more than 9 in base ten). Combining these two conceptions, she argued that .01 is less than .9 because the value comparison is reversed. She used similar reasoning to justify that .606 is less than .66.

This case study is reminiscent of previous research results that have established the idea that correct answers are not necessarily an indicator of correct conceptual understanding (e.g. Erlwanger, 1973). This case adds to the research literature because this particular interaction of conceptions is previously unreported. This result can be used to inform future research and improvements to teacher education on decimal numbers.

PRE-SERVICE TEACHERS’ DETACHED VIEWS OF MATHEMATICS

Rong-Ji Chen
California State University San Marcos
rchen@csusm.edu

In his review of research on mathematics teachers’ beliefs and affect, Philipp (2007) emphasizes the importance of teacher affect in mathematics teaching and learning. But there is a lack of research on teachers’ affect. While there are many dimensions of affect, I focus on the relation of subjectivity between mathematics and teachers as learners of mathematics. I ask the following questions: What do pre-service teachers (PSTs) perceive as their relationship with mathematics? How do they perceive themselves as learners of mathematics? To what degree do they find personal meaning and purpose in learning mathematics?

These questions arise in the literature on teacher affect and critique of current education policy and discourse in many Western countries (e.g., Greene, 1988). In the field of mathematics education, there is a loss of professional-ethical autonomy, and teachers are increasingly represented as objects rather than as subjects in policy discourse (Neyland, 2004; Walshaw, 2004). Therefore, it is important to understand how PSTs construct their subjectivity in relation to learning and teaching mathematics.

This is an on-going investigation into pre-service elementary school teachers’ development of ethical selves as learners and teachers of mathematics. The first phase of data were collected from 22 PSTs in a mathematics methods course, including drawings of what mathematics was to them, definitions of mathematicians, and reflection papers on their schooling experience with mathematics.

The most salient theme was that a significant majority of these PSTs alienated themselves from a meaningful and purposeful process of learning mathematics. They regarded mathematics as an external instrument for agendas set by others. They judged their learning and achievement in mathematics by recourse to external evidence such as grades and comparisons with peers. At stake was their power to pronounce personal meanings and purposes. I will share selected teachers’ drawings of mathematics and reflections on their learning experiences. I will also discuss the implications of the findings in relation to prevalent mathematics education discourses, in which the Platonic view of mathematics is the norm.

twhuang@mail.ncyu.edu.tw  bmiran@siu.edu

A recent international survey of student achievement, Trends in International Mathematics and Science Study (TIMSS), shows that that several Asian countries continued to greatly outperform the United States in math. Fourth-grade students in Hong Kong and eighth-grade students in Taiwan are the world's top scorers in math, according to the survey (TIMSS, 2007). However, studies of international comparison among pre-service teachers in math achievement are limited.

The present study focused on the comparison of Taiwanese and US pre-service teachers in procedural and conceptual knowledge (Hiebert & Lefevre, 1986). We were seeking to understand the strength and weakness of pre-service teachers’ knowledge of fraction operations in both countries.

The participants in the U.S. sample were enrolled in a teacher education program at a mid-western university. Fifty pre-service teachers, who were preparing to teach children in grades K-8, participated in this study. They were in their third year of study. The Taiwanese sample was similarly selected. The Taiwanese sample consisted of 47 pre-service teachers enrolled in a teacher education program at a university in central Taiwan.

Results indicated that Taiwanese pre-service teachers performed better in procedural knowledge on fraction operations than American pre-service teachers. No significant differences were found for conceptual knowledge on fraction division. Further, the correlation in this study showed that both Taiwanese and American pre-service teachers’ conceptual and procedural knowledge of fraction operations were weak.

REAL-LIFE CONNECTIONS: PROSPECTIVE ELEMENTARY TEACHERS’ PERCEPTIONS REFLECTED IN POSING AND EVALUATING STORY PROBLEMS

Ji-Eun Lee
Oakland University
lee2345@oakland.edu

The study explored perspectives of a group of prospective elementary teachers’ on real-life connections through posing story problems and evaluating the quality of sample story problems. The goal was to identify prospective teachers’ perceptions about teaching and learning mathematics in relation to real-life connections in an explicit way and to gain deeper insights into their current perceptions.

The analysis of data from 71 prospective elementary teachers, while they engaged in the posing and evaluating story problems, revealed the following results:

- **Positive beliefs with insufficient specifics.** Participants demonstrated predominantly positive beliefs about the purpose and effective use of real-life connections. However, the criteria that the participants proposed included very few specifics about their understanding of what it might take for teachers and students to incorporate real-life connections into their teaching and learning processes.

- **Themes on the paradigmatic-narrative spectrum.** In categorizing the themes identified by participants as “criteria for real-life connected story problems” I relied on the paradigmatic-narrative framework Chapman (2006) and Depaepe et al. (2009). Analysis indicated that the narrative-oriented responses were more dominant than the paradigmatic-oriented responses among the participants of this study.

- **Reality: How real is real?** Although, participants possessed strong beliefs about importance of reality in story problems. However, their story problems and their evaluation of peers’ problems revealed a vast discrepancy between how reality was defined and accepted by the them.

- **Utilitarian view.** The majority of participants perceive that real-life connection has a value because of its usefulness. Considering the role of story problems as the interplay between mathematics and reality, the participants’ perspectives were extremely unbalanced.

- **Noted gaps.** The story problems participants posed did not reflect their perceived beliefs on real-life connections. This suggests that prospective teachers were aware of the importance of utilizing real-life connections in their teacher education programs at the general level, yet they were not fully exposed to the teachers’ thinking process for the implementation of real-life context in mathematics education.

RETHINKING “UNLEARNING” TO TEACH MATHEMATICS: QUESTIONS FOR MATHEMATICS TEACHER EDUCATORS

Aaron Brakoniecki
Michigan State University
brakoni1@msu.edu

In Deborah Ball’s 1998 piece “Unlearning to Teach Mathematics”, she presents the case that preservice teachers do not enter their programs as empty sponges that will absorb and expel only information that is presented to them in teacher preparation. Instead they are a group of diverse learners who, before ever stepping into the classroom as teachers, have previous knowledge and have had prior experiences that can influence their views on teaching (Ball, 1988). However, at several points in this article, the previous experience is presented as obstacles for the preservice teacher classroom. This poster hypothesizes what a teacher education classroom might be like if, instead of obstacles, these previous experiences are treated as opportunities for learning about teaching mathematics.

This poster begins by briefly looking at what current research tells us about teacher preparation and teacher learning, based on Sowder’s chapter in the second handbook of research on mathematics teaching and learning (Sowder, 2007). Next, we present a sample of preservice teacher responses to mathematics teaching scenario prompts (Brakoniecki, 2009). This poster asks teacher educators to imagine these preservice teachers are in their mathematics methods courses and how they could incorporate their beliefs and knowledge about teaching mathematics into their methods courses. Lastly this poster presents different ways of responding to the preservice teachers’ responses to the prompts: one set if the classroom treats these experiences as obstacles, and one set if the classroom treats these experiences as opportunities.

Successful teacher preparation programs provide learning experiences that help candidates make the shift from "student" to "teacher." In this paper we explore a process for providing candidates such experiences. Utilizing the MATH process, prospective high school mathematics teachers explore rich tasks by solving the task, analyzing sample student work, designing a solution key and modifying the task. We use their engagement in these explorations and reflections on the process to analyze the development of candidates’ Content Knowledge and Pedagogical Content Knowledge.

Introduction

[I] solved the problem algebraically and hadn’t thought of another way doing so  
[A Teacher Candidate, EDT 430]

Successful teacher preparation programs provide learning experiences that encourage candidates make the shift from "student" to "teacher." This is not an easy transition, particularly for future school mathematics teachers. This transformation is often complicated by the fact that candidates’ interest in mathematics and self-efficacy regarding mathematics arises from their personal success in solving complex problems. Over the past several years, we have developed a five-step approach for examining rich content tasks with preservice teachers. The approach, which we refer to as the Mathematics as Teacher Heuristic (MATH), is designed to encourage candidates to shift their mathematical view from a student orientation to one embracing teacher-oriented perspectives. The MATH process requires candidates to revisit rich mathematics tasks from points of view rarely considered in content-oriented coursework. Candidates complete a five-step process that includes (a) solving a rich task as a student; (2) assessing student work samples associated with the same task; (3) constructing "classroom ready" solution keys for students; (4) developing scaffolded instructional materials addressing student misconceptions (gleaned from earlier analyses); and (5) reflecting on the process. Each step of the MATH process encourages candidates to reconsider rich tasks from increasingly teacher-centric points of view. Assessing student work and constructing solution keys are activities that encourage candidates to consider rich tasks from the perspective of younger learners.

Ultimately, the instructional materials that candidates create as part of the MATH process are shared with practicing teachers and their students. By creating work for audiences beyond the university classroom, candidates find the work more meaningful. As they construct solutions and materials for classroom teachers and their students, candidates recognize that "finding an answer" is no longer the central purpose of their mathematical work. Rather, problem solving is situated in the context of helping students learn mathematics (a teacher-oriented behavior rather than a student-oriented one). As candidates construct learning materials, they discuss mathematics content in the methods classroom from a learner’s viewpoint. The approach provides a useful basis to analyze the development of candidates’ Pedagogical Content

Knowledge (PCK) (Shulman, 1986), combination of Content Knowledge (CK) and Pedagogical Knowledge (PK).

In this paper, we analyze the work of one group of pre-service teachers as they explored a rich mathematics task using the MATH process. In particular, we examine candidates' analyses of student work, their solution keys, their modifications of the task and their reflections and insights on the MATH process as a whole.

**Related Literature**

Models for understanding the transition from "student" to "teacher" focus on dissonance and motivation in school settings, factors that occur regularly for in-service teachers in their day-to-day practice (Clarke & Hollingsworth, 2002; Edwards, 1994). Clarke and Hollingsworth (2002) and Loughran (2002) stress the importance of self-reflection in the development and evolution of teacher knowledge, beliefs, and attitudes. We believe that pre-service teachers need to experience similar dissonances in university coursework order to accept the need for change and reflect on their change process. Providing such opportunities for change and reflection is, perhaps, more difficult in the case of pre-service teachers at the very beginning of their course of study since they have fewer authentic teaching experiences to draw upon. Studies show that two main sources for dissonance in initiating candidate growth are in methods courses and student teaching.

Brown and Borko (1992) argue that there are three important issues in the process of "learning to teach;" namely, (1) the influence of the content knowledge, (2) novice's learning pedagogical content knowledge, and (3) difficulties in acquiring pedagogical reasoning skills. Furthermore, they assert that “one of the most difficult aspects of learning to teach is making the transition from a personal orientation to a discipline to thinking about how to organize and represent the content of that discipline to facilitate student understanding” (p. 221). In a case study of one teacher’s successful transition from student to teacher, Velez-Rendon (2006) identified a complex interplay between many factors during this transition including “the learning background the participants brought with her added to her knowledge of the subject matter” (p. 320). Similar to Brown and Borko’s (1992) results, Velez-Rendon concluded that the preparation of the subject matter for instruction was challenging for the student teacher.

Another related issue is the “tension between participants’ views of themselves as adult learners of mathematics and their practice with young children” (Brown and Borko, 1992, p. 215). Ball (1989) studied the role of a methods course for elementary mathematics teachers in helping candidates to learn to teach. Ball highlights the importance of content knowledge and the experiences of pre-service teachers as learners of mathematics. “Unless mathematics teacher educators are satisfied with what prospective teachers have learned from their experiences as students in math[ematics] classrooms (and most are not), this highlights a need to interrupt, to break in, what is otherwise a smooth continuity from students to teacher” (p. 4). In this sense, we see Ball’s suggestions to break with experience as an opportunity to create a dissonance.

Loughran (2002) explored the development of knowledge through effective reflective experience from student teacher to experienced teacher, comparing candidates’ views of teaching and learning with those of practitioners. Candidates' views regarding teaching and learning typically equated learning “with gaining right answers” (p. 41). This naive view of teaching contrasts markedly with teacher comments that emphasize the importance of “student . . . opportunities to be active and think about their learning experiences” (p. 41). Loughran's study illustrates the importance of giving prospective teachers opportunities to face their views, reflect
Moving from the back of the table to the front of the blackboard is not a smooth or simple journey. Pre-service teachers carry the baggage of their previous experiences obtained as students. Those experiences affect not only their journey and their content knowledge but also their beliefs, views, attitudes, and values. A candidates' affective domain influences how they utilize their own knowledge (content knowledge (CK), pedagogical knowledge (PK) and pedagogical content knowledge (PCK)) in classrooms and in their journey. How, then, can we help our pre-service teachers to distance themselves their student identity during their methods courses? We believe that a partial answer exists in reflective problem solving activities embedded within the MATH process.

Methodology

Participants

Participants in this study were candidates enrolled in EDT 430, the second course in a year-long methods sequence designed for prospective secondary mathematics teachers. Twenty-three of the 29 participants were undergraduates; six were graduate students who had returned to school seeking teacher licensure in secondary mathematics education. In the previous methods course (EDT 429), candidates spent significant time solving rich mathematics tasks as students. The intention of problem solving experiences in the first semester was two-fold, namely (1) to reintroduce the content of secondary school mathematics to candidates and (2) to communicate to candidates the notion of "rich" mathematical tasks.

In the follow-up course (EDT 430), we revisit a subset of these rich tasks with teacher candidates using the five-step MATH process. In the paragraphs that follow, we explore data generated through the exploration of one such task, namely the Bridgewater Problem. We analyze data generated from the task using a blend of quantitative and qualitative methods.

Candidate Tasks

Candidates solved the problem presented below in the first semester methods course.

Using the MATH process, we asked the candidates to complete the following tasks related to the Bridgewater Problem either in pairs or individually.
Results

In our analysis, we focus on Tasks 2 – 5 of the MATH process assignment. As previously mentioned, each step of the process encourages candidates to reconsider rich tasks from increasingly teacher-centric points of view. In Task 2, candidates begin to think about the problem from another person’s perspective. Task 3 requires candidates to internalize the idea of other perspectives and incorporate other viewpoints into their own work. Task 4 provides candidates with an opportunity to reconfigure the problem to guide/scaffold exploration by the student.

Analyzing Student Work

Whereas teacher candidates tend to solve the Bridgewater task in fairly similar ways - typically using rates and variables to construct functions and equations that may be solved to determine an answer - high school students use a wide array of approaches. Candidates' extensive experience with symbolic forms and function in their recent studies of calculus make it difficult for them to "see" numerical or geometric approaches such as those depicted in Figure 2.

Reflection on the Analysis of Student Work

We had never had an experience like this where we were critically thinking about students’ solutions, and this skill can be very helpful as we become teachers in the future. [Teacher Candidate, EDT 430]

Although many candidates were familiar with the notion that students solve problems in different ways, nevertheless many expressed surprised upon seeing the variety of solutions that students created for the Bridgewater problem. Nineteen of 20 reflections included comments expressing the sentiment that “after examining the student work it occurred to me that not only are there multiple ways to solve the problem, but there are different ways within the same basic approach.”

As candidates take initial steps towards becoming a teacher, they begin to realize that nothing is clear-cut and that there are no “cookie cutters.” Eight of 20 groups discussed difficulties they experienced during the interpretations of student work. Until this point candidates had only considered their own work and thought processes. The transition to teacher isn't easy. As one candidate noted, “Many of the solutions were hard to follow at first because of their seeming lack of logical procession...we did not expect to see the vast array of methods that the students used, none of which approached the problems in the same way that we did.” It was apparent that students’ reasoning was different from that of the prospective teachers. Eleven groups mentioned a similar issue. Some groups discussed their way of thinking or their solution and compared this to the students’ ways of thinking or solutions. Other candidates mentioned the need to be more aware of different solutions not just think about their own.

"We solved the problem algebraically and hadn’t thought of another way doing so. The project showed me that as future teacher I need be aware of any and all possible solutions for a problem, because I’m bound to have at least one student who takes that approach". [Teacher Candidate, EDT 430]

Candidates also discussed more practical issues regarding the analysis of students’ work. Five groups were surprised to see how much time it took to grade students’ assignments and the need for rubrics: “In a sense the task introduced us to the reality of being a teacher, such that we are going to have to face the fact that the grading and the understanding of each individual student’s work will take a significant of time.”

Creating an Answer Key

As prospective teachers, the participants rely on their previous experiences as learners when developing solution keys for students to follow. Although candidates were told that "classroom ready" keys would be shared with students and their teacher, the candidates' work resembled exam or graded homework solutions more than materials produced for younger learners. Several common weaknesses common in candidate solution keys including the lack of student guidance
and scaffolding, complicated or incomplete use of mathematical notations, and ambiguous text accompanying mathematical notation. Several examples are provided in Figures 3-5.

*Lack of Guidance/Scaffolding.* Prospective teachers did not provide detailed explanations of how they built the mathematical model to solve the problem. Participants also failed to provide a detailed explanation regarding what the mathematical formulas or variables stand for in their models.

*Incomplete Mathematical Notation.* In the solution key in Figure 3, the candidate explains variable t, however, the reader is left to guess what m, n and D represent.

![Figure 3. Solution Key with incomplete mathematical notation](image)

*Problems with Mathematical Notations.* Many prospective teachers failed to pay adequately close attention to labeling the units. They also chose to use complicated mathematical terms instead of contextual names. Figure 4 shows the work of a candidate who chose to label the columns of their table with vague descriptors.

![Figure 4. Solution Key with Vague Mathematical Labels](image)

The use of non-standard variables and inconsistent use of variables were the other issues that might complicate the answer keys that prospective teachers provided for their future students. Figure 5 shows an answer key with variables defined using superscripts. Here the use of superscripts is ill-advised since they look like exponents, which will likely confuse students.

Reflection on the Creating a Solution Key

In discussing their experiences in the development of the solution key, candidates identified the main struggle as deciding how to cater to the diverse body of students without providing multiple keys. As one candidate noted, “we also learned that it would be difficult to create an answer key based off of one method. It is impossible to use all the methods to make an answer key, but by choosing only one method it feels as though we are leaving out so much great work that the students could learn from.’ Clearly, the creation of a solution key provided another experience for the candidates in thinking not just about how they would do a problem but how others would do the problem and how they would evaluate and assess that work.

Modification of the Worksheet

We believe that when preparing a worksheet for students, candidates were more pedagogically oriented than was the case with their solution key preparation. For instance, candidates asked students to explain their answers in their revised materials. One group asked students to use technology to solve the problem. Another group included a rubric for their students to show how different parts of the problem were going to be evaluated differently. Two groups focused on helping students to extend the solution for different rates. Nevertheless, there were still some problems with some of the worksheets that prospective teachers created. For instance, many worksheets included vague questions, variables, or tables. A particular instance was a worksheet asking students to create respective formulas for the hikers but was not clear which distance was to be used: “Now create two formulas using distance and time to find George and Peter’s rates.” Not using units, the choice of seemingly arbitrary distances, and the use of non-standard variables were recurrent problems.

Candidates’ Reflection on Modifying the Task

In reflecting on their worksheet design some candidates discussed their struggle to balance the information provided in the worksheet to guide students while not revealing the answer but also serving the students with diverse learning styles and at different achievement levels with clarity.

Revising the worksheet was a challenge for me…I tried very hard to make sure that students are given hints, examples, and even answers if they look hard enough. [Teacher Candidate, EDT 430]
The creation of the new hand out we made forced us to consider the student perspective. This allowed us to read what we created as a student might, which allowed us to troubleshoot our worksheet by making it more clear what we wanted student to do through the use of unambiguous language and very clear directions. [Teacher Candidate, EDT 430]

The last quote above provides evidence of the change that some pre-service teachers underwent through the creation of a worksheet with students firmly in mind.

Discussion

Recall that Brown and Borko’s (1992) identified three important issues associated with the process of “learning to teach” namely, the influence of the content knowledge, novice’s learning pedagogical content knowledge, and difficulties in acquiring pedagogical reasoning skills. The task in which the participants in this study were engaged promoted development in each of these areas. The candidates Content Knowledge (CK) is engaged not only in solving the problem themselves but through the analysis of numerical, geometric and functional approaches to solving the problem in addition to the algebraic approach on which most of them relied.

Their Pedagogical Content Knowledge (PCK) is engaged both in their attempts to create a solution key and their reconfiguring of the problem as an exploration task. For both of these tasks the candidates had to engage with the idea of how someone else is thinking about the problem, how to anticipate other peoples responses and how to design a task which can account for many approaches not just their preferred one. “Not only can students learn from teachers, but we both learned a lot from these students.” Finally, Pedagogical Reasoning Skills are engaged throughout, particularly in Task 2, the analysis of student work, where the candidates have to reason through and understand a students’ thinking and think about how they could discuss the solution with the student. "Even though we are becoming teachers all of our classes so far … have never let us experience the role as a teacher … This was the first real chance we had to look at student work." These pre-service teachers were beginning to be able to see themselves getting up from the chairs and going to the in front of the classroom.

We believe that all five tasks in this project taken together provide a powerful mechanism for providing a candidates with a dissonant experience which forces them to reflect on their own understanding of mathematics but, more importantly, provides a framework to move prospective teachers from doers or learners of mathematics to being teachers of mathematics.

References

The aim of this research report is to analyze and document problem-solving approaches that prospective high-school teachers exhibited while using a dynamic software (Cabri-Geometry) to represent and explore textbook problems. Research questions that helped us structure the development of the study include: What type of questions do teachers pose and pursue during their interaction with the problems? To what extent their initial problem solving strategies are enhanced through the use of the tools? To what extent does the use of the tool help them identify and examine possible instructional routes to guide the development of their lessons? Results indicate that the use of the tool helped them visualize, explore, and present a set of new mathematical relations that open up new avenues to frame learning activities for students to construct mathematical knowledge.

Introduction

The National Research Council (2001) suggests that mathematical tasks are important for teachers and students to develop mathematical proficiency. Here, learner’s mathematical proficiency is conceived of as the learner’s development of a network of five interwoven and interdependent strands: (a) conceptual understanding that involves the learners’ construction of a web connections and meanings of concepts and ideas that allow them to develop a coherent an integrated mathematical knowledge; (b) procedural fluency that refers to the efficient access and use of procedures, rules and skills in problem solving activities; (c) strategic competence that involves the learners’ tendency to formulate questions, conjectures, and new problems that need to be represented and explored in different ways and by using diverse media including computational tools; (d) adaptive reasoning refers to the learners’ tendency to look for different arguments, including formal ones, to support and communicate mathematical relations or results; and (e) productive disposition that refers to the learners tendency to conceptualize mathematics as worthwhile discipline and useful and helpful to comprehend social and disciplinary phenomena. In this context, an important goal for teachers, while working on tasks, is to discuss that the extent to which the process involved during their interaction with the problems help them develop and reflect on mathematical activities associated with the proficiency’ strands.

In this context, the significant development and availability of computational tools such as dynamic software and hand calculators open up several ways to promote problem-posing activities in mathematical classrooms (Santos-Trigo, 2007).

Regardless of the particular tools that are used, they are likely to shape the way we think. Mathematical activity requires the use of tools, and the tools we use influence the way we think about the activity…[Understanding] is made up of many connections or relationships. Some tools help students make certain connections; other tools encourage different connections (Hiebert, et al, 1997, p.10).

In this study, we document and analyse the extent to which the use of a dynamic software helps teachers represent and explore textbooks problems dynamically. In this context, there is
interest to discuss ways in which teachers identify or construct a set of mathematical relations as a result of exploring the task dynamically. In particular, we document the extent to which the use of the tool helps teachers identify and explore potential instructional routes to structure the development of their lessons.

**Conceptual Foundations**

The conceptual support of a problem-solving approach relies on recognizing that teachers’ development of mathematical teaching knowledge could be promoted within an intellectual community that fosters an inquiring or inquisitive approach to mathematical tasks or activities. Tasks are considered a key component in promoting students’ construction of conceptual webs or networks, and developing a set of flexible strategies to be engaged in problem-solving behaviors. (Gueudet 2007) stated that: “Grounding a teaching design [focusing on knowledge organization and the development of different forms of problem solving strategies] should comprise a variety of tasks, allowing development of different solutions, in order to foster a form of students’ mathematical autonomy … Working with technological devices such as dynamic geometry environments, but also computer algebra systems … can be helpful in fostering flexibility” (p. 242). Learning mathematics and developing mathematical knowledge are processes that can be framed in terms of a set of dilemmas or problems that need to be represented, explored, and solved through the use of mathematical content or resources. A mode of inquiry involves challenging the status quo, and it demands a continuous reconceptualization of what is learned and how knowledge is constructed. Jaworski (2006) stated that “[in a community of inquiry] participants grow into and contribute to continual reconstitution of the community through critical reflection; inquiry is developed as one of the forms of practice within the community and individual identity develops through reflective inquiry” (p. 202). This process also can be used as a vehicle to construct new relations or to identify new routes to reach or reconstruct classic mathematics results (Santos-Trigo, 2008). This type of teachers’ interaction becomes relevant to foster and develop a problem-solving approach that involves:

*Seeing the mathematical content in mathematically unsophisticated questions, seeing underlying similarity of structure in apparently different problems, facility in drawing on different mathematical representations of a problem, communicating mathematics meaningfully to diverse audiences, facility in selecting and using appropriate modes of analysis (“mental”, paper and pencil, or technological), and willingness to keep learning new material and techniques (Cohen, 2001, p. 986).*

The use of computational technologies offers teachers and students the opportunity to participate in activities for:

*(a) gaining insight and intuition, (b) discovering new patterns and relationships, (c) graphing to expose mathematical principles, (d) testing and especially falsifying conjectures, (e) exploring a possible result to see whether it merits formal proof, (f) suggesting approaches for formal proof, (g) replacing lengthy hand derivations with tool computations, and (h) confirming analytically derived results (Borwein & Bailey, 2003, cited in Zbiek, Heid, & Blume, 2007, p. 1170).*

---

In this context, the use of computational tools becomes important for the community, not only to better identify and explore mathematical results, but also to discuss pedagogical paths associated with the potential instructional routes that can be useful for teachers to guide or orient their instructional practices.

Methodology

Six high school teachers participated in 3 hours weekly problem-solving sessions during one semester. The aim of the sessions was to select, design and work on a set of problems that could eventually be used in actual instruction. In this process, all the participants had opportunities to reveal and discuss their mathematical ideas openly and use both dynamic software and hand-held calculators to solve the problems. The idea was that the participants became familiar with the use of the software by representing themselves directly the mathematical objects dynamically. In addition, they also explored possible instructional routes to frame their lessons. While solving and discussing all the problems, themes related to curriculum, students’ learning, and the evaluation of students’ mathematical competences were also addressed.

During the development of the sessions, the participants worked on the problems individually and in pairs. And later, they presented their work to the whole group. In general, the instructional activities were organized around a particular pedagogic approach in which the participants were encouraged to use an inquisitive approach to deal with the problems. As Jaworski (2006) indicates:

*It [the instructional approach] is a social process in the sense that a participant is a member of a community (e.g., of teachers, or of students learning mathematics) with its own practices and dynamics of practice which go through social metamorphoses as inquiry takes place. It is an individual process in that individuals are encouraged to look critically at their own practices and to modify these through their own learning-in practice (p. 2002).*

Data used to analyze the work shown by the participants come from electronic files that they handed in at the end of the sessions and videotapes of the pair work and plenary sessions. In addition, each participant, at the end of the semester, presented the collection of problems and results that they had worked throughout the sessions. Here, it is important to mention that, in this study, we are interested in identifying and discussing problem solving approaches that emerge while the high school teachers use computational artifacts rather than analyzing in detail individual or small groups performances.

Results

We focus on analyzing what the participants showed while working on a task that is representative of the types of problems discussed during the sessions.

The task: Given two intersecting lines in the plane, find the geometric locus of all points whose sum of the distance from each point, on that locus, to the two lines is equal to a given length.

Comprehension of the task

All the participants read the statement and began to identify relevant objects to make sense of the problem. The questions that they posed and explored in this process involved: What does it mean

that the sum of the distances from a point on the locus to the lines is constant? How can we calculate the distance from a point to a line? Can the given length be any given number? What happens when the two intersecting lines are perpendiculars? The discussion of these types of questions led the participants to represent and visualize the problem in different ways. Indeed, those who used the software to represent the problem differed in ways to introduce the given length. Two participants drew initially a segment to represent the given lengths while two defined the constant from calculating the sum of the distances between a point (assuming that it was situated on the locus) and the two given lines (Figure 1 & 2). Two participants followed an algebraic approach in which it was not necessary to identify the constant length explicitly.

\[ \text{Formally, the two ways to identify or introduce the constant represent different initial conditions of the statement. Figure 2 relies on considering point P on the locus and from that point to calculate the constant, while in figure 1, the constant is given by the length of the segment and the problem is reduced to find the locus related to that length.} \]

**Initial approaches and particular cases**

The participants who used the dynamic software to represent the objects embedded in the problem, showed diverse paths to approach empirically the problem. For example, Hugo constructed Figures 3 and 4 to identify empirically the solution. In Figure 3, L and L’ are the given lines and point O their intersection. The length of segment AB is the given constant. On segment AB, he situated point Q such that \( d(AQ) + d(QB) = d(AB) \). From point P, he drew a perpendicular line to L’ and a circle with center P and radius AQ. This circle intersects the perpendicular at point C. He also drew a circle with center C and radius QB and a perpendicular to L from point C. The circle and the perpendicular intersect at point D. The loci of points C and D when point P is moved along line L’ are parallel lines (\( m \) and \( m’ \)) to L’ and line \( m’ \) intersects line L at point D2. From D2, he drew a perpendicular line to L that cuts line \( m \) at point C2. From C2, he drew a perpendicular line to L’ that cuts line L’ at P1. From the construction \( d(C_2, D_2) + d(C_2, P_1) = d(Q, B) + d(Q, A) = d(A, B) \). That is, point C2 is on the locus. What is the locus of point C2 when point Q is moved along segment AB? This question led Hugo to identify that segment EE1 is a partial solution to the problem (Figure 3). Later, by using arguments of symmetry, Hugo identified the rectangle EE1FG as the complete solution to the problem (Figure 4).

Victor used the dynamic software to draw lines L and L’ and a point Q in angle LOL’. He drew the perpendicular segments from point Q to both lines and found that the sum of the lengths of the segments was 4.04 cm. Hence, he used the number 4.04 as the constant (given length) and identified point R (by moving it) such that \( d(R, B) + d(R, B’) = 4.04 \) with segments RB and RB perpendicular to L’ and L respectively. Later, he drew a line QR which intersects line L and L’ at point S’ and S, and point P on that line, and he observed that when point P is moved along
segment SS', it holds the condition of the locus. That is, segment SS' is the partial solution to the problem.

**Figure 3. Partial solution to the problem.**

**Figure 4. The locus is a rectangle.**

**Figure 5.** Empirical approach to the problem

**Initial representations and approaches to the task**

Two participants who relied on an algebraic approach to the problem began by assuming that lines L and L' coincide with axis X and Y of a Cartesian system and that the condition of the problem could be expressed as $|x| + |y| = k$. They graphed this expression and concluded that the solution was a square. Similarly, James explored the case in which both lines are perpendiculars and their intersection is the origin O. Here, he assumed that the constant was 4 units and located two points B(4, 0) and C(0,4) on the locus. He noticed that all points on the hypotenuse of right triangle PBC also were part of the locus and concluded that the solution to the problem was the square BCJH (Figure 6).

**Figure 6.** Graph of $|x| + |y| = 4$.

---

The identification and exploration of mathematical relations

At this stage, all the participants recognized that the locus was a rectangle; however, they were aware that it was important to provide an argument to support their conclusion. To this end, Hugo and James found that the length of the given constant was the length FI that corresponds to a height of triangle DOG. Based on this observation, Hugo mentioned that to prove the conjecture it was sufficient to show that “for any isosceles triangle ABC with AB \neq AB = BC, it is held that for any point on segment AB, then the sum of d(P, E) + d(P, D) is constant”. To show this, Hugo relied on using that triangles ABC and PFP1 are similar and that triangles PBF1 and PEP1 are congruent and also that BF is the height of triangle ABC (Figure 10).

The participants also provided an algebraic proof by calculating the sum of the distances from the point to both lines and making the sum equal to four. In this case L is axis X y L’ is the line y = x (Figure 11).
Connections and generalizations

During the plenary discussion, the participants identified and explored three related problems: (i) Given two lines (L, L’) that get intersected at point O, find the locus of points P whose difference of distances to the lines is a constant k. (ii) Given two lines that get intersected at point O, determine the locus of the points whose product of the distances from the point to both lines is a constant \(k\). See figure 12. (iii) Given two lines L and L’ that get intersected at point O, find the locus of the points P whose quotient of the distances from that locus to both lines is a constant \(k\). The participants explored the three cases and identified interesting mathematical relations. For instance, Figure 12 shows that the locus in case (ii) is a hyperbola.

Another connection emerged when James presented to the group the case where the locus was identified as the hypotenuse of a right triangle. Here, the lines were perpendiculars and their intersection point O was the origin of the coordinate system (Figure 6). Hence, the participants noticed that the constant (5 units) could be associated with the perimeter of a family of rectangles inscribed in that triangle. That is, from each point on the hypotenuse it could be drawn a rectangle and asked from that family of rectangles (having the same perimeter of 5 units) where to locate that which has the maximum area. The response was when the coordinates of the point on the hypotenuse were (2.5, 2.5).

Discussion

The participants recognized that the initial comprehension of the task was crucial to represent the problem in terms of mathematical objects. Two empirical approaches emerged during the process of making sense of the problem statement: One in which the participants assumed one point on the locus and from that point the constant length was determined as the sum of the lengths of the perpendicular segments to each line, and the other in which the participants relied on the given length to identify a point on the locus. The latter approach became important to construct a dynamic representation of the problem in which concepts of perpendicularity, parallelism, and loci appeared relevant to find the solution. At this stage, the participants pointed out that it is essential for teachers to spend significant time discussing with their students not only the ways in which they make sense of the problem; but also the strengths and limitations of emerging approaches. For example, when the participants presented the algebraic approach, they focused on discussing where to locate the Cartesian system, so that the algebraic operations involved could be simplified. They recognized that the dynamic representation of the problem
offered them an opportunity to identify relations that were not present in the algebraic approach. For example, they noticed that the given length (constant) represented the height of an isosceles triangle that was formed with the diagonals and one side of the rectangle (the locus). In addition, when they moved the given lines to form a right angle, they noticed that the locus was a square. The participants recognized that the presentation and discussion of the individual approaches to the problem within the group led them to conceptualize the problem as an opportunity for them to visualize and explore diverse routes to solve the problem. For example, the initial empirical representation was important to visualize the locus as a segment, the dynamic approach became relevant to identify the rectangle as the locus and later the algebraic approach led them to examine the relation between the dynamic and the algebraic approaches. In general, all the participants agreed that working on the problem and discussing the emerging approaches was an interesting activity that could help them to identify crucial decisions or problem solving stages that they need to take into account during the organization of their instructional activities. In particular, they mentioned that the use of dynamic software offered them the possibility of identifying a particular mathematical relation (invariance or locus) that later could be explored numerically. Here, the dynamic approach unveiled interesting relations that were not visible in the algebraic approach to the problem. As a consequence, the participants agreed that their students should have opportunities to use computational tools to represent and examine relations from diverse perspectives. In general, several problem-solving strategies (dynamic models, use of particular cases, searching for loci, etc) seemed to be enhanced with the use of those tools. In addition, the use of the dynamic software helped them construct an argument to support conjectures or relations that emerged during the empirical approach to the problem. Finally, we argue that high school teachers need to participate directly in problem solving activities where they have the opportunity of revising and extending their mathematical knowledge and also discuss the advantages of looking for different ways to approach mathematical tasks. In particular they need to identify the potential in using various computational tools during the diverse problem solving phases that include representing, exploring and supporting mathematical relations.

COMPARING PRESERVICE TEACHERS’ PEDAGOGICAL IDEAS WITH THEIR PRACTICES AND THEIR STUDENTS’ BELIEFS

Center for Research and Advanced Studies, Mexico  
ablancarte@cinvestav.mx

In this article we describe the results of a research that had the purpose of finding out the beliefs of preservice teachers and how these relate to their own practice and to their students’ beliefs. This study was part of a special trial course in a teachers’ college which had the aim of improving the content and pedagogical knowledge of a group of students about to become teachers. Here we will focus on the pedagogical aspects. The classes of this course were analyzed, several questionnaires were applied and some classrooms presentations of this group of student teachers were observed. We also applied a questionnaire to their students receiving the lessons, about their beliefs. The study revealed that although the student teachers had a good pedagogical knowledge, their practices were mostly incompatible with it until they were given the opportunity to reflect on this knowledge and their own beliefs, and employ them in their practice.

Introduction

Professional development is a key aspect to improve education. Many studies have shown a strong correlation between the teachers’ knowledge and conceptions, and students’ achievements. With new principles, standards and approaches brought everyday into education, the preparation of teachers becomes even more crucial.

One way to improve education is to provide preservice teachers with the necessary elements for their future practice. Preservice teacher’s math education is complex since it involves not only different kinds of knowledge, but also beliefs, competencies and attitudes. Recognizing this, we initiated an educational project in a teachers college in Mexico which consisted of transforming one of the last courses of its program of studies. The student teachers in their last year of formal training already have a knowledge of mathematics and mathematics teaching, but the former is limited and based on procedural understanding, and the latter is composed of theoretical knowledge from previous years of instruction and conceptions and beliefs formed throughout their own experience. So it was felt necessary to introduce a special course that would give an opportunity to build on their previous knowledge and to restructure their conceptions and beliefs through group discussions, reflection and to put them into practice. The research project attached to it had the purpose of finding out the general knowledge and beliefs of these last year student teachers, how these influence their practice and the benefits of this didactical intervention.

The general term Pedagogical Content Knowledge (Shulman, 1986) refers to a complex mixture of knowledge related to many components like content, pedagogy, organization of topics and problems, student conceptions, models, representations, activities, curriculum, etc. Some facets of this teachers’ knowledge are more closely related to the mathematical content, like understanding and extending students methods of solution, deconstructing one’s own knowledge into its elemental parts to make it more evident or knowing the structure and connections of...
mathematical concepts and procedures. Ball and Bass (2000) associated this special knowledge with the term: Mathematical Knowledge for Teaching.

Based on different frameworks and methods of inquiry, there have been a number of research studies connected to teachers’ professional development projects in different countries. Amato (2006), within a mathematics teaching course for student teachers, conducted a study to improve their relational understanding of fractions, by playing games. In a study investigating the Pedagogical Content Knowledge (PCK) of elementary school teachers in the topic of decimals, Chick, et al. (2006) proposed a framework with three categories: 1. Clearly PCK; 2. Content Knowledge in a Pedagogical Context and 3. Pedagogical Knowledge in a Content Context. Like some other authors, Seago and Goldsmith (2006) studied the possibility of using classroom artifacts like students’ work and classroom videos to assess and promote MKT. In a collaborative action research, Cooper, Baturo and Grant (2006) uncovered some characteristics of instructional interactions that lead to positive results in student learning.

Teachers’ beliefs, on the other hand, direct their planning, content presented, decisions and evaluation related to their classroom. A very strong relationship has been observed between teachers’ practices and their beliefs and conceptions about the subject matter and the learning-teaching process. Thompson (1984) showed a correlation between the teachers’ ways of instruction and their beliefs about math. He also reported consistencies and inconsistencies with respect to how teachers believe math should be taught and their own practice, which shows that this research field is inherently complex. Some of these discrepancies can be accounted for with other factors like the social context in which the teaching is being done.

To give an overview, we cite some of the beliefs about math and its teaching that appear in the extensive literature, many of them repeatedly in several articles, in different forms.

**Teachers’ beliefs:** ✤ Math is a hard subject. ✤ Math doesn’t change. ✤ Math consists of calculations and procedures. ✤ Students should memorize the rules. ✤ There is only one correct method and answer. ✤ The objective is to obtain the right answer...

**Students’ beliefs:** ✤ Math does not relate to the real world. ✤ There is only one way to solve problems. ✤ Math is just a set of rules to follow. ✤ Exercises can and should be solved by the techniques given in the book or by the teacher. ✤ Problems can always be solved applying one or several operations...

Ernest (1989) suggested that beliefs are the main regulators of the behavior of the teacher in the classroom. He proposes three key elements that have an influence on the teaching of math: i) the teacher’s mental contents, specially his beliefs system; ii) the social context of the pedagogical situation, in particular, the limitations and opportunities provided and iii) the level of the teacher’s thinking processes and reflection.

In an article about cognitively guided instruction, Carpenter et al (2000) stressed the importance of the teacher’s knowledge about the mathematical thinking of children. The authors identified four levels of teachers’ beliefs that correlate with their mode of instruction. A brief explanation of these is: I. They believe that math has to be taught explicitly and therefore they show procedures and ask the students to practice them. II. They start to question this explicit mode and therefore they give to the students some opportunity to solve problems by themselves. III. They believe that students can have their own strategies so they provide problems and the students report their solutions. IV. The previous mode of working becomes more flexible, in which the teacher learns from his students’ productions and adapts his instruction to this knowledge. For a review of the literature on teachers’ and students’ beliefs, conceptions and practice we can refer to Leder, et al. (2002) or Ponte and Chapman (2006).

In addition to the quality of the mathematics content and pedagogy knowledge held by teachers, effective learning requires students to construct their own knowledge through exploration and interaction. According to Askew, Brown, Denvir, & Rhodes (2000), this process is productive if the next four components meet some necessary requirements: (a) Tasks are challenging, meaningful and interesting; (b) Talk facilitates learning and includes all sorts of teacher and students interactions; (c) Tools cover a range of modes and types of models; and (d) Relationships and norms help towards a social construction of knowledge. We used this framework to analyze the classes we observed of teachers during this study.

Methodology

A special pilot course was designed and given during the last semester of the formal courses to a group of 21 students in a teacher’s college in Mexico City (ENSM – Escuela Normal Superior de Mexico), preparing for teaching at the secondary school level. Each six hour class of this course was divided into two thirds of selected contents (fractions and decimals; mental calculation and estimation; algebraic thinking and functions; and probability and statistics) and one third of pedagogical elements (an approach that combines content and pedagogy would have been preferred but we decided to “separate” these due to lack of time for implementation). In this article we will describe only the pedagogical section of the course.

The content of the nine pedagogical sessions given was: 1) Discussion and probing further the responses given by the student teachers in the initial questionnaire. 2 and 3) Discussion of pre-read pedagogical articles and the ideas involved (for example: Cooper, et al. 2006; McDonough and Clarke, 2002; Schwartz, et al. 2006). 4 and 5) Worksheet design and discussion about its elements. 6, 7 and 8 ) Demonstrative classes given by three of the student teachers to their peers, and their analysis. 9 ) Discussion and probing further the responses given by the student teachers in the final questionnaire. In the remaining six weeks during the semester, the student teachers went to secondary schools to give practice classes.

To collect data, we applied an initial and a final questionnaire to the student teachers about some pedagogical elements and beliefs. The initial questionnaire consisted of 22 questions about characteristics of good teachers; about mathematics; and about elements related to the four components of Askew, et al. described before. The final questionnaire contained only three questions asking their perspective about: i) What they learned from the course; ii) How their beliefs and attitudes changed; and iii) The changes they observed in their own practice and what else they would like to achieve. In addition, we observed each of the three practice classes given to secondary students by eight (chosen at random) student teachers; one at the beginning (before the course started), one at the middle and one at the end (after the course finished). We also applied at the beginning, a questionnaire about their beliefs to one of the groups of students that received these practice classes, similar to the initial one given to the student teachers.

Results

Teachers’ responses to the initial questionnaire

We will describe here only the responses to some of the items of the initial questionnaire (some other answers will be given in other subsections below). Most of them coincide that students should participate actively, discovering concepts and be the ones talking and giving explanations, and that teachers should only direct, organize and, find out about the existing knowledge and uncertainties of the students. Some of the bad practices they mentioned are: to be very directive and not very flexible, to ignore students’ doubts and to give poor explanations.
When they were asked what they dislike about math, many responses were along the lines that some of the topics have to be taught in a traditional operative way so they could be understood, like geometric formulas or number algorithms, and that they have to be practiced. Almost all stated that mathematics is very important for every day life and that to construct and comprehend mathematics, real life examples and manipulating concrete materials were necessary. With respect to class organization, they prefer equally different forms, giving advantages and disadvantages (some replicated next): Team work (“not all of them work”; “hard to finish activities”); Whole class (many stated “disorder” and “hard to control”; “some don’t work”; “making fun of the others’ answers”); Individual work (“don’t understand”; “don’t ask questions”; “the advance is uneven”). Thus, overall the student teachers demonstrated in writing a reasonable blend of pedagogical knowledge, and a very constructive set of beliefs about the roles of the teacher and the students. Some weaknesses they mentioned are: to be able to capture the attention and interest of the students, and that their evaluation is centered mostly on exams.

Students’ responses to their questionnaire

As before, we will describe here only the responses to some of the items of the questionnaire (instead of giving proportions, we will give representatives of the most common responses). The students see a good teacher as someone who “explains in detail” and “asks about doubts”. Some of the things a teacher does wrong are: “only explains in one way”; “only explains the subjects once”; “doesn’t explain well so that we can understand”; “doesn’t pay attention to the students”; “make the problems bigger with detours”. About half claim they like math because “makes me think”; “it is useful”, but others don’t because “the operations are complicated”; “I don’t understand them”; “they are difficult”; “teach us things that we are not going to use in our lives”; “they are really boring”, although the great majority accepts that math is useful for everyday life. They would like activities “creative and enjoyable to stimulate students”; “entertaining to draw attention”; “interesting so I don’t get bored and fall sleep”; “with lots of examples”; “easy to understand”. With respect to class organization, they prefer team work, giving advantages and disadvantages (some replicated next): Team work (“only some work”; “some only play”; “there is not agreement”); Whole class (as the teachers, many stated “disorder”; “only the ones in front participate”; “not everybody understands”); Individual work (“you don’t understand the work”; “you don’t have support”; “we have many mistakes”). These are indications that teachers do not manage correctly these forms of organization.

These students’ conceptions and beliefs (the teacher has to explain; math is difficult and boring; would like interesting and enjoyable activities) contribute also to shape teachers’ practice since they are the expected behavior of teachers by their students.

Discussion about the elements of worksheets design

The student teachers designed some worksheets and then analyzed them in class. Among the aspects they saw as inadequate and listed “for improvement” were:

- Objectives and instructions are complex, directed more to other teachers than to the students.
- They are only repetitive exercises that emphasize memorization.
- They contain a lot of text.
- Centered on mechanical aspects.
- Figures are used for aesthetic reasons and not as helpful illustrations.
- Correction by the teacher is based only on results.
- They are very long.
With these in mind, they discuss the characteristics of a good worksheet and how it should be presented in the classroom (they were instructed to think further about the level the worksheets should have on issues like orientation, feedback, difficulty, reasoning, etc.)

The student teachers recognized that they had very little knowledge about worksheet design, giving previously to the students only “lists of exercises or problems” and that this activity gave them elements that have to be considered to really support the learning and teaching process. In the demonstrative classes given by three of the student teachers and in their last practice classes to secondary students, we found they designed very much improved worksheets. The main new feature was that they weren’t repetitive exercises anymore but instead, they were a sequel of a few problematic situations to analyze.

Analysis of demonstrative classes

In the three sessions programmed for this, a student teacher presented a demonstrative class and the others gave their comments organizing them into strengths and weaknesses.

Teacher P gave a class on fractions.

Some of the strengths mentioned were:
▪ Shows confidence.
▪ Gives the purposes of the class.
▪ Utilizes several representations for the fractions.
▪ Uses both individual and team work.
▪ Interacts with the teams, helping those who request it.

Some of the weaknesses mentioned were:
▪ Tried to cover too many contents (proper and improper fractions, their localization on the number line, equivalence of fractions and decimal representation).
▪ Didn’t use concrete materials.
▪ The activities weren’t challenging.
▪ Introduces the topics with a lecture and passing the students to the blackboard.
▪ Didn’t take advantage of the comments given during the lecture to open a discussion.
▪ During the interaction with the teams, gives only his conception or point of view. This teacher, although demonstrated some effort, showed reluctance to change his practice and to apply new approaches, due to his beliefs.

Teacher L gave also a class on fractions. He had all the positive comments that were listed above for teacher P, and in addition had:
▪ Did use games and concrete materials. Also, he had very few comments to improve like:
▪ The instructions to the games should be more clear so all the students understand them.

(Teacher F class is commented briefly afterward.)

This activity of demonstrative classes was very helpful since the student teachers saw a class presented and then heard from others, good and bad qualities of teaching. This make them reflect on their own practice, which is a requisite for change. It also shows that these students about to become teachers, have the pedagogical knowledge needed but the real problematic issue is to be able to implement it.

Comparison of initial pedagogical beliefs expressed and actual practices

1. Compatible.

Defines it as a good practice and follows it.
▪ Most of the teachers believe that classroom or homework activities shouldn’t be challenging and follow this. Some of the reasons they give are: “The students don’t have enough knowledge.” “We have to give it slowly so they can understand.” “Don’t make complicated exercises because we can discourage them.”
▪ Teacher J. P. expressed that he works in class in a traditional way and prefers to give the whole explanation himself and then give some practice exercises to the students. This is exactly what he does in class.

2. **Incompatible.**

2a. **Defines it as a bad practice but follows it anyway.**
- Teacher A wrote as a bad practice: “teaching the class to the blackboard and forgetting the group”. However, most of the time his class followed this technique with very little interaction with the students.
- Teacher L wrote as a bad practice: “give exercises based on memorization”. However, in his first observed class, he gave as homework to solve 18 similar equations of the form ax+b=c.
- Teacher O wrote as a bad practice: “to tell the students all the procedure so they just perform the operations”. However, in his class he posed a problem to the students but almost immediately he took over, giving the procedure that had to be followed.

2b. **Defines it as a good practice but doesn’t follow it or does the opposite.**
- Most teachers expressed that it is important the use of materials “to help students construct their knowledge” and “to motivate them and center their attention”. However, most of them had a very limited use of materials.

2c. **Other incompatibilities observed.**
- When asked if they prefer to explain first to the students, or let them find out by themselves, most agreed in choosing the second form (“the students should be the ones to investigate and explain”). However, most of them, were very directive teachers in their first practice classes, giving very little opportunities for the students to ask questions or to explain.
- Most student teachers answered in the questionnaire that it is important to learn math because they are useful in everyday life and they stated explicitly that they should show the connections with real life. However, in their initial practice class, they very seldom use examples based on real situations.
- Also the majority stated in the initial questionnaire that activities have to be “well structured”, “gradual”, “dynamic”, “with a purpose”, “allowing different strategies of solution”, “gradual in complexity”, “understandable”, “motivating thinking”, “generate conflict”, “attractive”, “based on problem solving”... However, these were not characteristics seen in their practice classes.
- Teacher F, in his demonstrative class of areas in geometry (given to his fellow classmates) employed a worksheet with nice drawings of composed figures, handed out paper figures and other materials and formed teams to work. His peers gave, in general, very positive comments on this class. However in his later presentation on the same subject to actual students, he didn’t employ the materials and instead, used the blackboard extensively and moved quickly into formulas. So he is not congruent with what he shows he believes and his actual practice.

**Classroom observations: changes observed**

We give only two representative examples, but in general the teachers improved in all four aspects: tasks, talk, tools and norms.

- The initial class of teacher A could be summarized simply as talking and writing on the blackboard, with the students listening and copying. He was rated either unsatisfactory or
poor in the aspects of teaching considered (tasks – C, talk – C, tools – C and norms – D, on a scale from A to D). In his second class after the course given, he designed worksheets, organized his students to work in groups of three and went to each group to discuss ideas. Due to the interest of the students in the activity, the discipline was much better.

- In the initial observation teacher L was rated B (good) in tasks and tools (with the use of many materials), but only C (unsatisfactory) on conversation (students asking questions only about what they didn’t understand from the materials) and C on norms. He was a directive teacher but at times, tried to explore his students’ ideas. After the course he used materials and software to motivate discovery by the students and his talk with them improved noticeably, being much more responsive. The norms also improved considerably, due to the same techniques used.

**Teachers’ responses to the final questionnaire.**

In the final questionnaire, teachers expressed what they thought they obtained from the course. They stressed the pedagogical aspect as being very important, while before, they didn’t think much of it. Some of their comments were: “It allowed me to see the general value of knowing the pedagogical side since it is a facilitator for us in class.” “I finally realized all the aspects a teacher should cover in his classroom... it is not only to present the subjects to the students... it is the planning, the looking for activities...” “Before, I placed my emphasis on the content. Now I can tell that the pedagogy gives you tools to be better and more effective.” “I learned the meaning of pedagogy... it is a series of activities that have to be planned with regard to the attitude and capacity of each student, it is searching the way for the student to acquire his knowledge.” “We have to let the students express their own ideas...” “We have to motivate students to write and validate their own methods and to propose activities that require thinking and not mechanization...”

About how they felt their beliefs were changed they wrote: “Yes, they changed. Much of this I already knew but didn’t put it into practice because my teachers didn’t do it either...” “Before I had a vague idea of the role of the teacher... Now putting into practice what I learned, I realized that we can achieve a more solid knowledge if we try to have the students analyze what they learn.” “Some how they changed because I had the idea that the teacher is the one that is right, that his way of teaching doesn’t change and that the students have to adapt. However we saw that the practice of teachers must be very varied.” “It changed because my worksheets have different characteristics now.” “A lot. I believed that math was unique, not related to real situations. Now I support myself with... and based on life situations.” It is interesting that they measure their beliefs according to their own practice.

Finally about the changes they saw in their practice they mention: “Before I didn’t think about the needs of the students, I would see them as a group that I had to face...” “... I changed some aspects, I restrain myself telling everything to the students, try to make more questions, especially to those that don’t participate so they realize their mistakes and can correct them.” “... give them more freedom to solve problems.” A big concern however was: “To find activities for the students to understand better, since it is very difficult to do so.” and also: “To know how to put real math challenges at their level to guide their learning.”

Some comments however showed some of the reality of Mexico: “Having a group of 40 to 50 students doesn’t allow you to put all this into practice and I haven’t seen a teacher that does it...” “The readings are studies in other countries with very different conditions from Mexico” Obviously, a very strong influence is the practice of others teachers they have observed.

---

Some student teachers had difficulties in adapting to these “new” ideas (somewhat conflicting from what they observe in normal classes) especially with respect to interacting with students and discerning their thinking, even that there is sometimes a good disposition for it. One possible factor is their limited general knowledge, but another obstacle could be the social context they live in, inside and outside the classroom. As Chapman (2002) expresses: “… belief structure can be complex and simply exposing mathematics teachers to alternative beliefs or contexts may not be sufficient to alter their teaching accordingly.” And looking more broadly at the social context she adds “Thus while a teacher may be willing to change her/his teaching, she/he may not be willing, consciously or subconsciously, to change other aspects of her/his identity.”

Conclusions

We found in general a good pedagogical knowledge among the student teachers and their expressed beliefs are in accordance with this knowledge. However, their practices were in general very traditionally oriented. It seems like their knowledge and beliefs articulated do not influence their actual planning, presentation and evaluation of their classes.

The normal instruction they received is in general very theoretical and their practice is in front of other teachers of the “old generation”, so they tend to imitate them even though their knowledge is contradictory to these practices. So it is not enough to let them know the new approaches in teaching. What we did in this special course is open spaces for them to discuss, analyze and design activities and ask them to bring this into their practice.

In a normal set up, the student teachers go and observe inservice teachers in their classrooms and then under their supervision they prepare and give some practice classes. This mode to proceed however, perpetuates the same kind of behavior in instruction, which in the great majority of cases is of directive type, the teacher in a dominating role, giving mostly procedures that have to be memorized and then followed in the practice exercises.

We observed that their practice could change if they are given the opportunity to examine their beliefs, change them accordingly and apply the new techniques taught in their courses.

This suggests that a new approach in training students to become teachers should be undertaken in Mexico, trying not to let the old practices influence their more current knowledge and beliefs. It is not easy to improve the practice of teachers, but it is clear that, to do so, theoretical aspects have to be combined with demonstrative and practical sessions in which they hear comments and make them reflect about their own practices and the obstacles they have.

"WHEN WILL I LEARN TO BE A MATHEMATICS TEACHER?: ALTERNATIVELY CERTIFIED TEACHERS, A CASE STUDY"

Michael Meagher
Brooklyn College -CUNY
mmeagher@brooklyn.cuny.edu

Andrew Brantlinger
University of Maryland
amb@umd.edu

The New York City Teaching Fellows (NYCTF) was started in 2000, in part to address “the most severe teacher shortage in New York's public school system in decades” (NYCTF, 2008, p. 1). Two-thirds of new mathematics teachers in the New York City Public School System are TFs. In this paper we present a case study of a first-year Mathematics TF. Through this case study we examine and interrogate the relationship between the theory, rhetoric and promise of Alternative Certification (AC) programs and the reality of the course an AC candidate navigates through her first year of the training program and of teaching.

Introduction

The New York City Teaching Fellows (NYCTF) was started in 2000, in part to address “the most severe teacher shortage in New York's public school system in decades” (NYCTF, 2008, p. 1). NYCTF is the largest program in the U.S. that provides an alternative route to teaching certification. Two-thirds of new middle and high school mathematics teachers in the New York City Public School System are “Teaching Fellows.” The NYCTF program is one of many Alternative Certification for Teaching (ACT) programs which seek to address the dearth of teacher candidates in traditional programs. We present a case study of the first-year of teaching of mathematics Teaching Fellow (MTF). Our aim in presenting this case study is to examine and interrogate the relationship between the theory, rhetoric and promise of ACT programs and the, sometimes consonant, sometimes not, reality of the course an ACT candidate navigates through her first year of the training program which coincides with her first year of teaching. We focus on her family and educational background, her beliefs as a novice teacher, preparation to teach mathematics, and first year experience teaching middle school mathematics in a high needs school in New York City (NYC) and place all of these factors in relation to claims made about the type and quality of candidate ACT programs claim to attract. We situate the case study using results from a larger observational and survey study of novice MTFs in order to substantiate our claim that our case study candidate is reasonably typical. Our analysis, and situating, of the case study is from a perspective which supports reform-oriented approaches to teaching of mathematics. Our data collection and analysis was guided by two questions:

1. How does an individual navigate through their first year of teaching in a large AC program?
2. What is the relationship between the framing of the AC program and the realities on the ground?

Theoretical Framework

There is a growing body of literature on ACT programs and teachers (Boyd, Grossman, Lankford, Loeb, & Wyckoff, 2006; Feistritzer, 2004; Grossman & Loeb, 2008) that reflects the growth of ACT programs in the U. S. (Feistritzer, 2004). Based on a summary of peer reviewed research in this area, Wilson, Floden, & Ferrini-Mundy (2002), conclude that high-quality ACT programs claim to include “high entrance standards; extensive mentoring and supervision;
extensive pedagogical training in instruction, management, curriculum, and working with diverse students; frequent and substantial evaluation; practice in lesson planning and teaching prior to taking on full responsibility as a teacher; and high exit standards” (p. 201).

Indeed, some researchers (e.g., Peterson & Nadler, 2009) and early advocates of ACT policy, find that ACT programs too often resemble the traditional, university-based route they were intended to replace. They argue that to be truly alternative, ACT programs should be “streamlined” - allowing candidates “early entry” into the classroom after taking the bare minimum of practical education courses (i.e., 12 to 18 credit hours). Advocates of streamlined ACT policy make several interrelated assumptions, namely, that: (1) the reduction of entry requirements, attracts academically talented candidates who otherwise would not consider teaching, (2) these candidates possess strong-subject matter backgrounds, relevant professional experience, or both, and (3) because of their strong backgrounds, ACT candidates require much less preparation than do candidates in traditional education programs (see also, Raymond, Fletcher, & Luque, 2001).

ACT programs generally promise intensive induction and mentoring to ACTs as they begin teaching. This induction is designed to help ACTs “learn to teach on the job”, to meet their individual needs, and to help with program retention (Kardos, 2004). However, research indicates that there is a gap between espoused and enacted induction support for ACTs, with many early-entry programs failing to fully provide promised support in the field (Humphrey et al., 2008; Johnson & Birkeland, 2008). Humphrey et al. (2008) note that, “mentoring, like other training components, varies considerably across and within [ACT] programs, not just in terms of the amount of mentoring provided, but in its quality as well” (p. 518).

Further complicating matters, many ACTs begin teaching in difficult teaching contexts - in high needs schools, with children that other teachers avoid (Humphrey et al., 2008; Johnson & Birkeland, 2008). In such contexts, new ACTs, and other novices for that matter, struggle with issues of instruction and classroom management. They often feel isolated and unsupported by administrators in these contexts (Goodnough, 2004; Humphrey & Wechsler, 2007; Kardos & Johnson, 2007).

In many district and school contexts, new teachers also are being asked to implement the same student-centered pedagogies (e.g., classrooms where students play an active role in the development, discussion and evaluation of ideas) that experienced teachers are expected to implement. Indeed, research indicates that as pre-service students, both traditional and ACT candidates articulate student-centered ideals about teaching mathematics (Flores, 2006; Noyes, 2007). However, many are unable to realize this vision and adopt traditional teaching methods (e.g., lecturing, emphasizing student memorization) once they become practicing teachers.

Additionally, in contrast to claims of advocates, there is mixed evidence that ACT policy enables early-entry programs to attract the “best and the brightest” to teaching (Shen, 1997; Wilson, Floden, Ferrini-Mundy, 2002). Based on an analysis of nationally representative survey data, Shen (1997) finds that, if anything, ACTs are slightly less well qualified than traditional candidates on average. In contrast to rhetoric by advocates which posits that ACT programs attract professional and experienced career changers, large numbers of ACTs are recent college graduates (Shen, 1997). Such ACTs tend to be exploring teaching as a possible career or to view teaching as a temporary (Shen, 1997).

Finally, while there is some evidence that ACT policy has helped diversify the teacher population, both the general population and that of mathematics teachers, the differences between the ACT and traditional teacher population are generally small (Shen, 1997, 1999). Like
the general teacher population, ACTs are predominantly white and female. At the same time, a large proportion of ACTs begin teaching in high needs schools where they are outsiders to the communities in which they teach. Martin (2007) argues that well-known ACT programs instill a missionary zeal amongst many such ACTs who are positioned as “saviors” of students of color. He claims that ACTs in these programs are taught to focus so narrowly on raising student academic achievement that they are blinded to social-historical forces (e.g., racism) and a consideration of student experiences and desires which are at play in their classrooms.

**Methodology**

This study was one of eight case studies of MTFs completed over a one-year period. Kelly's first year experiences and preparation in the NYCTF program was fairly representative of many MTFs, recent college graduates in particular.

**Study Context**

Over the course of the study, Kelly completed state-required master's coursework at Borough University (BU), one of four partnering universities that provide pre-employment training and Master's coursework in education for MTFs. In her first year, Kelly taught at a large middle school in a NYC neighborhood predominantly populated by African-American, Caribbean, and Hispanic families. NYC DoE data indicates that approximately three-fourths of student families receive public assistance at this school [http://schools.nyc.gov/SchoolPortals]. The school was in "restructuring year 2" which means that it had been failing for two years when Kelly started working there. The class that was the focal point of our study was, within the context of the school, a high track class. Kelly also taught two lower track courses in her first year. The high track class consisted of 17 Caribbean and African American girls, 4 Caribbean and African American boys, 3 Latinas, 4 Latinos, 1 Asian girl, and 1 Asian boy.

**Data Sources**

Working in teams of two, we collected observational data in our eight case study classrooms on an average of twice a month. In a typical observation, one of us took jottings while the other videotaped instruction. We also placed digital audio recorders on the teacher or in front near them. The jottings, audio and video data were used to create in-depth fieldnotes of each observation. Some of our case study teachers taught 90-minute block schedule periods, while others taught 45-minute periods. After each observation, we asked our case study teachers to reflect on the lesson that we had just observed.

We conducted in-depth interviews with the eight case study participants at the beginning and end of the 2006-2007 schoolyear. In the summer of 2007, we collected in-depth survey data from more than 85% of pre-service and inservice MTFs (Kelly became a second-year Fellow) at BU. Our survey study collected data from MTFs at the four NYCTF programs for mathematics. Interview and survey questions concerned the Fellows' educational background and preparation, ongoing Master's coursework, induction support, and teaching mathematics in NYC public schools. Having completed her first-year of teaching, Kelly filled out an inservice survey.

**Data Analysis**

**Fieldnote Analysis**

The coding scheme that we used to analyze our fieldnotes was produced in collaboration with a research team of approximately a dozen mathematics educators, most of whom were collecting
data on the seven other case study MTFs. Our schema included such codes as: classroom management, teacher math questions, and opportunity for meaning making. Specific codes allowed us to address our research questions by providing us with a detailed “thick” description of week-by-week progress of Kelly through her first year. The coding of the lessons and the reflections allowed us to examine and characterise important dimensions of her progress such as preparedness, influence of college classes, and scale and effect of mentoring from various sources. It also gave us an informed position to compare the reality of one candidate's experience of an AC program (situated in a larger group to control for “typicalness”) with the claims and promise of AC programs.

Interview Analysis
For the purposes of this paper, we focused on parts of the interviews and reflections that dealt with: (1) Kelly's background and preparation to teach in the NYCTF program, (2) experiences working in her school, particularly her induction experiences, and (3) her beliefs about the nature of school mathematics and effective mathematics teaching.

Survey Analysis
For the purposes of this paper, we focus on findings from survey data from 55 preservice and 42 first-year MTF respondents at BU - these respondents comprised some 95% and 80% of these two cohorts respectively. Although the surveys contained a range of issues, we examined only the parts of the survey that addressed the three categories outlined above. The design of the surveys, informed in part by interviews and the initial observational component of our larger study, allowed us to examine the representativeness of our 8 case studies to the MTFs who completed the surveys (e.g., their use of required textbooks, beliefs about students) and to compare these key participants' ideas to the aggregate data of the entire cohort.

Results
Kelly's Background and Preparation to Teach
Kelly, our case study subject, came to her position as an urban middle school teacher after having been away from exposure to any mathematics instruction for the six years she was in college and graduate school. While she reported receiving the highest possible score on the AP Calculus exam in high school, she also admitted that she was not interested in studying mathematics in college. Statistics 1 was the only mathematics course she completed in college. Our survey data indicates that Kelly was not atypical in this regard. While BU fellows completed 1.66 basic math courses (college algebra, basic statistics) on average, a large number did not take calculus or any advanced courses that typically follow calculus courses after college. Kelly graduated from a large Eastern State University with a double major in International Relations and Religious Studies. She was interested in pursuing a career with the intelligence services but postponed pursuing this option in order to complete a Masters degree in Islamic Studies.

Kelly's Preservice Views of Urban Mathematics Teaching
Before teaching Kelly was enrolled in a six-week Summer Course at Borough University (BU) in which she took courses in lesson planning and classroom management. In an interview conducted a week before she began teaching Kelly described her readiness and gratitude: “I think that [BU] is amazing at getting us ready for that first day of school.” Kelly did not have much educational or practical mathematical background to draw on as she entered her first year. While

Kelly appreciated the BU preservice preparation, she expressed concern about her lack of exposure to mathematics content or mathematics specific teaching methods prior to becoming a teacher of record. She declared that her primary goal was to gain control of her classroom. Her secondary stated goals were to help students overcome mathematics anxiety and help them in relating mathematics to their real lives. This was the most common response for first year MTFs, though those at BU felt somewhat better prepared than their colleagues at other university partners in terms of classroom management. On the first year survey, 25.5% of BU (preservice) respondents cited management as one of the “most effective aspects” of their instruction, compared to 13.8% of MTFs at other university partners.

Early in the school year
Observations of Kelly’s teaching early in the school year highlighted a number of significant issues which continued with Kelly through the year. First, despite the reform-oriented attitudes evinced in her pre-service interview, her teaching was teacher-centered and she controlled mathematical explanations. Second, she privileged students' correct answers leaving them unchallenged but regularly and immediately challenged incorrect answers with comments such as “interesting,” or, “Are you sure?” It can certainly be argued that these are common issues of concern for any novice teacher (Moyer & Milewicz, 2002) but these issues are often addressed early in student teaching leading to the implication for the NYCTF program that the summer school teaching may be inadequate as a student teaching experience for the Fellows. On the other hand, Kelly had not taken mathematics since high school nor had she received much training in mathematics pedagogy in the NYCTF program. As discussed above, she was typical of other preservice MTF’s in this regard.

At this early stage Kelly was struggling (at varying levels) with both content and content specific pedagogy including: listening to students, questions she asked students, tasks she designed and used in class. Her lesson plans also stuck closely to the required textbook. These, of course, may be viewed as common struggles among novice teachers. On the other hand, there were already very few management issues in Kelly’s class as she had developed a positive relationship with her students. In a post-lesson reflection Kelly stated: “I am feeling much more confident as the weeks go by [and I am] much more relaxed with my position as the teacher, and giving the students more responsibility in their own learning environment. She further observed, in the same interview, “I still want to work on the students being more reliant on each other and less on me for answers [and] I am still struggling with making the material interesting.” She felt that “there are only a few management issues such as getting out of their seats.”

At that stage Kelly might be considered to be in a reasonable position to develop as a teacher. Management was not really an issue in this class (although it still was in her other classes) and she had every reason to look to her university classes, her school's mathematics AP, her school's mathematics coach, and her university supervisor for help in improving basic aspects of her teaching. However, in her reflection on this lesson she wrote, “no one has helped me with much of anything in terms of math content.”

The Middle Part of the Year
Kelly's journey through the middle part of her first year was marked by a recession in instructional support she received from the school administration and the university representative with whom she worked.
Support

One of the central stories of Kelly's journey through her first year, a central story of MTF's more generally, is a consideration of the support she received. As a Teaching Fellow Kelly can expect to receive support in developing her teaching from at least four distinct sources

(i) University classes. Kelly was critical of ongoing Master's coursework she was taking during the year at BU. She was looking to these classes to help her develop not as a teacher in general but specifically as a mathematics teacher but ended up frustrated: “I'm not taking any classes on how to teach math. So, how am I supposed to be a good math teacher? They purposefully talk about other subjects because we're like, well you guys know about mathematics so let's talk about English, let's talk about science. Let's do a debate on technology and science classroom, or special education in the classroom … you want us to be well rounded, we're not even well rounded in our subject area yet.” This represented a shift; as mentioned previously, Kelly had been extremely positive about her summer school experience at BU and had felt well-prepared.

Following the Summer program Kelly had taken one class in Special Education, one class in Literacy in the classroom, and one in Web Design. She stated, however, that she felt these course did not help her learn how to teach mathematics.

(ii) University supervisor. Initially Kelly had a positive relationship with her University supervisor. He had taught in Kelly's Summer Program at BU. On the survey, Kelly wrote: “he came in and helped with my classroom setup. Also suggestions on how to deal with bad behavior.” However, the relationship lapsed as the school year progressed with Kelly commenting: “I'm not falling on my face, so he's got other things to do. Because he spends a lot more time with Ms. Brown than he ever did with me. He was here a lot in September. I really haven't seen him since. He stops in to say hello, but he even, he's supposed to see me once a month for Borough University but the last three times he's just stopped in for lesson plans so he can write it out because he trusts me.”

This story in its essence is reported throughout Kelly's support network. Because her classroom management skills were good and she had a positive relationship with the students she had gained the reputation of being a successful teacher. Kelly’s practice however, remained unexamined. She lacked the support she needed to improve in areas she felt less secure.

(iii) APs in the school. There were two Assistant Principals (APs) in the school who worked with Kelly to some extent. Her somewhat cynical summary of the extent to which they helped with her teaching is “They saw me in September or October. They realized I was competent … and then they've never helped me at all.” In fact the relationship improved and in the second half of the school year the AP for mathematics was coming into her class occasionally: “I asked [him] can you stop in and see how things are going because, so he's stopped in a few times and gave me some pointers.” He was giving her specific advice about the mathematics instruction that she considered to be useful. “He was telling me about how to develop from one idea to the next, connect, because I wasn't connecting … I was reviewing graphing and he said this is a good opportunity to do positive and negative numbers. He said that they're not good at it, so if you are creating tables [of values] you should also try, find time to stick in a little revision on adding and subtracting integers. I was like, oh I never even thought about doing that.” The APs thought highly of Kelly considering her highly motivated, very effective, and very dedicated. Indeed, she was characterized as an “excellent” teacher.

Kelly had indeed possessed some critical skills as a teacher. She was dedicated, organized, and successful in establishing good interpersonal relationships with the students. Somewhat more
surprising was the APs comments about Kelly's content knowledge and her content knowledge for teaching. He said: “What has impressed me is her knowledge. We have her teaching one of the more advanced eighth grade classes and teaching them high school. [I am impressed with] her knowledge in conveying the lesson, getting her lesson across to the kids.” We have observed in a number of Kelly's lessons that this was an area of concern for both Kelly and us.

(iv) DoE mentors: By law, the district is required to provide the fellows with mentor teachers. Kelly had a DoE mentor who visited her weekly. Most of these observations were short, this mentor only observed Kelly teach one full lesson per month. On the second-year survey Kelly wrote, “My mentor was great at helping me with personnel things--days off, death in the family, can I change schools, etc…” Kelly also felt that the content of courses she had taken was “useless” to her and believed she would have been better served by engaging in discussions that concerned her classroom needs.

At the mid-section of Kelly's first year of teaching we observed a highly committed teacher who showed good presence in the classroom and willing to learn. It was also clear early in the year that Kelly was experiencing typical difficulties that many novice teachers endure regarding command of content knowledge for teaching, pedagogical skills such as questioning, eliciting and responding to students’ explanations. Unfortunately, what we see develop through the year was that inadequate or insufficiently applied support system which did not allow Kelly to further develop as a teacher. The New York City Teaching Fellows enter the classroom with minimal training but under the assumption that there is a battery of support systems in place which are supposed to ensure that the kind of teacher development that would take place in the mentoring teachers entering through a traditional route are also in place for these alternatively certified teachers. Among the triumvirate of basic pedagogies: norms, tasks, and discourse (Henningsen & Stein, 1997), Kelly's training (together with her background and personality) was sufficient to help her achieve reasonable success with the norms. However, she continued to struggle with tasks and discourse components.

Observations of Kelly’s teaching in the latter part of the school year showed that she successfully established norms concerning small group work which allowed her to engage in extensive discussions with individual groups with only minimal disruption from outside. The tasks she used in her class were, however, highly procedural. Furthermore, her modes of discourse and question techniques tended to “funnel” (Wood, 1998) students toward a correct answer.

Discussion

In this paper we described the experiences of a new Teaching Fellow in a New York City public school. The story we tell is one of a teacher who we believe had the potential to be an effective Middle School teacher but was failed by the support systems expected to be in place to help her reach that potential. We highlighted that despite having taken a full set of university courses, and presence of at least three individuals in support/mentorship roles, instances of Kelly being guided to carefully examine her practice by a mentor were rare. Striking about Kelly’s case is that she herself was fully conscious of the failure of the system, as she asked: “When am I going to learn to be a mathematics teacher?”

Currently, a large number of New York City public schools are faced with the challenge of staffing positions and retaining their existing staff. In order to successfully address this challenge it is important that all aspects of training and support for incoming teachers are in place so to allow for effective experiences for both teachers and students are developed. Our
findings suggest that such a system is not currently in place for some new Teaching Fellows in the New York City public school system.

CHARACTERIZING MIDDLE AND SECONDARY PRESERVICE TEACHERS’ CHANGE IN INFERENTIAL REASONING

Maryann Elizabeth Huey
The University of Missouri
mehb79@mail.missouri.edu

In recent years, national standards have given greater emphasis to K-12 statistics. Unfortunately, many teachers have not had an opportunity to learn statistical content during their college coursework. Therefore, teachers are least prepared to teach statistics and probability according to the College Board of Mathematics and Statistics (2001). As a result, teachers have difficulties in both understanding and teaching core ideas of statistics. Moreover, there has been limited research about preparing teachers to teach statistics.

The following study provides a needed baseline of how well prepared preservice teachers are to teach inferential statistics from a reasoning perspective. A cohort (n=33) of preservice middle and secondary teachers enrolled in a statistics course designed specifically for preservice teachers participated in the study. Three parallel assessments were administered to the cohort to gauge their inferential reasoning progress throughout a semester (e.g., pre-assessment, midcourse clinical interview, and post-assessment). The assessments consisted of tasks that could be solved both formally and informally. The change in the preservice teachers’ statistical reasoning was characterized from cognitive perspective using a two-stage Structure of Observed Learning Outcomes (SOLO) taxonomy (Mooney, 2002; Biggs & Collis, 1982). General agreement exists that students’ learning and statistical reasoning progresses through a number of hierarchical levels and cycles. The two-stage taxonomy follows the work of Watson, Collis, Callingham and Moritz (1995) who claim that the first stage is primarily focused on developing conceptions (informal approaches), and the second stage consolidates and applies the statistical concepts (formal methods). The participants’ opportunity to learn was analyzed in terms of the statistical content covered in the course and the emphasis placed on reasoning. While students tended to incorporate more statistical concepts as they progressed through the semester, coordination of statistical concepts in their argumentation was lacking. Plausible explanation for these results will be discussed.

DIFFERENTIATION MODEL FOR MATHEMATICS PRESERVICE TEACHERS TO ENGAGE ALL STUDENTS IN THE LEARNING OF MATHEMATICS

Janet M. Herrelko
University of Dayton
janet.herrelko@notes.udayton.edu

This case study details the creation of a differentiation model of instruction that helps mathematics preservice teachers write lesson plans that address the needs of all classroom students. The study follows the model as it was developed over three years. Observations of highly qualified classroom teachers while they taught mathematics in a manner that was able to reach all students in a classroom were the start of the study. Professional development sessions that focused on readings about differentiation and discussions as to how practicing teachers differentiate in their classrooms revealed an automatic practice that sprang from teacher observations of students’ behavior causing the teacher to change an element in teaching or the requirements for a student. How to translate that automatic practice into a mode for student teachers was a perplexing problem.

The framework used in the study was informed by Response to Intervention (RtI) program, with some adjustments. In our model, student teachers have a three level framework in which to plan classroom engagement with mathematical content: students at grade level; students who needed a small amount of intervention by the teacher; those students who have an individual education plan and stipulated needs the teacher was required to address.

The new method was reviewed and used by in-service teachers. They used the format for their classes and identified a key missing element – a level of planning for the accelerated students. Thus, a four level method to differentiate emerged that student teachers would use to plan their lessons. Student teachers would be required to address and prepare for all the needs of students prior to teaching a lesson. The new method was tested by a student teacher who gathered data by comparing post testing on two units of instruction in which two of the laws of sines were the content. The first testing was preceded by a lesson taught in the fashion of the cooperating teacher. The second unit was taught using a review session that addressed the four levels method of differentiation. The student teacher identified only three levels of students in the class, levels zero, one, and two since this was a pre-calculus class there were no level three students in the class. When conducting a summation review of the scores between the two tests, there were solid point gains from the first to the second test. There were outlier differences that needed further data exploration to support the differences between the two tests. The t-test results noted that for the whole class of 22 students there was a significant difference between the two unit tests scores in favor of the differentiated teaching. When broken down into the three levels and t-tests conducted on each group the results varied. For level zero with six students, there was not a significant difference between the two tests. For level one with eight students, there was a significant difference between the two tests. For level two with eight students, the difference between the two tests was just slightly significant with a \( p \) value of .056.

IN-SERVICE MIDDLE GRADES TEACHERS’ USE OF DOUBLE NUMBER LINES TO MODEL WORD PROBLEMS

Günhan Caglayan  
Columbus State University  
caglayan_gunhan@colstate.edu

Chandra Hawley Orrill  
University of Massachusetts Dartmouth  
corrill@umassd.edu

Rachael Eriksen Brown  
Knowles Science Teaching Foundation  
rbrown@kstf.org

This study investigates in-service middle grades teachers’ approach to word problems that can be modeled with double number lines, which serve to represent quantities and their linear relationships arising from word problems. Our data consist of videotaped PD seminars with the participating teachers. We generated a thematic analysis supported by a retrospective analysis and constant comparison methodology. Our main result is that the teachers’ approach to the double number lines method evolved naturally, without overt intervention by the PD facilitator who taught from a constructivist viewpoint. Participants who attended to the measurement units inherent in the quantities and relied on iteration strategies had a more sophisticated interpretation of double number lines than the others.

Introduction

This study is part of the Does it Work? Building Methods for Understanding Effects of Professional Development (DiW) project that has as its main purpose the exploration of the connections between teacher professional development (PD) in mathematics, classroom practices, and student achievement. PD focused on middle grades teachers and sought to support their development of reasoning about rational number using drawn representations. This particular study is informed by recent research on teacher knowledge frameworks (Hill, Rowan, & Ball, 2005; Ma, 1999), which outline the elements that PD needs in order to help teachers learn more about the content they teach and how their students learn.

Our theoretical framework is based on Lamon’s study of ratio and proportion (1995), and Lobato’s and Siebert’s (2002) work on composed units of differences, which we regard as the basis for the double number lines representation. According to Lamon, “a ratio is a comparative index that conveys the notion of relative magnitude” (p. 171). Proportion, on the other hand, is about an equivalence of two ratios. “A student is reasoning proportionally when that student presents valid reasons in support of claims made about the structural relationships that exist when two ratios are equivalent” (pp. 172-173). The processes of unitizing and forming composite units are crucial components in proportional reasoning. Lobato and Siebert (2002) introduced the terminology “composed unit of differences,” which refers to a phrasal quantity such as “50 miles in 3 hours”, “12 degrees every 5 minutes”, or “3 cans for every 7 batches”. Such phrasal quantities, serving to demonstrate an existing relationship between pairs of quantities, may be represented using double number lines, where, the first number line is to be partitioned into units of the 1st quantity, and the 2nd number line is to be partitioned into units of the second quantity under consideration. The conceptualization and sense-making process may induce a reference to units-coordination (Olive, 1999; Steffe, 2002) and quantitative reasoning.

In this paper we investigate in-service middle grades teachers’ approaches to mathematical tasks that can be modeled using double number lines. This representation models pairs of quantities and their linear relationships arising from word problems. In particular, we looked at the processes our research participants went through, and the mathematical ideas to which they
referred in interpreting double number lines. To be more specific, our research question was “How did the in-service middle grades teachers participating in the professional seminars come to understand double number lines for representing pairs of quantities?”

**Context and Methodology**

Little is known about how the facilitator, teachers, and program elements that comprise a PD system (Borko, 2004) interact with classroom instruction that is shaped by further interactions among teachers, students, and content as embedded in instructional materials. To study this interaction, DiW offered a PD course to middle grades teachers in two large, urban school districts. The context of our study was one InterMath (http://intermath.coe.uga.edu) PD course on Rational Numbers, a 40-hour PD course aimed at developing teacher content knowledge in Rational Number concepts (fractions, decimals, and proportions) appropriate to the middle grades by engaging teachers in open-ended problems that are explored with technologies such as spreadsheets and Fraction Bars software.

This course included 15 teachers who met weekly for 14 weeks in three-hour PD seminars led by an experienced middle school teacher who had previously been a statewide trainer for the InterMath project. All course meetings were videotaped using two cameras, one focused on the seminar instructor and the other on the teacher participants. The videotapes were combined using picture-in-picture technology to create a restored view (Hall, 2000) of the learning environment. The corpus of PD video data were reviewed, along with their daily lesson summaries to generate possible themes for a more detailed analysis. These PD videos were revisited many times in order to generate a thematic analysis (with retrospective analysis using constant comparison) from which the following results emerged.

**Results**

The first problem to be modeled using the Double Number Lines (DNL) model was introduced in the fifth class meeting 7:08:39 PM (Figure 1).

![Figure 1. Cans and Containers Problem](image1)

**Figure 1. Cans and Containers Problem**

![Figure 2. Corey’s Algebraic (left) and DNL-Based (right)- Solutions to the Cans and Containers Problem](image2)

**Figure 2. Corey’s Algebraic (left) and DNL-Based (right)- Solutions to the Cans and Containers Problem**

Although he did not explicitly use the phrase DNL, Corey suggested the use of DNL and presented a solution based on a DNL. Corey first worked the problem with the traditional cross-multiplication algorithm and then developed a DNL-based representation (Fig.2).

Corey explained that he represented both quantities on a single number line with left endpoints 0 and 0; and right endpoints 6 and 2 ½. He marked the midpoints as 3 and 1 ¼. He then extended the number line and marked 9 and 3 ¾ as the new right endpoints. Jacinda, another participant, emphasized the necessity to extend the number line once more and mark 12 and 5 as the new right endpoints. The facilitator reproduced Corey’s solution on the board using a single number line, similar to the computer-based Figure 3 below.

Figure 3. Computer-based DNL for the Cans and Containers Problem

Before this conversation started, Jacinda said that she had solved the problem using “proportions,” meaning cross multiplication. As she gave directions to the facilitator to guide the drawing of Corey’s DNL, she used the phrase “extend the line” many times. We could deduce that Jacinda’s proportional reasoning was based on developing a set of coordinated pairs of units by iterating both units. We name this type of reasoning DNL in mind. In the next class meeting (class 6), the facilitator introduced the problem “7 containers hold 4 gallons of juice. How many gallons does one container hold?”, which triggered Jacinda’s willingness to set the problem as a proportion – which backs up our hypothesis on how Jacinda relates such pairs of quantities (with different measurement units and numerical values and for which a DNL model could apply) via proportional reasoning (PR). Jacinda’s interpretation of PR lies in her iteration strategy. The simultaneity refers to the fact that the pair of units that are coordinated via iteration meet at the same point on the DNL at each iteration. In week 8, the facilitator introduced another problem for which the DNL could be used: “1/4 serving is 2/3 of a candy bar. How much is one serving?” Jacinda stated “I saw this as a proportion “1/4 over 2/3 equals 1 over x””. She then solved the problem using the same proportional reasoning she had used in previous class meetings: She iterated the ¼ four times and obtained 1; she also iterated 2/3 four times and obtained 8/3. She explained, “Each ¼ represents 2/3, so substitution yields 2/3 plus 2/3 plus 2/3 plus 2/3” (Fig.4). Jacinda substituted a unit for another unit with which to be coordinated. In a sense, Jacinda treated the first quantity (1/4 serving) as a placeholder for the second quantity (2/3 candy bar). In this case, substitution stood for the fact that the quantities – that could be iterated at the same time – should meet at the same point on Jacinda’s DNL in mind (Fig.4). Also, Jacinda’s description, “Each ¼ represents 2/3” is similar to some other teachers’ willingness to connect the pair of quantities under consideration with a verb. A reference to a verb, such as represents in Jacinda’s statement can be thought as crucial in the sense-making process of solving a problem with a DNL.
In the week 9 meeting, the facilitator asked: Think about a “how much in one group?” story problem for $0.75 \div 1.25$ (dollars) and show your process in following DNL model.” Woodrow was bothered by the fact that both number lines were the same length. He raised this issue saying, “they put both of the values [.75 and 1.25] right at the same distance from 0. That’s kinda weird.” This statement indicated that Woodrow had not attended to the measurement units attached to the quantities, leaving him unable to reconcile the “equality” of .75 and 1.25. The notion of measurement units had, in fact, not been discussed by the participants or the facilitator in the InterMath sessions. In this problem, the verb costs connected the quantities 1.25 liters and 0.75 dollars. A reference to an equivalence and a verb is necessary using DNL to reason about two quantities meaningfully. The following protocol, which is an abridged transcript, illustrates the discussion on reconciling the quantities 1.25 liters and 75 cents.

Protocol I: Discussion between Woodrow and Jamal (from PD seminar on 11/10/08)

1. Jamal: I was thinking about it another way too. I was thinking like, if I were looking at it in terms of groups. If I could take the 1.25 liter (line) and break it into a certain number of groups and take the 75 (cent line) and break it up into a certain number of groups to where it would balance out equally. What I’m trying to say is, cause I noticed when you asked earlier, you said, this line represented 1.25 liters and this line represented 75 cents. They look equally. It’s really not – I don’t think it’s really saying they are equal. It’s saying that the 1.25 is broken up into a certain amount that it equals out to 75 cents. Do you know what I’m trying to say?

2. Facilitator: Um hmm.

3. Jamal: So, it’s not that they’re equal, it’s just that you get 1.25 liters for that amount. But, to say how much 1 liter would cost, you’ve got to find out what it is -- how it’s broken up.

4. Facilitator: Okay, that’s a good start, so how is it broken up?

5. Jamal: I mean, I guess you would have to kind of investigate and play around with it.

The fact that Jamal was working to understand the relationship between the explicitly stated pair (.25 liters and .15 dollars) may indicate that PR-based interpretation of DNL had not been achieved by Jamal at this stage. In fact, it appears that Jamal was not reasoning with composed units and was not coordinating the two sets of values in a meaningful way. When the facilitator asked why they should partition the first number line into quarters, Jamal replied, “Just to make it a nice round number because it stops at one and a quarter.” This may have indicated that Jamal wanted to partition only the first number line, reinforcing the notion that he was not reasoning with coordinated units. Jacinda provided a word problem that would model the given DNL: “If...
1.25 liters cost 75 cents, how much does 1 liter cost?”, which is then discussed by the participants.

As the discussion continued, Bree suggested using common multiples to determine partitions for the lines and determined the multiple could be twenty-fifths. Bree went on to explain that both lines could be divided into 25 parts, then one could determine how many twenty-fifths fit into 0.75. However, she was unable to create this representation when prompted. Bree did, however, seem to make sense of what the facilitator drew. We argue that the facilitator’s equipartitioning of both number lines strategy played a role in Bree’s sense-making process (Fig.5).

![Figure 5. Facilitator’s Computer-based DNLs](image)

Building from the computer-based DNL, the participants could see how the top number line could be broken into quarter liters. The next decision to be made was how to partition the bottom number line. Jacinda, who had previously reasoned by adding on the DNL, supported the idea of subtraction as illustrated in the following protocol (abridged transcript):

**Protocol II: How to partition the second number line (from week 9 session)**

Jacinda: Well mathematically we know that that space would have to be point fifteen. I know that the difference between [point 6] and [point 75] is zero point fifteen. So we find that by subtracting [inaudible] on the number line there.

Facilitator: What happens if we did not know?

Corey: Ok it’s going be over point five but less than point seven [This triggered the facilitator to add more points to the second number line as shown in Figure 5]

Jacinda: So if you were trying to explain this to your students you first draw a double number line up there and then you divide your first number line into five equal parts.

Facilitator: Why five equal parts?

Jacinda: Actually from zero to one is four spaces. So the bottom number line’s spaces have to match up. So you ask them now how are you gonna divide zero point seventy-five into five equal parts so that it matches up like that. So just divide it into five equal parts.

Facilitator: What do you guys think? How do I know it is fifteen cents?

Jacinda: You would have to kind of mathematically solve that somehow. So you would just say divide this [75 cents] by five.

Based on this protocol, we can hypothesize that Jacinda wanted to use the same number of partitions for both number lines so that the partitions matched up, indicating that she was relating the values of the top and bottom number lines. However, like Bree, Jacinda did not emphasize the pair of units – .25 liters and .15 dollars – had to be iterated at the same time. Further, it was not clear that the DNL was being used to represent quantities rather than to position two related
In class 11, the facilitator posed a new investigation “One batch of a certain shade of purple paint is made by mixing 3 pails of blue paint with 2 pails of red paint.” Teachers were asked to represent the problem using a table and a DNL. Once the teachers had worked on the investigation, the facilitator drew two number lines on the board: the top line in blue and the bottom line in red. Jamal opened the conversation saying, “Show one of them increasing by 3 and one increasing by 2. The first one would be counting by multiples of three and the second one you can count by multiples of two.”

In his first attempt to create a DNL model for this situation, shown in Figure 7a, Jamal placed the numbers on the number lines in an unevenly spaced manner. Figure-7a does not represent a DNL because the same multiples of two and three are not vertically aligned (e.g., 24 and 16 are 8 multiplied by 3 and 2, respectively, however, they are not vertically aligned). This indicated that Jamal, like Jacinda, was struggling to coordinate his knowledge of proportions, his approach to solving this problem, and the use of the DNL as a model for this situation. As Jamal drew his model on the board, Corey shared his work with Jacinda and the facilitator at his desk, as illustrated in the following protocol.

**Protocol III: Corey explains his DNL (from week 11)**

Facilitator: So what’s this here [pointing to the vertical line segments passing by both number lines].

Corey: This is one batch, two batches, three batches, four batches [pointing to these vertical line segments respectively]. Number of batches. This is the blue pail [pointing to the first number line] this is the red pail [pointing to the second number line]. The total will be five [pointing to the first parts of the number lines] because you gotta have five cans to make one batch.

Facilitator: So what do these one, two, three, four represent? [pointing to the vertical line segments passing by both number lines]

Corey: Number of batches (Fig.6). For instance, for one batch, you need one two three [counting the spaces with his finger] pails of blue and one two [counting the spaces with his finger] pails of red. And then for two batches you need one two three four five six pails of blue [counting the spaces with his finger] and then one two three four pails of red [counting the spaces with his finger]. In this you can see the increase, the increments [pointing to both number lines].

![Figure 6. Corey’s DNL (left) and Algebraic (right) Solution](image-url)
Corey’s diagram was the first evidence we observed of a teacher in this course iterating pairs of units coordinated by number of batches (the vertical line segments in his drawing). Corey not only coordinated the pair of iterated units with each other, but he coordinated this pair with another unit: number of batches at each iteration. Corey’s coordination scheme can be diagramed as follows:

- First Iteration: 1 unit of 3 units of blue pail AND 1 unit of 2 units of red pail → 1 unit of 5 COMBINED units
- Second Iteration: 2 units of 3 units of blue pail AND 2 units of 2 units of red pail → 2 units of 5 COMBINED units
- Third Iteration: 3 units of 3 units of blue pail AND 3 units of 2 units of red pail → 3 units of 5 COMBINED units, and so on.

While this conversation unfolded, Jamal got help from another participant as he tried to draw his DNL model on the board. In his second figure, Jamal relied on a same-multiples-of coordination strategy in placing the red and blue numbers on the corresponding number lines.

Protocol IV: Jamal’s DNL conception evolved (from week 11)

Jamal: What I did on the first number line… I did… multiples of three. Second number line I did it by multiples of two. I put 2 right under 3 because 3 pails of blue and 2 pails of red create one batch. So each one of those will be a batch. [hand gestures indicating vertical lines] We know that it takes 3 pails of blue and 2 pails of red to make 1 batch (Figure 7b).

Facilitator: How can we use these number lines to answer some of the questions we had? For example, how many pails of red paint will you need if you have 24 pails of blue paint?

Jacinda: Just read the 24 and read the corresponding number below [upon this, the facilitator draws a dashed vertical line segment passing through 24 and 16 – Figure 7b].

Facilitator: Does this double number line make sense?

Corey: I am being comfortable with it. Again I’d use the batches. It’s actually kind of similar to what [Jamal] did. But I actually showed the splits between each one. I, for instance, where he has the 3 and the 2, I’d put a line straight down and say that’s one batch. And I’d divide the blue up to three parts up to the one batch; and the red into two parts. It’s basically the same thing.

The facilitator then asked the whole group what they think about double number lines. In contrast to earlier conversations about this, the participants were now beginning to verbalize an understanding of the important aspects of the model for reasoning about proportions, though it was clear that the teachers were not seeing all of the mathematics of PR in the DNL. For example, teachers were still struggling to coordinate units in their reasoning with them.
In week 13, the facilitator introduced two more problems (Cookies Problem and Reservoir Problem) for the teachers to investigate with the DNL model (Figure 8).

1) Andrew has a recipe for cookies that calls for 3 cups of brown sugar to make 7 batches.
   a) How many batches can Andrew make with one cup of sugar?
   b) How many cups of brown sugar does Andrew need for one batch?

2) Erik is putting oil in his scooter. When he had 3/4 of a liter in the reservoir, he realized that the tank was 1/2 full. How many liters will the fully filled reservoir hold?

**Figure 8. Cookies Problem and Reservoir Problem**

With the Purple Paint Problem in week 11, Corey first used the DNL method, then provided the algebraic solution. For the Cookies Problem and the Scooter Problem, on the other hand, both Jacinda and Corey first solved the problem algebraically, then illustrated their solutions using a DNL. This was consistent with our earlier observations of Jacinda who, despite understanding composed units, was unable to determine values with the DNL. We noted that Corey, who also calculated first, continued to discuss DNLs as tools for estimating relationships. Interestingly, with the Cookie task, he moved away from the coordinated drawing of the previous week to rely on an estimation-like diagram (Figure 9). As he created his DNL for the Cookie task he drew a connecting line at 1 on the top line explaining, “Here, where we said there was one batch, you can draw a line to about 2 1/3.” Then, he drew a box around 1 and 2 1/3. Then he repeated this process for all of the relevant iterates. Unfortunately, his move away from the coordinated DNL was not discussed.

**Figure 9. Corey’s DNL for the Cookies Problem**

When the facilitator reconvened the whole group, Jamal volunteered to share his solution for the Cookies Problem. His use of the DNL model showed greater sophistication compared to his earlier efforts. He coordinated his 1st number line in increments of sevenths, and his 2nd number line with increments of thirds, in such a way that the 7 and the 3 were aligned (Figure 10a). He explained that he broke the first line into thirds, and the second line into sevenths. He emphasized that he first solved the problem algebraically using a proportion, then he drew his DNL. He continued, “7 batches would equal up to 3 cups of sugar.” His last statement is in agreement with our previous theories concerning Jamal, in that he feels the need to “connect” the two quantities via a verb, which was essential in fully making sense of DNL.

Jamal relied on a unit-coordination strategy in his reconciliation of the pair of quantities “7 batches and 3 cups;” he was able to iterate the pair of units 7 and 3 that were connected via the verb *equal*. Moreover, Jamal was aware of the unit coordination at the second level, which was
the iteration of the pair of subunits: 1/3 and 1/7. This unit coordination strategy can be derived from Jamal’s statements as illustrated in the following protocol:

Protocol V: Jamal’s Unit-Coordination based on subunits (from week 13)

Jamal: If we do one-seventh, two-sevenths, three-sevenths, four-sevenths, five-sevenths, sixth-sevenths, and this is one whole [marks the numbers 1/7, 2/7, 3/7, 4/7, 5/7, 6/7, 1 on the “sugar” number line]. So for one batch you need three-sevenths cup of sugar [connects the 1 from the top number line with the 3/7 from the bottom number line]

Facilitator: So for one cup of sugar how many batches will you need?
Jamal: For one cup of sugar it is gonna take two and a third [connects the 1 from the bottom number line with the 2 1/3 from the top number line – Figure 10b].

Facilitator: So you use the same number line to answer those questions.
Jamal: Yes you use the same number line to answer all the questions. Because when you had it all split up you can just kinda eyeball in it and that should give you the answer.

Figure 10. Jamal’s Unit Coordination Based on Subunits

Jamal’s unit coordination (UC) scheme can be diagramed as follows:

- First Level UC: 7 units of batches AND 3 units of cups \( \rightarrow \) “7 batches would equal up to 3 cups of sugar” \( \rightarrow \) coordination of the pair of units “7 and 3”
- Second Level UC: 1/3 unit of batch AND 1/7 units of cups \( \rightarrow \) coordination of the pair of subunits “1/3 and 1/7”
- Iteration of the Subunits: Three 1/3 unit of batch AND Three 1/7 unit of cup \( \rightarrow \) “for 1 batch you need 3/7 cup of sugar” \( \rightarrow \) coordination of the three-times-iterated pair of subunits “1/3 and 1/7”

Conclusions and Discussion

In this study, we observed DNLs being used in a way that was algorithmic. Often, teachers first used cross-multiplication to find an answer to a task that could be modeled with a DNL, which Lamon suggests, “does nothing to promote proportional reasoning” (1995, p. 167). Then, they used the DNL to draw their algebraic solution. In only one of the six tasks the group worked on together was a solution generated with DNL. And then, only one of the 15 teachers used the DNL in this way. We interpret this lack of using the representation to support problem solving as indicating that teachers were not comfortable in reasoning about proportional relationships and/or they had not developed an understanding of representations as tools for generating solutions and not just for illustrating them.

Despite issues with reasoning with representations and making mathematical connections, we did note that teachers were demonstrating multiplicative reasoning in the ways they conceptualized the relationships of variables in the problems. Several teachers consistently referred to phrasal quantities, which we interpreted as verbalized versions of what Lobato and Siebert (2002) call “composed unit,” which is critical for making sense of slope. In Lobato and Siebert’s research study, Brad appeared to construct ratio by forming the composed unit “10 cm in 4 seconds”, which, later was iterated by Terry to show that “walking 30 cm in 12 seconds is the same speed as walking 10 cm in 4 seconds” (p. 107). Our findings agree with Lobato and Siebert’s in the sense that our teachers felt the need to connect quantities of different units using a verb, which can be thought of as setting the stage for proportional reasoning, just as Terry does with reference to the be verb in the quote above.

In representing the situation with double number lines, an awareness of the equivalence of such phrasal quantities corresponds to the iteration of the pairs of quantities on the double number lines simultaneously. The process of looking at simultaneous iteration of the units and making use of phrasal quantities and connective verbs corresponds to teachers’ construction of ratios, in our research. For instance, in the Purple Paint Problem, Corey’s DNL provided the first evidence in this class of a teacher iterating pairs of units coordinated by numbers of batches, as shown in the vertical line segments in his drawing. He was not only able to coordinate the pair of iterated units with each other, but he was able to coordinate this pair with another unit, batches. A reference to a verb connecting the pairs of quantities was also established.

Problem solving forms the core of mathematical endeavor (English, Lesh & Fennewald, 2008). From 2006-2010, a team of mathematics educators from X University designed and implemented a professional development experience for mathematics teachers in four school districts called X University’s Partnership for the Enhancement of Teaching Mathematics (XUPET-Math). This paper highlights some findings in using Thinker-Doer tasks (Hart, L., Najee-ullah, D. & Schultz, K., 2004) in professional development settings and how teachers grew in their subject matter knowledge and pedagogical content knowledge using this professional development tool. We discuss teacher growth along a telling-listening continuum, and an individual-collaboration continuum.

Introduction

Problem solving forms the core of mathematical endeavor (English, Lesh & Fennewald, 2008), and a great deal of research has focused on the ways in which students develop as problem solvers (Schoenfeld, 1992; Hiebert, J., Carpenter, T., Fennema, E., Fuson, K., Human, P., Murray, H., Olivier, A. & Wearne, D., 1996). However, our experience with practicing teachers has indicated the need for helping classroom teachers develop as problem solvers themselves so that they can understand and model the practices they teach to their students.

From 2006-2010, a team of mathematics educators from X University designed and implemented a professional development experience for mathematics teachers in four local school districts called X University’s Partnership for the Enhancement of Teaching Mathematics (XUPET-Math). The XUPET-Math experience comprised a series of coordinated experiences involving lesson study, interviewing students and questioning techniques. One activity in particular—Thinker-Doer tasks (Hart, L., Najee-ullah, D. & Schultz, K., 2004)—focused on the development of problem-solving strategies and problem-posing through cooperation, communication, and content knowledge development. This paper highlights some of our findings in using Thinker-Doer tasks in professional development settings and how teachers grew in their subject matter knowledge and pedagogical content knowledge using this professional development tool.

Theoretical Framework

To provide a structure for our work with teachers and to provide a framework for understanding our progress in fostering the professional development of teachers as problem solvers and problem posers, we offer the model depicted in Figure 1. As Figure 1 suggests, we considered our work with teachers along two basic dimensions: (1) a telling-listening continuum, and (2) an individual-collaboration continuum. We decided to focus on these two dimensions.
Figure 1. The Telling-Listening / Individual-Collaboration Plane

Telling Teachers and Leading Questions

In three of the four partnering districts, classroom teachers were actively transitioning from traditional textbook series to reform-oriented teaching materials (e.g., *Mathematics in Context* [MiC], *Connected Mathematics* [CM]). Teachers in the fourth district were already using reform curricula - with elementary teachers using *Investigations in Number, Data, and Space* and middle school teachers using *CM*. Research indicates that the social constructivist orientation of reform materials poses significant challenges for teachers - particularly for those with extensive experience using traditional, teacher-centered materials (Smith, 1996). Because reform materials emphasize student knowledge construction and student-initiated problem solving strategies, successful implementation of the materials requires teachers to ask questions that help students develop their own hypotheses, methods, and generalizations. When such questioning is unfamiliar, teachers may inadvertently undermine student problem-solving development by posing questions that lead students to approaches favored by the classroom teacher.

As Wilson and Goldenberg (1998) note, many teachers feel uncomfortable when students struggle—although arguably it is in this struggle where learning occurs. Indeed, in their quest to "help" students "learn" mathematics, classroom teachers inadvertently convince many that "there is always a rule to follow in mathematics" (Dossey, Mullins, Lindquist & Chambers, 1988, p. 102) and mathematics problems must be solvable in five minutes or less (Schoenfeld, 1988). Indeed, such beliefs and practices remain pervasive among students and teachers in school classrooms today. With these obstacles in mind, the XUPET-Math instructional team decided to focus a considerable portion of XUPET-Math sessions on the development of teacher questioning strategies. In terms of the Telling-Listening / Individual-Collaboration Plane depicted in Figure 1, we aimed to encourage teachers to "slow down" and listen to others' mathematical thinking. As Pirie (1996) notes, "mathematical communication can take place effectively only if all participants are prepared to adopt both roles, to listen actively as well as to talk" (p. 105).
Conversations, Collaboration, and Problem Solving

Given the social constructivist orientation of reform teaching materials, a second aim of the professional development was to strengthen teachers' collaboration and communication skills—both central components of mathematical problem solving and that are embedded in the curriculum reform materials that they use with their students. For instance, students using the CM materials "present and discuss their solutions as well as the strategies they used to approach the problem, organize the data, and find the solution" (CM, 2010). Furthermore, they "pose conjectures, question each other, offer alternatives, provide reasons, refine their strategies and conjectures, and make connections" (CM, 2010).

Features of Thinker-Doer Tasks

The Thinker-Doer problems were used as a tool to help teachers focus on listening to students as they talked about their initial thoughts and plans as well as their strategies for solving rich tasks—all as a vehicle for informing teachers' instructional planning. The initial implementation of Thinker-Doer tasks followed the procedures outlined by Hart, Schultz and Najee-ullah (2004) (as described below), and later evolved to foster the collaborative aims of XUPET-Math.

Thinker-Doer Pairs

The process of completing a set of Thinker-Doer problems begins with the selection of two challenging rich mathematics tasks (of equal difficulty, if possible). The instructor divides teachers into two groups and gives distinct but related tasks to each group. Teachers retreat to different rooms to solve their problem collaboratively. After the groups solve the task, they discuss problem-solving strategies, alternative methods and the mathematics involved in their solutions, becoming "experts" of their own problem. Each person in the two large groups is now a "Thinker" for their particular problem.

When both groups finish solving their problems, they reconvene and partner with one of the teachers from the other group. The pair of teachers takes turns solving each other's problem. The "Thinker" encourages his or her partner (the "Doer") to read the unfamiliar problem aloud and asks if the partner understands the question or has any ideas about how to start the problem. The Doer's job is to try to solve the problem by thinking out loud. The Thinker does not interfere with the Doer's thought process. Instead, the "experts" are to listen carefully to their partner's problem solving strategies and mathematical explanations—only asking for clarification for their own understanding. When finished, the two partners change roles and tackle the other problem.

We found that listening rather than telling was a huge obstacle for our teachers; and it wasn't until the second or third set of Thinker-Doer problems that the teachers really started to listen to their partner's explanations. This multi-part process (large group initial solving and solving the two tasks in pairs) took a significant amount of time, but we felt that it was vital in helping our teachers learn more about what it means to really listen to their students even if the teachers believe that they know a better approach for solving a problem.

Thinker-Doer Triads

As our teachers became more familiar with the Thinker-Doer process, we reflected further on the model of the Thinker-Doer pairs. We found that some teachers were intimidated by solving challenging problems aloud as their partner recorded notes of their struggle. These teachers were often reluctant to share their mathematical strategies or explanations which in turn defeated one
of the primary purposes of the Thinker-Doer problems. Since we wanted to model problem solving as we would want to see it in the teachers' classrooms, we changed from Thinker-Doer pairs to Thinker-Doer triads. This process starts in a similar manner as before with three groups of teachers solving three different but related problems. Unlike in the original model, teachers are typically given time to think about and solve the problem individually before convening with the larger group. We found that individual thinking time was important to get each person engaged and committed to a particular strategy. Once the groups become “experts” of their own problems, we form triads of teachers selecting one from each group to work together. One expert poses his or her problem to the other two teachers. These two teachers work together to solve the problem, and are encouraged to think aloud communicating their own problem solving strategies. The teachers then rotate through all three problems, taking turns as the expert for their problem and the Doer of the two additional tasks. We found that this revised configuration further encouraged mathematical communication and helped to relieve teachers' anxiety of not knowing how to solve the problem.

**Methodology**

As part of the XUPET-Math professional development, participating in-service teachers completed three Thinker-Doer activities. The teachers completed a numerical self-assessment associated with each Thinker-Doer task, along with a written reflection. The reflection encouraged teachers to think about the mathematics content, student thinking, and ways to differentiate instruction to meet all students’ needs. The self-assessment consisted of nine statements, each rated by the participant using a Likert rating scale from 1 (little or no knowledge/agreement) to 5 (complete agreement/competence). The following is a listing of the nine statements:

1. I personally believe or feel comfortable with the level of mathematics in the Thinker-Doer problems for the grade level(s) I teach.
2. I personally believe or feel that my students will be able to solve these problems rather comfortably.
3. I personally believe or feel that I could predict what my students might be thinking when they are solving these problems.
4. After sharing with my Thinker-Doer partner(s), I understood the mathematics content more clearly than before.
5. After sharing with my Thinker-Doer partner(s), I understood what my students might think about the problem more clearly than before.
6. After this Thinker-Doer session was completed, I learned something new or came to a better understanding about mathematics content.
7. After this Thinker-Doer session was completed, I learned something new or came to a better understanding about ways to explore mathematics content.
8. After this Thinker-Doer session was completed, I learned something new or came to a better understanding about ways to predict how students or others may think about solving mathematics problems.
9. After this Thinker-Doer session was completed, I learned something new or came to a better understanding about ways to explain/facilitate mathematics learning.

In addition, teachers responded to the following writing prompts for each Thinker-Doer task.
Prompt 1: When I solved my problem as a Thinker I thought of the following things (i.e., mathematically with regards to math content and processes as I attempt to recount what I did while solving the problem).

Prompt 2: When I observed my Thinker-Doer partner(s) solve my original problem I thought of the following things about the way s/he worked through the problem as compared to my approach.

Prompt 3: If I had to prepare a problem similar to this in my grade level range (e.g., 3-6), my students’ content knowledge and mathematical understanding could vary, I might expect the following differences in content knowledge or mathematical understanding, and would adapt or differentiate instruction to meet my students’ needs in the following ways.

Results

Likert-Style Self-Assessment Data

As evidenced by the responses for Questions 1 and 2, most teachers were slightly uncomfortable with their own knowledge level of the mathematics content of the Thinker-Doers, and they did not feel that their students would be able to solve the problems comfortably. However, after completing the Thinker-Doers, these same teachers felt that they understood the content more clearly than before, they learned new ways to explore mathematics content, and they better understood ways to explain mathematics, as evidenced by the mean scores of 4 or higher on questions 4, 6, 7, and 9.

Question 3 asks whether the teachers felt that they could predict what their students might be thinking if they were to attempt to solve the problem. The mean score for this question was 3.1, and the scores that teachers reported ranged from 1.0 to 5.0. This indicates that some of the teachers felt very confident in their ability to predict what their students might be thinking while solving such problems, while others felt that they have little knowledge about what their students might be thinking. Question 5 then asked if after sharing information with their Thinker-Doer partner, they felt that they could more clearly understand what their own students might think about when solving the problem. The mean score for this question was 3.6, which was an increase over the mean of 3.1 on question 3. This could indicate that the discussions taking place between partners and in groups helped the teachers to understand various ways that different people think about solving problems. These insights were also evidenced in the written reflections, which will be discussed in the next section.

Analysis of Written Reflections

For the Summer 2008 workshop, teachers wrote a total of 53 reflection papers. The written reflections from the Thinker-Doers were examined against the objectives that were established for the XUPET-Math project and the Telling-Listening / Individual-Collaboration Plane.

One of the main goals of XUPET-Math was to document how teachers grew in their subject matter knowledge and pedagogical content knowledge using the Thinker-Doer professional development tool. Many of the teachers reflected on new understandings that they gained from acting as the "Thinker" and the "Doer." Many of the teachers mentioned how this activity helped them see the importance of peer collaboration. The following excerpts identify teacher growth along the individual-collaboration continuum.

“I believe this would be a terrific activity to use during Intervention, when I am working with a small group of students. By hearing the students discuss and ‘think out loud,’ I feel the teacher could gain so much insight into why/where a student is having difficulty with a problem.”

“I like the idea of partners working together and sharing their thoughts aloud. We do not do enough of this; we need to help every student have a voice in their learning. Being the teacher, I give too much aid to my students and this lesson showed me the power in being the listener and encourager over being the instructor.”

Other teachers discussed pedagogical strategies in their written reflections. The following excerpts identify teacher growth along the telling-listening continuum.

“This activity is a wonderful tool to help teachers understand the students’ thought process! I will definitely try this kind of activity to better assess the students’ needs by listening!”

"I had asked my partners repeatedly, ‘What does that number mean, what is it representing?’ That is a technique that requires the student to slow down and focus on what is being asked rather than finding a numerical solution.”

“It was fun to see that just questioning the students seemed to be the only thing that I needed to do to assist them. It is an ah-ha moment for me, that I don’t have to give hints over and over to assist.”

Discussion

Trends in the Likert-style and qualitative data, suggest teacher development along the two dimensions highlighted in the Telling-Listening / Individual-Collaboration Model. Figure 2 suggests this development visually. Most teachers—before they began working with Thinker-Doer tasks—identified with those in TD Set 1. These teachers strongly believed in the importance of telling learners (like their Thinker-Doer partners) when they were making mistakes and how to correct them. Teachers who completed Thinker-Doer tasks in their first iteration (where they were grouped in pairs and had to work independently while solving the new problems) identified with those in TD Set 2. At this stage, teachers practiced better listening skills (although they still relied somewhat on telling) but they still struggled with working collaboratively when solving problems. The Thinker-Doer pairings did little to help teachers progress along the Individual-Collaborative continuum. Teachers who regularly practiced Thinker-Doer tasks in their final iteration (where they were grouped in triads and were able to work with one partner when solving the problems) identified with those in TD Set 3. Here, they became much better at listening and providing scaffolding rather than telling while also appreciating the importance of discussing ideas with a partner.

Preliminary findings from open-ended responses suggest that the Thinker-Doer tasks (especially in the final iteration) fostered teachers' development as listeners. Teachers indicated that listening (rather than telling) was initially quite difficult but that the process became easier with practice. This is suggested by the left-to-right ordering of teacher placement in Figure 2. Likewise, collaboration was fostered through the implementation of the Thinker-Doer protocol. The revised Thinker-Doer triads made this collaboration more effective (and less daunting) for teachers, as suggested by the upward trend from Set 1 and 2 to Set 3.

![Figure 2. Development of teachers along the Telling-Listening / Individual-Collaboration Continua](image)

**Conclusion**

Thinker-Doer tasks served multiple purposes—they provided a context for both the development of teachers' subject matter knowledge as well as their pedagogical content knowledge. The tasks were used as launching points for subsequent discussions of specific content that teachers needed to know as well as ways in which the content could be delivered in their classrooms. In addition, the Thinker-Doer tasks gave teachers experience developing communication skills that they themselves would use when teaching students in an inquiry-based classroom. Teachers learned to listen as others solved problems and how to provide useful feedback that didn't detract from the solvers' experiences. This was not easy for all teachers to do and they expressed in their reflections the difficulty of using these experiences to make changes in their own practices.

Teachers also came to value the importance of working collaboratively when solving tasks. They began the project with the view that learning mathematics is an solitary process—that each person learns at his or her own rate and building on his or her experiences. While these claims are true, they ignore the importance of social constructivism and the knowledge that can be attained when working with someone else. Teachers realized the value of collaboration first-hand in moving from the Thinker-Doer pairs to the Thinker-Doer triads, and these experiences helped to establish a norm for group problem solving in their own classrooms.
References

This paper focuses on the development and problematization of a task designed to foster spatial visual sense in prospective and practicing elementary and middle school teachers. We describe and analyse the cyclical stages of developing, testing and modifying several ‘task drafts’ related to ideas around dilation and proportion. The task in its present form incorporates numerous considerations, including choices around materials, wording of questions and prompts, pedagogical structure, and sequencing of experiences.

**Introduction**

Research shows that increased attention to spatial, visual and kinesthetic approaches to learning mathematics helps students make connections between various representations of the underlying concepts (e.g. Goldin, 1998). Battista, Grayson, and Talsma (1982) found that pre-service elementary teachers often have poorly developed spatial visual reasoning skills for geometry, and have substantial anxiety about working with these approaches. Whiteley (2004) claims that visualization and mental imagery is central to mathematical reasoning. As such, we recognize a need for teachers to accure experiences with tasks and activities that make visible the underlying mathematical ideas and the connections between and among them. Both the NCTM and the CBMS stress the importance of spatial visual reasoning. In particular, the CBMS (2001) recommends teachers develop competence in visualizing, including becoming familiar with projections, cross-sections, and common two- and three-dimensional shapes. They also identify the importance of spatial visual reasoning in problem solving with 2- and 3-D objects.

In regard to these competencies we found that examples in the literature were often limited in scope (e.g., they focused specifically on mental rotation, or on shifting between 2-D and 3-D interpretations of a drawing) or they were developed for young students. For instance, Del Grande (1990) categorized skills that are key to children’s development of 2-D and 3-D geometry understanding: 1) spatial perception, 2) visual discrimination, and 3) visual memory. Clements (1999) suggests that children need opportunities to develop their visual and spatial senses, for example, by rotating objects in their minds. In considering older students, Eisenberg and Dreyfus (1991) reported that visual reasoning was often avoided (even by university mathematics students) in preference to algebraic reasoning. They theorized that a significant reason for this is that visual thinking requires more cognitive effort.

Despite the important contributions of these researchers, we did not find a structure of experiences that we believed would help teachers develop the spatial visual reasoning necessary to support students in spatial visual tasks and problem solving. In response, we set out to design a task that would foster such experiences. In line with the expressed content-based learning goals of the NCTM and the CBMS, our task addresses concepts in dilation and proportional reasoning.

**Framework for Task Design**

Sierpinska (2004) identifies task problematization (debating variations of a task and discussing the effects of such variation on the learning or research results) as central to studies in mathematics education. She proposes that design research is needed to clarify what is essential or...
arbitrary about tasks, as such knowledge would allow replication of task-based research results, and would inform the design of task sequences. An example of task design research is provided by Gadanidis, Sedig, and Liang (2004), who brought Human Computer Interaction (HCI) and mathematics education expertise together to examine an online mathematical investigation from two design perspectives - pedagogical and interface. We relate the cyclical process of design, develop, test, analyse, (re)design, (re)develop, (re)test, described by Gadanidis et al. (2004) to our design of visual spatial instructional tools. We introduce the idea of “task drafts”, which are discussed and analysed at each stage of the design cycle, and as such provide a mechanism within which task problematization can occur.

The design cycle begins with task designers’ consideration of broad principles, such as the importance of multiple representations and active participation, and computer interface design principles related to visual encoding and organization (Gadanidis et al., 2004). Such principles inform decisions about the inclusion of particular questions, prompts, materials, etc., and about how to orchestrate the task. At subsequent stages of development, the focus of the designer shifts to the responses of participant testers. Responses may reveal conceptual difficulties with the mathematical content, or they may bring to light underlying problems of the design. In the testing stage, participant actions and responses – particularly their non-actions and non-responses - enrich the task designers’ understanding of task elements and how they may interact to further the intended learning goal. In regard to the interactions of task elements our research draws on Sinclair’s (2003) research on the design of technological learning tasks, which revealed the importance of carefully structuring the links between prompts/questions and pre-constructed dynamic geometry sketches to support learning. That is, in the technological setting the task designer creates opportunities for students to investigate by including appropriate affordances – perhaps an onscreen button to add a line or measure an angle, or capabilities for revealing information in a novel way. The designer must also set prompts and questions to help learners using those affordances to notice, interpret, and extend their thinking. Relating these ideas to our study, we extend these perspectives to the design of 3-D hands-on investigations. For example, the materials we selected (hollow polyhedral shapes) needed to allow the learner to take appropriate action (e.g., holding, turning, moving, filling) in response to a prompt or question, which in turn needed to guide the learner as they acted. Throughout the design process we focused on developing links between prompts and models to support growth in spatial visual reasoning. This paper details three testing stages and task drafts in our on-going cycle of task problematization.

Methodology

The Task – Learning Goals

The motivation behind our task drafts draws on three themes: 1) ‘big ideas’ – the spatial visual concepts and experiences foundational for teaching elementary school mathematics; 2) making connections – experiences to foster and extend teachers’ thinking by linking ideas; and 3) strategies – enabling deep thinking about spatial visual concepts to recognize and address misconceptions. Our task drafts aim to (re-)develop spatial and visual skills, as well as develop relationships and connections among ideas related to dilation, ratio and proportion – ‘big ideas’ in school curricula (NCTM, 2000). We sought to foster connection-making among multiple representations and also between dimensions by including a kinesthetic component to the task, which incorporated manipulating 3-D models, and 2-D technological objects. The technology component was designed to provide opportunities to see dynamic change and develop imagery.
for such change. Through this component we aim to foster spatial visual strategies that allow learners to ‘see’ diagrams as encoding both 2- and 3-D information, and to explore both 2-D diagrams and 3-D objects.

The Task – Scope and Content

Specifics of The Filling Task are detailed below; however we briefly describe the scope and content here. The task has two distinct components – a GSP examination of dilation, and a 3-D exploration of cross-sections of polyhedral. Each of these subtasks was tested at three stages in the research process. The GSP task on dilation was intended to draw attention to the idea of center, to broaden the usual curricular treatment of scale diagrams, and to allow the user to investigate changes in length and area dynamically. The 3-D model task evolved out of a discussion around imaging cut surfaces (cross-sections), which we anticipated would be a new and interesting channel through which spatial visual skills could develop. Included in the appendix are the written prompts that accompanied the 3-D activity, as well as snap shots of a selection of the GSP screens, each from the third task draft.

The Participant Testers

Our task design occurred over three testing stages with pre- and in-service elementary and middle school teachers. The stages each lasted approximately two hours during which participants worked in small groups of two to four, and field notes were collected. Written responses to prompts and questioning were also collected and used to inform our analysis and task refinement. In the first phase of testing, 18 pre-service elementary teachers engaged with The Filling Task. The second testing phase occurred with 24 practicing elementary and middle school teachers. In the third session, our refined task draft was tested with another group of 18 pre-service elementary teachers. Participants in each of the testing phases were novices with respect to GSP, and our task design reflected the need to familiarize participants with basics of the software. The majority of participants at each stage were anxious about their understanding of mathematics in general, having not studied mathematics beyond the high school level.

Discussion: The Filling Task Testing Stages

Stage 1 Testing – The Initial Task Draft

Our initial task draft of the 3-D model included two sets of materials from which to produce cross-sections: objects to slice and objects to fill. The slicing material included plasticene shapes (e.g. pyramids, prisms), that could be cut parallel to the base to produce similar shapes. The filling materials included clear plastic shapes and water, which can show cross-sections and truncated 3-D shapes from multiple points of view. For the slicing approach, we observed that participants found it hard to create 3-D shapes with plasticene, and while the softer play dough could be shaped using plastic moulds, students had difficulty getting a clean cross-section cut (i.e. one that clearly showed the shape). The filling approach also posed some difficulties. Participants had difficulty identifying surface shapes because of the effects of surface tension, and some of the provided shapes were simply too small for making observations.

The GSP task included blank sheets on which participants were encouraged to construct and dilate shapes. Although instructions were provided, we noted that most participants needed more scaffolding and were often distracted from issues of dilation by the challenges of constructing shapes with the software. Despite the challenges, the GSP task did lead to a discussion of the
idea that the slices through the tetrahedron models could be thought of as dilations. This was an important connection for participants, and it motivated subsequent changes to our task design.

**Stage 1 Testing – Task Revisions**

As a result of the first testing session, we made a number of modifications to the GSP task. In resonance with Sinclair’s (2003) observations regarding directing student attention, and because of participants’ struggles with constructing polygons, we decided to shift to the use of pre-constructed sketches. The intent was to lessen the demand on participants and to help maintain their focus on dilation. The revised screens were designed to lead the learner through sequenced interactive investigations of ratios in connection with dilation.

Although slicing had engaged the students, the difficulty of getting a clean slice in the 3-D model task led us to focus on filling (despite our concerns about surface tension) as a more appropriate activity. Based on this testing session we also made decisions about the timing and focus of the activity. We determined that 1) we should work with just a few shapes: triangular and square-based pyramids; 2) to develop the idea of proportional reasoning, we should have the participants pour water gradually into a (stabilized) 3-D shape and examine the resulting shapes; and 3) we should make connections to and between a scale factor’s effect on side length and area, and the effect of tilting a pyramid on volume and surface area.

Thus, we developed the 3-D model task to focus on filling large, transparent plastic polyhedra with water; we emphasized tilting the objects; we focused questions on proportional reasoning; and in light of the interest participants showed in making connections between the filling activity and the GSP demo we deliberately linked the two tasks.

**Stage 2 Testing – A Revised Task Draft**

The revised GSP task included eight pre-constructed GSP sketches that addressed linear and area relationships of scaled figures through dilation. Instructions and prompts were included onscreen to focus attention on the sketches. Sketches were designed to be done in sequence, to ensure that participants learned GSP procedures at a modest pace, and to build mathematical ideas. Printouts of the screens were provided for recording purposes.

The GSP activity focused on the dilation of a triangle – it is easily manipulated by dragging and is a natural 2-D analogue of a pyramid. All screens were designed in light of the idea that visual cues such as colour, orientation, location on the page, etc. play an important role in learners noticing relevant mathematical ideas (Gadanidis, et al., 2004). Architectural measurements of segments and calculated ratios were included, as was a slider that participants could use to control the scale factor; these were intended to help participants connect a visual sense of dilation with the results they would get from applying a formula. We included “hide/show” buttons that toggled between the strictly visual representations and the numerical relationships. Text instructions and prompts were also provided on-screen. In resonance with Sinclair (2003), we acknowledged that text prompts are key to supporting mathematical understanding during technological investigations, as is directed dragging in the specific case of dynamic geometry software activities (Arzarello, et al., 1998). Such directed dragging was encouraged on several screens of the GSP activity. Appendix A presents the first screen of the activity, and exemplifies the design considerations mentioned. Despite the encouragement, we found participants were hesitant to explore shapes on their own. As before, participants had little experience with GSP. Our revisions to the prior task draft incorporated interface and pedagogical considerations (Gadanidis, et al., 2004), and motivated the inclusion of pre-constructed sketches,
so there was little need for participants to know GSP. Nevertheless, participants’ use of dragging appeared restricted and hesitant, rather than directed and purposeful. We also noted that participants were moving step by step through the screens but were not making connections between them; they seemed to lack an overall picture of the activity.

The second task draft of the 3-D model involved filling square- and triangular-based pyramids. The focus was on observing and comparing side lengths and areas of the surface shapes while the pyramid was in the upright position and then in a tilted position. Participants were encouraged to find how many different types of shapes they could create by filling and tilting the pyramid, and what their findings implied for cross-sections of other 3-D shapes. In this stage of testing, the 3-D model task succeeded the GSP activity. We noted that participants had difficulty making connections around scaling, similarity and proportional reasoning. They became distracted with pushing calculations and seeking formulae, rather than trying to use the model to see the possible connections and overall proportional changes. In the case of the triangular based pyramid, the filling activity linked closely to the work set up for the GSP task, providing a concrete model of dilation, with successive water surfaces acting as the “dilating triangles” and the bottom vertex as the center. While we observed that some participants could see the GSP sketch in two and (simulated) three dimensions immediately; for others, the activity of filling the pyramids helped make the connection. Further connections to proportional reasoning were supported by access to measurements provided in the GSP sketches.

Stage 2 Testing – Task Revisions

Despite the fact that a small number of participants recognized the link between the two subtasks, we decided in our revisions to reverse the order and place the 3-D model task first and the GSP dilation task second. While our intention is that subsequently learners will work back and forth between the two contexts, we contend that the hands-on investigation is better preparation for the GSP task, than the GSP task is for working with the 3-D models. Specifically, the change was motivated by the views that 1) children initially learn mathematical ideas from their 3-D experience of the world and only later are schooled into thinking in 2-D, and 2) elementary teachers often lack mathematical background and investigative skills, and we found that these deficiencies were more easily addressed during the hands-on investigations than when participants were working with the software. These considerations are analogous to interface considerations described by Gadanidis, et al. (2004) who contend that the arrangement of ideas intended to be communicated “mediates student engagement” (p.275).

Another change was to introduce a “guide” to the GSP dilation activity. Each screen was named, e.g., Explore Transform, Scale Factors, and these titles, with a short description of that section of the activity and several prompts were provided as a one page addendum to the activity. Though instructions were still embedded in the sketches, we developed the guide to provide a “big picture” and reveal the structure of the task. Instructions for the GSP task underwent considerable revising and we hoped that future task drafts would be more successful at directing participants towards the intended learning goals. Though not strictly part of the task draft, the revision included development of an introductory GSP session, which included opportunities to use and explore items in the construct, transform, and measure menus.

Stage 3 Testing – A Revised Task Draft

As indicated, the 3-D model task preceded the GSP task in this stage. A selection of written prompts for the 3-D model portion of this task draft are included in Appendix B, while snap
shots of some of the GSP screens appear in Appendix C. Starting with an exploration of the 3-D model encouraged participants to take a ‘playful’ approach to the task – they explored creatively and even initiated looking at extreme cases (e.g., by using very large angles for tilting). Although use of a model can reaffirm the belief that mathematics should make sense, physical constraints can be problematic when one is aiming to generalize. Our response at first was to improve our materials, but then during subsequent task drafts we reasoned: Noticing mathematically significant details requires ignoring imperfections - thinking about the perfect tetrahedron, or the imagined line of symmetry of an isosceles triangle in the water surface. A key aspect of visual interpretation is that we ignore almost all features of our current environment, and focus on the few features that we anticipate ‘matter’. This implies that an important strategy for working towards generalizing is acknowledging imperfections in physical objects and explicitly identifying the properties that one wants to attend to across cases, and ignoring most of the ‘mathematically irrelevant’ bits. In this testing stage, our participants learned what features were distracting and which were relevant to their reasoning.

Participants in this stage were also more confident using GSP than in the previous testing stages, which we attribute both to the introductory GSP session and to the atmosphere of exploration stimulated by the 3-D investigation. As in earlier sessions, the link between the GSP and the 3-D model tasks was noticed by participants. One example was quite striking - a participant looked at the very first sketch – two dilated triangles and a point labelled “center of dilation” – and said to her partner, “Do you not see lines here connecting these here and here?” pointing to the center point and corresponding vertices in triangles and actually connecting them with her ruler held in front of the screen. She was referring to lines which were not visible on the screen, yet she was “110% sure it’s a pyramid.” Overall, we found that participants made connections between the two sub-tasks more explicitly; we attribute this to the revisions, which provided clearer opportunities to notice the relationships. However we continue to see significant difficulty with the ‘scaling of area’ and are developing modifications to build up these links.

Through this lengthy (and still unfinished) process we have problematized a spatial visual task designed to help teachers broaden their understanding of dilation, ratio and proportion. Variations of the task have been tested and discussed with respect to their effects on learning. The task in its present form represents numerous decisions around materials, wording of questions and prompts, pedagogical structure, and sequencing of experiences.

Concluding Remarks

We designed The Filling Task to foster connections between 2-D and 3-D representations, to support proportional reasoning in geometric contexts with spatial visual skills, to give context and experience with cross-sections of objects, to support development of abilities in spatial investigations, and to provide a rich network of connections and representations that could act as a launching pad for extended explorations. The analysis of ratio and area concepts and measurements, and the idea of dilation as a transformation with a center in the GSP task can be seen as foundational for a rich exploration of the filling problem. Alternatively, the filling experience in the 3-D model task can be seen as a preparatory, kinesthetic experience to the more visual, symbolic, and numerical work in the GSP task.

Through our process of testing and refining task drafts, our research sheds light on the combined use of models and technology to foster connections and mathematical understanding. Due to space limitations, this paper offers a mere glimpse at the cyclical process of task design, but it highlights what we consider are some important pedagogical considerations. In particular,
our task illustrates how engagement with dynamic software can complement a 3-D exploration, for instance, by drawing explicit visual-numerical connections and by offering tools that allow the learner to ‘sit back and watch’ a 2-D realisation of their 3-D activity.

An important goal of ours was to design a task through which participants may develop a flexible imagery, in which changes can be explored mentally, and other variations not seen externally can be imagined. We continue to modify the task towards this end. We hope that our analysis of multiple ‘task drafts’ will inform the process of task problematization in mathematics education research and teaching.

Appendix B – The Filling Task 3-D Model, Testing Stage 3

Selection of written prompts provided as a hand-out.

1. Using the materials provided, embed the bottom vertex of a pyramid in play dough so that
   the top is parallel to the table.
   a. Pour in a small amount of water – record as best you can the shape of the surface of
      the water from the top (e.g. with a picture, verbal description…).
   b. Pour in an additional amount – record the shape.
   c. Pour again – record.
   d. Compare the shapes you have drawn as to their lengths of sides, surface area, and
      volume.
2. Repeat #1 for the same pyramid tilted at different angles.
3. Describe in your own words what was happening to each of the dimensions of the water’s
   shape as (i) more water was added, and (ii) some water was poured out.
4. Reflect on steps 1 and 2 above.
   a. In what ways, if any, did the shape of the surface area change when you tilted the
      pyramid?
   b. In what ways did the shapes’ measurements change?
5. Do the observations you made hold true for new shapes? Why or why not?

A MIXED METHODS INVESTIGATION IDENTIFYING CHARACTERISTICS OF INFLUENTIAL FACILITATORS OF ELEMENTARY MATHEMATICS PROFESSIONAL DEVELOPMENT

Sandra M. Linder
Clemson University
sandram@clemson.edu

This paper provides results from a research study that adds to the literature on professional development in elementary mathematics by focusing on the role of the facilitator in influencing teachers to be engaged during professional development experiences. An exploratory sequential mixed methods design was utilized to answer the central research question: How do United States elementary school teachers perceive an influential facilitator of elementary mathematics professional development (EMPD)? Phase one of this study explored teacher perceptions through a dual-phenomenological design, which informed the second phase of the study, the implementation of a survey to elementary school mathematics teachers on a larger scale.

Introduction

When examining the research related to mathematics professional development, there is a lack of focus in the literature on the facilitator’s role during professional development experiences. A facilitator of professional development represents a movement away from the traditional, or additive, approach to professional development where trainers transmit or tell information and teachers are passive recipients. A facilitator of professional development acts as a guide for teachers as they develop new knowledge through a variety of experiences. This paper describes results from a study analyzing teacher perceptions of influential facilitators of elementary mathematics professional development (EMPD). For the purposes of this study, professional development was defined as any teacher learning, district mandated or not, that is dedicated to improving teacher quality. Because this study focused on elementary mathematics teachers, Simon’s (2000) call for a change in knowledge and beliefs to be aligned with reform efforts was used as criteria for determining improvement in teacher quality. This definition of professional development excluded experiences that are additive in nature (Smith, 2001). When determining whether a facilitator is influential, in essence, we are examining the characteristics of the facilitator that motivate teachers and enable them to learn from the professional development experience. If teachers are unmotivated during professional development, they are unlikely to gain anything from the experience. An exploratory sequential mixed methods design was utilized to answer the central research question: How do United States elementary school teachers perceive an influential facilitator of EMPD?

Literature Review

Visions and goals for mathematics instruction call for a shift in beliefs about the nature of teaching and learning mathematics (Wilkins, 2008; Cady, Meier, & Lubinski, 2006; NCTM, 2000) along with a need to increase teachers’ level of pedagogical content knowledge in mathematics (Hill, Ball, & Schilling, 2008). This transformation in mathematics instruction can be described as a movement away from instructional practices focusing on the transmittal of rules and procedures and towards instructional practices that allow students to construct meaning and understanding about mathematics as a dynamic system of concepts (Romberg, Carpenter, &
Dremock, 2005). For these changes to occur, teachers require extensive professional development experiences designed to critically examine current instructional practices and provide them with the tools to implement reform practices in mathematics instruction (Loucks-Horsely, Hewson, Love, Mundry, & Stiles, 2003).

Current literature in mathematics education identifies characteristics that are necessary for high-quality mathematics professional development to occur. An effective professional development model is ongoing and situated in practice, focused on mathematical content, has student learning as the ultimate goal, and leads toward the development of a community of learners (Desimone, Smith, & Ueno, 2006; Weiss & Pasley, 2006; Guskey, 2003; Smith, 2001; NRC, 2001). Professional development should be transformative in nature, meaning that it is designed to alter or improve existing instructional practices. This type of professional development in mathematics differs from additive methods where teachers are given activities or tools to add to their existing practice (Smith, 2001). While the literature relating to effective practices in mathematics professional development is extensive, there is little focus on the role of the facilitator during these experiences. Just as a well designed mathematics curriculum can be negatively affected by poor instruction (Ball & Cohen, 1996), a well designed professional development model can be negatively affected by poor facilitation (Weiss & Pasley, 2006; Gibson, 2005). In a review of 133 peer-reviewed sources related to professional development, only 4% of the sources focused specifically on the facilitator’s role in mathematics professional development. Of this 4%, very few articles were identified as empirical research examining the role of the facilitator in elementary mathematics professional development (Sztajn, Hackenberg, White, & Alexsasht-Snider, 2007; Weiss & Pasley, 2006).

The theoretical framework guiding this study was grounded in motivation theory and adult learning theory. It is imperative that teachers be motivated during professional development in order to learn from the experience. The facilitator can play a key role in developing this motivation. This study primarily centers on Bandura’s social cognitive theory (1986). In this theory, Bandura identified three constructs: (1) environment, (2) self, and (3) behaviors; which act in a symbiotic manner to influence motivation. Embedded in this theory is the notion of self-regulation, or peoples’ ability to control learning through the combination of academic learning skills and self-control. Self-regulation focuses on the need for a person to recognize their own ability to learn, however, this recognition is dependent upon perceptions of the world around them. The rationale for examining teacher perceptions in this study is two-fold. First is the underlying principle set forth by Husserl and then refined into method by Moustakas (1994) that truths can be derived from the examination of perceived truths to identify common themes. Second, according to Bandura’s social cognitive theory (1986), perceptions play a key role in influencing motivation. A number of studies have shown how perceptions influence motivation (Watt & Richardson, 2007; Groth & Bergner, 2007).

Pellicer and Anderson (1995) identify the need for facilitators of professional development to build experiences around the tenets of andragogy as a means of motivating teachers to be engaged. Malcolm Knowles first introduced the theory of andragogy, or the study of how adults learn, as compared to pedagogy, the study of how children learn (Knowles, Holton, & Swanson, 1998; Knowles, 1994). In this theory, Knowles stipulates that certain conditions are necessary for adults to thrive in a learning environment. These conditions include the need for adults to be actively involved in learning tasks; the need for learning to be relevant to past experiences; and the need for self-direction (Brown, 2006; Merriam, 2001). According to this theory, adults prefer professional development experiences where they are able to give and receive feedback and can
actively test ideas rather than passively receive information. Adults are also self-directive in that they are present, rather than future orientated. This point is crucial for professional development experiences because teachers have to believe that what they are learning is useful to their current practices (Merriam, 2001). Theoretically, facilitators who utilize motivation theory and andragogy when implementing professional development experiences are more likely to have teachers learn from the experience (Pellicer & Anderson, 1995). However, a lack of empirical evidence exists determining if these principles alone will ensure teacher motivation in elementary mathematics professional development (EMPD).

**Methodology**

The central research question guiding the focus of this study was: How do United States elementary school teachers perceive an influential facilitator of elementary mathematics professional development (EMPD)? This question was examined using a mixed method methodology with an exploratory sequential design (Creswell & Plano Clark, 2007). In this study, an exploratory design was necessary due to a lack of empirical work identifying qualities of influential facilitators of professional development in elementary mathematics. Phase one of this design examined how South Carolina teachers describe influential facilitators of professional development. This question was examined qualitatively through a phenomenological design (Moustakas, 1994) where data was gathered through semi-structured interviews. In this first phase, two subgroups of teachers were interviewed to determine their perceptions of influential facilitators of professional development. While the results of phase one provided extensive data on how teachers in certain areas of South Carolina perceive influential facilitators of EMPD, it was unclear if these results would generalize to a larger sample of teachers in South Carolina or across the United States. It was necessary to use the results from the first phase of this study to inform the second phase of this study, which examined teacher perceptions of influential facilitators of EMPD across the United States. In this second phase, the results from phase one were mixed to develop a survey instrument that was administered to a larger sample of teachers to determine if their perceptions of influential facilitators were similar to those identified in phase one.

**Sampling Techniques**

The participants in this study were elementary school teachers who had experience with transformative mathematics professional development. These participants included kindergarten through fifth grade teachers who teach all content areas, those who only teach specialized areas such as math and science, and special education teachers who work in either inclusive or self-contained settings. Phase one contained two subgroups of teachers, one group who had experienced transformative professional development that is ongoing (labeled Group 1) and the other group who had experienced transformative professional development that is isolated into a one or two day session (labeled Group 2). Each subgroup was comprised of 10 participants. While more teachers have experienced isolated professional development that is transformative in nature, very few have experienced a model that is ongoing (NCES, 2006). Ball (2002) recognized the need to examine isolated professional development experiences that are devoted to improving teacher quality in addition to the ongoing model recommended by researchers in professional development. For the purposes of this study, it was necessary to complete a dual phenomenology examining teacher experiences of professional development models that were
ongoing in addition to those that were isolated to determine what teachers perceive as common characteristics of influential facilitators.

Phase two participants were identified through convenience and snowball sampling techniques. These potential participants were contacted through gatekeepers from a variety of areas in education, including state agencies, district personnel, curriculum publishing companies, university professors, and state and national educational organizations. A total of 49 gatekeepers participated in this phase of the study. The researcher provided each gatekeeper with access to the survey instrument, who then distributed it to participants. A total of 652 participants responded to the electronic survey. However, this sample was narrowed down to 565 participants after a cursory examination of the responses. Due to the nature of electronic surveys, many potential participants began the survey and did not complete it for various reasons, including not meeting the criteria necessary to be a participant or clicking on the electronic link without intending to complete the survey. These potential participants were omitted from the sample used during data analysis. Examples of sampling issues relating to electronic surveys are not uncommon and have been documented in the literature relating to survey research (Franklin, 2008; Davidson, 2008; Dillman, Smyth, & Christian, 2008).

Data Collection and Analysis

The researcher conducted 20 semi-structured interviews with the participants identified for phase one. Each interview was approximately 45 minutes to an hour in length. The data from each subgroup in phase one was examined separately in a primary analysis by isolating and extracting significant statements from interview transcripts. These statements were then used to create meaning units, which were clustered into common themes (Moustakas, 1994). Following this analysis, a secondary review identified common themes between groups.

Mixing occurred between phases to develop the survey instrument used in phase two. Qualitative data that had been organized by theme prior to data reduction were quantitized to determine how often each idea occurred. A total of 116 items were developed based on the themes that emerged in the qualitative phase of the study. These items were reviewed and reduced by two experts in the field of instrument development. Based on their recommendations, the items were reduced to a total of 65. The resulting survey was piloted to 35 elementary school teachers in South Carolina prior to the phase two implementation.

The final survey was distributed electronically to 49 gatekeepers in areas across the United States who, in turn, distributed it to elementary school teachers. The reliability coefficient was computed to establish the internal consistency of the survey instrument. Following this examination, construct validity and the dimensionality of items were analyzed using principle components factor analysis (PCA) (Thorndike, 2005; Ott & Longnecker, 2001). Once factors were identified and labeled, the researcher conducted a series of t tests to determine if participants in phase two agreed with the findings from phase one.

Results

Five themes emerged in phase one that outlined the essence of how teachers perceive an influential facilitator of EMPD: (1) Credibility, or qualities which allow participants to feel confident that the facilitator is qualified and capable to conduct professional development, (2) Support, or assisting and reacting to participants in a way that develops trust, (3) Motivation, or the facilitator’s rationale for conducting professional development, (4) Management, or the way the facilitator presents activities or tasks, and (5) Personality, or the demeanor of the facilitator.
Participants across samples identified a barrier or wall that exists between the facilitator and participants, mostly due to the nature of professional development as being something that teachers are required to attend. If a facilitator wants to influence participants to alter instructional practices, this barrier must first be addressed. The five themes emerging from the data provide a framework for facilitators to understand why this barrier exists. In order for the barrier between teachers and facilitators to deteriorate, it is necessary for the facilitator to possess the qualities inherent in all of these themes.

The reliability of the scale in phase two was .941. Principle components factor analysis (PCA) was conducted for data reduction and to examine the dimensionality of the items. A factor extraction yielded six factors with eigenvalues greater than one. The Kaiser-Meyer-Oiken measure of sampling adequacy yielded a high level of compactness (.945), further, Bartlett’s test yielded significant results ($p < .001$) therefore, factor analysis was appropriate for these data. Factor rotation was determined through a comparison of the scree plot and the amount of variance explained by each factor. Based on these results, five factors were rotated using a Varimax rotation procedure. Each of the five factors yielded an interpretable factor solution. Factor 1, labeled Support, accounted for 36.42% of item variance and was defined by 16 of the scale items. Factor 2, labeled Personality, accounted for 6.89% of item variance and was defined by six of the scale items. Factor 3, labeled Management, was defined by seven of the scale items and accounted for 5.15% of item variance. Factor 4, labeled Knowledge, accounted for 4.05% of the variance and was defined by six items. Factor 5, labeled Connections, was defined by five items and accounted for 3.6% of the variance. Factors 4 and 5 were comprised of items that related to the theoretical construct of Credibility. The five rotated factors accounted for a total of 56.10% of the variance. These results indicate a relatively high level of reliability and validity in the survey instrument.

Five one-sample $t$ tests were conducted on the survey responses to determine the extent to which participants agreed or disagreed that the items were characteristics of influential facilitators. The five factors identified through PCA were used in this analysis. Each had a scale of 1 (Completely Agree) to 8 (Completely Disagree). The test value was the midpoint of a summative score calculated for the items clustered under each factor. The alpha was set at .05. All of the $t$ tests yielded significant results ($p < .001$) with large effect sizes. Based on these results, it is evident that participants in phase two agree with the findings in phase one to a significant extent. Therefore, the findings from phase one were generalizable to a larger sample of teachers in phase two of the study.

**Conclusions**

Although extensive research has been conducted on professional development in mathematics, a review of the literature revealed a lack of research related to the role of the facilitator in EMPD. The current study was conducted in response to this gap in the research literature. Five themes emerged from the analysis of the phase one sample: (1) Credibility, (2) Support, (3) Motivation, (4) Management, and (5) Personality. The characteristics clustered under each of these themes were identified as influential by teachers across all samples. The characteristics related to Credibility included the need for the facilitator to have both classroom experience at the same grade level as participants and experience with the topic they are discussing, they must have knowledge of both content and pedagogy, they must provide specific data supported the practices they are promoting, and they must act in a professional manner during sessions. The characteristics clustered under Support included the need for a facilitator to
build trust by providing extra help before, during, and following professional development experiences. The facilitator must also react to participants in a positive way during professional development by answering questions and treating them as equals. Characteristics related to Motivation pertained to the facilitator’s rationale for conducting professional development. Facilitators should want to do their job so they can help teachers and students. They should believe in the methods they are promoting. Management characteristics included the way a facilitator moves around the room and engages with participants. Facilitators should hold teachers accountable during professional development to demonstrate that everyone can provide relevant information. The facilitator should also be organized in their management of materials and their methods of disseminating information. Finally, characteristics relating to Personality included the need for facilitators to connect with participants by having an easygoing demeanor and a sense of humor. They should be approachable and display a sense of confidence without seeming arrogant.

This need to possess characteristics across all themes in order to be influential holds implications for research relating to motivation theory. Research has been conducted on the roles people play in influencing motivation (Vogt, Hoecevar, & Hagedoren, 2007; Watt & Richardson, 2007; Groth & Bergner, 2007). Role models have been shown to increase motivation through such qualities as perceived competence, perceived prestige, or perceived connections (Bandura, 1986). Sztajn and colleagues (2007) identified the importance of perceived trust between teachers and facilitators of ongoing professional development. In the current study, a multiplicative effect that can be termed “perceived influence” was found to potentially increase motivation. It is important to note that each of the themes described in these findings must be present for a facilitator of EMPD to be considered influential by participants. If a facilitator has perceived credibility but does not exude perceived support, then that facilitator will not be influential for these samples of K-5 teachers. Future investigations of this multiplicative effect are necessary to determine if facilitators who are perceived as influential increase teacher motivation during professional development and to determine the implications that increased motivation holds for instructional practice.

DEVELOPING LOCAL THEORIES OF INSTRUCTION AND THE IMPACT ON TEACHING CHALLENGING CURRICULA

Jeffrey Choppin
University of Rochester
jchoppin@warner.rochester.edu

This study focuses on a form of teacher’s pedagogical content knowledge instrumental to enacting challenging tasks in ways that elicit and refine students’ mathematical reasoning. The teacher, chosen for how she consistently engaged student reasoning while enacting challenging tasks, showed evidence of possessing a local theory in that she articulated the ways student thinking developed over time, the processes by which that thinking developed, and the resources that facilitated the development of student thinking. Her knowledge informed how she revised and enacted challenging tasks in ways that elicited and progressively refined and formalized student thinking around integer addition and subtraction.

Introduction

In the U.S., a number of curricula have been developed that depart from conventional notions of curricula and that build from decades of research in the cognitive sciences of how children learn mathematics (Schoenfeld, 2006). Although these curricula were intended to support teachers’ efforts to engage students with challenging tasks, there has been little evidence that simply introducing these curricula changes teachers’ practices (cf. Collopy, 2003; Remillard & Bryans, 2004). Consequently, it is likely that teachers need to develop new forms of knowledge in order to enact the tasks in the materials in ways that elicit and build from students’ mathematical reasoning.

There has been much discussion about the kinds of knowledge that impacts teachers’ ability to engage children in ways that help them learn with understanding, with a particular focus on the role of pedagogical content knowledge (PCK) (e.g. Grossman, 1990; Shulman, 1986), which Gess-Newsome (1999) describes as “the transformation of subject matter, pedagogical, and contextual knowledge into a unique form – the only form of knowledge that impacts teaching practice” (p. 10, author’s italics). More recently, Hill, Ball, and Schilling (2008) have attempted to refine notions of PCK into various components, including situating PCK in particular mathematical domains. Thus, the most relevant knowledge is conceived as transformed while teaching and has some explanatory power with respect to how students learn in particular domains. The research on teacher knowledge, however, has primarily shown an association between forms of PCK and student learning, with a need to further elaborate how PCK functions to help teachers organize instruction to elicit and refine student reasoning through the use of challenging tasks.

I explore teacher knowledge in terms of a local theory of instruction as a form of PCK situated within a particular instructional sequence. A local theory of instruction is an empirically-tested set of conjectures about how students learn in a specific mathematical domain, or what diSessa and Cobb (2004) call domain specific learning processes, with respect to a particular instructional sequence. The testable conjectures include both the processes by which students learn in a particular mathematical domain and the resources that influence or support those processes.

This study focuses on one teacher who consistently elicited and organized instruction around students’ reasoning. The goal of the study was to explore the nature of the teacher’s knowledge and how it helped her to enact tasks from challenging curriculum materials. The research questions that guided this study were:

1. What knowledge was evident in the teacher’s practices and reflection on those practices, particularly with respect to her understanding of how student thinking developed across an instructional sequence related to integer addition and subtraction?
2. How did the teacher’s knowledge help her to use challenging tasks to elicit and build from students’ mathematical reasoning?

**Methods**

Video data were collected and analyzed and used to stimulate the teacher’s reflection on her enactments of an instructional sequence based on integer addition and subtraction. The teacher, Ms. Graham, was selected because she had the highest rating of the ten teachers in a broader study in an analysis of classroom discourse in terms of the extent to which she engaged students’ in conceptual discourse around challenging tasks. Ms. Graham was using materials from the Connected Mathematics Project (CMP) curriculum (Lappan, Fey, Fitzgerald, Friel, & Phillips, 2006), which was designed as a problem-based curriculum using funds from the U.S. National Science Foundation. The CMP materials differ from more conventional texts in that they are comprised largely of tasks that are designed to be implemented at a high level of cognitive demand.

**Description of Phases in the Instructional Sequence**

The analysis of the sequence focused on eight tasks divided into three phases that roughly constitute a progression from informal to informal and that focused on the early development of resources that formed the basis of subsequent activity. In the first part of the sequence, the tasks constituted a phase in which students’ reasoning based on prior experiences with integers was elicited. In the next part of the sequence, there was a focus on developing representations and models that facilitated the development of student strategies in subsequent tasks. In the third phase, students focused on patterns in the operations they had carried out earlier in the sequence to develop conjectures and ultimately strategies for integer addition and subtraction.

**Results**

**Eliciting Students’ Informal Reasoning**

Ms. Graham used the tasks early in the sequence to elicit students’ reasoning around integers, in part to begin the process of collectively discussing ideas and to build from students’ prior experiences with integers. She stated:

> These opening discussions are to help students tap into what they already know... to help them draw upon that as a basis for a foundation... what I want them to do in those beginning discussions is make connections ... to either problems that they’ve done before or contexts (Video-Stimulated Interview [VSI], August 28, 2009).

In several classroom episodes from the first tasks in the sequence, Ms. Graham engaged students in several free-ranging discussions, in which she repeatedly asked students to express their reasoning and to comment on other students’ reasoning. These discussions were intended to

be informal and to provide opportunities for students to make connections to their prior knowledge and to begin more formal consideration of the properties of integers. She did not attempt to formalize the ideas raised by the students, and instead emphasized the sense-making aspects of the early tasks, allowing students to state claims without directly evaluating them.

**Developing Models and Representations**

Ms. Graham described the role of models and representations in developing student reasoning beyond the informal phase. She described how these models and representations served as resources in terms of coordinating the discussion between number sentences and operations and in terms of establishing the basis of claims made about integer addition and subtraction. For example, early in the sequence Ms. Graham focused on developing number sentences that could be subsequently used to make conjectures about the relationship between integer addition and subtraction. The goal, as Ms. Graham stated, was to have students “write multiple number sentences that represent the same situation so that we can draw on those examples later when they’re trying to make their generalizations about how the operations work” (VSI, August 28, 2009). She also discussed the role of the number line and chip board models in allowing students to develop and justify conjectures, and the need for students to have informal experiences with the models. She stated for example that it was important to get students “to talk about the number line and make sense of it and mess around with it, (e.g.) where is big or where is small or what’s happening over here with these negative numbers” and emphasized the number line early because “I knew the number line was going to be used as a model later in terms of adding or subtracting” (VSI, June 4, 2008). Several episodes from the fourth (of seven) lessons showed how Ms. Graham focused students on the actions represented by number sentences and the connections between the number sentences, the number line, and the operations used to arrive at an answer.

**Generating and Refining Conjectures**

Ms. Graham used tasks in the latter part of the sequence to help students reflect on and refine the conjectures they had stated throughout the sequence. For example, she had the students record their conjectures, from which she selected a sample to collectively pose to the students to discuss their accuracy. In her class, the students spent 60 minutes (February 4, 2009) reflecting on the conjectures around subtraction. She stated that she emphasized students’ conjectures because the early part of the sequence did “not formally or explicitly draw kids’ attention to what they were actually doing and help them to draw generalizations” (Joint Interview [JI], March 25, 2010). The goal of the emphasis on student conjectures was to “support [the students] towards writing …about what they’re noticing” (JI, March 25, 2010), as a precursor to developing efficient yet comprehensive strategies. In the latter part of the sequence, Ms. Graham continued to focus on helping students generate efficient yet sensible strategies for adding and subtracting integers. Several episodes in the latter part of the instructional sequence showed how Ms. Graham explicitly engaged students in the processes of refining their thinking and language with respect to integer operations and how she continually relied on the resources developed throughout the unit, such as the number line and chip board models.

**Discussion**

Ms. Graham showed evidence of having a local theory of instruction and that, furthermore, this local theory helped her to orchestrate student engagement from challenging tasks in ways
that elicited and refined their reasoning around integer addition and subtraction. First, she described a broad learning trajectory in terms of the sequence of tasks and how the sequence provided students opportunities to connect to their prior experiences, to develop the tools and experiences to subsequently make sense of integer addition and subtraction, to generate and refine conjectures, and ultimately to develop sensible and efficient strategies. Second, Ms. Graham noted a variety of resources that were influential in helping students to make sense of integer addition and subtraction. Notably, she emphasized the use of the chip board and number line models throughout the sequence, initially to help students to develop an understanding of integer operations and then to use as tools to describe and justify their emerging conjectures. Third, Ms. Graham described the processes by which students developed an understanding of integer addition and subtraction. She described the need to ‘mess around’ with models and with integer operations, alluding to the necessity of engaging in pre-formal experiences that would serve as a ‘foundation’ for subsequent work in the sequence.

Ms. Graham’s knowledge of the instructional sequence informed how she enacted the sequence. She adapted tasks over the years to better establish and utilize the resources in the instructional sequence and to provide greater opportunities for students to build from their own reasoning. For example, she adapted a task in which students were to notice and develop conjectures around patterns of grouped addition or subtraction problems. The written task separated the problems by whether the operands had like or unlike signs. She revised the task by ungrouping the problems in order to focus students on the operations used to solve the number sentences rather than on the more superficial characteristic of whether the operands had different signs. She felt that this was a more productive focus in light of the development of algorithms that followed and in light of the variety of conjectures the students had developed previously. This adaptation helped students to observe a variety of possible ways to group the problems, each way related to some characteristic of integer operations, including but not limited to differences in signs. Furthermore, this adaptation showed evidence of how Ms. Graham revised the instructional sequence based on her understanding of how tasks influenced the development of student thinking across the sequence.

Implications

The development of Ms. Graham’s local theory co-emerged with her close observations of student engagement with challenging tasks and her revisions of those tasks that helped her to elicit and refine students’ mathematical reasoning. The local theory, as it developed, guided her discussions of when to formalize students’ ideas and when to let them ‘mess around’ with contexts and models. Her theory helped her to recognize key ideas in students’ contributions and to focus discussion on the ideas, while the theory’s focus on progressive formalization allowed her to hold off establishing formal terminology and procedures until the end of the sequence. These practices related to her theory provided students’ opportunity to engage with challenging tasks in ways that explicitly elicited and developed their mathematical reasoning. Finally, she developed her local theory by observing how students engaged with tasks from the materials over multiple enactments, suggesting that such knowledge takes years to develop and requires close attention to student thinking.

DISCUSSION OF LEARNING GOALS AND STUDENT DEVELOPMENT DURING A COLLECTIVELY PLANNED DIVISION LESSON

Julie Amador  
Indiana University, Bloomington  
juliemamador@gmail.com

Teruni Lamberg  
University of Nevada, Reno  
terunil@unr.edu

This study examines how teachers talk and think about student development and how lesson goals are determined during a joint planning session. Lesson study is utilized in this research to highlight the considerations teachers make regarding cognitive, language, and social development of students. Likewise, how teachers collectively plan a lesson to advance student development is analyzed in relationship to learning goals for the lesson.

Introduction

Lesson planning is often an individualized activity (Bage, Grosvenor, & Williams, 1999); however, lesson study takes this individualized activity to a group (Fernandez, 2002) where minds collectively make an agenda for action (Lampert, 2001). Lesson study is a joint decision making process utilized for professional development, with the purpose of improving the practice of teaching. The process is used in mathematics education to improve teaching through goal setting and collective decision making. In the process of lesson study, one lesson is planned and analyzed over an extended period of time, typically spanning three to four weeks. During this process the group collectively plans one lesson and one teacher in the group teaches the lesson, while the others observe and take field notes (Fernandez, 2002). Finally, the group meets back together to discuss the observation, reflect on the lesson, and make changes if necessary.

Theoretical Perspectives

The lesson planning process is an important phase in the teaching cycle, during which learning goals should be made explicit (Hiebert & Grouws, 2007). When teachers are explicit and design goals to promote the understanding of concepts, students are able to benefit by developing mathematical skills. These learning goals should be determined based on students’ needs. Therefore, in the lesson study process, teachers should set mathematical goals for students and be explicit about their desired learning outcomes for students.

When determining learning goals, the developmental levels of the students should be at the forefront of teacher thinking. Developmental levels refer to a multidimensional pathway of interactions involving “physical, social, emotional, cognitive, and linguistic” elements in which students progress toward goals (Horowitz, et al., 2005, p. 94). These levels lead the teacher to make a hypothetical learning trajectory for students, which allows students to progress developmentally along the trajectory (Simon, 1995).

One form of development teachers should consider when planning lessons is cognitive development. Cognition is defined as the knowledge a child possess at a given time (Horowitz et al., 2005), meaning cognitive development is the advancement of knowledge to progress toward goals and the obtainment of knowledge. To support cognitive development, teachers should know what individual students know and do not know in a particular content area. After consideration of the cognitive abilities of all students, teachers should select the appropriate materials, design the lesson format, and create a learning environment that promotes meaningful understanding and cognitive advancement.
In addition to considering the cognitive development of students, teachers should also consider the language development of their students (Horowitz et al., 2005). Content is taught through language, so students should be able to make connections in their learning between the language being use and the content (Bransford, Brown, & Cocking, 1999). When connections in language use are made, students are able to develop by advancing their abilities with language.

Finally, teachers should consider the social development of their students when planning mathematics lessons (Horowitz et al., 2005). The relationship students have with their peers directly impacts their learning, so fostering learning environments where students come together to work collaboratively promotes development. Rogoff (1990) explains that “children are already engaged in a social activity when they actively observe and participate with others” (p. 16). As a result, when children come together in a learning environment, the opportunity for social development exists; teachers should be cognizant of development when planning lessons.

This study examines how teachers consider these developmental aspects of learning, specifically when collaboratively planning through the process of lesson study, with the aim of setting achievable learning goals for students. The lesson study process allows for analysis of teacher thinking on an in-depth level. Therefore, this process highlights teacher considerations and makes teacher thinking explicit. Knowing what teachers consider allows for the determination of areas where teachers would beneficial from additional professional development support to improve teaching. As a result, this study will answer the following question:

How do teachers jointly discuss learning goals along with cognitive, language, and social development when collectively planning an elementary division lesson?

Methodology

Data for the study comes from a larger three-year Math Science Partnership Project involving five school districts and twenty-two schools in a western state. The project was a collaboration among the state department of education, the school districts in five counties, a university, and a regional professional development program. The project engaged practicing elementary teachers in three years of professional development, focused on math and science content and pedagogy.

In the three years of the project, teachers involved were held accountable for maintaining an understanding of current research literature in the area of mathematics education. These teachers were responsible for reading current research articles and discussing best practices collaboratively. As a result, many of the teachers were focused on improving their instructional practices based on their new knowledge from the professional development sessions, readings, and activities.

Teachers were immersed in algebraic thinking and spent time solving their own mathematical problems. This practice allowed the teachers to gain an understanding of the problem-solving process from the students’ perspectives. Pedagogically, teachers were given opportunities to collaborate and work on improving their teaching practices through multiple methods. Lesson study is one format that was used for professional development for the teachers.

When the data for this study was collected, teachers had completed two-and-one-half of the three years of professional development of the program. The teachers in the study varied in experience, age, and background. The participants consisted of one female first-grade teacher, one female second-grade teacher, one female third-grade teacher, one female fourth-grade teacher and one male sixth-grade teacher. Teaching experience ranged from less than three years to more than fifteen years, and all teachers worked at the same rural elementary school.
Data included a video of the lesson study session along with a video of the planned lesson being taught. A debriefing session after the lesson was also recorded on video. Data was analyzed using a grounded theory approach with the purpose of describing the thinking and considerations of teachers and adding to the theory on learning goals and student development (Corbin & Strauss, 2008). The purpose of utilizing grounded theory was to lead to a theoretical explanation about the thinking that occurred throughout the lesson study process.

**Results**

Results indicate that teachers considered cognitive, language, and social development distinctly when collectively planning, but also simultaneously considered language and cognitive development, and language and social development; this was all done while thinking about the lesson goals and the purpose of the lesson, along with lesson activities that would help students achieve these goals.

From the three developmental areas analyzed, cognitive development was discussed most frequently and in the greatest detail by the teachers in the group. The teachers discussed cognition and learning goals simultaneously, as they relate to student knowledge. The first one-and-a-half hours of the lesson study planning session were devoted to determining an appropriate student learning goal based on areas of mathematical difficulty. The group determined the content area of measurement was a continual struggle for student across grade levels; however, the group ultimately determined that students often struggle with problem solving when learning division. As a result, they decided to teach a third grade problem posing lesson, allowing students to create and solve division word problems.

After determining the lesson content, the teachers considered advancing student knowledge to help students develop conceptual understanding of division. To plan the specific lesson, the teachers relied on their knowledge from previous experiences and thought about student cognition by considering how students learn and the necessary prerequisite lessons and knowledge that would be needed. The teachers discussed the progression of taking the students from concrete to abstract, based on learning goals and desired outcomes. To do this, the teachers discussed activities that would promote development, based on the understanding of the students:

Maria: You know that sub sandwich problem they had last year? Do you think third graders could do it? I bet they could, especially if they are doing all of these other activities. It is something like all of these kids go on a field trip and there are different versions and each version can feed a different number of students, so each group like gets this number of sandwiches. It is a set amount for each of the three groups. One group is five, one is seven, one is three, or something. What is the fraction that each one gets? That is not using whole numbers, but you can maybe have a problem that is similar using whole numbers. You know? And then asking if each student should get….which group would you rather be in? Did any of the groups have any remaining Skittles or something? You know, whatever your problem is and then they would have to work the problem to solve it. And they can actually pass things down or something. Would that work for them?
Laura: (Nods head).
Jonie: So, are you having? I guess I misunderstood because I was visualizing having them pose a problem and create a story problem, but you are more …. Laura: That is the ultimate goal.

As the teachers planned the problem posing activity, they considered their previous experience with activities related to the concept of division and discussed transitioning students from reading problems to writing and solving problems.

The teachers went beyond writing out a set of activities for the lesson; they considered cognitive development by thinking about how the students would approach lesson tasks. The teachers worked together and utilized their past experience and knowledge of the students to determine areas where common misconceptions would arise as students conceptualized division.

Greg: They try a lot and they get it mixed up with multiplication, so if you could somehow show one that is multiplication, what is the difference between. They would be looking at like a Venn diagram or something.
Tracy: What would be another thing that kids might do when they would do a division problem?
Laura: They could start with what would be a factor instead of a product.
Tracy: So that might be another misconception.
Fatima: What is that?
Laura: They might start with the factor instead of the product.
Laura: I am thinking of the unknowns.
Fatima: They might not know which numbers to put in which place in the problem.
Laura: Exactly.

This discussion demonstrates the ability of the teachers to think about learning from the child’s perspective. The group considered cognition in greater detail by considering how they would address misconceptions during the lesson.

Tracy: Do they understand what a division situation is? Do they understand? Do you want to use a story context?
Laura: But, I am still going to have misconceptions.
Tracy: So the question is instead of having to teach every little group, how do you get them to a whole class discussion? Make the misconception explicit and then see if there is a conceptual change through discussion. Do you see what I am talking about?
Maria: I know exactly what you are saying.
Tracy: How do you?
Maria: How do you stop the whole class when they are on their own reasoning process in their own small groups?
Maria: Do you then at that time say, “Everyone, some of our friends are having, you know whatever, we want to give them some help here,” and all of a sudden they’re thinking about their own little problems and then do you stop the whole class at that point in the middle? Because then, you are like mid thought for a lot of kids when you are stopping to help someone else. You might see another group that is being very successful and you might be able to take that group and say you know I seem to think that you really understand how to write them well, maybe you can come over and we can work with this other group.

To address the misconceptions, the teachers thought about specific misconceptions students commonly have with division and made a plan to address the misconceptions and advance the understanding of students. This process highlighted teacher thinking about learning goals for
students in relation to anticipated areas where students would have trouble meeting the objectives. Together, the teachers in the lesson study group jointly thought through the entire process of the lesson and made specific plans to ensure that students would understand the lesson content.

During the process of planning the mathematics lessons, the teachers repeatedly discussed language development as it relates to learning mathematics. They discussed student background knowledge with language and considered how to provide language support to ensure students would understand the language used when teaching division with problem posing.

The process of lesson study allowed the teachers to come together to discuss the background knowledge of students and ways they would support student learning of unfamiliar terms. Teachers set specific learning goals related to language for the students by jointly determining that students should verbally use mathematical terms in the lesson.

Tonia: Yeah, that is going to be something you could introduce in a previous lesson? I would think, because that is a standard.
Fatima: They need to know the vocabulary.
Tonia: They need to know the vocabulary.
Fatima: But if it has already been introduced is that when you explain your problem? I expect to hear you using those terms.

The teachers scaffolded the vocabulary in the lesson by deciding to incorporate specific terms into previous lessons and learning. They determined that if students were already familiar with specific terms they would expect students to use those terms in the lesson. In this way, the teachers thought about a logical progression of language development and incorporated support for students to allow them to develop until mastery, which would be demonstrated through the verbal use of newly learned terms in the lesson.

Additionally, the teachers discussed specific terms students would need to understand when learning division. Specifically, they discussed the terms divisor and dividend and made a plan to support language development for the students.

Tonia: We do talk about it a lot, divisor and dividend.
Tracy: I think if they get the idea, what is the meaning of divisor and dividend, they can describe, then maybe they can introduce the vocabulary.
Greg: Up here we already said….that is the thing we brought up is that students confused it.
Maria: Well, you need to have an interactive writing lesson prior to that where you have all labeled, like done a diagram of a division problem, you know the three ways of writing a division problem or something.
Fatima: But I would say, when you write your problem, be sure you identify your divisor and dividend.

After determining that students would need support for the language in the lesson, the teachers further discussed student language development by considering ways they could support the development of terms for the students. The teachers decided they would utilize an interactive writing lesson utilizing the terms divisor and dividend in the week prior to the lesson, to scaffold the learning and support students in their language development.
The teachers went beyond determining how to support the acquisition of new language and discussed student understanding of word meaning in relation to conceptualization of the lesson goals. They thought about multiple meaning words students use, but may confuse.

Maria: No, but I have had kids who have had, have had, there have been multiplication problems that have said altogether, how many….
Tonia: Well, multiplication is addition.
Maria: Right, well that is my, that is when you bring up, you say, “Well, that word is used for both of these problems because aren’t we repeatedly adding when we multiply?” And then, they are like, “Oh yeah, you know, okay,” so it works for both addition and subtraction.

In this situation, the teachers discussed the term altogether and came to a joint decision that students often neglect to fully consider the context and meaning of the word. Instead, students associate the term altogether with addition and do not think of multiplication as a process of repeated addition. By making this point explicit in their discussion, the group demonstrated their cognizance in considering students’ language use.

The teachers considered language by thinking about how to support development for students learning new terms and how to clarify meanings of words with multiple definitions. They jointly planned to address the language needs of the students by supporting students through scaffolding based on lessons that would be taught prior to the problem posing lesson.

Social development was also discussed and considered by the teachers in the lesson study process. The teachers thought about including activities that would promote social learning through the use of student groups and joint decision making. Additionally teachers planned to foster an environment where students would be engaged by working with other students.

The teachers considered the development of students on a social level by planning lesson elements that would require students to justify their thinking and reasoning with their peers. This would hold students accountable to their group members.

Laura: My thought about this is that if they are given a bag and they have written the problem on big pieces of chart paper, then we come back whole class. They haven't solved it and nobody has solved the problem and everyone is analyzing the problem and the way it is written. So then, first of all, the group decides…is it a division problem?
Tracy: (Nods) Mmm, hmm.
Laura: And the group decides….is it clearly written? And the group follows a rubric possibly to evaluate this problem. Nobody has solved it. Not even the group that did it yet. Or maybe they have. I don’t know, but they are not showing. They are not solving the problem. They are modeling the problem.

The teachers planned to advance the social development of students by having them jointly make decisions about their mathematical thinking. Through this process, students would work with each other to evaluate a problem, given a rubric. This situation would hold all students accountable for learning and would foster a social context where all students would be involved through discussion.

In the lesson planning process, teachers determined student decision making as a group would be coupled with solving mathematical problems, which resulted in a simultaneous consideration of cognitive and social development. The teachers planned to create a context for

social development, and within this context they planned to enhance cognitive development through the use of problem solving as a social activity.

Maria: Because our last math program did that a lot. They would say, “Have students write a multiplication problem,” or, “Have students write division problems,” and then they would just write out a problem, but they didn’t even know if it was solvable. They don’t even know if maybe they worded it in a way that makes no sense, so I just thought that step with them as a group, having to solve their own problem prior to having to give it to another group of students and then to explain their thinking, (Tracy nods) their own reasoning with the problem solving process to you first. It is like I was saying.

Tracy: So, you want them to explain it to you?

Maria: They would, well, my thing is if they, they explain it to the whole class everyone is going to know how to solve the whole problem and it takes the fun out of being able to test their friends.

In this instance, the teachers considered the social interaction of students and planned for learning as a direct result of peer interaction. The planned process combined the consideration of social development and cognitive development because students would be interacting with their peers while discussing mathematical concepts and problems.

Additionally, the teachers combined the consideration of cognitive development and language development. This occurred as the group considered the relationship between specific words the students needed to know and the concepts and meanings associated with those words.

Tracy: So, is this a partitive question or a quotitive? They don’t need to know the words, but I don’t know if that distinction is important for third grade, but you can base if off to look at dividing.

Maria: What are you doing with the number?

Tracy: One is putting it into groups and the other is seeing how many groups go together.

Laura: Exactly, and that is what I did with that information. Do I now how many groups or do I know how big my groups are? Or, whatever.

The teachers discussed the terms partitive and quotitive and determined that third graders do not need to know the specific words, but students should have an understanding of the meanings behind the terms. By considering the relationship between the terms and the meanings, the teachers jointly considered language development and cognitive development simultaneously, as the terms relate to the problem posing lesson.

Discussion

Throughout the lesson study process, the teachers adhered to the recommendation by Horowitz et al. (2005) and routinely considered the cognitive, language, and social development of the learners. At times, the teachers considered components to development independently and at other times development in one area was considered in conjunction with elements of development in another area. Throughout the discussion, the consideration for the development of the students along with the learning goal was apparent.

When considering cognitive development, the teachers thought about ways to support students by providing scaffolding to advance cognition. They considered the background

knowledge of students and planned lesson activities that would allow for attainment of the learning goal. Additionally, the teachers thought about mathematics content areas where students would need more or less support to understand the concepts being taught.

When discussing the language development of students, the teachers understood that many elements of a lesson are taught through language (Bransford, Darling-Hammond, & LePage, 2005), so they discussed how they would support the development of students in this area. The teachers jointly thought about key words, vocabulary, and ways to provide a context in which learning could take place through language. Once they had determined what the students would need to know, they thought about how they would scaffold the learning, so that students would understand the language at the time of the lesson.

Likewise, the teachers thought about ways to provide opportunities for students to work together and interact through discourse (Cobb, Boufi, McClain, & Whitenack, 1997). The teachers determined that small groups and whole-class discussions would take place, so that students could learn from working with each other. This situation would then foster a cooperative learning environment (Rogoff, 1990) where students could utilize the thinking and language of their peers to advance their social development.

This process of lesson study as a professional development tool demonstrates that teachers are making considerations about the development of their students as they jointly plan lessons. The group set goals, collectively planned the lesson, and worked with each other to refine the lesson in the planning process (Fernandez, 2002). In this way, the teachers took a commonly individualized activity of lesson planning (Bage, Grosvenor, & Williams, 1999) and extended it to a joint planning session that allowed for collaboration and decision making with the purpose of increasing student learning and development.

Language is essential to mathematics learning and demonstrating understanding. This study reports on a year-long professional development program designed to enhance urban mathematics teachers’ ability to address issues related to language and mathematics in their classrooms. Twenty-three teachers from one urban district participated in the program. We report on the math-related language strategies they developed as well as issues that arose as they made deliberate efforts to develop their pedagogy in this regard.

Introduction

Language is recognized as a vital mediator of learning (Vygotsky, 2002; Wertsch, 1991). Recommendations related to mathematics instruction for all students, including the growing population of English language learners (ELLs) (NCELA, 2006), prompt explicit attention to academic language, rich mathematical discourse, and justification, a language-intensive mathematics practice (Brenner, 1998; Moschkovich, 2002, 2007). To accomplish this goal, teachers must find ways to build off students’ everyday language practices and scaffold the development of their students’ mathematics register.

In his seminal work on mathematical language, Pimm (1987) notes the importance of increasing student awareness of different registers and the recognition that “the grammar, the meanings, and the uses of the same terms and expressions may vary within them and across them” (p. 109). Pimm follows this recommendation with the statement, “In my opinion, a major question yet to be explored by the mathematics education community is how the awareness may be fostered and cultivated” (p. 109). Aligned with Pimm’s ideas, we contend that an important first step is to increase teacher awareness of language issues inherent in mathematics education. This awareness, and concomitant set of teaching skills, is critically important in schools with linguistically diverse student populations. Without this, teachers may inadvertently deny students’ access to participation in the lesson (including meaning making of concepts) (Brenner, 1998) and teachers may not attend to language-related learning goals (Lucas, Villegas & Freedson-Gonzalez, 2008), which impact students’ long-term success with mathematics (Echeverria, Vogt & Short, 2010) and short-term success on State tests.

Data on teachers and teaching suggests that such comprehensive skill sets are not widespread among teachers (NCES, 1999), and perhaps particularly mathematics teachers. Preservice teacher programs rarely address such issues of language in-depth (Valdés, Bunch, Snow, Lee & Matos, 2005), and when they do, it is not often with attention to the subject area. A similar situation may be present in inservice training as well. Indeed, the teachers in this study reported minimal to no prior experience with language-focused professional development linked to the teaching and learning of mathematics. Of 23 teachers, 9 reported having some PD related to academic language or ELLs, 9 reported having some PD related to the academic content of the institute (algebraic or proportional reasoning), and only 3 of 23 teachers reported having both.

This research documents the design and results of the ACCESS Project, a one-year professional development program for teachers of mathematics in one urban district. ACCESS stands for Academic Content and Communication Equals Student Success. ACCESS aimed to increase teachers’ awareness of mathematical language and pedagogical repertoire for bridging everyday and mathematical language and to foster the development of students’ academic language (here, the mathematics register) and promote their mathematical proficiency. In addition, we sought to develop in collaboration with teachers, a broader repertoire for working on these issues with students in mathematics classrooms.

In this paper, we document language-related mathematics instructional practices that the group of ACCESS teachers developed to foster their students’ increased awareness of the mathematics register/academic language and support improved mathematical performance. We also document some aspects of the process and questions that arose for them as they made deliberate efforts to implement ideas from the one-week professional development program in their classrooms. This is the challenging work of teacher learning – the shift of “having knowledge” to “knowing in practice” (Kazemi & Hubbard, 2008).

Theoretical and Conceptual Frameworks

This research draws on diverse perspectives. Sociocultural theory (Vygotsky, 2002; Wertsch, 1991), with its contention that learning is mediated by language, along with theories of language (e.g., linguistics, sociolinguistics, and functional linguistics) (Halliday, 1987; Pimm, 1987; Schleppegrell, 2007) provide frameworks for focusing on classroom discourse. In particular, we focus on the mathematics register. Halliday (1978) described the mathematics register as “meanings that belong to the language of mathematics (the mathematical use of natural language, that is: not mathematics itself)” (p. 195). He further states, “It is the meanings, including the styles of meaning and modes of argument, that constitute a register, rather than the words and structures as such” (p. 195).

To guide our work designing and implementing the ACCESS Program, we developed a conceptual framework comprising three principles or “pillars” that research has found to be critical for the development of students’ mathematical proficiency. These pillars are: appropriate and effective development of students’ academic language; student engagement in mathematical practices of justification and collective argumentation; and access by all students to rigorous mathematics (Truxaw, Staples & Ewart, 2009). Although only the second one focuses explicitly on language, the first and third pillars have an important language component as well.

Math Discourse Pillars

Students’ academic language. As noted above, a key aspect of developing students’ academic language is to create a bridge from everyday, informal language toward academic language and use of the mathematics register (Halliday, 1978; Pimm, 1987). This goal is pertinent for all students, but particularly so for students whose first language is not English (Cummins, 2000; Schleppegrell, 2007). Too often, attention to language in mathematics classrooms focuses merely on vocabulary. Rather, it should include attention to how language is used to express mathematical ideas (functional linguistics) and the development of the mathematics register (Pimm, 1987; Schleppegrell, 2007).

Justification and collective argumentation. Student participation in justification, meaning making, and argumentation have been implicated as critical components for supporting students in learning mathematics (e.g., Brenner, 1998; Hiebert et al., 1997; NRC, 2001; Wood, Williams
& McNeal, 2006). There is evidence that participation is particularly effective in supporting the learning of lower attaining students or ELLs (Boaler, & Staples, 2008; Moschkovich, 2002).

Access by all students to rigorous mathematics. Teachers need to ensure that all their students, who vary in their prior mathematical background, language ability and other characteristics, have access to participating in cognitively demanding mathematical activities. Inequitable access leads to inequitable learning opportunities and learning gains (Cohen & Lotan, 1997; Gee, 2003).

An earlier paper reported on the ACCESS Project teachers’ growth in professional knowledge related to the weeklong summer PD (Truxaw, et al., 2009). This research builds on those results, following the teachers as they worked to move beyond knowledge to knowing in teaching practice (Kazemi & Hubbard, 2008). We address two research questions: 1) what language-related instructional practices develop among the group of teachers as they move from their knowledge of language to knowing in practice? 2) What issues – pedagogical or otherwise – did the teachers find themselves facing as they engaged this work?

Data Sources and Modes of Inquiry

Context

The research took place over one year in an urban school district in the northeastern United States where 45% of the students spoke a non-English home language, over 95% of students qualify for free/reduced priced meals, and 96% of the students are categorized as “minority students” (State Strategic School Profiles, 2008). The project was supported by a Teacher Quality Partnership Grant that allowed for 45-hours of summer PD for 23 teachers (grades 4 -10) from four schools in the district. Nineteen of these teachers participated in the academic year component as well that comprised a modified form of lesson study where teachers (3 hrs/month), organized in grade-band teams, collaborated to develop, implement, and debrief higher order thinking (HOT) lessons that used pedagogical strategies related to each of the three pillars. Surveys conducted at the end of the summer PD indicated that teachers felt they had learned useful information with respect to language and mathematics (knowledge of) and were confident that they could promote the development of students’ academic language (Truxaw, et al., 2009).

Although our focus is teachers’ practices, student mathematical performance was monitored throughout the project. Open-ended, single-item pre-post tests (released items from State assessments) were administered to students. These prompts required higher order thinking and justification. Prompts were double-scored according to State criteria; discrepancies were resolved by a third scorer. Across all grade-levels, mastery increased and scores of 0 decreased. To gauge whether growth in the project classes was beyond what could be expected in a typical year, we administered pre-post tests in non-project classes. Overall, project classes in the same grade levels performed better than non-project classes. For example, grade 5 class scores of 0 decreased markedly (74% in the pre-test as compared to 10% in the post-test), as compared with non-project classes (83% to 62%) and mastery scores increases (0% to 24%), as compared with non-project classes (3% to 15%). These results suggest that the instructional practices used by the project teachers had a positive impact on student mathematical performance.

Data Collection and Analysis

To document language-related instructional practices, we examined 25 archived HOT lesson plans developed by teams of teachers (see http://www.crme.uconn.edu/lessons/). We reviewed the objectives of the lesson to determine if language objectives were included, and if so, the type

of language objective. We used categories established in the literature related to supporting ELLs, including: key vocabulary, language functions, language skills, and grammar or language structures (Echevarría, Vogt, & Short, 2007). An example of a language function objective is “Students will be able to express the likelihood of various events using everyday language.” An example of language skills is “Students will be able to restate the problem in their own words.”

To further document language-related instructional practices, we reviewed selected field notes, written documentation of meetings, audio recordings, and transcripts from teacher collaborative sessions, focus groups, and teacher interviews. Initial themes had been developed in an ongoing manner as the project and data collection were in process. To refine these themes, standard qualitative techniques (Creswell, 1998; Strauss & Corbin, 1990) were used. Two researchers reviewed data to finalize themes.

**Results and Discussion**

Analysis of the data revealed that the teachers developed and used an expanded repertoire of language-related practices that were associated with students’ improved mathematical performance and enhanced verbal and written justification. We report our findings in terms of the work teachers did in planning instruction and implementing instruction. The first category focuses on language objectives and task design. The second category focuses on pedagogical strategies used as the lesson unfolds. We then turn our attention to some of the questions and issues teachers faced as they advanced their practice.

**Planning Instruction**

*Language objectives.* The HOT lesson plans teachers developed collaboratively included both content and language objectives. An analysis of the language objectives demonstrated all lessons had appropriate language objectives that addressed a range of language-related learning goals. Not surprisingly, the category of language objective that occurred most frequently among the 25 HOT lesson plans was “key vocabulary” – 84% of the lesson plans included one or more language objectives related to this theme. Although the teachers reported that developing language objectives outside the “key vocabulary” category was challenging (focus groups), 92% of the HOT lesson plans included one or more language objective outside that category as well. These language objectives included focus on everyday language necessary to explain contexts of problems and mathematical language necessary to express and justify mathematical ideas.

Overwhelmingly, the teachers noted that the explicit inclusion of language objectives, including sharing them with the students, helped to enhance their teaching and student learning. For example, Mr. Borreca, a fourth-grade teacher said, “I like having the objectives written out. I never thought I would like that, to be completely honest…writing out the content and the language, but I do it … if for anything else, it focuses me” (mid-year focus group).

In meetings, developing language objectives was not automatic. Generally, it was difficult to identify these objectives at the beginning of planning (in contrast to the content objectives). It often took some time working on the planning before it became clear what the linguistic challenges might be, and which ones would be appropriate to address during the lesson.

*Deliberate task design.* As the teachers worked in their collaborative teams, they deliberately designed certain features into tasks to promote the development of students’ language. A specific strategy, evidenced on many of the HOT lesson student handouts, was the use of “check points” – a strategy that had been introduced during the summer and which the teachers found very useful for promoting language. Check points were built into tasks. When students hit a...
checkpoint, they called the teacher over. All members of the group needed to be prepared to explain the work and respond to questions, which encouraged group conversation and explanations. A more individualized strategy was the inclusion of “hint” and “think” cards in lesson materials. Hint cards supported language by asking questions like, “What does the word pair mean?” or, “When you wear a pair of shoes, do you wear one shoe or two shoes?” Think cards offered challenges like asking students to explain alternative strategies and solutions.

In addition, full components of tasks – including class warm-ups – were designed with particular language goals in mind. Some of these focused on building context, an important strategy identified in the literature (Echevarria et al., 2007), which was often motivated by the teachers’ pursuit of the access for all pillar. As the teachers started to think about building context, this often led them to think about the bridge between the language students would readily bring to the context and what needed to be developed to be successful with the lesson.

For example, as the teachers started a unit on probability, they wanted to find ways to help students make sense of notions such as “a probability of .8”. They noted that students find little meaning in this phrase, but do have a sense of “pretty likely.” They hoped to connect students’ already extant notions of probability (embedded in their daily lives and everyday language) and extend that to the more precise, mathematical quantification of likelihood. They designed an introductory activity with a “probability continuum” from 0 to 1. They used white boards or large papers and had students generate as many words as they could that represented ideas related to likelihood (or probability). This component of the lesson focused students on everyday words that had to do with likeliness. The teachers felt that it “helped them [the students] understand better what probability was all about” (Ms. Vargas, end-of-year written reflection).

Implementing Instruction

A main focus during the implementation of instruction was getting students to produce language to express mathematical ideas. Teachers encouraged the use of language frames, a technique to scaffold verbal and written responses. For example, in a lesson using pattern blocks to represent fractions, the language frame, “I think ____ (shape) is ____ (fraction) of the whole because ____,” supported students’ ability to explain and justify their responses while still requiring that they work through the mathematics. Particularly the grades 4-6 teachers began to recognize that literacy strategies, already familiar to them as they were in self-contained classrooms, could be useful in math instruction. For example, the reinforcement of time/sequence words (e.g., first, then, next, finally) was a literacy strategy used to help students organize their ideas, moving toward academic language in their written explanations.

In addition to literacy strategies, teachers actively sought to promote student discourse. Attending to student explanations both in whole class discussions and in small groups supported the development of language, mathematical understanding and justification. To support whole class discussion, teachers practiced “talk moves” (Chapin, O'Connor, & Anderson, 2003) and asked open-ended, “HOT questions” (described by teachers as questions that go beyond skills and procedures to deeper understanding of concepts, mid-year focus group), for example, “Why?” “How do ____ and ____ compare?” “Do you agree/disagree … and why?”

All of the strategies reported here are present in the literature. What is important to note is that these are the strategies that teachers gravitated towards in their first year of deliberate work towards developing students’ language. They found these the most accessible and useful, and were able to integrate these on a fairly regular basis. It is also interesting to consider the resources they drew upon to enhance their pedagogy. The teachers reported using materials from

the summer institute (e.g., books, strategies, graphic organizers, web links, etc.) when they were preparing HOT lessons, and they highly valued the collaboration of the yearlong activities, using one another as resources. In addition, we found that the elementary grades teachers began to see connections between the work in mathematics class and the other content subjects. For example, they drew on literacy strategies such as sentence frames, KWL charts, and word walls.

**Issues Arising**

We now turn our attention to some of the issues that came up for teachers as they worked to advance their practice with respect to language. Teachers acknowledged sometimes becoming overwhelmed while trying to unpack language aspects of a mathematics lesson. They grappled with how and when to introduce vocabulary. They dealt with how to provide easy access to language (e.g., through highly engaging contexts such as playing card games) and then, how to move on from the initial context toward the use of the language in mathematical context. There were times when they felt that they had spent too much time on language aspects of the lesson, neglecting mathematical content. Other times, they recognized that not attending to language sufficiently may have impeded the understanding of mathematical content.

*Collateral teacher content learning.* An unexpected outcome of the teachers’ focus on language was a deepening of their own thinking about the mathematical concepts at hand, and not just the language, and what it would take for their students to fully understand the ideas. As the teachers planned, their mathematical understanding – or lack of understanding – posed a productive challenge for them to work through in order to successfully design and implement the HOT, language-rich lesson. For example, in the probability lesson described above, teachers explored for themselves the multiple ways that we represent likelihood. As they discussed the language and developed the continuum activity, they began to realize how the different representations of likelihood, which included verbal representation, decimal representations, percent representations, and fractional representations, were indeed distinct ways of knowing and understanding probability. Whereas they were fairly fluid moving among these, their students were not, and they needed to account for this in their teaching.

As a second example, a group of grade 9 teachers worked on a World Wealth and Population lesson (adapted from Gutstein, 2006). They started with a mathematical goal. They wanted students to reason about which region of the world was the wealthiest by using a data table that included the population and gross domestic product (GDP). They decided it would be productive to have students do this informally first (before computing any percentages or ratios). They pursued this because it promoted sense making (2nd pillar) and they expected it to promote language use (1st pillar). The teachers then looked at the language demands of doing this kind of work, which required the teachers to think about what a “good” response would be. They realized that students had to coordinate two quantities (population and wealth) and be able to talk about the relative relationship between these and another population-wealth pair. Cognitively, this was certainly beyond the demands of comparing the unit rate or the percentages which only required comparing two quantities which, although proportions, were compared absolutely. In examining these language demands, the teachers unpacked the mathematics in the lesson in a way that they may not have if they had remained focused on the content.

Another example of teachers deepening their own thinking about mathematical concepts through a focus on language came from a grade 4-5 lesson study team. The teachers developed a HOT lesson related to identifying patterns in the classic handshake problem (i.e., if x number of people shake hands with each other, how many handshakes take place?). A language objective

---

was “students will be able to explain the way the pattern worked.” In planning the lesson, the teachers decided to use yarn strung between the students as they modeled the handshakes – one string of yarn for each handshake. This created a visual and tactile model of the connections and helped to illustrate the progression of the pattern. Students were able to translate the yarn representations to diagrams and tables – all that assisted them as they worked to uncover and explain the strategies they used and the patterns they noticed. Mrs. Shaw reflected that in order to come up with representations that supported explanation, she had needed to analyze the mathematical concepts inherent in the task. “I have to develop from my weaknesses because I know the kids will have some of those same weaknesses … I have to work through it to make sense of it” (mid-year focus group). Although Mrs. Shaw did not see herself as naturally mathematically strong, the focus on language provoked her to understand the mathematics more deeply so that she could ask her students HOT questions. “When the next person comes in, why is that number [of additional handshakes] increasing by 1 each time? They have to look at what is causing this increase, rather than, ‘Oh, I know what comes next.’ Well, why is that? Why is it working that way?” (Mid-year focus group).

For these teams of teachers, focusing on language enhanced not only the language, but also the mathematics – for both students and teachers. Mr. Barreca, for example, said, “I feel I have improved my basic content knowledge of math” (end-of-year written reflection), and, “I’m able to look at math more conceptually…more holistic, understandable” (end-of-year focus group).

**Conclusions**

This investigation documented language-related strategies developed by one group of urban mathematics teachers as they moved from their learning about issues related to language and mathematics to knowing-in-practice. The study identifies promising instructional practices, particularly those that might be most accessible to mathematics teachers as they begin this kind of work. The study also suggests some of the anticipated issues that might arise. Though not surprising in retrospect, we did not anticipate that a focus on language would lead to a deeper understanding of the content for the teachers. This reinforces the importance of having professional development focused on language issues in mathematics, as the details of a general strategy must be worked out within a particular mathematical context and set of understandings.

HOW-I-TEACH-MATH STORIES INTEGRATED/EXPERT IDENTITIES

Joy A. Oslund
Alma College
oslundja@alma.edu

This paper describes and examines a type of stories of mathematics teaching practice that elementary teachers began to tell as they continued to implement new mathematics pedagogies after learning about them from a professional development course. These stories, how-I-teach-math stories, emerged as teachers began to view themselves as the kinds of teachers who routinely taught using the new pedagogies. The significance of how-I-teach-math stories and implications for teacher professional development are discussed.

Introduction

Professional developers working with experienced teachers have yet to attend to something that preservice teacher educators know: the development of identity is important to becoming a teacher (Britzman, 2003). However, how experienced teachers' develop new identities as a result of mathematics Professional Development (PD) is relatively unstudied. In this study teachers told stories about teaching mathematics using new practices they had learned in a PD course. As they implemented the new mathematics teaching practices over time, some teachers began to tell a kind of story I call how-I-teach-math stories—general narrations of how they generally teach mathematics and students tend to respond (as opposed to narrations of specific events). The teachers began to tell these stories about their uses of the new mathematics teaching practices at various times and in various ways. These narratives functioned to claim some new mathematics teaching practices as the teachers' own—to identify them as teachers who use particular practices. I examined teachers' how-I-teach-math stories as narrative performances of teachers' emerging integrated/expert identities (that is, the ways they identify that integrate their new ways of being mathematics teachers and their identities as experts). I seek to uncover ways that these narratives, though characterized by certainty, can be resources for mathematics teacher learning.

Theoretical Framework

Mathematics reform documents (e.g. NCTM, 2000) advocate methods that are likely different from those teachers have experienced. One result has been a proliferation of PD workshops, the effects of which are unknown (Wilson & Berne, 1999). The work of teaching impacts teachers (Waller, 1932), and teacher preparation impacts the identities of preservice teachers (Britzman, 2003). However, the effects of the implementation of new mathematics pedagogies on the identities of experienced teachers are unknown. How are teachers' identities different after they have integrated new ways of teaching mathematics (and new ways of identifying themselves as mathematics teachers) into their practices?

Identity has been operationalized as narratives one tells in order to be perceived as a certain kind of person (Holland et al., 1998; Sfard & Prusak, 2005; Sfard, 2006, 2007). Through narratives (and indeed all discourse, but narratives are a particularly rich site for identity construction) people perform stories of their experiences and invite their audiences to respond in certain ways (Juzwik, 2004). Especially powerful are direct identifying statements, which are statements about oneself that are reified (that is, treated as objects that are true regardless of time), endorsed (meaning that they are believed to be true) and significant to the storyteller's self-
understandings (Sfard & Prusak, 2005). Because "how something is said is a part of what is said" (Hymes, 1974), I examined the rhetorical and theatrical tools teachers use to tell these stories. Crespo & Juzwik (2006) studied the performative aspects of teachers' expository stories about mathematics teaching. Expository stories are final draft stories told without invitation for dialogue. How-I-teach-math stories are a subset of expository narratives.

Oslund (2009) has described ways in which integrating new mathematics teaching practices into their repertoires required teachers to integrate previous identities with newer ones. For example, a teacher who identified as one who gave a lot of assistance to students desired to become a teacher who stood back and watched students struggle before intervening. In order to do so, she needed to integrate her identity as a teacher who gives with an identity as a teacher who steps back. In this paper, I report on how teachers began to identify as experts after they had spent various amounts of time working toward these integrated identities.

Specifically I ask, "How do the performances of how-I-teach-math stories told by elementary teachers help us to better understand the identity development of experienced teachers learning to implement new mathematics pedagogies?"

Methods

Participants and Context

Participants are four elementary teachers who participated in a workshop on using Complex Instruction (CI) (Cohen, 1994; Cohen & Lotan, 1997) to promote rigor and equity in mathematics and had reported using CI as a result. The weeklong PD workshop, Designing Groupwork in Mathematics, was facilitated by Dr. Lisa Jilk of Teachers Development Group and was offered during two different summers at a university. The workshop was about using CI, which is a particular form of cooperative groupwork, to teach mathematics. What makes CI different from other programs of cooperative groupwork is its attention to status in small groups. Teachers learn to identify status issues that interfere with learning in groups and are taught several interventions for disrupting status so that all students can engage in mathematical tasks (for example, using tasks that require multiple abilities, setting norms and roles for group interactions, and publicly assigning competence to students with low status).

Teachers attended the workshop voluntarily. The participants for this study were volunteers from among both cohorts of the workshop who reported having implemented CI to teach math after the workshop and desired to continue doing so. They were teachers of grades one, three, four, and five in three different school districts (one urban, one suburban, and one rural). This study spanned eight months during which the teachers were teaching mathematics using CI.

Data generation and analysis

Data was generated in multiple contexts in order to attend to gain a comprehensive understanding of teachers' identities. Teachers told stories about teaching specific math lessons with CI in individual interviews. They participated in focus group discussions where teachers told stories about teaching math with CI to each other, raised problems of practice, and shared ideas for teaching. They also presented CI teaching stories to a group of teacher educators who had not participated in the PD. These teacher educators had heard about CI and were interested in learning more.

Sessions were audio-recorded and transcribed. Narrative portions were arranged into idea units, lines and stanzas (Gee, 1991), highlighting their poetic aspects. Transcripts were analyzed for parallelism, alliteration, shifts in point-of-view, the rhythm of the syllables, subjects and

objects of idea units, and other poetic aspects of language. I also studied the syntax and grammar of teachers' idea units. In this paper I report only on teachers' use of verb tenses to reify their stories and identify as expert CI/mathematics teachers.

In the following section I present one how-I-teach-math story about teaching mathematics with CI from each teacher and report on the timeline for which this type of story emerged in the teachers' storytelling. Three of the teachers told how-I-teach-math stories about how they move through whole CI lessons or parts of CI lessons. However, in the case of Glynnis, she only told a how-I-teach-math story about one small part of one CI lesson. In the discussion section I theorize these stories as narrative performances of the teachers' emerging CI/mathematics teacher identities—that is to say that the teachers began to identify as "teachers who use CI to teach mathematics" through the reification of experience into integrated/expert identities.

**Generalized Narratives**

*Patricia*

Patricia had been using CI for one school year when the study began. When I walked into her classroom for her first individual interview she began to talk about CI before I had an opportunity to ask a question. I interrupted her and asked if I could turn on the audio recorder. When the recorder was on, I said, "So tell me what you were going to tell me." She began:

> I use the Group Solutions book (Goodman, 2000). I walk through it from the very beginning. Actually, I don't walk through it from the very beginning. I start with jobs. I describe the jobs, and we model the four different jobs. The jobs are not listed as they are in the [the CI course materials]...the information on the back tells them what to do, and the model conversation that they can have is still the same on the back. But on the front I just gave the little picture, because first graders know that, so that everybody's involved and understands. The jobs rotate. The groups actually rotate too. About every six weeks I change desks, so they may end up with different people. Some kids say, "Well, I was material manager two times in a row," but it all works out in the end...we review [the roles] almost every week. And there'll be an emphasis one too. Like, I'll say, "The questioner is the person who begins, and then we go clockwise." That way, we talk more about the questioner and we ask the other people what the questioner is doing so that they're more aware of, a little bit of observation, with it...At the end, of the activity we all get together and we talk about how we solved things.

In using the word "jobs", Patricia is talking about what was called *roles* in the CI course. Roles are an important instructional strategy in CI. Students are given roles that are specifically designed to engage them in the mathematics at stake in a *groupworthy task*.

This is a how-I-teach story about using CI to teach mathematics. At times, Patricia tells narratives using present tense terms (I walk... I describe...) indicating how she always or usually is when doing CI lessons. Remember that direct identifying statements are *reified*; that is, that they are spoken of as detemporalized objects (Sfard & Prusak, 2005). In this story, Patricia has reified verbs by using present tense, thus identifying herself as the kind of teacher who routinely carries out these practices as a part of teaching. She identified as a CI teacher.

*Jonathan*

Jonathan had also been teaching mathematics using CI for a year when this study began. Jonathan told the story that follows during the first focus group meeting. (This meeting happened...
after the first set of individual interviews, during which Jonathan did not tell a how-I-teach-math story about CI. Teachers were asked to come prepared to share stories of using CI to teach mathematics. They took turns sharing the stories they prepared. Jonathan said:

*I might give the group, inside a laminated or clear sheet, this page with the other one to the back, so they can see them both. They're on a clear sheet so they don't really write on them. One of the things I've been working with is this idea of putting the math skills that that they're going to be working on the page, and then the groupwork skills that they're going to be working on below that, and then some of the materials they might need, and then I put the directions there...To back up and tell you how I do this. I don't do a task every week. I don't always do a task every month. I tend to do a task toward the end of a unit, because for me it's a really nice way to bring together a lot of new skills they've learned and share them out. Sort of showcase. Look at this, we've done, we can do this now. We can do this. We can do this. And then other people will go, yes. Yes. No. Yes. You know? And so I find it very powerful to do it like that...they're group one. I don't like names. They're strictly groups one to seven. Everybody writes their name, whatever seat they're on. And as they finish the task they are required to call me over. They don't know who in the group's going to have to explain it. And so I'm, you know... I have a little stamp, and I'll stamp [their task card], and then they can go on to the next task.*

Notice that Jonathan moved back and forth between generalized and specific talk about his teaching in his first how-I-teach story about using CI to teach mathematics. Like Patricia, much of Jonathan's language was in the present tense when he refers both to how he teaches mathematics with CI (I don't, I tend to, I find it) and what his students do (They don't know, everybody writes). By using present tense Jonathan identified as a teacher who does CI and does it in a certain way.

It is interesting that Jonathan did not tell a how-I-teach story about CI in our first individual interview but did tell this type of story in the first teacher group. Within the teacher group there were teachers who had only been using CI for a couple of months and teachers who had been using it for over a year (including Jonathan). One way that Jonathan and Patricia identified themselves as the *old-timers* to CI (Sfard & Prusak, 2005) was to tell stories that identified themselves as people who use CI and who use it in an individualized way.

**Joanna**

Joanna was one of the teachers who had been teaching mathematics using CI for only a couple of months when the study began. In her first individual interview, she said:

*[The students] don't want to follow the rules like, make sure you've talked this over with everyone in your group before you ask the teacher for help. There's always, three, somebody from three different tables jumping up that, you know, that impulsiveness they want to ask me it.*

Joanna had used CI to teach mathematics a couple of times and told this story that included the type of generalized language that is a marker for a how-I-teach story. However, it is not really a how-I-teach story (which are about how teachers teach math using CI) but a story about how students respond to her attempts at teaching mathematics using CI. She only spoke in this
generalized manner about her students. She did not talk about herself in a generalized way, or identify herself as a certain kind of CI teacher. She continued the story differently, however:

We have talked about this since the beginning of the school year. We've repeated it since the beginning of the school year.

When she continued the story to include herself in the action, she switched back to speaking about the past. "We have talked" sets her story in a specific time. Her use of past participles indicates it has happened more than once. However, she is not detemporalizing her behavior, so this is not a how-I-teach story.

However, when presenting her work to teacher educators who had not been to the PD (the last data generation session of the study), Joanna told a how-I-teach story about using CI to teach math. She said:

I start out modeling with tasks from Group Solutions Too (Goodman & Kopp, 2007), the other book. It gets my kids accustomed to the norms and roles by using those tasks...but I try to use other tasks too. I try to use tasks from Balanced Assessment (Dale Seymour, 1999). Something in the classroom that I'm curious about are the norms, what we just call group rules that I have in the classroom...those are some of those things are things that we instill throughout the school day in everything that we do. They're very familiar with them but I keep them posted when we do any kind of a [CI] task...The kids, in the sharing process, they'll raise a hand and they'll ask a team, "What do you mean by that. I really don't get it. Can you explain that to me?" There's just a lot of dialoguing that's going on...I rotate [the groups] in my grade book. I go by whatever their seating arrangement is. I just pass the cards out to each group and I just put a sticky note on and I just say, "This time you're the organizer. This time you're the captain. This time you're the recorder/reporter." I just pass them out. They just hold on to them and it helps give little reminders about what their responsibility is within their group.

As both Patricia and Jonathan did in their how-I-teach stories, Joanna spoke of herself primarily in the present tense, indicating that these are things she continues to do. While she had spoken this way about her students at the beginning of the data-generation time period, she had not spoken this way about herself until this point in time (the end of the study).

The audience to which Joanna told this story was different than the audience of the individual interviews (where I was the audience) or in the CI/math teacher group meetings (in which other teachers who had been using CI to teach math for various time periods were the audience). In this context, with instructors who had not taken the CI course, Joanna identified as a CI teacher who generally used CI in a certain way. She identified as a CI expert in relation to her audience for these stories. In that context she had more experience with CI than her audience did, which was not true for her in the other contexts.

Glynnis

In her presentation to teacher educators who had not participated in the CI PD, while Joanna was sharing materials she used to teach math with CI, she mentioned that she created different names for some of the roles than teachers had seen in the CI course. Glynnis interrupted and suggested that the names for the roles in the CI course were problematic. She said:

I try to tell the kids that everybody has a role and none of them are more important than the other. That they each are all very important roles. Because otherwise they're like, "Oh, she wants me to be the captain," and the status is already there. Because the 4th grade, especially, they've had years and years of it.

Glynnis only told this one short segment of a story of teaching mathematics with CI in which she reified her actions using present tense verbs. In this story, Glynnis spoke in generalized terms about how she dealt with one possible problem with the roles. Glynnis did not tell how-I-teach stories about how she did any other part of the process, including preparing tasks, organizing her classroom for instruction, or implementing instructional strategies. Again, it is notable that she only told this type of story about CI teaching in a context where she was someone who had used CI and there were people in the audience who had not. In that context, in this small part of a story, she identified herself as a person who typically dealt with this issue in this way. In doing so she identified herself as an expert in dealing with possible conflicts that might come about because of the role cards.

Discussion

I have shown a particular type of narrative that teachers told about their use of CI in mathematics—the how-I-teach-math stories. These narratives function to claim some new ways of teaching as the teachers' own and reify the teachers' experiences into integrated/expert identities. In the discussion that follows, I posit how-I-teach stories to be markers of teachers who identify as "CI teachers" with integrated/expert identities.

Integrated/Expert Identities: What it Means to Identify as a CI Teacher?

As stated in the theoretical framework, direct identifying statements are statements about a person that are reified, endorsed, and significant. A statement is said to be reified if talk about actions or processes have been replaced with talk about detemporalized objects. For example, "I gave the students a problem solving task" is not reified because it talks about an action that a teacher has taken, but "I am a problem-based teacher" is a reified statement because the teacher is then describing a characteristic of herself as true regardless of time (Sfard & Prusak, 2005).

The stories in this chapter are not direct identifying statements because in these stories the teachers have not made succinct, reified statements. Reification is defined as turning actions or processes into objects (Sfard, 2008). In these stories the teachers are not talking about objects; they are still talking about actions. However, they are not talking about specific actions. They are describing general ways they act regardless of time. For example, instead of saying, "We modeled the first four jobs," Patricia stated, "We model the first four jobs." She identified as the kind of teacher who models the roles with her students on a regular basis as opposed to having done that at one specific point in time. She could have identified even more strongly had she said, "I am a modeler."

If we conceptualize narratives on a continuum (as opposed to categorizing narratives that are reified and those that are not) it is logical that a teacher's narratives would move along that continuum in the process of her identity work. For example, a teacher might first say about a CI math lesson, "I modeled." She may later speak of her CI math teaching practice saying, "I model," and finally say directly, "I am a modeler."

Integrated identities. Persisting in the implementation of CI required the teachers to integrate new ways of identifying as teachers with their prior ways of identifying. How-I-teach stories...
about CI in mathematics are one indicator that some teachers were able to accomplish this integration of identities.

For example, in the theoretical framework I described how Joanna had struggled to integrate her identity as a teacher who gives with an identity as a teacher who steps back to allow children to struggle through a math problem. Eventually she discovered that, as a teacher who stepped back, she was also being a teacher who gave a new resource to students—the resource of each other's competencies. At the same time, Joanna continued to modify her use of CI in order to align it with her ways of identifying, including using tasks from a book received during the PD, Group Solutions Too (Goodman & Kopp, 2007), because she felt that the tasks were short enough that she did not need to step in during groupwork to intervene. By the end of the study she told how-I-teach stories about CI in math class. In one story, she stated, "I start out modeling with tasks from Group Solutions Too (Goodman & Kopp, 2007)". In doing so, she was identified as a teacher who does this. She was also performing her newly integrated identity: the teacher-who-gives and the teacher-who-steps-back. Because these types of narratives are indicative of integration of two identities, I call them integrated identities.

Expert Identities. In telling how-I-teach stories about their use of CI to teach mathematics the teachers were identifying as having expertise in one or many areas of teaching with CI. This is not to say that an outside observer would necessarily label each teacher as an expert CI teacher. I came to see these particular types of expository narratives as expert identities because of the contexts in which the stories were told. Patricia and Jonathan, the two teachers in the group with the most experience using CI to teach math, told how-I-teach stories at the beginning of the study. They used these stories to identify as the teachers in the group with expertise to share. Joanna and Glynnis told how-I-teach stories about using CI in math when the audience was a group of instructors who had not yet taken the CI math course. Therefore, in that context, Joanna (and to a lesser extent, Glynnis) identified as having some expertise to share with novices.

Implications

How-I-teach stories seem to be characterized by certainty and a sense of stability. On the one hand, they represent a transition from one mathematics teaching identity to another--part of the goal of PD events that seek to change practice. On the other hand, when teachers identify with such certainty teacher educators may become concerned that their certainty will impede future learning and reflection. I posit that how-I-teach mathematics stories could be a fruitful area for generative discussions about practice and student learning. For example, how-I-teach-math stories could be leveraged as potential questions for teacher inquiry. Perhaps in a next phase of the PD teachers could inquire into their own practices by collecting data on student learning to study the effects of the behaviors identified in their how-I-teach stories.

INCORPORATING A MEASUREMENT LEARNING TRAJECTORY INTO A TEACHER'S TOOLBOX FOR FACILITATING STUDENT UNDERSTANDING OF MEASUREMENT

Jeffery E. Barrett  
Illinois State University  
barrett@ilstu.edu

A learning trajectory for measurement provides a detailed explanation of the ways in which children think about measurement and prescribes tasks that will motivate students to think in more sophisticated ways. This paper reports on the potential use of a Measurement Learning Trajectory (MLT) as a means of supporting a teacher’s understanding of her students’ conceptual knowledge of measurement concepts. We found this tool useful in supporting the teacher’s growing knowledge of her students’ ways of thinking and her ability to evaluate and develop tasks to assess student understanding.

Introduction

A proficiency in measurement is essential to students’ understanding of the mathematics they will encounter in their future lives. The NCTM (2006) Focal Points document identifies measurement as one of the content areas that form the foundation for future mathematics learning. Lehrer, Jenkins, and Osana (1998) suggest that length and area measure “constitute the building blocks for developing a mathematics of measure” (p. 152). Although a conceptual understanding of measurement concepts is essential to students’ future mathematical understanding, Clements and Battista (1992) found that many children use measurement tools in a rote fashion and fail to understand the concepts behind the tools. Similarly, Lehrer (2003) concluded that the conceptual aspects of measurement are often left “unpacked” resulting in a procedural view of measurement (p. 188).

This paper describes how one teacher, with the support of a researcher used a Measurement Learning Trajectory (MLT) for length and area (Clements & Sarama, 2004; Barrett & Clements, 2003) to uncover her own students’ conceptual understanding of measurement ideas. Table 1 and Table 2 show the portions of the length and area trajectories that were used in this study.

Theoretical Framework

As students develop and learn mathematics, their thought processes become more sophisticated. These more sophisticated levels of thinking are central to Simon’s (1995) notion of hypothetical learning trajectories (HLTs). Clements and Sarama (2004, 2009) view the HLTs as, “descriptions of children’s thinking and learning in a specific mathematical domain and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking” (p. 83). The use of research-based accounts of students’ more sophisticated levels of thinking allows teachers to use an HLT to assist in assessment and instructional decisions.

Once a teacher establishes the level at which a student is operating, an informed decision can be made as to which tasks may be helpful in motivating the student to move towards developing more sophisticated levels of thinking. A cycle of task implementation, analysis of student thinking, and development of tasks to address the student’s misconceptions is critical to the
development of instructional interventions meant to motivate growth from one level into the next level. In the hands of a teacher, initially supported by a researcher, an HLT can be used as a tool to engage a teacher in the process of what Steffe (1991) found to be essential to the understanding of students thinking processes. This process of “hypothesizing what the learner might learn and finding ways of fostering this learning” will assist the teacher in her developing understanding of the strategies students use (Steffe, 1991, p. 83).

</table>

---

Methodology

A veteran fifth-grade teacher (Kathy) in a rural school in the Midwestern United States was encouraged to assume the lead role in the cyclical process of hypothesis, testing, and reflection pertaining to two of her students (Eliza and Isaac). In order for the teacher and the researcher to better understand the students’ knowledge and misconceptions concerning measure, they used Steffe’s (1988) notion of teaching experiments in which a researcher generates and tests hypotheses about a student’s thinking strategies and then tests those hypotheses in individual interviews (Steffe & Thompson, 2000) to investigate students’ understanding. With the support of the researcher, the teacher used the measurement learning trajectories (MLTs) for length and area as a research-based framework to guide her reflections about her students’ thinking processes and to develop tasks to use in predict/check cycles with two of her students.

To gain a clear picture of the students’ understanding and the teacher’s use of the MLT, the researcher analyzed video recordings of the teacher and researcher working with two focus students in sessions that were referred to as “teaching episodes.” On an alternating basis, the two focus students each participated in six 20-minute teaching episodes for a total of 12 weeks. Also analyzed were the teacher’s and the researcher’s ongoing and retrospective analysis of the students’ thinking strategies in the form of written reflections and audio recordings of the collaborative meetings between the teacher and researcher. These collaborative meetings included analysis of the videos of the teaching episodes, as well as the discussion of the predict/check cycles of the teaching episodes. The 12 weeks of video and audio recordings, as well as the written reflections over this time period comprise the data sources for this paper.

Results

We first describe a brief sequence of teaching episodes that focused on Eliza’s understanding of length as a compilation of equal sized units and her misconceptions concerning the ruler as a tool for measurement, which resulted in her inability to understand the correspondence between tick-marks and units. Next, we describe a sequence of teaching episodes that focused on Isaac’s lack of understanding of the array structure of area. We use both Kathy’s and my own accounts of the student’s thinking and the narrative of our thinking about the student’s progress or struggles as we conducted the sequence of sessions to describe how the students were thinking about the particular task. By describing the thinking of myself as researcher, of Kathy as both teacher and professional development learner, and of the students directly, we portray the situation that is fundamental to this research on the use of a MLT as a tool for professional development.

Eliza

On the initial assessment (January 13 and 14, 2009) Eliza successfully completed End-to-End (EE) tasks as well as the Unit Relater Repeater (URR) tasks. She was unable to attain the correct answer to perimeter task, which would indicate thinking at the Length Measurer level (LM). She did complete a blank ruler by paying close attention to equal spacing of units and subunits. Kathy thought Eliza’s attention to spacing and her accurate estimate of an inch was evidence that she was operating at the URR level.

Tasks were designed to check that Eliza was indeed thinking at the URR level for most tasks by presenting tasks that required the use of thinking at the prior level (EE). Eliza was able to consistently complete tasks at the EE and URR levels, however, we had yet to offer Eliza sufficient opportunities to complete tasks that required thinking at the LM level, thus we...
presented a task that required the use of a broken ruler. Kathy predicted that Eliza would be able to use the broken ruler, numbered from 7 to 11, broken on both ends, to determine the length of a 4-inch strip. However, Eliza explained her answer of “five inches” by counting tick marks from 7 to 11.

When Eliza was then given an unnumbered ruler to use to measure a 5-inch strip she called the five-inch strip “six” by counting ticks. Kathy then asked her to use a traditional ruler to measure the 5-inch strip in order to motivate Eliza to confront her misunderstanding. Eliza aligned the strip with the beginning of the ruler and read off the number that aligned with the end of the strip, which was five. Kathy asked, “What do you think of that? Do you think the paper ruler is not correct?” Eliza aligned the unnumbered paper ruler with the end of the traditional ruler to see that they were the same. Kathy asked Eliza to show us how she got five using the traditional ruler and Eliza explained by counting the tick marks, however, this time she did not count the 0th tick mark. Kathy then asked her to use the traditional ruler to help her mark off the five inches that she had measured. Eliza placed ticks along the segment, including one at the beginning of the strip. When she was done, she said, “But that’s six!” Kathy asked why that was six and Eliza responded, “Because of the zero” and pointed to the beginning of the ruler.

After Eliza’s consistent use of the tick counting strategy while using a variety of unnumbered measuring tools and her confusion with the role the zero plays on a ruler Kathy decided to try a task that the MLT described as useful in motivating students to confront their strategy of tick counting. Eliza was asked to use an unnumbered ruler to draw line segments of decreasing length from four inches to one inch. Due to Eliza’s reliance on tick counting, Kathy predicted that Eliza would use the ticks to help her draw segments, but that Eliza would not count the 0th tick and succeed due to the previous statements Eliza had made that indicated she was aware of the 0th tick causing her measurements to be off by one. However, Eliza counted ticks, including the 0th tick to draw her segments, thus she made segments that were always one inch less than they should have been. When she had to draw the one-inch segment, she said, “I can’t.” This prompted Kathy to ask why and when Eliza did not respond, Kathy asked, “Did you run out of lines?” Eliza smiled and said yes. Kathy and the first author (JM) had planned on focusing Eliza’s attention on the fact that a ruler is made of inches placed end-to-end, therefore, we asked Eliza to use a special ruler (one-inch strips placed end-to-end and taped together) that Kathy suggested Eliza make prior to this episode to measure her line segments. Using this tool to measure, Eliza surprised us by correctly counting ticks on this ruler instead of the spaces. When we asked how she got “four” for the 3-inch strip the first time, she explained that she had counted the 0th tick by accident. We were not satisfied with this strategy, as we wanted to motivate her to see and count the individual inches, which would have been evidence of the LM level of thinking.

Isaac

After analysis of the initial assessment, we had placed Isaac at a Partial Row Structurer (PRS) level. In most instances when asked to find area, he either wrote in a number with no explanation or drew in individual tiles that were not uniform in shape and size, but seemed to follow some row or column structure in various portions of the figure. Kathy predicted that Isaac would quickly move into the Row and Column Structurer (RCS) level.

The first task we describe asked Isaac to look at part of a five by six grid with the bottom right portion erased from view. Because one complete row and one complete column were in view, we hoped this would motivate Isaac see the row and column structure of the grid. Kathy
predicted that Isaac would get frustrated when she did not give him a pencil to complete this task so she gave him a pencil at the beginning of the task. Even with the pencil, Isaac touched each square and imagined square with the eraser and counted along each row and got 28 tiles. Since there were 30 tiles in the original drawing of the 5 x 6 array, he was now short by 2 tiles. We took this as evidence of thinking at the level of (PRS).

Next, Kathy asked him to try to fill in the missing tiles. He drew individual squares and was less accurate in the open spaces and ended up drawing 33 tiles (See Figure 1). To motivate the need for uniform tiles, Kathy gave him a square tile to use to iterate along the rows. Kathy asked if the tile was the same size as the squares on the grid and he said that it was not the same as all of them (because his squares were often too small or odd shaped). Kathy asked, “Does it make a difference that some of the squares you drew in were not the same size?” He said, “Kinda.” Kathy asked, “Would it be helpful to make them all the same size?” He said “yeah” and she asked him to explain why it would be helpful. Isaac replied, “So you could get the exact measurement.” Kathy asked him if there would be another way to partition the space instead of drawing individual squares and he could not think of any way. He used the tile and iterated it along each row and got 30. Isaac’s drawing and iterating along the rows of the rectangle confirmed our claim that he was indeed operating at the PRS level.

Kathy became convinced that Isaac’s inability to represent uniform area units was a result of his need for a ruler to draw in the tiles. She predicted that a task that used rulers in some way would help Isaac “see” the uniformity of the tiles and thus, begin to think of area as rows or columns of area tiles. JM showed Kathy a task that had two sets of two unnumbered rulers placed perpendicular and there was a three by eight rectangle on one set of rulers and a six by four rectangle on the other set of rulers (See Figure 2). Isaac was asked to compare the areas of the two rectangles. We decided that if he arrived at the area by using the formula, Kathy would ask him to show her the 24 units. Kathy predicted that he would again draw in individual tiles, but do a better job of making them uniform because the rulers were there for a guide. She thought that Isaac viewed a ruler as a tool for precision and that would motivate him to be careful with his drawing of the area units.

![Figure 1. Isaac’s Record of the Ink Blot Task](image-url)
Kathy asked Isaac to compare the areas. He said, “Well this one has three here (pointing to the side with three units) and eight here (pointing to the side with eight units).” He thought the four by six rectangle was bigger. “The big one is 24 and this one (3 by 8) is ….24.” Kathy asked if that surprised him? He said no. We asked him to show us the 24 square inches by drawing them in. He did not understand what we meant by this so Kathy went back to a prior task that involved a completed 3 by 4 grid to show him what she meant.

Kathy asked Isaac to compare the areas. He said, “Well this one has three here (pointing to the side with three units) and eight here (pointing to the side with eight units).” He thought the four by six rectangle was bigger. “The big one is 24 and this one (3 by 8) is ….24.” Kathy asked if that surprised him? He said no. We asked him to show us the 24 square inches by drawing them in. He did not understand what we meant by this so Kathy went back to a prior task that involved a completed 3 by 4 grid to show him what she meant.

He then drew tiles in one at a time and left gaps and did not attend to the size of each tile. He ended up with 27 squares. Again, Kathy thought he would do better if we emphasized the ruler so she gave him a regular ruler to see if he could use that to help him. He did not think the ruler could help and said that although he drew in 27 tiles, he knew that the area was really 24. His drawing led us to believe that he was still operating at the PRS level because he continued to draw non-uniform individual square tiles.

To motivate Isaac to see rows as rows and iterate rows we designed a task that presented Isaac with a pile of square tiles. Some of them were taped together forming rows of six tiles and others were loose. Kathy asked him to use the tiles to make a rectangle with a length of six and a width of seven. Kathy predicted Isaac would start out using the individual squares and would get three rows into the construction before he realized he could use the strips. If this did not happen Kathy planned to point out the strips of six and ask him if he thought he could use those to help him.

He began by placing a set of six squares on the left and right side of an open space. He then placed seven individual tiles along the bottom in between the left and right sets of six tiles. Along the top he placed a set of six tiles and one loose tile. Kathy gave him a ruler and had him check how long the top was. He found that the sides were six and the top and bottom were nine. He took the top strip of six away and placed seven individual tiles in between the two columns of six and re measured. To remind him of his goal Kathy said, “Ok, I want a rectangle that’s six by seven.” Isaac removed two loose tiles, one from the top row and one from the bottom row, so that he had seven across the top and bottom. He used the ruler and said, “That’s seven inches long.” Kathy asked, “So what would the area of that be?” He said “42 squares.”

Kathy then asked him what the perimeter was. He individually counted around and touched the table beside each tile as he counted correctly. He did not use the algorithm, which is how he apparently got the 42 squares that he found for area because there were no tiles in the interior of his rectangle. This told Kathy that Isaac did not seem to understand how the figure and the area

---

formula were connected. Because he struggled to make the rectangle and did not indicate that he understood the row and column structure of area, we thought he was still operating at the PRS level. Isaac apparently was struggling to see the area in terms of rows and columns. However, if we were to do this task again, Kathy would ask him to make a complete rectangle from the start. We did not anticipate that he would see the square tiles and think in terms of perimeter.

**Conclusions**

Eliza’s confusion concerning the role of the zero on the ruler and her unwavering reliance on counting tick marks to determine length when using a nonconventional ruler surprised Kathy. Isaac’s inability to see the row and column structure of area units, frustrated Kathy, as she believed we could design tasks that would motivate Isaac to confront the misconception and quickly move into the next level. Although I was there to help analyze these episodes with Kathy and discuss her predictions of Eliza’s and Isaac’s responses to the tasks, Kathy began to make her own decisions about what tasks to use next and even created some tasks based on her own professional knowledge of teaching measurement. The brief descriptions above show instances where Kathy took the lead role in choosing and developing tasks, as well as asking questions that probed students’ understanding. For Kathy, this was an opportunity to investigate ways to prompt her students to confront their misconceptions and attempt to increase their level of thinking without teaching students in a “show and tell” manner. Although there were times when Kathy struggled with her desire to “just tell them how to do it”, she continued to work with these students using a more critical lens for viewing her role as a facilitator of knowledge and creator of appropriate and useful assessment tasks.

**Discussion**

This brief example of Kathy’s ability to use the MLT to guide task creation to assess her students’ understanding of length and area offers insight into the practical use of this research-based framework. Although some teachers might be able to incorporate the ideas of the MLT quicker or in more meaningful ways than Kathy did and others might not have the same level of success Kathy found with the MLT, this example offers a glimpse of the potential impact the MLT could have on a teacher and the way she views the quality and the role of assessment tasks in her desire to increase her students’ competency in the area of measurement. If further research finds that Kathy’s growth and development is typical, then we know what to expect of other teachers in a similar context. However, if it turns out she is unusual in her ability to grow, then we will have to make changes to our methods for introducing and encouraging teachers to use the MLT in practice.

This investigation is to determine whether a classroom-based mathematics coaching professional development model has a positive impact on student mathematics achievement in low performing elementary and middle schools. Relevant literature is practically void of research connecting a professional development program, particularly on coaching, to improved student mathematics achievement. Findings suggest that this mathematics-coaching model has made large and significant impacts at all grade levels and each level effect sizes range from 0.5 to nearly 0.9. These results may provide a framework for discussion of why so many ‘proven-to-work’ research-based instructional strategies fail to yield desired results in student mathematics achievement.

Introduction

In 1983, A Nation at Risk was published describing the perils in education that must be addressed for school systems to succeed. The report clearly represented the condition of the United States educational system as dismal. A Nation at Risk calls for refining mathematics curriculum and instruction for which it has been calling now for over a century. Federal funding sponsors such as the National Science Foundation and the United States Department of Education have spent hundreds of millions of dollars over the last 30 years producing only small gains in mathematics achievement scores (NAEP, 2008; Hiebert et al., 2003).

Within a parallel timeframe, learning theories were further refined to better suit the teaching and learning of mathematics. The genre of research focused on cognition and instruction has provided insight into the teaching and learning of mathematics (Cobb, 2001) suggesting ways in which student thinking may be enhanced. Progress was made in not only understanding how children learn but also in how to effectively teach to promote understanding (Franke, Kazemi, & Battey, 2007) motivated by the desire to break away from the traditional textbook.

With findings and funding in place, professional development became key to changing practice. Experts in professional development have studied and designed quality experiences for teachers with promising results (Darling Hammond & McLaughlin, 1995; Shifter & Fosnot, 1993; Sparks & Loucks-Horsley, 1990). With all of these trends and forces converging, it was hoped that all mathematics classrooms would soon transform into research-based, theory-driven spaces where teachers and children would engage in mathematics using reform-based best practices. However, there still remains little gain in mathematics achievement.

Mathematics instructional coaching is fairly new as a model of school-based professional development. However, there are instances of coaching in the literature even though it is not referred to as such (e.g., Borko, Davinroy, Bliem, & Cumbo, 2000; Breyfogle, 2005; Franke, Carpenter, Fennema, Ansell, & Behrend, 1998). Coaching emerges in a variety of structural approaches and has not been studied extensively. Coaching is grounded in the notion of capacity building for change and having highly trained practitioners working with their colleagues to support learning. As a professional development model, the method capitalizes on collegial interactions to improve practice (Becker, 2001). The use of such a model in the mathematics
education community as a means to enhance teaching and learning has gained momentum (Davenport, 2008).

The Mathematics Coaching Program—Our Model

The design and structure for our mathematics-coaching model are original while the content of the professional development is based on our conceptual framework that is well grounded in theory and research. The model has four sections: 1) MCP Conceptual Framework, 2) Coaches’ Professional Development, 3) Design and Structure for Implementation, and 4) Accountability and Quality Control. The MCP conceptual framework is representative of what is valued in the MCP, how we organize those values, and how they together combine to make a whole. The fundamental goal of the MCP is to help students become active and informed agents of their own mathematical learning, making learner-responsive mathematics education the core of our work and the framework.

The foci for all MCP professional development sessions include: a) deepening mathematics content knowledge; b) deepening pedagogical knowledge and sharing research-based best practices for mathematics learning and teaching; c) attending to socio-cultural elements of mathematics teaching and learning; d) focusing in on student thinking and learning how students can learn mathematics; and e) learning to transfer knowledge to classroom teachers through coaching and teaming; f) using the NCTM Process Standards in all facets of teaching and learning mathematics; g) defining coaching as teaming with teachers in classrooms 4 days per week; and h) working with data to enhance program elements and progress.

Pedagogy in the MCP is student-centered, student-responsive, problem-based, and provides many opportunities for students to use all the NCTM Process Standards. In our work over the last 20 years we have become strongly grounded in several specific learning theories and research-based instructional strategies. Theoretically, we use a social cognitive, social constructivist, and social justice perspective in the teaching and learning of mathematics. Specifically, our work is grounded in Cognitively Guided Instruction (CGI) (Carpenter, Fennema, Franke, Levi, Empson, 2000; Carpenter, Fennema, Peterson, Chiang & Loef, 1989); using teaching experiments (Cobb, 2000) and rethinking mathematics teaching and learning to close achievement gaps using a social justice perspective (Gutstein & Peterson, 2005; Frankenstein, 1987).

The MCP instructional approach is drawn from scholars who focus on the critical features of instruction (Hiebert, J., Carpenter, T., Fennema, E., Fuson, K., Wearne, D., Murray, H., Oliver, A., & Human, P., 1997), teacher content knowledge and content knowledge needed for teaching (Ball, Hill & Bass, 2005; Leinhardt & Smith, 1985; Lampert, 1990; Ma, 1999; Hill, Shilling & Ball, 2004), and teacher pedagogical content knowledge (Leinhardt & Smith, 1985; Ball, 2000; Pinar, Reynolds, Slattery & Tubman, 1995; Shulman, 1986, 1987; Wilson, Shulman & Richert, 1987). These scholars recognized the complexity of teacher knowledge and the role of both content knowledge and pedagogical content knowledge (PCK) in effective instruction. Furthermore, PCK is about how to teach the content and in that how to understand students’ thinking, cultural identities and how they impact learning, and learning styles and preferences.

The MCP instructional approach also incorporates Lipping Ma’s (1999) notion of addressing teachers’ content simultaneously with student learning. Ball & Cohen (1999) also acknowledged professional development should be situated in the context of practice. In addition to these recommendations, research on professional development in mathematics education and in education in general provides insights as to the qualities of effective professional development.
(Darling Hammond & McLaughlin, 1995; Shifter & Fosnot, 1993; Sparks & Loucks-Horsley, 1990). All of this is in alignment with recommendations from the National Council of Teachers of Mathematics (NCTM).

The Design and Structure of the Coaching Model

The MCP requires mathematics coaches to team in classrooms with a small group of four teachers everyday for six weeks, and all coaches must participate in professional development four-days per month. At the end of a coaching cycle, the coach begins working with a new group of four teachers while maintaining lessened contact with previously coached teachers. The MCP provides support to coaches for approximately 300 hours per year for up to three years.

The Study

Our overarching goal is to investigate how professional development must be conducted so that teachers learn, internalize, implement, and perpetuate successful teaching and learning of mathematics leading to improved and sustained student achievement. In this paper we intend to determine whether mathematics coaching using the model described herein has a positive impact on student mathematics achievement and if so, is the impact significant?

About the Participants

The Mathematics Coaching Program’s effort is situated within some of the lowest-performing urban and rural schools from across the state. Statistically these schools are rife with disproportionate numbers of students in poverty, minority subgroups, disabilities, and/or students with limited English proficiency reside. The State Department of Education administrators privileged the mathematically lowest-performing schools in the state to be first in line to receive the professional development they sponsored. To determine which schools would be on the most-eligible list, schools had to be in School Improvement Status and Title I served. Additional mostly undisclosed state criteria were used to narrow the pool, one of which was size of district.

Since the state department was funding schools across the state to participate in either a mathematics-coaching program or a literacy-coaching program, the list of eligible schools would, by Principal’s choice, result in schools having no coach, a literacy coach, or a mathematics coach. School principals hired their own coach from within their building or otherwise.

MCP teachers. Teachers in participating schools self-select whether he/she is willing to work with a mathematics coach. All teachers who teach mathematics from grades K through 8 are invited to participate. Once willing teachers are identified, the mathematics coach takes time to prepare for the first six-week cycle. Teachers are required to supply the coach with copies of curricular materials, textbooks, pacing guides, and a list of students. There are only two requirements that teachers must abide by while working with the coach. First, teachers are required to team teach with the coach at all times and second, teachers are required to meet with the coach at least one time per week for planning and debriefing. Enforcing these two requirements allows the program to have a chance at building capacity across the staff and subsequently having principals seeing the benefits and sustaining the program after the project is over.

Facilitators. Facilitators are professional educators with a mathematics background who the MCP would be able to hire for four days per month. People who are able to make such a commitment include but are not limited to college/university professors, professional development specialists, educational service center professionals, district curriculum supervisors,
and retired mathematics teachers or MCP graduates. Two days per month, the facilitators join their assigned coaches at the MCP Professional Development sessions so that they learn exactly what the coaches are learning and expected to do. The other two days per month, the facilitators call small group meetings in their local area to provide a layer of support that has proven to be priceless to the success of this program.

*Students tested.* The state Achievement Test (AT) is given to all public school students in this state and all students in community schools (those public schools that are run by private entities). The AT is optional for all private schools – including parochial schools. However, most all of these schools choose to take these exams as well. There are no exemptions from the test. Students with IEP’s have testing accommodations, or, in severe disability cases, alternative assessments are given.

*Methods*

Data were collected from the state testing website from school report cards. The data collected were from all schools on the state’s eligibility list, of non-coached, literacy coached, and MCP coached schools. Specifically, the data used for this study included grade level percent passing rates at or above proficient levels. To determine whether the MCP had an impact on student mathematics achievement a structural equation model was used to measure effect size. All student mathematics achievement test data for all schools at all grade levels tested in grades 3-8 in the first four years of the program were used. Thus, there were hundreds of schools at each grade level providing the numbers needed for credible results. To test for significance, two-tailed multi-year T-tests were conducted. The results of these measures are displayed in Table 1.

*Results*

*Effect Sizes and Significance Levels.*

In Table 1 there are many data points to analyze. First, the data are reported in grades 3 through 8. For each grade level there are data reported from two groups, the schools that participated in the Mathematics Coaching Program and those that did not. In each grouping the various numbers of schools, mean scores of mathematics achievement at or above proficient, and standard deviations are presented. The final two rows show P-Values, and Effect Sizes for each grade level.

The data in Table 1 were from a large number of schools accumulated over four years. This large number reduces the concern of non-randomization of school choices and the control of student population and teacher variations. If there are two schools that have major contextual or constitutional differences, the outlier effect can be “averaged out” with a large number of schools having diverse contexts and backgrounds. A second observation shows that the mean values are greater in the coached group at every grade level. Studying the means further shows that grade 5 has the lowest mean value in each group. This is true in all 5th grades statewide. One of MCP’s foci for Year Five is to examine Grade 5 more closely so that we may better understand this phenomenon.

Effect size has been widely used to evaluate the impact of an education treatment. Generally the evaluation of impact in terms of effect sizes ranges from small (<0.3), medium (<=0.5), large (>0.5), and very large (>0.8). In Table 1, the effect sizes for the MCP data are all large. This finding alone leads the researchers to conclude that the Mathematics Coaching Program as a whole does have a positive impact on student mathematics achievement.

With the effect sizes all indicating a large positive impact on student mathematics achievement, it is also important to note that the respective p-values were all at significant levels, which is the natural outcome of large size samples. To view the impacts pictorially, a sample of two grade level charts is presented in Figures 1 and 2.

In Figure 1, the data represent hundreds of schools having 5th grade students as well as whether schools have a mathematics coach or not. Each school has an average percentage of 5th graders who scored at or above proficient on the mathematics achievement test. This figure shows two line graphs, one representing the non-coached schools and the other representing the MCP schools. Looking at the first graph, the line shows a large percentage of the non-coached schools aligning with the lower percentage of students at or above proficient. This non-coached line also indicates that there were 0% of schools scoring more than 85% of its students at or above proficient. The coached data show that more schools scored higher percentages of students at or above proficient. There is an observable spike on the high end of the achievement scale. This spike shows a sizable rise in the percentage of schools having an 85% to 100% of students scoring at or above proficient.

Figures 1 & 2. Percentage of schools compared to percentage of 5th and 8th grade students in those schools averaging at or above proficient levels in mathematics.

Data in Figure 2 are gathered and organized the same way as in Figure 1. The data represent hundreds of schools having 8th graders scoring at various averages of at or above proficient on the mathematics achievement test. In this case, the results are similar in that greater percentages of schools in the non-coached schools have larger percentages of 8th graders scoring at or above proficient at the low end of the scale. The MCP coached schools at this grade level are showing greater percentages of schools having even greater numbers of 8th graders scoring at or above proficient. This greater percentage shows a much greater effect size. The results of both graphs also show that the changes of student performances happen rather uniformly at low through high performance schools. This suggests that the coaching model benefits schools at all performance levels.

**Discussion**

Many professional development providers maintain long held traditions including presenting too many ideas to an auditorium full of classroom teachers all day everyday for one or two weeks during the summer with the expectation that the teachers learned what was intended, interpreted learnings as intended, implemented ideas as intended, and that all children will not only learn the mathematics but will achieve highly on high-stakes testing. The effectiveness of this approach has long been challenged. After 30 years of trial and error, American students’ mathematics achievement in national and international theatres remains the same—high achievers remain high, low achievers remain low (NAEP, 2008; Heibert et al, 2003).

The move towards designing job-embedded, sustained experiences for teachers in order to advance teacher learning in ways that alter classroom practice has been well grounded in the community’s best thinking on transformational learning about teaching (Ball, 2000). However, relationships between such models and student achievement, in large scale, have not been widely explored. In this paper we presented empirical data on the positive impact of Mathematics Coaching Program and student achievement in settings where traditional professional development plans, nationally, had not been successful. These results fully position us to challenge traditional views on teacher development approaches and argue that providing teachers with information is not sufficient to improve practice. Teachers need to be provided with a classroom-based professional development system that is ongoing, consistent, and long term.

Indeed, the MCP Model for Professional Development provides ample evidence that student achievement in low performing schools can improve at significant levels. Therefore, we argue that our approach merits attention and further study. Our goal in this paper was to establish whether the Mathematics Coaching Program, as a whole, had a positive impact on student mathematics achievement, and if so, was the impact significant. The findings show that the MCP has had a large positive impact on student mathematics achievement at all grade levels 3 through 8 and that the impact was significant at all grade levels. Considering that our work is conducted in some of the lowest performing schools in the state gels some hope for other schools that are otherwise not expected to improve.

Having established a positive relationship between our PD model and student achievement our research team is now engaged in a critical study of several critical issues associated with explaining these results, namely: a) What do mathematics teachers and coaches need to know and be able to do to help struggling learners become successful? b) What MCP elements are most critical to the learning process? c) How are the underrepresented subgroups of students performing? d) What other statistical models may be used to dig deeper into the MCP database to produce additional credible findings in a non-randomized classroom-based program? e) Does...
this program increase mathematics and pedagogical knowledge among the participating teachers and coaches, and if so, in what ways does this happen? f) What is happening in MCP classrooms and how do we know if the mathematics coaches are following the program as intended?

These findings also give way to variations of professional development approaches that can make a difference. Further, it may be the case that when examining elements of the Mathematics Coaching Program researchers from across the nation may create hybrid models of this program by making context-specific adaptations for others challenged by school mathematics.

This paper reports research results on the impact of a mathematics coaching Professional Development Program on student proficiency levels. The program prepares classroom teachers to serve as mathematics coaches for their respective schools. This study examined state achievement test results for schools with first-year coaches in their buildings. Data were analyzed for grades 3-8 and compared for schools participating in the mathematics coaching program with similar schools not involved in the program. The number of students at each proficiency level – limited, basic, proficient, accelerated, and advanced – was investigated and compared using data from the year prior to participation in the program with data from the end of the first year of participation. Results show significant gains.

Introduction

Mathematics education in the United States has been unfavorably compared to that of other countries for decades (Miller, Sen, & Malley, 2007; Nelson, 2003). There is evidence that a majority of the students in U.S. schools lack both an understanding of and an appreciation for mathematical literacy and by the time many of them reach high school, mathematics is one of their least favorite subjects and they fail to see its relevance to any aspect of their lives. Calls for the need to change this pattern have been voiced by scholars and professional organizations. Some evidence indicates that the quality of teacher knowledge may have an impact on students’ performance.

Elementary mathematics education sets the foundation for each student’s future success. However, most students at this level are taught by teachers with limited mathematical preparation as few were probably required to take more than two or three mathematics content courses and maybe one mathematics content pedagogy course (Fennell, 2007). Most elementary school teachers, through no fault of their own, lack the necessary mathematical content or pedagogical knowledge to effectively instruct students so that they have a thorough understanding of mathematical concepts. The Virginia Math and Science Coalition Task Force Report (2005) confirmed this for teachers in Virginia in a study designed to present a case for using mathematics specialists in their elementary schools. In a separate study, it was found that the mathematical content knowledge of teachers significantly affected student gains at the first and third grade levels regardless of years of teaching experience (Hill, Rowan, & Ball, 2005). Literature confirms that teacher preparation programs as well as professional development need to emphasize both mathematical content knowledge and mathematical content pedagogical knowledge (Cavanagh, 2008; Hill et al., 2005; Li, 2008; Reys & Fennell, 2003). In light of these suggestions, calls for designing professional development programs that target teachers’ subject matter understanding while increasing their sensitivity to children’s thinking...
have been widespread (Becker & Pence, 2003; Bruce & Ross, 2008; Cavanagh, 2008; Hill et al., 2005; Li, 2008; Murray, Ma, & Mazur, 2009; Reys & Fennell, 2003). Despite this, the relationship between coaching professional development programs and student achievement remains mostly unexplored (Murray et al., 2009). The purpose of the research reported here was to address this gap.

This report is part of a larger longitudinal research project that closely studies the link between a Mathematics Coaching Professional Development model on teacher and student learning. While there are several studies examining how mathematics specialists or coaches impact teachers (Becker, 2001; Bruce & Ross, 2008; Gerretson, Bosnick, & Schofield, 2008; Lord, Cress, & B. Miller, 2008; McGatha, 2008; Murray et al., 2009; Olson & Barrett, 2004), a concern remains regarding the impact of coaches on student achievement (Murray et al., 2009). In general, researchers assume a positive impact but literature provides little in the way of empirical evidence to support this assumption.

**Theoretical Framework**

Job-embedded professional development programs for coaches are grounded in a constructivist orientation (Becker & Pence, 2003). The focus of existing programs is on development of mathematics coaches who work collaboratively with teachers, administrators, parents and community with the overall goal of improving mathematics achievement for all students in their school. Collaborative classroom coaching has shown to help teachers rely more on their own knowledge and judgment than that of textbooks and encourages them to be more receptive to trying new strategies. Such a pathway facilitates transitioning from traditional to more reform-based methods of instruction (Becker & Pence, 2003; Lord et al., 2008).

While there are few empirical studies with respect to coaching professional development and its impact on student achievement, what little research exists points at some common perceived benefits of these programs. Collaboration is the most often mentioned strength of using a mathematics coach. Most teachers appreciate the opportunity to share ideas, techniques and strategies and as a result are willing to move their instruction towards more standards-based methods (Bruce & Ross, 2008; Gerretson et al., 2008; Murray et al., 2009). Movement in this direction had a positive effect on student achievement (Gerretson et al., 2008). In their discussion, Bruce and Ross (2008) state, “When a teacher receives positive and constructive feedback from a respected peer, there is even greater potential for enhanced goal setting, motivation to take risks, and implementation of challenging teaching strategies.” (p. 348)

Literature divides mathematics specialists along three conceptual models. The first type is the Lead Teacher Model where the classroom teacher has extra duties as a mathematics resource person. The second type is the Specialized Teaching Assignment Model where a classroom teacher’s only responsibility is to teach mathematics. The third type of model is the Mathematics Coach Model where the specialist works collaboratively with other teachers but is not responsible for his or her own class (Gerretson et al., 2008; Pitt, 2005). The Coach Model represents the type of mathematics specialist used throughout the entirety of this research project.

**Roles and Responsibilities of the Mathematics Coach**

In general, a coach works with administrators, teachers, parents, and the community providing leadership and direction for the mathematics program of their school. Literature (Fennell, 2007; McGatha, 2008; Reddell, 2004; Virginia Mathematics and Science Coalition Task Force, 2005) summarizes roles and responsibilities of mathematics specialists into the...
following categories: (1) Implementing standards and research; (2) Planning and facilitating professional development; (3) Working collaboratively with classroom teachers; (4) Analyzing and interpreting data; (5) Organizing and coordinating mathematics resources; (6) Communicating with parents and community. This paper focuses on the collaborative working relationship between the mathematics coach and the classroom teacher. Of the six categories of responsibilities for mathematics specialists, collaboration with classroom teachers would seem to necessitate the greatest attention. Collaboration includes such activities as co-planning, co-teaching, modeling a lesson, and coaching. The coach and classroom teacher can work together to plan a lesson discussing instructional methods, questioning techniques, and possible areas of concern for student learning. Reflecting on a lesson prior to its implementation can help teachers anticipate difficulties that may occur. They can also work together to teach the lesson and upon completion of a lesson, the teacher and coach can then reflect on its overall effectiveness and, for future classes, adjust it as necessary. The strength of an effective mathematics coach is with their expertise in mathematical content knowledge and mathematical content pedagogy (Feger, Woleck, & Hickman, 2004; Powell, 2009). By working collaboratively with classroom teachers, the mathematics coach can pass on their knowledge with the goal of improving instructional practices and ultimately, student learning. However, these assumptions, while intuitively sensible, remain theoretical due to lack of empirical data.

**Background**

In this work we consider “Mathematics Coaching Program” (MCP), which has been in schools throughout Ohio in partnership with The Ohio State University. MCP is in its fifth year and has grown from a K-6 program to a K-8 program. Initial and current focus of MCP is to work with teachers from the lowest performing school districts, as determined by Ohio Achievement Test (OAT) results, with the goal of improving their mathematical content knowledge and pedagogy. To achieve these goals, MCP recruits teachers from participating school districts and, through ongoing professional development, prepares them to serve as mathematics coaches in their respective buildings. Professional development consists of two full-day monthly sessions for eight months and then five full-day sessions in May. The focus of these sessions is to provide research-based activities to engage coaches in mathematical and pedagogical exploration. Coaches also have two additional full-day sessions each month to meet with their facilitator groups to discuss experiences as well as problems and concerns. Facilitator groups include coaches from different school districts and the group facilitator. To progress through a complete cycle of training, coaches remain with MCP for three years at which time the opportunity usually exists to become a facilitator.

Coaches who participate in MCP have no classroom responsibility of their own. They cannot be assigned more extra duties than other classroom teachers. Their primary focus is to work collaboratively with teachers in their building to help them gain the knowledge, confidence, and necessary instructional practices needed to effectively teach mathematics. Coaches work with a maximum of four teachers each time for a period of six weeks spending part of each day in the classroom of each teacher with whom they work. At the end of the six-week period, coaches begin working with a new set of four teachers. At the time of this study, MCP trained first, second, and third year coaches from a variety of low performing school districts. Ongoing research investigates the impact of the program on teacher and coach knowledge development, change in instructional practices, and student achievement. The study reported here aimed to address the relationship between MCP and student achievement.

Methodology

This study analyzed student achievement data from eighteen schools with twenty-one first-year MCP coaches. Fourteen schools had one coach, two of the K-8 schools had three coaches each, and one coach served at two schools. Results of the MCP-coached schools were compared with eighteen non-MCP coached schools similar in grade span, enrollment and typology. Data were organized according to grade level, including students from grades 3-8, with the number of subjects at each grade level indicated in Table 1. It should be noted that only six of the eighteen MCP-coached schools and eight of the eighteen non-coached schools contain subjects from all grade levels.

Table 2 displays the school typology as designated for their district by ODE.

Student achievement data were obtained from Ohio Achievement Tests from the 2007-2008 and 2008-2009 academic years. A group of first-year coaches from the above-mentioned schools joined MCP in the fall of 2008. The 2007-2008 data served as baseline data for subjects from participating schools prior to MCP and the 2008-2009 data were for subjects from the same schools at the end of the their first year with MCP. The 2007-2008 and 2008-2009 OAT results of subjects in similar schools were used for comparison with non-MCP schools. Specifically, OAT results for both MCP and non-MCP schools were analyzed according to grade level and proficiency levels as defined by the Ohio Department of Education (ODE). The five proficiency levels, in order from lowest to highest achieving, include limited, basic, proficient, accelerated, and advanced. This study focused on the number of students at each level of proficiency in the year prior to MCP and at the end of one year of participation in the program. For comparison, the number of students at each level of proficiency was also analyzed for similar non-MCP schools. For each school and grade level, state report cards provided a percentage of students at...
each proficiency level. The number of students at each proficiency level and grade level was determined by multiplying the percentage given on the report card by the grade-level student enrollment as provided by ODE. These values were then totaled for each grade level and proficiency level combination and divided by the total number of students for the respective grade level to obtain a weighted average percentage of students at each of the five proficiency levels. These calculations were performed for the baseline data and the post-MCP data for both coached and non-coached groups. By subtracting the baseline data percentages from the post-MCP data percentages, the relative change was determined for each of the grade and proficiency level combinations for both coached and non-coached groups. Finally, using these values, the non-coached relative changes were subtracted from the coached relative changes to determine an overall relative change for each grade and proficiency level combination. A positive result indicates that the relative change for coached data was greater than that of non-coached data and the reverse is true for a negative result. Using these overall values, the following three data summaries were determined:

1. Relative change on “Proficient and above” by grade level.
2. Average of relative change for each of the five proficiency levels for all grade levels combined.
3. Average of relative change on “Proficient and above” for all grade levels combined.

It is noted that “Proficient and above” refers to the proficient, accelerated, and advanced levels combined. With regard to the OAT, student achievement at any of these three levels of proficiency satisfies necessary state requirements.

Results

Figure 1 summarizes the results of this study. For all grade levels combined, the average relative change for students achieving the proficient level or higher was 4.65% greater for MCP-coached schools than non-coached schools. At the opposite end of the spectrum, the average relative change for students achieving only the basic or limited level was 4.46% greater for the non-coached schools. Combined, this represents more than a 9.00% difference between MCP coached schools and non-coached schools.
Figure 2 further breaks down the results summary into each of the five proficiency levels. For all grade levels combined, proficient (1.36%), accelerated (2.73%), and advanced (0.55%) levels’ average relative change was greater for students from MCP-coached schools than non-coached schools. The average relative change for basic (-0.56%) and limited (-3.91%) was greater for non-coached schools.

Figure 3 provides a summary by individual grade level of the relative change of students achieving proficient, accelerated, and advanced levels of proficiency. Relative changes were greater for students in MCP-coached schools than non-coached schools for grade 3 (0.55%), grade 4 (6.75%), grade 5 (10.07%), grade 6 (7.63%), and grade 8 (4.87%). However, the relative change for grade 7 (-2.00%) was greater for non-coached schools. Again, the average relative change across all grade levels (4.65%) was greater for students from MCP-coached schools than non-coached schools.

**Discussion**

In this study, we examined whether a mathematics coaching program (MCP), focused on improvement of teacher knowledge and instructional practices, would have a positive impact on student proficiency levels. Results provide encouraging evidence that even after only one year with the program, students at MCP-coached schools performed better on statewide achievement tests than students at non-coached schools. The statistical significance of the results is reported in Table 3.

Data analyzed represented a weighted average percentage of students at or above the proficient level for grades 3-8. Since data for this study did not include individual student data, two sample t-tests were used for each grade level. The p-value gives the statistical significance of the relative change at each grade level indicating that they were all statistically significant except for grade 3. Further, it can be stated that MCP made positive impacts on student achievement for grades 4, 5, 6, and 8 with moderate to large effect sizes. It is noted that grade 7 results did not indicate a positive impact on student achievement. At present there is no obvious reason as to why grade 7 deviated from the general trend, but this certainly could be a focus area for future studies. Results at the grade 5 level offer an interesting perspective as well. On the 2008-2009 OAT, fifth grade students had the lowest passage rate of any grade from 3-8 yet the results of this study showed that their relative change was statistically significant with the largest effect size of all the grades. One reason for this result could be that at the time of this study and relative to the other grade levels, they had the most room for improvement. The average relative change of 4.5% was also statistically significant with a moderate effect size of 0.27. These results provide evidence of a positive impact of MCP on student achievement.

Conclusion

Lack of empirical evidence with regard to professional development programs for coaching and their impact on student achievement served as a guiding force for this study. Indications are that coaching programs utilizing classroom-embedded professional development focused on standards-based research had a positive impact on student achievement. While this report is only a small piece of a very large research project, its results are certainly encouraging. However, much more research and empirical evidence in this area is necessary before any definite conclusions are possible.

MATHEMATICS COACHING AND ITS IMPACT ON URBAN FOURTH GRADE STUDENTS’ MATHEMATICS PROFICIENCY ON HIGH STAKES TESTING

Scott Coniam
The Ohio State University
Coniam.1@osu.edu

This study examines mathematics coaching, as defined by the Ohio Mathematics Coaching Program (MCP), a classroom-embedded professional development model that focuses on student thinking in low-performing schools. Fourth grade students at eleven MCP-coached schools all in their second year in the program, in a major urban school district in the Midwest participated in pre-and post testing. The pretest consisted of items released from the prior year’s state achievement test and the posttest was the official state achievement test. Results indicated significant gains in all content strands.

Introduction

Students from low-performing schools generally struggle learning mathematics. It has been a national trend to use coaching as a form of professional development to assist teachers in enacting research-based instructional strategies shown to work with low-achieving students. The Mathematics Coaching Program (MCP) was designed for such a purpose. The idea was to place a mathematics coach into four teachers’ classrooms each day for six weeks to find out how students could learn, as they were not learning the way they were being taught. Since the Ohio Department of Education (ODE) organizes mathematics into five content standards, this provided a challenge to any professional development program trying to positively influence mathematics achievement in low-performing schools.

For the past two years, I have worked with MCP at The Ohio State University examining proficiency data for our coached students as a collective. I wondered whether or not MCP was having an impact at the student level in each of the five mathematics content standards: Measurement; Number, Number Sense, and Operations (hereinafter Number); Patterns, Functions and Algebra (hereinafter Algebra); Data Analysis and Probability (hereinafter Data); Geometry and Spatial Sense (hereinafter Geometry).

Literature Review

Mathematics coaching is a fairly recent arrival to the realm of professional development, one whose available evidence is promising for classroom implementation (McGatha, 2009). Rather than having an outsider come into a school once or twice a semester to impart new content-knowledge or ‘best practices’ upon a group of teachers, the rationale behind coaching is to have someone in the building on a regular basis, helping shape teaching strategies and acting as a support person. Many coaching models do not pull students out of the classroom, but rather insert another qualified teacher into the classroom to help guide the teacher in new pedagogical methodologies. This person also can act as a level of support for content knowledge as well.

Staub, West, and Bickel (2003) address the issue of content-focused coaching in the first chapter of Staub and West’s book Content-focused coaching: Transforming mathematics lessons. This text, along with works by other researchers (Neufeld & Roper, 2003), suggest an organizational structure for developing a content-focused mathematics coaching program. They note that coaching should provide structure for ongoing professional development aimed at:
helping teachers design content-specific lessons; examing methodology in terms of student thinking; is based on a core philosophy; enriches pedogogical content knowledge; and encourages commincation skills. Coaching models should help to empower the teacher to use current (reform) practices in the classroom, to change their instructional style without fear of criticism, and to embrace collaborative efforts on teacher-teacher and teacher-coach and teacher-administrator levels (Neufeld & Roper, 2003). Each of these levels of communication is paramount in developing a successful coaching program, and Neufeld and Roper (2003) provide instruction to not only teachers and coaches, but administrators and district personnel as well.

In developing a mathematics coaching program, all personnel involved need to collaboratively address several key elements: the content to be learned, how and why that content should be taught, and why the content should be taught in a specific manner. (Staub, West, & Bickel, 2003). In addition, the teacher and coach should both reflect on what they know about the given content and how that content relates to other mathematics content. Possessing limited content knowledge can significantly impact the effectiveness of curricular reform efforts (Olson & Barrett, 2004). The result of this reflection and collaboration should help determine a shared vision of how the mathematics classroom should look (Becker, 2001).

Perspective

Unlike some other programs, MCP does not focus on solely mathematical content knowledge or procedural knowledge, rather they seek to promote rich connections between both types of knowledge (Baroody, Feil, & Johnson, 2007) while assisting teachers better their own pedagogical content knowledge. As such, MCP does not focus on any one specific mathematical content standard set forth by ODE. They feel that addressing all mathematical content, and the inherent mathematical processes involved, are the only way to build true mathematical understanding. Using Baroody, Feil, and Johnson’s (2007) reconceptualization of mathematical content and procedural knowledge as my basis, I sought evidence of improvement in mathematical understanding from students in MCP coached classrooms. Assuming that MCP’s methods work, achievement scores in each of the mathematical content standards should show improvement, rather than in one or two.

Methodology

Participants

This project is a study of 110 fourth grade students chosen from eleven schools that participated in the Mathematics Coaching Program in the 2006-2007 Academic Year. Ten students were selected at random from each school. These schools are all from a major urban school district in the Midwest and were in their second year of participation in the program. The students are of different racial backgrounds and different socioeconomic standing. Of these 110 students, 13 were excluded from future analysis due to lack of reported pre-test data. One school lacked pre-test data, and, thus, had its ten students excluded. Either the test was not administered to these students and/or their scores were not reported. After exclusions, I had a sample of 97 fourth grade students from 10 schools: 47 male, 50 female; 31 Caucasian, 66 minorities; 81 receiving free- or reduced-lunches, 16 had no reduction in cost. Given the small number of students with no reduction in lunch cost, that factor was not used in analysis.

Data Sources

The student data included a pretest and a posttest. The pretest, administered to the students in Fall 2006, and is comprised of released items from the 2005 Fourth Grade Ohio Achievement

Test (OAT). Each pretest item was graded collaboratively by the mathematics coach and the students’ teacher. The coach then entered the data into a spreadsheet that was submitted to MCP. The posttest is the official OAT administered in spring 2007, as graded by ODE. The students’ scores are provided to MCP in fulfillment of program requirements.

Each score on both the pretest and posttest is broken down by mathematical content standard. Students received a raw score for each of these standards. ODE used these scores below, at, or above standard. Using ODE guidelines, I did the same with the pretest results.

**Instruments**

All items from both the pre- and post-tests are official items from the OAT. Table 1 presents the results of the reliability analysis of the raw scores from both pre-test data and post-test data, as broken down by standard, when run through SPSS:

<table>
<thead>
<tr>
<th>Test</th>
<th>Cronbach’s Alpha</th>
<th>Cronbach’s Alpha Based on Standardized Items</th>
<th>N of Items</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-test</td>
<td>.81</td>
<td>.82</td>
<td>5</td>
</tr>
<tr>
<td>Post-test</td>
<td>.85</td>
<td>.87</td>
<td>5</td>
</tr>
</tbody>
</table>

**Data Analysis**

Cronbach’s Alpha was used to determine the reliability of the instruments. Significance for trial refers to differences between the pre-test and post-test forms of the instruments. The repeated measures MANOVA and repeated measures Univariate Analysis of Variance were used for each dependant variable. ANOVA was used to determine whether there were any significant main or interaction effects for trial, gender, ethnicity, or school as they relate to mathematics content standards. The Pearson product moment correlation was used to determine the correlation between gender, ethnicity, school, pre-test and post-test raw scores, pre-test and post-test standard indicators. Only the 97 students who had both pre- and post-test data were used in the data analysis.

**Results**

The Multivariate Analysis revealed two significant 2-way interaction effects: within subjects by trial by school ($F_{(45, 271.5)} = 1.45, p = 0.039$), and within subjects by trial by ethnicity ($F_{(5, 60)} = 2.36, p = 0.051$). The Multivariate Analysis within subjects did not reveal any 3-way interaction effects or any 4-way interaction effects.

The ANOVA for standard raw score by trial revealed significant interaction effects for Number, Algebra, Data, and Geometry. The ANOVA for standard raw score by trial by school revealed a significant interaction effect for Data ($F_{(45, 271.5)} = 2.96, p = 0.005$). Additionally, the ANOVA for standard raw score by trial by ethnicity revealed a significant interaction effect for Number ($F_{(5, 60)} = 7.52, p = 0.008$). Only significant interactions were reported in the table.

Table 4 reports the means and standard errors for the Data Standard by trial by school. In the Data Standard, most schools showed modest gains. School 2 showed a slight drop from ($M = 4.63, SE = .80$) to ($M = 4.60, SE = .75$). Two schools however showed noticeable gains: School 3 rose from ($M = 3.85, SE = .89$) to ($M = 7.78, SE = .83$) and School 5 rose from ($M = 1.87, SE = .89$) to ($M = 5.55, SE = .83$).

Table 5 reports the means and standard errors for Number by trial by ethnicity. For Number both ethnic groups showed noticeable gains. Caucasian students rose from ($M = 3.55$, $SE = .36$) to ($M = 10.37$, $SE = .64$) and minority students rose from ($M = 3.18$, $SE = .25$) to ($M = 7.77$, $SE = .45$).

</table>
Figure 1. Number of students below, at, or above standard by content standard (pre-test)

Figure 2. Number of students below, at, or above standard by content standard (post-test)

Figure 1 illustrates the number of “below”, “at”, and “above” standard students by mathematics content standard on the pre-test. As seen in Figure 1, the number of students deemed “below standard” on Number is disturbingly large. Figure 2 illustrates the number of “below”, “at”, and “above” standard students by mathematics content standard on the post-test.

The numbers of “below standard” students dropped in each of the five content standard areas. The number of “above standard” students also increased in each of the five content standard areas. The only content standard area in which there were more “below standard” students than “above standard” students was in Number.

Table 6 shows the Pearson Product Moment Correlations. There were significant positive correlations at the .001 and .01 levels between the pre-test raw scores from Measurement,
Number, Data, and Geometry and the post-test raw scores from all five content area standards. The pre-test raw scores from Algebra had fewer significant correlations to post-test raw scores. These scores were only significant at the 0.05 level with the post-test raw scores for Number \( r = .23, p = .023 \) and with post-test raw scores for Data \( r = .22, p = .035 \). Neither school nor gender showed any significant correlations to any other variables, so they were left off the table.

Note. * p < .05. ** p < .01. *** p < .001

---

Ethnicity showed significant negative correlations to four other variables. There was a significant negative correlation ($r = -.27, p = .007$) between ethnicity and Measurement, ($r = -.37, p = .000$) between ethnicity and Number, ($r = -.23, p = .022$) between ethnicity and Data, and ($r = -.31, p = .002$) between ethnicity and the Geometry. Caucasian students achieved higher in each of these four content area standards than their minority counterparts. There was no significant correlation between ethnicity and Algebra.

Conclusions

My goal for this project was to determine MCP’s impact on each of the five mathematical content areas. We appear to have made great strides from pre-test to post-test in all areas with students in low-performing urban schools as evidenced by the dramatic decrease in the number of ‘below standard’ students and corresponding increase in the number of ‘above standard’ students in each standard. These gains are a testament to the commitment of our staff and coaches, as well as the teachers and administrators who participate in the program. Without support and resources from both MCP and each institution, we would not have made such gains.

Every program must recognize its weaknesses if it wants to continue to improve and grow. With MCP, it seems that our weakest content area is Number. Admittedly, this is probably the most challenging standard to address directly, but it is also probably the most important standard to address. Given the interconnectedness of procedural and conceptual knowledge, it is of paramount importance to instill a better sense of number in our students in order to give them the opportunity to excel in all areas of mathematics. Without a fundamental understanding of number and operations, their success in other areas will be limited by this factor. Additionally, there was a negative correlation between ethnicity and several of the content areas. While that indicates in this instance that Caucasian students did better in these areas than their minority counterparts, this does not necessarily translate to the general population. In the random sample, minority students outnumbered their Caucasian counterparts more than two-to-one.

In future examinations, alternate methods of sampling will be considered, either based on population or trying to balance the groups in equal numbers. Certainly, there were a number of limitations involved in this analysis, several of which have been corrected for future use. The first limitation was with the data collection tool itself, and that has been rectified. Secondly, inter-grader reliability may have been an issue for the pre-test scores. MCP uses the pre-test grading predominantly as an exercise for the teacher and coach to discuss student thinking. Additional limitations arose from my method of sampling students. The random number generator used to select the samples did so without regard to the completeness of their data, balance of ethnic or gender groups, and balance of their prior achievement. Also, this data presents only one year’s worth of data, while each school can participate in MCP for up to three years.

There is also a question regarding the ability to generalize the findings to other settings. In future studies, with better controls, I think this problem could be alleviated. As generalization to other settings was not my initial aim, I didn’t include these factors in my design.

Implications

The results of research bodes well for MCP and its associated classrooms. We now know that the student-level data that we collect can be analyzed to our benefit and the future benefit of...
our coaches, teachers, and students. Findings suggest fruitful venues for future research, including:

- Analysis structured to balance groups (gender, ethnicity, achievement) according to population breakdown to look for specific correlations.
- Individual items analyzed on the pre-test to determine specific content areas of concern.
- A longitudinal study of student growth throughout a school’s involvement in the program to examine number sense and abstraction results.
- An examination of whether or not MCP’s instructional philosophy has an impact in other academic content areas.
- A comparative study of MCP and other similar mathematics projects.

Currently, the innovative practice of content-focused coaching in mathematics is being implemented by districts with very little understanding of its effectiveness. Theoretically it seems plausible that allowing teachers to have access to expertise in the form of mathematics coaching can assist teachers in developing ambitious mathematics instructional practices. This study aims to analyze mathematics coaching through the use of social network analysis in order both to uncover important aspects of the institutional setting and to clarify how those aspects relate to teachers’ utilization of coaching.

Introduction

Over the past two decades, ambitious mathematics reform goals and standards for student learning, grounded in research on student learning in specific mathematical domains, have been proposed (e.g., see National Council of Teachers of Mathematics 1989, 1991, 1995, 2000). Meeting these goals and standards requires considerable learning on the part of practicing teachers, many of whom learned to teach under a different paradigm (Stein, Smith, & Silver, 1999). The necessary learning is transformative, requiring fundamental changes in deeply held beliefs, knowledge, and routines of practice (Thompson & Zeuli, 1999).

While it is challenging to support a small group of teachers in improving their classroom practice, it is even more demanding to provide learning opportunities for large numbers of teachers (Coburn, 2003; Gamoran, 2003; Elmore, 2004). One proposal for facilitating teacher learning at scale is to provide them with access to a more knowledgeable other in the form of a mathematics coach (Penuel, Riel, Krause & Frank, 2009). Many districts are implementing coaching designs as part of their instructional improvement efforts. In fact, a recent report on teacher development in the United States indicates that the adoption of school-based coaching programs is increasing rapidly, with about 46% of the teachers polled reporting that they participated in some form coaching at their school (Darling-Hammond, Wei, Andree, Richardson & Orphanos, 2009). Coaching as an instructional improvement strategy is currently being used by districts with very little understanding of its effectiveness.

One way to analyze the efficacy of mathematics coaching is through the use of social network analysis. Penuel and colleagues (2009) argue that social network analysis of teachers in a school offers a method for understanding how teachers’ interactions relate to instructional change. In particular, investigating the extent to which the coach is central within networks is a first step toward uncovering important institutional structures that support teachers’ access to instructional expertise. A number of studies document that teachers’ instructional practices are shaped to a considerable degree by the materials and resources that they use in their classroom.
practice, the instructional constraints that they attempt to satisfy, and the formal and informal sources of assistance on which they draw (Cobb, McClain, Lamberg & Dean, 2003; Coburn, 2005; Stein & Spillane, 2005). Cobb and Smith (2008) indicate that the findings of these studies call into question an implicit assumption that underpins many reform efforts, “that teachers are autonomous agents in their classrooms who are unaffected by what takes place outside the classroom door” (p. 4). If empirical work has shown that teachers’ practices are shaped by the settings in which they work (Cobb & Smith, 2008), then it is reasonable to assume that coaches’ practices, too, are shaped by the settings in which they work. By combining information about the coaches’ positions within teachers’ social networks with interview data, we can uncover important institutional structures and resources that influence the extent to which teachers’ have access to expertise.

**Methodology**

This study is part of a larger, four-year longitudinal study in which we are collaborating with four, large urban districts that are attempting to support all middle-school mathematics teachers’ development of ambitious instructional practices. One of these districts (District B), on which we focus in this study, has implemented mathematics coaching as a key strategy to support middle-school mathematics teachers’ learning. District B designed its mathematics coaching program to support the implementation of an inquiry-oriented, NSF-funded, middle-school mathematics curriculum. As part of the design, principals in all middle schools in the district selected a mathematics teacher leader who would teach mathematics for half of the day and spend the other part of the school day working to provide learning opportunities for teachers. The selected mathematics coaches then received extensive professional development on the curriculum and how to work with teachers in their schools. District leaders intended that coaches would: 1) provide one-on-one instructional support to their colleagues in the classroom, 2) act as a resource for the principal on matters of the mathematics content, and 3) deliver professional development to middle-school mathematics teachers on district-wide PD days. The district intended the coaches to be a central mechanism in assisting teachers when they had questions about teaching mathematics.

This study draws upon online survey and interview data collected during the second year of implementing the coaching program. Our purpose in analyzing these data was to explain variation in how the coaching design was enacted in the seven schools participating in the study. The schools were selected to represent the range of all middle-schools schools in District B in terms of their capacities for instructional improvements. In October, we interviewed 15 district leaders to determine the current district design for mathematics coaching. In particular, we asked about the hiring of coaches, the envisioned role of coaches, the types of activities in which coach were expected to engage with teachers and principals, the professional development plan for coaches, as well as other supports provided for coaches. Between January and March, we collected data on how the design was being realized in the seven middle schools. In each school, we interviewed and surveyed the principal, the mathematics coach, and 3 to 5 randomly chosen mathematics teachers for total of 32 mathematics teachers in the district. In addition, all the participating teachers completed an online network survey. In interviews and in the surveys, we asked about participants’ perceptions of the role of the coach and about their interactions with the coach. Similarly, we asked the coaches about their interactions with teachers and principals, as well as how their work is supported.

The online network survey asked teachers to whom they have turned for advice or information about teaching mathematics. In addition, we asked about the frequency, influence, and the types of advice or information they sought from the people they identified. We then examined the teachers’ social networks in an attempt to characterize the centrality of the coach within each of the seven schools. We used UCINET social analysis software (Borgatti, Everett, & Freeman, 2002) to create sociograms in order to understand the extent the teachers turned to the coach for advice in each of the seven schools. Because our focus is on the influence of individuals within the teacher networks, we defined centrality of an individual as the in-degree centrality, or the ratio of the number of ties directed toward that individual to the total ties that could be directed toward that individual (Hanneman & Riddle, 2005).

Using in-degree centrality, we calculated coach centrality in each of the seven schools. Table 1 contains information about the numbers of teachers within the schools, the number of survey respondents, and the calculated measure of coach centrality. We used this information to assign schools into three categories of coach centrality: central, somewhat central, and not central.

We coded all of the interview transcripts for the 32 teachers and their coaches and instructional leaders across the 7 schools. We created a coding scheme with categories that were developed from a review of the literature on coaching and supporting teacher learning, and from an initial reading of the interview transcripts (e.g., based on the questions that were asked and the participants’ responses). The coding scheme was designed to characterize the following aspects of coaches’ work in the schools: 1) activities in which the coach engages with teachers individually and in groups either in or outside the classroom, 2) additional responsibilities assigned to the coach beyond assisting teachers, 3) activities in which the coach engages with the principal, 4) evidence that teachers view the coach as a legitimate source of instructional expertise, 5) consistency of communication related to mathematics instruction or instructional improvement, and 6) the support the coach receives from the district and within the school to improve his or her practices. The first author coded teachers, coaches, and other instructional leaders (e.g., principals, assistant principals) interviews in order to take into consideration different people’s accounts of the role of the coach. After coding all of the participants’ interviews and considering coach centrality within teacher networks, we looked for patterns in the variation across the seven schools.

**Case Selection**

We conducted a cross-case comparative analysis because we wanted to uncover contextual conditions of the school (Yin, 2003) that support or impede a coach’s efforts to support teachers’

development of increasingly effective instructional practices. By comparing teachers’ networks and aspects of the school setting, we uncovered some of the factors that appear to influence the extent to which mathematics teachers turn to the coach for advice or information about mathematics, and the extent to which the coach is able to support those teachers. The coach was unable to do the coaching work in two schools (one had health problems and the second was assigned to teach full time) and we did not have sufficient data from a third school (less than 50% of the mathematics teachers in the school competed to the online network survey). We therefore focused on four schools in order to examine centrality of the coach within teachers’ social networks (2 central: School 5, School 6; 1 somewhat central: School 7; 1 not central: School 2).

**Results**

Despite the variation in coach centrality, we found similarities across the four focal schools: most of the teachers indicated that the coach had visited their classrooms and that they met weekly as a math department with the coach in attendance. Differences included: the reasons why coaches visited classrooms, whether or not the coach and teacher engaged in a follow-up conversation after the classroom visit, how often the mathematics department met, the purpose of the meetings, and whether the coach led the meetings. In addition, we found differences in structural aspects of the school (e.g., the size of the school) and the principals’ views of their role in supporting coaches and teachers.

First, we report the structural aspects of the school that seem to support a coach in being central in the teacher network at that school. By structural, we mean aspects that are related to organizational characteristics of and organizational arrangements in the school (e.g., the size of the school, the physical proximity of mathematics teachers’ classrooms, whether the department head is also the coach), and to characteristics of school personnel (e.g., the years of experience of the teachers, the grade level the coach teaches). We found that it is easier for the coach to be central in smaller schools primarily due to the fact that there are fewer teachers who might need their support. Although the mathematics teachers in all four schools met weekly as a department, the focus of the meetings and who led them differed. In the schools in which the coach was more central, the coaches led the meetings and were therefore able to set the agenda. In these same schools, the meetings frequently focused on issues of instruction (e.g., lesson planning, looking at student work) rather than on administrative issues (e.g., planning for Saturday school). We also found that the grade level the coach taught seemed to have implications for which teachers turned to her for advice. Recall that the coaches in District B also taught students for half of the school day. In all four schools, same grade-level colleagues identified the coach as someone they go to for advice. A significant proportion of teachers who taught at other grade levels said that they go to another same grade-level colleague before turning to the coach. Finally, physical proximity was also a factor – some teachers indicated they went to the coach because her classroom was nearby. These different structural aspects of the school influenced how frequently teachers interacted with the coach and thus the extent to which the coach was central within the teacher networks.

The centrality of the coach was also affected by the relationship between the coach and principal, how the principal envisioned the coach’s role, and how the principal supported the coach’s work. The principals have been given responsibility for hiring the coach, and all four principals indicated confidence in their selection, citing the coach’s capabilities as a mathematics teacher and, in some cases, also describing their abilities as a coach (e.g., the coach is a good listener). However, the principal’s vision for the coach’s role and the ways in which they

---

interacted with the coach differed. The principals all describe the role of the coach as that of supporting teachers; however, the principals in the two schools where the coach is more central were able to articulate how the coach was expected to assist teachers in more detail. In addition, principals in schools in which the coach was more central tended to assist their coach by: 1) procuring resources that the coach needed to support the teachers, 2) assisting the coach in identifying teachers to work with, 3) meeting with coaches on a regular basis, 4) assisting the coach with issues that arise as a result of being a teacher leader, 5) negotiating a vision of how instructional improvement in mathematics will occur in their school, and 6) sharing responsibility for enacting that vision. Furthermore, in the schools with more central coaches, the principals attended the mathematics department meetings regularly, pressed for an instructional focus in these meetings, and spent time in teachers’ classrooms observing instruction and providing feedback. These principals were therefore in a better position to have conversations with their coach about teachers’ instructional practices and could assist the coach in making decisions about teachers on which to focus and in what ways.

Teacher social networks are emergent phenomena that are continually regenerated in the course of ongoing interactions (Penuel et al., 2009). In other words, the emergence of teacher networks is influenced but not determined by organizational structure and social relationships, such as that between the coach and principal. We acknowledged the role of (institutionally situated) personal agency in our analysis by also examining the reasons why teachers might choose to turn to the coach. These reasons include the teacher’s perceptions of the coach as a mathematics teacher, the teacher’s perceptions of the coach as someone who can assist them in improving their instruction, and the prior history and level of trust between the coach and teacher. Teachers were more likely to interact with the coach when they felt the coach had a certain amount of expertise to offer the teacher, when they felt comfortable talking to her or identified her as someone who was a good listener, and when they had a history of working with the coach.

Discussion

The reasons why the teachers in our study did or did not seek advice from the coach have implications for some of the criteria that school or district leaders might use when selecting or hiring coaches. We found that certain structural aspects of the school, such as the size of school and who led mathematics department meetings, influenced coach centrality. In the schools in which coaches were central, the principal that structured time for coaches to meet with teachers and pressed them to work in meaningful ways on instructional issues. When teachers worked with the coach on instructional issues in department meetings, they were more likely to go to the coach outside the meetings, presumably because they had a history of doing that type of work together. These findings have implications for school leadership. By arranging the school day to allow for teachers to meet with one another to work on issues of instruction and encouraging the coach to set the agenda on key instructional issues and lead the meetings, school leaders can better support the role of the coach. This finding also has implications for how the district might support the coach. The district needs to not only continue to provide professional development specific to mathematics for coaches, but should also support them with in learning how to facilitate teacher meetings, and in coming to understand what types of activities might best support teachers’ development of ambitious instructional practices.

Our findings have implications for districts when they create and implement designs for coaching. It is important for district leaders to negotiate the intended role of the coach with principals. Principals and district leaders need to discuss the coach’s primary responsibilities and

---

whether or not any secondary responsibilities might be added. We found that in those schools in which coaches were central, the principals were able to describe the coach’s role and how they should work with teachers in some detail. These principals saw the role of the coach as assisting all teachers in improving their instructional practices over time whereas principals in the schools in which the coach was not as central saw the role of the coach as working with weak teachers. In all of the schools in our study, the coaches might have been more central in teacher networks if the principals had not assigned additional responsibilities that took the coach away from working directly with teachers. In each of the schools, coaches described extra duties (e.g., serving as department head or coordinating tutoring programs) that they carried out during the time that they were supposed to be working directly with teachers in their classrooms. District leaders can hold principals accountable for ensuring that the coaches’ responsibilities do not grow beyond those intended by the design.

Our findings indicate that principals described their role in supporting coaches in different ways. In the schools with central coaches, the principal assisted the coach and collaborated with her to support instructional improvement. The principals and coaches in these schools shared responsibility for supporting teachers in implementing the adopted curriculum effectively. The principals in these schools attended mathematics department meetings and could monitor whether the agenda focused on instructional issues. In addition, these principals spent a considerable amount of time observing classroom instruction and could therefore discuss with the coach the types of assistance they believed teachers needed. In contrast, in schools where the coach was not central, discussions between the principals and coach were more likely to be about compliance issues (e.g., whether teachers were turning in lesson plans each week). Again, principals can be supported by being held accountable by district leaders for assisting coaches in assisting teachers to improve their instruction.

Another way that principals can support coaches is to assist them with achieving legitimacy in their school. Our findings indicate that teachers’ decisions to seek advice from the coach are influenced by the extent to which they perceive the coach to be a legitimate pedagogical authority. We found that trust is an important factor related to gaining legitimacy. If the principal expects the coach to take on an evaluative role, or uses information from the coach in an evaluative manner, then this undermines the teachers’ trust in the coach. Principals impact coach legitimacy significantly, and district leaders need to support principals in creating the appropriate conditions for the development of trust between teachers and the coach in their schools.

All of the schools in our study were, to some extent, under pressure to raise student achievement scores. To prevent this demand from influencing the implementation of the coaching design adversely, it becomes important for district leaders to assist principals in appreciating that the work of the coach is integral to the goal of improving the quality of instruction and thus student achievement. In the absence of this support, principals’ responses to accountability pressures might result in differences in the responsibilities assigned to the coach, what the teachers perceive themselves to be responsible for, and the issues that are the focus of mathematics department meetings. It is therefore important that district leaders develop relationships of trust with school leaders by holding them responsible primarily for improving the quality of instruction.

In the study reported in this paper, we investigated the implementation of a district’s design for coaching by examining how aspects of the institutional setting influenced the extent to which the coach was central in teacher networks. We identified several factors that district leaders

should consider when designing and implementing coaching programs. With regard to future research, it will be important to investigate whether interactions between teachers and the coach give rise to opportunities for teachers to improve their instructional practices. Future research should also seek to identify the specific types of activities (e.g., modeling, co-teaching) in which coaches might engage with teachers that involve significant learning opportunities for teachers. Finally, it will be important to investigate what the coach needs to know and be able to do in order to provide high quality support for teachers. Understanding what high quality coaching looks like will allow districts to be able to hire better candidates from the start and know what types of professional development and other support those coaches will need.

A CHILD’S VIEW: WHEN DOES HE/SHE START LINKING THE WORLD OF MATHEMATICS?

Barba Aldis Patton
University of Houston-Victoria
pattonb@uhv.edu

The study consisted of individual interviews with approximately 100 children ranging from PK (4 years old) through 6th grade (12 years old). Each child was presented with two slide presentations. The eleven photos on each presentation were the same and were of various snapshots that most children would see in their everyday life i.e. buildings, railroad tracks, object made with Lego, etc. The first presentation asked the child to just describe what they saw in the photo such as a traffic sign, trees, blue sky, etc. The second presentation asked questions such as “Do you see any math in the picture” or “Do you see any math in the carriage? This particular slide was a horse-drawn carriage which had a big hotel in the background.

The concept of patterns is introduced to children in PK, yet when presented a picture of a Lego object, only a sixth grader reported the photo illustrated patterns. When asked if there was any math used to create the object in the photo, one 3rd grade student answered, “No, you just use your imagination and have fun.” Most of the other students reported similar answers.

The focus of the current study was to try to determine if some of the math concepts are actually being taught at times which the child is not developmentally ready. With the study being limited to approximately 100 students, it is not possible to make generalizations to all children but it can be the vehicle to develop some further studies.

These children did not attend the same schools so it was very interesting to review the results of a number of the children. It became very apparent that they most likely had been studying a concept in their math class. Several thought there was measurement in every situation. Several others thought there was geometry in every photo. The slides will be shared in the presentation as well as the results of the interviews. Title: A Child’s View: When does he/she starting linking the world to math?

In the first show the child was asked to just explain what they saw with no mention of math. After the first slide was completed, the child was asked to view the slide show again. This time he/she was asked to explain it they saw any math in the photo? For example PK children are making patterns yet, in the pilot test only a 6th grade child made the connection in the photo. Although the study involved a small sample (approx 100) which cannot allow generalizing, information can create a curiosity which may lead to larger studies.

In this poster presentation we will report on the findings resulting from the analysis of teachers’ interviews with children during a professional development summer workshop. As part of the two-week summer workshop, teacher participants (grades K-9) interviewed children (identified as struggling students) who would be coming into their classrooms in the following school year. This activity required teachers to develop interview tasks for their student, interview the student, transcribe and analyze the interview, and plan for future instruction. The research questions investigated include: (a) To what depth do teachers analyze the mathematics of children when asked to find strengths in children’s mathematical understanding? (b) To what extent do teachers use the findings from their interviews to plan meaningful experiences for the child?

The theoretical framework used for planning this experience is based on the works of Schifter (2001) and Little (2004) in which teachers’ analysis of student work grounds teacher learning in professional development experiences, and Simon (1995) in which he emphasizes the need to understand students’ thinking in crafting their hypothetical learning trajectories.

It is clear from our preliminary analysis of the written reflections that it is difficult for teachers to engage in non-evaluative listening and that, upon reflection, teachers became aware of the challenges. One particular challenge was overcoming the urge to provide corrective instruction during the interview. As one teacher wrote, “Throughout this interview it was evident to me that the decisions I made as an interviewer and observer were critical to the information that I gained...It is pertinent that I think more critically about the unplanned questions I asked during the interview.” Additional findings will be featured on the poster.

LEADERS’ SENSE MAKING OF FRAMEWORKS FOR FACILITATING MATHEMATICAL WORK IN PROFESSIONAL DEVELOPMENT

Rebekah Elliott, Matthew Campbell, Kristin Lesseig, Cathy Carroll, Judy Mumme, Elham Kazemi, Megan Kelley-Petersen

Researching Mathematics Leader Learning (RMLL) is a five-year project investigating mathematics PD leaders’ understandings and practices associated with fostering mathematically rich learning environments for teachers in PD. RMLL researchers’ current focus is on connecting practices for orchestrating discussion (adapted from Stein et al, 2008) and fostering sociomathematical norms (adapted from Yackel & Cobb, 1996) to the development of teachers’ specialized mathematical knowledge for teaching (Ball et al., 2008) through skilled and strategic use of mathematics tasks in PD.

This poster provides data from research on leaders’ understandings of project frameworks as inventoried with a series of instruments. Profiles of leaders were constructed based on analyses of data from a cohort of leaders (n = 35) using responses to: (1) a Learning Mathematics for Teaching & Leading Survey (LMT), comprised of items selected by RMLL staff, (2) a pre and post seminar (quantitative and qualitative) questionnaire, and (3) a pre and post seminar scenario elaborating the project’s frameworks in the context of mathematics PD. The coordination of these three instruments provides a unique means to purposefully organize data and identify patterns in leader responses with an associated LMT score.

As a result of generating these profiles, researchers were able to better identify the impact of leaders’ sense making of these frameworks and how they drew on these resources in their work on mathematics tasks in leader seminars. Contrasts within leader profiles brought to light additional factors at play in leaders’ work as participants in seminars and in their experiences facilitating PD. For example, further examination of PD participation and facilitation was required for leaders who took hold of important aspects of PD, such as attention to sociomathematical norms and developing teachers’ MKT, yet had relatively low LMT scores. Given how little is known about the learning and work of mathematics PD leaders, these findings help further identify the resources drawn upon in the work of facilitation and how these ideas are taken up in leader development seminars designed to promote practices associated with productively engaging teachers in mathematical work.

THE “FARMER DAN” PROJECT: IMPLEMENTATION OF JAPANESE LESSON STUDY IN RURAL MATHEMATICS CLASSROOMS

Katie A. Hendrickson
Ohio University
Kh232602@ohio.edu

In 2006, a team of middle school mathematics teachers received a grant to implement Japanese Lesson Study within their classrooms. The middle school had recently increased the length of 7th and 8th grade mathematics classes from 44 minutes to 88 minutes each day in order to improve mathematics achievement test scores. To effectively utilize the additional class time, teachers were interested in developing lessons that addressed problem solving and metacognition, as well as increasing relevance to students. In rural areas, science, technology, engineering, and mathematics (STEM) jobs are not as prevalent as they may be in urban areas, making it challenging for mathematics teachers to connect the content to students’ lives. The team identified a topic for the lesson, area and volume of geometric solids, that spanned grade levels and was an area of poor student performance. The teachers then developed a lesson that incorporated word problems, locating resources, and writing about mathematics, as well as a connection to local farming and hay production. Further, the lesson reversed this school’s traditional lesson cycle of lecture, practice, and re-teach; instead presenting a situation and investigation to encourage the students to search for the needed information as they progressed.

Following a modified version of Japanese Lesson Study to develop and improve the lesson, the teachers followed a cycle of teaching, modification of the lesson, and reteaching. While one teacher presented the lesson to the class, the other team members acted as non-participant observers. After the lesson, the team met to discuss lesson modifications based on observations and student input through consensograms and plus/delta charts. This cycle was followed through three implementations with different students. As a result of this project, teachers improved collaboration through professional development, and students benefited from different pedagogical techniques and assessments.
WHEN PROFESSIONAL DEVELOPMENT PRODUCES TEACHER CHANGE: A CASE STUDY OF MRS. G

Sharilyn Kay Owens
Appalachian State University
owenssk@appstate.edu

Professional development is often credited with promoting teacher change but evidence of success is sketchy at best. Classrooms exist, however, where goals for teacher change are realized and active student learning is the focus. Studying these environs may highlight strategies that could be replicated in teacher preparation and professional development. While collecting data for a connected classroom project, such a case came to light. The larger project sought to use Texas Instruments Navigator™, a wireless system, to open communication between students and teacher in mathematics classrooms, specifically Algebra I.

The four-year IES funded project aimed to promote student learning by enhancing classroom practices such as enriched classroom discourse, quality and levels of questioning, self-regulated learning and utilization of formative assessment. Recognizing that simply the presence of new software does not ensure teacher change, the project designers implemented many avenues for reflection and professional development. The professional development opportunities of the larger project include: making ideas relevant to participants, allowing time to change, offering ongoing support and encouraging participants to reflect on their learning. Formal professional development, led by practicing high school teachers who were also Teachers Teaching with Technology (T³) instructors, was offered at summer institutes. Professional development sessions were also provided at T³ international conferences. Additional support included a listserv, technical support and telephone interviews.

“Human motivation is a complex phenomenon, so it follows that mastery orientation is dependent on many…factors, not necessarily explainable by a single theory,” (Owens et al., 2005). The conclusions of this study are that if teachers are going to engage in life-long, they must be treated as professionals and given a voice in their own educational pursuits. In the words of Mrs. G, “Learning sets people on fire…but necessarily] the professional development must be relevant.”

VIDEO CLUB AS A TOOL TO INCREASE TEACHERS’ PROFESSIONAL VISION OF STATUS ISSUES

William Day
University of Washington
wld@uw.edu

This poster describes an effort to use a video club to foster teachers’ consciousness of status issues within interactions in secondary mathematics classrooms. A video club is a gathering of professionals for the purposes of viewing, analyzing, and discussing video of practice.

This poster follows closely the theoretical framework put forth by Sherin and van Es (2009) whose study focused on the impact of video club on teachers’ professional vision, a concept introduced by Goodwin (1994). Sherin and van Es instituted video clubs that aimed to foster teachers’ professional vision of interactions in which student thinking was visible.

In contrast, the video club of this project endeavored to use professional vision as a lens through which to address issues of equity within classroom interactions. In particular, we concerned ourselves with teachers’ consciousness of status, which is described by Cohen and Lotan (1997) as “an agreed-upon social ranking where people believe that it is better to be in the high than in the low state” (p. 64). Status mediates participation by creating a classroom environment where participation rights may be distributed inequitably among students. According to Cohen and Lotan (1997), unequal participation is of particular importance, because learning correlates with participation; that is, the more a student participates, the more he or she will learn.

The data for this poster was gathered from a video club that included 14 secondary mathematics teachers from three urban high schools in a large school district in the Pacific Northwest. Three data sources were analyzed: notes from video club conversations, teacher interviews conducted at the start and end of the school year, and video of teachers’ lessons at the start and end of the year.

The results of our analysis indicate that teachers exhibited an increasing consciousness of status issues in their video club contributions as the year progressed. When viewing a clip, teachers were more likely to comment on unequal participation patterns among students. Similarly, they were more likely to hypothesize about actions that a teacher might take in order to ameliorate such patterns.

The analysis points to several important findings. First, video clubs are a useful tool for improving teachers’ professional vision of status issues. Second, the study establishes the viability of several video club design elements including a large participant roster and a multiplicity of participating schools.

Although skilled mathematics educators often “know” when interruptions in the flow of the lesson provide an opportunity to modify instruction to improve students’ mathematical understanding, others often fail to recognize or act on such moments. These moments, however, are key to instruction that builds on student thinking about mathematics. Video of beginning secondary mathematics teachers’ instruction was analyzed to identify and characterize “pivotal teaching moments” in mathematics lessons and to examine how such moments play out during the lessons. Recognizing pivotal teaching moments and effective responses to them is an important first step for learning to capitalize on such moments.

Introduction

Accumulating evidence suggests that it is possible to identify instructional practices that lead to student achievement gains in mathematics. The list of such practices includes engaging students in using and discussing rich tasks, building on students’ current thinking, and helping students connect mathematical ideas (e.g., Fennema et al., 1996; Stein, Smith, Henningsen, & Silver, 2000). This identification has prompted the study of how to best support teachers in implementing these ideas in their classroom.

One idea that has emerged from this work is the consideration of how teachers can be supported in learning to focus their attention on the features of classroom practice that are most important to student learning—student ideas, evidence of student understanding, and the relation between student thinking and pedagogical decisions (e.g., Santagata, Zannoni & Stigler, 2007; van Es & Sherin, 2008). Ball and Cohen (1999), for example, discuss the notion of teachers learning in and from practice that involves teachers “siz[ing] up a situation from moment to moment” (p. 11) and using what they learn to improve their practice. Van Es and Sherin (2008) use the term noticing to describe teachers’ attending to important elements of instruction that support student learning and then reasoning about them in order to make instructional decisions. Although the specific language researchers use to describe the practice of keying in on important moments during instruction varies, the idea is the same—teachers need to pay attention to students’ ideas and consider how to use these ideas to advance student learning.

Although skilled teachers and teacher educators often intuitively “know” when important mathematical moments occur during a lesson and can readily produce ideas about how to capitalize on such moments, these moments frequently either go unnoticed or are not acted upon by others in the profession, particularly novices (Peterson & Leatham, 2010). This raises the question of how teacher educators can help novice teachers recognize important moments during their instruction and use them to support student learning. Characterizing the circumstances likely to lead to such moments is an important first step in making them visible.

In this study, we define a pivotal teaching moment (PTM) to be an instance in a classroom lesson in which an interruption in the flow of the lesson provides the teacher an opportunity to modify instruction in order to extend, or change the nature of, students’ mathematical understanding. This is related to Remillard and Geist’s (2002) idea of openings in the curriculum in the context of teacher professional development, which they characterize as moments in which teachers’ questions, observations, or challenges require the facilitator to make a decision about how to incorporate into the discussion the mathematical or pedagogical issues that are raised. The nature of the facilitator’s decision determines the extent to which the teachers’ ideas advance the learning of the group. Similarly, when a PTM occurs in a classroom lesson, a teacher first needs to recognize it as such, and then make a decision about how to handle the interruption. Depending on the action taken by the teacher, the PTM may or may not support the development of students’ mathematical understanding. Because teachers may or may not act on a PTM, determining whether an event is such a moment is independent of the teacher’s actual decision in response to the interruption. Consequently, an event can be characterized as a PTM even if the teacher does not notice it. The distinction here is that we are not trying to capture whether the teacher did modify instruction to support student understanding, but, instead, whether the events provided an opportunity for the teacher to do so.

To better understand the nature of these PTMs and how teachers might act on them in ways that support student learning, this study uses videos of beginning teachers’ classrooms to investigate the following questions:

1. What are characteristics of pivotal teaching moments faced by beginning secondary school mathematics teachers during classroom instruction?
2. What types of decisions do beginning mathematics teachers make when a pivotal teaching moment occurs during their instruction, and what is the relationship between these decisions and student learning outcomes?

Perspectives

The idea that there are important moments or events within a mathematics lesson that a teacher needs to notice and act upon is grounded in a particular vision of teaching. Consistent with reform recommendations for mathematics education (e.g., National Council of Teachers of Mathematics, 2000), this vision is one in which teachers build on student thinking during instruction; this is accomplished through the teacher continually reflecting on the mathematical ideas that underlie students’ comments or solutions and then using these comments or solutions in ways that help the class as a whole construct meaningful understandings of the mathematical ideas. Inherent in this vision of teaching is a need for teachers to reflect-in-action (Schön, 1983) in order to adapt instruction as it unfolds in response to students’ current understandings (Ball & Cohen, 1999). In order to do so, teachers need to both notice important mathematical moments when they arise and have the mathematical knowledge and dispositions necessary to act on them in ways that support student learning.

In their Learning to Notice Framework, van Es & Sherin (2002) highlight three main components of teacher noticing in the context of analyzing artifacts of classroom practice: (a) identifying important aspects of the situation, (b) reasoning about these aspects, and (c) connecting what is observed to more general ideas about teaching. Although related, we view the type of noticing that teachers engage in post-instruction as quite different than that in which they must engage during instruction. During instruction, teachers have the benefit of neither time to systematically analyze student thinking and consider alternate interpretations of it, nor colleagues...
to help draw attention to important moments in instruction. Instead, teachers need to quickly draw on their own mathematical knowledge to recognize moments that may be mathematically important and then make decisions about how these moments could be capitalized on either to help address the goals of the lesson or to make connections to larger ideas in mathematics. Given the cognitive demand of this work and novice teachers’ need to simultaneously pay attention to developing other more routine aspects of their practice (Berliner, 2001), it is not surprising that they are often unable to recognize these important mathematical moments and, if recognized, have difficulty making pedagogically sound decisions about them.

Although capitalizing on PTMs may be difficult for a novice teacher to accomplish, an important first step is recognizing that such moments exist. Without this awareness, teachers may experience \textit{inattentional blindness} (Simons, 2000)—a phenomenon described in the psychology literature as a failure to focus attention on unexpected events. In the context of teaching, a teacher’s failure to recognize that a student’s ill-formed idea may be mathematically significant may be a result of a failure to recognize that this could be the case. This is also related to the idea of \textit{framing} (Levin, Hammer & Coffey, 2009)—the way in which a teacher makes sense of a classroom situation. From this perspective, whether teachers notice the value in student thinking depends on how they frame what is taking place during instruction. If, for example, a teacher views a student error as something that needs to be corrected, he or she is unlikely to consider the mathematical thinking behind the error or whether the error could be used to highlight a specific mathematical idea. On the other hand, a teacher who views an error as a site for learning is more likely to consider both the mathematics underlying the error and how it could be used to develop mathematical understanding.

\textbf{Modes of Inquiry}

As part of a larger research project examining teacher learning using practice-based teacher education materials, over 45 hours of video of classroom instruction were collected from six beginning teachers. All of the teachers were graduates of an NCTM (2000) Standards-based secondary mathematics teacher education program that focused on teaching mathematics for student understanding. At the time of the data collection, they were teaching in grades 8-12 in a variety of school settings. The data included recordings of two classes per day for three consecutive days of instruction. We focused on beginning teachers because we hypothesized that the decision-making process involved with PTMs may be more obvious with this group than with skilled teachers. That is, skilled teachers may recognize a PTM and make the decision to act so quickly and smoothly that the interruption wouldn’t be easily observable by someone who wasn’t intricately familiar with the teacher’s plan for the lesson. Furthermore, it is rare that a written lesson plan would have enough detail to note any but the most obvious changes in direction. Beginning teachers, on the other hand, were predicted to have a slower response time—slow enough that, although the thinking process itself wouldn’t be visible, the fact that they were making a decision would be. This hypothesis was supported during our classroom observations. The analysis of the data reported here involved three phases: (a) reducing the video data to potential sites for PTMs, (b) identifying PTMs, and (c) characterizing PTMs.

Two graduate students who were experienced secondary school mathematics teachers completed the initial reduction of the video database. On their first pass through the video, they eliminated from the database any non-instructional activities, such as listening to school-wide announcements and completing individual assessments. On the second pass, they narrowed the video of instructional time down to episodes that had the potential to include PTMs. They

individually identified any episodes that they felt had potential and then conferred to verify that the episodes warranted further exploration by the full research team. At the end of the reduction process, 65 episodes totaling 3 hours and 57 minutes remained in the database. The process of identifying PTMs involved a research team of the authors and, during much of the process, a fourth researcher. All were experienced observers of mathematics teaching. The episodes were first watched by the team to determine whether they agreed that a PTM had occurred during the episode. If it was agreed that one had occurred, the episode was transcribed for further analysis. At the end of this stage of the process, 28 episodes totaling 2 hours and 38 minutes remained in the database. Next, the four researchers individually watched these episodes and marked on the transcript the locations of the PTM, the teacher decision made in response to the PTM, and evidence of the outcome. At weekly research meetings, these individual notations were compared and discussed until agreement was reached.

As a result of this work, the research team was able to identify a preliminary coding scheme that was used to characterize the PTMs, the potential they had for advancing students’ mathematical understanding, the teacher decision, the way in which the decision was implemented, and the likely impact on student learning. The researchers first coded the videos individually using the video analysis program Studiocode (SportsTec, 1997-2010) and then merged their video coding timelines for comparison. Again, differences were discussed until agreement was reached and the coding definitions were modified to reflect the refined use of the codes. Figure 1 gives the final labels used in the coding.

Examples of Episodes Containing Pivotal Moments

Episode 1
A class of Algebra 2 students have worked in small groups on a task that describes how a soccer ball is kicked and asks them to “sketch the path of the soccer ball and to find an equation for the parabola that models it.” Verbally, the teacher had prompted them to first construct a graph, including axes, and then use the graph to find the equation. The teacher asks a student to draw her graph on the board. Although hesitant because she’s not sure her graph is correct, the student draws her graph, which does correctly model the situation (although the teacher does not say this). The teacher then asks if anyone drew a different graph. A second student says that she

did, and is invited to draw it on the board. This student draws a picture of the situation, complete with a soccer player and a ball flying through the air, but without axes or coordinates. A third student questions the graph, and subsequently imposes axes on the second student’s “graph.” The second student objects, claiming that all the extra lines make it confusing. After one more (correct but different) graph is drawn on the board, the second student again expresses confusion about the situation because there are three different depictions displayed on the board. The teacher responds by saying, “Then [student name], you don’t have to do it this way. You can do it that way,” implying that all three representations are equally valid. Another student says, “So you pretty much are saying we could do it whatever way in the world,” to which the teacher responds, “You can do it a ton of different ways and still get the right answer.”

**Episode 2**

As an Algebra 1 teacher is at the board discussing how to write an equation in the form \( y = mx + b \) for the graph of a linear function, a student asks how one would know what number to add or subtract, that is, how to find the “\( b \)” in \( y = mx + b \). The teacher explains that the number that is added or subtracted is always the value at which the graph crosses the \( y \)-axis. He uses a graph with a \( y \)-intercept at \((0, 1)\) as an example, saying, “See, this is a positive one [points to the graph], so this is a positive one [points to the equation].” He then refers to another graph that was previously drawn on the board to show a second example with a \( y \)-intercept of negative one. At this point, a student asks if there can be “two dots”—referring to two different \( y \)-intercepts. The teacher responds, “There won’t be two dots on the \( y \)-axis. That’s a good question, though, you’re thinking bigger,” and then continues with his prepared explanation.

**Episode 3**

In their Algebra 2 class, students have worked on simplifying the expression \((16x^2y^2)^{-1}(xy^2)^3\) as part of their homework. Following a brief small-group discussion time, a student is selected to present her solution to the class. After she writes her solution on the board, another student expresses confusion. In the ensuing discussion, the teacher asks, “Did you just start a different way?” to which the student responds, “Yes. Her second step was, like confusing, but that’s cool.” The teacher asks whether she ended up with the same answer; the student confirms that she did. The teacher then invites her to explain what she did differently than the first student. After other students push her to do so, she writes her solution on the board and points out what she did differently. The teacher highlights the differences in the two solutions and confirms that the two solutions are both “fine.”

**Preliminary Framework for Looking at Pivotal Moments**

*When Pivotal Moments Occur*

Pivotal teaching moments seem most likely to occur when students are actively engaged in the mathematics lesson—regardless of the nature of the classroom instruction or the curriculum used. That is, they can occur in classrooms where students are doing mathematics themselves and sharing their thinking with their classmates (as in Episode 1), as well as in classrooms where students are listening to the teacher present information and asking questions about what they are hearing (as in Episode 2). Five different circumstances leading to PTMs that we noted in our data are elaborated on in the following paragraphs.

One circumstance that seems to guarantee a PTM is when students make a comment or question that goes beyond the mathematics that the teacher had planned to discuss. For example,
in Episode 2, the teacher was focused specifically on explaining how the “m” and “b” in the equation \( y = mx + b \) can be found from the graph of a linear function. By wondering if it were possible to have more than one \( y \)-intercept, the student opened up the possibility of extending the lesson to make a connection with the definition of a function.

Other PTMs occur when students are trying to make sense of the mathematics in the lesson. Verbalization of this sense-making often provides opportunities to clarify or highlight critical mathematical components of the lesson. For example, a student who is trying to conceptually understand what is being presented as a purely procedural explanation may raise a question about why a procedure works. The student’s push for meaning is an indicator to the teacher that the lesson isn’t making important connections and is a prompt to begin to do so. A variation of this also occurs in lessons in which sense-making is the focus. In the process of trying to make sense of the mathematics, students may over-generalize or misconstrue aspects of the mathematics that, when surfaced, can provide learning opportunities for the entire class.

PTMs often occur when incorrect mathematical thinking or an incorrect solution is made public. In some cases an error does not qualify as a PTM—as when it is based on an incorrect calculation or something else that isn’t likely to interfere with or provide opportunities to improve students’ mathematical understanding. In other instances, however, the error is likely to affect what students take away from the lesson. We see this in Episode 1 where the student’s incorrect representation of the situation provided an opportunity to clarify the difference between a mathematical representation of a situation and a picture of the situation—a common idea with which algebra students struggle (Wagner & Parker, 1993). Not addressing the incorrect representation created the very real possibility of students leaving the lesson thinking that a picture is a valid mathematical representation, thus reinforcing this common misconception.

The occurrence of a mathematical contradiction also seems to generate a PTM. This can be as straightforward as two different answers to a problem that clearly should have only one answer, or as complex as two competing interpretations of a mathematical situation. Regardless, the contradiction creates an opportunity for the teacher to bring to the students’ attention the nature of mathematics that makes such contradictions unacceptable, as well as critical aspects of the mathematics at hand that can help them determine which of the options holds up under scrutiny. The very process of this scrutiny—the justification needed to support the different options and the making of a decision—can create a powerful learning opportunity.

Finally, a student’s expression of mathematical confusion can also lead to a PTM. It is important to distinguish general confusion—when a student expresses that they don’t know what is going on or they cannot follow what someone has just explained—from mathematical confusion. Confusion seems to lead to a PTM when a student can articulate mathematically what they are confused about. In Episode 3, for example, the second student was able to point to the second step of the first student’s solution as being her point of confusion. This gave a mathematical focus to the confusion—the properties of exponents that were used in that step—and created an opportunity for the teacher to refocus the students on the meaning behind the procedures they were applying to the problem.

Potential of Pivotal Moments

We drew on aspects of Stein and colleagues’ (2000) work on cognitive demand of tasks to think about the potential of PTMs to have a positive impact on students’ understanding of mathematics. Some PTMs, such as the one in Episode 1, seem to have an inherent high level of cognitive demand attached to them. Others, such as that in Episode 3, seem to involve a lower
level of cognitive demand. Initially, we hypothesized three levels of potential for PTMs—high, medium, and low—but as we analyzed the data further, the episodes that led us to generate the low category no longer met our evolving definition of a PTM. That is, if the potential for learning was low, it was not a PTM. High potential PTMs involved rich mathematics and, frequently, connections among mathematical ideas. Often they provided a gateway to discussing important mathematical ideas that were not part of the planned lesson, but were an important part of the mathematical terrain the students were traversing. Medium potential PTMs often related to attributes of mathematics, such as its usefulness or coherency, and provided the opportunity to better understand procedures, definitions, or concepts.

The decision a teacher makes about how to respond to a PTM—ranging from to ignore or dismiss it, to using it as an opportunity to extend or enhance the planned lesson—shapes whether the potential of the PTM is actualized. The resulting outcome of the PTMs ranges from significantly increasing student learning opportunities, to having a negative impact, as seen in Episode 1. In that episode, the teacher’s decision to pursue and support a student’s thinking came at the expense of the mathematics in the lesson. As a result, rather than achieving the high potential of the PTM, the teacher’s decision led to the PTM having a negative impact on student understanding. One of the things we are interested in exploring is whether certain PTMs—such as those arising from incorrect mathematics—are more likely to have a negative effect on student understanding and, thus, must be dealt with more proactively by a teacher.

As can be seen in Figure 2, we are currently conceptualizing these events in the classroom as triples that include the pivotal moment, the teacher decision, and the likely impact on student learning. We are particularly interested in using our data on beginning teachers to determine whether there seem to be types of PTMs that are more likely to lead to improved student learning opportunities. It may also be that there are types of PTMs that are not likely to do so; if this is the case, knowing so would allow teachers to more accurately and efficiently make decisions that would minimize unproductive use of class time.

Figure 2. Triple of a pivotal teaching moment, the corresponding teacher decision, and the opportunities they provide for student learning

Conclusion

The intent of this work is to provide a means to capitalize on pivotal teaching moments that occur during classroom instruction. Teachers are faced with a myriad of decisions on a moment-by-moment basis in their classrooms. We argue that PTMs, by their very nature, prompt teacher decisions that can have a high impact on the learning that goes on in a classroom. As such, they are worthy of analysis so that high-leverage PTMs and effective responses to them can be identified and shared with teachers. This is particularly useful in the case of novice teachers who have less experience and knowledge to draw on as they make their decisions. Being able to recognize a PTM and effective responses could improve beginning teachers’ ability to act in a way that would increase their students’ mathematical understanding.

While this work is an important first step, we recognize that strong mathematical knowledge for teaching is key to responding to PTMs in ways that enhance students’ mathematical understanding. For example, to productively respond to a PTM, a teacher needs to decipher the mathematics underlying a student’s response and consider how it fits with the goals of the lesson or broader goals of the course. Future work around conceptualizing the mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008) required to act on these moments in a way that supports student learning will provide important insights into the process of becoming the kind of mathematics teacher advocated by the NCTM (2000).

QUANT PROGRAM EVALUATION AND REVISION BASED ON AN ANALYSIS OF
TPACK GROWTH AMONG THE PARTICIPANTS

Blake Regan
Ohio University
regan@math.ohiou.edu,

Gregory D. Foley
Ohio University
foleyg@ohio.edu

Quantifying Uncertainty and Analyzing Numerical Trends (QUANT) is a yearlong professional
development program for high school mathematics teachers focused on statistics, probability, and
data analysis. QUANT is designed to develop teachers’ statistical proficiency for teaching using
technological pedagogical content knowledge (TPACK) as a framework. This paper describes the program, its goals, and results from an exploratory pre-post investigation and a participant survey, both designed to evaluate the program’s effectiveness and to revise the program itself. Results show that program participants gained content knowledge, pedagogical content knowledge, and increased their confidence and desire to incorporate technology into their instruction.

Introduction

As many U.S. states are moving toward requiring four years of mathematics for all high school students, in accordance with the National Teachers of Mathematics (NCTM) Math Takes Time position statement (2006), it is vital for teachers to be prepared to teach subjects that go beyond the concepts taught in algebra and geometry classes while engaging students in tasks that promote reasoning, communication, and connecting mathematics to the world outside the classroom. Thoughtful implementation of data collection, data analysis, and statistical activities is one of the best ways of providing students with such experiences. Teaching mathematics in a way that assists high school students to develop statistical reasoning, however, presents challenges distinct from teaching other forms of mathematical reasoning (Ben-Zvi & Garfield, 2004; Cobb & Moore, 1997; Groth, 2007). One of these challenges involves a subtle yet profound shift in focus with regard to context. Cobb and Moore note that mathematics often purposely ignores context to focus on the underlying structure of a problem situation. In statistics, however, context is what provides much of the meaning for a given problem. Despite this, Ben-Zvi and Garfield (2004) assert that students can struggle with the context involved in a statistical task. This is often due to the amount of complex mathematics involved as well as students’ focusing too much on the numbers and calculations without truly engaging with the task. In addition, the concept of variability plays a critical role in statistics, as does the ability to formulate a question in a way that attends to the context and anticipates variability (Franklin et al., 2007). A final challenge is that many practicing high school mathematics teachers have had little formal education in data analysis, probability, and statistics.

In recent years, leading professional organizations and national initiatives have begun to recognize the need for statistics education in Grades K–12 (American Diploma Project, 2004; Common Core State Standards Initiative, 2009; Franklin et al., 2007; NCTM, 2009b). Concerning the need for learning statistics and probability, NCTM (2009a) states,

In our increasingly data-intensive world, statistics is one of the most important areas of the mathematical sciences for helping students make sense of the information all around them, as well as for preparing them for further study in a variety of disciplines (e.g., the health

sciences, the social sciences, and environmental science) for which statistics is a fundamental tool for advancing knowledge. (p. 73)

The construct of *quantitative literacy*, or *numeracy*, varies from author to author. For Paulos (1988/1990), numeracy was the ability “to deal comfortably with the fundamental notions of number and chance” (p. 3), coupled with logical reasoning. Steen (1990) took a broader view of numeracy as grounded in pattern and including dimension, quantity, uncertainty, shape, and change. For us, *quantitative literacy* is a form of general literacy that includes: (a) numerical reasoning, (b) a working knowledge of measurements and indices, (c) statistical reasoning (a la Franklin et al., 2007), (d) all of Steen’s modeling components, (e) the ability to link contexts with appropriate mathematics (modeling), and (f) facility in the *mathematics register*, academic mathematical speaking and writing (Schleppegrell, 2007).

The needs of teachers in the areas of data analysis, probability, statistics, and quantitative literacy are a serious concern for those who care about mathematics education in the United States. These needs are precisely what are driving the ongoing research and development of the *Quantifying Uncertainty and Analyzing Numerical Trends* (QUANT) project.

**The QUANT Professional Development Program**

QUANT is designed to develop *statistical proficiency for teaching*. The RAND Mathematics Study Panel (2003) identified “developing teachers’ mathematical knowledge in ways directly useful for teaching” (p. 7) as a priority for their research and development program targeted at enhancing the mathematical proficiency of all students. Although the concepts, strategies, and reasoning processes differ between mathematics and statistics, a key premise of our theory of action is that the National Research Council’s (2001) components of mathematical proficiency—*conceptual understanding*, *procedural fluency*, *strategic competence*, *adaptive reasoning*, and *productive disposition*—are critical dimensions of statistical proficiency as well. Following Foley, Strayer, and Regan (2010), we define statistical proficiency for teaching as teachers’ knowledge and skills that are useful in promoting the statistical proficiency of their students.

The mechanism that QUANT uses to develop this statistical proficiency for teaching is technological pedagogical content knowledge (TPACK) (Neiss et al., 2008). QUANT addresses TPACK in the areas of (a) measurement and data collection, (b) data analysis and descriptive statistics, (c) combinatorics and probability, and (d) statistical inference. These content foci are combined with a pedagogical and classroom implementation focus on selecting, setting up, and enacting high cognitive level tasks (Boston & Smith, 2009; Stein, Smith, Henningsen, & Silver, 2009). The technology addressed and used in QUANT includes data collection, data transfer, memory management, lists, spreadsheets, and interactive statistical software.

QUANT is a yearlong professional development (PD) program for high school mathematics teachers. The goals of this PD include the following:

- To engage teachers in investigating cognitively demanding mathematical and statistical tasks as a way to learn mathematics and statistics.
- To help teachers learn how to set up and maintain cognitively demanding mathematical and statistical tasks in their classroom instruction.
- To develop teachers’ capacity in the areas of data collection, data analysis, probability, and statistics.
To develop teachers' comfort level and facility in using handheld data collection and data analysis technology, and connectivity and statistical software, as tools for instruction.

The QUANT program begins with an intensive 2-week summer institute that explores data collection, data analysis, probability, and statistics concepts and problems using technology. The program includes online support and daylong follow-up workshops during the ensuing school year. During the 2008–2009 implementation phase of QUANT, the mathematical tasks framework as a tool for teaching and learning mathematics was introduced to the QUANT participants during the third such follow-up workshop (Boston & Smith, 2009; Stein et al., 2009). Because Boston and Smith demonstrated that using the mathematical tasks framework significantly altered mathematics teachers’ decisions to select and implement high-level tasks, the QUANT team decided to incorporate the framework’s use in the program.

The activities incorporated in the PD stress the four components of statistical problem solving articulated in the *Guidelines for Assessment and Instruction in Statistics Education (GAISE) Report* framework (Franklin et al., 2007):

1. Formulate questions.
2. Collect data.
3. Analyze data.
4. Interpret results.

With these components in mind, the activities are focused on hands-on, inquiry-based, technology-enhanced, content-rich tasks in data analysis, probability, and statistics. The instructional sessions model a learning environment that uses technology to “support teachers’ efforts in fostering students’ understandings and intuitions by engaging them in conceptual conversations” (Knuth & Hartmann, 2005, p.162). These conceptual conversations are aimed at creating an environment that encourages reasoning and sense making in the mathematics classroom.

QUANT institute activities are aligned with NCTM’s (2009a) assertion that focusing on reasoning and sense making does not need to be an extra burden for teachers. In fact, a focus on reasoning and sense making provides context for students who struggle because they find mathematics unconnected to their life outside the classroom. The QUANT institute models NCTM’s belief that “with purposeful attention and planning, teachers can hold all students in every high school mathematics classroom accountable for personally engaging in reasoning and sense making” (p. 6).

**Context of the Research**

The QUANT project employs an iterative research and development design to address the research question: *How can professional development improve the statistical proficiency for teaching of high school mathematic teachers?* The PD materials and resources and their effectiveness are objects of research, as are teacher variables. The research reported herein is part of this overall research agenda. As with other exploratory evaluations of QUANT, the purpose of the studies reported here is to provide feedback to refine the materials and instructional methods. The QUANT team has hypothesized that improving teachers’ use of high

---

cognitive level tasks in data analysis, probability, and statistics will have a positive impact on the statistical proficiency and quantitative literacy of their students. There are many steps from the proposed intervention to the anticipated student outcomes. In keeping with Foley, et al. (2010), Figure 1 provides a framework for our theory of action.

Three exploratory QUANT programs have been offered to date. Each involved a summer institute:

- QUANT 1 at Ohio University in Athens in June 2008 involved 5 practicing teachers, 9 teacher candidates, and 4 teacher educators.
- QUANT 2 at the Ohio Resource Center in Columbus in August 2008 involved 10 practicing teachers and 5 teacher educators.
- QUANT 3 at the Ohio Resource Center in Columbus in June 2009 involved 8 practicing teachers.

Each of these programs included implementation and follow-up during the ensuing academic year. Additional QUANT programs are planned for Summer 2010 through Spring 2011. This paper focuses on an analysis of pretest and posttest scores and an exploratory survey to evaluate the QUANT 1 and QUANT 2 programs, both of which were conducted from Summer 2008 through Spring 2009.

![Figure 1. Model illustrating the interaction among the current and anticipated objects of research in the QUANT project](image)

In Figure 1, the left-to-right arrows show a chain of events from developer planning to student outcomes. The arrows looping back to the left represent the ongoing development that is based on feedback from teacher practice and student attainment. This feedback is being used to refine the professional development materials, and even the premises of the design itself, as needed to achieve the desired outcomes. (Figure and caption from Foley et al., 2010, p. 3)

**The Studies**

This paper reports on two separate research studies. One of the studies consisted of a quantitative analysis of pretest and posttest scores from QUANT 1 and QUANT 2 participants to evaluate change in content knowledge and pedagogical content knowledge. The other study was a fellowship research project based on a survey addressing what QUANT participants acquired from the PD program, together with an analysis of the responses (Regan, 2009). The survey collected both quantitative and qualitative data that were used to identify (a) QUANT participants’ confidence in teaching statistical and probabilistic concepts; (b) confidence in using technology
in the classroom; and (c) factors that influenced confidence and implementation of QUANT materials.

**Methodology**

The sample for the pretest and posttest analysis included nearly all of the QUANT 1 and QUANT 2 participants. It should be noted that one of the pretests and one of the posttests for QUANT 1 were not included in this analysis as they were from participants that attended only one week of the institute. The pretests were administered in the afternoon on the first day of the summer institutes, after a few brief introductory activities. Questions included single-answer multiple-choice items, multiple-answer multiple-choice items, open-response numerical items, open-ended essay items, and graphical interpretation items. The posttest was identical to the pretest and administered on the final day of the summer institute. The data were analyzed using a dependent *t*-test as well as a *sign test of the median*. Only QUANT 2 participants’ change in pedagogical content knowledge was analyzed because the pretest and posttest of QUANT 1 contained no items assessing pedagogical content knowledge. The QUANT 2 items addressing pedagogical content knowledge were scored using a continuous scale from –1 to 1; a score of −1 meant a correct answer on the pretest and an incorrect answer on the posttest, a score of 0 meant no change, and a score of 1 meant an incorrect answer on the pretest and a correct answer on the posttest. External evaluator Reed and a graduate research associate Regan assigned these scores, given them a somewhat subjective quality.

The survey was emailed to participants a week before the final follow-up meeting and participants had the option of returning by email or bringing a hard copy to the follow-up meeting. Of the 24 participants who attend QUANT 1 and QUANT 2, 19 surveys were returned. The qualitative data were analyzed to find the demographics of QUANT participants as well as their confidence in teaching statistical and probabilistic concepts, their confidence in using technology, and factors that influenced their implementation of QUANT materials. Descriptive statistics of the variables corresponding to the survey were calculated, and the data were used to determine whether there was a significant growth in confidence as a result of the institute. The qualitative data were analyzed for themes about how QUANT participants had used the materials they received at the summer institute as well as why some participants had not implemented some materials. For the quantitative analysis, *Wilcoxon Sign Rank tests* as well as the *Kruskal-Wallis tests* were used to determine significant differences in attitudes of the ordinal data.

**Results**

Results from the analysis of pretest and posttest scores showed significant gains in content knowledge for participants of QUANT 1 and 2 and significant gains in pedagogical content knowledge for participants of QUANT 2. The sign test of median showed a .0017 probability of results occurring without the institutes. In addition, the 8-item subscale assessing pedagogical content knowledge showed growth at the .05 level of significance. This subscale included items to assess the participants’ knowledge of the mathematical tasks framework, criteria for high-level tasks, the four steps for statistical problem solving, and the importance of context in statistical problem solving.

The results from the quantitative analysis of the survey data showed significant gains in confidence when teaching statistical related concepts and incorporating technology in one’s classroom. The data also showed that participants were generally confident when implementing the materials they had obtained during the QUANT institute. Various tests revealed that

---

confidence levels did not significantly depend on gender, years of teaching, type of school (public or private), location of school (rural, suburban, or urban), or type of teacher (pre-service, in-service, or college faculty). While analyzing the qualitative data, two main concepts emerged: technology and learning community. Many participants made comments about how the QUANT institute helped them feel comfortable using technology and incorporating it into their classroom.

I am really glad I had the opportunity to work so much with the TI-nspire calculators. Since I felt that using technology was a weakness for me, I really feel prepared to use the calculator for activities with my students, especially for data representation and such (Answer to survey question reported in Regan, 2009).

Yet, it should be noted that many participants were concerned with the availability of that technology outside of the institutes. As for the learning community aspect, many participants mentioned how they enjoyed the sense of community involved with the institute. Many participants shared thoughts about how they enjoyed collaborating with other educators in similar fields and positions as well as with the QUANT team. These results align with those reported in by Reed (2009). Some of the materials that teachers found helpful and useful were the technology and compatible software, the textbooks and reference materials, and the QUANT activity worksheets. In response to a question about what has hindered the implementation of materials, participant answers included student knowledge base, statistics did not fit into their course’s objectives, lack of technology, and lack of time to incorporate QUANT materials and activities.

Implications for the Revision of QUANT

The research reported in this paper focused primarily last two goals of the QUANT program:

- To develop teacher capacity in the areas of data collection, data analysis, probability, and statistics.
- To develop teachers’ comfort level and facility in using handheld data collection and data analysis technology, and connectivity and statistical software, as tools for instruction.

In regard to developing teacher capacity in the areas of data collection, data analysis, probability, and statistics, the analysis of pretest and posttest scores shows that the QUANT program can help educators significantly increase their statistical content knowledge and pedagogical content knowledge. The survey collected data that showed evidence of participants increased comfort level and capability of incorporating handheld data collection and data analysis technology.

Some recommendations for future QUANT institutes to make it more effective include:

- To include discussions about how activities can be implemented into non-statistical classrooms.
- To include discussions on how to adapt activities to meet the needs and knowledge base of one’s students.
- To explicitly discuss how to maintain the cognitive level of tasks.
- To discuss possible funding options for technology and other materials.
- To add tutorials on how to write grant proposals.

Discussion
The QUANT team used the results from these studies to revise the program for 2009–2010: the QUANT materials developed specifically for the program, the resources given to the participants, and the methods used to measure teacher change as a result of their participation in the program. Some of the changes that were made included increased time to discuss implementation plans and concerns, an online resource site for all QUANT participants, as well as giving all participants a copy of Implementing Standards-Based Mathematics Instruction (Stein et al., 2009). “The 2009 QUANT institute was not just a replication of the 2008 pilot institutes; it was an improvement” (Wagner, 2009, p. 10). The QUANT team is now the process of revising the QUANT program for 2010–2011. One of the challenges for the QUANT teams is adapting the Survey of Preservice Teachers’ Knowledge of Teaching and Technology (Schmidt et al., 2009) to practicing secondary school teachers and to the TPACK content associated with the QUANT program. Specifically, the team intends to measure TPACK in the areas of

1. Formulating questions and designing statistical studies,
2. Measurement and data collection,
3. Data analysis and descriptive statistics,
4. Combinatorics and probability,
5. Interpreting results and drawing statistical inferences.

The QUANT program for 2010–2011 will include two formats. One will be the original format: 2 weeks of face-to-face instruction along with follow-up workshops and online support. The other format will replace 3 days of the summer institute with six 3-hr instructor-led online modules. Ultimately, the QUANT program will be offered in three delivery formats: (a) face-to-face, (b) instructor-led online, and (c) online self-study. The future challenges for the QUANT team will be to refine the materials to fit these multiple formats, while keeping in mind the recommendations mentioned above as well as to develop student assessments to evaluate whether and to what extent the QUANT program has a positive effect on student learning. Through ongoing formative research the QUANT program will continue to improve its ability to assist teachers in their development of statistical proficiency for teaching and hence help students in their development of statistical proficiency.

SUPPORTING STUDENTS BY SUPPORTING TEACHERS: COACHING MOVES THAT IMPACT LEARNING

Mathematics coaches are being hired in an effort to improve students’ mathematics learning by supporting teacher development. However, little is known about the activities of coaching and how those activities translate into teacher learning and better instruction. This paper unpacks the coaching moves of one high school mathematics coach as she facilitates conversations with a collaborative team of teachers. Our analysis points to particular coaching moves that engage teachers in a process of guided participation. These moves include maintaining focus, assigning competence, and generalizing teachers’ stories. Initial findings indicate that this work has a positive effect on teachers and their students. This research has direct implications for those interested in shaping the work of coaching in secondary mathematics.

Introduction

The National Mathematics Advisory Panel (2008) reported that many schools across the country are calling for math specialists, including mathematics coaches, to increase students’ mathematical understanding and academic achievement, despite a lack of clarity in both research and practice about how coaches effectively support teachers to improve instruction. As part of a larger research study and professional development project aimed at reforming high school mathematics instruction, researchers implemented a coaching model for algebra and geometry teachers in two urban high schools in the Pacific Northwest. This study looks in-depth at the work of an instructional coach in an effort to name specific coaching moves that impact both teacher and student learning. We use a socio-cultural learning framework to frame the analysis.

This paper first provides a brief overview of the coaching literature followed by a description of the larger research project in which this study is situated and the theoretical framework used in this work. Results are discussed along with implications for coaching in general, and mathematics coaching in particular. This work has the potential to aide those seeking to understand this relatively new and increasingly popular educational role.

Literature Review

The concept of coaching stems from the professional development literature that indicates the most effective way to support teacher change is through personalized and differentiated development. For example, in a study using teachers’ self-reported changes, Garet and colleagues (2001) claimed that “professional development focused on academic subject matter (content), gives teachers opportunities for ‘hands-on’ work (active learning), and is integrated into the daily life of the school (coherence), is more likely to produce enhanced knowledge and skills” (p. 935). In addition, the authors reported that professional development is most effective when it spans time (see also Hawley & Valli, 1999). Such results have influenced K-12 leaders to implement instructional coaching as a means for improving teaching and learning.

The literature on coaching, however, is thin. Much of what has been published is either anecdotal or conceptual. Few empirical studies exist that describe rigorous methodology. Terms are often left undefined and ambiguous. Additionally, little effort has been made to explicitly...
connect coaching to theoretical frameworks of learning. Research on mathematics coaching, particularly in secondary mathematics classrooms, is even more scarce. The National Council of Teachers of Mathematics reported only seven studies in the past 20 years focused on mathematics coaching, with no common claims across the studies (NCTM, 2009).

The existing literature provides some insight into the sorts of activities expected of coaches. Typically, the main job of an instructional coach is to meet with teachers, although the content and form of these meetings is often not well-defined. The assumption is that when coaches and teachers meet, teachers are subsequently better able to support student learning. For example, Knight (2006) worked with many coaches and claimed that effective coaches “spend the bulk of their time working with teachers on instruction” rather than completing clerical or non-instructional tasks (p. 37). Gibson (2006) demonstrated how individual meetings between a coach and a teacher after observations enabled the teacher to improve reading instruction. In another school, coaches met daily with grade-level teams or individual teachers (Dempsey, 2007). While no distinction is made between working with individuals or groups, meetings with teachers through observations and follow up debriefing is most often the crux of the research literature about coaching.

The meetings between coaches and teachers often take the form of observations and feedback cycle. Dole’s (2004) found that the coach feedback from to be critical for improving teachers’ practices. Shanklin (2007) also recognized the key role of observation and feedback in coaching for the improvement of practice. Observations and feedback sessions appear in the literature as the crux of the work of coaches. However, the content of both observation and feedback is vague and rarely discussed.

Research concerning instructional coaching in mathematics suggests that coaches should meet with teachers, observe classrooms, and offer feedback as they help teachers improve instruction. However, the content of these meetings and the focus of the observations have not been thoroughly explored. Coaching has not been comprehensively studied or explicitly connected to theories of teacher learning. The research presented in this study attempted to bridge this gap by investigating specific coaching moves of a successful coach working with a secondary mathematics teaching team.

**Purpose of Study**

The work discussed in this paper is part of a larger research study and professional development project aimed at high school mathematics reform. The overarching goals of project are to: 1) train teachers to use powerful pedagogies aimed at disrupting typical hierarchies of status that often negatively impact students’ participation and access to rigorous tasks with a broad range of students in urban schools, 2) build and sustain site-based teacher learning communities that take up problems of practice and, 3) restructure what it means to be a mathematics teacher and learner in secondary math classrooms for the purpose of increasing students’ engagement and learning.

In this larger project, teachers engage in several professional development opportunities that focus on developing understanding of students’ mathematical thinking and learning. Teachers attend a monthly Video Club (Sherin & Han, 2004) focused on teacher moves that support equitable student participation and mathematical understanding. The math teachers also work collaboratively within their departments. They are provided a daily common planning time to plan instruction and reflect on their practice. The expectation is that the teachers will develop a professional learning community as a result of their participation. Such communities have been

---

found to positively impact student learning (McLaughlin & Talbert, 2001; Vescio, Ross, & Adams, 2008). Finally, an instructional coach works with the teachers involved in this project. She spends one day a week in each school facilitating common planning time and engaging in one-on-one coaching with teachers. Through these different learning opportunities, it is expected that teachers will be better equipped to implement ambitious pedagogies designed to specifically address issues of academic and social status that often effect students’ decisions for when and how to engage in the learning opportunities provided. These practices are grounded in the belief that all students are intellectual resources and capable of academic success (Jilk, 2007). In this study we analyzed specific coaching moves made by the instructional coach, Jill, while she worked with mathematics teachers during their daily common planning time.

Participants

Fourteen secondary mathematics teachers from three public high schools participated in the larger research project in which this study is located. For the purposes of this paper, we focused on one particular school, Lotus High for several reasons. First, the teachers at Lotus made significant changes in their professional interactions during the first year of this project. They increased the amount of time they collaboratively discussed mathematics, their students, and how to teach mathematics. Second, the entire team of teachers continued their participation in the second year of the project, and another department member chose to join the team. Finally, preliminary analysis of student achievement data at Lotus indicates that 70% of students passed algebra and geometry compared with only 40% when this project first began. Additionally, student enrollment increased in upper-level mathematics courses.

Lotus High is a traditional comprehensive urban high school with the following student demographics: 55% Black, 25% Asian, 10% Hispanic, 6% White and 64% free and reduced lunch (NCES, 2010). Lotus’s proximity to a major research university with a focus on urban education makes it a prime location for intervention-focused research. The school has experienced many reforms over the years. The entire school staff worked with a motivational framework as well as a variety of professional development foci from its district in 2008-2009. Additionally, a new principal, known for successfully improving schools, was placed at Lotus with the goal of improving standardized test scores.

The math department at Lotus High School consisted of seven teachers, although only four were involved in the work discussed in this paper. These four teachers, Jennifer, Natalie, Carly, and Akira were all relatively new, each having less than ten years of teaching experience. Both Jennifer and Carly were new teachers to Lotus High, and Akira joined the department during the second half of the previous year as a long term substitute. Jennifer and Carly are both White women. Natalie and Akira are both of Asian-American descent. Natalie is female and Akira is male. Jennifer and Natalie taught algebra, and Carly and Akira taught geometry.

The principal investigator of the study served as the mathematics coach and was employed by a nearby university. Prior to joining this research project, this coach served as a consultant and now works as both participant researcher and coach. She has significant expertise in mathematics education and equity-focused instruction but was never formally trained as a coach.

Data Collection

Several data collection strategies were used in this study. Relevant to the findings discussed in this paper are two main sources of data: videotapes of common planning time and teacher interview transcripts. Common planning time, facilitated by the coach, was videotaped three
times during the 2008-2009 school year. Each video tape was approximately one hour long. In addition, teachers were interviewed twice during the school year using a semi-structured interview protocol. These interviews focused on how teachers understood the reform work in which they were involved and how their ideas about teaching and learning mathematics changed over time.

**Theoretical Framework**

The literature suggests that coaching is a mechanism to help teachers improve their instructional practices, but theories of learning do not explicitly undergird this research. In this paper, the concept of guided participation, originally developed by Rogoff (1990) is used to understand the work of coaching in this context.

Guided participation regards learning as a process that requires both guidance from a companion and participation in culturally meaningful activities. Contextual factors are always considered. Rogoff (1990) asserted that “development is assumed to proceed throughout the life span” (p. 11). She defined development as increasing one’s ability to effectively manage the problems of everyday life and contribute to community. This could also serve as a definition of learning. Therefore, although guided participation was initially used to make sense of student development when guided by teachers, it is apt to apply it to this context to understand teacher learning alongside the guidance of an instructional coach.

Guided participation suggests that learning involves two processes. First, “building bridges from present understanding and skill to reach new understanding and skills” (Rogoff, 1990, p. 8). This is similar to Vygotsky’s (1978) concept of the Zone of Proximal Development. Learning requires guidance, support, and challenge from a companion (or companions) to help bridge a person’s current knowledge with new knowledge and understandings.

The second process involved in learning is participation in a culturally valued activity. Here, participation refers to active involvement in building shared understandings among participants. Rogoff (1990) explained, “from guided participation involving shared understanding and problem solving, children appropriate an increasingly advanced understanding of and skill in managing the intellectual problems of their community” (p. 8). The same could be said of teachers involved in guided participation - by developing shared understandings and solving problems with others, teachers appropriate more advanced skills to manage problems of practice.

Thus, learning, defined as increasing one's ability to manage everyday problems, occurs when one participates in building shared understandings of culturally meaningful activity with the guidance of someone who can help build bridges from current understandings to new understandings. Additionally, Rogoff (1990) cautions that learning takes place in a larger context which cannot be overlooked. This context involves individual effort, social interactions, and societal influences. She explains,

> My stance is that the individual’s efforts and sociocultural arrangements and involvement are inseparable, mutually embedded focuses of interest. Rather than examining context as an influence on human behavior, I regard context as inseparable from human actions in cognitive events or activities. I regard all human activity as embedded in context; there are neither context-free situations nor de-contextualized skills (p. 27).

This framework for learning, involving guided participation within a context of individual, social, and societal influences can be applied to teacher learning. Under such a framework, a...
coach guides the learning of teachers and provides activities in which teachers participate. This study investigates how an instructional coach engaged in such work.

**Findings**

_Interviewer_: What do you see Jill’s (the coach) role having been in the common planning time?

_Natalie_: I think she was our guiding light. ‘Cuz she really was! Like, “Okay. We want our students to be ‘here’. So what do we need to do to get them ‘here’? Here are some of the things that I’m thinking is good. I don’t know. What do you guys think? Oh, okay, let’s try it. Oh, it didn’t work. Okay. So what else?” And she…it was like we know “This is our goal”, and so it was nice to have a goal. Not “nice”—it was _helpful_ to have a goal that we need to get to. She…I don’t know! She just kind of strips everything from it and just says, “Okay. What do we want the students to know? What do they need to know? What will they need to do to show us that they know this, and what can we do to back that up, or what do we do to make sure that they do that?”

In many ways this exchange exemplifies the findings of this study. The teachers reported that Jill, their instructional coach, successfully engaged them in guided participation, and her presence and involvement positively affected their work. Jill built bridges through discussions with teachers in which she asked questions and stated observations. She also developed shared understandings with teachers, particularly around the implementation of the particular pedagogical approach they were using to mitigate issues of status in their classrooms (Cohen, 1994). According to the teacher interview data, all members of this team came to value their work with Jill as a critical tool for improving their practice and continually expressed a desire to learn more.

It must be noted that in addition to the lack of turnover within this team, the context of Lotus High may have contributed to the beliefs these teachers had about their success with students and their work as a collaborative team. The new administrators at this school worked with the entire staff to implement changes aligned with the goals of complex instruction, and both the principal and assistant principal showed significant support for this professional development project.

As Rogoff (1990) suggests, it appeared that effective coaching that built bridges and developed shared understandings within a context that was conducive for positively impacting teacher learning. However, this does not explain how such work took place. A closer analysis of the data in this study offers some possible explanations. Coding the data for the types of coaching moves made throughout all video tapes, three themes emerged: the coach (1) maintained focus, (2) assigned competence and (3) generalized teachers’ stories into larger principles of teaching and learning.

**Maintaining Focus**

During the first year of this project, the math team at Lotus made great strides in their learning. They met daily to discuss planning and instruction, adopted many of the practices of complex instruction, and exerted great efforts to change their teaching practices. The team expressed a sense of accomplishment both in individual interviews and during common planning times. As a result, conversations often took on a celebratory feel, where teachers talked about using their new learning to change classroom practices during the next school year. Admittedly, community celebrations are critically important for developing coherence in any group and

motivating continued engagement. However, it is also common for such conversations to deter teachers from the work at hand and quickly turn into sharing and storytelling rather than critical reflection and thoughtful planning (Little, 1990). Therefore, rather than simply chatting about their day, Jill provided teachers with both direction and support to move away from sharing and storytelling towards meaningful discussions about students, mathematics, and instruction.

To illustrate what is meant by maintaining focus, we offer the following two examples. During a common planning meeting at the end of the first semester, the mathematics teachers strayed from a conversation about the end-of-course exam content and began imagining future classroom practices based on current successes. Although exciting, this conversation drifted from the important issue at hand. Jill first allowed the excitement and celebration to continue for a few minutes before bringing the teachers back to thinking about student learning at the end of the term. This coaching move kept the teachers’ conversation on topic rather than spiraling into an imagined world without crushing the enthusiasm being expressed.

Another focusing move that Jill frequently made again related to the ways in which the teachers attributed their problems and frustrations to larger systemic structures. Although issues such as the school’s attendance policy, rules for placement in honors courses, or administrative discipline procedures, often affect what happens in teachers’ classrooms, Jill would not let the team use them as excuses for lack of student achievement or to derail discussions about changing instruction. Instead, Jill acknowledged teachers’ concerns and shifted the conversation back to mathematics classrooms where teachers had more agency over the changes they were seeking.

This finding is significant, because it suggests that structures for teachers’ collaboration may not be enough to create an environment where efficient teacher learning happens. Jill’s focusing moves allowed this group of enthusiastic and sometimes frustrated teachers to engage in reflective dialogue focused on student understanding and learning rather than getting distracted by their own celebrations, stories or frustrations.

Assigning Competence

To assign competence means to tell someone what they have done well as it is directly related to the activity at hand. A statement of assigning competence is specific and public (Cohen, 1994). Jill frequently assigned competence during team meetings. She named particular instructional moves teachers made as evidenced from her classroom observations. This coaching strategy did two things for teachers’ learning. First, it highlighted specific teaching moves that Jill valued and wanted teachers to take up as part of their practice. Second, it distributed expertise across the team such that teachers recognized and valued each other’s intellectual contributions. It is assumed that when people’s contributions are valued, they are more likely to participate and continue to engage in their learning communities (Cohen, 1994). Below is an example of how Jill assigned competence to Natalie during a common planning time meeting.

*You are pushing more for clarification and they (the students) are not pushing back as much. So the more you do it, the more they get used to it. You are also holding them more accountable for your follow up. Like when you said, ‘I want you to do this,’ and then you would come back and check in with them about what you told them you wanted them to do. You are getting more [participation]. There’s been a shift in your personality at the front of the room. Like, ‘I expect this,’ and ‘I really expect it,’ not just, ‘I’m saying it because I have nothing else to say.’*
In this statement, Jill assigned competence to Natalie by referencing a specific instructional move she used in her classroom, that of holding students accountable for engaging with a task and explaining mathematical ideas. Jill described the teaching move and how it affected students, and she discussed the experience in the public presence of the entire math team. One might easily imagine this conversation taking place between Jill and Natalie as part of their observation debrief in the privacy of a one-on-one meeting. However, when Jill assigned competence to Natalie, she made this artifact of Natalie’s practice available to the entire team. Holding students accountable in such a way now belongs to everyone and can potentially be used as part of the teams’ repertoire of practices. Simultaneously, Natalie is more likely to contribute during team meetings, because her ideas and practices were valued and validated by Jill. Natalie likely feels that she has something important to offer her colleagues as they work collaboratively to improve their teaching.

**Generalizing Stories**

The third coaching move Jill consistently used was one of generalizing teachers’ stories into larger principles of teaching and learning. “Generalizing, or making claims that extend beyond particular situations, is a central mathematical practice” (Jurow, 2004, p. 279). In this situation, the act of generalizing helped the team make connections between the particulars of their own classroom contexts and the instructional strategies they were working to implement.

During one of the collaborative team meetings, the math teachers discussed conversations they had with students about their expectations for behavior and participation. After some of the teachers shared particulars from these events, Jill connected this practice of whole-class discussion to creating classroom communities focused on equitable participation and assumptions for competence. At another point in the same conversation, teachers talked about specific students who questioned the reason for homework. Jill again pointed out how this concern was related to the norms for learning that the teacher team was creating across all math classes. This move reminded teachers that although homework was a particular issue they needed to address, it was couched within a larger framework with particular goals for student participation and learning. Teachers’ stories then shifted from isolated events to connected activities focused on the goal of creating equitable and engaging classrooms, a conversation which the entire team could then take up and address, regardless of specific occurrences within their own classrooms.

**Conclusion**

Jill, the coach in this study, engaged teachers in guided participation. She learned about their individual teaching practices and built bridges between those and a larger set of pedagogical practices known to effectively engage students. Jill actively created a community of teacher learners who developed shared understandings around a set of ambitious pedagogies. She did this in many ways, but most prevalently through her facilitation of common planning time which included maintaining focus, assigning competence to teachers’ ideas and instructional moves, and generalizing specific stories of classroom events. Perhaps these moves contributed to comments such as the one made by Natalie who said, “Every Tuesday when she (Jill) steps into the building there is this magic that happens in the classroom.”

Despite its popularity in practice as a means for improving students’ mathematical achievement, instructional coaching is an underexplored area in research. This study looked in-depth at the work of one coach who was perceived as successful by the mathematics teachers.
with whom she worked in a high school where students' mathematical achievement was on the rise. This research provides a learning framework and three specific coaching moves that have great potential to positively impact both teachers and students’ learning.

PROFESSIONAL DEVELOPMENT: A CASE STUDY OF MRS. G

Sharilyn K. Owens
Appalachian State University
owenssk@appstate.edu

This report is a case study of a teacher who participated in a project to investigate the effect of a wireless communication system on student algebra achievement. The longitudinal study aligns her instruction with the pedagogy promoted in the professional development sessions provided by the project. Classroom observations and teacher interviews were key data for analysis of classroom discourse, levels of questioning and formative assessment. The results of this study indicate Mrs. G’s practice was consistent with the project PD.

Introduction

One of the significant concerns regarding education reform today is that the American education system is “always reforming but not always improving,” and the most alarming aspect is we have “no mechanism for getting better” (Stigler & Heibert, 1999, p. ix). Professional development (PD) is often credited with promoting teacher change but evidence of success is sketchy at best. Studying environments where goals for teacher change are realized and active student learning is the focus may highlight strategies that could be replicated in teacher preparation and PD. While collecting data for Classroom Connectivity in Mathematics and Science (CCMS), such a situation came to light.

The larger project sought to use Texas Instruments TI-Navigator™, a wireless system, to open communication between students and teacher in mathematics classrooms, specifically Algebra I. The author was assigned to collect data from project participants based on geographical convenience. One such participant was perceived to be excited about the project and open to the new technology. Students demonstrated an enthusiasm for participation and learning. The seasoned teacher demonstrated an authentic passion for student understanding. The author was motivated to make a rich description of this classroom scene.

The four-year IES-funded project1 aimed to promote student learning by enhancing classroom practices such as enriched classroom discourse, quality and levels of questioning, and utilization of formative assessment (CCMS, 2005). Recognizing that simply the presence of new technology does not ensure teacher change, the project PIs implemented many avenues for reflection and PD. Clarke (1994) gives a framework for effective professional development. The professional development opportunities of the CCMS project were aligned with this framework and include: making ideas relevant to participants, allowing time to change, offering ongoing support, and encouraging participants to reflect on their learning. Formal professional development, led by practicing high school teachers who were also Teachers Teaching with Technology (T³) instructors, was offered at summer institutes. PD sessions were also provided at T³ international conferences. The PIs of the project provided direct instruction focusing on the theoretical and pedagogical issues addressed by appropriate implementation of the new technology. The gap between theory and practice was more effectively bridged by T³ instructors who provided real-life examples of classroom activities. Additional support included a listserv, technical support and ongoing telephone interviews.

---

Theoretical Framework

“Human motivation is a complex phenomenon, so it follows that mastery orientation is dependent on many factors, not necessarily explainable by a single theory,” (Owens et al., 2005, p.10). However, this paper is framed on social constructivist theory, whereby individuals build knowledge based on prior experiences, and that knowledge is constructed in a social environment. Much emphasis has been placed on students’ learning in exploratory environments. Unfortunately, the same theory has often been neglected in teacher learning (Clement & Vandenberghe, 2000; Sowder, 2007). Construction of knowledge is greatly hindered, in an environment where one person is the holder of knowledge and continually dominates the conversation, and the other person simply follows along. Critical thinking occurs when both parties are held responsible for asserting and justifying new ideas and opinions. “For learning to be mutually beneficial, especially among adults, all parties must engage in critical thinking” (Nyikos & Hashimoto, 1997, p. 508, emphasis added).

Modes of Inquiry and Data Sources

Transcripts and videotapes of Mrs. G’s classroom observations, post observation interviews and telephone interviews serve as data. The researcher looked for indicators from Mrs. G’s interviews of her perception of implementing the pedagogy supported by the project PD in her classroom practices by employing formative assessments and initializing classroom discourse by using questioning. Evidence of these constructs in her classroom transcripts were compared with the transcripts of the project PD sessions. Although it is impossible to isolate which elements of the PD are credited with changes in Mrs. G’s classroom practices, an alignment of the PD sessions, Mrs. G’s comments about her implementation of the technology and the pedagogy supported by the PD sessions, with evidences from her classroom observations are indicators of success of the PD. The author conducted a classroom observation after Mrs. G left the project to ascertain whether she continued to employ the aforementioned constructs.

The research question for this paper is: How do Mrs. G’s classroom practices align with the PD provided by CCMS project? Studying a seasoned teacher who continues to learn about desirable constructs in her classroom can add to the knowledge base of successful PD. It is worth examining PD that has been implemented so that the education community can glean from it something that works and attempt to replicate it in subsequent PD opportunities.

Data Analysis

Classroom Discourse

In the PD sessions, specific references were made to utilizing the technology to instigate classroom discourse. An example of this is comments made by Stephen Pape, co-principal investigator of the larger project at the opening day of the summer institute, “And the immediate feedback, and the discussions that you can have after it, are what got me into this grant. I am so excited about that data that you can get…Now this is some math problem, but you have these data now. What kind of conversations would you have about that?”

In keeping with a social constructivist paradigm supported by the PD sessions, participants were encouraged to participate in small and large group discussions. Participants brainstormed ideas projecting how they might use the TI-Navigator™ to foster discussion. Among several comments was Mrs. G, “What I find a lot is there's only one right answer in math. And when they see this, they're going to know that there's more than one right way to present your answer.”
Comments about classroom discourse made by Mrs. G during her tenure in the project include this at the conclusion of her first year in the project, “It has assisted and validated the way I have been teaching. I feel it’s a battle to get them to think on their own, and Navigator has fostered more discussion from quieter kids that normally you wouldn’t get.” In the middle of her second year in the project, she made this observation about classroom discourse, “I probably would only interact otherwise with those who are more vocal. It fosters more discussion about the ‘hows’ of doing a certain problem. It allows you to interact with the quiet ones as well.”

Levels of Questioning

Embedded in the conversations supporting classroom discourse was the notion that the teacher fosters a desirable environment with the type of questions she asks. Levels of questioning, while embedded within discourse, were treated as an additional construct. It was suggested that the questioning techniques employed by the teacher inform the classroom climate for discourse. A T3 instructor addressed the issue of changing her questioning as a result of having the TI-Navigator in her classroom, “With Quick Poll and later with Class Analysis, it changed my way of questioning. Instead of saying, ‘Well, how did you get that?’ That's too accusational. Even though I wasn't meaning that. I now change it to say, ‘How would someone get that?’ It alleviates that feeling of, ‘I'm the only one that was wrong, and how am I supposed to explain it? I have no idea.’ But it also gives the students who frequently or most often get things right, it gives them an opportunity to look at perhaps someone who has not done it the same way they did, and they can help talk through what would be the possibility of getting that.”

In a post-project interview, Mrs. G offered the following comments regarding questioning in her classroom, “I usually question to assess what they already know on a topic before we start a new topic or to connect something we have learned to something we are going to be learning. I question for understanding. I question for keeping students on task… and to basically assess whether or not they are understanding…it directs what I’m going to do next. Whether I keep going, or back up to re-explain or back way up…re-teach something they need before we go on.”

This research employed a deductive analysis of the data, using a coding system developed in an emergent and initial analysis of the data (Pape, 2009; Pape et al., 2008). NVivo software was used in a line-by-line analysis of the data so that every utterance from the transcripts was counted. The constructs in Table 1 are a sub-group of the constructs from the CCMS project (Pape, 2009). Table 1 reports counts for multi-directional discourse and levels of questioning. In defining each utterance, the author of this report used the codebook for which she was co-author. The abbreviated codebook definitions are listed below. The recorded counts in Table 1 have been standardized to a 60-minute lesson. The final column in Table 1 represents a post-project visit. This was a two-day visit, but only the first day was transcribed. The second day of the observation, students were playing a review game that required them to work in teams. The teams selected a question that was appropriately challenging for themselves, and they worked on it together. Although the entire lesson was an excellent example of classroom discourse, levels of questioning, and formative assessment, it was not transcribable due to the nature of game.

Definitions for Table 1

Initiation, response, evaluation [IRE]. Typically, a 3-conversational turn sequence during which (a) the teacher initiates by asking a question, (b) a student responds, and (c) the teacher evaluates the student’s response.

Uptake. Uptake of correct and incorrect responses or student comment or question refers
ways in which the teacher “takes up” (i.e., explores, engages with, discusses, critiques, reasons about, provides rationale to support) responses and comments as objects of classroom discourse.

High order cognitive load question. Elicit responses that may involve manipulation of information and ideas in ways that transform their meaning and implications—combining facts and ideas to synthesize, generalize, explain, hypothesize, or arrive at some conclusion or interpretation. (The code “st” refers to students.)

Low order cognitive load question. Elicit recalling and stating information or known facts; carrying out a simple algorithm, math procedure, or problem-solving steps to complete a task.

Teacher press for elaboration, explanations, and justifications. Teacher presses students to elaborate their ideas or to make their reasoning explicit—a request for deeper thinking.

Teacher press for involvement. Teacher strategies for increasing involvement for all students.

Student-to-teacher mathematics comment. All mathematics statements from a student to the teacher including direct response to a teacher question.

Student-to-teacher mathematics question. The direction of the mathematics question is from a student to the teacher. (The code “wpc” refers to words per comment.)

Student-to-student mathematics comment. All mathematics statements between students.

Student-to-student mathematics question. The direction of the mathematics question is from a student to another student.

Teacher-to-student mathematics comment. All mathematics statements from the teacher to a student or students including lecture about mathematics content.

Teacher-to-student mathematics question. The direction of the mathematics question is from the teacher to a student.

Authentic question. Open-ended, no specified answer by question source.

Recitation question. Pre-scripted answers are known by question source.

Discussion of Table 1

Initiation, response, evaluate (IRE). Typically, IRE is an undesirable pattern in a classroom because it usually consists of low cognitive load questions and may be used as more of a lecture masked as student involvement. The evaluation component deems the teacher as the mathematical authority. So, an increase in IRE would be a disappointing result. The NVivo results show that Mrs. G increases from 14.4 episodes of IRE in year one, winter of 2006, and 4.67 episodes in year one, spring of 2006, to as many as 29 episodes of IRE in year three, winter 2007. However, Mrs. G employed nontraditional uses in her IRE pattern. An example of transcripts that were coded as IRE, yet were used as a discourse generator is:

Mrs. G: Oh, okay. Let me get so I can see all your numbers. Okay, all right, so talk to me about this one compared to the other two. Say something about that line. Carla, just say something. There’s no right or wrong, I’m just asking you to make an observation.
S: It’s a straight line.
S: It’s a positive slope.
Mrs. G: It’s another positive slope. Good.
S: It’s a straight line.
Mrs. G: Yeah, it’s a straight line.
S: Instead of like one more down, it goes like up.
Mrs. G: Oh, give it another name; more up.

</table>

**Uptake.** Mrs. G spent a large percentage of time taking up student comments and questions as objects of classroom discourse. This exercise validated student contributions and therefore encouraged student input. The first and third observations show nearly one fourth or more of the class time is spent on comments and questions instigated by students, thereby validating student contributions and allowing them to be holders of their own knowledge.

**Types of questions.** The recitation questions were all posed by the teacher, but the authentic, higher cognitive load and lower cognitive load questions were occasionally posed by a student. That count is represented in the table with an “st.” The highest percentage of student questions is found in the authentic code. This is reasonable since authentic questions are ones in which the answer is not known. It is interesting to note that the teacher frequently relinquished her authority by asking authentic questions, placing herself as a learner along with her students.

**Teacher press for involvement and teacher press for elaboration, explanations, and justifications.** Mrs. G pressed her students for explanations and justifications of their comments, more so in the first and last observations. She also used many verbal cues to keep her students involved in the lessons. Some prompts that Mrs. G used to press her students to be involved were: I want to ask Monica because she’s falling asleep, and I want to wake her up; Somebody who disagreed, can you tell me what you got for an answer? Dave, since you brought it up; 14-15 people. Are the rest coming? Where’s everybody else? Okay, talk to me about what the word maximum means. Jonathan; I’m asking you anyway, especially because you didn’t do it.
Comment and question directionality. This is a combination of the question and comment constructs from Table 1 addressing all instances in which the teacher makes a comment or question to a student (T-S MC, T-S MQ) a student makes a comment or question to the teacher, or another student (S-T MC, S-T MQ, S-S MC, S-S MQ). An interesting observation is that Mrs. G’s students made many times the comments that she made; however the words per comment (wpc) were fewer for the students, indicating that their comments were probably not as sophisticated as those of the teacher. In year one, winter of 2006, the students made 72 mathematics comments to the teacher, and the teacher makes 29.14 mathematics comments to the students. In this case, the students made 2.47 times the number of teacher comments. In year one, spring of 2006, the students made 1.53 times the number of teacher comments. In year two, spring of 2007, this number jumped to 3.07 times the number of teacher comments; and in year three, winter of 2007, nearly four times the number of teacher comments. In year three, winter of 2007, the number is reduced to just over twice the number of teacher comments. Note that in IRE, the response is always coded as a student-to-teacher mathematics comment; however, her low levels of IRE would not account for a great percentage of the student-to-teacher comments, ranging from 11.5% in year one, spring to 20% in year one, winter 2006. These percentages were calculated by dividing the number of IREs by the number of student comments. Likewise, the teacher-to-student questions are somewhat accounted for in IRE, but only ranging from 22.8% in year one, spring 2006, to 28.5% in year one, winter 2006. These percentages were calculated by dividing the number of IREs by the number of teacher-to-student questions. The student-to-student comments and questions may not be adequately represented by the count in Table 1 because the students had time every day that they worked at their desks on a warm up, reviewing homework or exploring a new idea, and took advantage of time to discuss something quietly with a neighboring student. These instances were viewed on the videotapes, but were not audible, so did not appear on the transcripts; therefore, these comments were not counted.

Formative assessment. After the principal investigators and T3 instructors spent some time in the PD sessions establishing the importance of discourse, the next big idea was, what does the teacher do with the knowledge gained from listening to the students? Assessment is a key reason for providing an environment where students can speak freely about their mathematics. As students expose their ideas, they also expose their misconceptions. Once the misconceptions are brought to light, they can be rectified. Stephen Pape made these comments at the summer, 2005 institute regarding formative assessment:

You have this information, and you have to think about which road to take. One of the questions we have in the research is about the critical junctures in a lesson when you use the Navigator. When will you make that decision in a lesson about when to use... Quick Poll? Nothing preplanned; but you're noticing something, and you say, ‘Oh, let me get this data.’...I think that's going to be interesting, and perhaps it makes your job somewhat more complex... We always ask questions, but we're getting that information back (S. Pape, 2005).

Mrs. G made many references to using formative assessment to evaluate student understanding. She claimed that formative assessment has traditionally been her practice; however, the TI Navigator made the students’ needs more visible. In every telephone interview and post-observation interview, Mrs. G remarked that she did change the course of the day’s lesson to accommodate student learning. The following comments came from her post-observation interviews: After her first semester in the project:

I taught the material yesterday. They weren’t as comfortable as I wanted them to be. I was shocked that there was still so much work to do because my plan was to go on to some word problems. . . . I can’t write a plan in advance. I mean, it changes (Mrs. G, 2005).

After her first year in the project:

We backed up from what we originally planned because after taking a quiz, I realized the kids were not ready to write equations of lines from scatter plots. Well, some of them, those five who got it, they’re solving system of equations right now (Mrs. G, 2006).

After two years in the project: “I try to get as much student involvement and feedback as I could. I could get a better picture of how they were doing.” After three years in the project: “I decided to whip out that TI-interactive calculator [i.e., TI- Navigator™]. I hadn’t planned that. I could see they were struggling.”

Conclusions

The results of the qualitative analysis and Mrs. G’s comments indicated that the PD offered by the larger project was implemented in her classroom practices. Participation in the CCMS project was not Mrs. G’s first exposure to the constructs of classroom discourse, levels of questioning and formative assessment, she indicated that the PD sessions of the summer institute and yearly conferences aligned themselves with her belief system. When asked to compare the PD of her own choosing such as CCMS, with the professional offerings mandated by her administration, Mrs. G stated:

PD needs to be relevant to your profession. [As a mathematics teacher] I am looking for PD that is relevant to me. How can I use this in the classroom? And how is this going to improve student learning and understanding? Because those are my goals. My goal as a teacher is...to have students understand what I teach them. The generic PD that gets handed down through the county...is just a process that I didn’t see the relevance for. It was time consuming, and I did not see the relevance for it in my classroom. Whereas, I sought out the Navigator project because I saw Navigator as something that would help me understand student learning and improve student learning. It was going to be a motivator for students. It was going to allow students to talk more about math, so that PD was meeting my goals and my requirements for teaching mathematics. The PD sessions we had at Ohio State and Denver and other places were all research based. Nobody was saying, “You have to do it this way.” The way it was presented allowed you as a professional to choose whether or not it was [going to be useful in your classroom]. There have been other PDs that I have chosen to do that I felt were beneficial...They are probably geared more toward my style of teaching, and that is why I gravitate towards them: investigative, discovery, hands-on approaches to learning math (Mrs. G, 2009).

Recommendations for Practice

This case study can inform pre-service and in-service instructors to build programs that nurture a desire for teacher learning. Current trends that are an “emphasis on correcting deficits rather than encouraging professional growth” are listed as an impediment to staff development sessions (Clarke, 1994, p. 41). The result is a most frustrating situation where teachers are not
treated as professionals (Romberg, 1988), but rather bludgeoned with speakers, workshops, consultants, new curriculum, new materials, new math, new activities and an overwhelming offering of other potentially useful, but thoughtlessly mandated, programs. “The most common form of staff development…in the United States… continues to be the one-shot in-service seminar in which an external expert makes a presentation, with little active involvement and no follow-up” (Clarke, 1994, p. 42). Furthermore, “two thirds of U.S. teachers state that they have no say in what or how they learn in the PD opportunities provided to them in schools” (Bransford, Brown, & Cocking, 2000 p. 193)

Teachers must be allowed to have a choice of which PD opportunities they will undertake. However, there may be many in this profession who have chosen it for their passion for teaching and not a passion for learning. The latter must be cultivated in pre-service teachers. It is possible that many teachers do not know how to choose appropriate PD for themselves because the expectation is that they will be told what to do. In order for in-service programs to be effective, pre-service programs must incorporate the expectation that its graduates will continue to seek appropriate learning opportunities for themselves. Pre-service teachers must be educated in the opportunities available to in-service teachers and must leave their programs armed with a plan to continue their education in an area that is relevant to them. Perhaps assertive teachers with a plan will be less likely to fall prey to generic sweep of stagnating workshops.

Endnotes

With current reform efforts and demands on teachers, quality professional development is more important than ever. There is a growing interest in practice-based professional development, an approach that aims to provide opportunities for teachers to learn mathematics and to make connections between the mathematical ideas, students' ways of thinking about those ideas, and related pedagogy. In this paper, we explore one type of practice-based professional development task that has not received great attention in the literature - where teachers write a lesson plan, teach the lesson to a "class" of fellow teachers, and discuss the demonstration lesson as a group.

Introduction

With current reform efforts and demands on teachers, quality professional development is more important than ever (Borko, 2004). Research suggests that professional development experiences should be grounded in particular content and in the practice of teaching (Borko & Putnam, 1996; Smith, 2001). Yet, much is still needed to understand and implement effective strategies for educating teachers (Borko, 2004).

Large-scale studies of professional development in mathematics and science suggest some general guidelines for creating quality learning experiences for teachers. Specifically, Garet and colleagues found that teachers' knowledge and skills are positively impacted by professional development that is focused on content, includes active learning opportunities, and is aligned with other school goals and activities (Garet, Porter, Desimone, Birman, & Yoon, 2001). In addition, Penuel and colleagues found that when activities were focused on specific content and were perceived to be consistent with other goals, teachers' felt more prepared to help students engage in inquiry. Time for planning was also related to implementation (Penuel, Fishman, Yamaguchi, & Gallagher, 2007).

Recently there has been a growing interest in practice-based professional development, an approach that aims to situate teacher learning within the profession of teaching (Silver, 2009; Smith, 2001). This approach utilizes artifacts of teaching, such as curriculum materials, lesson plans, and student work, to create Professional Learning Tasks (PLTs). These tasks accomplish particular learning goals by engaging teachers in aspects of their work and drawing on their experiences as teachers (Smith, 2001). However, Silver (2009) suggests that empirical evidence is lacking for theoretical claims about PLTs. In particular, there is a need to better understand whether and what teachers are learning from the tasks, what features of the task facilitate this learning, and how this learning might transfer to the classroom.

Model Teaching

The focus of this paper is on a professional development activity that we refer to as model teaching. Model teaching occurs when participants collaboratively plan a lesson, teach the lesson to a "class" of fellow teachers, and discuss the demonstration lesson as a group. Although model teaching has not been focused on in the literature, it is closely related to another, more extensive literature - microteaching. Microteaching, where preservice teachers teach lessons to their peers.
as a part of methods courses, has a long history in teacher education with roots in the early 1960s (Kasten, 2008). In its earliest form, the lessons were taught to small groups of actual students, but peers were later used in order to make the practice logistically feasible for regular use (Davis & Gregory, 1970). Microteaching provides an opportunity for preservice teachers to practice teaching skills in a simplified environment; hence, the class size is small, and the lessons are short and often focused on a particular pedagogical skill (e.g., student involvement). Typically, the lessons are videotaped for subsequent viewing and analysis by the presenter and a supervisor, but a number of variations to the practice have emerged over the years, including variations on the mode, style, and source of feedback. Research on microteaching suggests that participants enjoy the activity and feel it has value. The feedback after teaching is especially important, both by the observers and in the form of self-analysis (Kasten, 2008; MacLeod, 1987). However, the research has not been entirely conclusive (MacLeod, 1987). Some have argued that these environments may have been oversimplified, that "what was stripped away may have been the very aspects of teaching that make it difficult" (Grossman & McDonald, 2008, p. 190-191).

Several differences exist between microteaching and model teaching. First, microteaching has most often been used with novice teachers (MacLead, 1987). As such, microteaching is often a way for novice teachers to work on 'gross' teaching skills such as clear directions, presentation style, and student involvement (Kasten, 2008), whereas model teaching is intended to help experienced teachers explore more nuanced aspects of teaching. Related, the microteaching environment is meant to reduce the complexities of teaching so that the preservice teacher can practice particular skills and receive feedback on them (MacLeod, 1987). On the other hand, model teaching is expressly meant to help teachers consider and practice a new (and more advanced) skill, while simultaneously considering the complexities of teaching. Teachers are encouraged to embed the skill in a complete lesson in order to consider how it might be integrated into daily practice. Also, the debriefing period following the lesson is not aimed so much at the particular teacher and his or her execution, as much as it is a collaborative reflection about the lesson's ability to effectively use the new skill to help students learn.

**Current Study**

As suggested by Garet et al. (2001), the professional development activities in the current study were grounded in particular content (i.e., the teaching of algebra) and included multiple active learning opportunities, all of which were designed to help teachers integrate the new materials into their current practices and to merge them with regular classroom materials (e.g., texts). In particular, the goals of the professional development were to: 1) introduce teachers to comparison as a tool for fostering flexibility in algebra; 2) train teachers to use materials created for this purpose; and 3) assist teachers in finding ways that these materials could be easily implemented in their own classrooms.

Star and colleagues have identified comparison as a particularly effective means for promoting the development of students’ flexibility in mathematics (Rittle-Johnson & Star, 2007; Star & Rittle-Johnson, 2009). Within their work, several practices for the effective use of comparison in mathematics instruction were found to be important. These instructional practices include using side-by-side presentation of problems and solution methods; engaging students in subsequent discussion of these multiple solution methods to highlight the similarities and differences among problem solving techniques; helping students evaluate and compare the accuracy and efficiency of different solution methods; and making connections to the underlying
The current study investigated how teachers learned to implement these practices within a practice-based professional development institute.

The study is guided by two research questions. How do teachers implement the model teaching activity? In what ways do teachers’ implementation of the model teaching activity foster the integration of mathematics content, student thinking, and pedagogy?

Method

Participants

In July of 2009, a one-week professional development institute was held for a group of middle and high school algebra teachers local to a large city in the northeastern part of the United States. The teachers were participants in a pilot year of a multi-year research project on using comparison to teach Algebra I. Of the 13 teachers, 8 taught in high schools and 5 in middle schools. All of the teachers had taught either algebra or pre-algebra courses in their schools. The range of schools varied from public urban and suburban schools to private suburban. The number of years teaching ranged from 2 to 25, with an average of almost 10 years.

Professional Development Structure

Daily overarching questions were used to frame the discussions and organize the activities during the week of professional development. In particular, on Monday the overarching questions were: What are some benefits of promoting multiple strategies for solving problems? What are some benefits of using comparison to promote the use of multiple strategies? On Tuesday the questions were: What sorts of comparisons are useful for learning algebra? What might these comparisons look like within the algebra curriculum? Which comparison problems can be easily woven into your instruction? On Wednesday: What kinds of questions/activities will facilitate the use of these comparison problems? How might the materials work together to foster flexibility with algebra? On Thursday: How might comparison might be implemented within your own classroom? On Friday, the guiding questions were: What difficulties do you anticipate/concerns do you have about the use of comparison? How will the study be conducted? Typically, each day included an activity designed to address the guiding questions and promote active learning opportunities. The activities ranged from solving mathematics problems to watching videos to planning and enacting lessons.

The Model Teaching Activity

During the professional development week, several activities were included to introduce teachers to the new teaching methodology, underlying educational research, and comparison curriculum materials. The activities were meant to provide teachers the opportunity to explore new ideas and make connections to their own teaching practices. Each activity was followed by a group discussion. The focus of the current paper is the activity that occurred on Thursday – the model teaching activity. For this activity, teachers chose side-by-side comparison problems from the curriculum, referred to in the curriculum as Worked Example Pairs (WEPs), and worked in small groups to design a lesson plan. (The 13 teachers divided into five small groups for the purposes of this activity.) Each group then co-taught the lesson to the other participating teachers, who played the role of students. The presenting teachers selected their own topics from those that were part of the curriculum, which included finding the slope of a line, solving a system of linear equations, factoring, and solving quadratic equations. All five of the teacher presentations were videotaped, and observational notes were taken at the time of presentations.

Prior to designing their own lessons, the teachers participated in a demonstration lesson taught by one of the professional development leaders. Within this lesson, characteristics of effective implementation were modeled. In particular, desired implementation of the WEP included three phases: understand (e.g., what are the two methods?), compare (e.g., what are the similarities and differences between the methods?), and make connections (e.g., why is one method more efficient?). The presenter did not narrate the lesson; instead, he enacted the lesson as if he was the teacher and the participants were his students. Before he began, he emphasized that his lesson was just one way to implement the materials.

Analysis

To begin the analysis process, two of the authors independently observed all five demonstration lesson videos. Subsequent analysis of the videos proceeded in three phases: writing detailed descriptions of the lessons; identifying features of the implementation; and coding the lessons for mathematics content, student thinking, and pedagogy. After an initial phase of independent analysis followed by discussion (iteratively for the first two videos), subsequent analysis were completed by one coder and checked by the other.

In particular, the detailed descriptions were used to characterize different phases of the lesson, use of WEPs, and aspects related to enactment of the lesson (e.g., did the teachers narrate or play the role of a teacher?) These characterizations were then used to identify trends in the way that mathematics, student thinking, and pedagogy were addressed within the model teaching activity. Video were reviewed as often as necessary to understand and confirm the trends.

Results

The results for this study are organized according to the research questions. Before describing these results, however, it seems important to note that teachers' reactions to the activity were quite positive. Semi-structured interviews conducted with each participant before and after the professional development week revealed that the majority of them viewed the model teaching activity to be the most meaningful part of the week. Several teachers noted that this activity helped them to think about the implementation process and how to “blend the [materials] into the lesson.” One of the teachers noted, “The part I enjoyed the most was watching other teachers implement the [materials]...anything from how they wrote it on the board to the questions they just asked the class in general.” Another teacher commented that the teacher presentations "were incredibly helpful, and it was the springboard for a lot of ideas that are sort of percolating right now."

Implementation of the Model Teaching Activity

Our first research question focuses on teachers' implementation of the model teaching activity. Three types of implementation features were examined in this study: lesson sequence, use of WEPs, and enactment of the lesson.

Lesson sequence. With regard to lesson sequence, a general trend was found that included: warm-up problems to review what students already knew about a mathematical topic; introduction and discussion of the WEPs; opportunities to apply the methods presented in the WEPs and draw conclusions about them; and an “exit ticket” problem to assess understanding of the methods and general conclusions. Not surprisingly, this sequence was quite similar to the one demonstrated by the professional development leader.
Slight variations in lesson sequence among the five presentations were primarily due to personal teaching styles and also classroom environment where the participating teachers would be using the curriculum materials. For example, one of the teachers had students of different levels of achievement in her class and she had to be conscious in how she would adjust the comparison materials and pedagogy to fit the needs of her class. Another teacher was working with non-English native speakers and for her, the major challenge was to think about ways to integrate this new approach and be able to support meaningful discussions without adding an additional load on students’ language comprehension. Another variation involved the use of a second, teacher-made example to extend students’ thinking about the particular methods being examined in the WEP.

**Use of WEPs.** During the use of the WEPs, all of the groups included the *understand*, *compare*, and *make connections* phases. These first two phases were quite similar for all groups. In the *understand* phase, all of the groups asked students to read through the example and understand how each method worked. A small difference was that some of the groups asked the students to read the example and discuss the solution methods with their partner before beginning the whole class discussion, while other presenters began a whole class discussion right after their students read through the problem. In the *comparison* phase, all five groups asked their students about the similarities and differences between the solution methods.

The most variability in the lesson sequence occurred during the *make connections* phase. For example, three of the groups were focused on helping students understand why and under what circumstances a particular method might be preferable. For example, after discussion about which method was more efficient and strategic for a problem that involved factoring with a leading coefficients greater than 1 (e.g., $2x^2 + 14x + 24$), a presenting teacher in one group said, “I want to ask a follow-up question. How does a factoring of GCF here affect the length of the solution?” In these three groups, these teachers wanted students to pay attention to the affordances of certain methods, given particular problem characteristics. Again, classroom environment seemed to also play a role for this questioning phase. For example, one teacher explained that his target class was quite advanced and consequently, he spent most of his time in the *make connections* phase. In two other groups’ implementation of the *make connections* phase, the teachers were concerned with helping their students generalize mathematical ideas related to the WEPs. For example, one group asked the students to state general rules about the slopes of horizontal and vertical lines, based on the discussions following the use of the WEPs.

All five groups included an “exit ticket” problem at the end of their lesson. Perhaps due to the time limitations for each of the presentations, the teachers generally did not discuss these problems in detail.

**Enactment of the lesson.** The last aspect of implementation examined in this study was the enactment of the lesson. The most notable finding here is that none of the five groups stayed “in character” throughout the lesson, although the groups differed in the extent that they stopped to make comments. The comments generally fell into one of six categories; most typically, teachers stepped “out of character” to explain their approach or view about something in the lesson. For example, one teacher stopped to explain that she tells her students the slope of a vertical line is undefined rather than telling them it has no slope. In a few cases, teachers stepped “out of character” to explain what students in their classes typically think or do. As one teacher noted, “You also have to remember to remind the kids to bring the GCF down, because they do pull it out, work on the expression, and then forget it. That is a common thing.” Teachers also stepped “out of character” to explain their rationale for decisions within the lesson, to describe what
might happen in part of the lesson they did not enact, to explain the context of the lesson, or to comment on logistical issues such as time or materials.

The other notable finding about the enactment is that the lessons tended to become shorter with each group. The first lesson was the longest (49 minutes), during which the teachers enacted most details of the lesson. The last one was the shortest (18 minutes), during which the teacher focused primarily on the implementation of the WEP. It was unclear whether this change was a result of teachers becoming tired near the end of the day, the teachers gaining confidence in how comparison might be implemented and therefore not finding it necessary to enact all components of the lesson, or both.

The Integration of Mathematics, Student Thinking, and Pedagogy

Our second research questions concerns the ways that teachers' implementation of the model teaching activity fostered the integration of mathematics content, student thinking, and pedagogy. On the whole, it appeared that the model teaching activity did foster the desired integration. Our analysis of the five model lessons indicated that content, pedagogy, and student thinking were regularly addressed by teachers and were often intertwined.

Signs of this integration were seen in teachers' enactment of the lessons and seemed to be especially influenced by the fact that all teachers served both as presenters and (in others' presentations) as "students." In other words, when in the role of "students," teachers did act like students -- not by modeling student misbehavior but rather by illustrating ways that students might think about or approach the given problems. Although the "students" often gave correct answers, they also asked questions that revealed student misconceptions and difficulties. Initially (as the first group taught its lesson) there was some discomfort among presenters when "students" asked questions that revealed points of confusion, but teachers seemed to grow comfortable with it as the activity continued. The teachers seemed to want to know how their peers would handle common points of confusion, such as dividing by zero and understanding the difference between no slope and a slope of zero. To illustrate, a "student" asked how one can know the graph of a particular equation is going to be a vertical line. The presenting teacher responded by suggesting a table of \(x\) and \(y\) values where \(x\) was always 3 could be useful for showing that "every single time \(x\) is going to be 3, it makes no difference what \(y\) is." She then asked the "student" to give her "some points for \(y\)." Instead, the "student" demonstrated confusion by saying, "But there is no \(y\)." After pausing, the presenting teacher again encouraged the "student" to provide some values for \(y\) so that she could show "what is going to happen." Once the table of values was created, the presenting teacher plotted the points on a graph to demonstrate that the points formed a vertical line.

In addition to asking questions, participants playing the role of the student also made comments that revealed what students struggled with, such as being able to manipulate multiple negative numbers in the same problem. The presence of "students" appeared to play a particularly critical role in connecting pedagogy, content, and student thinking. Note that teachers were not given explicit instructions on how they should behave when in the role of "students"; rather, the group seemed to spontaneously recognize the value (to teachers' learning) of having "students" model the thinking and misconceptions of actual students.

Another second way that implementation of the model teaching activity showed integration of content, pedagogy, and student thinking was in teachers' spontaneous parenthetical comments while teaching. Recall that the model teaching activity began with the presentation of a demonstration lesson by one of the leaders of the professional development; in this presentation,
the leader did not step out of character or offer any parenthetical comments. Yet presenting teachers frequently offered parenthetical asides to their peers, as a way to explain teachers' thinking and underlying rationale for pedagogical decisions. For example, after introducing the elimination method for solving a system of equations, one presenter asked the "students" to describe which of two equations had been modified and how, but she did not have them actually solve the system. Before moving to the next problem she commented on this decision and how she would use this approach to help focus her own students on the process instead of the answers. She said, "And I would actually, in the lesson - sorry, this is just an aside - at this point, I wouldn't finish that one. Because my whole point, with the next couple of these, is just getting the kids to think about what am I changing and why am I changing it."

**Discussion**

Our interest in the present study was in exploring one type of practice-based professional development task - where teachers write a lesson plan, teach the lesson to a "class" of fellow teachers, and discuss the demonstration lesson as a group. Despite the prevalence of practice-based professional development tasks in mathematics teacher professional development, empirical evidence is largely lacking about the effectiveness of these tasks (Silver, 2009). The model-teaching task is particularly under-explored, despite the apparent potential of this task to help teachers make connections between mathematical ideas, students' ways of thinking about those ideas, and related pedagogy.

Our results indicated that the model teaching task was powerful and useful in the context of our week-long professional development on comparison. First, this task provided us with a useful means of assessing teachers' learning from the professional development. Recall that the task was used at the end of the professional development, as a culminating activity. Our analysis of the model teaching lessons showed that teachers appeared to understanding the importance of comparison as well as how to implement our comparison-based lessons using our three-phase discussion model. Additionally, their lesson sequences indicated that they were able to integrate the WEPs into a typical classroom routine, making it more likely they will do so within their own classrooms.

Second, the model teaching task showcased the variety of ways that teachers could implement our materials. This activity gave teachers an experience for thinking about what examples would fit their lesson goals and then planning step-by-step the lesson sequence followed by the practice presentation. In addition to providing teachers with a comprehensive lesson planning and implementation stages, the teaching activity offered a unique opportunity to learn from each other’s implementation approaches. As one participant noted, "It was good for me to get up and do it myself, and it was beneficial to me to see how other people do it. It was also beneficial to work in the team that I did, not simply to do it by myself." In sum, participants were able to demonstrate and share their own customization of our curriculum, which also provided evidence that personalization of the curriculum was not necessarily at odds with implementing our approach with fidelity.

Finally, the model teaching activity seemed to foster the integration of several aspects of teacher knowledge. In particular, having teachers act as "students" served as a powerful way to highlight issues of student thinking, to identify student misconceptions, and to consider pedagogical strategies for addressing particular student difficulties. In fact, teachers seemed to spontaneously focus on what students might be thinking about the mathematics, as evidenced by their questions and comments. Prior research suggests that getting teachers to focus on student
thinking can be challenging (Perry & Lewis, 2009). Research by Lin (2002) and van Es and Sherin (2010) indicates that videos and narrative cases can be effective in helping to shift teachers' focus from teacher behaviors to student thinking, but it generally takes time for this shift to occur. It may be that, by observing the lesson as a "student," a greater and more immediate focus is placed on student thinking. As one teacher noted, "I think it is good that we are doing this because it is really making me think more about what it looks like to the kids."

Prior research on practice-based professional development has emphasized the importance of using artifacts from teachers' own classrooms in order to help teachers reflect on practice and learn new pedagogies or mathematics (Lin, 2002; van Es & Sherin, 2010). However, such artifacts (e.g., videos) may not be available in the initial stages of a professional development program. The current study describes a professional development activity that allows teachers to simulate what they do on a daily basis, in order to help them learn to incorporate new ideas into their practice. The unique features of this task seem to forefront student thinking, an important aspect of teacher knowledge, as teachers learn the new ideas. Such an activity holds promise for helping newly acquired knowledge be accessible and usable in the classroom.

MATHMATICS TEACHER RETENTION: FOUR TEACHERS’ VIEWPOINTS ON STRESS IN THE PROFESSION

Molly H. Fisher
The University of Kentucky
molly.fisher@uky.edu

Up to half of teachers leave the profession by the end of their fifth year and teachers of mathematics are found to have one of the highest departure rates when compared to teachers in other disciplines. This paper studies four mathematics teachers from diverse backgrounds and teaching situations and reports their attitudes and beliefs on teacher stress, mathematics teacher retention, and their feelings about the needs of mathematics teachers, as well as other information crucial to resolving the mathematics teacher retention problem in the United States.

Introduction

It has been reported that the retention rate of teachers is a continual problem. This is more prevalent in the areas of mathematics and science and in urban settings (Ferrini-Mundy & Floden, 2007; Rotherham & Mead, 2003). The most recent Teacher Follow-up Survey indicates that Special Education teachers are the most likely to leave the profession with secondary level teachers of core subjects such as mathematics, English, and social sciences as the next highest number of departures (Cox, et al., 2007). Ingersoll (2003) reported on the prior version of the Teacher Follow-up Survey in which secondary mathematics teachers held the highest percentage of departures.

Studies have been conducted that attempt to find the reasons that teachers are leaving the profession. The results of these studies are mixed and, at times, contradictory. For example, Ferrini-Mundy and Floden (2007) and Cwikla (2004) suggest there is not enough preparation in mathematics content for college students who want to teach mathematics after graduation. However, Paul (2005) reports that the current undergraduate mathematics courses required for a degree in mathematics can be a “filter” that eliminates potential mathematics teachers. This is a commonly discussed issue in teacher preparation, and it is also noted that currently a third of students in grades 7-12 do not have a teacher with a major or minor in mathematics (Reys & Reys, 2004).

Stressful situations occur in all areas of teaching. The Teacher Follow-up Survey revealed 32% of teachers who changed schools stated “poor working conditions” as a reason for their move. Additionally, over 37% of teachers who left the profession stated they were going to “pursue a job outside of teaching” (Cox, et al., 2007). A teacher’s stress can be elevated by poor student behavior (Geving, 2007), lack of administrative support (Lambert, O’Donnell, Kushnerman, & McCarthy, 2006; Blase, Blase, & Du, 2008), and the plethora of additional tasks required of teachers such as extra duties like hall monitoring, bus duty, and bathroom patrols (Brown, 2005).

Studies conducted on teacher stress and retention rarely focus on one specific content area. Stress is generally studied with large groups of teachers from varying subject areas and grade levels. This paper aims to focus primarily on mathematics teachers by studying four secondary mathematics teachers from diverse backgrounds about the stress placed on teachers of mathematics and how it effects their satisfaction with the teaching profession. This paper aims to answer the following questions:
1. From the viewpoint of the teachers, what are school administrators doing to help reduce stressors and increase retention?
2. What efforts are being made to retain mathematics teachers?
3. Do mathematics teachers believe they have the same needs as teachers in other disciplines?

**Methodology**

The teachers participating in this study were randomly chosen from a group of teachers used for a larger study on teacher stress and burnout. The teachers in the original study (n=385) were stratified into four groups based on their stress level and preventive coping skills and one mathematics teacher was randomly selected from each group. The groups were defined as low stress with low coping, low stress with high coping, high stress with low coping, and high stress with high coping.

Each teacher was interviewed using a semi-structured interview protocol. In order to determine the major commonalities and differences between the four participants, a thematic analysis will be used to analyze the data (Coffey & Atkinson, 1996). Outlying themes were determined through theory and the interview protocol was designed based on these themes. The themes chosen for the interview protocol were the following: Stress and Coping, Retention, Mathematics, and other miscellaneous questions. Topics addressed throughout the interviews also included their perceived needs of mathematics teachers, mathematics teachers’ college preparatory courses and how it affected their preparation for teaching mathematics, professional development, collaboration with other teachers at their schools, high-stakes testing, salary, and the “perks” and “downfalls” of the profession. The participants’ responses were entered into a meta data analysis table created in a spreadsheet to compare and contrast the results from each theme.

**Group 1 (Low Stress, Low Coping) Representative: Candace**

Candace was chosen as the participant from Group 1. She is a public school teacher that has been teaching for thirty years at the same school in a state in the southeast United States. Her school uses a traditional schedule. Candace holds a Master’s degree and stated she is very satisfied with the teaching profession.

**Group 2 (Low Stress, High Coping) Representative: Maggie**

Maggie has only been teaching for four years and has taught at only one school. She teaches at a fine arts magnet school in a different state in the southeast United States. She holds a master’s degree in Mathematics Education. At the time of the interview she was working towards an educational specialist degree and was contemplating entrance into a doctorate program in the future. Maggie’s school also uses a traditional schedule. She stated she is only somewhat satisfied with the teaching profession.

**Group 3 (High Stress, Low Coping) Representative: Becky**

Becky has been a teacher for nineteen years and has taught at five different schools. At the time of the interview she taught at a public school in a state in the south-central United States. Her school operates on a 4x4 block schedule. In addition to teaching Becky had worked in other professions for seven years. She holds a bachelor’s degree in Mathematics. Becky also stated to be only somewhat satisfied with the teaching profession.
Group 4 (High Stress, High Coping) Representative: Janel

Janel works at a private school in the northeast that uses a hybrid block schedule. She has been a teacher for only three years, but has taught at two different schools. The first school at which she taught was in the same state as Becky, but changes in her life required her to move out-of-state. She worked at another profession for one year between her two teaching assignments. Janel holds a bachelor’s degree in Statistics and Mathematics Education. She indicated she is very satisfied with the teaching profession.

Stress and Coping

Different Schools, Different Stress

With the exception of Candace, who has taught at the same school for thirty-one years, the teachers all felt that the stress levels were different at each school where they have taught. Maggie has been teaching for only five years, all at the same school, but she could still remember vividly her student teaching experience and how the stress level at that school was not as high as the stress levels at her current school. At the time of the interview, she was teaching for a top-ranked magnet school in her state. While she stated that the pressure for teachers to produce top ranked results was significant, she also stated that it is acceptable as a tradeoff since they taught “great students.”

Becky spent some time teaching at two middle schools before she settled into teaching high school. She described her time while teaching middle school as “doing time” because it was her first four years of teaching and she felt she was being suppressed because she did not have enough experience to find a job she was truly qualified for.

Middle school to me was just a far more stressful period. That is not my first love, that’s not what my training was for, but it was where I could find a job. You know I always joke about that, I refer to those first four years of teaching as ‘doing time.’

Janel had more difficulty discussing the difference between the stress levels at the two schools where she had taught. She taught at the first school for only one year before getting married and moving out-of-state thus having to change jobs. She agreed that she was much more stressed during her first year of teaching, but she felt that her judgment might have been clouded by the fact that it was her first year of teaching and not necessarily the school where she taught. She feels the small age difference between her and her students played a role in her stress level that year, as well as the fact that she had to study the material she was teaching every night in order to stay current with her lesson plans.

Stress Relief: Other Teachers, Family, and a Nap

The teachers were asked what methods they use to relieve stress. The overwhelming response centered on the support of other teachers and that of their family. Becky, Janel, and Maggie all agreed that being around other teachers with whom they could decompress was the best form of stress relief for each of them.

Janel stated that a stressed teacher is detrimental to their students. So, she felt it was most important to take care of herself and calm herself down so she can be more supportive of her students. When asked about the most stressful days at work, both she and Maggie stated they went home and took naps to help them feel refreshed.
Becky was perhaps the most candid of all of the teachers about her methods of relieving stress. She passionately described how her husband, grandson, her dog, as well as her religion get her through difficult days.

*I go home and I have a wonderful husband who will let me rant and rag, let me blow it out, and I know this will probably sound crazy to a lot of people, but there is nothing more relaxing than curling up with my dog...and just petting her and talking to her and stroking her. She’s always happy to see me, animals are wonderful you know, and I go to see my grandson a lot, if I’ve had a really, really bad day I go to see my grandson on the way home and sit...and if he’s sleeping I can just sit and look at him sleep and all is right with the world you know? And...I am very active in church, I prayed a lot this year and that’s no lie, I have probably prayed more this year.*

**Test Scores and Administration**

All teachers interviewed were asked, “Do you feel the pressure of high stakes testing causes teachers to leave the profession?” None of the teachers hesitated before they said “Yes.” During the conversations with these four teachers, the concern over test scores was a constant reference in their stories and feedback. Their responses ranged from a “laissez faire” attitude to one of being extremely nervous. The underlying concern, however, was the same: Administrators put tremendous pressure on teachers to produce high test scores.

Candace articulated the idea simply by stating that the pressure on testing forced teachers to teach how to take the test and, because of this, teachers lose autonomy in the classroom. Becky also expressed the idea that standardized testing costs a tremendous amount of money for school systems and too much time and money is “wasted on testing.” Janel teaches in a private school where state standardized tests are not required. She has friends in the profession in public schools, however, and they have been told that their job status depended on their students’ test scores. Maggie, the teacher in the top ranked school, almost yielded to her administrator’s pressure for test scores. She spoke about how she almost quit teaching the previous year because of the tremendous pressure.

*That’s one reason I thought about leaving. I don’t know why, but last year it really got to me. It was almost too much to handle, but again I think that might be a personality issue too...is that I take it too personal, that I have to just...I really have to know that if I try my best, I can’t control whether someone sleeps through the test.*

While administrators can place enormous pressure on teachers to produce high test scores, there are other things that they can do to help alleviate stress on teachers. Teachers expressed the importance of discipline support from administrators. This support allowed teachers to teach without disruptions from those who did not wish to learn. Candace stated that in addition her administrator attempted to reduce the amount of paperwork and extra duties in which they must participate. Similarly, Becky appreciated that her administrators did not require them to attend every after-school event and meeting. This allowed her more time for doing her job completely.

Janel seemed to have one of the simplest suggestions for helping teachers alleviate stress from administrators: “I think they have to remember what it was like when they taught.” She says that most administrators were previously teachers and many of them may have forgotten...

---

how demanding the profession can be. Maggie also added that simple encouragement also can increase the confidence level of teachers.

_I think they could do a better job of encouraging. I think sometimes they get caught up with their people...breathing down their throat about how numbers have to be. Then they're breathing down our throat about how numbers have to be and they forget to say 'hey, we think you're doing a really great job.'_

### Mathematics Teacher Retention

#### Needs of Mathematics Teachers

The teachers interviewed did not seem to feel that mathematics teachers had _more_ needs than other teachers, but they have _different_ needs. The most prevalent need mentioned by these teachers for mathematics teachers was the need for specialized professional development. Becky and Maggie both noted that mathematics courses undergo more curriculum changes than courses in other disciplines. Therefore, they stated, there is a greater need for professional development when these changes occur. Maggie also stated that mathematics teachers have to participate in after-school tutoring and remediation sessions more often than teachers in other disciplines. Teachers of other disciplines often used this extra time for their lesson planning and grading.

#### Mathematics Teacher Shortage

Only one teacher interviewed felt the need to increase the salary for teachers of mathematics. Others felt a differentiated salary increase was not fair to teachers in other disciplines who may work just as hard as a mathematics teacher. Janel proposed a novel concept for retaining mathematics teachers. She suggested letting mathematics teachers specialize in a specific area of mathematics. Many teachers of history and science specialize in one aspect of that discipline and she felt that mathematics teachers could benefit from the same process. She stated that if mathematics teachers teach only in one area such as Algebra, Geometry, Calculus, or Technical Math, then they would not feel they are “spread too thin” among their courses. This could result in a stronger ownership of courses and more successful teachers.

Candace discussed the need for more respect in the teaching profession by stating the following: “If your doctor says something, you would never think to refute them, but if a teacher does, a lot of time parents don’t even think twice about saying ‘I don’t think that’s right.’” This lack of respect from parents was a common issue among all of the interviewees. All teachers interviewed agreed that communication with parents is not a desirable part of the job. Becky and Janel both recounted instances within the last year where parents were excessively rude with them to the point at which they could not continue the conversation. In Becky’s case, the parent wanted a conference with her, but she refused the conference unless an administrator was present. Maggie believed her personality causes her to dread this portion of her job as she did not like confrontation and admitted that communicating with parents usually involved some sort of confrontation. She dismissed this issue; however, and stated that “no job is perfect.”

### College Preparation

The participants in the study were asked about their college preparatory classes for becoming teachers. They were asked if they felt the mathematics courses they were required to take as undergraduate students were too difficult for potential teachers. They all agreed those courses were very difficult for them at the time, but none seemed to think they were not

necessary. Candace and Maggie both stated that they felt the courses were relevant to them later in their careers because they helped build logical connections between mathematical topics and the courses prepared them to be better problem solvers. Maggie joked that she felt they “made us take those advanced mathematics courses in college in order to feel what it’s like to not understand something so we can sympathize with our students.”

Janel was the only participant who inferred that she did not think that her higher level mathematics courses were necessary. She never specifically stated she felt they were not needed. Instead, she expressed her disappointment in the lack of pedagogical courses that trained her how to teach mathematical concepts. She felt an exchange would have been optimal where they reduced the number of mathematics content courses and replaced them with mathematics pedagogical courses.

I feel like the downside to the math education programs in colleges, as much as I think they do a great job on the education side, we take all these advanced math classes and then we go teach like algebra one and no one’s told us how to teach factoring. We did all these advanced things and then we go back and teach the most basic, and so I think that sometimes it is hard to remember how to go back and teach the way we can do it.

Why They Stay

When asked what they feel are the “perks” of the teaching profession, a number of tangible results were discussed ranging from health and retirement benefits to the fact that teaching is “family-friendly” (except during emergencies such as sickness), they all expressed their love for teaching and the students. Becky stated that she could go home frustrated, aggravated, and ready to quit and her husband would ask “Tell me again why you teach?” She would respond:

I love the kids, they’re not students to me, they’re my children and ever since I’ve gotten back into high school they are my children...I go back the next day because I don’t believe that anybody else will take as good of care of my children as I will.

She also stated when asked about the perks that “I get to spend my day with kids everyday and I love it.” She went on further to say:

I don’t know, I think the perks of teaching is that if you love kids it’s a way to spend time with kids and hopefully feel that you can make some kind of difference in their lives...I mean we spend a lot more time with them than their parents do at this high school age, a lot of them, not every one of them, but a lot of them, so it’s the opportunity to give them a positive influence.

Candace described the feelings she had when her students come back to the school to visit after they have graduated.

When they come back and talk to you, that’s when you actually know that effect, that you have touched somebody’s life, and then that gets passed on to the next generation, so even if I, if I do die, I know that a little part of me is all these people. That’s how I think about it.

Janel saw as a reward when students made good grades in her class. This reward, to her, outweighed the less desirable parts of the profession.
I just feel like the reward is greater…when that kid gets an A on the test or I just love being around the kids so…I can deal with all the rest of it because I feel like there’s a reward there you know. I feel satisfied at the end of the school year…when I see the kids graduate…I feel like I accomplished something.

When asked why she remains in the teaching profession, Maggie jokingly responds “because I signed a contract.” She then describes the reason as:

When it comes down to it, it’s not about the test scores and when I really think about it, it’s more about the students and I still enjoy interactions with students and making those interactions every day. When it comes down to it, that’s what I always get down to, that’s why I stay, because that’s why I got into teaching. It’s not because I have this great love for math, like I am still trying to decide if I even like math. It’s just that I got into teaching for the students and so that’s why I continue to stay.

**Discussion**

Kate Walsh, President of the National Council on Teacher Quality (NCTQ, 2008), states that the time period of the third through the fifth year of a teacher’s career is “an opportunity lost for the health of the teaching profession” because of the high rates of teacher attrition within that valuable time of a teacher’s career. Becky specifically stated that she seriously considered leaving the profession after her fifth year of teaching.

I had all of the bottom barrel weakest classes, had no bright spot in my day. That was the year I had three students that went to prison, you know, and it was just emotionally, it just tore me apart and I was frustrated, I felt like I was working myself to death and they weren’t getting any better, like I was working really hard but the kids weren’t working very hard…and no matter what I tried, I would try games, I would try you know different approaches...oh it was crazy and it was...just in a very difficult situation where I just thought, I do not know if I want to do this the rest of my life.

Maggie also discussed thoughts of leaving the profession. She seriously considered leaving at the end of her fourth year due to pressure from her administrators to produce high test scores. Studies, such as the “Teacher Follow-up Survey,” also use the fifth year as a significant cut-off for years of experience (Cox, et al., 2007). The significance of using the fifth year as turning point is an interesting concept that could warrant future research.

Although the teachers in the study admitted that their administration has a tendency to increase their stress levels with added pressure on test scores, the teachers interviewed in this study were able to supply some specific items their administrators were currently doing to help alleviate their stress. Support with disciplining students, not requiring teachers to attend every afterschool meeting and event, and cutting down on paperwork and extra duties were all mentioned that help teachers do their job with ease. Previous studies have found student discipline problems and time management are problems for teachers and this support seems to parallel those findings. The lack of more significant responses could reveal that the efforts to retain teachers are not advertised enough to truly be effective, but it could also mean that there are no specific strategies in their school systems for retaining teachers and reducing stress.
Further investigations that pose the same question to administrators would be an interesting angle on this problem of teacher retention.

When questioned about how their schools retain mathematic teachers, none of the teachers could give specific, current, and relevant answers. Becky mentioned that a neighboring school system was offering signing bonuses for teachers of mathematics. More drastically, Maggie noted that her state was contemplating a rule that new teachers hired in “high needs areas”, such as mathematics, would be hired and begin their pay scale at the salary as those teachers with five years of experience in order to entice more teachers in those areas. Maggie did not condone this idea as she felt that was unfair to teachers in other disciplines who work just as hard as mathematics teachers. Once again, a study where this question was posed to school administrators may result in drastically different responses. Perhaps the participants’ lack of specific responses about their current school system’s tactics show that they are not enticed to stay in the profession by extravagant resources and outpouring of financial sources. They are more attracted to feeling “worthwhile” (Becky), having “great students” (Maggie), the reduction of menial tasks (Candace), and fewer meetings (Janel).

None of the teachers felt mathematics teachers were more privileged than teachers in other disciplines, but they did feel that some of the needs were different. The most common response was the need for specialized professional development. Becky and Maggie both stated that mathematics curriculum undergoes more changes in the standards more often than other disciplines. They were in agreement that mathematics teachers need to be better trained when these changes occur. On the contrary, Becky felt that all disciplines have varying needs, indicating that mathematics teachers were not more in need of items than teachers in other disciplines. Candace, being a science and mathematics teacher, felt that science teachers had more needs that teachers in other disciplines due to the “rather subjective” nature of the material and the time required to prepare for lessons. Surprisingly, none of the teachers mentioned specific tangible items that could be purchased with additional funding. An occasional mention of technology did occur, but only when the teachers were at a loss for a more descriptive answer. None of them seemed overly passionate that they were at a loss of technological resources that they needed in order to do their job effectively.

Teaching is a stressful career and few will refute the significance of the amount of stress involved in the career. Numerous studies exist researching stress and burnout. When Freudenberger (1974) initially began his research on burnout, he started by researching burnout on all professions, not specifically education. This led up to discussions on the teaching profession. When discussing who is prone to burnout, Freudenberger claims those most at risk are “the dedicated and the committed” who are “seeking to respond to the recognized needs of people.” When even more pressure is added from administrators, stress levels increase and burnout worsens resulting in more weary teachers who’d rather find other professions than teach children.

Reflections on Teaching Spreadsheet-Based Functions ‘Outside the Classroom’ and Teachers’ Practical Rationality

M. Faaiz Gierdien
University of Stellenbosch (RUMEUS) & Stellenbosch University
faaiz@sun.ac.za

This report presents my reflections on teaching particular spreadsheet-based functions to teachers ‘outside the classroom’. The reflections are framed in terms of interactions between two different practices, my own as a mathematics teacher educator and that of a teacher’s practical rationality. The framework will enable us to pursue our thinking further in regards to the potential that spreadsheets offer as an instrument for optimising teacher understanding of functions and ways of engaging teachers’ practical rationality. Findings have implications such as the need for aligning spreadsheet-based discourse, which is associated with functions, with official mathematics discourse in the classroom.

Introduction

Part of my practice entails teaching functions, by using spreadsheets, to teachers ‘outside the classroom’. By ‘outside the classroom’ I refer to, and mean, the teaching and learning of mathematics that does not take place within the confines of a school classroom. In contrast, ‘inside the classroom’ refers to the teaching and learning of mathematics in the school classroom. Various studies point out the centrality of functions in school mathematics and teacher education (Even, 1990; Nyikahadzoyi, 2006). When teachers observe the interrelationship between quadratic and linear functions, as shown by means of spreadsheets, their responses to such observations reveal the conflict which tends to accompany the use of spreadsheets in the classroom. The integration of electronic spreadsheets (Pea, 1985) in classroom teaching, as is the case with any other technology, is marginal, according to Hoyles, Noss and Kent (2004). Observing teachers’ responses outside the classroom to the use of spreadsheets, in relation to algebra teaching and learning with a focus on functions, therefore makes sense. The current paper, consequently, considers what we can learn from teachers’ responses, in terms of their practical rationality, when they observe my teaching of spreadsheet-based functions outside the classroom.

Theoretical framework

The theoretical framework is driven by the research question, which draws on different, though overlapping, bodies of literature, such as those relating to spreadsheets as part of information communications technology (ICT), to school algebra reform, to varieties of mathematics and to teachers’ practical rationality regarding mathematics teaching.

The body of literature on the potential for ICT, including the use of spreadsheets in school algebra teaching and learning with functions, is growing (Dettori, Garuti & Lemut, 2001; Haspekian, 2005; Sutherland & Rojano, 1993; Yerushalmy, 1999). Yerushalmy and Chazan’s (2008) review of the prevailing discontinuities in school algebra assesses the role of various ICT components, such as spreadsheets, in the study of functions. In their review, they indicate the instructional benefits to be gained from the use of spreadsheets, one being the way in which multiple representations (whether graphic, tabular or symbolic) are made possible. With an appropriate habit of mind (Cuoco & Goldenberg, 1996), spreadsheets (in the form of Excel) can
enable the user to adopt a problem posing (Brown & Walter, 1993) approach when it comes to the teaching and learning of functions. When such an approach is adopted within a learning environment, such as a school, the teaching of algebra can be rethought in such a way as to defy traditional curricular interpretations, including those which pertain to the separation of linear and quadratic functions. Pea (1985, p. 170) alludes to such reconceptualisation of traditional interpretations as an instance of the reorganisation metaphor, rather than of the amplification metaphor. Classically, the amplification metaphor is taken as referring to the adoption of a unidimensional focus, which retains the basic structure, meaning that straight lines and parabolas are treated as distinct objects. The reorganisation metaphor, in contrast, entails the emphasising of curricular continuities, such as exploring functions from an ‘interesting middle’ (Schwartz, 1995), in such a way as to show the interconnections existing between different functions.

The demonstrations of spreadsheet-based functions which I, as a teacher educator, have presented to groups of teachers are instances of where our mutual teaching practice connects. In part, my practice is informed by the mathematics of a mathematics education researcher (MER mathematics) and its particular form of discourse (Sfard, 1998). According to Julie (2002), MER mathematics is the variety of mathematics which deals mostly with elementarised versions of mathematics, such as with the connections between, and the development of, mathematical ideas by means of spreadsheets, as in the current case. Julie further explains that MER mathematics is structured in terms of insights gleaned from learning theories, pedagogy, and the history and philosophy of mathematics. School mathematics teaching, to which he alludes as ‘school-teaching mathematics’, is what teachers do, being their practice. Watson (2008) expounds on such a variety of mathematics, which she calls ‘school mathematics’, arguing that it is a special kind of mathematics, which is subject to institutional constraints. An example of school mathematics is the official mathematical discourse of the classroom, which is the preferred term used in the current study to refer to such teaching. Unifying concepts such as a focus on the conceptual connections within and between functions may not be desirable, she notes, in school mathematics teaching. During my demonstrations, I use a form of MER mathematics discourse which is peculiar to spreadsheet use, about which I provide more detail later in the paper. As such discourse does not form part of the official mathematics discourse of the classroom (Hoyles et al., 2004), a discrepancy between the two varieties of mathematics and the practice of each is inevitable.

The French school on the instrumentation of spreadsheets in mathematics teaching (Haspekian, 2005) informs my teaching of MER mathematics. For instance, while working with spreadsheets, I use the Excel spreadsheet program and its capability, together with my knowledge of computer hardware and mathematics, to instrumentalise my classes. In this way, I can explore particular mathematical operations by means of such instrumented actions as ‘fill downs’. Figure 1 provides an example of such action, in which cell B5 contains =A5*A5 for the function f(x) = x^2.

The spreadsheet shown in Figure 1 is a numerical representation of a given phenomenon (Friedlander & Tabach, 2008), which, in the current case, is a parabola, f(x) = x^2, according to school mathematics and the teaching thereof. An acute awareness of the intimate connection between the calculation activated by the equals sign in cell B5 and the structure of x^2 is required for the learning of mathematics (Hoyles & Noss, 2009). The ‘opened up’ nature of cell B5 in Figure 1 reveals the connection of its contents to those of A5, indicating that a functional relationship exists between the two columns, A and B. The user and viewer of such a spreadsheet should, thus, be aware that they need to look through the spreadsheet, as well as at it (Artigue,
Teachers generally adopt an approach to their mathematics teaching that is governed by practical rationality (Herbst & Chazan, 2003). For example, when they encounter the use of spreadsheets in relation to school algebra teaching and learning, such an encounter tends to impact on the ways in which they think about their own teaching practice. The teaching of mathematics at school level is shaped by various institutional, situational, epistemological, temporal and material conditions that prevail in the classroom (Watson, 2008), with such conditions serving to shape the use of spreadsheets in the reform of algebra teaching. Such reform will, inevitably, only take place over time. In order to impact on the approach taken by teachers of mathematics, according to Bourdieu (1998), they need to become sensitised to the use of spreadsheets outside the classroom in order that they might learn how most effectively to use them in the classroom.

**Figure 2. A diagrammatic representation of the theoretical framework of the current study**

Figure 2 is a diagrammatic representation of a theoretical framework which I constructed to portray the alignment of the two practices. The primary setting for the current study is outside the classroom, comprising the holding of meetings with, and the giving of spreadsheet-based demonstrations to, the teachers concerned in the study. The nature of such a setting is revealed in the first two columns in the figure. The third column is presented as a broken line, due to the current absence of data on spreadsheet-based approaches to classroom-based functions. The information which belongs in the third column was inferred from the specific concerns and questions raised by, and sourced in the practical rationality of, those teachers who attended my spreadsheet-based demonstrations. The middle column indicates the positioning of the space in which I appealed to their practical rationality. The epistemological implications of Figure 2 lie in the way in which the figure captures ways of knowing and doing which are related to my

---

practice as a mathematics teacher educator, and how such practice is interpreted by those whom I teach. In addition, Figure 2 has methodological implications, which will be elaborated later on in the course of the paper.

**Methods**

The methods of inquiry used in the current report are qualitative, stemming from constructs in the theoretical framework. Evidence of spreadsheet-based functions is provided by references to words and phrases in the first column in Figure 2. Evidence of teachers’ practical rationality is present in data fragments, which were gleaned from teachers’ responses to my teaching of the spreadsheet-based functions. In addition, the methodology employed made use of ‘insider’ research (Ball, 2000), in that it forms part of my own practice, so that the study is earmarked by both proximity and distance (Adler, Ball, Krainer, Lin F-L & Novotna, 2005). As findings must be treated with scepticism (in keeping with academic distancing) and subjected to a critical perspective, one way in which to conduct analysis is to reframe (Schön, 1983) data fragments by comparing them with forms of school mathematics, which is contained in the standard school mathematics curriculum. Reframing in such a sense is a type of comparison (Corbin & Strauss, 2008) between what happens outside the classroom with what happens inside it. For such a reason, I placed the notion of framing and reframing in the central column in Figure 2. In addition, I am aware that those findings which resemble MER mathematics should not be dismissed as solipsistic (Ball, 2000), due to their value in terms of illuminating the continual interplay between the varieties of mathematics resulting from instrumented activity conducted by means of spreadsheets.

**Data sources, evidence, objects and materials**

The data for the current report originates in a larger research project which was conducted into the role of spreadsheets in school mathematics reform relating to teacher education. In relation to the pre-service teacher education programme of a large university in the Western Cape, South Africa, we (Gierdien & Olivier, 2009) explored the possible use of spreadsheets with prospective teachers who were to be certified to teach mathematics up to Grade 10 in public schools in South Africa. Recently, both Olivier and I have started to work with practising teachers, who used to be marginalised under the apartheid regime, which officially ended in 1994. The involvement of officials (curriculum advisors) of the provincial Education Department and of the professional teachers’ association in such work has made contact sessions with the teachers concerned more regular than they used to be.

The data fragments that will be presented for analysis in terms of the current study come from the related formal and informal meetings which were conducted with the teachers, as well as from a 50-minute presentation, titled *Drawing families of functions using spreadsheets*, which was attended by practising secondary school mathematics teachers and Education Department officials. In the demonstration, I used a data projector and spreadsheet software to construct the functions outlined in Figures 3 and 4 (see below). After observing my demonstration those teachers participating in the study commented on it, and also raised concerns and questions about the demonstration. It should be noted that the teachers did not have access to laptops or computerised aid during or after the demonstration. The venue was a normal classroom which could seat up to 40 students. The demonstration was undertaken mainly from a problem posing perspective, in terms of which questions were raised regarding what happens when we systematically vary linear functions and multiply them. Such pedagogical moves are in line with

---

the notion of an ‘interesting middle’, which calls for a reorganisation, and not an amplification, perspective on linear and quadratic functions. Such moves should be viewed as examples (and evidence) of the practice of MER mathematics, with the goal of pointing out the connections between functions, for example, in terms of the approach which is taken by teachers in respect of practical rationality.

A more detailed description of the demonstration will reveal the instrumented actions involved. At the beginning of the demonstration, I drew the equivalent of a pencil and paper list of different linear functions on the board, after which I composed quadratic functions, based on the linear ones, as are shown in Figure 3 below.

<table>
<thead>
<tr>
<th>Linear function</th>
<th>Quadratic function</th>
</tr>
</thead>
<tbody>
<tr>
<td>( F_1(x) = x )</td>
<td>( F_1xF_1 = x^2 )</td>
</tr>
<tr>
<td>( F_2(x) = x - 1 )</td>
<td>( F_1xF_2 = x(x - 1) )</td>
</tr>
<tr>
<td>( F_3(x) = x - 2 )</td>
<td>( F_1xF_3 = x(x - 2) )</td>
</tr>
</tbody>
</table>

**Figure 3. A pencil-paper equivalent composition of linear and quadratic functions**

I then proceeded to use the spreadsheets to construct the functions (see Figure 4) in multiple ways, with an emphasis on showing how to compose quadratic functions based on linear ones. In terms of a pencil and paper exercise, I considered the general case of the parabola \( f(x) = ax^2 + bx + c \), where \( a = 1 \); and \( c = 0 \). My intention was to explore the parameter \( b \), and to ask what happens if \( b = 0, -1, \) or \( -2 \). Such choices had been made prior to the demonstration, due to the time limits on such an exercise, as well as the epistemological benefits to be gained from starting in an ‘interesting middle’. Such a move amounted to a reorganisation of the traditional way of progressing from straight lines to parabolas which keeps the two conceptually separated from each other. The attention of the teachers concerned was then focused on the parameter ‘\( b \)’ in \( f(x) = x^2 + bx \). Such decisions were in line with the habit of asking ‘what if?’, and with making an appeal to the practical rationality of the teachers concerned, in the hope that they might notice the conceptual connections within and between functions and how a particular use of spreadsheets enables such functions to occur in a different sequence, and at a different rate, compared to more traditional ways of using such functions. In the demonstration, I relied on the instructional affordances allowed by the spreadsheets, including the tabular, graphic and...
symbolic representations. Additional data sources for the exercise consisted of my own reflective notes and observations. Figure 4 shows the evidence provided in the form of spreadsheets data.

The above demonstration resulted from my instrumented actions and the degree to which I have made an instrument of spreadsheets, in terms of the French school of thought, and a tool for presenting and representing the various functions. During my construction of the various spreadsheet-based functions, I used a form of discourse which is peculiar to spreadsheet use, including use of the term ‘fill down’, and use of such concepts as parameters, cells, recursion, the selecting of columns in order to plot the various functions by means of the ‘scatter’ function, and multiple representations. I mention the use of such discourse to draw attention to the discrepancy between it and school mathematics teaching, or official classroom mathematical, discourse, which has to do with straight lines, parabolas, turning points, roots or zeroes, and the y-intercept.

In the current paper, I shall present an analysis of the following three incidents during the demonstration. The incidents serve as evidence of interactions between my practice and the practical rationality of teachers, which is associated with school mathematics teaching. The three incidents analysed bear witness to a comparison between the two practices. In addition, such incidents are significant, as they have implications for mathematics teacher education and the (lack of) learning opportunities to which they allude.

1. “What kind of mathematics is this?” was a question raised by a few teachers towards the end of the presentation.
2. A few teachers commented on the ‘mother function’ \( f(x) = x^2 + c \) and its connections to the spreadsheet-based graphic representations in Figure 4.
3. Some teachers argued that the learners must first know the algebra concerned before they use the related spreadsheets.

My analysis is predicated on the notion framing/reframing, in terms of which I draw a comparison in order to keep the appropriate degree of academic distance.

Findings

My demonstration leading to the functions represented in Figure 4 evoked a lively discussion among the teachers concerned. One of the results of this discussion was that a few of the teachers asked the above-mentioned question. By means of instrumented actions, I used the spreadsheets to reorganise the straight lines and parabolas with which teachers are familiar in novel ways, as indicated in Figure 4. The figure reflects an instance of the reorganisation metaphor, according to which familiar functions are conceptually connected by means of spreadsheets. The demonstration fell in the field of MER mathematics, with its peculiar discourse regarding spreadsheet-based linear and quadratic functions. Further evidence of operating within an MER mathematics framework lies in the title of the demonstration: families of functions. Such a title differs from that which would be assigned to such a demonstration in terms of a school mathematics perspective, as the denotation of such interrelationships would be highly unusual in school mathematics and the practice of school mathematics teaching, both of which tend to be highly fragmented. The teachers who participated in the study might have had difficulty in understanding the connections between the spreadsheet-based functions, especially as they had not only been required to look at the functions but also through them. The teachers were required to follow the peculiar discourse associated with the instrumented actions which I constructed for the various functions shown in Figure 4. The cells and tables used in the spreadsheet in Figure 4

lie on the arithmetic side, making it difficult for those who are new to the field to recognise the
different algebraic functions when looking at the cells and tables for the first time.

In Figure 4, columns A through F can be seen to contain the numerical (integer-valued)
representations of known objects, with straight lines and parabolas being reflected in the first
column. In the given instance I relied on the instructional affordances, namely on the integer-
valued linear and quadratic sequences in the tables and cells, in order to construct the
spreadsheet-based functions. I inserted the headings ‘x’, ‘x(x – 1)’, and ‘x(x – 2)’ in Figure 4 in
order to allow the teachers viewing the demonstration to relate the content to their conventional
school mathematics teaching. My appeal to the teachers’ practical rationality in the given
instance was mediated by the computerisation of the school mathematics, using straight lines and
parabolas, along with a reorganisation of familiar school mathematics content. Rather than
giving a fact-oriented presentation of the various functions, my demonstration aimed at stressing
the connections between the different functions, primarily by means of adopting a ‘what if?’
approach to the subject covered. The MER mathematics discourse associated with my
instrumented actions might have resulted in the teachers asking “What kind of mathematics is
this?” Such a question is significant, because it is evidence of the uniting of the two practices –
my own as a mathematics teacher educator, and theirs as mathematics teachers. This type of
reconceptualisation of the subject, which my demonstration required the mathematics teachers to
undertake, demanded that they relinquish their traditional approach to the teaching of
mathematics. Furthermore, I am aware that the content of Figure 4 is not covered in such
assessment regimes as the Grade 12 final examinations, which is of pivotal importance to both
teachers and learners alike.

‘Mother function’ f(x) = x² + c

The practical rationality of the teachers participating in the study was shown, in relation to
their reference to the ‘mother function’, as a way of connecting with the type of MER
mathematics which they witnessed during the demonstration. I intentionally started my
demonstration with the linear function f(x) = x, with the goal of constructing quadratic functions
by means of systematically varying the parameter b. Some of the teachers expressed the opinion
that of f(x) = x² + c could be considered as the ‘mother function’ and that it could be used to
build other related quadratic functions, such as f(x) = x² – 1; f(x) = x² – 2; and f(x) = x² – 3.
Evidently, they argued from within the framework of school mathematics in the given instance,
because they explicitly referred to such a mother function as falling within the scope of the
mathematics curriculum. Their use of the mother function framework for understanding the
linear and quadratic functions which I constructed in terms of those instrumented actions which
are shown in Figure 4 was apparent. However, the ‘mother function’ with which I started my
demonstration was f(x) = x, instead of f(x) = x² + c, because I wished to stress the relations
between the functions, as well as to begin at an ‘interesting middle’, where such relations
become visible. In terms of the school mathematics framework, the two functions concerned are
characterised by curricular discontinuity. A focus on epistemologically different mother
functions might, therefore, be seen as a fruitful way in which to engage the practical rationality
of teachers.

*Learners must first know the algebra concerned before they can use the related spreadsheets*

My agreement with “[l]earners must first know the algebra concerned” rests on my
interpretation of such a statement as meaning that learners should have opportunities to see, and
to explore, straight lines and parabolas as linear and quadratic integer-valued numerical sequences, respectively. However, I hold that they should, simultaneously, be offered opportunities of exploiting the affordances of the spreadsheets. In this way, they should learn how to represent, in multiple ways, such sequences as spreadsheet-based expressions, which can be found in the work of Friedlander and Tabach (2008), among others.

Lacking evidence of what the teachers concerned meant by ‘algebra’ in the given statement, taken from a school mathematics perspective, such algebra probably was not that which is explicitly conceptualised as numerical sequences per sé. Instead, by ‘algebra’ the teachers might simply have meant straight lines and parabolas. Overall, the statement concerned highlights the challenge of engaging with teachers’ practical rationality, and especially their pedagogical beliefs, about the potential that spreadsheets offer in terms of the learning of algebra.

My demonstration was, in many ways, focused on the technological mediation of algebraic knowledge, namely functions. A necessary epistemological condition for the discovery of spreadsheets as a tool or instrument with which to learn algebra outside the classroom is that teachers have opportunities for nuancing the meaning of ‘know’ and ‘algebra’. As we saw earlier, some teachers attending the demonstration had difficulty in recognising the algebraic formulation shown in Figure 4. Whether the learners concerned actually understand the conceptual relationships between the different functions illustrated in the figure, which are numerical representations of known school mathematics, consisting of straight lines and parabolas, was explored for just under an hour with the teachers concerned. In the given case, such understanding related to coming to know what would happen if the integer values of ‘x’ and ‘b’ varied, and how ‘families of functions’ would be represented in multiple ways as a result of such variation. In terms of expert knowledge how changes in the values of ‘b’ affect $f(x) = x^2 + bx$ is ‘explicitly trivial’ (Yerushalmy, 1999). In contrast, however, such a concern is understandable when such relations are reframed from a school mathematics teaching perspective, in which context the potential for spreadsheets in algebra learning has yet to be embraced.

**Conclusion**

The findings reported on in the current paper have implications for mathematics teacher education. The interaction of my practice of MER mathematics and teachers’ practical rationality, with its roots in school mathematics teaching practice, has been demonstrated in this paper. Some of the teachers participating in the study had difficulty seeing familiar algebra in computerised form, with many conceiving of, and seeing, the connections between spreadsheet-based functions and the ‘mother function’ with which they are familiar in terms of teaching mathematics at school level. Other teachers disagreed with the role played by spreadsheets in the learning of algebra. The incomplete theoretical framework presented will, hopefully, help us to extend our thinking about how the two practices can benefit teacher, and, in turn, student, understanding of spreadsheet-based functions. The use of spreadsheets in teaching indubitably affects the teaching of mathematics at school level. The technological mediation which is provided by the use of spreadsheets allows for a new understanding of the subject in terms of generally recognisable mathematics, such as straight lines and parabolas. The three incidents explored in this paper indicate the need for a developmental approach to tool use in respect of spreadsheets in cases where spreadsheet-based discourse and the official classroom mathematical discourse align with each other. The attendant degree of skills and sophistication needs to be developed over time, with spreadsheets becoming an instrument for the learning of algebra. In

the research cited earlier in the current paper, there is ample evidence of a place for spreadsheets in optimising the understanding of such an algebraic object as functions with numerical origins. As the three data-related incidents typify the kind of responses which have been encountered in the current researcher’s ongoing meetings with teachers, much, clearly, still needs to be done in terms of making pedagogical moves to bridge the two practices concerned.

TEACHER CHANGE FACILITATED BY INSTRUCTIONAL COACHES: A CUSTOMIZED APPROACH TO PROFESSIONAL DEVELOPMENT

Erin E. Krupa  
North Carolina State University  
eekrupa@ncsu.edu

Jere Confrey  
North Carolina State University  
jere_confrey@ncsu.edu

Although professional development can help teachers become familiar with new teaching practices, changing their instructional practices is still very difficult once removed from the professional development. We present results from a case study of teachers involved in a three-year professional development designed to provide teachers with an instructional coach during the school year. Results show that teachers are able to change certain instructional practices over time and important interactions among instructional coaches and teachers are highlighted.

Introduction

Professional development is more effective at changing teachers’ instructional practices when teachers engage in the professional development with their colleagues (et al., 2002). What happens when teachers are either isolated as the only mathematics teacher at their school, or are the only teachers at their school teaching a particular course? The purpose of this paper is to report findings from one model of sustainable professional development centered on the use of an instructional coach who provided customized support for teachers as an extension of a summer program.

Theoretical Perspective

Implementing reform mathematics curricula represents a challenging transition for many teachers (Ziebarth, 2003), especially for those whose perceptions of mathematics education are grounded in traditional views of teaching mathematics. Although many view the textbook as the most important catalyst for changing what occurs in mathematics classrooms, the adoption of the curriculum alone is not likely to transform teachers’ instructional practices (Wilson & Lloyd, 2000; Arbaugh et al., 2006). Further, research has shown convincingly that teachers are not likely to change their practices by attending isolated professional developments, as they need ongoing and sustainable support (Ball, 1996; Ball & Cohen, 1999; Guskey, 2002; Loucks-Horsley, Love, Stiles, Mundry, & Hewson, 2003; Putnam & Borko, 1997; Wilson & Berne, 1999). The Principles an Standards for School Mathematics (NCTM, 2000) recommend teachers to take part in “ongoing, sustained professional development” (p. 369), but research on how to provide continuous support for the types of collaborations necessary to facilitate changes in teacher practices is limited.

In our model instructional coaches facilitate interactions among teachers and provide them with the customized support they need to make changes to their classroom practices. Ball (1996) states, “the most effective professional development model is thought to involve follow-up activities, usually in the form of long-term support, coaching in teachers’ classrooms, or ongoing interactions with colleagues” (pp. 501-502). Through an analysis of research on different types of teacher training, Joyce and Showers (2002) found that training programs which incorporate a coaching component are more effective in increasing teachers’ knowledge, skills, and transfer to practice than trainings without such a component. Presented in this paper is an analysis of the
changes teachers make through their interactions with an instructional coach and activities the instructional coach used to support these changes.

**Context**

*The North Carolina Integrated Mathematics Project*

The North Carolina Integrated Mathematics Project (NCIM) was developed to create and support a community of teachers using the *Core-Plus Mathematics* (CPMP) integrated curriculum materials particularly in high needs schools. Its aim was to educate teachers about the content and pedagogy of using integrated mathematics by creating a sustainable professional development model that could be replicated across the nation. Spread throughout the rural parts of the state, the seven partner schools were identified as low-performing (based on North Carolina accountability measures). The average student population for the project schools for the 2008-2009 school year ranged between 110 to 163 students and the ethnic make-up consisted of: 1% American Indian or Asian, 6% Hispanic, 16% White, and 77% Black. Approximately 72.8% of students at each school qualified for free and reduced lunch. The schools joined a collaboration called the New Schools Project and each had a focus on STEM (Science, Technology, Engineering and Mathematics) education. Twelve teachers were actively involved in the project, some who were the only mathematics teacher at their school. One aspect of the project was to assist rural schools in establishing statewide collaborations to address the challenges of isolation.
Four Components of the Professional Development Model

The coaching model was situated within a larger project, to prepare teachers to implement CPMP, in order to strengthen and invigorate STEM education at these schools. The goal of the overall professional development model was to improve and strengthen teachers’ mathematical content and pedagogical knowledge (Loucks-Horsley, et al., 2003). The four main elements of the professional development model (see Figure 1) included a summer workshop providing in-depth education on use of curricular materials (one or two weeks), a web-based environment supporting information exchange, two face-to-face follow-up conferences, and instructional coaches who visited each site monthly. The project had two experienced teachers as instructional coaches, who had successfully used CPMP. This type of customized mentoring has been found to be responsive to individual teacher needs (Darling-Hammond, 1997).

Methodology

Participants

The participants in this study included the two instructional coaches, Linda and Margaret, and twelve NCIM project teachers from six of our partner schools. The project has grown since its inception in the spring of 2008 to include new teachers each year and has lost two due to teacher turnover. Included in this analysis are four teachers from the spring of 2008, 8 from the 2008-2009 school year, and 10 from the 2009-2010 school year. Of the twelve teachers involved in this study, five are mentored by Margaret and seven by Linda.

Data Collection

Data were collected from classroom observations of both teachers and of their interactions with their instructional coach, semi-structured interviews with both teachers and instructional coaches, a teacher content knowledge assessment, and instructional coach reports (see Table 1). Instructional coaches completed a report after each of their site visits to document their observations and activities with each teacher. The reports provided information on the teachers’ use of time and pacing, instructional behaviors, collaborative learning, use of technology, formative assessment, and classroom management. Since the inception of the project in 2008, there have been approximately 140 reports. However, since some of the instructional coach visits occur on teacher workdays or during the summer, the majority of the results presented below are from the 89 reports in which our classroom observation protocol was used.

Analysis

Since multiple sources of data were collected, detailing a “bounded system” over time, a case study was an appropriate method for this analysis (Creswell, 1998). Teachers were nested in different schools and assigned one of two different instructional coaches, thus an embedded analysis (Yin, 2008) was used to track changes in teachers’ instructional practices over multiple units of analysis. Further, to determine which activities and behaviors seem to promote or detract from teacher growth overtime an analysis was also conducted across both instructional coaches.

Results

The Activities of the Instructional Coach

During the course of the project, the research and implementation team developed a listing of activities that mentors could engage in with teachers, helping them improve their instruction. The list was first brainstormed by the team and then revised in light of the first year instructional coach reports. The activity list then served as the basis for the reports to produce data on the relative frequency of the different activities. The broad categories for reporting are: (1) Curriculum and content assistance (2) Lesson planning, enactment and reflections (3) Assessment, feedback and grading, and (4) Professional community interactions.

Once the categories and subcategories (see Table 3) were identified all reports of the content specialists were reviewed, and each time a behavior in the list was reported, a single instance was marked at the level of sub-categories. At the level of the categories, all tallies were totaled and the ratio of the tallies for that category to the total number of tallies for all categories was reported as a percentage (see Table 2). This yielded the results of the relative percent of instructional coach reports of distinct activities that fell into each of the four categories; percentages were also determined for each of the instructional coaches.

Then within each category, we report the ratio of the number of tallies per subcategory in relation to the total reports for that category as a percentage. This permits gauging the relative frequency of each of the subgroups within the category (Table 3).

Within the lesson planning category, Linda was more likely to model teach during her site visits. In an interview, Linda noted her favorite activities to engage in with teachers were model teaching and helping small groups, as she enjoyed student interactions. Her enjoyment of model teaching is evident from the activity list where she model taught about 22% of the time she was engaged in activities from the lesson planning category. Another activity that Linda performed more often than Margaret was promoting professional interactions (30.90%), and within this category she worked on developing collaboration with other STEM teachers (27.27%). Not only had Linda encouraged teachers to become model teachers for beginning teachers at their school, but Linda also took teachers that were isolated, as the only mathematics teacher at their schools, to observe teachers in other districts who had experience teaching CPMP.

Almost sixty percent of the activities Margaret engages in with the teachers were within the lesson planning, enactment, and reflection category. When Margaret was asked to explain her experiences as an instructional coach she replied, “It depends on the classroom I am in. Sometimes [I] interrupt group discussions and clarify content or go up to the board and help teach. Some teachers really just want me to sit and watch and give them feedback.”

A big focus Margaret had was customizing the professional development based on the needs of each individual teacher, while trying to improve their whole-class discourse strategies (24.59% of the lesson planning category). During the 2009-2010 school year she reported progress in four out of five teacher’s whole-class discourse. In one of her reports she noted, “I observed the teacher asking for more than the correct answers, asking students for reasoning. She allowed the students to do more of the explaining than last year.” And yet another she reported, “Students were engaged while working in groups and discussing things as a class…I have seen this teacher develop this over the last few years with these students.”

**Time Spent With the Instructional Coach**

On average instructional coaches spend approximately 120 minutes with each teacher during each visit, with a range from 15 to 240 minutes. The average amount time instructional coaches spent with each teacher is consistent for each year of participation in the project (see Table 4). Further, Linda and Margaret spend about the same amount of time at each site, 116 minutes and 127 minutes respectively.

</tr>
</tbody>
</table>

There is a wide discrepancy in the range of time instructional coaches spent with each teacher. Linda reported both the minimum and maximum times from her observations with Maria, who has received an instructional coach for two and a half years. Maria has made major changes to her teaching practices, which she attributes to the support of Linda and to her attendance at the workshops. One of her greatest accomplishments has been her transition to a facilitator in the classroom, and she points out that to get students to rely on one another she “goes around the asking them questions and every time they ask me a question, I ask them another question.” At the beginning of the 2009-2010 school year Linda spent 240 minutes helping Maria prepare to teach a new course, the third course in the CPMP sequence. A week later, two new teachers joined the staff at Maria’s school, both unfamiliar with reform mathematics and one with a language barrier. Linda consulted with the principal at the school and determined that she should spend more of her time with the two new teachers. While she still spends time in Maria’s classroom and communicating with her via email, Linda is confident in Maria’s growth that during one site visit she only devoted 15 minutes to observing Maria.

**Teacher Change Overtime**

*Time management.* Time management and pacing had become a tremendous concern for teachers and instructional coaches at the end of the 2008-2009 school year. Many teachers did not complete the final chapters of their textbooks before state assessments and others skipped crucial chapters in the middle of the book because they felt the sections were unimportant. During the 2009 Summer Workshop eight hours were reserved for long-term planning and there was a mini-afternoon session devoted towards effective time management strategies.

Using the observation protocol, instructional coaches report if time was used effectively for what the class needed. Instructional coaches respond on a 1 (ineffective or inappropriate) to 4 (effective and appropriate) scale, where the average effective time index for all project teachers is 2.87 (see Table 5). Further analysis showed that the longer teachers are involved in the NCIM project, the more effective they utilize class time.

### Table 5. Average Effective Time Index

</tr>
</tbody>
</table>

*Pacing.* Instructional coaches also report if a teacher is on pace for the year. Separated by instructional coach, Table 6 indicates the percentage of teachers that were adhering to pacing guides they developed with their instructional coach. The differences between the pacing of teachers involved by instructional coach are surprising. The teachers Margaret coaches have a much higher percentage of being on pace for the year than Linda’s teachers. There are two explanations for this discrepancy. First, based on a separate analysis of the instructional coach reports, Margaret reported in 28 of her 37 reports that she discussed daily lesson planning and in 29 of her 37 reports she discussed long-term pacing. Whereas Linda only devoted 24 of her 52 visits to daily lesson planning and 22 to long-term pacing. Second, Margaret made eight visits (to four teachers) before the beginning of school for planning sessions with teachers, whereas Linda...
made only three visits (to three teachers) before school was in session. During these visits Margaret helped teachers develop pacing guides for the entire year. The upfront time Margaret committed to long-term pacing resulted in having the higher percentage of teachers on pace.

</tr>
</tbody>
</table>

Content Knowledge. A content knowledge assessment is given at the beginning and end of each Summer Workshop to measure teachers’ knowledge of mathematics. Initial results (see Table 7) are disheartening, however teachers show marked improvement at the conclusion of the workshop. On the observation reports when asked what assistance teachers need, instructional coaches most frequently respond that teachers need content support. Instructional coaches also report on the content delivery quality of teachers they observe.

<td>60.27%</td>
<td>10.55</td>
</tr>
</tbody>
</table>

Below is part of an interview transcript where Margaret discusses the difficulties she sees in teachers’ content knowledge:

Margaret: She does really good stuff, but she has trouble with the content and when I’m there that’s what we talk about. I very rarely talk about what happened in class that day. Except if it’s affecting the content. We talked about how her warm-up took a really long time this time, but only because she isn’t going to cover all her content if she sets her classroom up like that.

Interviewer: Is it strange for you to talk to teachers about content when they are math teachers?

Margaret: NO, because I see how weak they are! I’ve seen all of them make math mistakes.

Longitudinal results show that the longer a teacher was involved in the project, the more accurate they delivered content during (see Table 8). These results are encouraging for positive teacher change overtime, as inaccurate content delivery decreases and accurate content delivery increases with each additional year teachers are a part of the NCIM professional development.

Formative Assessment. A final topic examined based on the analysis of the instructional coach reports was how often teachers recognized when students were lost or misunderstood mathematics content (see Table 9). Formative assessment was an important component of the 2009 Summer Workshop based on an early evaluation of the instructional coach reports that highlighted a need for teachers to monitor and assess student progress. By their third year, 60% of project teachers began to frequently recognize when students had a misunderstanding about mathematics and another 20% occasionally noticed when students were confused or lost (the 20% that never recognized was one teacher who only attended week one of the workshop).
findings suggest teachers are more likely to consistently employ formative assessment measures based on the number of years they participate in the project.

**Discussion**

A model of professional development that has helped teachers in our project transition to teaching reform mathematics is to provide them with an instructional coach. Over time, by incorporating reports from instructional coaches and suggestions from teachers, project directors created a professional development in the context of teachers’ classrooms that allowed them to make changes to their instructional practices. This type of coaching is aligned with Guskey’s (1999) argument that “professional development is an ongoing activity [which should be] woven into the fabric of every educator’s professional life” (p. 38) (our parenthetical added).

The embedded analysis presented throughout this paper is evidence that when provided with support, teachers are able to transfer the knowledge and skill that were learned from the collaborations with an instructional coach and during the workshops into practice. Though not all participating teachers experience the same level of success, findings show the long-term benefit of working one-on-one with an instructional coach. It is also important to realize the changes in instructional practices were gradual and the treatment with the instructional coaches took time and were influenced by the types of activities teachers engaged in with their coach.

NCTM standards specifically call for instructional programs that enable all students to make and investigate mathematical conjectures as well as develop and evaluate mathematical arguments and proofs (NCTM, 2000).

Hanna (2000) argued that school mathematics must reflect the range of functions proof serves in mathematics to include proof as verification, explanation, systemization, discovery, and communication. However, as Hanna noted these functions might take on different levels of importance in the classroom where the key role of proof is to promote student understanding. Similarly, we argue that a conceptualization of mathematical justification in PD must be situated in the work of teaching and the purposeful development of mathematical knowledge for teaching (Ball, Thames & Phelps, 2008). The teacher learning goals might include providing teachers with explicit knowledge of proof and its role in the mathematics discipline. PD might also target the development of a more unpacked understanding of justification (or specialized content knowledge) so that teachers might recognize the strategies students employ in justifying algebraic ideas or the assumptions that underlie a students’ empirical argument.

In this poster, I present a framework for considering the purpose of justification in mathematics professional development that couples research on the role of justification and proof in the mathematics discipline and mathematics education with Ball and colleagues’ elaboration of the mathematical knowledge needed for teaching (Hanna, 2000; Ball et. al, 2008). Examples from a current research and development project with math teacher leaders illustrate how this framework was elaborated to analyze leaders and teachers’ understandings of justification and its use in teaching. This work thus begins to address the question of what teachers need to know or learn about justification in order to meet the current vision of reform and what this might then demand of PD leaders.

Researching Mathematics Leader Learning (RMLL) is a two-phase research and development project investigating leaders’ understandings and practices associated with developing mathematically rich learning environments for teachers. We illustrate how our framework and design evolved to focus on developing teachers’ specialized content knowledge (SCK) as a key purpose for engaging in mathematics during professional development (PD). The project began with a framework for leader learning based on sociomathematical norms (Yackel & Cobb, 1996) and practices for orchestrating discussions (Stein, et al., 2008). Analyses of data from Phase I focused on how leaders made sense of these constructs in seminars and how they took up these ideas in their own facilitation. These analyses led us to more fully explicate purposes for doing mathematics in PD and distinguish how mathematical work with teachers can and should be different from work with students (Kazemi et al., 2009). In particular, we found that the purpose for doing mathematics in PD was underspecified and needed to link to developing teachers’ mathematical knowledge for teaching (MKT) as described in the work of Ball and colleagues (2008). Based on these findings, we made significant revisions to seminars in Phase II. Our current design and research frames mathematics tasks to orient leaders to SCK, considers the negotiation of sociomathematical norms for developing teachers’ MKT, and outlines practices for facilitating mathematical work in PD.

We examine tasks and consider the facilitation work in explicating mathematics that unpacks key concepts and practices such as mathematical models for operations and mapping across representations to explore change. Given that a purpose of developing teachers’ SCK is a relatively new idea in PD, it is important to consider what this mathematical work might entail and how to research this endeavor.

INTRODUCING IMPULSIVE DISPOSITION VIA MATH PROBLEMS

Samten Wangchuk
University of Texas at El Paso
swangchuk2@miners.utep.edu

Kien H. Lim
University of Texas at El Paso
kienlim@utep.edu

In solving mathematics problems, “doing whatever first comes to mind … or diving into the first approach that comes to mind” (Watson & Mason, 2007, p. 307) is commonly observed among students. Lim, Morera, and Tchoshanov (2009) use the term impulsive disposition to refer to students’ proclivity to spontaneously proceed with an action that comes to mind without checking its relevance. We believe that math teachers should be aware of this undesirable habit of mind so as to not reinforce this habit in their classrooms. The information presented in this poster presentation was based on a 2.5-hour workshop conducted for a larger study that was aimed at testing a survey for assessing problem-solving disposition along the impulsive-analytic dimension. The objective of the workshop was to introduce impulsive and analytic dispositions to a group of 27 in-service and 10 pre-service teachers by allowing them to experience their own disposition via solving three math problems. The three problems were designed to elicit impulsive disposition. The first problem involves inferring the value of speed at a particular instant from a distance-time graph involving only linear segments. Participants with an impulsive disposition tended to apply the $r = \frac{d}{t}$ formula ($d$ on the graph represents distance from home and $t$ represents number of minutes passed). The second problem begins with “Suppose $p$ kilometers is equal to $q$ feet” and then asks which statement is correct: $p > q$, $p < q$, or $p = q$. The third problem is “Jorge is offered a raise if he can increase his weekly productivity by 15%. If Jorge works a five day week, how much does he need to increase his productivity each day?” Participants were asked to write their reasoning prior to voting their answers via clickers (personal units for a classroom response system).

Participants’ answer choices were tabulated, written responses were analyzed, and solution strategies were identified. For example, 22 of the 37 respondents chose 3% each day for the third problem; their strategy of dividing 15% by 5 was considered an indicator of impulsive disposition. When polled about the lesson, about 96% of the participants scored a 4 (agree) or 5 (strongly agree) that the lesson was interesting, and was valuable. Participants’ written comments about what they had learned from the workshop included “don’t go for the first idea without attending to meaning,” “read the problem carefully and understand the wording before we answer,” and “mathematics cannot be solved by using formula but using logic.”

This paper examines the effects of the first year of a two-year project to investigate formative assessment in a networked classroom. Participants were divided into two groups; one group receiving professional development on formative assessment with networked technology while the second group received professional development only on formative assessment. Data were gathered on participants’ knowledge of formative assessment, teacher pedagogical content knowledge, mathematics background, and attitudes toward technology. Student data were collected and analyzed to examine the effects of teacher variables on student achievement.

Introduction

Past studies indicate professional development (PD) was the difference between teachers using technology to emphasize critical-thinking and problem-solving skills versus skill and drill (Wenglinsky, 1998; Brannigan, 2002). Thus, PD for integrating technology into the teaching of mathematics must include a strong focus on pedagogical approaches that have potential for impacting learning. This paper describes two models of PD for formative assessment and classroom-connected technology and reports on results from the first year of implementation. Building upon theory and practice that showed positive outcomes, Project FANC (Formative Assessment in a Networked Classroom) was designed to address concerns raised about both the use of formative assessment and integration of technology. Teachers, recruited from 15 middle schools, were assigned to two models of PD. Each group participated in a five-day summer PD with five follow-up sessions during the school year along with in-school coaching. The design of both models took into consideration that one of the most salient characteristics of effective PD is providing teachers with opportunities to work with colleagues, both in their school building and beyond, giving them opportunities to learn from one another’s successes and failures and to share ideas and knowledge (National Center for Research on Teacher Learning, 1995).

Theoretical Framework

Connected Classroom Technology

In How People Learn (NRC, 1999), one of the most promising technology-based innovations noted for transforming the classroom environment was the use of networks. In prior research on the implementation of a networking system, the use of TI-Navigator was found to support the development of a collaborative classroom environment by enhancing student interactions, focusing students’ attention on multiple responses, and providing opportunities to peer- and self-assess student work. The ability to display class data or responses supports a problem-solving approach to developing skills and concepts (Dougherty, Akana, Cho, Fernandez, & Song, 2005;
Mackay, Olson & Slovin, 2006). One of the most promising uses of TI-Navigator is its potential to overcome a significant hurdle to improving formative classroom assessment: the collection, management and analysis of data (Roschelle, Penuel, & Abrahamson, 2004). While feedback loops in a regular classroom are slow, classroom networked technology can provide rapid cycles of feedback in real time. Beaty and Gerace (2009) remind us that technology is a tool and that pedagogical approaches aid or impact learning. Yet, although Owens, Demana, Abrahamson, Meagher & Herman (2004) found teachers in TI-Navigator classes perceived as more responsive to individual needs, more focused on knowledge building and assessment, and more community centered, they may not have changed their instruction based on information obtained.

There are four distinct, intertwined, functions of the TI-Navigator system particularly helpful for implementing formative assessment: 1) Quick Poll—to immediately collect and display all the students’ answers to a question; 2) Screen Capture—to monitor individual students’ work at anytime; 3) Learn Check—to administer quick, frequent formative assessments and provide timely feedback; and 4) Activity Center—allowing students to work collaboratively to contribute individual data to a class activity. While these tools are directly appropriate for formative assessment, teachers who may make significant changes in the use of technology in their classes do not necessarily make full use of the potential of the connected classroom for formative assessment (Owens, Pape, Irving, Sanalan, Boscardin, & Abrahamson, 2008).

**Formative Assessment**

Similarly, evidence has shown that appropriately implemented formative assessments can produce substantial learning gains at various ages and across subjects (Black, Harrison, Lee, Marshall, & Wiliam, 2004; Black & Wiliam, 1998b; Wiliam, Lee, Harrison, & Black, 2004). Black and Wiliam defined “formative assessment” as “all those activities undertaken by teachers, and/or by their students, which provide information to be used as feedback to modify the teaching and learning activities in which they are engaged” (p. 7). Formative assessment for learning includes activities such as questioning, discussion, seatwork, and student self-assessment. Teachers’ preparation in assessment is often non-existent and teachers’ content knowledge may be insufficient for deep understanding of concepts and principles they teach and assess (Heritage, 2007). Moreover, Heritage suggests that while there is no best way to carry out formative assessment, assessment and teaching are reciprocal activities, and need to be firmly situated in the practice of educators. Black and Wiliam (1998a) demonstrated that formative assessment improves student achievement if it guides changes in day-to-day practice. Shavelson, Yin, Furtak, Ruiz-Primo, Ayala, & Young (2006) classified formative assessment techniques into three categories on a continuum based on the amount of planning involved and the formality of technique used: 1) on-the-fly formative assessment, when teachable moments unexpectedly arise; 2) planned-for-interaction formative assessment, used during instruction but prepared deliberately before class to align with instructional goals; and 3) formal and-embedded-in-curriculum formative assessment designed to be implemented at the end of a unit of instruction to ensure students reach important goals before moving on. Despite their variety, when formative assessments are used, common steps are explicitly or implicitly involved: 1) determining achievement goals students are expected to reach—the expected level; 2) collecting information about what students know and can do—the actual level; 3) identifying the gap between the actual level and expected level; and 4) taking action to close the gap.

Many formative assessment strategies, however, are challenging because they take too much time to be used practically (Black & Wiliam, 1998b). It is time-consuming to count students’
responses, and almost impossible to provide specific feedback on each student’s work in a
typical teaching load of four to six classes and 20 to 30 students per class. Even if teachers
believe the time investment for formative assessment will yield reward in the future, Black and
Wiliam (1998b) noted that teachers’ work loads are often overwhelmed by agendas and
dominated by district curriculum specifications and high-stake tests.

Methodology

Project FANC is a three-year research project funded by the National Science Foundation to
investigate the use of formative assessment in a networked classroom as it affects 7th grade
student learning of algebra concepts. Thirty-two teachers from 15 schools were recruited and
randomly assigned within schools to the Formative Ssessment (FA) or Navigator (NAV) group.
This randomized-block design helps control for extraneous variables, such as student background
and school context (e.g., teachers’ work load, curriculum, class equipment, and community
support). In the first year of the project, students’ understanding of algebraic concepts taught by
7th grade teachers participating in the NAV group were compared to students’ understanding of
algebraic concepts taught by 7th grade teachers participating in the FA group.

While Project FANC provided PD to participants over a two-year period, only the first year
of the PD is described since results are being reported only for that period. Input from the eight
Advisory Board members along with numerous articles on PD, formative assessment, technology
and related topics (Ayala & Brandon, 2008; Black & Wiliam, 1998a, 1998b, 2005; Gearhart, &
Saxe, 2004; Guskey, 2007/2008; Wiliam, Lee, Harrison, & Black. 2004) were taken into
consideration to design the two models of PD. The formative assessment model (Stiggins, Arter,
Chappuis, & Chappuis, 2004, p.42), questioning strategies, and rich mathematics activities were
essential components in both PD experiences, although the actual delivery and focus varied. The
PD models delivered to two groups, FA and NAV, are briefly described below.

FA teachers participated in five days of PD on strategies for using formative assessment in
their classrooms (not using TI-Navigator). In addition, five follow-up days and coaching were
conducted throughout the academic year. The formative assessment model, questioning
strategies, and mathematics activities focused on designing appropriate tasks where students
could demonstrate thinking. In-depth discussions were held on techniques to analyze student
work and interpret results in terms of revealing student understanding. FA participants were
provided with opportunities to examine tasks and lessons and discussed how the tasks fit
expected learning progressions. Participants worked on selecting and modifying tasks using
processes of reversibility, flexibility, and generalization to deepen students’ understanding of
content. Ideas on creating a learning environment that included an assessment conversation with
student-to-student interactions were shared with participants. At follow-up sessions, participants
shared progress on implementation, examples of student work, and changes in the classrooms
climate and were given opportunities involving classroom activities and questioning strategies.

NAV teachers participated in five days of PD on formative assessment and strategies for
using TI-Navigator in their classrooms. In addition, five follow-up days and coaching were
conducted throughout the academic year. The formative assessment model, questioning
strategies, and activities were connected to the use of TI-Navigator. Significant time for hands-
on experiences with TI-Navigator was provided. As participants practiced using handheld
technology and TI-Navigator, emphasis was on creating and choosing good tasks and asking
good questions. The PD focused on the ‘added value’ of handheld technology in a connected
classroom. During follow-up, participants shared how they implemented formative assessment with TI-Navigator and discussed troubleshooting tips and changes in classroom climate.

At the beginning of the project all participants were given MacBook laptops, LCD projectors, Elmo visualizers (document cameras), and a classroom set of TI-73 graphing calculators. NAV participants were provided TI-Navigator Systems for their classrooms.

**Data Collection**

The results in this paper focus on student growth in achievement on a student assessment of algebraic concepts with a focus on patterns and relations, teacher’s responses on questionnaires, and assessment of teachers content knowledge. A student assessment was developed to determine the extent to which participating students showed pre-post gains after implementation of the intervention. As much as possible, algebra items were drawn from existing sources such as state assessments and released NAEP, TIMSS, and SAT items. Items were reviewed for content, perceived alignment with the project’s target content, perceived difficulty, and quality (e.g., clarity of item stems, etc.). Eighty-five items were selected from these sources. Once standards and knowledge levels were reconciled, items were selected for pilot testing. Two versions of a pilot-test were created from 48 items and piloted with over 1000 students in Grades 7 and 8. Item Response Theory was used to select items included on FANC Student Assessment.

To measure the growth of participants’ content knowledge for teaching (CKT), the University of Michigan’s *Learning Mathematics for Teaching* (LMT) instrument was administered at the beginning of the summer institute in year one, and then again after one year of participation. The LMT measures have been shown to be a significant predictor of student achievement (Hill, Rowan, & Ball, 2005). Teacher data were collected with three instruments that were developed for the study: a) the Teaching Practice and Perceptions Questionnaire includes two scales about teacher collaboration and four about teacher support; b) the Assessment Knowledge, Self-Efficacy, and Practice Survey includes four scales about assessment knowledge (assessment in general, student learning, subject content, and formative assessment) and one about teacher self-efficacy in using formative assessment; and c) Using Technology Questionnaire includes four scales about teachers’ perceptions of using technology.

**Results**

*Proposed Model*

The analysis reported here is for 23 participants (FA (11), NAV (12)) for whom complete student data (1,629 students) was collected. A two-level hierarchical model (Luke, 2004) included one student covariate, the pretest score, and eight teacher variables. The six continuous variables included: a) teacher pretest score (labeled “TeaPre”); b) teachers’ years of teaching experience (“TeaExp”); c) teachers’ efficacy in formative assessment (“FAefficacy”); d) teachers’ efficacy in technology (“TCHefficacy”); e) teachers’ perception about their students’ motivation (“StuMotiv”); and f) teachers’ perception about overall support from school, colleagues, parents, and students (“Support”). The two discrete variables included a) the experiment group (FA vs. NAV) and b) teachers’ mathematics or mathematics education major (major and minor vs. no math background in university, labeled “NoMath” and “Math”).

The level 1 units were students taught by teachers who participated in FANC. The level 2 units were the teachers in FANC. Multilevel modeling was conducted using SAS PROCmixed, Version 9. At the student level, the intercept was the only random component. A model in which the student pretest score was entered as a random variable failed to converge; therefore, the
decision was made to treat the covariate as fixed effect. No interactions were hypothesized at the teacher level. Interactions between the level 2 predictors as well as between the level 1 and level 2 predictors were not significant. As anticipated, the interaction effect between the pretest score and the experiment group was not significant. This means students’ pretest scores did not differ across the FA and NAV groups. Another interaction effect between the pretest score and teachers’ mathematics education was also not significant, suggesting students’ pretest scores did not differ by whether teachers had mathematics education in undergraduate and/or graduate schools. Based on these preliminary examinations, the following model is proposed:

Level 1:
\[ Y_{ij} = \beta_{0j} + \beta_1 (\text{Pre}) + r_{ij}, \]
where \( r_{ij} \sim N (0, \sigma^2) \), \( \beta_{0j} \) a random intercept for a teacher \( j \), \( \beta_1 \) a fixed slope of students’ pretest scores, and \( r_{ij} \) random error associated with student \( i/teacher \) \( j \).

Level 2:
\[ \beta_{0j} = \gamma_{00} + \gamma_{01} (\text{TeaPre}) + \gamma_{02} (\text{ExpGp}) + \gamma_{03} (\text{MathBack}) + \gamma_{04} (\text{TeaExp}) + \gamma_{06} (\text{FAefficacy}) + \gamma_{07} (\text{THefficacy}) + \gamma_{08} (\text{StuMotiv}) + \gamma_{09} (\text{Support}) + \mu_{0j}, \]
where \( \mu_{0j} \sim N (0, \tau_{00}) \), \( \gamma_{00} \) the grand mean of students’ posttest scores, \( \gamma_{0k} \) the slope of the variable \( k \) where \( k=1,2,..,8 \), and \( \mu_{0j} \) the random deviation of students’ mean posttest score of teacher \( j \) from the mean.

**Preliminary Analysis**

Table 1 presents descriptive statistics for student pretest and posttest scores. Table 2 presents descriptive statistics for six continuous variables in the model at student and teacher levels.
The initial step of the multilevel analysis was to examine the unconditional means model to ascertain whether the data warranted a multilevel model. Estimated variance at teacher level ($\tau_{00}$) was found to be 18.330 ($p<.01$), and estimated variance at the student level ($\sigma^2$) was 42.624 ($p<.01$) in this null model. Hypothesis tests indicated that both variance components were significantly different from 0. These estimates suggest students’ scores differ among teachers in average posttest scores, although there is more variation among students within the teachers than between teachers. The intra-class correlation, 0.301, shows that about 30% of the total variance occurs at the teacher level—a substantial proportion. This cluster of variability between different teachers’ students’ scores suggests that an OLS analysis of these data would likely yield misleading results.

**Random Effects**

This proposed model was significantly better than one in which the intercept was included at the initial step, $\chi^2 (9) = 10790.422 - 6891.167 = 3899.255$, $p< 0.01$. Table 3 presents random effects at level 1 and level 2. The conditional component representing variation among students’ scores within the teacher level ($\sigma^2$) decreased from 42.624 in the unconditional means model to 20.484 ($p<.01$) after including the student level covariate, student pretest score. This indicated that inclusion of this student pretest score explained about 52% ($\frac{42.624 - 20.484}{42.624} = 0.519$) of variation within teachers. Even though the students’ variation within the teacher level was substantially explained by student pretest score, the significant random variation of 20.284 shows possibilities to explain the remaining random variation using other student level variables.

The variance component representing variation between the teachers ($\tau_{00}$) drastically decreased from 18.330 in the unconditional model to 3.369 ($p<.05$) after controlling for the student and teacher level covariates. The predictors included in this proposed model explained substantive amount of variation in students’ posttest scores at the teacher level. The intra-class correlation was 0.155, meaning that the proportion of between teacher variance to the total variance was 15.5% after controlling for the predictors. The change of intra-class correlations from 0.301 in the unconditional means model to 0.155 in the proposed model also demonstrates that the teacher level predictors explained well the variation of students’ posttest scores at the teacher level. Even though these results showed the random variations at the student and teacher levels were substantially explained by the predictors, the remaining clusters of variability at the teacher level as well as at the student level warrants further development of the multilevel model.

**Fixed Effects**

Table 4 shows results of hypothesis tests for fixed effects of student level and teacher level predictors. The fixed effect of students’ pretest score was significant after controlling for the teacher level predictors. One of the variables of interest was Group, indicating whether a teacher...
belonged to the FA or NAV group. The student posttest mean in the FA group was 3.462 points higher than that of NAV group after controlling for the students’ pretest scores and other teacher background variables. Teachers’ knowledge in the subject content was a significant predictor. When a teacher scored 1 point higher in the pretest, their students achieved 0.448 higher points after the influence from the other variables was partitioned out. Teachers’ years of experience in teaching and mathematics education did not significantly influence students’ achievement.

The variables asking the teachers’ perceived efficacy in formative assessment and in technology use were not significant, nor was the teachers’ perception about their students’ motivation in class a significant predictor, after taking into account the other student and teacher level predictors. Finally, teachers’ perception about overall support from school, colleagues, parents, and students showed a positive effect on students’ achievement. Teachers who differ by 1 point in their perception about overall support differ by 3.041 points in students’ achievement.

Conclusions and Discussions

The purpose of the study was to use Year 1 data to examine if students' achievement in the FA and NAV groups was different, after taking into account students' pre-test scores and teachers' initial statuses such as their knowledge, teaching experiences, efficacy, and content knowledge for teaching. Student’s understanding of patterns in the FA group was significantly better than students in the NAV group. The teacher variables that significantly affected the students' achievement on the post-test were the teacher’s content knowledge and the support from the school, parents, and students. Data from nine of the 32 Project FANC participant’s student data were not included in the analysis because they were involved in the pilot testing of the student assessment. However there were no significant differences on the teacher variables between the 9 teachers and the 23 teachers who were included in the analysis. While PD can be designed to increase teacher’s content knowledge, support from the school, parents, and students is a much larger issue. During Year 2, the FA group will have PD experiences with using TI-Navigator for formative assessment and the NAV group will have a continuation of PD using the Navigator for formative assessment with more emphasis on formative assessment strategies. Extensive analysis of Project FANC will be completed at the end of Year 2.

Endnotes

1. The research reported in this paper was generated through The Effects of Formative Assessment in a Networked Classroom on Student Learning of Algebraic Concepts (DRL 0723953) funded by National Science Foundation (NSF) REESE program. The views expressed in the article are views of the authors and do not represent the views of NSF.

2. TI-Navigator™ is a networking system developed by Texas Instruments that wirelessly connects each student’s graphing calculator to a classroom computer.

This on-going design-based research study focuses on Grade 4-6 students’ guided task-based interaction with a novel computer-based hand-tracking system built to suggest the limitations of naïve additive schemes and create opportunities to develop core notions of proportionality as elaborations on these schemes, even before engaging numerical semiotic forms. Study participants struggled with canonical issues inherent to rational numbers. They formulated a string of insights leading up to a new type of equivalence class. Reported as a case study of Itamar, a 5th-grade middle-achieving student, our analyses reveal emergence of conceptually critical mathematical meanings in an activity that initially bears little mathematical significance.

Introduction

This paper draws on empirical data elicited in the context of an ongoing design-based research project that aims to foster and investigate Grade 4-6 student learning of the fundamental notions of ratio and proportion (Abrahamson & Howison, 2010). Drawing on grounded cognition theory (Barsalou, 2008), we conjectured that the enduring conceptual difficulty students experience with proportional reasoning (e.g., Lamon, 2007) may arise in part because everyday experience rarely affords opportunities to engage these quantitative notions sensomotorically; thus, students lack appropriate embodied experiences from which to construct the key concepts upon simulated dynamic imagery. Accordingly, we sought to engineer for students an embodied-proportion experience conductive to constructing these targeted concepts.

The particular experience designed for the study involved a non-routine activity—the student used two handheld devices, one in each hand, to remotely manipulate the vertical positions of two virtual objects displayed on a large monitor (see Figure 1). Unbeknownst to the student, the apparatus compared the ratio preset by the experimenter on a hidden monitor, e.g., a 1:2 ratio, to the ratio between the measured heights of each of the two handheld devices above the desk, e.g., 20 cm and 30 cm, respectively—a 2:3 ratio. The display’s background color provided feedback to the student on how closely the performed ratio matched the unknown ratio, with red indicating “incorrect,” yellow indicating “almost correct,” and green indicating “correct.” Students were tasked to “make the screen green” but were given no direction as to how to accomplish this task.

Students’ guided inquiry into this mystery apparatus was designed to give rise to a succession of insights into the mathematical principles that covertly governed the automated feedback pattern they experienced as they manually explored the problem space. So doing, we expected, students would initially bring to bear naive “additive” reasoning and then cope with cognitive conflicts engendered by such contextually inappropriate reasoning. For example, students might expect the within-pair vertical distance to be constant across all “green” location pairs; therefore, once they found their first green location, they would tend to “lock” the vertical distance between

their hands and raise this fixed-difference hand pair, only to see the green screen turn red; surprised, the students would then attempt to account for this anomaly by formulating and testing rules and strategies to enable the determination and enactment of further “green” locations. Thus, students were to reinvent core notions of proportionality by attempting to master an unknown computational function embodied in emergent features of an interactive apparatus.

Our rationale was that the color green, an arbitrary perceptual stimulus, would initially constitute for the student an objective, then serve as the student’s source of performance feedback while attempting to achieve that objective, and would ultimately give rise to an equivalence class—a collection of hand-location pairs which the student perceives as “the same” by virtue of their common effect on the screen. By subsequently introducing discursive prompts, measurement overlays, and representation templates, we hoped to guide students toward articulating mathematically principles governing this initially opaque yet gradually emerging class.

The above design-based research study serves in the current paper as an empirical context for examining the following pair of related questions on the nature of mathematical learning: (1) Can students develop mathematical meanings, signs, and concepts through engaging in a task that initially does not cue mathematical treatment as relevant to the solution of a problem, and if so, how?; (2) From the perspective of pedagogy and instructional design, what personal resources, technological artifacts, and discursive mechanisms could possibly give rise to mathematical meanings under circumstances of ostensibly a mathematical problems? These questions appear germane to the PME-NA 32 theme, Optimizing Student Understanding in Mathematics.

We sought to explore our research questions by analyzing videographed footage from a set of individual-student task-based clinical interviews, in which a protocol structured their interactions with the mystery device. As we report below, analyses of these sessions suggest that students constructed the targeted mathematical principles through engaging in the guided activity. In the conclusion we will advance a tentative assertion that, given appropriate materials, activities, and facilitation, students can tackle canonically difficult aspects of mathematical concepts while still engaged in presymbolic quantitative reasoning. Specifically, we submit, students learning the subject matter of proportions can become aware of their own inclination to reason in terms of additive-only rather than multiplicative relations and, moreover, begin to juxtapose and reconcile these two basic types of quantitative reasoning even before inscribing mathematical expressions.

Background

The ongoing investigation reported in this paper draws on two theoretical perspectives of current interest in the mathematics-education research literature—embodied cognition and semiotic mediation—and seeks to explore relations between them. Our attention to the role of

---

embodied action was inspired by grounded cognition theory (Barsalou, 2008), a rising cognitive-sciences paradigm that resonates well with genetic epistemology (Piaget, 1968), phenomenology (e.g., Husserl, 2000), and the construct of tacit knowledge (Polanyi, 1967; see also Varela et al., 1991, on enactive cognition). Grounded cognition rejects earlier notions of the mind as an information processing machine operating separately from the body’s sensorimotor systems. Rather, perception, kinesthesia, and cognition are viewed as functionally linked, because reasoning consists of simulating fragments of embodied experiences. Quantitative reasoning, too, is thus necessarily grounded in sensorimotor experience (c.f. Lakoff & Núñez, 2000). It follows, we argue, that mathematical notions may differ with respect to the learning challenges they present to students as contingent on the everyday availability of embodied experiences that form the concepts’ simulation substrate, so much so that in the absence of appropriate embodied experiences, students may be disadvantaged in developing grounded understandings of certain mathematical content. Specifically, we view the notion of ratio as “conceptually ambidextrous”; that is, the embodied substrate of a ratio, interpreted as isomorphism of measures (Vergnaud, 1983), could simulate the simultaneous enactment of two changes, such as the dynamic co-production of two hand gestures, a slower and a faster one. We conjecture that proportionality is challenging to students conceptually (see in Davis, 2003) in part because everyday experiences rarely if ever afford opportunities to perform and practice such actions physically as requisite of developing an embodied artifact that could then be leveraged to mathematize proportion.

Accordingly, the Kinemathics activity has been designed with the explicit goal that students construct what we call an embodied artifact as an object-to-think-with—an externally induced coordinated physical action that, similar to the embodied cultural legacy of martial arts, dance, or instrumented musical performance, students learn to perform even before, yet as a condition for, developing disciplinary meanings. Indeed, the semiotic potentials (Mariotti, 2009) of physical discursive action performed in the context of math instruction have been broadly demonstrated in gesture studies (e.g., Goldin–Meadow, Wagner Cook, & Mitchell, 2009). Our interest in such action-before-concept learning (ABC) is part of our larger inquiry into cultural precedence for pedagogical practice within explicitly embodied domains, wherein procedures are initially learned on trust yet subsequently—only toward perfecting the procedures toward mastery and further dissemination—are interpreted by experts as encoding emergent disciplinary knowledge.

The materials and protocol designed for this study, and in particular the initial absence of explicit mathematical signs in the core activity, appear to create an amenable empirical arena for studying artifacts and teachers’ inter-connected roles in the semiotic mediation of mathematical knowledge (cf. Mariotti, 2009; Radford, 2009; Wertsch, 1979), because the gradual introduction of mathematical tools helps researchers disentangle these roles. That is, by initially refraining from enlisting mathematical signs to explain the task yet subsequently overlaying the situation with a set of graphical–numerical elements familiar to the students, we hoped to create data of students negotiating between naïve and scientific meanings for the variety of spatial magnitudes embedded in the situation. Specifically, we expected students to alternate between two types of mathematical reasoning that draw on different epistemological resources: presymbolic quantitative reasoning evoked by the hands-only activity and mathematical schemas evoked by symbolical mediation of this same activity (Abrahamson, 2009; Bamberger & diSessa, 2003).

We maintain that these two approaches—the embodied and the semiotic—can and should be modeled as pedagogically complementary resources for mathematics instruction aiming for deep understanding, precisely because they are co-instrumental in the learning–teaching dialectic (see diSessa, 2008, on dialectic theory; see Cole, 2009, on obuchenie). Researching student behavior
around the Kinemathics task, wherein the embodied and semiotic are differentiable, could constitute a step toward further illuminating this dialectic. Accordingly, our study sought not so much to evaluate the effect of this brief intervention on students’ understanding of the targeted content as much as to model the emergence of mathematical meaning in this non-routine design.

**Methods**

The device described above is a type of *Mathematical Image Trainer (MIT, Abrahamson & Howison, 2010)*, which tracks the vertical positions of each of the student’s hands. Infrared rays emanate from the device, reflect off special tape covering tennis balls held by the student, and are then sensed, interpreted, and visually represented on a display in the form of two crosshair symbols (trackers). The display is calibrated so as to continuously position the crosshairs at the actual physical height of each hand, in an attempt to enhance the embodied experience of virtual remote manipulation. Also, the researcher can control the error tolerance of students’ hand positions. Finally, this MIT has a mode in which the trackers are controlled by inputting numbers into a ratio table rather than by remote handling. The color green, students’ “correct” feedback, is a pedagogical scaffold for mathematizing proportional relations: this computationally fabricated *product of measure* indicates as equivalent a set of *isomorphism-of-measure* relations (cf. Vergnaud, 1983), thus supporting students’ experience of embodied ratios as perceptual gestalts.

This paper draws on 20 interviews (total \( n = 24 \)) conducted in an ongoing study with Grade 4-6 students from a private K-8 suburban school in the greater San Francisco Bay Area (33% on financial aid; 10% minority students). These participants were selected from a larger pool of student volunteers, all prior to formal instruction in ratio and proportion, in an attempt to achieve equal representation in terms of grade, gender, and teacher-ranked mathematical capability. Each student participated in a semi-structured interview (duration: mean 69 min.; SD 20.35 min.). Elsewhere, we report on results from pre/post-interview card-sorting tasks—one pictorial (a pair of hot-air balloons), the other numerical. In each of these tasks, students could assemble and narrate card sequences depicting either a “fixed-difference” or a “different difference” story.

The heart of the interview consisted of working with the MIT (see Figure 2a). At first, the condition for green was set as a 1:2 ratio, and no feedback other than the background color was given (see Figure 2b). Next, a grid was overlaid on the display monitor to help students plan, execute, and interpret their manipulations and, so doing, begin to articulate quantitative verbal assertions (see Figure 2c). In time, the numerical labels “1, 2, 3,...” were overlaid on the grid’s vertical \( y \)-axis to help students construct further meanings by more readily recruiting arithmetic knowledge and skills and better distributing the problem-solving task (see Fig. 2d, partial view). Next, we asked students whether it was possible to keep the screen *continuously* green while moving the hands up and down. If students could not perform this task, the interviewer would do so by literally manipulating their hands up and down, enabling them gradually to assume agency.

Figure 2. MIT: (a) system; the display in (b) free mode; (c) with grid overlay; (d) also numerals
After working with the 1:2 ratio, students were told that the “rule for green” would change, and ratios of 1:3 and then 2:3 were used. Finally, the technology was reset from manual to numerical control. The interviewer introduced students to the numerical mode by inputting and “running” a set of green ordered pairs the student had just discovered in the previous activity. The interviewer then cleared the ratio table, typed a new pair of numbers in the top row, and asked the student to fill into the table numbers that would generate a green screen throughout the run. While working in the numerical mode, students were allowed to revisit the manual mode.

Our research team has been analyzing the videographed sessions collaboratively by applying microgenetic analysis (Schoenfeld, Smith, & Arcavi, 1991). Whereas variability in students’ mathematical competence was manifest in their performance, we discerned family resemblance among their trajectories. For this brief report we collapsed the variability and focused on the resemblance. General results will lead to a case study of Itamar, a G5 middle-level male student. An edited video of Itamar’s interview accompanies the results (http://www.tinyurl.com/edrl-mit).

### Results and Analyses

Recall that students were initially instructed to “make the screen green.” As expected, after stumbling upon their first “green location,” students attempted to create another by moving both hands while maintaining a fixed distance between them. They were surprised when the screen consequently turned red and moved their hands about until they found green again, whether in the same or a new location (see Figure 3; beams and sensors are three feet left of the monitor).

![Figure 3. Searching for green: (a) Itamar finds his first “green pair”; (b) his fixed-distance upward motion turns the screen red; (c) he lowers his left hand and finds a new green location](image)

As students began to find more green pairs, they were inclined to determine principles underlying this emerging equivalence set of hand positions that each caused the screen to be green. Students tended to assert that as the hands rise, the greater the distance between the hands must be so as to sustain green. Students’ gestures and utterances suggested they were surprised by this equivalence set, in which magnitudes are not fixed but, rather, grow across instances (different differences). Thus students shifted from viewing the within-pair relation as constant to viewing it as covariant with (vertical) location. Yet, prior to the Cartesian reticulation, they still conceptualized individual hand locations irrespective of their height above the desk.

The introduction of the grid appears to have imposed a pedagogically effective tradeoff en route to reinventing proportion, because students adopted a “snap-to-grid” discretization of the continuous Cartesian space. Namely, whereas students now confined their manual search for new green locations to integer-unit locations (upon the gridlines), so doing they discovered that as the left hand rose 1 grid unit up from a green location, the right hand must rise 2 grid units in order
to re-green the screen, what we call the “per change” solution strategy. Thus the grid afforded or enhanced opportunities to engage in the mathematical activities of measurement, comparison, and counting, cueing students to objectify their hand locations and hand motions numerically.

Introducing numerals along the grid’s vertical axis further supported the emergence of multiplicative meanings for the activity. Initially, the numbers afforded succinct naming for the hand positions as a practical means of replicating these positions with precision and speed. Yet so doing, students became conscious of the particular number pairs and responded to them. Our selection of 1:2 as the protocol’s first unknown ratio proved supportive—it enabled students to leverage their familiarity with simple multiplicative relations (e.g., double, half). Such naming of multiplicative relations, in turn, was critical to the emergence of proportion, as we now elaborate.

Prior to introducing the grid, students had focused on the distance between the hands. Equipped with the grid, students viewed hand locations individually, then re-focused on relations between different hand-pair positions, namely on “per change” recursive productions, but no longer on the relation within each pair (distance), even though this relation remain proportionally invariant amid transitions between pairs. Introducing numbers as new tools in the working space appears to have refocused student attention upon within-pair properties of green pairs, contingent on their multiplicative fluency. For example, students were generally able to correctly assert that one hand magnitude should be double the other so as to recreate green. In sum, whereas the pre-grid portion of the activity sequence launched students’ construction of proportion by refuting their additive expectation and supporting a qualitative alternative, the grid and then numerals provided students with semiotic means of objectifying this embodied experience as additive, then multiplicative relations. We thus witness a compelling case where conceptual understanding emerges reflexively, contingent on the availability of notational systems supportive of inquiry.

Nevertheless, the meanings students built for proportion up to this point in the interview were still markedly discrete in nature. For example, asked if he could move his hands up the screen from bottom to top while keeping it continuously green, Itamar said he could not move his hands fast enough to prevent the screen from flashing red as he transitioned between two green pairs, in this case [2 4] and [3 6]. Itamar thus seems to have viewed his hands as transitioning between two discrete green states, rather than moving through a continuous set of green pairs. In other words, Itamar only attended to [2 4] and [3 6] while ignoring all hand location pairs in between.

With Itamar’s permission, Dor held his hands and gently demonstrated the ambidextrous feat of keeping the screen green while moving both hands up simultaneously and then down again.

Dor: So we start at you said 1 and 2. Here we go. [Moves hands up while maintaining green]
Itamar: Then 2 and 4.
Dor: Look, how am I doing it? [Refers to continuous production of green “despite” the grid]
Itamar: Oh, because it’s the same amount of space, and then this one’s slowly going higher.
Dor: Uh huh! This one’s slowly going higher, and that one’s going faster going higher?
Itamar: Oh! It’s like the air balloons! It’s like the hot-air balloons. This one’s going faster than the other one. They start at the same spot, and then one goes faster than the other.

Apparently, dynamic motion of two objects moving up at constant yet different speeds evoked for Itamar imagery of the balloons pictures used in the pre-interview card-sorting task, despite his not having constructed a proportional story during that pretest. He had only constructed a fixed-difference sequence, and when asked to compare the balloons’ speeds had insisted that they rose at the same speed, as evidenced in the following, earlier exchange during that pretest:

---

Dor: Now is one of them going faster than the other one, and if so, which one?
Itamar: Well if one was going faster it would be the red one [the higher balloon, on the right],
but I don’t think one is going faster, I think one just started before the other.

We now return to the interview. Whereas the previous meanings constructed for green
involved discrete extensive quantities—either the distance between the hands or the per-change
amounts between pairs—this portion of the protocol introduced rate-based intensive-quantity
meanings, namely speed (distance/time). Introducing alternative meanings for one and the same
situation is not just a matter of accumulating meaning. Rather, with a teacher’s guidance,
multiple meanings set up opportunities to struggle with and synthesize disparate notions into
more complex conceptual structures. Importantly, understanding relationships between amount
and rate is a key learning issue in both ratio-based and non-ratio-based contexts (Stroup, 2002).

Having manipulated the MIT manually, students then turned to operating the device
numerically, using the virtual ratio table. In this phase, some students regressed from their
multiplicative insight to additive fixed-difference reasoning. For instance, after inputting the
sequence [2 3], [4 6], [6 9], [8 12] that he had found in the hands portion of the activity, Itamar
correctly noted that the left side was counting by 2 and the right side by 3. Yet, prompted to
begin from [3 4], he input [5 6], [7 8], [9 10] so as to “add 2 for each one.” He had thus reverted
to fixed-difference reasoning. We believe, though, that through further reflective interaction with
the MIT, students could learn to articulate their nascent hands-on insights in numerical forms.

In sum, setting off from haphazard hand waving yet progressively discovering the MIT’s
systematicity, students offered the following sequence of observations that address many
learning issues of the targeted notion of proportionality, with the more advanced students
tackling and connecting more of these ideas: (a) the locations of both hands are necessary to
achieve green; (b) the critical quality for achieving green is a type of relation between the hands’
respective locations; (c) these locations should be reinterpreted as magnitudes—the objects’
heights above the base line; (d) the difference between the heights of the hands in correct pairs
should not be constant—it will change between correct pairs; (e) this difference should increase
as the pair’s height increases; (f) moving from one correct position to another can be achieved by
increasing these heights differentially, for example the left hand should rise 2 ad hoc units for
every 3 units the right hand rises—a constant coordinated-change principle that can be used
iteratively; (g) the multiplicative relation within each pair, too, is a constant that characterizes
that particular problem; and (h) one and the same number pair expresses three aspects of the
interaction—the lowest integer-pair location on the grid, the differential additive change pair,
and the multiplicative relation within each and every correct pair: for example 2 and 3 units are
the lowest correct integer pair of heights, raising the left hand by 2 units for every 3 raised by the
right results in another correct location, and 2/3 or 3/2 is the constant within-pair multiplicative
relation. Along the way, students also realized that there are infinitely many location pairs, so
that in fact one can simultaneously raise both hands, thus reinterpreting the solution as two hands
moving at different speeds that could be characterized as, for example, 2 and 3 units per beat.

Conclusion

Students’ successful modeling of a problem situation even before engaging normative
mathematical media, notation systems, and formats, suggests promise in instructional designs
affording embodied, presymbolic quantitative reasoning. Such experiences enable students to
struggle with qualitative aspects of a mathematical domain and discover its quantitative

principles before they are burdened with the supplementary cognitive load of the disciplinarily requisite inscription and calculation procedures. Namely, as students are guided through a sequence of insights into the properties of a mathematical phenomenon, they can perform core conceptual work even prior to symbolic articulation. Through the appropriate introduction of canonical semiotic means, students can then be guided to formulate these insights normatively: as Itamar summed up, referring to the within-pair differences of 1, 2, and 3 in the ordered-pair sequence [2 3] [4 6] [6 9], “the difference doesn’t have to stay the same.” That is, by virtue of mastering a computational device that engaged yet challenged their additive reasoning, students constructed a new type of equivalence class articulated as a proto-proportional elaboration on robust pre-multiplicative schemes. For just one hour, we propose, these results are promising.

Though this is pioneering work and further research is underway to validate and substantiate our arguments, the empirical data thus far tend to support our conjecture concerning the potential pedagogical role of embodied artifacts as presymbolic objects-to-think-with. Furthermore, our action-before-concept design appears to resonate with the view that learners often engage in social activities prior to, yet as a condition of, interpreting their own behaviors in accordance with adult definitions of the situation (see Wertsch, 1979). Building on these emergent insights, we can now better guide students to optimize their development of personal meanings, invoked by engaging with the artifact, into normative mathematical meanings. Moreover, through studying student learning, we, in turn, are better positioned to optimize our theory of learning.

In this report we analyze and discuss the role of CAS with two 10th grade students on a task related to simplifying rational algebraic expressions. The theoretical elements adopted in this study are based on the instrumental approach. Results indicate that CAS and a technical-theoretical-oriented task provoked students to theorize on certain aspects of the simplification of rational expressions, thus illustrating the role of CAS in improving specific technical-theoretical components of algebra learning. However, the results also indicate that good task activity and CAS may not be enough for other related technical-theoretical understandings in this domain; the teacher’s intervention may also be necessary.

Introduction

In the past few years, many research studies have reported the potential of calculators (e.g., Computer Algebra Systems, CAS) in facilitating symbolic manipulation in algebra learning (e.g., Kieran & Damboise, 2007; Kieran & Drijvers, 2006; Thomas, Monahan, & Pierce, 2004; among others). For instance, Kieran and Damboise (2007) point out how students who are weak in algebra can improve both technically and theoretically by means of a CAS experience involving the factoring of algebraic expressions such as $x^2 + px + q$, with $p$ and $q$ whole numbers. Taking into account Kieran and Drijvers (2006), it can be seen how the use of calculators and tasks that promote the interaction between CAS and paper-and-pencil environments leads to increasing the quality of students’ algebraic thinking.

One concept that the algebra research community considers central to algebra learning is that of the equivalence of algebraic expressions. Kieran (2004), for example, views this concept to be a critical component of algebraic transformational activity. Not incidentally, it is well known (e.g., Davis, Jockusch & McKnight, 1978; Matz, 1980; among others) that students make frequent, common and persistent errors when they try to simplify rational expressions, appearing to neglect issues of equivalence. Some researchers have studied student thinking in this domain within CAS environments (e.g., Ball, Pierce & Stacey, 2003; Kieran & Drijvers, 2006). However, the majority of the reported research on algebraic syntax errors made by students has been carried out in paper-and-pencil environments (e.g., Booth, 1984; Davis, Jockusch & McKnight, 1978; Matz, 1980; Kirshner & Awtry, 2004; among others).

In the reports of these studies, different explanations are offered regarding the origins of many of these errors, as well as a variety of remedial teaching treatments (e.g., the use of different syntactical approaches) to help students overcome such errors. With respect to the use of technology-supported instructional treatments, among the few studies we note the research of, for example, Sutherland (1991, pp. 40-41) who points out that a computational environment influences students’ algebraic conceptualization and helps them to overcome difficulties in the comprehension of algebraic symbolism. Similarly, Tall and Thomas (1991) argue that a computational environment helps students to overcome difficulties and errors due to their interpretation and notion of variable. Another related study on the influence of technology in the
learning of algebraic concepts is by Guzmán and Martínez (2009), who point out that CAS is useful in the sense that it helps students to identify certain kinds of frequent and persistent algebraic errors. However, little is known about the influence of this kind of technology on students’ thinking in relation to the simplification of rational expressions — a topic in which common algebraic syntax errors are made in a very persistent way due to a lack of conceptual comprehension on the part of students regarding the manipulation of this kind of expression.

Thus, the aim of this study is to answer the following research question: How do CAS and a task designed with a technical-theoretical approach influence students’ thinking about the simplification of rational expressions?

**Theoretical Framework**

The instrumental approach to tool use has been recognized as a framework rich in theoretical elements for analyzing the processes of teaching and learning in a CAS context (e.g., Artigue, 2002; Lagrange 2003; Trouche, 2005; among others). The instrumental approach encompasses elements from both cognitive ergonomics (Vérillon & Rabardel, 1995) and the anthropological theory of didactics (Chevallard, 1999). According to Monahan (2005), one can distinguish two directions within the instrumental approach: one in line with the cognitive ergonomics framework, and the other in line with the anthropological theory of didactics. In the former, the focus is the development of mental schemes within the instrumental genesis process. Within this approach, an essential point is the distinction between artifact and instrument (for more details see Drijvers & Trouche, 2008).

In line with the anthropological approach, researchers such as Artigue (2002) and Lagrange (2003, 2005) focus on the techniques that students develop while using technology (such as CAS). This approach is grounded in Chevallard’s anthropological theory. Chevallard (1999) points out that mathematical objects emerge in a system of practices (praxeologies) that are characterized by four components: task (expressed in terms of verbs), in which the object is embedded; technique, used to solve the task; technology, the discourse that explains and justifies the technique; and theory, the discourse that provides the structural basis for the technology. Artigue (2002, p. 248) and her colleagues have reduced Chevallard’s four components to three: Task, Technique, and Theory, where the term Theory combines Chevallard’s technology and theory components.

Within this (Task-Technique-Theory) theoretical framework, not only does the term theory have a wider interpretation than is usual in the anthropological approach, so too does the term technique have a wider meaning than is usual in educational discourse. Here, a technique is a manner of carrying out a task; it is a complex assembly of reasoning and routine work and has both pragmatic and epistemic values (Artigue, 2002, p. 48). For Lagrange (2003, p. 271), technique is a mixture of routine work and reflection; it is a way of doing a task and it plays a pragmatic (in the sense of accomplishing the task) and epistemic role. With regard to the epistemic value of technique, Lagrange (2003, p. 271) has argued that: “Technique plays an epistemic role by contributing to an understanding of the objects that it handles, particularly during its elaboration. It also serves as an object for a conceptual reflection when compared with other techniques and when discussed with regard to consistency”. So, this epistemic value of techniques is crucial in studying students’ conceptual reflections within a CAS environment. In our study, this T-T-T framework was taken into account in all aspects, including the designing of the tasks to be used, the conducting of the interviewer interventions, and the analyzing of the data that were collected.
The Study

This report is part of a wider research on common literal symbolic errors and the use of CAS. The analysis and results presented here are based on a pilot study that involved three sets of task activities, each one designed to take into account a different common error in algebraic syntax. Here, we analyze and discuss just a part of one of those activities.

Methodology

The Population

The participants were eight 10th grade students (15 years old) of a Mexican public school. The selection of the students was made by their mathematics teacher, who believed that they were strong algebra students. It is also well known that students of this particular grade level make errors in trying to simplify rational expressions – the kinds of errors that we were interested in investigating. None of the students were accustomed to using CAS calculators; consequently, at the outset of the study, all the students received some basic training from the interviewer on how to use the calculator for basic symbol manipulation (use of the commands FACTOR, EXPAND, and SOLVE).

Task Design

The task proposed in this study concerns the simplification of rational expressions, both with paper and pencil and CAS. In this report, we use the term activity to refer to “the set of questions related to the task”. For the design, theoretical elements from the instrumental approach were used. In other words, the activity was designed so that technical and theoretical questions were central to the task and, hence, that students would have the opportunity to reflect on both the technical and theoretical aspects in both paper-and-pencil and CAS environments. In the present report, only the following parts of the activity are reported: first, students’ paper-and-pencil work (with technical and theoretical questions); second, their subsequent CAS work (technical question); and, finally, theoretical questions related to their work in both environments.

Implementation of the Study

The data collection was carried out by the interview method, led by the researcher. Students worked in pairs; each work session lasted between two and three hours. Each team of two students had a printed activity as well as a TI-Voyage 200 calculator. Every interview was audio and video-recorded to register the students’ performance during the sessions.

Analysis and Discussion of the Data

In this report, because of lack of space, we analyze and discuss only one team’s work on a subset of the actual task questions that were proposed. This team was chosen (we’ll call each member of the team student A and student B) for this report because we consider that their work is typical and represents the role played by both the CAS and the designed task. The analysis, which is qualitative in nature, is based on the team’s work sheets, as well as the video-recorded interview. The analysis and discussion of the data is detailed below.

The Role of the Proposed Task

We take the first part of the task as solved by the students A and B. As per the task design, the first section of the activity helped us to know how the students simplify, with paper and pencil, the given rational expressions. Figure 1a illustrates the students’ techniques and their...
explanations related to the simplification of rational expressions. From this, we confirm that, in this environment, students made the expected errors: they eliminated the ‘literal components’ that were common to both numerator and denominator, without taking into account whether these ‘literal components’ were, in fact, a factor of both the numerator and the denominator.

Figure 1b. Simplification of expressions: CAS work

This part of the task allowed students to describe their paper-and-pencil technique for simplifying these expressions. We note that their explanation uses the terminology of dividing (see the second example of Figure 1a, where the students wrote, “we divide the same letters”). We also note that, whenever there are parentheses, the students first expand the expressions of the numerator and denominator before cancelling (see the first example of Figure 1a). The fact that the students spontaneously expanded expressions and didn’t first observe them in terms of...
factors was something that hindered their theoretical reflection and seemed to lead them to make
the kinds of errors that are reported in the literature.

Next, the students arrived at the part of the activity where they used the CAS calculator
(Figure 1b). This allowed them to contrast their paper-and-pencil results with those obtained
from the CAS. The differences between the two sets of results led them to wonder about their
paper-and-pencil techniques and explanations. They began to question the theoretical
underpinnings of their work. Hence, the design of the task (technical and theoretical questions in
both environments) clearly led the students to confront their paper-and-pencil results (i.e., their
initial techniques and theory) with the ones obtained from the calculator and promoted the search
for other techniques in order to explain the CAS results.

Theoretical Reflection Promoted by the CAS in Students

From the analysis of the students’ conversation following the surprising CAS results, it was
clear that the results given by the CAS (Figure 1b) provoked in students a conceptual change (the
epistemic role of the techniques, in this case the CAS technique). In other words, the use of the
CAS in the context of the designed task led the students to rethink their techniques and
explanations and provoked a theoretical reflection that could explain for them the results given
by the CAS. For the expressions that involve just one term in the denominator (as in the first
element of Figure 1a), the students could see that their paper-and-pencil technique was not
correct, but could also see how to fix it. As the following extract suggests, they were able to
make a quick adjustment to this technique so as to eliminate the discrepancy between the results:

[1] Student A: What is it? [She asked for the result given by the calculator for the first expression
of Figure 1b]
[2] Student B: x plus 3 [the CAS result for the first expression of Figure 1b]
[3] Student A: And we wrote 3 plus x squared [She refers to the result which they got by paper
and pencil for the first expression of Figure 1a]
[4] Student B: Yes. We must’ve taken off only one x [Meaning that they had to eliminate
another x]. No matter. What’s next?

It seemed a minor matter to student B to make this kind of adjustment to their technique for
handling the simplification of rational expressions with a single term in the denominator – an
adjustment that called for cancelling each occurrence of the given term in the numerator. But it is
noted that no accompanying theoretical justification seemed forthcoming. However, for the
second and third examples, the students could not easily come up with a simple adjustment to
their paper-and-pencil technique for simplifying rational expressions containing a binomial as
the denominator and two terms in the numerator – that is, an adjustment that would allow them
to arrive at the same result as that produced by the CAS. The following extract illustrates their
bewilderment at the CAS result for the second expression:

[5] Student B: Four [She refers to the result obtained by the calculator for the second expression
of Figure 1b]
[6] Student A: Uh! [Expressing surprise] We are wrong too [Because it doesn’t match up with
their paper-and-pencil result for the second expression of Figure 1a]
[7] Student B: But I don’t know why. Here I don’t really know why.
[8] Student A: Neither do I.

American Chapter of the International Group for the Psychology of Mathematics Education. Columbus, OH: The
Ohio State University.
For this expression, the students had cancelled the $x$ in the numerator and the denominator, as well as the $y$ in both, which had left them with $4 + 4$, which they simplified to 8. Yet, the CAS result had been 4. They were similarly unable to explain why, for the third expression, the CAS did not simplify at all, but merely returned the given rational expression:

[9] Student B: Yes, here [Refer to the first expression of the Figure 1b], it makes sense [the result given by the calculator] because the $x$'s were taken off, it first multiplied and we missed taking off the two $x$'s. [She states the multiplication procedure that she thinks the calculator did, just as they had expanded the numerator of the first expression of the Figure 1b]. But in here, I’m not quite sure why it’s 4, neither the result in here [Referring to the last two results (Figure 1b) given by the calculator]. Why it is the same [referring to the 3rd result], I don’t have any idea.

The two students continue to think about the discrepancies. While they could accommodate the result given by the CAS for the first example, the other two examples remained mysterious. They kept asking themselves if there were other ways to think about these simplifications. How might they justify the results offered by the CAS? The following extract underlines their dilemma, but then Student A suddenly had an idea:

[10] Student B: It’s believed that in this case we should’ve taken off the $x$ and the $y$, we take off both [The repeated terms in the numerator and the denominator of the 2nd expression in Figure 1b]. But why is it 4? [The result given by CAS]

[11] Student A: Let’s see [Pause]. This is a division of polynomials!

In line [11], it is clear that the CAS result, for these two examples, has provoked a conceptual change in one of the students, which was understandable by the other. The theoretical reflection induced by the discrepant results moved the students from a technique involving eliminating literal symbols that are repeated in the numerator and the denominator to a technique involving division of polynomials. Thus, the numerator and denominator of the rational expression are now viewed as dividend and divisor respectively. But this new theoretical perspective, and its related technique of dividing the numerator by the denominator, is deemed necessary (by the students) only for rational expressions where the denominator is a binomial. For those cases where the denominator is a monomial, they continue to believe that the technique of cancelling the monomial of the denominator with all of its occurrences in the numerator is workable:

[12] Student A: In numbers 2 and 3 [The last two expression of Figure 1a], we didn’t divide well.

[13] Interviewer: What do you mean by you didn’t divide well?

[14] Student A: Ok, well, in here… we took off the $x$’s and the $y$’s. And [Pause].

[15] Interviewer: And can’t we do that?

[16] Student A: Well [Pause] it would do if it were a division of a polynomial by a monomial.

The interviewer then asked the students to illustrate their new paper-and-pencil technique and to show (see Figure 2) how it helped them to avoid the errors they had made when simplifying the last two expressions of Figure 1a.
Finally, based on their new technique (long division of polynomials) for simplifying rational expressions containing a binomial for the denominator, the students were able to explain the results given by the CAS. For them, to simplify such a rational expression came to mean that one should divide (numerator divided by denominator). They found, on their own, that if the quotient works out exactly, then the rational expression can be simplified -- the quotient of the division being the final simplification. But if the division is not exact, then the rational expression can’t be simplified and the CAS calculator will give as the result the same expression. It’s interesting to see how the students came to adapt their new technique and theory so as to make it also fit the case of rational expressions that could not be simplified. And so, through the technique of polynomial division, the students came to explain the results given by the CAS. However, the connections between this technique and the one they used to simplify rational expressions where the denominator was a monomial were never made. For these connections, teacher intervention would clearly be necessary.

Conclusions

The present report shows that CAS and a task that promotes technical-theoretical thinking, within an environment involving the reconciling of paper-and-pencil and CAS results, can provoke in students a conceptual change regarding the simplification of rational expressions whose denominators are binomials. The change we observed involved moving from, on the one hand, simplifying expressions through the technique of cancelling out terms that were repetitive in the numerator and in the denominator to, on the other hand, the division of polynomials technique. The use of CAS to verify paper-and-pencil work, and the obtaining of surprising results by the CAS, led students to a theoretical reflection that provoked the use of a new technique and new theoretical explanations for both justifying the CAS results and rethinking their paper-and-pencil procedures of simplification. However, such theoretical reflection was not enough for them to understand the simplification of rational expressions in terms of cancelling out common factors of the numerator and denominator. These results thus suggest that, in spite of good tasks and the use of CAS, in order for students to more fully understand rational expressions and their simplification, including the relation between polynomial division and factored forms within rational expressions, the importance of teacher intervention is inescapable.
Endnotes

The study presented in this report was supported by the grant from “Consejo Nacional de Ciencia y Tecnología” (CONACYT), Grant # 49788-S. The authors express their appreciation to the students who participated in this research, their teacher, and the school authorities who offered us their facilities for the data collection.

THE USE OF DGS TO SUPPORT STUDENTS’ CONCEPT IMAGE FORMATION OF LINEAR TRANSFORMATION

Shiva Gol Tabaghi
Simon Fraser University
sga31@sfu.ca

“Vision, spatial sense and kinesthetic (motion) sense” is one of the six major facilities that significantly contribute to the development of mathematical thinking (Thurston, 1994, p.4). Drawing on embodied cognition theories, Núñez (2006) argues that mathematical ideas and concepts are ultimately embodied in the nature of human bodies, language and cognition. In this paper, I aim to examine the role of dynamic interactive representations of mathematical concepts in developing students’ spatial and kinesthetic sense. In particular, I show how the spatial and kinaesthetic sense of thinking that students develop in their interactions with dynamic geometry software models greatly improves their previously operational understanding of linear transformation.

Introduction

Dynamic Geometry Software (DGS) offers the possibility for representing mathematical concepts symbolically and geometrically. The interactive feature of DGS enables students to perform multiple actions and generate a large number of examples effortlessly (Hollebrands, 2007; Mariotti, 2000), thus they can explore the relationships between the two representations. Research in this area has mostly focused on the design of tasks, students’ use of technological tools, and the role of multiple representations in the learning of geometry (Hollebrands, Laborde & Straber, 2008). The use of DGS has been found to be effective in a variety of school mathematics subject areas, including geometry and algebra, and, also, the teaching of calculus, both at the high school and undergraduate levels (Hollebrands, 2003; Falcade, Laborde and Mariotti, 2007; Habre and Abboud, 2006). However, despite its appropriateness to other undergraduate subject areas, its potential in courses such as linear algebra has received less attention.

Prior research suggests that the use of DGS in linear algebra context has shown that DGS facilitate students’ construction of their own mathematical objects and avoid the obstacle of formalism (Sierpinska, Dreyfus, and Hillel, 1999). This has motivated me to investigate the effect of the use of interactive dynamic representations of linear algebra concepts on students’ concept formation. Given that representations are fundamentally dynamic and that time and motion play an important role in mathematical thinking (Lakoff & Núñez, 2000; Núñez, 2006; Thurston, 1994), I have become interested in investigating the effect of dynamic mathematical representations on students’ modes of thinking. In this study, I explore the importance of dynamic representations of the concept of linear transformation in the development of “vision, spatial sense and kinesthetic (motion) sense,” which Thurston (1994) includes as one of the six major facilities in the development of mathematical thinking (p.4).

Theoretical Background

Based on theories of embodied cognition, Núñez (2006) argues that mathematical ideas and concepts are ultimately embodied in the nature of human bodies, language and cognition. He has also shown that static objects can be unconsciously conceived in dynamic terms through

imposing fictive motion; as he illustrates cases of the concepts of limits, curves and continuity. Recent research confirms Núñez’s theory and shows evidence of time and motion in mathematicians’ thinking about concepts such as eigenvectors (Sinclair and Gol Tabaghi, 2009). Research on students’ modes of thinking has shown that visual ways of thinking include kinesthetic and dynamic imageries (Presmeg, 1986). Studies on the interrelationships between visual and analytic thinking also confirm that visual imagery sometimes is dynamic (Zazkis, Dubinsky, and Dautermann, 1996). These studies, as well as the emergence of embodied cognition theories, suggest we pay closer attention to the role of time and motion in mathematical thinking. It has been surmised that perceiving dynamic processes and objects requires the formation of more complex mental images than perceiving static objects (Zazkis, Dubinsky, and Dautermann, 1996). That could be due to extensive exposure to static representations of concepts. I hypothesise that the use of dynamic representations can help in the development of kinesthetic and dynamic imageries and thus, support concept image formation of mathematical ideas. This has motivated me to probe university students’ modes of thinking in the presence of dynamic representations of concepts. More precisely, I wish to investigate whether dynamic representations of concepts affect students’ ways of thinking.

In order to probe their ways of thinking, it is helpful to study students’ linguistic expressions and bodily movements. Recent research has shown that speech and gesture are two facets of the same cognitive linguistic reality. In particular, research claims that gestures provide complementary content to speech content (Kendon, 2000) and that gestures are co-produced with abstract metaphorical thinking (McNeill, 1992). From a mathematics education perspective, gestures play an important role in cognition and can contribute to creating mathematical ideas (Arzarello et al., 2005, 2007; ESM special issue 2009). Therefore, gestures should be an effective way of providing evidence of kinesthetic and dynamic imageries (Núñez, 2006).

Sfard’s theory on the dual nature of mathematical concepts (structural and operational) provides additional support in discerning students’ ways of thinking. According to her, operational thinking involves conceiving a mathematical entity as a product of a certain process or to identify a mathematical entity with the process itself. In contrast, structural thinking, which usually evolves from operational thinking, involves conceiving a mathematical entity as an object. The two modes of thinking are not mutually exclusive, and are in fact complementary. One challenge in mathematics education is to help students make the transition from operational to structural thinking, a difficult transition when instruction is focused primarily on procedures and algorithms. Sfard notes that non-pictorial mental images (inner representations) are more pertinent to operational thinking, whereas pictorial mental images seem to support structural thinking (Sfard, 1991). She uses the terms inner representation, mental image, and visual representation interchangeably in describing ways that students envision mathematical concepts. Similarly, the term concept image is used to refer to "all the mental pictures and associated properties and processes" relating to the concept (Tall & Vinner, 1981, p.152). I shall use the terms concept image and mental image in my analysis.

In the context of linear algebra, studies have reported that linear algebra students mostly develop operational thinking and their level of thinking does not advance into structural level (Hillel and Sierpinska, 1994; Alves Dias and Artigue, 1995; Stewart, 2008). These studies have identified the lack of cognitive flexibility between different modes of thinking as one source of linear algebra students’ difficulties. Because of its capacity to represent pictorially and dynamically a range of mathematical concepts, dynamic geometry software might enable students to enhance their concept images.
Research Context and Participants

I asked students to interact with sketches designed in *The Geometer’s Sketchpad* (Jackiw, 1991) that involve a variety of linear algebra concepts such as vectors, spans, linear transformations and eigenvectors. I designed interviews using a set of tasks aimed at eliciting students’ ways of thinking while they were interacting with sketches. I interviewed five students who were enrolled in a linear algebra course at the time of interviews, which has already covered the concepts mentioned above. Each interview lasted between 30 and 40 minutes. Interviews were videotaped and transcribed.

In this paper, I only present the analysis of two interviews focusing on the concept of linear transformation. More specifically, I report on students’ understanding of transformation of a two-dimensional object on a plane. The participants, Julia and Mary, were second year university students who volunteered their time to participate in my study. Both verbal and gestural communication are used to provide evidence of dynamic and kinesthetic imageries.

Analysis of Study

I refer to Sfard’s classification to discern students’ ways of thinking about the concept of linear transformation. I also analyse the participants’ linguistic and non-linguistic expressions to find out evidence of time and motion in their ways of thinking.

Interview Sketch and Tasks

Before seeing the designed dynamic sketch, participants were asked to describe linear transformation. Then, they were presented the linear transformation sketch (see Figure 1) that illustrates a linear transformation of a non-symmetrical object (blue-coloured F) under the matrix of transformation $T$. Users can drag either the pre-image or the image to any location on the screen. Additionally, the values of the matrix can be changed, which will result in a dynamic update of the image. The participants were asked to predict the image of F under different transformations: (a) $T = \begin{bmatrix} 3 & 0 \\ 0 & 3 \end{bmatrix}$, (b) $T = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}$, (c) $T = \begin{bmatrix} 2 & -1 \\ 0 & 2 \end{bmatrix}$ and (d) $T = \begin{bmatrix} 2 & 1 \\ 4 & 2 \end{bmatrix}$.

![Figure 1. The linear transformation sketch](image-url)
Analysis of Speech and Gestures: Julia

Julia initially described linear transformation as “changing vectors into something else so like mapping vectors to something else so it could be a matrix or anything else”. It seemed that she recalled linear transformation in terms of matrix multiplication. She only mentioned transformation of vectors, which suggests she did not think of transforming other objects. This showed that she had developed an operational understanding of the concept of linear transformation as reported in the literature (see Stewart, 2008).

After her description, she was given the sketch (see Figure 1) that represented the transformation of an object under the transformation matrix \( T = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix} \). Looking at the sketch, I asked her to describe her observations of the image of F in regard to the given transformation. She said “expanded the original F by 2 in y-direction and x-direction, so there would be the four times of original size because it is 2 times 2.” It was interesting that she compared the area of image and pre-image. She was then asked to predict the effect on pre-image F of the transformation (a). She predicted that transformation (a) would map the pre-image F into another F that would have three times expansion in its dimensions and nine times enlargement in its area. After her prediction, she was asked to change the values of the matrix into the transformation given in (a) to verify her predication.

Next, she was asked to predict the image of F under transformation (b), whereupon she whispered and used her right index figure (see Figure 2) to write up mental calculation on the desk. After a few seconds, the interviewer prompted her to explain her thought processes.

**Figure 2. Julia’s use of her right index figure to write up mental calculation**

Interviewer: Can you explain what are you calculating?
Julia: I am just thinking of that as, um, so that would be the matrix and then say I have my \( x_1 \) and \( x_2 \) that would be my vectors so then if I have that vector times the matrix. So right now that would be two one zero two if I change \( a_{12} \) to one so then it would be, if you multiply them it would be two \( x_1 \) and then plus one \( x_2 \). Then I do not know how that changes the figure, but in what way.

In order to predict the result of the transformation, Julia must rely on her operational knowledge to complete the matrix-vector multiplication. As she said herself, she did not know “how that changes the figure”. Her gesture, using her index finger to write up the calculation, also revealed that her concept image of transformation was pertinent to operational thinking. I
next asked her to predict the image of F under the transformation (c). She said “so now it is slanted that way, -1 would be slanted other way”. This showed that she referred to the sketch representation for the transformation (b) and compared the entries of two transformation (b) and (c) to predict the image of F. As she described what would happen, she held her right hand out and moved it from right to left, apparently also describing the slanting of the image of F (see Figure 3). This gesture was markedly different from her previous gesture using right index figure to write up the calculations since it communicated something about the transformation of the pre-image. This suggests that the dynamic representation enabled her to develop a pictorial mental image where she could manipulate the mental image “almost like real object” (Sfard, 1991, p.7).

![Figure 3. Julia’s gesture as she describes transformation (c)](image)

Next, she was asked to predict the image of F under transformation (d). She said “so two one zero two was like that before, um, it would be more fat, um, I do not know”. She recalled the entries of the transformation (b) and the sketch representation of it, then she used her right hand; slanted her hand to the right (see Figure 4) to illustrate the direction of the image of F under the transformation (b). Her gesture indicated that she evoked the representation of transformation (b) in her mind. That is evidence of kinesthetic and dynamic imageries that enabled her to think in terms of movement and direction so that she reconstructed the direction of the image of F in space and time using her hand.

![Figure 4. Julia’s gesture as she describes the transformation (d)](image)

Her prediction that the image “would be more fat” was incorrect. I asked her to use the sketch to show transformation (d). She was at first surprised when she saw that the image of F is a line segment, however, she immediately said “oh yeah because they are linearly dependent”. She realized the dependency between column vectors of the transformation (d) so that she
justified the representation of the line segment on the sketch. This showed that she was able to coordinate the symbolic and geometric representations of the given linear transformation.

**Analysis of Speech and Gestures: Mary**

Mary initially described linear transformation as “like taking one vector and something, and transforming it using a set of like rules so then becomes something else.” She recalled linear transformation in terms of transformation of a vector into something else. Although the use of term “something else” gives a sense that she was presented with the idea of transformation being able to transform anything, she did not seem to have any example of what could actually be transformed. In response to the prompt, predict the image of F under transformation (a), she mentioned that transformation (a) maps the pre-image F into another F that is “wider, bigger, and three times the size”. After her prediction, she used the sketch to create the transformation (a). This showed that she had a sense of how the matrix actually affected the transformation of the pre-image.

Next, she was asked to predict the image of F under transformation (b). But, she was unable to articulate the shape of the image of F under transformation (b), so she immediately used the sketch to create this transformation. The sketch representation of the image seemed to prompt her memory, as she said “oh, it is a shear transformation”. It is worth mentioning that thus far no gesture accompanied her speech. In response to the next prompt, predict the image of F under transformation (c), she said the image would be “twice as large as now and sheared”. She also moved her right arm and hand upwards and to the right to depict the direction of the image of F (see Figure 5).

![Figure 5. Mary’s hand represents the direction of the image of F under transformation (c)](image)

Although, her arm and hand depicted a right-slanted image of F, the image would be left-slanted. Her gesture, movement of hand and arm, was a dynamic gesture that she used to illustrate the direction of the image of F under the transformation (c). This was evidence of kinesthetic and dynamic imageries that enabled her to reconstruct the image of F, to impose motion on it, and to position it in space. This showed that the use of dynamic interactive sketch had an impact on Mary’s ways of thinking. She then tried to create the transformation (c) using the sketch. While changing the values of the transformation matrix, the image of F became a line segment for \( T = \begin{bmatrix} 0 & -2 \\ 0 & 3 \end{bmatrix} \). Mary, who was surprised by the sketch representation, tried to justify the representation and said that “oh, okay because \( a_{11} \) and \( a_{21} \) are zero”. She also gestured as she tried to justify the sketch representation: she moved her right hand that was slightly right-slanted from up to down to depict a line segment (Figure 6). Her gesture showed that she started
to use kinesthetic and spatial senses to reason about the representation. I prompted her to explain more about the image, but she offered no further explanation.

![Image](image-url)

**Figure 6.** Mary’s hand represents the image of $F$ under $T = \begin{bmatrix} 0 & -2 \\ 0 & 3 \end{bmatrix}$

**Discussion**

The two participants’ initial descriptions of linear transformation at the beginning of the interviews confirmed research findings that students mostly develop operational understanding of linear algebra concepts—recall that these students had already completed the unit on linear transformations in their linear algebra course. Their concept image of linear transformation involved only operations (especially for Julia) and did not seem to include a pictorial mental image to support structural thinking.

After interacting with the transformation sketch, both participants developed a pictorial mental image of linear transformations, as evidenced by the descriptions they give of what will happen to the image (that it will slant, or that it will be fat, sheared, twice as large). Their descriptions indicate that they became focused on *how* the transformation changes the figure, and not simply on the calculations involved in the matrix multiplication. Their kinaesthetic conceptualisation is evidenced in their gestures, which describe the actual motion of the pre-image to the image. This is interesting in that the sketch does not actually show the continuous transformation of the pre-image to the image so that the participants actually impose this motion on the objects.

My findings suggest that the use of dynamic representations to illustrate the relationships between symbolic and geometric representations could support a pictorial concept image formation of advanced mathematical ideas such as linear transformation. Although the participants have not fully developed a structural understanding of linear transformation, they have developed pictorial mental images that support structural thinking. The structural understanding of a linear transformation involves understanding that transformation preserves linearity, i.e. the operations of vector addition and scalar multiplication. The dynamic and interactive features of DGS enable the designing of models appropriate for representing the linearity of transformation. Based on these results, I am pursuing further research to investigate students’ understanding of the linearity of transformation.

In this paper we outline the design and results of the implementation of a computer system with interactive activities about the ratio and proportion topics used with 6th grade Mexican students (children under 11 years of age). The design of these activities was informed by studies in the computation and educational technology. The goal was to nurture psycho-pedagogical knowledge in mathematics and in the area of computing and educational technology.

Introduction

The call to help students enrolled in basic education programs develop the type mathematical competencies and cognitive structures needed for grasping more sophisticated ideas studies in school is currently one of the Mexico’s major goals. Furthermore, attention has also been guided towards using technological environments as vehicles to engage children in such learning. Combined, these two issues, has raised the need for a careful examination of what and how research based teaching strategies might be utilized in designing a system of educational software that would support learning core mathematical concepts such as ratio and proportion. The goal here is to identify the theoretical foundations underlying the choice for inclusion of each of the instructional sections that make up this support tool for learning and teaching the concepts of ratio and proportion. In Mexico, the concepts of proportion and ratio are introduced in elementary grades and provide the basis for more study of more advanced mathematical topics including direct proportional change, linear function, among others.

This article focuses on describing our efforts at supporting the construction of the knowledge about concepts of ratio and proportion among children, for which we developed a computer system with interactive activities. The design of the proposed activities was based on observations and Ruiz’s (2002) previous research with teachers and students in the sixth grade (primary education in Mexico) on the topics of ratio and proportion. The goal of the research project reported here was to identify whether the technology based activities designed for teaching of the concepts of ratio and proportion would support the development of proportional thinking among a group of adolescents (11 year olds).

Proportional thinking is based on qualitative surveys creating linguistic categories of comparison, as large or small. In qualitative terms also includes the intuitive, based on experience and empirical and the perceptual that relies on the senses. Quantitative proportional thinking refers to activities that allow students to count, measure and quantities used in the procedures.
Theoretical Background

Piaget (1978) noted that children between the ages of 11 and 12, begin to experience the notion of “proportion” in different areas and contexts, including spatial proportions (similar figures), the relations between weights and lengths arms in the balance of probabilities, and so on. Relying on the results of several experiments, Piaget (1988) indicated that the child acquires the identity qualitative rather than quantitative conservation and makes a distinction between qualitative comparisons and true quantification. Indeed, Piaget's notion of proportion begins in a qualitative manner before it is quantitatively structured. His theory emphasizes that in order for children to develop proportional and qualitative reasoning they must first begin to grasp notions of extension and reduction-- following the idea of the copier or drawing to scale. Furthermore, according to Piaget and Inhelder (1978), upon the development of perceptual receive of order children are then prepared to learn to compare quantities --which can be detected when they use phrases such as, "greater than...", and "less than ....”.

The transitional phase from qualitative to quantitative analysis is what Piaget referenced as intensive quantification. At a later phase, the student uses measurement to make comparisons among quantities--first confronting parts of the object and superimposing a figure in another, and then using measuring instruments, conventional or unconventional, to complete the action. Freudenthal (1983) described such comparisons as maintaining two forms: direct and indirect. The direct method of comparison is when an object overlaps another object, while the indirect method is when given two objects (A and B) and a third element to match (C).

Streefland (1991), regarding the emphasis to be given when teaching about ratio and proportion in early grades, suggested that the instructional approach must start from qualitative levels of recognition of these concepts and make use of educational resources that foster the development of perceptual patterns in support the corresponding process of quantification. It refers to the teaching of mathematics as a core activity, and highlights the importance of teaching tools developed by the designer and this is mentioned Freudenthal Teaching Phenomenology (1983), together with other background information considered realistic for the construction of mathematical knowledge. Similarly, Freudenthal posited that the understanding of the ratio may be guided and deepened by visualization and these can be illustrated using detailed constructions, where the pictures are different and show what items fit together in the original and the image. For example, in two contiguous figures extension or reduction of the other, in which the same linear rate can be established in each segment of the figure. The author further suggested that working the ratio of lengths of plane figures are used as means of representation, expressions of more global comparisons in the sense that the student is provided qualitative and quantitative understanding of magnitudes through visual perception.

In her doctoral thesis, Ruiz (2002) found various difficulties that students experienced as they worked through such structure, as described below.

There hasn’t been exploited to maximize the quality of students thinking about proportionality, which concentration was observed when expressed in one of the dimensions of the figures were asked to reduce or amplify. For some students, the qualitative is scarcely raised as a prelude to the quantitative, since within linguistic categories identified in them are the following: "is greater than ...", is smaller than ...", This reflects a certain understanding of proportion, but these same students did not find other categories by which showed greater understanding of the idea of proportion.
Showed confusion in establishing relationships between quantities, so it was necessary to emphasize that to arrive at the notion of ratio.

Technology and Learning
Some investigations have been done to determine if the use of learning environments based in web might help student learning. Galbraith and Haines (1998), for instance, showed that students who used the computers in the course of their mathematics learning, enjoyed mathematics. The authors reported that learners enjoyed the flexibility characteristics provided by the computer, they expended too much time using the computer to complete a task and liked to try new ideas. They also concluded that the web applications helped to elevate the level of trust, motivation and interaction among the learners.

Other scholars (Nguyen & Kulm, 2005; Combs, 2004; Gourash, 2005; Engelbrecht & Harding, 2005a, 2005b), pointed out that the use of computer in an educative manner can help individual to seek and attach meaning to what they do. This results from the increased capacity for discovering relationships and concepts which in turn helps them to be more reflexives.

Drawing from the suggestions of research described above, Table I summarizes the referred indicators of understanding associated with the concepts of ratio and proportion as well instances of didactic actions associated to such indicators. Table 2 illustrates the relationship between the activities in Table 1 with the actions performed on the computer.

**Methodology**

In this section we describe the participants in the study, the elements of the computer system to perform the educational activities, and the educational activities themselves.

**Participants**

The participants in the study consisted of 29 Mexican students who were attending sixth grade in primary education (children under 11 years of age) at the time of data collection.

**Sequence of activities and their presentation in the computer system**

In designing and sequencing the activities both the didactic actions identified in the theoretical framework, and the theoretical elements associated with learning and teaching the concepts of ratio and proportion were utilized as described below.

**Activity 1 Select the figure reduced, or amplified to that given by viewing**

This activity is based on the ideas of "reduction" and "extension" type models supported by the experience of the scale drawing and photocopier, which is handling the situation of similarity, using the perceptual and observation. It assumes, as noted by Piaget, Streefland and Ruiz, that early teaching of ratio and proportion should be built on quality and level of recognition of this concept. Hence, we first used activities that did not require the use of numbers for arriving at solutions. We also took into consideration Freudenthal’s suggestion that an understanding of the ratio maybe guided and deepened by visualization and these can be illustrated using detailed constructions, where the pictures are different and show what items fit together in the original and the image. For example, in two adjacent figures, an enlargement or reduction of the other, in which the same linear rate can be established in each segment of the figure.

In designing the figures used in the computer system we were also sensitive to what was meaningful to adolescent boys (11 years of age). We used objects to which they could related, for example: a boat, a bus, a star, a dog, but made with line segments.

**Way it appears in the computer system**

The environment shows 4 figures that are similar but with minor differences among them; is also one of these 4 figures but at double or triple or half or third of the size, linearly, and prompts the user to choose between the 4 figures, which is confined to the original (See Figure 11).

When any of the figures is selected by the user, we examine the choice made and immediately send a response including the test result to the individual taking the test. We ask if the individual would try again. Depending on whether the response is received and its content, the individual can restart the exercise or continue with the next activity.

**Activity 2 Select the figure reduced, or amplified to that given by comparison**

Case 1 Overlap a figure in another

The figure in another overlay allows students to recognize relationships of similarity between figures intuitively. The figures compare action is the beginning of the measurement without
using a conventional instrument and is given by the superposition of them, as suggested by Freudenthal (1983).

Way it appears in the computer system

The user has the option of using the mouse to drag any of the four figures to overlay on the original and review by looking at it to see if the figure is enlarged or reduced on all sides by the same amount (see figure 1).

Case 2 using the grid

Using the grid gives the transition from qualitative to quantitative thinking and proportional reasoning (Ruiz, 2000). Count is used as the unit of measurement using the side of a grid box where the figures are. The result of counting the sides of the figures was made in order to get relations with the quantities obtained quotient, or ratios. This also allowed for recording of equivalence relations between two ratios or proportions.

Way it appears in the computer system

We show the user a figure on a grid. A grid is also shown where the user can draw a drawing of the figure. We asked the user to draw the figure at double or half, or third scales (see Figure 2). We support the figure that is in the grid and compare it to what the user draws. The user is notified if the answer is correct or not and you are if they wish to repeat the exercise. The users will respond if they wish to continue or repeat the exercise.

Activity 3. Using a Table.

The table was used as a mode of representation for the determination of internal and external ratios (Freudenthal, 1983). They worked proportional change problems, where to obtain quantities was not only through the use of the operator, but establishing relationships among ratios. Finally, we worked the equivalence relation as a relation of proportionality. Figure 3 shows an example of how one student used the table and her ratios.

Results

Activity 1, select the figure by visualization

Eleven of 29 students chose the figure reduced by observing. The remaining 18 students chose to compare the figures by placing one over the other. To do this, they dragged the mouse and managed to see whether length or width were twice or half or a third part that I commented at the meeting. This result is consistent with what was proposed by Freudenthal (1983). If the figure was a circle, they compared the radius or diameter. Thus, all students managed to

determine whether the figure was reduced by choice and they chose to drag and overlay a figure on the other to make the comparison. This form of student reaction is similar to that reported by Combs (2004).

**Activity 2, Grid**

Twenty three of the 29 students managed to draw correctly on the grid the similar figures that were requested. The remaining 6 students did about two to three attempts to achieve success on this task. The computer system was very useful because it presented the participants the option of working with different figures. Therefore, the activity did not become mechanical. Additionally, the student had the opportunity to discover what was happening. The recognition of ratios like a comparison, by a quotient of two magnitudes. It worked the notation as a fraction a/b with b different from (Is this what children did? Or what you had intended for the activity to support?)

**Activity 3, using the table**

Twenty of the 29 students filled the table correctly, they relied on numerical evidence to obtain the unit value if the result was wrong. Other students established ratios by reading from the table and wrote them as fractions. All participants used the calculator function of the environment. They did so to determine the operations to be realized. Figure 3 shows the case of Luis, as an example problem.

What Luis said in the activity was:
"I noticed that 3 should be 2 times in 6, and then 3 liters of milk will require 6 bars. Hmmm. That is, it takes twice chocolate bars. Ah, a liter then requires two bars, two-liter four 3 liters 6. Is better if I use the calculator and multiplying by two to fill the data they ask me"

![Figure 3. Luis answers in the activity](image)

In the case of Luis, it was observed that she established the relationships between two variables, milk and chocolate bars, as external rations, using Freudenthal’s terms. Figure 4 illustrates a second case, representing Manuel’s work. Manuel was asked to give a conclusion. He stated:

*The conclusion is that you ask me ..., well, that to the chocolate bars have to use the multiplication table of 6, i.e., first hold 6 bars for 3 liters of milk, then 12 bars to 6 liters of milk, after 18 bars to 9 liters, so if I compare liter bar that is twice liter bar.*

---

As such, Manuel managed to establish relationships between the data given in two columns. This construct is what Freudenthal called internal rations.

What Manuel said to solve the activity was: See Figure 4. "I checked how changing the amounts in the column of chocolate bars, because they give us more numbers in that column. I saw that started with the 6, after there was a space to fill, then was 18 and soon 24. I used the calculator and divided 18 between 6, I got 3, then divided 24 between 6 and I gave it 4 then 6 multiplied by 2 and got 12, that is the value of the second and the last column is what I got 6 for 5 is 30."

![Figure 4. Filling the table by Manuel, first column filled with gallons of milk](image)

The use of the table allowed the students to establish relationships between magnitudes of figures, approaching towards constructing internal and external ratios (as defined by Freudenthal). Lastly, The participants managed to use different registers of representation (drawing, table and numeric) to solve problems of ratio and proportion. These findings suggest that working with interactive activities allowed the students to construct a conceptual understanding of the concepts of ratio and proportion, rather than just using the algorithm to work on these problems. These results are similar to those reported by other scholars (Galbraith & Haines, 1998; Nguyen & Kulm, 2005; Combs, 2004; Engelbrecht & Harding, 2005a,b).

**Conclusions**

Our findings suggest that the theoretically grounded, and research based activities designed to support children in consolidating the concepts of ratio and proportion were appropriate. The participants showed great interest in working with the computer system and were autonomous about how they resolved tasks. Although the teacher had to pose tasks (give them a figure and ask that they compare it with others to see which was smaller or larger), but the students developed that ability to respond to these questions through the proposed activities in the system. On basis of this finding we are compelled to infer that the participants developed both qualitative and quantitative proportional thinking. They showed a great deal of experimentation by freely dragging the mouse, using the grid, filling in tables, without being asked by the teacher to do so. Lastly, they developed visual and perceptual skills, that is, qualitatively proportional reasoning.

The presence of the table feature of the environment allowed the students to establish relationships between magnitudes of figures. This helped them to realize the internal and external ratios (as defined by Freudenthal). The different registers of representation (drawing, table and numeric) available to students when solving solve problems of ratio and proportion in...
interactive activities allowed the students to construct the concepts of ratio and proportion meaningfully, rather than using algorithms mechanically. This is consistent with the results reported by other scholars (Galbraith & Haines, 1998; Nguyen & Kulm, 2005; Combs, 2004; Engelbrecht & Harding, 2005a,b).

The computer system was able to support the development of students’ skills with the board down. However, this skill development did not occur for all participants.

This paper presents a novel learning environment designed to support Algebra teaching and learning using a classroom network. We analyze a class session first at the level of the whole class, and then through more detailed examination of simultaneous activity in three student pairs. Classroom activity in this environment was organized around successive task goals that emerged from dynamic interactions among teacher, students and tools. The interplay between these emergent objectives and other features of the learning environment presented students with resources that they were able to organize into emergent solution strategies.

Introduction

A rich body of prior research has explored ways of using classroom networks of handheld calculators or computers to support classroom interactions (Hegedus & Penuel, 2008; Stroup, Ares & Hurford, 2005; White, 2006). Designs for learning activities featuring classroom networks often emphasize the collective construction of a set of mathematical objects—each student in the classroom group uses his or her device to contribute a distinct member of a family of functions, a locus of points, or a class of equivalent expressions to an aggregation on a teacher’s computer publicly displayed via LCD projection. In each case, the collective construct illustrates a map between the set and its elements that mirrors the relations between the classroom group and each individual student member, using the social organization and structure of the classroom as a resource for directing student attention to the relations among these objects and guiding classroom discussions about patterns within and generalizations across the array.

This paper reports on an ongoing design-based research project that seeks to build on these previous studies by exploring ways classroom networks might support not only mathematically rich collective activities at the level of the whole class, but also mathematical conversations and interactions among pairs and small groups of students. To this end, our design approach uses network links among student devices to align pairs or small groups of students with mathematical objects that participants in a pair or small group must alternately or jointly manipulate through their networked devices. Such objects are collective to the extent that they or their attributes appear—and change—simultaneously on multiple devices or in a shared display as a consequence of contributions from multiple students. Broadly, we aim to structure tasks around these collective mathematical objects in order to make the successful solving of problems dependent on contributions from and coordination between all participants in a small group. A central aim of our current work is to investigate the potential for these collaborative classroom network designs to reorganize or reshape conventional classroom activity structures—to study designs that blur the boundaries between forms of instruction oriented toward individual students, small groups, or the whole class. Below, we briefly discuss theoretical perspectives involving mathematical objects and introductory algebra, and then describe an activity design intended to support student learning about those concepts. We then present an analysis of the kinds of whole- and small-group classroom mathematical activity supported by this environment.

Collective Algebraic Objects

The meaning of algebraic expressions likely comes from a variety of sources, including the structure of those symbolic expressions themselves as well as their other representational forms, the problem contexts in which they are enacted, and other learner experiences and interactions exterior to the mathematical situation (Kieran 2007). For present purposes, we focus on the first (structural) and last (external) of these sources. Studies from a structural perspective emphasize the complexity of cultivating learners’ recognition of such expressions as mathematical objects (Sfard & Linchevski, 1994). From a perspective more attuned to exterior sources of meaning, coming to understand algebraic expressions as mathematical objects is part of a broader social process of objectification, in which learners become aware of objects as stable elements of sociocultural practice through interaction and reflection (Radford, 2006). In the design and study of the learning environment and activities described below, we sought to attend to both these structural and interactional elements of algebraic learning.

The Terms and Operations Design

The learning environment described in this paper was created using the NetLogo modeling platform (Wilensky, 1999) and HubNet architecture (Wilensky & Stroup, 1999) in concert with a classroom set of Texas Instruments graphing calculators connected through a TI-Navigator™ network. In the activity design called Terms and Operations, student pairs share responsibility for constructing a polynomial expression. Each student can use the directional arrow keys on a calculator connected to a network server to move an icon in a whole-class shared display (Figure 1) populated with a variety of floating monomial terms (of order, sign, scale and number set by the teacher prior to each activity). The right side of this display also includes a field that monitors the current state of the collective polynomial expression for each pair.

Figure 1. Terms and Operations
shared display with floating terms and collective expressions
In the activities for the present study, the members of each pair took turns capturing and operating on a monomial term to construct a new collective polynomial expression. Each time a student captures a term, she chooses an operation (Figure 2a) and enters the result of combining these with the pair’s previous expression (Figure 2b). If this combination is equivalent to the new entry, the collective expression updates accordingly. Typical activities in this environment involve either asking different groups to construct the same expression in different ways, or to construct different expressions that all share particular characteristics. Having student pairs construct these expressions by aggregating terms under different operations is intended to use both pair-level and whole-class interactions as contexts for engaging learners in dynamic construction activities which emphasize both (structural) equivalences among successively more complex objects, and the (operational) consequences of actions on those objects.

![Figures 2a and b. Student calculator screens featuring captured term and operation choices and a collective expression under the chosen term and operation and an equivalent student entry](image)

**Method**

The *Terms and Operations* design was implemented in a classroom-based design experiment with two groups of 16 9th grade Algebra I students. Four days of *Terms and Operations* activities with each of these groups were part of a year-long project in which students participated in classroom network activities for a one-hour session each week as a supplement to their regular mathematics program. These sessions were taught by the first author; this arrangement reflects a researcher-teacher (Ball, 2000) approach in the larger design-based research project, and was intended to provide a context for nuanced investigation of forms of teaching practice supported by those designs. On the basis of informed consent, three student pairs in each class were selected as focus groups and videotaped during all activities. All screen states of the public computer display were recorded as a video file for each class session, and an additional camera with a wide zoom setting captured this projected display along with the whiteboard at the front of the room, as well as whole-class discussions and other teacher moves. Server logs recorded all terms and operations selected and expressions entered on student calculators. Below, we present data from the fourth session with one of these classes in order to examine the forms of whole and small-group classroom activity supported by the *Terms and Operations* environment.

**Analysis**

Table 1 summarizes the sequence of collective expressions constructed by each student pair during the fourth day of *Terms and Operations* activities. These successive expressions reflect an evolving set of goals that emerged over the course of the session, taking the shape of at least four distinct and overlapping tasks posed by the teacher and taken up to varying degrees by each student pair. In the next section, we describe the ways these emergent tasks unfolded through the interplay between students, teacher and tools in this learning environment.

---

Whole Class-Level Activity: Emergent Tasks

After beginning the class with a brief review of the distributive property from the previous session, the teacher opened the Terms & Operations activity by asking each student group to make a collective expression that featured parentheses. When Group 2 completed this task by writing 5(5x), the teacher pointed out what they had done to the whole class, and then asked Group 2 pick up a new term, and to write their next expression without parentheses. As the other groups finished writing expressions with parentheses they were likewise given the same subsequent task. Continuing to build a succession of expressions with and without parentheses became an ongoing goal for each group throughout the remainder of the session.

Emergent Task 1. As other groups continued to produce initial expressions that included parentheses, they tended to follow the format of Group 2’s initial solution by writing a constant term in front of a set of parentheses containing a linear term (as in the second entries in Table 1 for Groups 1, 5 and 7). While several pairs were generating their next expressions without parentheses, the teacher rewrote their respective initial solutions (5(5x), 2(4x), 3(3x), 4x*(x), 2(2x), 4x+(2)) on the board and highlighted the similarity, and then encouraged these groups to build new expressions that included two terms and an operation within the parentheses.

Emergent Task 2. Eleven minutes into the activity, and as other groups were continuing to operate on new terms and write resulting expressions with and without parentheses, Group 6 created an expression with an $x^2$ term. Taking note of this expression as it appeared in the public display, the teacher pointed it out to the whole class and noted that there were no $x^2$’s among the floating terms. The teacher then prompted Group 6 to write a new expression that again featured parentheses, and meanwhile challenged the other groups to see if they could likewise construct an expression with an $x^2$ term.

Emergent Task 3. Over the next twelve minutes, groups continued to work on some combination of the parentheses and quadratic term challenges as the teacher alternated between assisting individual groups and leading brief discussions with the whole group. Twenty-three minutes into the activity, the teacher noted the successes by Group 3 (28$x^2$+24x+5) and Group 2 (75$x^2$+4x) in constructing quadratic expressions, and presented a fourth task, prompting them to try factoring these expressions by rewriting with parentheses but no $x^2$ term. When both groups initially struggled with how to simultaneously factor their current expression and pick up a new term, the teacher told the whole class about a discovery made earlier in the session by Group 8 (reported below) that they could keep their expressions the same by choosing a 1 as their new

term and multiplication as their operation. In the final remaining minutes of the session, Group 2 was able to use this approach to rewrite their expression as $x(75x+4)$.

**Discussion.** The four main tasks (writing increasingly complex expressions alternately with and without parentheses, including two terms and an operator within the parentheses, writing an expressions with a quadratic term, rewriting to eliminate the square) undertaken by students during this session were all initiated by direction of the teacher. However, while the initial alternating parentheses task was the planned emphasis for the activity, both the revision of the task to include an operator within the parentheses, and the subsequent challenges involving quadratic terms and factoring, emerged as responses by the teacher to specific student constructions appearing in the public display. We take these emergent objectives as both a consequence and a characteristic of the kind of classroom activity supported by this designed learning environment—as resulting from the superposition of small-group engagement with dynamic objects and teacher-led whole class discussion about those group-level objects as they appeared in fairly rapid succession on the collective display. In the next section, we examine three student pairs during a portion of this session in order to consider the relations between whole-class and small-group level activity in the *Terms and Operations* environment.

**Pair-Level Activity: Collective Objects and Emergent Solutions**

Table 2 presents a set of transcripts that span the simultaneous dialogue of three student groups, as well as comments made by the teacher both to the whole class and through tableside conversations with one of the groups, over a three-minute segment of the Terms & Operations session described above. In particular, this segment begins with the teacher’s observation that Group 6 had constructed an expression featuring a quadratic term, and follows the varying degrees to which these groups took up this new challenge or continued to work on other tasks. Below, we briefly examine the work of each pair during this segment.

**Group 8.** The start of this episode found Group 8 actively blurring the lines between small- and whole group activity, picking up on the teacher’s efforts to call the class’s attention to the public display by first looking around the room to figure out which of their classmates were in Group 6 (lines 1-5), and then finding Group 1’s expression on the screen and calling across the room to ask how they made it (lines 8-10). As the teacher set other groups to work generating an $x^2$ term, Group 8 agreed that they were “lost” and should ask for help (lines 16-17). Having previously constructed $-4(4x + 2)$, they had repeatedly attempted to pick another term and to remove the parentheses without success, each time failing to correctly distribute the $-4$ to rewrite their current expression before incorporating the new term. On arriving at their table, the teacher looked at Anna’s calculator and noted that she had just picked up a 1 and selected multiply, but not yet entered a new expression (lines 21-22). The teacher asked them about the effect of multiplying by 1, and then encouraged them to use this circumstance as an opportunity to simplify their current expression without also having to incorporate a new term and operation (lines 22-35). As the teacher moved away, the students discussed how to multiply both $4x$ and 2 by -4, and soon correctly entered $-16x-8$. Thus while other groups were taking up the new task of constructing a squared term, the teacher and these students were using their coincidental choice of an identity term and operation to resolve some persistent confusion about distributing over parentheses. This emergent solution would later mark an opportunity (described above) for the teacher to showcase this pair being successful and to share this lesson about multiplying by one, and become an important resource for other groups as they worked to rewrite increasingly complex expressions.
Group 1. In the moments preceding this segment, Group 1 had been struggling to pick up and operate on a new term that would allow them to rewrite $9x(-25)$ with two terms and an operation inside parentheses. Just before the teacher interrupted to show the class Group 6’s expression, they had chosen to add a 3. As they returned to pair work, Melissa suggested adding this 3 to the -25 would generate $9x(-22)$ (lines 12-14). Just as the calculator showed that this new expression was incorrect (lines 16-18), the teacher encouraged all groups to try to construct an expression with a squared term. Melissa appears to have taken this new direction as an opportunity to sidestep their difficulties in inserting another term to their current set of parentheses using addition or subtraction; instead, in that moment she sought out a $2x$, selected multiplication, and wrote a new set of parentheses in which she combined the new term and operation with their current $9x$ (lines 19-23). In this case, then, a newly emergent task (multiplying linear terms to construct a quadratic) also became an emergent solution to the previous task.

Group 2. As the teacher called the class’s attention to Group 6’s quadratic expression in the public display, the students in Group 2 discussed how Group 6 managed to “get a squared” (lines 1-6). As the teacher directed Group 6 to rewrite their quadratic expression using parentheses (line 7), the students in Group 2 wondered what they should be doing next (lines 8-14). Overhearing this comment, the teacher invited Group 2 and others looking for a new task to make an expression featuring $x^2$ (line 15). Group 2 immediately took up this challenge, seeking out a -$1x$ to pick up and multiply times their current expression (-$75x+6+5$) in order to both “get a squared” and “change the negative” (lines 16-26). In doing so, however, Ben felt they should also continue with the alternating parentheses task (lines 27-8). Similarly, in arguing that they should keep both uncombined constant terms inside the parentheses along with the linear term (lines 34-37), Jorge appears to have been continuing to attend to the emergent task constraint of writing multiple terms and an operator inside the parentheses. They merged these various tasks over the course of writing their next two collective expressions, first building -$1x(-75x+6+5)$ in lines 27-39, and then distributing and adding $3x$ to form $75x^2+4x$ in the minutes following this segment. Thus they were able to construct successively more complex objects and to integrate new challenges by successfully layering these with a progression of previous task constraints.

Discussion. These simultaneous episodes found each group negotiating an important set of challenges: because the environment required them to pick up and operate on a new term even as they undertook newly emerging tasks related to the construction of equivalent or more complex expressions, pairs had to simultaneously deal with the previous expression as object to be rewritten in different but equivalent form, and the chosen operation as process of combining old and new terms. In the first case, pair 8’s choice of an identity operation enabled them to focus on collaboratively working through and resolving some confusion about the process of rewriting an equivalent expression without worrying about a new transformation. Similarly, in abandoning their unsuccessful attempts to add a constant term and instead multiplying by a linear, Group 1 turned the occasion of the second emergent task into a means of accomplishing the previous objectives. And Group 2 carefully selected a new term and discussed steps that would allow them to simultaneously accomplish several construction tasks. In each case, features of the learning environment—the properties of an arbitrarily chosen term and operation, system feedback via the calculator about the equivalence of expressions, the public display of another group’s construction—provided resources that pairs were able to incorporate into emergent solution strategies.

Table 2. Overlapping teacher comments and dialogue of 3 student groups during a three-minute segment of the class session.
Conclusion

We summarize two main themes from the analysis presented in this paper. Firstly, classroom activity in this learning environment was organized around successive and overlapping task goals that emerged from dynamic interactions among teacher, students and tools. In addition to those objectives initially set by the teacher, other tasks and constraints arose as both teacher and students attended to new expressions constructed by groups and publicly displayed via the network. Secondly, the interplay between these emergent objectives and other features of the learning environment presented students with a dynamic set of challenges reflective of the complexity of this classroom activity, and also with an emergent set of resources that they were able to organize into solutions to those challenges. We take the above episode to illustrate a novel form of classroom mathematics activity supported by this learning environment, one which blurs the boundaries between conventional instructional modes such as student-centered small group work and teacher-led whole class discussion. This hybrid activity structure is mediated by collective objects belonging to each group but publicly displayed for the whole class, thus providing emergent resources for the teacher to orchestrate, and for all students to actively and successfully participate in, simultaneous mathematical activity across multiple groups.

We chart a historical analysis of a collaborative design-based research project investigating the emergence of mathematical meaning from embodied interaction with a technological tracking-system supporting the learning of proportionality. Recounting iterative cycles of a conceptually critical perceptual feedback element, we articulate three interconnected images of research-based designers: (a) Janus the two-headed keeper of passageways who sees artifacts alternately as a student would or as an expert would; (b) an investigator searching to explicate design decisions coherently in light of learning-sciences theory; and (c) a reflective practitioner who embraces tradeoffs and is open to constructive criticism and to implementing radical changes to design and theory. Ultimately, we posit, we as researchers are continuously developing professional vision for our own design even as the design changes.

Introduction

Design-based research (DBR), a fast evolving major approach to the investigation of human learning, is still nascent. Accordingly, whereas the approach has led to important ontological innovation and “humble theory” (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003; diSessa & Cobb, 2004), it still receives formative criticism as methodologically volatile (Kelly, 2004), under-theorized (Abrahamson, 2009), and rhetorically inchoate (Puntambekar & Sandoval, 2009). In this paper, we—a DBR team investigating mathematics learning by developing and implementing innovative instructional technology—reflect on milestones in an evolving project in an attempt to respond productively to some of these constructive observations.

We view our team-based design processes through the same theoretical models of learning that have been applied to students and teachers engaged in collaborative problem solving, particularly in open-ended construction-based learning (e.g., Blikstein, 2008). Several philosophical, cognitive, and practical dispositions converge in our analysis: (1) an epistemological perspective on knowledge as emerging from learners’ explorative, highly divergent, yet possibly guided goal-based interaction with materials bearing semiotic potential (Bartolini Bussi & Mariotti, 2008; Lakatos, 1976); (2) a pedagogical commitment to constructionist learning in which bricolage antecedes hypothesis (Papert, 1996); (3) a methodological technique of collaborative qualitative microgenetic analysis (Schoenfeld, Smith, & Arcavi, 1991); and (4) a coherent view of designers as reflective learners (Schön, 1992). Engaging this reflexive analysis, we bear in mind the methodological limitations of introspection, moreover group introspection, and the exacerbating factor of professional capital at stake and the consequent vulnerability of practitioners revealing the meandering, backtracking, abductive processes underlying their products. Nonetheless, we are committed to a view of insight as emerging from previous dedication, creativity, hard work, and collaboration (Sawyer, 2007).
Thus, to the extent that we can contribute to design theory by studying design, we wish to shift the investigation focus from design product to design process.

In sum, designers are learners just as much as their product consumers, the students, are. Whereas students engage in problems supporting content learning, designers engage in projects where interesting problems relating to epistemology, cognition, pedagogy, and design emerge. For designers, these problems are the semiotic potential of the evolving designs. And yet this potential can be availed of only in a collaborative culture of discourse. Just as teachers identify “teachable moments” bearing potential learning gains for students, so designers ought to identify “researchable moments” within their own design process that appear to bear potential learning gains for other designers and theoreticians—ontological innovations for the practice of design-based research. Similarly, just as classroom discussion is critical for students to avail of the semiotic potential of pedagogical artifacts, we submit, so design-team discussion is critical for researchers to avail of the theoretical potential of design decisions as revealing issues of cognition and instruction as well as design principles (cf. Edelson, 2002).

This paper is built as a reflective recounting of our collaborative design process in building instructional materials for the Kinemathics project, which centers on tapping Grade 4-6 students’ physical action and embodied reasoning as a means of scaffolding their mathematization of proportionality (Abrahamson & Howison, 2010). The process involved numerous iterations of innovative technology. Whereas the iterations implemented superficially similar interactive affordances, reflecting on implications of nuanced differences among the iterations drove us to reconsider our foundational conjecture pertaining to the function of embodied artifacts in mathematical learning.

### Background and Theoretical Framework

**Beyond Historical Revisionism: Toward Dynamic Coherence of Project, Process, and Product**

Reflecting on our mathematics background, the authors note one characteristic shared by mathematical proofs and design reports: the disproportionate emphasis on the product, which is often positioned as if it appeared ex nihilo. Initial attempts at problem solving, however relevant to consequent refinement or reorientation of the study, are oftentimes relegated to “just pilot talk” or, in the worst-case scenario, ignored wholesale or even ignominiously cashiered as unprofessional. In short, historical revisionism—reading onto the beginning of a process that which emerged only at its end—serves, by and large, as the normative modus operandi.

Yet it is precisely those early forays and bold conjectures that unshackle innovative design of extant unsatisfactory precedents, mark the unique character of the project, and lend functional coherence to the evolving group ethos and orientation—a coherence that enables the researchers to marshal and contain numerous local product oscillations typical in iterated development cycles of design-based research. If this historical process remains opaque, we submit, then the grounding of new theory may also remain opaque. We further submit that rendering the design process more transparent, and thus allowing a broad range of DBR practitioners operating in diverse domains to learn from one another’s design decisions, is a crucial step towards developing DBR as a rigorous pan-project methodology.

### Design ‘Seeing’ as an Emergent Process: Conversations With Material and Semiotic Potential

In his analysis of design, Donald Schön posits that the activity of design is necessarily knowing-in-action (1992)—that is, design acumen is implicit or procedural—and that, therefore, designers may gain best access to their professional knowledge when put in the actual mode of
designing. Furthermore, due to limited information-processing capacity, designers cannot, in advance of implementing a particular “move,” consider all the consequences and qualities that may eventually be considered relevant to its evaluation. The immediate corollary is that some design decisions emerge organically through the designer’s conversation with the material of a design situation; that is, the designer analyzes the design material, plans and executes the design move, then reflects on the (oftentimes unintended) consequences of this move—a process Schön refers to as seeing-moving-seeing. The term “seeing” can be interpreted as sense-making: “in all this ‘seeing,’ the designer not only visually registers information but also constructs its meaning—identifies patterns and gives them meaning beyond themselves” (p. 133).

The clarity of Schön’s construct of seeing-moving-seeing notwithstanding, we found the work of Maria Alessandra Mariotti and collaborators (Bartolini Bussi & Mariotti, 2008) particularly useful in helping us better understand what a researcher sees when engaged in reflective design (cf. Abrahamson, 2009). Mariotti approaches issues of knowledge construction by examining epistemological and cognitive virtues of goal-oriented guided interaction with pedagogical artifacts—the artifact’s semiotic potential. She distinguishes between personal meanings—constructed meanings arising in the individual from using the artifact as a means of accomplishing the prescribed task, and mathematical meanings—meanings that an expert recognizes as mathematical when observing the student’s use of the artifact. Thus, cultural pedagogical artifacts, such as a compass, an abacus, or a geometry module, may offer valuable semiotic potential with respect to particular educational goals: by taking advantage of its semiotic affordance, the teacher utilizes the artifact to occasion opportunities for students to develop personal meaning into mathematical meanings that constitute the didactical goals.

We believe that Mariotti et al.’s theoretical constructs are applicable in arenas beyond teacher–artifact interaction. That is, we posit that one thing designers strive to see through collaborative conversation with an evolving design artifact is precisely the artifact’s semiotic potential—both project-specific and practice-general—in terms of issues akin to foreseeable learning trajectories based on implementing this potential. We thus propose to imagine the design artifact as a gateway between personal and mathematical meanings. Like Janus—the two-headed Roman deity of gateways, passages, beginnings and endings (the mythological as well as etymological epistemic janitor)—designers approach their work with one face turned towards personal meanings and the other turned towards mathematical meanings, constantly striving to reconcile the two; designers construct the gateway–artifact and constantly modify and prune its corridors so as to optimize its wanderers’ learning trajectories.

In the following sections, having introduced our study’s orientation, objectives, and thesis, we present a design narrative consisting of vignettes of researchable moments that we view as indicative of the design process as a conversation wherein the emerging artifacts’ semiotic-cum-theoretical potentials are elicited; we then interpret the narrative through our theoretical lenses.

Research Context: An Embodied-Design Study of Presymbolic Proportional Reasoning

The study we report on is a subpart of Action-Before-Concept (ABC), a cluster of cross-disciplinary studies centered around questions respecting relations between procedural and conceptual knowledge, ultimately focused on the procedural–conceptual relation in mathematics instruction. ABC, writ large, is an inquiry into cultural precedence for pedagogical practice within explicitly embodied domains, wherein procedures are initially learned on trust yet subsequently—only toward perfecting the procedures toward mastery and further dissemination—are interpreted by experts as embodying disciplinary knowledge.
The particular study we report on is *Kinematics: Kinetically Induced Mathematics* (Abrahamson & Howison, 2010), an investigation into how students operating interactive mathematical artifacts develop the emerging tacit, embodied, sensori-motor coupling with the device into mathematical meanings. Specifically, Kinematics puts forth and pursues the bold conjecture that some mathematical concepts are difficult because ordinary life does not offer physical opportunities to develop multi-modal dynamical images by which to simulate these concepts mentally. Our approach is to devise tools and activities geared to induce in students physical experiences that are initially of little if any mathematical context yet gradually are seen as mathematical by having students appropriate strategically available disciplinary instruments as epistemic–discursive means of enhancing their inquiry and communication (see Abrahamson, 2009, for an outline and demonstration of this DBR meta-rationale).

Ultimately, this paper will focus on the evolution of a particular feedback element. At this point, however, we will build context for the subsequent discussion by overviewing the design’s history through the perspective of its key artifact, the *Mathematics Imagery Trainer* (MIT).

The original MIT, MIT1, was implemented as a mechanical device using pulley wheels with 4” and 6” diameters to effect a 2:3 ratio in movement of the attached ropes. The student holds handles attached at the ends of the ropes, and the researcher cranks a lever to raise and lower the ropes at a steady rate (see Figure 1a). MIT1 was limited, particularly insofar that its somewhat cumbersome mechanism allowed for the student to experience only a single ratio, a structural constraint liable to limit the ultimate semiotic potential of generalizing the phenomenon of proportion (Janus frowned). These perceived limitations impelled us to redesign MIT2 in an attempt to increase the design’s mathematical flexibility, performance precision, electronic module interactivity, and dissemination potential.

In our second iteration, MIT2, we leveraged the high-resolution infrared camera available in the inexpensive Nintendo Wii remote to perform motion tracking of students’ hands, similar to work by Johnny Lee (http://johnnylee.net/projects/wii/). The Wii remote is a standard Bluetooth device, with several open-source libraries available to access it through Java or C#. An array of 84 infrared (940nm) LEDs aligned with the camera provides out light (source), and 3M 3000X high-gain reflective tape attached to a tennis ball allows effective motion capture at distances as far as 12 feet. In use, infrared rays emanate from the MIT2, reflect off tape covering tennis balls held by the student, and are then sensed, interpreted, and visually represented on a large display.

---

in the form of two crosshair symbols (trackers). The display is calibrated so as to continuously position the crosshairs at the actual physical height of each hand in an attempt to enhance the embodied experience of virtual remote manipulation. Advanced MIT2 prototypes provide visual feedback of the student’s performance on a green–red gradient, a design feature we discuss in the following section (see Figures 1b and 1c; source and sensors are three feet left of the monitor).

MIT2 is our current technological vanguard, being successfully utilized in a study with Grade 4-6 participants. Analyses of twenty-one videotaped task-based interview sessions, in which individual or paired students worked with MIT2, suggests that participants struggled productively with canonical issues inherent to rational numbers, as evidenced by a succession of insights grounded in the embodied nature of the artifact. Namely, students first brought to bear naïve additive reasoning yet eventually assimilated the system’s unexpected behavior as a new type of equivalence class that builds multiplicative structures upon additive reasoning. In our analysis of students’ reasoning, we view mathematics learning as making connections between complementary mathematizations rather than progressive decontextualization. In this view, the MIT-induced embodied artifact of ambidextrous motion is proportionality, yet tacit proportionality initially unconnected, undisciplined: it needs to be reflected upon, signified in standard mathematical inscriptions, and substantiated and elaborated through explicit solution procedures. We detail our preliminary findings elsewhere (Reinholz, Trninic, Howison, & Abrahamson, 2010, in these same PME-NA32 proceedings; also see http://www.tinyurl.com/edrl-mit for a video overview).

**Researchable Moments: The Trajectory of “Green”**

Our decision to forsake MIT1 and re-embody our design in MIT2, and in particular our shift to an electronic medium, introduced both a wealth of opportunities and, concomitantly, a slew of new design challenges. Namely, whereas in MIT1 students were initially passive participants hanging onto the pullies, MIT2 required students to immediately take agency, and so a question emerged as to how this agency should be framed, elicited, and guided. That is, what were students to do in MIT2? What would be their task, how would they accomplish it, and what form of feedback might they receive on the quality of this performance? Our initial response was to create electronic “targets”—two circular symbols that move up and down the monitor screen at preset rates; we would task participants with tracking these targets by remotely manipulating two virtual crosshair symbols (trackers), thus constituting a digital analogue of MIT1’s rope tautness.

Once the development of the MIT2 program and user interface had progressed to a point that we could present it to a larger circle of researchers, we were prepared to reengage issues of feedback engineering and optimization, particularly with respect to orienting young students towards task completion. Critical to this collaborative reflection was the question of how to optimize the task such that students could best avail of the technological affordances of this innovative design through exploring its embodied problem space. We had already considered implementing on the monitor a symbol-based feedback mechanism in the format of “2: x”. Namely, “2” would remain constant while x varied according to the height of the participant’s right hand as detected in the instrument’s sensory field. However, the discussion session strongly suggested to us critical limitations of the “2:x” solution as a performance feedback: in addition to electronic calibration challenges of determining and displaying x, a selection of alphanumerical feedback was perceived as prematurely mathematizing students’ essentially embodied activity—the group opined that students should be given ample “free range” opportunity to explore and discover quantitative properties of the novel situation initially unfettered by potential arithmetic
encumbrance and biases invoked by symbolical mediation. Having debated the plausibility of various feedback types, ranging from purely numerical outputs to graphical animations such as growing flowers, it was suggested that color-based feedback might offer an adequate solution. In particular, the color green was suggested due to its positive cultural signification. Thence, the color red was selected in binary contradistinction to indicate poor performance. Finally, a color gradient between green and red would indicate intermediate performance. Yet, still a question remained: How exactly would the color feedback be implemented? Herein lay the rub.

Having established the green-to-red gradient as our feedback sign, we discussed the plausibility of coloring the targets themselves as feedback rather than presenting the colors as standalone signs. A dissenting group member suggested the alternative option of flooding the entire background with the feedback color. An evaluation of this suggestion, which was ultimately endorsed, led us to look anew at the very utility and purpose of incorporating targets in our design, in light of our intention to use color feedback. We concluded that the targets were now redundant and ultimately unwieldy. Specifically, participants’ exploration would be limited by the requirement to track moving targets. In contrast, we wanted to provide students with an opportunity to move the trackers freely, without the restrictions introduced by moving targets. Furthermore, to our surprise, we recognized that green, initially conceptualized as feedback, could in fact serve as a goal onto its own (analogously, urban drivers might deliberately attempt to effect a “25 mph” radar feedback). We thus decided to remove the trackers from the design entirely and implement the green/red background as the primary goal-cum-feedback element. Students’ task thus became, somewhat enigmatically, to “make the screen green.”

A routine of our design team is to simultaneously track changes implemented to the design and articulate these changes in terms both of their apparent improvement on earlier versions and their implications for subsequent iteration of development and implementation. So doing, we strive to cohere with the learning-sciences constructs guiding our research. However, attempting to make sense of an ostensibly simple question—“What is green?”—proved unexpectedly challenging. Our initial definition of green as a feedback indicating appropriate interface actions, namely “correct” hand-to-hand ratio, seemed incomplete. A subsequent two-week email flurry following the adoption of green feedback evidences dogged pursuit of one recurring question: “What is green?” Gradually we came to reason as follows: to a participant, green would initially constitute an objective; then green would serve as the performance feedback in attempting to achieve the same objective; and would ultimately give rise to an equivalence class—a collection of hand-location pairs that the student would perceive as “the same” by virtue of their common effect on the screen. Given appropriate guidance within this context, we surmised, the semiotic potential of green could be cultivated into notions of proportion and reformulated numerically.

The green quandary settled, we faced a dilemma: having abolished the targets, would our design still enable learning processes consistent with the ultra-radical-constructivist version of our action-before-concept conjecture? That is, we worried that by having designated green as the students’ goal-cum-feedback, students would not occasion opportunity initially to engage “meaninglessly” with the MIT. We had reasoned that MIT1 provided students with such passive participation, and this passivity cohered with our embodiment thesis; in contrast, MIT2 rushed students to a highly prescribed activity. Ultimately, we resolved this dilemma by modifying the ABC theoretical framework: rather than strive for completely meaningless activity—a design objective at odds with the Vygotskian thesis that complements our constructivist commitments—we start from an activity whose performance objective is prescribed and demands immediate agency, yet whose disciplinary semiotic implication is initially covert.

Discussion and Implications for Design

The episode above captures much of what we mean by “recognizing semiotic potential through collaborative conversation with material”: by implementing green feedback and reflecting on it, our research team could recognize in the design hitherto latent potentials as well as constraints. In particular, identifying emergent incongruence between the design and our theoretical commitments drove us to consider, and then implement, modification in our theory—a form, if you will, of productive cognitive dissonance. This is a particular advantage of working in the DBR approach: the seeing-moving-seeing cycles provide ample opportunities for both illuminating the design’s semiotic potential and reflecting on underlying and emerging theory. Furthermore, inasmuch as the discussion helps other designers understand and improve their own processes, the episode would indicate the importance of avoiding historical revisionism in reporting design decisions as well as the value of persevering in making sense of intuitive design decisions (Abrahamson, 2009). Note that it is not the case that we introduced green feedback in order to replace the targets—claiming this would constitute historical revisionism and obscure the dynamic interactive nature of our collaborative design process. Rather, deciding to use green feedback led us to reflect in depth on the targets’ semiotic potential within the protean context of the evolving artifact, which in turn led to their removal from the design and our consequent focus on making sense of “green.” Thus a seemingly minor design decision resulted in drastic changes in both the semiotic potential of the resulting artifact and, consequently, the emerging theory.

The analysis of our shared design history, presented in this paper, portrays DBR practice as a complex, emergent system, with small sparks gathering together over time, multiple dead ends, and the constant reinterpretation of previous ideas (Sawyer, 2007). Our navigation of this maze, in particular the moment-to-moment contextual shifts framing the evolving artifact, yielded three images of design-based researchers: (a) Janus the two-headed keeper of passageways who sees artifacts alternately as a student would or as an expert would and strives to facilitate cognitive entries into, and safe passages through, these learning corridors; (b) an investigator doggedly searching to explicate design decisions and elements coherently in light of learning-sciences theory; and (c) a reflective practitioner who embraces tradeoffs as rules of the game, logs all design decisions, shares deliberations with colleagues, and is open to constructive criticism and the possibility of implementing radical changes to both design and theory. We have found the above images, which emerged from this study, helpful in structuring our project and, so doing, allowing us to constantly revisit (and frequently revise) our theoretical framework in productive ways. Though design-based research may follow divergent paths, it is not a random walk.

In closing, we wish to underscore the critical role of vigorous reflection and respectful challenge within the collaborative progress of a design team. Expressed within a collegial atmosphere, genuine dissent encourages divergent thinking and thus creativity (Nemeth, 2009). This cognitive and epistemic plurality, coupled with dogged insistence on systemic coherence, enabled us to pursue divergent research directions, including emergent issues of apparently nugatory significance that consequently proved crucial in advancing our theoretical understanding of students’ reasoning. Moreover, by engaging these materials as a group, a wide range of the artifacts’ semiotic potentials were broadcast, simulating some of the design’s interpretive diversity as we entered our empirical site and engaged our study participants. Note, though, that we do not restrict collaboration to the oral medium: indeed, the very activity of co-authoring and revising this text served to push our collective underdeveloped intuitions beyond the realm of “stygian shades” (Vygotsky, 1978) and towards articulated discursive coherence.
Ultimately, we as researchers are recursively developing professional vision for our own evolving design.

EIGHTH GRADERS’ USE OF DISTRIBUTIVE REASONING FOR MULTIPLICATIVE TRANSFORMATION OF UNIT FRACTIONS

Jaehong Shin  
Korean National University of Education  
jhshin@gmail.com

Soo Jin Lee  
Montclair State University  
leesoo@mail.montclair.edu

As an extended investigation of children’s construction of Rational Numbers of Arithmetic (Olive & Steffe, 2010), the present study explored how two 8th grade students constructed a scheme to multiplicatively transform a unit fraction into another unit fraction through a year-long teaching experiment. The results of this study indicate that distributive reasoning was essential and provided a base to explore the operations that produce the transformation.

Introduction

There have been a lot of efforts in mathematics education to investigate children’s learning of fractions since Davis, Hunting, and Pearn (1993) commented that "the learning of fractions is not only very hard, it is, in the broader scheme of things, a dismal failure" (p. 63). One group of researchers, whom Pitkethly and Hunting (1996) mentioned as one of the two main schools in the research on children’s initial fraction concepts, argued that the equidivision of a unit into parts, the recursive division of a part into subparts, and the reconstruction of the unit were essential for developing rational number meaning (Kieren, 1992; Mack, 1990; Steffe & Olive, 1990). Specially, Steffe and Olive (1990) conducted The Fractions Project to investigate children’s construction of fraction schemes using operations that produced their number sequences (Biddlecomb, 1994; Olive, 1999; Steffe & Tzur, 1994; Steffe, 1992, 2010). From their teaching experiment, Steffe and Olive introduced a scheme, called the rational numbers of arithmetic (RNA), in which fractions have become abstracted operations. A child can be judged to have constructed the RNA when “the child is aware of the operations needed not only to reconstruct the unit whole from any one of its parts but also to produce any fraction of the unit whole from any other fraction” (Olive, 1999, p. 281). For the construction of RNA, Olive argued that a child integrates the operations of his or her generalized number sequence (GNS) with the operations that produce fractions as measurement units. He also argued that the process of children’s construction of the RNA should be investigated because the operations that produce the RNA would be those operations that undergird the division of fractions. Therefore, the present study, as an extended investigation of children’s construction of RNA, was conducted using a year-long teaching experiment with two 8th graders in order to explore how the two eight-grade students constructed fraction schemes based on their GNS.

Configuration of Research Questions

Olive and Steffe (2010) reported that students modified their existing counting schemes to form a connected number sequence (CNS) with their own fraction language. In their teaching experiment, Nathan, who had constructed a GNS, constructed fraction schemes during the first year of the teaching experiment that surpassed the fraction schemes the other students, who had only constructed the explicitly nested number sequences (ENS), produced throughout three years. He developed schemes of operations with fractions that allowed him to add fractions with unlike denominators, find a fraction of a fraction, rename fractions, and simplify fractions to lowest terms (Olive & Steffe, 2010). Further, they observed the harbinger for the construction of RNA...
in the construction process of Nathan’s fraction schemes. Producing a co-measurement unit [one-sixth is a co-measurement unit of one-half and one-third because both are multiples of one-sixth] seemed essential for students’ construction of RNA. Nathan was able to produce comeasurement units for fractions with which he could produce any fraction from any other fraction. For example, Nathan was able to make 1/9 of a unit stick using 1/12 of the stick by finding 1/36 as a co-measurement unit for both 1/12 and 1/9.

However, it was not reported whether he was explicitly aware of the multiplicative relationship between the two unit fractions while engaging in the transformation process. We would attribute a scheme to multiplicatively transform one unit fraction into another to a student when he or she is not only able to transform a unit fraction into another unit fraction, but also explicitly aware of the fraction to be used for the transformation. After Nathan transformed 1/9 of a stick into 1/12 of the stick, it is questionable whether he could find that 1/36 was a co-measurement unit of the two fractions because this would involve reflectively abstracting the sequence of operations in which he engaged into a program of operations. Further, the role of distributive reasoning for students’ construction of RNA is yet to be investigated even though Olive and Steffe (2010) maintained that the construction of distributive reasoning enabled their students to establish a fraction composition scheme in relation to fraction multiplication.

Reasoning with distribution likely requires having abstracted a three-levels-of-units multiplicative structure that can be brought to a situation prior to activity (Hackenberg, 2007).

Our study basically explored how two eighth-grade students constructed fraction schemes based on their GNS. Specially, in this paper, we will focus on the students’ construction of a scheme the purpose of which is to multiplicatively transform a unit fraction into another unit fraction by addressing two main questions:

1. How did two eight graders construct distributive partitioning operations using their GNS?
2. How did construction of a scheme for multiplicative transformation between two unit fractions emerge as a modification of the students’ prior knowledge (GNS or distributive reasoning)?

**Method of Inquiry**

The data for the present study were collected from a year-long teaching experiment (Steffe & Thompson, 2000), in which the first author participated as a teacher-researcher with a pair of eighth graders at a rural middle school from October 2008 to May 2009. The experiment is part of a larger, longitudinal study whose purpose is to bring forth and understand middle school students’ algebraic reasoning. Rosa, one of the two participants, was chosen after an individual selection interview conducted on October of 2008. Carol, the other participant, had been chosen on October of 2007 and was paired with Rosa for her second year of teaching experiment. The criterion for selection of the two students was the ability to use composite units as iterable units, which was an indicator of the GNS. During the teaching experiment, the first author met once or twice a week in about 40-minute teaching episodes and the findings for this study were derived from seven episodes among them. All teaching episodes were videotaped with two cameras for on-going and retrospective analysis. One camera usually captured the whole picture of interactions among the pair of students and the teacher-researcher, and the other camera followed the students’ written or computer work with the aid of two witness-researchers. The role of the witness-researchers was not only in assisting video recording but also in providing other perspectives during all three phases of the experiment: the actual teaching episodes, the on-going analysis between episodes during the experiment, and the retrospective analysis of the videotapes.
In terms of data analysis, the first type of analysis was ongoing analysis that occurred by watching videos of the teaching episodes and discussing and planning future episodes. For the most part, the resources from two cameras were mixed for a single, digitalized video file on the day of each teaching episode. In this way, we created a restored view of our teaching experiment. “A restored view is a wider view of activity than can typically be captured with an individual camera, but is still a selective view that reflects the researchers’ perspective of the recorded lesson” (Olive & Vomvoridi, 2006, p. 21). Then a sequence of summaries for the teaching episodes were created, each of which provided not only written descriptions of the participating students’ mathematical activities and interactions with the teacher-researcher, but also emerging key points in the students’ thinking and learning that were taken into account for the next teaching episode. The second type of analysis was a retrospective analysis. The purpose of the retrospective analysis of the sequence of teaching episodes was to make models of the students’ ways of operating mathematically through conceptual analysis of the students’ mathematical activities. We, first of all, attempted to understand what the students’ behaviors were and hypothesized why the students behaved in such ways. Then the attribution of the researchers’ construction of a scheme to the students was made at this stage.

**Data Excerpts**

Although finding a co-measurement unit for two given unit fractions [a fractional unit that can be used to exactly measure each unit fraction] would be essential for students to transform one of the unit fractions into the other (Olive & Steffe, 2010), the results of this study indicate that distributive reasoning was essential as well and provided a base for the students to become aware of the operations that produced the transformation. During the teaching experiment period, the two participating students demonstrated that they had constructed distributive partitioning operations in the context of a sharing situation, which might be considered as a partitive division problem involving fractions. However, the observation that they used distributive partitioning operations in their transforming a unit fraction into another was unexpected.

Even though a difference was revealed between Carol’s explicit use and Rosa’s implicit use of distributive partitioning operations, in this paper, we will follow the overall constructive itinerary for multiplicative transformation between two unit fractions based on distributive reasoning, mainly by focusing on Carol’s mathematical operations. The detailed discussion for elaborating the distinction between implicit and explicit use of distributive partitioning and significance on further mathematical activities is beyond the range of the paper.

**Distributive Partitioning Operations in a Sharing Situation**

On the 10th of February, Carol demonstrated that she had constructed distributive partitioning operations in a sharing situation. Upon the request to find one person’s share when six persons equally share five candies using JavaBars1 (Olive, 2007), Carol made five bars for five candies on the screen, divided each bar into six pieces and pulled out one piece from each of five bars, which was cut into six pieces. This was an indication of distributive reasoning. That is, she formed a goal of a distributive partitioning scheme, say, to share five identical candy bars equally among six people. She then partitioned each candy bar into six parts and distributed one part from each of the five candy bars to each of the six persons with understanding that the share of one person could be replicated six times to produce the whole of the five candy bars. She also knew that five-sixths of one candy bar was identical to one-sixth of all of the candy bars. Rosa also similarly drew five candy bars on the screen, partitioned each bar into six pieces and took
five pieces out of thirty little parts (see Figure 1). Her comment, “So each person gonna get one-sixth of the candy bar and since there is five total candy bars... basically one person’s gonna get five-sixths of one whole candy bar,” corroborated her construction of distributive partitioning operations in the context of the sharing situation.

Figure 1. Rosa’s drawing for sharing five candies among six people

Emergence of Distributive Partitioning Operations in Transforming a Unit Fraction into Another

Since a scheme for a multiplicative transformation between two unit fractions requires being explicitly aware of the fractional operator to be used in the transformation as well as the transformation activity itself, the teacher-researcher decided to pose transformation problems in the milieu of Geometer’s Sketchpad (GSP) using a DILATION option. The DILATION option opened the way to allow the students to produce a multiplicative geometric transformation. In contrast to the program, JavaBars, where the students could produce their transformation activities step by step, the DILATION option in GSP directly asked to generate a scale factor for the transformations (cf. Figure 2). In that sense, transformation activities in GSP provided an occasion for the students to reflect on and abstract their mathematical activities for the transformations, which might lead to construction of a scale factor, that is, the number to be multiplied by [the multiplier]. On the 30th of March, the teacher-researcher posed a problem to find a multiplicative fractional operator to transform one-fourth of a meter into one-tenth of a meter using dilation in GSP (See Figure 2).

Figure 2. Multiplicative transformation using dilation in GSP

However, even though Carol and Rosa were familiar with the effect of dilation through several teaching episodes, say, transformation of a 2-meter segment into a 1/3-meter segment by dilating...
by one-sixth, they seemed stuck with finding one number that they could use to dilate 1/4-meter into 1/10-meter. Such a transformation activity in the GSP environment seemed too abstract for the students. Therefore, the teacher-researcher turned to using JavaBars in order for the students to possibly abstract their transforming activities. Carol and Rosa were asked to transform a 1/4-meter bar into a 1/10-meter bar using JavaBars. Both students started with the 1/4-meter bar and then copied it three times and joined the copies with the original 1/4-meter bar to make a 1-meter bar. Then Carol partitioned each 1/4-meter bar into ten parts and pulled out one part from each of the four 1/4-meter bars (see Figure 3). Her distributive reasoning was explicit in the sense that she anticipated one-tenth of the whole of the four parts could be found by taking one-tenth of each part and joining the four parts together, prior to engaging in the actual activity. When she was asked to reflect on her transformation processes in JavaBars in GSP environment and to find the number to be used in the dilation, she found four-tenths based on her construction in JavaBars. Although she already demonstrated the use of her distributive reasoning in a sharing situation, this transformation problem was a novel situation for her to use her distributive reasoning. In contrast, Rosa’s distributive reasoning was not clear in that partitioning activities were usually initiated by Carol. Rosa then assimilated Carol’s reasoning and imitated it. For Rosa, distributive reasoning did not emerge explicitly in such transformation situations during the teaching experiment.

Figure 3. Carol’s transformation from 1/4-meter to 1/10-meter

Multiplicative Transformation of Units Fractions based on Distributive Reasoning

On the 15th of April, Carol’s behavior indicated construction of a scheme to multiplicatively transform one unit fraction into another based on her distributive reasoning. When the teacher-researcher asked the students to find a scale factor for transforming a 1/11-meter segment into a 1/13-meter segment using dilation in GSP, Carol immediately said “11/13” with an explanation that she had to multiply the 1/11-meter by 11 to get to one meter and then dilated the one meter by 1/13 to get 1/13, which led to the answer 11/13. The ability to take one-thirteenth of her represented 11/11-meter segment using her distributive partitioning operation seemed to enable her to find the fractional operator, 11/13, for the transformation by combining 11 with 1/13. On the other hand, Rosa could not independently establish the number to be used in dilation prior to activity throughout the teaching experiment even though she was able to enact transforming a unit fraction into any other unit fraction without such an explicit awareness. Rosa’s implicit use of her distributive partitioning operations seemed to constrain her transformative activity.

Educational Importance of the Study

Only enacting the multiplicative transformation between two fractions is insufficient to construct the RNA because the RNA entail, “the construction of abstracted fractions as an
ensemble of operations of which children are explicitly aware" (Steffe & Ulrich, 2010, p. 266). The RNA serve as an intermediate step in the constructive itinerary of students from fractional numbers to rational numbers of arithmetic as the latter are understood in conventional mathematical terms as an equivalent class of fractions. So, understanding the processes that are involved in students’ construction of the operations that enable them to construct a multiplicative relation between any two fractions serves in understanding students’ construction of the rational numbers of arithmetic in conventional mathematical terms. It also serves in understanding the steps that are involved in students’ construction of fractional division and reciprocal reasoning. Further, this investigation of students’ construction of multiplicative relations between two fractional quantities will contribute to the research in proportional reasoning, a form of a mathematical thinking that involves a sense of multiplicative co-variation.

Endnotes

1. JavaBars, a computer software, opens the possibility for students to create and enact a variety of different operations (i.e., partitioning, disembedding, iterating, etc.) on rectangles and squares. For instance, with JavaBars, students can create a rectangle, horizontally or vertically partition it into four parts and then pull out one of the four parts to construct three-fourths of the original referent whole by iterating it three times.

SECONDARY TEACHERS FIRST WAYS OF INCORPORATING MATHEMATICS TECHNOLOGY INTO CLASSROOM PRACTICE

Verónica Hoyos
Universidad Pedagógica Nacional (México)
v_hoyos@mac.com

In this paper we present and analyze ways in which fifteen secondary teachers utilized technology in their classrooms having participated in an online technology training course for six months. The online course consisted of a series of activities designed for teachers to revise teaching some of the basic concepts relevant to high school mathematics, using technology and also HTML and JavaScript languages. Our training work hypothesis was that the uploaded activities would permit participating teachers to take up high school math innovatively through utilization of the conceptual or technological tools acquired by the mediation of the instrumental activity displayed along the mentioned course. Data consisted of the videos that the teachers submitted at the end of the OTC, demonstrating how they integrated technology in their teaching.

Introduction

The need to utilize new technologies throughout the educational system is now one of the prominent educational goals of one of current Mexico’s official educational policies. To achieve this goal, Mexico’s 2007-2012 National Development Plan (PND) states that adoption of new classroom technologies may be accelerated by offering teachers certified courses so that they become educated on how to use technology-mediated modalities in their instruction. As a consequence, efforts have been invested in designing learning environments for optimizing teacher development in that area.

Zbiek & Hollebrands (2008) argued that in order to assist develop technological competencies teachers must be considered as learners who move toward deeper understanding of what it means to use mathematics technology effectively with their students (p.288). In operationalizing this perspective, the authors endorse Beaudin and Bowers’ (1997) PURIA model as a possible venue for PD design.

The PURIA model open some research-intervention issues that notably could facilitate or promote teachers development along a learning continuum. In fact, the model implies that the teachers experiment with different modes or development states to advance towards successful incorporation of technology in their instruction.

As Zbiek and Hollebrands (2008) stated, the growth during these modes includes the transition of the technology as the developer’s tool into the teacher’s instrument for doing mathematics, a crucial aspect of learning to use technology captured by the notion of instrumental genesis. Similar ideas were suggested by other scholars (Verillon & Rabardel, 1995; Ruthven & Hennessy 2002).

Ruthven and Hennessy (2002) investigated the teachers’ conceptions about what might constitute as successful practice using mathematics-focused technology. According to the authors, teachers’ successful practice has to be considered as only tentative. Ruthven (2007) also argued that teachers would attain that ideal model only if they could develop knowledge through their own practice (craft knowledge). That is, starting from their craft knowledge teachers would be able to construct some more satisfactory ways for using new technologies into classroom.
Ruthven (2007) posited that craft knowledge is the largely reflex system of powerful heuristics which teachers bring to their classroom work. It draws on proceduralised and automated routines, tailored to the particular circumstances in which the teacher works. In particular, Ruthven (ibidem) said that much of the proposed innovation entails modification of this system (Ibidem, p. 6/16).

The PURIA Model

In a synthesis of the research regarding the use of technology into mathematics classroom practice, Zbiek and Hollebrands (2008) elaborated and extended what Beaudin and Bowers (1997) described as the PURIA Model (Play, Use, Recommend, Incorporate and Assess modes). According to Zbiek and Hollebrands (Ibidem), the extended PURIA Model considers the following five modes of using technology:

\[ P \] is the mode that involves playing with the technology. During this mode the use of technology does not have clear mathematical purpose.

\[ U \] is the mode that involves using technology as a personal tool. It is to say that the use of technology is for doing mathematics of one’s own design. May be using it in a classroom setting and not using it with students.

\[ R \] involves recommending technology to others. For instance, recommending use to a student, a peer, or a small group of students or peers. This likely is not in a formal classroom setting and it is not an integrated part of instruction.

\[ I \] involves incorporating technology into classroom instructions. In this mode, the teacher integrates the technology into classroom instruction. This mode occurs to varying degrees.

\[ A \] finally, this mode involves assessing students’ use of technology. Here, the teacher examines how students use the technology and what they learn from using it (Zbiek & Hollebrands, 2008, p.295).

According to the authors, the resulting PURIA modes reflect the teacher becoming familiar with the technology as a tool for doing mathematics in the Play and Use modes. The growth during these modes includes the transition of the technology as the developer’s tool into the teacher’s instrument for doing mathematics, a crucial aspect of learning to use technology captured by the notion of instrumental genesis (Guin & Trouche, 1999; Trouche, 2000. Cited by Zbiek & Hollebrands, Ibidem).

In the Incorporate and the Assess modes, the teacher’s attention turns, implicitly or consciously, toward the use of technology as a pedagogical tool, including the development of instructional orchestrations (Trouche, 2000) or elaborated plans regarding use of technology in the social dimensions of classrooms. The Recommends mode seems marked by a transition between mathematical and pedagogical aspects of the technology (Zbiek & Hollebrands, 2008, p.295).

The first two modes in the PURIA Model suggest that the teachers use the technology free of stress because they want to do so. If their initial experiences are successful, they will immediately proceed to work in a more pedagogically structured manner; in accordance with the Incorporate and Assess modes. Finally, the Recommend mode acts as a transitional phase from the teacher’s initial experiences with technology to those pedagogically structured.

Zbieck & Hollebrands (2008) point out that the mathematical situations where the teachers find unexpected results, and the follow up on these tasks via opportunities for them to research,
explain, and debate such situations, are experiences that may become the essence of powerful intervention when the teachers are using technology in accordance with the PURIA mode called Play or personal (p. 322). Finally, the authors mentioned that they found in this model a perspective that allowed for explicit consideration of teacher’s needs to learn to use technology, to learn to do mathematics with technology, to use the technology with students, and to attend to student learning as a guide for innovation.

The Instrumental Perspective and the Growth of Knowledge

According to Verillon and Rabardel (1995), artifact’s structure and function will foster certain knowledge or effect in cognitive development. That is, the introduction and use of instruments, whether material or psychological (language, computational means, symbols, diagrams, maps, and so on), leads to consumption of many structural and functional changes in learner’s cognition. These authors perceive development to be the result of an extensive artificial process in which the acquisition of instruments plays a central role. Thus, it is not so much the instrument in itself which determines growth, but rather the functional reorganization and deployment that their acquisition and use impose onto innate mechanisms at distinct levels: sensory-motor, perceptive, mnemonic, representational, etc (Verillon & Rabardel, 1995, p.82).

Structure of Teaching Practice Using Technology

From our perspective, the activities implemented in the online course could and would allow participating teachers to learn to use technology and learn to do mathematics with technology. Moreover, asking teachers to incorporate technology into the classroom, with free choice of topic and technological tool, permitted us to study the participants’ responses to the proposals for use of technology we had presented during the online course. It was important to examine how teachers responded to our technology teaching proposals implicitly included in the design of the activities uploaded for the course. According to Ruthven (2007): “If the technology must find a place in classroom practice, it must be examined in the context of class life, [just] as teachers life it.” (Kerr, 1991, p. 121. Cited in Ruthven, 2007, p. 3). From Ruthven’s point of view there are five key components of the structuring context of classroom practice: working environment, resource system, activity format, curriculum script and time economy. If researchers have these components on mind, they will draw on a range of more general work on classroom processes and teaching craft knowledge.

Methodology

Different Technological Resources Displayed Throughout the Online Training Course

We set up 24 weeks of activities uploaded in a moodle platform (link: http://upn.sems.gob.mx/main.php) that were designed for 15 high school mathematics teachers to help them learn how to appropriately use technological tools in their classrooms. Computer programming topics were addressed, particularly introduction to HTML and JavaScript programming, design of algorithms and their representations, algorithm development, flow charts, and codification, specifically with the purpose of teachers would experiment a change in the way they used to see or to approach to study mathematical algorithms.

The training course also included sequences of activities on the use of interactive software (eg. Logo, Geogebra, Aplusix, Excel, RecCon, FunDer); and exploration of a wide range of possibilities put in the Internet, for example, the library of virtual materials (eg. http://nlvm.usu.edu/en/nav/vlibrary.html) of Utah University (USA).

On the Mathematical and Pedagogical Tasks along the OTC

The mathematical topics covered in the activities included: Introductions to the fundamental arithmetic theorem, Goldbach’s conjecture, graph theory, and calculating roots of polynomials (with the bisection method and the Regula Falsi method, the secant method, and Newton’s method) purposed to review some of the algorithms important to these contexts, as well as the distinct possibilities of representing them in mathematics and computing. Although these topics are notably more advanced than what is included in the curriculum of Mexico’s high schools, they were planned so as to challenge teachers’ own existing knowledge by engaging them in solving problems that they may not have seen before or feel in control.

In relation to the pedagogical activities displayed throughout the OTC, we included four weeks of activities (two at the end of the first 10, and two at the end of the next 10 weeks). At the conclusion of OTC activities the teachers had to complete an assignment. The assignment asked that the teachers to first select one topic from high school mathematics curriculum, along with the software, tools, or digital materials they thought it would be useful to use on teaching the chosen topic. They then had to instrumentate a classroom work session with their students in a convenient way according to their chosen digital material. Following the video-recording of the work session, they had to upload a seven minutes long version of that recording to YouTube. Lastly, they had to upload their movie to the training platform a descriptive report of the video’s content together with its URL. The results were based upon the analysis of the videos from five classrooms from the uploaded movies by teachers.

Results

The data illustrated that teachers displayed the PURIA modes of Play, Use, and Recommend. Additionally, the teachers also started to Incorporate mathematics technology into the classroom. More specifically, the analysis of the participants’ videos revealed five different ways in which teachers’ began to use technology in their instruction. These included use as: (1) A pattern of incorporation that derived from the classic approach to teaching, where the teacher use some technological tools mainly to explain to the students the topic they should learn (see Fig.1); (2) a modified version of this pattern that added teacher interaction with the students, basically by teacher questioning to the whole class (see Fig.2); (3) instrumentalization of the activity (Verillon & Rabardel, 1995; Assude et al., 2006) led by the use of a script (see Fig.3); (4) the teacher is orchestrating (Trouche, 2004) the activity using technological tools and leading comparisons between advantages and disadvantages of using paper and pencil techniques (see Fig.4); and finally, (5) organization of cooperative work centered on student appropriation of technology and project learning (see Fig.5).

An example of each mode of usage is presented below (detailed videos can be accessed at the listed URL address):
A.  http://www.youtube.com/watch?v=PlLYsIO-Vh0&feature=related (See Fig. 1).

Figure 1. The teacher use some technological tools mainly to explain to the students a mathematical topic

B.  http://mx.youtube.com/watch?v=N1FwbEo5KGI (As an example, see Fig. 2).

Figure 2. Classic approach to teaching, adding teacher questioning to the whole class
C. http://es.youtube.com/watch?v=yhXs8BLMFlM (See Fig. 3.)

Figure 3. The teacher is conducting an instrumentalization of the activity led by the use of a script

D. http://mx.youtube.com/watch?v=gwGcPtyXYbs (See Fig. 4)

Figure 4. Orchestration of the activity using technological tools and comparing advantages and disadvantages of using paper and pencil technique

Moreover, analysis of videos evidenced the presence of four of the five components Ruthven (2007) had distinguished as key elements to the structuring context of classroom practice with the goal of improving it. Specifically, these included the state of working environment, resource system, activity format and curriculum script, and teaching craft knowledge on the use of technology into classroom.

In relation with these components the evidences we obtained indicated that in a majority of the video-vignettes we reviewed the insufficient equipping of computers in the schools was patent, insufficient to providing one machine to each student and permit individual work. That is, in these cases the teachers only had one single computer in the room, (most likely their own,) and an LCD projector. Also, 37% of the teachers were able to complete their teaching practice in the computer lab that was fully equipped so that each student (or pair of students) had access to a machine. Nevertheless, the teachers showed competence selecting and mastering the technological tool to use into their classroom instruction, and choosing the topic to address. The teachers also showed different planning levels in relation with their interventions during their planned practice using technology. In particular, it was noticed that the teachers included more detail in their lesson planning and one more advanced mode they displayed during their practice, as it was the case of those that showed negotiation of meaning and organization of cooperative work between the students.

Finally, the different degrees teachers displayed to integrate mathematics technology into classroom instruction allow us to do a qualitative appraisal of the state of the development of their craft knowledge.

So that it becomes feasibly to predict progress in the process of learning to use the technology for teaching mathematics, in according to the extended PURIA Model, and when the participants OTC teachers were involved in assessing their students’ learning, and when these
teachers do their planning and their practice using the acquired technological and conceptual tools recently showed.

Conclusions

The advent of new technologies confronts teachers with great challenges as the one of having to learn to teach using new artifacts and technological tools into the mathematics classroom.

In this paper we focused on teachers’ practice. Our specific interest was to consider how the teachers started to incorporate mathematics technology into their mathematics classrooms. We analyzed this process throughout the extended PURIA Model (Zbiek & Hollebrands, 2008), which is a development model based on different modes of use of the mathematics technology into the classroom. According to this model, the Assessment mode would be the one to reach, and it is reaching it when teachers would center their attention on the students as a guide for practice innovation.

Data was collected and analyzed using the video-vignettes of teachers’ own practices. For some of the teachers (particularly those that included negotiation of meaning and organization of cooperative work between the students) developed competency to organize the instrumentation of the activity into their classroom. Therein underlies a latent potential to advance the thinking and development of the teachers towards the assessment of students’ learning, the final stage in the PURIA Model of the learning process to teach with technology into mathematics classrooms.

Advances in technology are only useful to educators if they can be applied in a practical and appropriate way to daily instruction. A mobile learning device (MLD) is accessible technology that can be used to enhance mathematics instruction. Previously, students with learning difficulties found accessing the general education curriculum challenging. This study investigates the effectiveness of MLDs in mathematics instruction for typically performing students and students who have Individual Education Plans (IEPs). The findings of this study suggest that MLDs are beginning to have a positive effect on mathematics instruction for all students, including those with IEPs.

Introduction

Recently, the popular press and academic literature have published numerous articles concerning the use of cell phones in K-12 learning environments (Franklin & Peng, 2008; Liu, 2007; Traylor, 2009). While the topic has been debated in several publications, there is a paucity of research on the effectiveness of this technology on learning and student achievement (Dick, 2008). This study investigates the effectiveness of using mobile learning devices (MLDs) as a learning tool for all children in the general education classroom. We analyzed the results from standardized tests with special attention paid to students with individual education plans (IEPs) that included mathematics goals from a small school district in northwest Ohio who has been using MLDs for the past two years.

MLDs are educational technology that acts as a conduit between students who are digital natives and teachers who are digital immigrants (Prensky, 2006b). The National Council of Teachers of Mathematics (NCTM, 2000) suggests that “technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students’ learning” (p. 24). Technology is important, but how it is used and applied to the learning situation is even more critical. Some districts have specific goals and objectives when it comes to the use of technology, while others have no overt policy about the use of technology in the daily education of their students.

The technology mission statement for the participating school system is focused on creating life-long learners (Menchhofer, Sommer & Riepenhoff, 2009):

1. Technology creates a global learning environment.
2. The use of technology encompasses all learning styles.
3. Technology provides motivating and collaborative experiences.
4. Technology facilitates self-discovery for all learners.
5. Technology can transform the roles of teacher and learner.

The participating school system’s primary technology goal is to sanction the use of technology as a transparent tool, assuming “Infusing technology into the classroom instruction will create the students who are academically competitive, technology literate, motivated and engaged in the learning process. The students will be proficient information users who have the ability to access, process and effectively communicate information in order to improve their learning and exceed in the national educational standards.” (Menchhofer, Sommer & Riepenhoff, 2009, p. 4).

While many educators advocate and use certain school sanctioned technology (Smart boards, calculators, and laptops), many school systems across the United States do not advocate the use of mobile technology on school property. These policies ignore the learning potential of the relatively inexpensive mobile devices that are an integral part of the daily lives for a majority of students. These devices are often seen as a barrier to their students’ learning while on school property. In order to capture students’ interest, knowledge, and excitement, using MLDs, should be the goal of the 21st century education. These devices used daily can become a tool leading to success for typically performing students and students with special needs. Therefore, harnessing a technology students already successfully use should not be underestimated. We maintain that MLDs can be a crucial link that engages a typically marginalized group of students, children with learning difficulties. The purpose of research project reported here was to examine the effectiveness of MLDs in students’ learning of mathematics, as well as to compare the effectiveness of MLDs in mathematics instruction for students with and without IEPs.

**Theoretical Framework**

**Technology and 21st century students**

The Pockets of Potential (Shuler, 2009) highlights five opportunities to seize mobile learning’s unique attributes to improve education:

- Encourage “anywhere, anytime” learning;
- Reach underserved children;
- Improve 21st-century social interactions;
- Fit with learning environments; and
- Enable a personalized learning experience.

The first step in reaching students is to understand the role they play in the learning process. It seems logical to ask students what excites them about learning. However, educators often neglect or ignore the ideas of children who are the most affected by the educational decisions. It is not an effortless task to learn about what children think, especially for students with processing problems. By observing and discussing with students about their needs; their thoughts about learning are important data when determining the kinds of technology to be used in classrooms. Teachers and students need to be active partners in the design, as well as participate as informants in the testing and redesign of content (Druin, 2002). Engaging teachers and students from the beginning of the technology-content process allows for a greater chance to increase learning achievement, especially when the adults’ and children’s perspective are included in the redesigned content based learning modules (Lim, 2008; Prensky, 2008a). Teachers need to evolve in their roles as technologically advanced content facilitators if they wish to successfully teach today’s students.
We maintain that in the 20th century education model, students attended school to learn the content that empowered them to use that knowledge outside the classroom. In the 21st century education model, students bring knowledge (i.e. technology) into the classroom, such as the ability to access information and the teachers are the facilitators for the processing, acquisition, accessing, analyzing, and translating the information into useful knowledge outside the classroom (Prensky, 2008b). Learning to implement the 21st century curriculum, which involves consistent use of technology, is a skill that teachers need to become proficient at and bring into the classroom (Freyvaud, 2008; Prensky, 2006a; Zbiek, Heidi, Blume, & Dick, 2007).

MLDs technology levels the learning field, because they are an inexpensive, accessible technology for most households, including those households that lack laptops or desktop computers and internet connections. The project brings those students with limited or no access to technology at home into the “digital natives” generation (Prensky, 2006b). Students with learning difficulties generally have the same access as typically performing students. Even the students, who have not had constant access to technology at home, are still part of the “digital natives” generation, because of their consistent exposure to the vocabulary and information associated with almost instant access to information (Prensky, 2006b).

Students with Learning Difficulties

The Individuals with Disabilities Education Act (IDEA) and No Child Left Behind (NCLB) mandate that all students with special needs are expected to participate in general education classrooms. Motivating students to participate in instruction is often frustrating and a challenge for all educators. NCTM (2000) states that “technology offers teachers options for adapting instruction to special student needs” (p. 25) and that the computer or technology environment would be beneficial for students with attention and organizational issues. MLDs can provide a transition into the curriculum that is often a challenge for these students. Teachers must identify the content causing the struggle, such as computation, and then apply needed modifications (Peltenburg, van den Heuvel-Panhuizen & Doig, 2009). Also, teachers must examine their teaching behaviors and explore how teaching with technology opens up modification and accommodation options.

MLDs at the participating school were available to all students included in the general education mathematics classes. The special education teacher was a co-teacher and co-planner throughout the process and made sure the needs of any student on an IEP were being met. The students needed very little modification. Most students were very familiar with how MLDs work. Therefore, the training process was not any longer for students with IEPs than those without. A very small number of students needed a larger screen and were given a monitor to connect to their MLD, so that the print appeared on the monitor and, therefore, larger. If students were already have work modified in terms of less problems to solve or remember notes about formulas those modifications were easily built into the technology. The teachers were pleased at the progress that students with IEPs made. The device helped them to pay more attention to content that was more difficult for them than their typically performing peers. Learning how to use the MLD is part of a larger professional development process.

This process needs to include specific professional development that begins with technology facilitation training, rather than teachers’ random attempts to insert the technology into their classrooms (Kimmel, et. al, 1999). The short term goals of technology use included engagement in instruction and access to the curriculum for all students. The long term goal was to assist all students, especially students with learning difficulties, to realize their potential as active...
members of the community and workforce. This means these students also need exposure to Science, Technology, Engineering, and Mathematics (STEM) careers with emphasis on putting into place the skills they need to make this important transition (Lam, et. al, 2008).

**Methodology**

**Data collection**

This study investigated the effectiveness of MLDs in students’ learning of mathematics, both typically performing students and students with IEPs, by analyzing students’ performance on the SUCCESS test (https://reports.success-ode-state-oh-us.info/Login.aspx). The SUCCESS data analyzed in this study are provided by the Ohio Department of Education for dissemination of test data to the schools. Since student SUCCESS data is password protected via the educators' workroom link, the authors did not have a direct access to the data. The participating school district removed students’ names and provided three years of SUCCESS data, 2007 - 2009 to the authors. The academic year 2008 was a pilot year, the first year for the participating schools using MLDs. Six teachers in grades third through fifth used MLDs in order to pilot test the effectiveness of the devices in education. In 2009, the second year, all the students used MLDs in grades third through sixth from two elementary schools and one middle school. More than 600 students used the MLDs daily, and their SUCCESS data were analyzed in the study.

**Data analysis**

The Spring SUCCESS data of 2007, 2008, and 2009 were analyzed using three variables:

1) The mathematics scale score,
2) The raw scores for the state five content standards: Measurement; Number Sense and Operations; Patterns, Functions, and Algebra; Data Analysis and Probability; and Geometry and Spatial Sense, and
3) The math total raw scores.

The descriptive analysis for the whole population was followed by the descriptive analysis comparing students with IEPs and the non-IEP student population. Due to the size and the nature of the sample, t-test for independent groups was used to compare students’ scores for different years for IEP and Non-IEP student populations separately. Since students were at different grades each year taking different tests, they were treated as independent groups.

**Results**

Table 1 summarizes the data for the mathematics scale score, individual raw scores for five content standards: Measurement, Number Sense and Operations, Patterns, Functions, and Algebra, Data Analysis and Probability, and Geometry and Spatial Sense. The total mathematics scores for the whole population are also included. The average of total mathematics score for 2009 is higher than the other years. The mean score for the mathematics scale score in 2009 is also the highest. Mean scores for Measurement, Algebra, and Geometry gradually increased over the three years, but Data analysis and probability mean score does not show improvement. Mean score for Number and Number sense increased in 2009, but 2008 score was much lower than 2007. In contrary, mean score for Data analysis and probability show a noticeable improvement in 2008 but no increase in 2009.

Figure 1 provides a comparison of the data for students with and without IEPs for the mathematics scale and the total mathematics scores for 2007, 2008, and 2009 combined.

![Figure 1. Comparison of IEP and Non-IEP populations](image)

Approximately 16 percent of the whole population is comprised of students on IEPs. Their scores compared to Non-IEP students are lower in all areas, which was predictable. However, this result can inform teachers with an overall picture and help diagnose where the biggest gap exists between students with and without IEPs. The ratio of students with IEPs and students without IEPs is different for each content standard. The biggest gap between students with and without IEPs appears in Algebra and the least difference in Geometry. Considering the new nation’s emphasis on Algebra in high school graduation requirement (Achieve, 2009), early intervention in Algebra needs to be discussed between mathematics and special education teachers, especially ways to use the MLDs in Algebra instruction.

The t-test results for Non-IEP and IEP population are summarized below:

a) There was a significant difference between years 2007 and 2009, \( t(1091) = -2.259, p < .05 \), with 2009 mathematics total raw score for the Non-IEP students being higher than 2007.

b) There was a significant difference between years 2008 and 2009, \( t(1058) = -2.013, p < .05 \), with 2009 mathematics total raw score for the Non-IEP students being higher than 2008.

c) There was a significant difference between years 2008 and 2009, \( t(185) = -2.060, p < .05 \), with 2009 mathematics scale score for the students with IEPs being higher than 2008.

d) There was a significant difference between years 2008 and 2009, \( t(180) = -3.147, p < .05 \), with 2009 mathematics total raw score for the students with IEPs being higher than 2008.

Figure 2. Comparison of IEP and non-IEP population for Math scale and total math scores

According to a) and b), Non-IEP students’ mathematics total raw score shows statistically significant improvement in 2009. Findings summarized in c) and d) indicate that students with IEPs’ mathematics scale score and total raw score show statistically significant increase in 2009 compared to 2008. Both students with and without IEPs had to learn new instructional technology, MLDs, in 2008. Students both with and without IEPs performance did not show a significant increase from 2007 to 2008, and it is possibly due to their slow learning pace compared to Non-IEP students. In other words, it is possible that students with IEPs took longer
time to get familiar with and adopt MLDs into their learning style, compared to Non-IEP students. Fortunately, their scores in 2009 show significant improvement.

**Discussion**

The findings of this study suggest that MLDs are beginning to have a positive effect on mathematics instruction for all students, including those with IEPs. Students with IEPs show an increased math score in 2009 versus 2007 when they had no instruction with MLDs. While the students without IEPs showed a slightly higher total math score in year two, the total math score did increase from the start year. The increase appears to indicate that the teaching with MLDs is becoming more effective and leading to increased mathematics knowledge. Each school year is unique, as are the students, so the fact that scores are rising for students with IEPs is promising. In addition, comparison data between students with IEPS and Non-IEP students’ performance in each mathematics content standard informs mathematics teachers in various aspects: students with IEPs need more help with Algebra and Number and Operations; or Geometry is the area IEP students can enhance their understanding the most.

Future implications include extending the use of MLDs to other districts in other states and providing well structured teacher training on how to use MLDs and how to develop effective activities for MLDs. To accomplish this, targeted professional development is needed to create comprehensive teaching modules. While the goal of many technology-based games encourages basic review and drill; instructional modules should engage students at higher thinking levels. The content in the MLDs should be what draws the student in, not the device itself. Students already have a great understanding of the device, but teachers will continue to learn to exploit that in a way that increases content knowledge and readiness for STEM careers. It is the hope that with this added dimension, achievement scores will continue to increase and curriculum goals would be met for all students.

AN INVESTIGATION OF DEVELOPING REPRESENTATIONS OF LINEAR FUNCTIONS IN THE PRESENCE OF CONNECTED CLASSROOM TECHNOLOGY

Brian Morton  
The Ohio State University  
Morton.65@osu.edu

Douglas T. Owens  
The Ohio State University  
owens.93@osu.edu

This poster presents an investigation of the use of representations of linear functions in the classroom in the presence of connected classroom technology and its impact on student ability to transfer among different representations of linear functions using data from the Classroom Connectivity in Promoting Mathematics and Science Achievement (CCMS) project. CCMS is a national research study examining the impact of connected classroom technology on student achievement, self-regulated learning and dispositions of students toward mathematics and science. The research design is a randomized crossover field trial in 118 Algebra 1 classrooms (Owens et al., 2008). The intervention of the CCMS project consisted of providing teachers with Texas Instruments TI-Navigator™, a wireless classroom device that networks students’ handhelds to the teacher’s computer and pedagogical training to support implementation of this technology. Two major components of this training focused on the development of formative assessment and classroom discourse. The combination of formative assessment, classroom discourse and TI-Navigator’s™ representational capabilities should provide a rich environment to develop representational thinking, since representation is inherently a social activity comprised of the social construction of shared meaning of mathematical representations (Pape & Tchoshanov, 2001).

The data from the CCMS project being used in this investigation consists of an algebra pretest, algebra posttest, teacher interviews, a survey on student perceptions of instruction and video data of classroom lessons. Teachers were observed two consecutive days each year of the project. For the investigation, fifteen teachers were chosen because their videotaped lessons were on linear topics. The algebra posttest was analyzed using Cunningham's (2005) guidelines for items requiring transfer of representations and 12 items were found. A qualitative analysis of the video tapes will be conducted to see the relationship of the connected classroom technology use and the use of linear representations. Statistical analysis will be conducted to determine if there is a difference between students being taught with a navigator™ and without on their ability to transfer among linear representations. Results of both analyses will be presented.

References

The proliferation of interactive white boards (IWBs) in schools across the world represents a bold attempt to improve education via significant financial investment. Unfortunately, classroom-based research indicates that because teachers are only given scant amounts of training and support, they tend to use only the superficial affordances of these technologies without changing overall interaction patterns or resulting test scores (Lerman & Zevenbergen, 2007). This study examines how a teacher used various features of an applet that was designed to leverage the features of an IWB to enhance students’ efforts to solve challenging tasks. Our work is guided by a commognitive view of learning which suggests that interpersonal communication and individual thinking are two facets of the same phenomenon. This socially-oriented perspective highlights the central role of tools as mediators of communication and thinking. Our goal as tool developers is to support teachers’ efforts to engage students in thought/communication activities that leverage the unique aspects of whiteboard to mediate these discussions.

This work involved iterative cycles of design and research. We began by imagining how an applet might have affected the class discussion that Henningsen and Stein (1997) describe in which students offered innovative strategies for representing portions of grids. We then designed an initial interactive tool and videotaped groups of high school students using the applet to solve similar tasks. A second round of design and research involved comparing results of groups with and without an interactive whiteboard.

Preliminary results indicate that while the groups of students who used the applet projected onto a screen without an IWB were able to communicate their ideas, they were hindered by the fact that they had to describe moves such as “Drag the third red dot down two places”. These indexical statements separated their activities from the underlying mathematical ideas that supported them. In contrast, when students were using the IWB and sharing the interactive pen, their efforts to think, gesture, and debate were fused as they interacted with the mathematical representations. In particular, their words and gestures ignited shifts in activity that resulted in new ways of conceptualizing the task that made use of the various features built into the activity for use with IWBs. We argue that these features enabled the students to communicate ideas in an interactive public space that could not have been replicated using pencil and paper or the projector alone.

cjhazard@hazardoussoftware.com

Maria Droujkova
Natural Math
maria@naturalmath.com

Our study addresses the research problem of constructing an interdisciplinary conceptual framework for analyzing math games through a series of design decisions. While we focus on computer games, many of the principles apply to physical space games. Definitions of decisions come from game theory research and gaming studies (Gee, 2007; Myerson, 1997). The gameplay consequences of each decision are analyzed based on existing games viewed through the lens of these definitions. The mathematics education consequences of each decision are then analyzed based on the pedagogy embodied in the gameplay, and viewed through the lens of learning theories (Piaget, 1970; Pirie & Kieren, 1994; Vygotskii & Kozulin, 1986). A series of parallels between gaming concepts and pedagogical notions helps mathematics educators make sense of game theory concepts, and apply these concepts to teaching. The resulting structure makes it clear that some types of math games are overused, and other promising types are rarely employed by mathematics education game developers.

The decisions, as well as their mathematics and math education parallels, are made along these dimensions that provide dichotomies, gradients or levels:

- **Abstraction dichotomy**: narrative-based vs. abstract; situated vs. formalized
- **Revelation gradient**: full disclosure to hidden information; open-book to closed-book
- **Strategic gradient**: strategic to typed; problem-solving to exercises
- **Resource levels**: bounded rationality gameplay or not; level or stage learning theories
- **Agency and autonomy gradient**: high to none; open-ended to closed-ended tasks
- **Planning levels**: interactions, tasks, tactics, strategies; order of math tasks
- **Depth gradient**: expert to superficial knowledge; deep learning to expository learning
- **Goal gradient**: sandbox play to clear goals; conceptual learning to procedural fluency

FIFTH GRADERS’ CONCEPTION OF FRACTIONS ON NUMBERLINE REPRESENTATIONS

Zelha Tunc Pekkan  
Carnegie Mellon University  
zelha@cs.cmu.edu

Vincent Aleven  
Carnegie Mellon University  
aleven@cs.cmu.edu

While students’ experiences related to representations, such as pie charts (Cramer, Wyberg, & Leavitt, 2008) and rectangular objects, and how they conceive fractions in relation to those representations are well investigated (Cramer, et al., 2008), students fraction conceptions related to number line needs further investigations. In addition, comparing students’ conceptions of fractions in different external representations and which representations might support students conception of fractions (Taber, 2001) is also a research focus that deserves attention.

In this study, our purpose was to investigate the ways in which eight 5th graders conceived fractional numbers with different representations such as pie chart, rectangles, and number line. The eight students were interviewed for 45 minutes long sessions on 16 fraction problems as part of data collection for a bigger study. The problems had different representations and aimed to investigate different fractional knowledge such as partitioning, iterating operations as well as multiplicative reasoning. The data and analysis is part of the bigger research with which students had a computer tutor intervention that had hint and feedback features. The analysis of interview data revealed that while students are much more familiar with fractional numbers with pie chart representations, their conceptions of where fractional numbers are located on the number line is usually (unlike their interpretations of fractions with pie charts) independent from the whole/unit on the number line and the activities that produce fractional numbers discussed in the literature (Steffe, 2002; Norton & Wilkins, 2009).

THE NATURE OF CLASSROOM DYNAMICS IN HIGH SCHOOL MATHEMATICS CLASSES WHERE GRAPHING CALCULATORS ARE USED

Levi Molenje
Grand Valley State University
molenjel@gvsu.edu

Several studies have shown mixed findings about the roles of teachers in technology-enriched classrooms. Doerr and Zangor (2000), Farrell (1996), and Slavit (1996) found that teachers assume the roles of fellow investigator, facilitator, and consultant when they teach with graphing calculators while Goos, Galbraith, Renshaw, and Geiger (2003) reported mixed results as did Tharp et al. (1997).

This study investigated the nature of classroom dynamics in high school mathematics classes where graphing calculators were used. Participants were six high school mathematics teachers from a midsized urban school district in the north eastern United States. Data were collected through classroom observations. Analysis of the data revealed that the nature of classroom discourse tended to influence the role for which the graphing calculators were used. I found four of the five roles of graphing calculator use discussed by Doerr and Zangor (2000). These findings can be summarized in two major results:

(1) Teacher directed lessons were characterized by teachers demonstrating specific calculator functions, making decisions about particular calculator settings, and correcting student errors and/or confirming solutions. On the other hand, lessons involving student exploration were characterized by teachers involving students in decision making regarding calculator use, guiding students in refining their thinking with regard to calculator use, and challenging students to interpret calculator results in the context of the problem situation and communicating this understanding to the whole class.
(2) During student explorations the graphing calculator was mainly used as a visualization tool, a checking tool, or a data collection and analysis tool. During teacher directed sessions the graphing calculator was mainly used as a computational tool.

USING TECHNOLOGY TO ENAHANCE THE STUDY OF MATHEMATICS

Belinda P. Edwards  
Kennesaw State University  
bedwards@kennesaw.edu

Sarah Ledford  
Kennesaw State University  
sledfo10@kennesaw.edu

Technology plays an important role in teaching and learning mathematics. The effective use of technology often depends on the teacher. As students engage in a variety of mathematical activities in the classroom, the teacher must decide when and how best to apply technology to assist in the learning of mathematical concepts. Cognitive technological tools such as computer software and handheld graphing technology, if used appropriately in the mathematics classroom, have the potential to enhance teaching and learning of mathematics by empowering students to concentrate on more advanced problems. Cognitive technological tools have the potential to transcend the limitations of the mind in “thinking, learning, and problem-solving activities” (Pea, 1987, p.91).

Zbiek, Heid, and Blume (2007) identified two types of mathematical activity: technical and conceptual. The technical refers to the procedural actions and performance on mathematical objects; actions such as numerical computation, algebraic manipulations, graphical transformation, and solving equations. Conceptual mathematical activity, on the other hand, involves understanding, communicating, using and making mathematical connections, conjecturing, representing, and proving. The distinction between the two dimensions of activity can play an important role in understanding how best to integrate technology throughout the curriculum in a way that fosters student understanding. When engaging in cognitively demanding mathematical inquiry activities, carrying out procedures can be performed by technology and reflecting on those procedures, interpreting results, describing connections between representations, making predictions, generalizing, and making conjectures can be emphasized. This can lead students to deeper mathematical thinking and understanding. When learning mathematical algorithms and doing complicated computations are not the goal of the problem solving process, the computer software “does the math” which allows students to focus on the deeper ideas of the problem.

In this poster presentation, an examination of how cognitive technological tools such as the computer algebra systems (CAS) handheld graphing calculator, Excel, and TI-Interactive! are used as students engaged in different types of mathematical activity in an undergraduate mathematics and mathematics methods course.

WHERE IS MATH 2.0? ALARMING TRENDS AND NEW HOPES

Maria Droujkova
Natural Math
maria@naturalmath.com

Math 2.0 Interest Group
MathFuture
mathfuture@googlegroups.com

The Math 2.0 Interest Group (Math 2.0 Interest Group, 2010a, 2010b) is an international network of mathematics educators, online developers, teachers and families working on social media and computational mathematics projects. Directions of Group’s work include analysis of math-rich social objects, studies of mathematical behavior online, development of courses and curricula, and organization of meetings and conferences for researchers and practitioners.

The trend that alarms us most is the lag of mathematics behind other subjects in class-centered online communities, and a larger lag in other communities. Mathematics remains confined to classes, homework, and tests. Most class-centered communities are not sustainable, dissolving after the class ends. The existing sustainable math communities can be intellectually elitist and demographically exclusive, and isolated from one another.

We identified (Deubel, 2010; Droujkova, 2009) four directions for support, development and promotion in the immediate future, and as tracks for events and publications we host:

- **Community mathematics**: networks, content sharing, clubs, grassroots curriculum
- **Executable mathematics**: software, manipulatives, programming platforms, social objects
- **Humanistic mathematics**: visual arts, digital storytelling, ethnomathematics
- **Psychology of mathematics**: meta-cognition, attitudes, learning theories, well-being

Mathematical authoring, including content creation and sharing by students, and development of activities, communities, curricula and software by educators, is at the heart of all four directions.

As the title suggests, this Working Group has a dual focus on issues of mathematics teaching and learning and issues of equity and diversity. This includes topics identified at the Working Group in 2009 such as pre-service mathematics teacher education for social justice, culturally relevant and responsive mathematics education, and supporting mathematical discourse in the linguistically diverse classroom. In addition, we focus on questions about systematic inequities and their impact on the teaching and learning of mathematics, and on methodologies that allow researchers to examine the complexity of the socio-political contexts of mathematics teaching and learning. This work attempts to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships, including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Brief History

This Working Group builds on and extends the work of the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME is a group of emerging scholars (new faculty and graduate students) who graduated from, or in some cases are still studying at, three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA). The Center is dedicated to creating a community of scholars poised to address some critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).

The DiME Group (as well as subsets of that group) has already engaged in important scholarly activities. After two years of a cross-campus collaboration dedicated to studying issues framed by the question of why particular groups of students (i.e. poor students, students of color, English learners) fail in school mathematics in comparison to their white (and sometimes Asian) peers, we presented a symposium at AERA 2005 (DiME Group, 2005). This was followed by the writing of a chapter in the recently published Handbook of Research on Mathematics Teaching and Learning which examined issues of culture, race, and power in mathematics education (DiME Group, 2007). Further, in an effort to bring together and expand the community of scholars interested in this work, DiME, at AERA in 2008, sponsored a one-day Professional Development session examining equity and diversity issues in Mathematics Education. In addition DiME members have joined with other scholars in joint presentations and conferences. A book on research of professional development that attends to both equity and mathematics issues is currently in press (Foote, in press). Many DiME members as well as other scholars contributed to this volume.
Moreover, the Center has historically held DiME conferences each summer. These conferences provide a place for fellows and faculty to discuss their current work as well as to hear from leaders in the emerging field of equity and diversity issues in mathematics education. Since the summer of 2008, the DiME Conference opened to non-DiME graduate students with similar research interests from other CLTs such as the Center for the Mathematics Education of Latinos/as (CEMELA), as well as graduate students not affiliated with an NSF CLT. This was an initial attempt to bring together a larger group of emerging scholars whose research focuses on issues of equity and diversity in mathematics education. In addition, DiME graduates, as they have moved to other universities, have begun to work with scholars and graduate students with connections to other NSF CLTs such as MetroMath and the Urban Case Studies Project in MAC-MTL whose projects also incorporate issues of equity and diversity in mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Theoretically we have been building on the work of such scholars as Marta Civil (Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Megan Franke (Franke, Kazemi, & Battey, 2007), Eric Gutstein (Gutstein, 2006), Danny Martin (Martin, 2000), Judit Moschovitch (Moschovitch, 2002), and Na'ilah Nasir (Nasir, 2002). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and again Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

A significant strand of the work of the DiME Center for Learning and Teaching included implementing professional development programs grounded in teachers’ practice and focusing on equity at each site. The research and professional development efforts of DiME scholars are deeply intertwined, and much of the research thus far produced by members of the DiME Group addresses issues of equity within Professional Development. Additionally, since the majority of the DiME graduates, as new professors, along with a number of current Fellows, are engaged in teaching Mathematics Methods courses, the integration of issues of equity with issues of mathematics teaching and learning in Math Methods has become a site of interest for research. These scholars have learned through their work that collaboration is a critical component to our work. We were pleased for the opportunity offered by the first year of being a Working Group at PME 2009 to continue working together as well as to expand the group to include other interested scholars with similar research interests. We were encouraged that our efforts were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group.

**Focal Issues**

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, Professional Development, pre-service teacher education (primarily in Math Methods classes), student learning (including the learning of particular sub-groups of students such as African-American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an
important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics.

Existing research tends either to focus on professional development in mathematics (e.g., Barnett, 1998; Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Kazemi & Franke, 2004; Lewis, 2000; Saxe, Gearhart, & Nasir, 2001; Schifter, 1998; Schifter & Fosnot, 1993; Sherin & vanEs, 2003), or professional development for equity (e.g., Sleeter, 1992, 1997; Lawrence & Tatum, 1997a). Little research exists, however, which examines professional development or mathematics methods courses that integrate both. The effects of these separate bodies of work, one based on mathematics and one based on equity, limits the impact that teachers can have in actual classrooms. The former can help us uncover the complexities of children’s mathematical thinking as well as the ways in which curriculum can support mathematical understanding in a number of domains. The latter has produced a body of literature that has helped to reveal educational inequities as well as demonstrated ways in which inequities in the educational enterprise could be overcome.

To bridge these separate bodies of work, the Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes, and how these culturally bound distinctions afford and constrain opportunities for students of color to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions that the Working Group will consider are:

**Teachers and Teaching**

- What are the characteristics, dispositions, etc. of successful mathematics teachers for all students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving and equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?
- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher’s background?
- What are dominant discourses of mathematics teachers?

**Students and learning**

- What is the role of student academic and mathematics identity in achievement?
- How do students’ out-of-school experiences influence their learning of school mathematics?
What is the role of perceived/historical opportunity on student participation in mathematics?

Policy

- How does an environment of high-stakes standardized testing affect whether and how teachers teach mathematics for understanding? How does this play out across a variety of local contexts? How can we support teachers to teach mathematics for understanding in that environment?
- How do we address issues of tracking/ability grouping and in particular the grouping of students by test designation?

Plan for Working Group

The overarching goal of the group continues to be to facilitate collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education. The PME Working Group provides an important forum for these scholars to come together with other interested researchers who identify their work as attending to equity and diversity issues within mathematics education in order to develop plans for future research. Our main goal for this year, then, is to continue a sustained collaboration around key issues (theoretical and methodological) related to research design and analysis in studies attending to issues of equity and diversity in mathematics education.

In order to support this collaborative research, smaller research groups were formed from participants in the large Working Group. The plans and goals for these sub-groups are detailed in the final section: Previous Work of the Group and Anticipated Follow-up Activities.

Much of our work is qualitative in nature and we recognize that one way to increase the number of participants is to conduct research across several sites. In order to do this, we need to use the same protocols for data gathering. One of our sub-groups has taken as its charge to develop an observation protocol. We intend that, during what we hope to be the long life of this Working Group, this and other research protocols may be developed and used across a variety of research projects. Although this was not a topic in 2009, it is anticipated that one aspect of the sub-group meetings will be to discuss potential funding opportunities. Here we may identify and begin to draft grant proposals to fund research across contexts. More specifically, for PME 2010 we will proceed as follows.

SESSION 1:
- Presentation and discussion of goals of Working Group.
- Introduction of participants.
- Reports of the work of sub-groups during 2009-2010.
- Adjustment (addition or collapsing) of current sub-groups as appropriate.

SESSION 2:
- Sub-group meetings to discuss and delineate further plans to address and expand research questions developed at PME 2009.

SESSION 3:
- Sharing and discussion of work from Session 2.
- Planning for further collaboration.
- Developing a tentative agenda for future Working Group meetings.
Previous Work of the Group and Anticipated Follow-up Activities

The Working Group met for three productive sessions at PME 2009. In the first session, we identified areas of interest to the participants within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. During the second session, participants met in an identified sub-group of their choice. Within these sub-groups, rich conversations ensued regarding theoretical and practical considerations of the topics. Sub-groups began to identify plans and goals for the 2009-2010 academic year. During the third session discussions continued, sub-groups finalized their plans, and then reported to the large Working Group. What follows are the plans and goals of the sub-groups formed at PME 2009. The activities stated in these plans are currently in progress.

Pre-service Teacher Education that Frames Mathematics Education as a Social and Political Activity

This sub-group acknowledges tensions in our work focusing on equity and social justice in relationship to reform mathematics. Frameworks are needed to understand these issues. These can build on work in culturally relevant pedagogy (Ladson-Billings, 1995), teaching for social justice (Gutstein, 2003), funds-of-knowledge (González et al., 2001) as well as more general issues of equity, diversity, social analysis, and critical pedagogy. We need to begin by defining what we mean by these terms (e.g. reform mathematics, social activity, political activity); and how we recognize them in the classroom. This group would like to develop a collection of materials, resources, and activities that are being used in Math Methods courses. Another aspect of this work may be studying our own professional development as mathematics teacher educators oriented toward incorporating equity issues centrally in our Math Methods courses.

Goal for 2009-2010. We intend to design a common lesson and teach it in varied contexts (different universities, different grade levels of methods, alternative certification teachers that are also pre-service teachers).

Culturally Relevant and Responsive Mathematics Education (CRRME)

The title reflects the fact that the responsive piece is a bit different from the relevant piece and that we want the mathematics piece included. We are interested in language, discourse, ethnicity, ways of interacting, family, community, experiences, generational issues, expectations (not high and low, but individual or community’s expectations). We want to examine what we mean by social justice. Issues can be examined, such as teaching (a) about social justice (the context), (b) with social justice (status and participation), and (c) for social justice (power and question). Various aspects of CRRME include (a) local contexts, (b) local associations, (c) using cultural referents, (d) ethnomathematics, (e) critical pedagogy, and (f) teaching “classical” math. We are concerned as well with how literature on culturally relevant pedagogy is grounded in existing theory and research on culture and social constructivism.

Goal for 2009-2010. Since many in the mathematics education community are not familiar with what social scientists say about culture, we intend to review that literature with a focus on how it relates to research in mathematics education.

Creating Observation Protocols around Instructional Practices

This group hopes to develop a protocol that can measure instructional practice AND be a tool to help teachers improve their instructional practice. Our focus is on the importance of improving instruction for students of color; this is our goal. We recognize that protocols have limits (and
dangers!). For example, protocols do not necessarily look at microgenesis, teacher change, structural issues, dispositions.

Goal for 2009-2010. We plan to have at least three conversations together as a group over the next year. During these conversations, we will (a) discuss existing protocols posted on google groups to stimulate rich discussions around questions such as: What do we like? What are they missing? How might we combine, extend, and so forth; (b) move conversation to issues of teacher change/microgenesis; (c) discuss what it means to develop this protocol and train people in its use as we don’t want people to take any tool we develop and usurp it, using it in ways detrimental to teachers; and (d) discuss the importance of theoretical grounding of this work. Our longer-term goal is to produce a paper or report that is the theoretical grounding of an observation tool that does not ignore issues of race, class, and so forth.

Feminist Theory Literature Group:
This will be a reading group. Currently feminist theory is under-utilized in equity research.

Goal for 2009-2010. We plan to create a bibliography and report next year to this group about how feminist theory can be used to inform equity research.

Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms
This will begin as a group reading widely in the area of language and discourse.

Goal for 2009-2010. We intend to begin reading widely in the area of language and discourse and create a bibliography that can serve as a resource.

Plans for 2009-2010
It is anticipated that Working Group participants will leave the conference ready to (a) continue to (and in some cases begin to) work on developing particular aspects of their research (such as particular data gathering methods) and/or (b) continue (and again in some cases to begin) a collaboration with other Working Group participants. It is our hope that the work of this group that began at the PME Conference in Atlanta in 2009 will continue in Columbus, Ohio in 2010 and for many years after.

This working group will bring together researchers interested in investigating learning and teaching mathematics that seeks to build on students’ current ways of reasoning to develop more formal and robust ways of thinking in the content domain of linear algebra. Linear algebra represents a content domain that is a critical juncture for students as they transition to more abstract courses and that is of interest to the broader community. The main activities of the working group will be (a) reflection on students’ current ways of reasoning and how these ways of reasoning progress; (b) theoretical elaboration on what such progress entails, from both psychological and sociological points of view; and (c) explicit attention to issues of instructional design. In broad terms, the sessions will allow time for participants to work through some of the mathematical ideas for themselves, to discuss core theoretical underpinnings on cognition and instructional design, to examine instructional tasks, and to discuss video of student work on these tasks.

A prominent problem in the teaching and learning of K-16 mathematics is how to build on students’ current ways of reasoning to develop more conventional, generalizable, and abstract ways of reasoning. This problem is particularly pressing in undergraduate courses that often serve as a transitional point for students as they attempt to progress from more computationally based courses to more abstract courses that feature reasoning with formal definitions and proof construction. Such transitional courses can block students from continuing to pursue a science, technology, engineering or mathematics (STEM) major. It is well documented that the number of students in STEM majors in general, and mathematics majors in particular, is decreasing, despite the fact that a greater percentage of the population is attending college (Bressoud, 2009; Holton, 2001). This problematic trend is not unique to the United States.

This working group will bring together researchers interested in investigating learning and teaching that seeks to build on students’ current ways of reasoning to develop more formal and robust mathematics. The main activities of the working group will be (a) reflection on students’ current ways of reasoning and how these ways of reasoning progress, (b) theoretical elaboration on what such progress entails, from both psychological and sociological points of view, and (c) explicit attention to issues of instructional design. Progress on these three fronts requires a
content domain that is of interest to the broader community and that is a critical juncture for students as they transition to more abstract courses. In the following section we explicate why linear algebra is an appropriate content domain for the working group. This is followed by a discussion of key theoretical perspectives on learning and instructional design that will likely inform the working group. The final three sections detail the plan for the active engagement of participants, anticipated follow-up activities, and ways in which the working group builds on and extends prior collaborations.

Why Linear Algebra?

Linear algebra is an especially relevant site for the working group for several reasons. First, it is a conceptually rich domain in which concepts and procedures are intimately connected. The unifying power of linear algebra is particularly elegant and beautiful, and offers students a glimpse into what often excites and motivates mathematicians. Second, there are many opportunities for working with formal definitions and abstractions. These opportunities also present challenges to students as they attempt to relate their current ways of thinking to more formal and abstract mathematics. Third, there is a plethora of applications of linear algebra to science, engineering, and economics. As such there are many opportunities to use these applications to motivate and develop mathematical ideas. Fourth, linear algebra is a complex domain for interpreting and creating various symbolic and graphical representations. Hence there are many opportunities to study how students mathematize their current ways of reasoning. Finally, linear algebra is situated between courses with more of a problem solving or computational emphasis, such as calculus, and courses with a primarily proof-based emphasis such as abstract algebra and real analysis. All of these reasons point to the fact that linear algebra is a critical and often difficult juncture in students’ university studies.

Given the complex and difficult nature of this content domain, there has been and continues to be fairly broad interest, both nationally and internationally, in improving the teaching and learning of linear algebra. A brief review of this prior work is in order because it lays the foundation for new work that builds on contemporary learning theories and instructional design perspectives.

In the late 1990’s, research in linear algebra conducted by Harel and Sowder (1998) in the United States resulted in the articulation of a trajectory that characterizes the evolution of how students understand and use proofs. Harel (2000) also proposed the following three principles for learning: the concreteness principle, the necessity principle, and the generalizability principle. These principles emphasize the need for curriculum that (among other things) begins with situations that are sensible to students and can be generalized to the important abstract or more formal constructs of linear algebra.

In Canada, Sierpinska (2000) noted the difference in what she calls theoretical thinking and practical thinking. This difference in thinking is related to the distinction between students working from their concept image (practical thinking) versus working from a concept definition (theoretical thinking). This distinction is central to students’ transition from their current ways to reasoning to more formal or abstract ways of reasoning. In related work, Hillel (2000) described three languages (representations or modes) in linear algebra that students must coordinate: the abstract language of the general theory, the algebraic language of $\mathbb{R}^n$, and the geometric language of two and three-dimensional spaces. The necessary coordination of all three modes of reasoning is one reason why linear algebra is often such a challenging course for students.
In France, Dorier, Robert, Robinet and Rogalski (2000) have noted that there appears to be an insurmountable obstacle to formalism inherent in the learning of linear algebra. Dorier (2002) summarized this obstacle as follows:

Students’ difficulties with the formal aspect of the theory of vector spaces are not just a general problem with formalism but mostly a difficulty of understanding the specific use of formalism within the theory of vector spaces and the interpretation of the formal concepts in relation with more intuitive contexts like geometry or systems of linear equations, in which they historically emerged. (p. 877)

There has been considerable activity on the part of French researchers in developing a program for the linear algebra course that occurs during the first year at French universities for science majors. In the United States and Mexico this course occurs later in the university program and these students do not have the same secondary school experience with proof that French students do. In Mexico there is also a research project to understand students’ construction of Linear Algebra concepts (Trigueros & Oktaç, 2005; Kú, Trigueros & Oktaç, 2008).

In addition to research that either categorizes what students struggle with doing or explains what an expert thinks is necessary to understand an idea, more recent work has examined the productive and creative ways that students are able to interact with the ideas of linear algebra. In Mexico, Possani, Trigueros, Preciado, and Lozano (2010) analyzed the use of a teaching sequence that started with a real life problem. The authors reported on student progress as they advanced through different solution strategies. For instance, they found that students learn what they are supposed to learn and they can even do more than what is normally expected from them when given the opportunity. In a similar spirit, Larson, Zandieh, and Rasmussen (2008) reported on ways that students were using their current ways of reasoning about vectors and matrices to develop algebraic methods to determine the eigenvectors and eigenvalues of a given matrix. In particular, the authors present a key idea that emerged as a central and powerful way in which students came to reason and eventually develop the formal ideas and procedures for eigenvalues and eigenvectors. These two lines of more recent work in linear algebra are particularly relevant to the charge of the working group because rather than detailing student difficulties, they detail progress in building on students’ current ways of reasoning to develop more formal and conventional mathematics. In the next section the theoretical foundations for these two lines of work are detailed.

Theoretical Foundations

This section describes several different ways to characterize student progression from their current ways of reasoning to more formal ways of reasoning as well as the perspectives underlying these characterizations. The way in which researchers operationalize this transition is essential because these underlying perspectives bring forth possibly different aspects of the same phenomenon. Part of the goal of the working group is to clarify and contrast these underlying perspectives in order to sort out points of real difference and real similarity (although different terminology might be used). The following paragraphs identify a few of the more prominent approaches to characterizing the progression from students’ current ways of reasoning to more formal ways of reasoning.

The term “concept definition” refers to the formal definition whereas “concept image” refers to the “set of all mental pictures associated in the students’ mind with the concept name, together with all the properties characterizing them” (Vinner & Dreyfus, 1989, p. 356). A student’s concept image is typically the result of his or her experiences with examples and nonexamples. One strand of studies within this theme details how students often reason from their concept image even though they “know” the definition. Paradigmatic of this type of study is the analysis reported by Vinner and Dreyfus (1989) in which students stated essentially correct definitions for function but failed to use the definition in their analysis of whether a given graph/equation/table is or is not an example of a function. Instead, students used their concept image, often relying on a prototypical example in order to decide whether the given example is or is not an example of a function. Similarly, Edwards (1997) found that although real analysis students knew the formal definition of continuity, many tended to reason from their concept image, and Moore (1994) found that even though undergraduate mathematics majors in a transition to proof course knew a formal definition for a one-to-one function, they had difficulty using the definition to structure or organize a proof that a given function is one-to-one.

These studies provide examples of a framework that was developed from an individual cognitive point of view and is typically used to compare student current concepts relative to more formal mathematical definitions. The definition game, described next, can be thought of in terms of individuals, but is oriented more toward students’ mathematical activity than their internal cognitive structures. In relation to the theme of the working group, the definition game characterizes a type of interplay between student current ways of reasoning and their introduction to new, formal mathematical definitions or settings. The definition game takes a variety of forms, including using an unfamiliar definition in a familiar mathematical setting and using a familiar definition in an unfamiliar mathematical setting. More generally, playing the definition game consists of using a ________ definition in a ________ mathematical setting, where either blank can be filled in with adjective along the unfamiliar to familiar continuum (Zandieh & Rasmussen, in press).

For example, Dahlberg and Housman (1997) investigated the strategies senior and junior undergraduate mathematics majors used when presented with a new definition in a relatively familiar setting. In particular, students were presented with the definition of a fine function (a function with a root at each integer), something that none of the students had previously encountered, and were asked to generate examples of fine functions, to decide whether given functions were fine, and to determine the validity of different statements about fine functions.

In contrast to Dahlberg and Housman’s study in which students used an unfamiliar definition in a relatively familiar mathematical setting, Borasi (1991) described a lesson with two secondary school students where they used a familiar definition of circle in an unfamiliar mathematical setting. The unfamiliar mathematical setting was that of taxicab geometry, which is an idealization of an urban area with a regular grid pattern of streets. Although street grids were familiar to these students, this environment was mathematically unfamiliar to students due to the way distances are measured.

The Action-Process-Object-Schema (APOS) theory (Asiala et al., 1996; Dubinsky, 1991) offers a particular cognitive framing for how cognitive structures evolve as students progress from their current conceptions to more formal conceptions. In this perspective, an action conception is a transformation of a mathematical object by individuals, according to an explicit algorithm that is conceived as externally driven. As individuals reflect on their actions, they can interiorize them into a process. Each step of a transformation may be described or reflected
upon without actually performing it. An object conception is constructed when a person reflects on actions applied to a particular process and becomes aware of the process as a totality, or *encapsulates* it. A mathematical schema is considered to be a collection of action, process and object conceptions, and other previously constructed schemas, which are synthesized to form mathematical structures utilized in problem situations (Baker, Cooley, & Trigueros, 2000). These schemas evolve as relations between new and previous action, process, and object conceptions and other schemas are constructed and reconstructed. Their evolution may be described by three stages that Piaget and García (1983) refer to as the “triad.” At the general *intra-* stage some operational actions are possible, but there is an absence of relationships between properties. At the *inter-* stage, the identification of relations between different processes and objects, and transformations are starting to form but remain isolated. The *trans-* stage is defined in terms of the construction of a synthesis between relations to form a structure (Cooley, Trigueros, & Baker, 2007). Also, although it might be thought that in APOS theory there is a linear progression from action to process to object and then to having different actions, processes, and objects organized in schemas, this often appears more like a dialectical progression where there can be partial developments, passages and returns from one to other conception (Czarnocha, Dubinsky, Prabhu, & Vidakovic, 1999). What the theory states is that the way a student works with diverse mathematical tasks related to the concept is different depending on his or her conception.

The application of APOS theory to describe particular constructions by students requires researchers to develop a genetic decomposition—a description of specific mental constructions one may make in understanding mathematical concepts and their relationships. Some clarifications are pertinent. A genetic decomposition for a concept is not unique: it is a general model about how a concept may be constructed. Different researchers can develop diverse genetic decompositions of how students in general construct that particular concept, but, once one is proposed, it needs to be supported by research data from students. Frequently, gathered data reveal overlooked constructions, which then give rise to a revised genetic decomposition.

In comparison to perspectives that mainly account for an individual’s cognitive structures or activity, some work has focused on constructs that allow one to track collective discipline specific practices that begin with students’ current reasoning and move toward more formal reasoning. For example, Rasmussen, Zandieh, King and Teppo (2005) tracks the progression of the practices of symbolizing, algorithmatizing and defining across such a continuum by elaborating and extending of the framework of horizontal and vertical mathematizing (Treffers, 1987). Zandieh and Rasmussen (in press) detail more thoroughly the case of defining, framing the analysis within the theory of Realistic Mathematics Education (RME). In particular, these researchers adapted the RME heuristic of emergent models (Gravemeijer, 1999) as a means to organize and reflect on a significant learning experience that involved creating and using definitions.

The intention of the emergent model heuristic is to create a sequence of tasks in which students first develop *models-of* their mathematical activity, which later become *models-for* more sophisticated mathematical reasoning (Gravemeijer, 1999). In a similar way, Zandieh and Rasmussen (in press) demonstrate that definitions can first come to the fore as a *definition-of* students’ previous activity and later these definitions serve as tools for (that is, *definitions-for*) further mathematical reasoning. The shift from model-of to model-for (or definitions-of to definitions-for) is compatible with Sfard’s (1991) process of reification. While the literature offers several examples of emergent models, the precise meaning of the term “model” is left implicit. To add clarity to the field, Zandieh and Rasmussen (in press) define models as student
generated ways of organizing their activity with observable and mental tools. By observable tools they mean things in their environment, such as graphs, diagrams, explicitly stated definitions, physical objects, etc. By mental tools they mean the ways in which students think and reason as they solve problems – their mental organizing activity.

As described by Gravemeijer, Bowers and Stephan (2003), the model-of / model-for transition is reserved for a significant conceptual transition in student activity, where activity includes mental activity. Otherwise, each act of symbolizing would be labeled as a model-of / model-for transition and hence lose analytic power. The model-of / model-for transition is therefore concurrent with the creation of a new mathematical reality.

The models and modeling perspective, on the other hand, focuses on the development of conceptual tools which are useful in decision making. Researchers working from this perspective (Kelly & Lesh, 2001; Lesh & Doerr, 2003, Lesh & English, 2005) have developed criteria that the problems to be posed to the students must satisfy in order to be successfully applied in the classroom to contribute to the learning process of students. Here, the main idea in modeling consists of introducing realistic complex situations where students engage in mathematical thinking and generating complex products and conceptual tools to accomplish the intended goal. These products are constructed during cycles of work and reflection and can be, in each cycle, self-evaluated by students.

Plan for Active Engagement of Participants

In this section we describe the specific tasks we expect to accomplish during the three working group sessions. In broad terms, the sessions will allow time for participants to work through some of the mathematical ideas for themselves, to discuss core theoretical underpinnings on cognition and instructional design, to examine instructional tasks, and to discuss video of student work on these tasks.

Session One

A brief presentation of the goals of the working group will be presented. Two different linear algebra problems will be presented together with the following questions to be discussed:

1. What linear algebra concepts do you believe can be introduced with the problem?
2. What strategies do you anticipate will motivate students to start working on these problems?
3. What kind of activities or questions would you introduce to help students move their strategies forward?

Participants will be split into small groups, and one of these two problems will be assigned to each group so that half of the participants work on one problem and the other half work on the other problem. After a period of discussion in small groups, the whole group will discuss the answers to the questions. As a closure to this session we will talk briefly about what will follow in the next sessions.

Session Two

After a brief introduction to the session we will go back to the problems and present the results of the discussion from the previous session and present the activity for the present session. Results from actual student work with the two problems introduced in the first session will be
presented to the participants; these can be parts of video recording or written work. Participants will split again to work in groups and work with the data to answer the following questions:

1. What did students do and how does it compare with what we expected them to do?
2. How would you analyze these data?
3. Are there specific results you can describe from your analysis?
4. Write a summary of your findings.

It is important to note that work from students used in this part will be bilingual. The group will reunite to discuss the answers to these questions. Groups that worked with one problem will present their conclusions to those working with the other problem and then the same will be done by the groups that worked with the other problem. As we anticipate answers to the posed questions will depend on the selected theoretical framework chosen by different groups, we will close the session by talking about the focus of the third session, theoretical frameworks.

**Session Three**

Organizers will start the session by summarizing work from the previous sessions. The organizers will present and discuss some results they found for the same problems using the theoretical lens each group used. The group will split into small groups to discuss the possibilities for the application of different theoretical frameworks to research on models, in particular models related to linear algebra. Discussion can be focused by the questions:

1. What restrictions on the way problems are posed are imposed by different theoretical frameworks?
2. What specific contributions to the analysis of student modeling activities can different theoretical approaches make?
3. What limitations can be expected from the use of different theoretical frameworks?

Each group will write down their answers to the questions to be discussed by the whole group. The group will reunite to discuss the answers to the questions and possibilities for future work.

**Anticipated Follow-up Activities**

We anticipate three follow-up activities: a wiki for further interaction throughout the year, a special issue in a journal on the group’s theme, and a second working group in 2011. First, we will create a wiki for the purposes of the dissemination of ideas and further communication amongst members of the working group. The wiki will be an interactive community centered on the activities of the working group, housing tasks that are presented at the working group and possibly other tasks from interested parties. Accompanying these tasks will be teaching notes and materials designed to help teachers and researchers to better implement the tasks in their classrooms. Those who use the tasks will have the opportunity to post their thoughts and reactions to the tasks. The intention is to provide a forum for participants to refine their understanding of student thinking about linear algebra, how the tasks are able to elicit and refine student thinking, and how student’s transition from informal, intuitive ways of thinking to formal understandings.

Second, we will seek to create a special journal issue focusing on the theme of transitioning from students’ current ways of thinking about mathematics and mathematical situations towards more formal ways of reasoning in mathematics. While the issue will be primarily centered on instructional design and student thinking in linear algebra, there will also be opportunities for other authors to include work in other content areas, given that the work is consistent with the theme of the working group. In conjunction with the international makeup of this working group’s organizers, the journal issue will be intended for an international audience and hence could be written in Spanish as well as English in order to reach a wider community of mathematics education professionals.

Third, we plan to have another PME-NA working group in 2011 in order to continue the work started in 2010 and capitalize on the activity that the wiki instigates over the course of the year. A new working group in 2011 will allow members of the 2010 working group to congregate and continue their work on the themes of the original group. Furthermore, we anticipate that new issues will arise as a result of conversations and work done on the wiki. The 2011 group will allow the participants to address these issues and discuss how to further connecting students’ current ways of reasoning to the more conventional, formal ways of reasoning in mathematics. Finally, the 2011 working group will be an opportunity for people not already a part of the group to take part in our ongoing activities. As this group matures, we would make our work available via the Linear Algebra Education section of the International Linear Algebra Society website.

Prior Work and Collaborations

The proposed working group builds on and extends the working group proposers’ previous collaborative efforts. The collaborative work of the USA researchers stems from their involvement in an NSF-funded project that investigates the transition from informal to formal reasoning of students within the context of undergraduate linear algebra. Under the direction of Chris Rasmussen and Michelle Zandieh, this project is composed of two main research strands, one of which is a linear algebra stand. Within this strand, there are three primary goals: (a) to detail student conceptions of fundamental ideas, (b) to trace students’ intellectual growth from informal to more formal ways of reasoning, and (c) to create instructional sequences that support students’ growth.

The Mexican research team, funded by the Consejo Nacional de Ciencia y Tecnologia, is also investigating the teaching and learning of linear algebra. The goal of their project is the design of modeling activities to teach linear algebra concepts in an application context. The activities are designed so that students can discuss and reflect not only on the potential of application of the concepts involved in each activity, but also their properties and the relation with other concepts. The intention of the project is to promote significant learning of the abstract concepts included in a Linear Algebra course. The modeling activities are being used with different groups of students and research is being conducted on the way students use mathematics they already know, the strategies they follow when working with the activities, and how this leads to more formal and conventional mathematics.

In 2008, Maria Trigueros and Asuman Oktaç organized a symposium focused on linear algebra education at the 15th Conference of the International Linear Algebra Society in Cancun, Mexico. They alerted the US team to the conference and encouraged them to apply to present their work at the symposium. As a result, members from both the Mexican and US team presented their work at this conference (Possani, Preciado, & Lozano, 2008; Trigueros, Ku, &
Oktaç, 2008; Zandieh, Larson, & Rasmussen, 2008). It was at this meeting that the two research teams became aware of their similar interests in the use of modeling problems in order to investigate ways to assist students in transitioning from their current ways of reasoning to more formal or conventional ways of reasoning in linear algebra. In particular, the American researchers have been designing, implementing, and studying a curriculum for an undergraduate linear algebra course that is based on student inquiry and conceptual development of key ideas, and the researchers at the Instituto Tecnológico Autónomo de México have had a similar ongoing project.

Since meeting in Cancun, the researchers have conducted regular meetings via Internet video and audio chats during which they share ideas, results, and innovations for task development and implementation in their respective linear algebra classrooms. They have convened a face-to-face meeting at the Instituto Tecnológico Autónomo de México in Mexico City on November 9-11, 2009. At this meeting, the two research teams worked on various modeling tasks that have been used in their respective linear algebra classrooms, shared results of how these tasks functioned in the classrooms, and collaborated towards refinement of these problems. The bringing together and the merging of two research teams that are working from different yet compatible theoretical perspectives have proven invaluable to both in the past. Building upon this foundation at the working group, where additional experienced researchers in mathematics education will have the opportunity to participate and contribute, will be beneficial for all involved.

CONTINUING DISCUSSION OF MATHEMATICAL HABITS OF MIND

Annie Selden
New Mexico State University
js9484@usit.net

Kien Lim
University of Texas at El Paso
kienlim@utep.edu

The idea of “mathematical habits of mind” has been introduced to emphasize the need to help students think about mathematics “the way mathematicians do.” There seems to be considerable interest among mathematics educators and mathematicians in helping students develop mathematical habits of mind. The objectives of this working group are: (a) to continue the discussion of various views and aspects of mathematical habits of mind begun at PME-NA 31, (b) to explore avenues for research, (c) to encourage research collaborations, and (d) to interest doctoral students in this topic. In the Proceedings of PME-NA 31, we provided an overview of mathematical habits of mind, including concepts that are closely related to habits of mind—ways of thinking, mathematical practices, knowing-to act in the moment, cognitive disposition, and behavioral schemas. Below we provide a summary of the discussions held at PME-NA 31. We invite returning participants, as well as other mathematics educators who are interested in mathematical habits of mind, especially those who have conducted research related to habits of mind, to our discussions.

An Overview of Mathematical Habits of Mind

The term habits of mind was introduced by Cuoco, Goldenberg, and Mark (1996) as an organizing principle for mathematics curricula in which high-school students and college students think about mathematics the way mathematicians do. Lim and Selden (2009) highlighted two key attributes of habits of mind: the habitual characteristic and the thinking characteristic. The habitual nature of habits of mind was underscored in Goldenberg’s (1996) description of habits of mind, which “one acquires so well, makes so natural, and incorporates so fully into one's repertoire, that they become mental habits—one not only can draw upon them easily, but one is likely to do so” (p. 13). Mason and Spence’s (1999) notion of knowing-to act in the moment accentuates this habitual character. They have differentiated between two types of knowledge. The first type, referred to as knowing-about, consists of Ryle’s (1949, cited in Mason & Spence) three classes of knowledge: knowing-that (factual knowledge), knowing-how (procedural skills), and knowing-why (personal stories to account for phenomena). The second type, referred to as knowing-to, is tacit knowledge that is context/situation dependent and becomes present in the moment when it is required. This distinction is important because “knowing to act when the moment comes requires more than having accumulated knowledge-about . . .” (Mason & Spence, 1999, p. 135).

Knowing-about ... forms the heart of institutionalized education: students can learn and be tested on it. But success in examinations gives little indication of whether that knowledge can be used or called upon when required, which is the essence of knowing-to (Mason & Spence, p. 138).

Mason and Spence advocate the practice of reflection as a means to help students improve their knowing-to act in the moment. Students should be encouraged to reflect on (a) what they have done after an action, and (b) what they are doing while enacting it, which were termed by

The thinking characteristic differentiates habits of mind from behavioral habits such as knuckle cracking and nail biting. Costa and Kallick (2000) identified sixteen habits of mind that can and should be cultivated in schools. Habits of minds in Costa and Kallick’s list that are related to mathematical thinking and learning include persisting, managing impulsivity, thinking flexibly, metacognition, striving for accuracy, and thinking and communicating with clarity and precision. Cuoco (1996) differentiates mathematical habits of mind, such as talking big thinking small, talking small thinking big, thinking in terms of functions, and mixing deduction and experiment, from more general ones like pattern-sniffing, experimenting, formulating, tinkering, inventing, visualizing, and conjecturing. Harel’s (2008) distinction between ways of thinking and ways of understanding highlights two complementary subsets of mathematics: the former refers to conceptual tools or mathematical habits of mind that are used for creating the latter, which refers to collections of institutionalized definitions, theorems, proofs, problems, and solutions. These two aspects of mathematics are analogous to the two types of standards—process and content—outlined in the NCTM’s (2000) *Principles and Standards for School Mathematics*.

According to Levasseur and Cuoco (2003), mathematical habits of mind should not “be the explicit objects of our teaching, rather, each student should internalize them as they do math” (p. 34). Mathematical habits of mind can be fostered by providing students opportunities to engage in authentic mathematical activities such as modeling and realistic problem solving (see Lesh & Doerr, 2003; Schoenfeld, 1985). The National Council of Teachers of Mathematics published two books on *Teaching Mathematics through Problem Solving*; one for Grades PreK-6 and the other for Grades 6-12. There is a chapter on mathematical habits of mind in each book: (a) Goldenberg, Shteingold, and Feurzeig (2003) discuss five habits of mind that are particularly relevant to elementary grade levels: they include thinking about word meaning, justifying claims and proving conjectures, distinguishing between agreement and logical necessity, analyzing answers, problems, and methods, and seeking and using heuristics to solve problems; and (b) Levasseur and Cuoco (2003) discuss how secondary school students can acquire habits of mind such as guessing, challenging solutions, looking for patterns, conserving memory, using alternative representations, thinking algebraically, and classifying carefully. Driscoll and colleagues (1999, 2007) have created professional development materials to foster algebraic thinking and geometric thinking. Their goal is to help teachers and their students develop algebraic habits of mind such as doing/undoing, building rules to represent functions, abstracting from computation, reasoning with relationships, generalizing geometric ideas, investigating invariants, and sustaining reasoned exploration by trying different approaches and stepping back to reflect. Lewis (2008, January) commented that their professional development project was designed to help teachers develop “habits of mind of a mathematical thinker” and in turn foster these habits in their students. Rasmussen (2009, January) emphasized the need for teachers to be deliberate about initiating and sustaining particular classroom norms so as to promote certain desirable habits of mind and effect students’ beliefs and values.

The *Standards for Mathematical Practice* in the Common Core State Standards in Mathematics (CCSSI, 2010) highlight the following habits of minds that mathematics educators at all levels should seek to develop in their students:  

---

• Make sense of problems and persevere in solving them
• Reason abstractly and quantitatively
• Construct viable arguments and critique the reasoning of others
• Model with mathematics
• Use appropriate tools strategically
• Attend to precision
• Look for and make use of structure
• Look for and express regularity in repeated reasoning

A collection of lists of habits of mind from various sources, including CCSSI (2010), can be downloaded from http://works.bepress.com/kien_lim/19/. More information on mathematical habits of mind can be found in the Mathematical Habits of Mind Working Group paper in the Proceedings of PME-NA 31 (Lim & Selden, 2009) and on the website: http://www.math.utep.edu/Faculty/kienlim/mhom.

The working group on mathematical habits of mind met for the first time in September 2009 at PME-NA 31. There were three meetings. We began with individual presentations on research related to habits of mind. We then had an open forum to discuss theoretical and pedagogical issues related to this topic followed by small subgroup breakout sessions. We concluded the meeting by having reports from the various subgroups. To facilitate the continuation of this working group at PME-NA 32, we summarize below the information gathered during the previous working group sessions.

Individual Presentations at the PME-NA 31 Working Group
The working group began with six 10-minute presentations. Below are the title, name of the presenter(s), and a short summary for each presentation, listed in the order they were presented.

Mathematical Habits of Mind for Preservice Elementary Teachers
Richard S. Millman, Georgia Institute of Technology
The concept of mathematical habits of mind urges preservice teachers to use, in their teaching, ideas such as posing questions (e.g. “Is there a different way to think about this problem?” and “What is there that I am not seeing?”), seeking possible generalizations, considering the necessity and use of careful definitions, and dealing with the vagueness of open-ended questions. These ideas are aimed at having preservice elementary teachers understand how mathematicians might think. In the presentation, Millman described how mathematical habits of mind could be introduced in a mathematics content course for future elementary teachers through their inclusion in the textbook, Mathematical Reasoning for Elementary Teachers, 5th Edition (Long, DeTemple, & Millman, 2009). He provided some reactions of pre-service teachers, as well as those of eleven reviewers of the text (six of whom used the textbook and five of whom didn’t), concerning the inclusion and emphasis of mathematical habits of mind in the textbook.

Undesirable Habits of Mind of Preservice Teachers
Kien H. Lim, University of Texas at El Paso
Many preservice K-8 teachers enter college with undesirable habits of mind such as (a) spontaneously proceeding with the first action that comes to mind without analyzing the problem situation, and (b) not attending to meaning of numbers and symbols. Such habits of
mind can negatively impact what and how they learn mathematics. For example, students often tend to focus on procedures for solving problems rather than on underlying mathematical structures. In the presentation, Lim offered several strategies to help prospective teachers address their undesirable habits of mind. One strategy is to pose problems for which a recently learned idea will not work, and thereby present students with a need to investigate the principles that underlie that idea. Another strategy is to emphasize the need for understanding the quantities embedded in a problem situation and how these quantities are related. A study was conducted to investigate the viability of using nonproportional missing-value problems to address students’ tendency to overgeneralize proportional approaches (see Lim & Morera, 2010). An instrument, called the likelihood-to-act survey, has been developed to assess students’ problem-solving disposition along the impulsive-analytic disposition (see Lim, Morera, & Toshanov, 2009).

**Transforming pre-service teachers’ dispositions towards mathematics through reflection in-activity and post-activity**

**Dionne I. Cross, Indiana University-Bloomington**

Mathematics education is still undergoing a transition from a transmission view of instruction to one that involves students actively engaging in “doing” mathematics. One way to address this problem is by working with pre-service teachers to begin transforming their ideas about mathematics and mathematics learning. Using examples, the transformation of the teachers’ approaches to non-traditional problems were described—from initially being unable to solve problems that do not have a singular solution or problems that prioritized thinking and reasoning to making generalizations and aligning algebraic notation with specific aspects of a problem. Students’ development of these habits of mind (Driscoll, 1999) were attributed to focused efforts to teach students (a) how to engage in reflection both during an activity and following the activity (Schön, 1983), and (b) how to articulate their thoughts both verbally and in writing.

**Habits of Mind in the Proving Process**

**Annie Selden & John Selden, New Mexico State University**

The Seldens view the proving process as a sequence of mental or physical actions that cannot be fully reconstructed from the final written proof. Such actions often appear to be due to the enactment of small, automated situation-action pairs that they call *behavioral schemas* (Selden & Selden, 2008; Selden, McKee, & Selden, 2010). A common beneficial behavioral schema consists of a situation where one has to prove a universally quantified statement like, “For all real numbers $x$, $P(x)$” and the action is writing into the proof something like, “Let $x$ be a real number,” meaning $x$ is arbitrary but fixed. Focusing on such behavioral schemas, that is, small habits of mind, has two advantages. First, the uses, interactions, and origins of behavioral schemas are relatively easy to examine. Second, this perspective is not only explanatory but also suggests concrete teaching actions, such as the use of practice to encourage the formation of beneficial schemas and the elimination of detrimental ones.
Mathematics Immersion and Educators' Habits of Mind: Preliminary Results from Two Programs

Karen Graham & Todd Abel, University of New Hampshire

Mathematics immersion is a form professional development where educators are encouraged to work through unfamiliar mathematical content in ways that simulate the activities and practices of mathematicians. Graham and Abel briefly described two such programs that they have examined. The first program was a one-week summer institute, participated in by 18 faculty members and 7 graduate students. Analysis of participant journals and follow-up surveys uncovered the following themes: (a) freedom to experiment, conjecture, and guess, (b) value in using multiple points of view, and (c) joy in doing mathematics. The second was a two-summer professional development program participated in by 50 high-school and middle-school teachers. Analysis of pre-and-post interviews with six participants revealed the following themes: (a) the motivational role of pattern-sniffing, (b) the importance of mixing deduction and experiment, and (c) the importance of classroom practice (e.g., the usefulness of activities for classroom work). Mathematics immersion increased participants’ awareness of, but did seem to impact participants’ use of, habits of mind.

Richard Lesh, Indiana University-Bloomington

Do students develop rigid and unchanging profiles of habits, dispositions, and attitudes? Or, do productive problem solvers manipulate their own profiles to suit circumstances? Evidence was presented to show that (a) productive-but-implicitly-functioning habits of mind can be developed using reflection activities similar to those used by athletes and performing artists; (b) students can develop more powerful ways of seeing (or interpreting) their own problem solving experiences; (c) both learning and application of ideas and processes develop synchronously during mathematical model-development activities; and (d) the productivity of relevant processes, beliefs, dispositions, and habits of mind vary across time. Productive students can learn to manipulate their own profiles to suite circumstances. This research is based on models and modeling perspectives of mathematical problem solving, learning, and teaching.

PowerPoint slides or write-ups for the above presentations can be downloaded at http://www.math.utep.edu/Faculty/kienlim/mhom. In addition, other presentations on this topic at the 2008 and the 2009 Joint Mathematics Meetings are posted at http://www.math.utep.edu/Faculty/kienlim/hom. Presenters at those sessions included Hyman Bass, Al Cuoco, Paul Goldenberg, Guershon Harel, Kien Lim, Chris Rasmussen, Annie Selden and John Selden.

Questions Raised During the Brainstorming Session

A number of ideas and questions emerged during a brainstorming session by the working group last year. These ideas and questions can be grouped into four broad categories: epistemology, cognition, pedagogy, and research.

Epistemology-related questions. What do we, or should we, mean by mathematical habits of mind? What is meant by a mathematical disposition? Can we get to a common understanding of what we mean by mathematical habits of mind? What does it mean to think mathematically? How do mathematicians’ (whether pure, applied, or statisticians) views of mathematical habits of mind differ from those of mathematics teachers? What are engineers’ views of mathematical
habits of mind? With the introduction of technology (e.g., computers and calculators), are there new mathematical habits of mind that it would be beneficial to acquire? Are there special mathematical habits of mind that are useful when using internet resources?

_Cognition-related questions._ How are mathematical habits of mind different from beliefs, metacognitive strategies, or problem-solving strategies? Is curiosity a habit of mind? Is being meticulous a habit of mind? What is not a habit of mind? What are some tacitly functioning mathematical habits of mind? How have mathematicians acquired mathematical habits of mind? Is it adaptive or useful for students to think like mathematicians? Are there negative mathematical habits of mind? What are they? What impact do positive (or negative) mathematical habits of mind have on students’ problem solving ability?

_Pedagogy-related questions._ Are there progressive stages to developing mathematical habits of mind? What are some impediments or obstacles to acquiring positive mathematical habits of mind? Can you teach positive mathematical habits of mind to students? If so, how? Is there teacher-to-student transfer or professor-to-teacher-to-student transfer of mathematical habits of mind? How do teachers’ mathematical habits of mind affect their teaching? What are some ways of assessing the acquisition of positive mathematical habits of mind?

_Research-related questions._ What sorts of theoretical frameworks could one use in researching mathematical habits of mind? Are mathematical habits of mind culturally influenced? Is their acquisition a matter of enculturation into the larger mathematical culture? What is the role of language in acquiring mathematical habits of mind? In general, how would one conduct research on mathematical habits of mind?

**PME-NA 31 Working Subgroup Discussions**

The larger working group at PME-NA 31 broke-out into four subgroups to discuss the following topics: (a) Defining habits of mind and the role of language in developing mathematical habits of mind; (b) How does one help teachers or students to develop mathematical habits of mind? (c) Small mathematical habits of mind (behavioral schemas) in proving and problem-solving, including tacit habits of mind; and (d) Negative mathematical habits of mind.

**Defining mathematical habits of mind.** The first subgroup came up with the following definitions and characteristics of habits of mind which they summarized for the entire working group. Habits of mind are automatic mental processes in response to stimuli that can produce behavior. There is a hierarchy, or spectrum, of habits of mind from low level to high level. An example of a low-level of habit of mind is helplessness (e.g., the response of “show me how to do it”) often exhibited by novices. A middle-level habit of mind might be the ability to go through several problem-solving strategies, often exhibited by those developing expert habits of mind. A high-level of habit of mind includes reflecting, monitoring, and questioning, as is often exhibited by experts.

**Encouraging mathematical habits of mind in students.** The second subgroup took as their starting point Cuoco, Goldenberg, and Mark’s (1996) view that “Much more important than specific mathematical results are the habits of mind used by the people who created those results.” The subgroup also considered mathematical habits of mind to be “the methods by which mathematics is created, and the techniques used by researchers.” They considered the following aspects of, and questions related to, mathematical habits of mind: Justification and defense of results to others in the community. Are there mathematical versus non-mathematical habits of mind? Are mathematical habits of mind dependent on personal experience? Is there some aspect

---

of enculturation? How do the habits of mind used by researchers in the creation of new mathematical results develop? For possible research questions, they suggested: (a) By what processes does a person develop the habits of mind that are typical of mathematicians? (b) How does a person become enculturated into mathematical practices? (c) How do young children develop early mathematical habits of mind?

Small, possibly tacit, mathematical habits of mind. The third subgroup considered the question: Why does it matter to have a small, possibly tacit, habit of mind? They viewed a small, possibly tacit, habit of mind as having two components: (a) the interpretation component, of which one is aware, and (b) the execution, or doing, component, which is often automatic and of which one is usually not aware. The interpretation of the situation is the key, or important, part of the habit. Having an automated habit doesn’t take up much working memory, so one can concentrate on other things.

This subgroup made some basic assumptions: (a) Habits of mind develop over time (as there must be a time when one did not have a particular habit); and (b) People have profiles, or constellations of related habits of mind. The following research question was proposed: How do such small, possibly tacit, habits of mind, or other habits of mind, develop?

The subgroup also considered whether there were habits of mind with, and without, understanding the underlying habit. Is doing so a mathematical habit of mind? It was observed by one of the group members that he had not found a habit of mind that was not sometimes counterproductive.

The group made the following observations: (a) The tacit part of some small habits of mind are absolutely critical; (b) People can have habits of mind, and other habits, and not know they have them. For example, some people walk in a certain way. Other people know this and can recognize them from their walk, but they aren’t aware of the way they walk; and (c) From problem solving studies, it has been observed, for example, that the observer can say a student is drawing a picture, but that’s what the observer thinks is going on. However, the student may say that’s not what he/she was doing. If one questions the student, he/she may say, “I was trying to figure out what was going on [not drawing a picture].”

Dick Lesh reported a recent study conducted with two groups of students. One group watched a PBS program, Cyberquest, about problem-solving teams. Both groups of students were given two problems to solve at the start and two problems to solve at the end. The researchers were given a list of things to notice, such as the role of individuals (the leader, etc.); group functioning, data gathering and data processing. Most of what they observed could be considered habits of mind. At the start, both groups of children had the same number of habits of mind. At the end, both groups invoked the same habits of mind, but the students who watched the program got the problems correct. Further, there was no correlation between the number of processes (habits) and whether the students got the problems right. So what was the difference between the two groups? The group that got the problems correct did them (the habits of mind) at the “right time” and for the “right reasons.”

Negative habits of mind. This subgroup considered mainly negative instances of spontaneous, or impulsive, disposition or tendency to act. For example, when a student is asked to solve \((x + 3)(x - 4) = 0\) and automatically multiplies the left hand side. It seems that students are doing what is familiar to them, that they are programmed to react to certain patterns in certain manners, and that this might be the result of certain instructional environments. Such spontaneous dispositions may be limiting to, or block, cognitive growth.

---

Another example considered was geometrical. The figure below shows a right triangle NQR and a rectangle PQRS; NQ = 5 cm, QR = 12 cm, and RS = 3 cm. When asked to find the length PM, a student may begin by using the Pythagorean theorem to find the length NR. Such a student is said to be impulsive because he or she spontaneously applied the first idea that came to mind without checking its appropriateness.

This subgroup generated the following research questions. (a) How can we detect spontaneous dispositions in situations when the responses are correct responses? (b) What situations/tasks elicit a spontaneous disposition? (c) Is a spontaneous disposition visually influenced? What is the case for blind people? And (d) Can eye tracking collect useful information that can help us understand a student’s impulsive disposition?

**Plans for the Working Group at PME-NA 32**

At the request of the 2009 participants of the Working Group on Mathematical Habits of Mind, we do not intend to have formal presentations. Instead, during the first session we will determine the interests of the participants and formulate an agenda for subsequent sessions. We hope to make progress in this second working group by accomplishing the following:

- Come up with an operational definition that is useful for research purposes.
- Identify important issues/questions and develop research agendas to address/answer them.
- Form collaborations to conduct research.
- Discuss the usefulness and viability of having a support group for those who are conducting research on mathematical habits of mind, and explore the interest in and feasibility of having a special issue of a research journal dedicated to mathematical habits of mind.

Participants with similar interests will team up to discuss theoretical, pedagogical, and/or research issues related to mathematical habits of mind. These teams will report back their discussions and findings to the entire working group at the final working group session. We will conclude the working group with a discussion of next steps.

To facilitate communication and discussion among individuals who are interested in mathematical habits of mind, we have created a site at http://habitofmind.ning.com/. Anyone can register and be a member of this professional network.

Mathematics education researchers face a set of professional challenges that are unique to their discipline. The primary purpose of this PME-NA working group is to discuss, develop and ultimately document effective models for localized professional support in research, writing, and publication, as well as opportunities for cross-institutional collaboration. The objectives of this working group are: (a) to discuss the needs of the mathematics education research community regarding professional support and collaboration, (b) to explore models for successful localized mathematics education research working groups, (c) to facilitate mathematics educators to form localized working groups, and (d) to establish a plan of assessment for evolving localized working groups. This working group will be appropriate for anyone interested in forming their own localized mathematics education research group.

### Background

National organizations focusing on mathematics education and mathematics education research such as the National Council of Teachers of Mathematics (NCTM), the School Science and Mathematics Association (SSMA), Psychology of Mathematics Education-North American Chapter (PMENA), Special Interest Group of the Mathematical Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME), and the Association of Mathematics Teacher Educators (AMTE) provide rigorous outlets for reporting research studies completed or in progress, action research, and for disseminating research frameworks, practitioner knowledge, and other ideas. However, support for on-going development of

---

researchers and for connecting local communities of researchers must also come from local or web-based formats. Formation of local, cross-institution, research groups attends to the ongoing local mentoring, collaboration, and research needs of individual researchers and also alleviates possible obstacles in connecting to the greater research community such as issues of time for travel, funding for travel, and other acute regional needs.

Recognizing a need to facilitate the development of a professionally supportive network of mathematics education researchers across Texas, the mathematics education group at Sam Houston State University in Huntsville, Texas organized the Mathematics Education Research in Texas (MERiT) conference, which has been held three times since 2008. The majority of time at MERiT is devoted to small-group discussions among participants from different institutions. The informal and collegial atmosphere at the MERiT meetings fosters professional interactions that often focus on the beginning stages and design aspects of research in addition to the later stages of summarizing and presenting findings. Some conversations provide opportunities for feedback on individual research efforts, while others focus on collaborations for grant proposals, manuscripts, research projects, and presentations. Thirty-five participants representing 16 different institutions have attended one or more of these MERiT conferences.

At the third MERiT conference, this supportive environment for mathematics education researchers served as a catalyst for the formation of two smaller ongoing working groups. One group formed as the result of common research interests, and the second group grew out of geographic proximity. The first group is a state-wide group of mathematics educators with a research interest in mathematics teacher efficacy. This group is currently focused on the development of secondary mathematics teachers and is in the process of developing a teacher efficacy instrument with Algebra as the focus. The second group is made up of mathematics educators at universities in North Texas, who decided to form a local working group that could meet monthly for support in research, writing, and publication. The group members represent research and teaching universities as well as departments of mathematics and education. The participants represent all stages of academic careers, from newly graduated Ph.D.s, to full professors.

**Developing a model for a mathematics education working group**

Not having a roadmap for how to proceed, this latter group, aptly named the Mathematics Education Research Group in North Texas (MERGiNT), started meeting and began to establish goals. Several themes emerged regarding the unique opportunities such a group afforded. First, many members of MERGiNT experience some level of institutional or departmental isolation in that they were either the only or one of very few mathematics educators in their department or university. This isolation directly hampers the pursuit of research and publication due to both a paucity of formative feedback and a lack of creative discourse needed from colleagues pursuing similar goals. In addition, expanding the number of collaborators on research studies in progress or in planning stages arose as a common need. For example, some researchers at smaller institutions need access to larger populations of pre-service teachers. MERGiNT participants’ proximity to each other facilitates regular meetings focused on providing peer review and feedback as well as discussions on appropriate theoretical frameworks. Also, it seems likely that opportunities for collaboration will increase at the local level both because of the logistical feasibility of meeting and the common school systems in which various local universities have investment and influence.

The second theme that emerged was the issue of presence and influence within local school districts. Much of MERGiNT participants’ research interests connects to schools and inservice teachers in the region and educational frameworks and structures in the state. The benefits from collaboration and coordinated regional efforts may assist in building stronger networks for maintaining awareness and effective feedback mechanisms for local, regional, and state levels efforts. An added strength may be that a cross-institutional working group streamlines communication with school administrators, staff, and teachers by presenting common goals, rather than disparate competitors asking for collaboration on competing projects. The potential of MERGiNT becoming more visible to the school districts provides the group greater opportunity for cooperation from districts and collaboration with each other.

The need for professional support and regional presence with school systems is not at all unique to the mathematics education researchers of North Texas. The MERiT conference, out of which our organization grew, similarly addresses these needs at the statewide scale. This PME-NA working group seeks to explore how the national mathematics education research community in other regions could benefit from developing similar systems of support.

This working group brings forward the need for local cross-institutional collaborations among mathematics education researchers to help establish more frequent opportunities for mentoring, refining research agendas, and forming local initiatives that present common regional goals versus individualized institutional goals to local school districts and other institutions. We learn from the research literature on collaborative research groups to inform this work and aim to define a process for which the goals of helping researchers grow professionally and of fostering further near-peer collaborations.

**Effective models for professional support and collaboration: structures and characteristics**

The two primary goals of the MERGiNT group are to support its members’ full individual professional development as mathematics education researchers and to foster collaborations within the working group. To develop a structure that supports these goals, we turn to the research literature on collaborative working groups.

One of the challenges for university faculty is balancing multiple responsibilities including teaching, scholarship, and service. In addition to navigating multiple roles, new faculty also express feelings of isolation (Savage, Karp, & Logue, 2004). One means of helping junior faculty acclimate to the community of higher education is mentoring. Savage et al. (2004) describe six goals of mentoring: support new faculty in their professional growth, advance faculty fulfillment by building community, recruit and keep faculty by specifically outlining institutional expectations, encourage relations between new and experienced faculty, guide the transition of new faculty into the new culture, and help new faculty in balancing their duties. However, if a new faculty member is the only mathematics educator on campus, the mentor can contribute cultural knowledge and professional support but cannot provide insider knowledge of the field of mathematics education. Therefore, despite the aforementioned benefits of mentorship programs, there are potentially some limitations.

Another means of inducting new faculty into the university community is support groups. The idea of support groups among teaching professionals is not a novel concept. Educators at all ends of the spectrum, such as inservice teachers, principals, preservice teachers, and college professors, have formed groups to support one another in their endeavors. For instance, Balach and Szymanski (2003) found that through their diverse group of educators that progress was made in the form of “dialogic skills, a shared understanding of how teachers must lead a life of

---

the mind, and realization of how to create a context supportive of change” (p.25). Sterrett and Haus (2009), two principals from the same school district, formed a collaborative group to help improve their schools from the top down. They met with certain goals in mind and helped each other develop plans for school enhancements. Even specific groups like Science, Technology, Engineering, and Math (STEM) programs (Hamos, et al., 2009) have developed across the country to bring individuals from different disciplines together. Through all these various types of meetings, many educators have benefited from support and encouragement, as well as higher productivity rates.

The idea of higher productivity also applies to master’s and doctoral students in collaborative support groups. Similar to new faculty members, graduate students, at the thesis or dissertation writing stage, often feel a sense of isolation which is one of the factors contributing to delays or abandonment in completing the degree (Conrad & Phillips, 1995). In these support groups, graduate students discuss their progress and research findings with each other. Members of a group of three master’s students, who were all writing their thesis and met monthly with their supervisor, outlined the benefits of their collaboration: “(1) Support; (2) help in gathering materials; (3) seeding of ideas, stimulation; (4) the alternative perspectives that the others provided; (5) a timetable and pressure; (6) experience in ‘thinking on your feet’; (7) elimination of ‘blocks’ [to writing]; (8) encouragement to write; (9) and help in clarifying and communicating ideas” (Conrad & Phillips, 1995, p. 315). University faculty members could also gain from this type of collaborative mentoring from a working group made up of fellow faculty members, especially those in their field, with respect to writing manuscripts for publication.

Whether supporting each other’s individual endeavors (first goal) or working together on projects (second goal), the key idea is collaboration. Collaboration occurs when members work together on a shared project or toward a shared goal. Each member contributes toward the effort. All members have a shared vision and communicate with one another to provide progress toward fulfilling that vision (Leonard, 2002). As teacher educators, there is further imperative for collaboration: “If collaboration is a valued skill for teachers, then it is essential that teacher educators find ways to make collaboration a more integral part of the university context” (Ross, et. al. 2005, p. 278). This last quote is corroborated by several associations including the Association of Teacher Educators (ATE), the National Association for the Accreditation of Teacher Education (NCATE), Interstate New Teacher Assessment and Support Consortium (INTASC), and the National Board for Professional Teaching Standards (NBPTS), which all incorporate collaboration in part of their standards, and the Association of Mathematics Teacher Educators (AMTE), which includes collaboration in its mission and goals.

In an attempt to formulate a model of cross-institutional collaboration, the characteristics of other types of collaborations such as professional learning communities and partnerships between universities and schools will be discussed. A professional learning community (PLC) is a group of teachers, often within a school, who work together to improve student learning. The definition of a PLC can be gathered from the three words in the term. The teachers are professional who collaborate in fulfilling their responsibilities of their learning and the learning of their students. Community is, “individuals coming together in a group in order to interact in meaningful activities to learn deeply with colleagues about an identified topic, to develop shared meaning, and identify shared purposes related to the topic” (Hord, 2009, p.41). Hord (2009) identifies conditions for success of PLC’s, several of which can be extended to a cross-institutional working group. The members of the PLC must decide how they are going to
structure their experiences. There must be a dedicated time and space for meetings including the idea that the location of the meetings be rotated. Parr and Ward (2006) found that collaborations among K through 12 teachers via the internet may not be productive, resulting in limited sharing of materials and website use, supporting the importance of face-to-face meeting time. Finally, the power and the authority must be shared, also termed distributed leadership.

Distributed (or distributive) leadership, a concept primarily used in K through 12 schools, has a bottom-up versus top-down orientation. Whitby (2006) states that, “Distributive leadership involves the leadership functions of a school being shared by many people in ways that strengthen the whole school community, intensifying a sense of engagement and shared responsibility while making the workload more manageable” (p. 2). Brown and Littrich (2008) used and assessed the distributive leadership model for a cross-institutional collaboration which planned a conference roundtable on assessment. The project participants identified eight characteristics of distributive leadership: generates engagement; acknowledges and recognizes leadership irrespective of position; focuses on people’s strengths; is different things in different contexts; is enduring; requires the development of strong relationships and networks; is about capacity building and development; and assists and informs succession planning. Using surveys and reflective discussions to evaluate the framework based of these eight characteristics, it was found that the collaboration, on the whole, aligned with the principles. However, the authors also noted that although the project opened up the possibility of further collaborations (intra- and cross-institutional), there was more success with collaborations within institutions.

There is also documentation about collaborations between institutions of higher education and elementary, middle, and secondary schools. For example, Dolly (1998) discussed numerous research articles and how professional development schools work as environments where new collegiate faculty can learn about working at the university level, as well as partner with others on university issues. Frost, Coomes, and Lindeblad (2009) researched the characteristics and outcomes of a collaborative professional development project between secondary school mathematics teachers and postsecondary mathematics faculty. They were focused on the difficulties that students face when they transition from secondary mathematics courses to postsecondary mathematics courses. Their activities included readings, discussions, and comparison of student work. They also used activities such as team goal setting and analysis of school curricula and in-school teamwork with the aim of creating a sense of belonging to smaller PLCs within the larger group. DuFour and Eaker (1998) referred to this arrangement as a nested PLC. Participants in Frost, Coomes, and Lindeblad’s (2009) study developed a sense of safety, trust, and mutual respect for each other. Postsecondary faculty also valued the opportunity to work with high school teachers.

Robbins and Cooper (2003), working with schools and at a university, respectively, described their collaborative endeavors over a nine-year period. They identified several “rules” by which they worked together including maintaining communication, establishing mutual respect, upholding confidentiality, and regularly identifying and assessing shared goals. The majority of the piece discusses the various phases through which their collaboration progressed highlighting the evolutionary nature of the collaboration. Since they were working in two different contexts they needed to find a place in the middle to meet; that is, they sought to, “construct’ their own spaces for shared professionalism” (Robbins & Cooper, 2003, p. 225).

In terms of external collaborations in higher education, the majority of the research is about why the collaboration exists such as sharing resources or enhancing authority, effectiveness, and/or product (Kezar, 2006). In addition to sharing the reasons for forming our working group,
we plan to identify the characteristics that support cross-institutional collaboration by drawing on the literature of other types of collaborations. The result will be a framework of collaboration that applies to our situation of building a “space of shared professionalism” among mathematics education researchers from multiple institutions in a localized area.

**Purpose of this PME-NA working group**

This PME-NA working group builds on the development of three localized cross-institutional working groups for mathematics education researchers in different regions of Texas. The primary purpose of the working group is to discuss, develop and ultimately document effective models for localized professional support and collaboration that are transferrable to other regions. We expect interest from other mathematics educators who face the same assortment of unique professional challenges.

The objectives of this working group are:

- To discuss needs of the mathematics education research community regarding professional support and collaboration
- To explore models for successful working groups
- To facilitate mathematics educators to form localized working groups
- To establish a plan of assessment for evolving localized working groups

**Proposed Activities for this PME-NA working group**

**Session 1: Goals & Structure of Mathematics Education Research (MER) Working Groups**

- Introduction of participants
- History and development of the MERGiNT and MERiT groups
- Presentation and discussion of goals and structure of a MER working group
  - Why create a MER working group?
  - Needs of the community and major needs of the MER working group
  - Characteristics needed to be a successful evolving working group
- Individual presentations, if any, on research related to developing models for localized cross-institutional mathematics education research groups

**Session 2: How to Get Started**

- Review needs of working groups, as identified in Session 1
- Discussion of:
  - How to start a working group?
  - How to identify other people to participate?
  - Role of community colleges
  - Building interdisciplinary connections
    - Education Faculty + Mathematics Faculty + K-12 Teacher

**Session 3: Models of MER working groups**

- Discussion of:
  - Various models of working groups
    - State working groups & subgroups
• Cross institutional working groups
• Working groups within institutions
  o How to collaborate and share resources?
    ▪ Websites, Blackboard, Skype, Wikis, etc.
  o Developing a framework
  o Assessing your framework
  o How is the working group meeting the needs of the educational community?
• Planning for further collaboration and dissemination
• Developing tentative timeline for creation of future Working Groups

**Anticipated follow-up**

We anticipate follow-up activities on two levels. We expect that this PME-NA working group will be a platform for the formation of new mathematics education research working groups. We plan to document the evolution of these groups, and on a local level, we plan to use the insights gained in this PME-NA working group to develop a framework for assessing the growth and success of the MERGiNT group.

• Identify the new groups formed from this working group
  o Determine nature of group (similar research interest, geographic proximity, other)
  o Have new groups establish tentative goals and meeting format/times
  o Each new group submit a progress report to MERGiNT prior to PMENA 2011

• MERGiNT group:
  o Develop a theoretical framework to support the formation of MER working groups
  o Is the theoretical framework of this type of group unique to mathematics education or are there universal traits to such a group?
    ▪ Theories are like toothbrushes…everyone has their own and no one wants to use anyone else’s. (Campbell, 2006)
  o Develop possible ways to assess the effectiveness of a MER working group

Mathematically Important Pedagogical Opportunities (MIPOs) are instances in a classroom lesson in which the teacher has an opportunity to move the class forward in their development of significant mathematics. Although this construct is widely recognized in the literature as important to mathematics teaching and learning, it is neither well defined nor clearly identified as a construct that can be studied. This working group will build on the efforts of two research groups, represented by the organizers, to define, identify, and characterize MIPOs. Specifically, Session 1 will focus on identifying MIPOs, including questioning and critiquing working definitions and preliminary dimensions of MIPOs. Session 2 will explore sub-constructs of MIPOs and the potential of sub-constructs to provide leverage in studying the broader construct. The first two sessions will include examining instances of classroom practice (written/video) that have been identified as containing MIPOs. Session 3 will focus on issues around developing a research agenda for investigating MIPOs and generating plans for continuing work on MIPOs.

History of Working Group

We propose a new working group focused on investigating mathematically important pedagogical opportunities. The two research groups represented by the organizers have been interacting over the past year, including meeting informally at PME-NA 2009, around their overlapping work on defining, identifying, and characterizing mathematically important pedagogical opportunities. The working group will be an opportunity to expand this work to include a broader range of researchers interested in this topic.

Focal Issues

Although skilled teachers and teacher educators often intuitively “know” when mathematically important pedagogical opportunities occur during a lesson and can readily produce ideas about how to capitalize on such opportunities, the literature reveals a construct that is not well-defined. Ideas related to these opportunities are mentioned in many different ways. For example, Jaworski (1994) refers to such opportunities as “critical moments in the classroom when students created a moment of choice or opportunity” (p. 527). Davies and Walker (2005) use the term “significant mathematical instances” (p. 275) and Davis (1997) calls them “potentially powerful learning opportunities” (p. 360). Schoenfeld (2008) refers to such moments as “the fodder for a content-related conversation” (p. 57), as “an issue that the teacher judges to be a candidate for classroom discussion” (p. 65) and as the “grist for later discussion or reflection” (p. 70). Schifter (1996) spoke of “novel student idea[s] that prompt teachers to reflect on and rethink their instruction” (p. 130). In the context of teacher professional development, Remillard and Geist (2002) described openings in the curriculum as moments in which teachers’ questions, observations, or challenges require the facilitator to make a decision about how to incorporate
into the discussion the mathematical or pedagogical issues that are raised. The nature of the facilitator’s decision determines the extent to which the teachers’ ideas advance the learning of the group. Similarly, when a MIPO occurs in a classroom lesson, a teacher first needs to recognize it as such, and then make a decision about how to respond. Depending on the action taken by the teacher, the MIPO may or may not support the development of students’ mathematical understanding.

Thus, there is clear recognition that such opportunities, whatever they are called, are important to mathematics teaching and learning. These opportunities, however, frequently either go unnoticed or are not acted upon by many teachers, particularly novices (Peterson & Leatham, 2010). This raises the question of how teacher educators can help teachers recognize MIPOs during their instruction and use them to support student learning. The purpose of this working group is to engage with the construct of MIPOs in order to consider ways that researchers can identify, explore, and study these opportunities.

In the following, we first give a brief overview of the work around MIPOs done by each of the two research groups. We then provide a description of how we will engage participants with the construct of MIPOs during the three working group sessions, and end by outlining potential follow-up activities.

**A Broad View of Mathematically Important Pedagogical Opportunities**

**Leatham & Peterson**

For us, a MIPO is when students’ observed mathematical thinking provides the teacher with an opportunity to move the class forward in their development of significant mathematics. MIPOs are driven by significant mathematics and observed student thinking. When students articulate mathematical ideas, expert mathematics teachers use their professional knowledge to discern whether there is evidence that students are ready, at that moment, to engage with important underlying mathematics. Many teachers, however, do not recognize MIPOs in their classrooms. From our observations of novice teachers, MIPOs often go unrecognized because of the wide variation of circumstances under which they occur. We describe four types of variation in MIPOs: two related to the nature of mathematics within a MIPO (focus and problematization) and two related to the way in which a MIPO surfaces (visibility and predictability). Our belief is that an awareness of these variations is a first step to helping teachers recognize MIPOs more often in their classrooms.

![Layers of mathematical goals one might consider in recognizing MIPOs](image)

**Figure 1. Layers of mathematical goals one might consider in recognizing MIPOs**

The nature of the mathematics in MIPOs varies in at least two important ways: focus and problematization. First, MIPOs vary in the degree to which they support the mathematics a given lesson or discussion was designed to elicit. Thus, although MIPOs could lead to discussion about the mathematics within the content of the day’s lesson, they could also lead to discussion about mathematics related to broader goals of the unit, course or mathematics as a whole (see Figure 1). To be prepared for such variation in mathematical focus, Leinhardt and Steele (2005) suggested that teachers need “both a primary mathematical agenda… and sensible, valued, predefined classes of situations that suggest deviating from the agenda” (p. 110).

Second we consider variation with respect to problematization. For us MIPOs are always an opportunity to help students to clarify important mathematical ideas. There is variation, however, in the degree to which students initially see the need for this clarification—that is, already see the mathematics of the situation as problematic. On one extreme, students may raise the problematic nature of the mathematics themselves (e.g., “But yesterday you said…”). On the other extreme students may share their thinking, yet not be aware, as far as the teacher has evidence, that there is something problematic or noteworthy in the mathematics at hand. In such situations teachers have the opportunity to help students to problematize the situation.

In addition to variation related to mathematics, the third and fourth dimensions relate to the ways in which teachers observe students’ mathematical thinking in a MIPO: visibility and predictability. The third dimension is the variation in how MIPOs are made visible to teachers. On one extreme, students may simply share their thinking with little teacher elicitation (e.g., student raises their hand and asks a question). On the other hand, the teacher may have observed students’ mathematical thinking as they worked in small groups or individually. In these instances, the teacher may choose to share the thinking (e.g., “I saw several students using this strategy…”) or ask the student to do so. Thus MIPOs initially may become visible to the teacher in the context of whole class, small group, or individual work, and may or may not be made public by the students themselves.

Finally, MIPOs vary in the degree to which they are predictable. For example, teachers often engage students in tasks that are meant to elicit particular mathematical thinking; thus teachers often anticipate certain solution strategies and the mathematics to which those strategies give rise. In addition, over time teachers begin to recognize common student conceptions and misconceptions. Because of this anticipation and knowledge of students’ thinking, opportunities often arise that are predictable. Even when the thinking is predictable, however, the details often are not. For example, we may anticipate that students will respond in certain ways, but just when they do so and how they articulate their thinking are often less predictable. Some MIPOs are even less predictable. There are a multitude of pathways down which students’ thinking can take them, particularly when they are engaged in classrooms that encourage them to try to actively make sense of the mathematics at hand.

In our experience, teachers most easily recognize MIPOs with these characteristics: (1) the mathematical focus aligns well with the day’s lesson, (2) there is evidence that students see the mathematics at hand as problematic, (3) the thinking is made visible in the context of a whole class discussion, or (4) the thinking was anticipated. An understanding of the variations we have just described, however, can help teachers to recognize less obvious variations of MIPOs, particularly when the mathematical focus is beyond the day’s lesson, students do not yet perceive the situation as problematic, the thinking is made visible in small group or individual conversation, or the thinking is unexpected. Although we find these variations useful, they do not help one to identify when occurrences of student mathematics thinking are MIPOs. To aid in
their identification, we are in the process of describing common types of MIPOs. Two common types are (1) incorrect or incomplete responses and (2) multiple responses or solutions. First, incorrect responses are often MIPOs because giving students opportunities to discuss the thinking behind their responses leads to important mathematics related both to why the response was incorrect as well as the mathematics underlying a correct response. Similarly, vague or incomplete thinking is also a potential MIPO. Encouraging students to elaborate and clarify often reveals confusion and questions related to important underlying mathematical ideas.

Another common type of MIPO occurs when there exist multiple student responses or solutions to a given question. These situations give rise to MIPOs for a couple of reasons: (1) the solutions are inconsistent or (2) there are commonalities between different methods. When solutions are inconsistent by one being correct and the other incorrect, students can evaluate the thinking that supports these solutions to identify the critical elements of the underlying concepts. If two correct solutions have relied on different methods, a comparison of these methods can highlight the underlying mathematics that is common to both. An awareness of these common types of MIPOs can help teachers learn how to identify them. We expect there are other common types worth exploring.

**Pivotal Teaching Moments as a Sub-construct of MIPOs**

Stockero & Van Zoest

We have narrowed our work on MIPOs to focus on a sub-construct that we call *pivotal teaching moments* (PTM). We define a PTM as an instance in a classroom lesson in which an interruption in the flow of the lesson provides the teacher an opportunity to modify instruction in order to extend, or change the nature of, students’ mathematical understanding. We ground our work in classroom observations of beginning teachers’ practice based on the hypothesis that the decision-making process involved with PTMs may be more obvious with this group than with skilled teachers. That is, skilled teachers may recognize a PTM and make the decision to act so quickly and smoothly that it wouldn’t be clear that they had modified their instruction.

We believe that an important first step in capitalizing on PTMs is recognizing that such moments exist. Without this awareness, teachers may experience inattentional blindness (Simons, 2000)—a phenomenon described in the psychology literature as a failure to focus attention on unexpected events. This is also related to the idea of framing (Levin, Hammer & Coffey, 2009)—the way in which a teacher makes sense of a classroom situation. From this perspective, whether a teacher notices the value in an unexpected event depends on how he or she frames what is taking place during instruction. If, for example, a teacher views a student error as something that needs to be corrected, he or she is unlikely to consider the mathematical thinking behind the error or whether the error could be used to highlight a specific mathematical idea. On the other hand, a teacher who views an error as a site for learning is more likely to consider both the mathematics underlying the error and how it could be used to develop mathematical understanding. Thus, we began our research by investigating the circumstances in which PTMs seem likely to occur.

In general, PTMs seem most likely to occur when students are actively engaged in and contributing to the mathematics lesson in some way—either by the design of the lesson or by their own initiative. In our work to date, we have identified five circumstances that are fertile grounds for PTMs. These are circumstances in which: (1) student comments or questions go beyond the mathematics that the teacher had planned to discuss; (2) students are trying to make sense of the mathematics in the lesson; (3) incorrect mathematical thinking or an incorrect

---

solution is made public; (4) a mathematical contradiction occurs; and (5) confusion is expressed about specific mathematical ideas.

Drawing on Stein, Smith, Henningsen, and Silver’s (2000) work on cognitive demand of tasks, we have conceptualized PTMs as triples that include the PTM, the teacher decision and the likely impact on student learning. We further characterize the first component of the triple, the PTM, by the circumstance that led to it and the potential of the moment to improve students’ opportunities to learn mathematics. The second component, teacher decision, is characterized by the action the teacher takes and how effectively they implement that action. Teacher actions that we have identified include: (1) ignoring or dismissing the interruption; (2) incorporating the interruption into the plan; (3) pursuing student thinking; (4) emphasizing the meaning of the mathematics; and (5) extending the mathematics or making connections to other topics. The final component of the triple, likely impact on student learning, is identified as negative impact, neutral impact, or low, medium, or high positive impact.

This PTM work provides an instance of studying a sub-construct of MIPOs that can be used to inform the working group’s thinking about developing frameworks and methodologies for studying the broader MIPO construct.

**Plan for Working Group**

**Session 1: Identifying mathematically important pedagogical opportunities**

Session 1 will begin with introductions of the working group organizers and participants to gain a sense of participants’ contexts and the reasons they are interested in working on or thinking about the MIPO construct. In order to allow participants to more easily become engaged in discussions about MIPOs, particularly those for whom the idea is new, a short presentation will be given by the organizers related to defining, characterizing, and identifying MIPOs. This will be followed by small and large group discussions that will provide participants an opportunity to question and critique the ideas that have been presented. The group discussions will center on questions and ideas about MIPOs with which the organizers have been wrestling, including:

- How does one know “mathematically important” when one sees it?
- To what extent does the working definition capture the idea of a MIPO? What is not being captured by this definition?
- Do the dimensions described in the presentation help one think about MIPOs? Are there other dimensions that should be considered? What is the relative importance of these dimensions?
- Can MIPOs be both planned and unplanned?

Classroom video or written clip(s) that have been identified as containing MIPOs will then be shared both as a means of further engaging participants with the idea of a MIPO and of introducing the types of activities in which participants will engage in Session 2. Session 1 will conclude with a short discussion related to issues that will be discussed further in Sessions 2 and 3, including how the MIPO construct might be narrowed in order to gain some traction in understanding the construct and issues of practicality and interest. In particular, Sessions 2 and 3 will be responsive to the interests of participants through the selection of the instances of classroom practice and the implementation issues on which we will focus.

The goals of Session 1 are to:

- Develop an understanding of participants’ contexts and interests in MIPOs in order to structure the working group sessions in a way that is responsive to the participants.
• Engage participants in thinking about the idea of a MIPO by presenting an example of how they have been defined, characterized, and identified.
• Begin to refine definitions and ideas related to MIPOs through small and whole group discussions.

Session 2: Exploring mathematically important pedagogical opportunities

To stimulate a conversation about the possibility of sub-constructs that could be used to gain leverage in making sense of the broader MIPO construct, Session 2 will begin by introducing pivotal teaching moments (PTMs) as an example of a sub-construct. The PTM work was chosen because it provides an example of how narrowing the scope of the MIPOs can lead to the development of frameworks and methodologies that may be applicable to studying the broader MIPO construct.

After giving a brief overview of work on PTMs, we will engage working group members in examining instances of practice (written/video) that have been identified as containing MIPOs. This will provide an opportunity to begin to test out and refine existing definitions and frameworks related to both PTMs and the broader MIPO construct, as well as raise additional issues about MIPOs.

The goals of Session 2 are to:
• Test out and refine existing MIPO definitions and frameworks.
• Consider sub-constructs of MIPOs that might provide leverage in studying the broader construct.

Session 3: Setting a research agenda for investigating mathematically important pedagogical opportunities

Session 3 will focus on issues around developing a research agenda for investigating MIPOs. We will begin by considering what the field needs to know about MIPOs in order to use the construct to improve the practice of both mathematics teacher educators and classroom teachers. For example, what knowledge or dispositions might teachers need to capitalize on MIPOs? Specifically, we will discuss:
• What questions need to be addressed?
• What methodologies might be appropriate?
• What contexts should be considered?

Based on these discussions, small groups will be formed around the working group participants’ expressed interests. Collaborative endeavors will be encouraged and venues for continuing MIPO work will be discussed.

The goals of Session 3 are to:
• Outline a research agenda for studying MIPOs.
• Generate plans for continuing MIPO work.

Anticipated Follow-up Activities

The work of the group will be continued by the core research teams through ongoing collaboration. If there is sufficient interest among working group participants, the organizers will facilitate broader research collaborations and additional working group sessions through venues such as PME-NA conferences, AMTE pre-sessions, and web-conferencing.

MODELS & MODELING WORKING GROUP

Subgroup Leaders: Dick Lesh (Indiana), Tamara Moore (Minnesota), Helen Doerr (Syracuse), Miriam Amit (Israel), Lyn English (Australia), and Bharath Sriraman (Montana).

The Models & Modeling Working Group has been one of PMENA’s most active working groups – beginning with the very first PMEMA that Dick Lesh held at Northwestern University. And, it has a long history of encouraging collaborations among group members – and of including junior colleagues in a variety of research and development activities. Consequently, since the founding of PMENA, models & modeling perspectives (MMP) have provides a useful framework a large number of books, journal publications, funded projects, and conference presentations that featured collaborations among multiple working group members.

For the 2010 meeting of PMENA, the MMP working group will focus on four topic areas:

(a) modeling activities for primary grade children,
(b) modeling activities focusing on integrated approaches to algebra, calculus, statistics, probability, and geometry,
(c) modeling-based activities for teacher development,
(d) modeling-focused design research methodologies. …

Newcomers are very welcome. Please bring 1-2 page handouts for any projects you would like to discuss.

This working group continues its focus on preservice elementary teachers’ content knowledge in mathematics for teaching. Participants continue the discussion of (a) a synthesis of the current research on the knowledge on preservice teacher content knowledge, (b) pedagogical principles they developed for working with preservice teachers, and (c) ways to support the development of such knowledge, for example how video and other artifacts of children’s mathematical thinking can be used to address PSTs specialized content knowledge for teaching. Dialogues (on- and off line), resource sharing, as well as collaboration among members of the study group will be continued, encouraged, and facilitated during and after the conference.

Foci and Aims of the Working Group

The goal of this working group is to examine the various types of knowledge needed for teachers of mathematics focusing in particular on describing specialized content knowledge for teaching (Hill, Ball, & Schilling, 2008) and the development thereof. Building on previous work by this group at various meetings (for example: PME-NA 2007, PMENA 2009, AMTE 2008, AMTE 2009, AMTE 2010) we will continue discussions to gain a better understanding of what preservice elementary school teachers should know and how they come to know in order to become effective teachers and to explore how mathematics educators can assist preservice and in-service elementary school teachers in developing such knowledge. In particular we will continue our discussions on (a) the synthesis of the research on preservice elementary teachers’ content knowledge, (b) a common pedagogy developed by this group, c) ways to help PSTs develop more sophisticated conceptions, for example, using artifacts of children’s mathematical thinking, and (d) possible collaborations. Below we outline what we have accomplished thus far and what we intend to accomplish at PME-NA 2010.

Synthesizing the Research on Preservice Elementary Teachers’ Content Knowledge and Identifying Areas of Further Study.

This working group has begun to synthesize the research on PSTs’ content knowledge and to identify areas of further study. Various members of the group took the lead to examine the current state of knowledge in a particular content area. The content areas examined by this group (with a select number of citations) are: Whole Numbers and Place Value (Southwell & Penglase, 2005; Thanheiser, 2009a, in preparation-b), Decimals (Putt, 1995; Stacey, et al., 2001; Zazkis & Khoury, 1993), Fractions (Deborah Lowenberg Ball, 1990; Graeber, 1989; Newton, 2008), Algebra (Deborah Loewenberg Ball, 1990; Bednarz, Kieran, Lee, & International research, 1996; Doerr, 2004), Geometry & Measurement (Fujita & Jones, 2006; Jones, Mooney, & Harries, 2002; Olkun & Toluk, 2004), Statistics (Groth, 2007; Groth & Bergner, 2006; Leavy & O’Loughlin, 2006), and Probability (Canada, 2006).

We are working on synthesizing the research findings relative to PSTs content knowledge in each of these areas and plan to create a combined synthesis across all content areas. A rough draft of the synthesis is expected to be finished by October 2010. Working group participants are encouraged to contact the first author to receive a copy of the current document prior to the conference.

The synthesis of the current research is essential for us to know for the following reasons:

1. We need to understand the conceptions with which the PSTs enter our classrooms so we can build on those conceptions (Bransford, Brown, & Cocking, 1999). To help teachers develop the content knowledge needed to teach mathematics, educators need to understand the PSTs’ currently held conceptions. As the authors of The Mathematical Education of Teachers suggest, “The key to turning even poorly prepared prospective elementary teachers into mathematical thinkers is to work from what they do know” (CMBS, 2001, p. 17).
2. To identify research needs we need to know what has been established in terms of PSTs’ content knowledge and how that knowledge has been developed and what we still do not know or understand.

Mathematics teacher educators need more empirical evidence of what learning opportunities contribute most to more knowledgeable and confident teachers in order to make more informed changes to their programs (Mewborn, 2000). Once the synthesis paper is completed we envision this to be a starting point to conduct further research on PSTs’ content knowledge and the development of that knowledge. In addition we will examine similarities and differences in PSTs’ content knowledge and the development thereof across the various content areas.

Further developing a common pedagogy developed by this group.

Our pedagogy is based on the framework for mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008; Hill, et al., 2008; Hill, Rowan, & Ball, 2005). Hill, Ball, & Shilling (2008) introduced a framework for distinguishing between different types of knowledge included in the construct of mathematical knowledge for teaching. This framework distinguishes between subject matter knowledge and pedagogical content knowledge. Subject matter knowledge is subdivided into common content knowledge, specialized content knowledge, and knowledge on the mathematical horizon. Pedagogical content knowledge is subdivided into knowledge of content and students, knowledge of content and teaching and knowledge of curricula. Hill,
Rowan & Ball (2005) provide empirical support linking teachers’ mathematical knowledge for teaching to student achievement gains.

The authors of this working group find the mathematical knowledge for teaching framework to be useful when discussing different types of knowledge they want their preservice teachers to develop. However, much work remains in determining what kinds of learning opportunities effectively help preservice teachers to develop such knowledge. Therefore our attention is focused on the question of how we can use our current understanding of mathematical knowledge for teaching as a framework to address content preparation of PSTs’ content knowledge in content and method courses.

Through examination of their collective work, several participants of this working group found they shared a common framework of design principles:

1. Mathematical ideas are built on preservice teachers’ currently held conceptions.
2. Classes for preservice teachers should model teaching for understanding (i.e. we teach our PST the same way we want them to teach their children)
3. We focus on developing connections between content knowledge and:
   • Knowledge of teaching;
   • Knowledge of children’s mathematics;
   • Knowledge of curriculum.

Further collaborative work will allow the group to continue to refine this framework and build on it.

**Ways to support the development of specialized content knowledge**

Building on the pedagogy developed by this group we consider the uses of artifacts of children’s mathematical thinking as a concrete example of ways to address the PSTs’ specialized content knowledge. This group has begun to examine this question and our plan is to continue to do so at this working group session. Using the pedagogy outlined above we developed a framework for various uses of artifacts of children’s mathematical thinking (see Figure 1). We will address all three elements of the pedagogy but our focus for this working group lies on the first element, being informed by the other two.

**Example: Use of a sequence of two artifacts of children’s mathematical thinking**

For example, to address the PSTs’ currently held conceptions, artifacts are carefully chosen to match/question PSTs’ currently held conceptions. In the context of multidigit whole numbers, for example, we know that many PSTs think of the digits in a whole number in terms of ones, rather than in terms of their values (Thanheiser, 2009b, in preparation-b). These PSTs may think of the regrouped digits in the context of subtraction (see Figure 2) in terms of ones rather than their values. One PST, for example, explained “You put a 1 over next to the number and that gives you ten … I don’t get how the 1 can become a 10. One and 10 are two different numbers. How can you subtract 1 from here and then add 10 over here? Where did the other 9 come from?”

To address the question of how children think about algorithms, research has shown that children, if allowed, will invent their own algorithms (which make sense to them). This strengthens their place value understanding in terms of connecting digits to their values and relating between place values (Ambrose, 1998; Hiebert & Wearne, 1996; Constance Kamii, 1994; Constance; Kamii, Lewis, & Livingston, 1993; Sowder & Schappelle, 1994). However, children
who are not developing their own algorithms often view digits in terms of ones rather than their values (just as the PSTs). Based on this information we can now choose artifacts of children’s mathematical thinking which will: (a) address the PSTs’ incorrect interpretation of the regrouped digit as 1, (b) build on that incorrect interpretation to develop a more meaningful interpretation, (c) model how we integrate such thinking into our classroom, (d) connect to knowledge of content and children (how do children think about this?), (e) connect to knowledge of content and teaching (address the teaching of this topic), and (f) connect to knowledge of content and curriculum (address curricular issues of this topic). One such artifact is a video clip of a 2nd grader adding 274+368 (San Diego State Foundation, Philipp, & Cabral). This child initially adds 200+300 =500, then 70+60=130 and then 4+8=12. He then adds those partial sums together to get his answer (see Figure 2).

### PEDAGOGY

1. Mathematical ideas are built on preservice teachers’ currently held conceptions.

2. Classes for preservice teachers should model teaching for understanding (i.e. we teach our PST the same way we want them to teach their children)

3. We focus on developing connections between content knowledge and:
   - Knowledge of teaching;
   - Knowledge of children’s mathematics;
   - Knowledge of curriculum

### USING ARTIFACTS

Use of artifacts of children’s mathematical thinking to address and build on PSTs’ currently held conceptions.

Use of artifacts of children’s mathematical thinking allows us to ‘model’ how such thinking could be addressed in a classroom setting. It also allows us to ‘model’ how thinking could be addressed at all levels.

Using artifacts of children’s thinking allows us to draw connections to other areas.

---

**Figure 1. Using artifacts of children’s mathematical thinking within our pedagogy**

**Figure 2. One PSTs’ application of the standard algorithm for regrouping in 527-135**

**Figure 3. 2nd grader’s strategy to add 274 + 368 (San Diego State Foundation, et al.)**

---

PSTs’ reactions to this video clip vary widely and thus offer a good starting point for discussion. Sample PSTs responses to this video are:

- “[the child] thinks too quickly without understanding the rules of place value.”
- “It seems as though [the child] is thinking in a manner that helps him add large numbers in an easier way than having to carry numbers over. His thought process was a little confusing at first, but once I caught on to what he was doing I realized that it was a very smart way to go about adding such large numbers at a young age. He was thinking in a mathematically developed manner which actually made quite a lot of sense”
- “He added the hundreds and then added the tens and then added the ones. To find the final answer, he added all three numbers together.”

At the beginning of a discussion of an artifact like this not all PSTs are in a position to understand the child’s thinking. PSTs who think of the digits in terms of ones may not consider breaking a number like 274 up into 200 and 70 and 4. Reacting to a child doing this requires the PSTs to decide whether it makes sense and if it does why it works. Using this particular artifact could raise the issue of values of digits in a classroom. In addition it could be used to examine regrouping. How is it that the child adds 70 + 60, what exactly happens in his process? While this strategy may seem obvious to the reader it is not to all PSTs. When PSTs were asked how this child might add 389 + 475 (using the same strategy), only 12 of 22 PSTs (Thanheiser, in preparation-a) were able to do so. Thus, this artifact could be used to address the three aspects of the pedagogy outlined above (see Figure 4).

**Figure 4. Relation of a partial sums artifact to pedagogy**
A second video clip of children’s mathematical thinking is used in combination with the one described above. While the previous one is an alternate correct strategy that raises several mathematical issues, some of these issues may still be dismissed by the PSTs as different from their own. Some PSTs may not be ready to listen to alternate viable strategies until they see a limitation of their own (Thanheiser, 2009c). An artifact of children’s mathematical thinking addressing this limitation shows a child who has successfully used the strategy described above with 2-digit numbers but struggles with 3-digit numbers. She solves the problem by adding single digits (see Figure 5).

The goals of this video clip are to address the insufficiency of a conception of seeing all digits in terms of ones and emphasizing the need to relate digits to their values. It also emphasizes the need for making sense of alternate strategies. The coupling of a correct and an incorrect solution allows PSTs to examine alternate correct mathematical thinking and examine why it makes sense and address their own conceptions and issues with those they may not have been aware of.

![Figure 5. One student’s correct solution to 38+45 and incorrect solution to 638 + 456](San Diego State Foundation, et al.)

**Collaboration**

This group began its collaborations in 2007. A small subgroup of the current group began to meet at PME-NA, NCTM and AMTE meetings on a regular basis since then and has presented at several of those meetings (NCTM, 2007, PME-NA 2009, AMTE 2009, AMTE 2010). Our research is similar in its focus pertaining to preservice elementary teachers’ content knowledge but varies in specific content, use of prior work (conceptual analysis of content, prior work with children, prior work with adults), and theoretical framework.

At PME-NA 2007 we agreed on the need for the construction of a research base for the study of preservice teacher content knowledge. This includes a need to synthesize and summarize existing (completed and current) research and develop a research agenda. At PME-NA 2009 we began this work by dividing content areas between organizers and synthesizing the existing literature. At AMTE 2010, we met to refine the guidelines for creating these individual syntheses and at PME-NA 2010 we plan to refine a rough draft of the combined syntheses (we encourage interested participants to contact the first author for a copy of this draft before the conference). The aims of this working group are to continue established collaborations (synthesis paper, developing our pedagogy, addressing the pedagogical issues with artifacts of children’s mathematical thinking), develop new collaborations, and support each other in our work.

**Outline of Working Group Sessions**

In our first session, we will start with a brief introduction and overview of the working group. This will be followed by a brief summary of the last working groups (PME-NA 2007, 2009) and other activities since (working groups at AMTE 2008, 2009, 2010; symposium at NCTM 2007).

---

We will then share the current version of the individual sections of the synthesis paper. Using a common framework each content area leader will present a 5-10 min presentation on what the findings are in their area.

After individual presentations we will discuss commonalities and differences among the various content areas and discuss the synthesis paper as a whole (drafts will be available to participants).

In our second session, we will address the use of children’s mathematical thinking artifacts to address/develop PSTs specialized content knowledge. We will pay particular attention to the constructs of noticing and authentic listening. Noticing requires PSTs to (a) attend to the child’s strategy, (b) interpret the child’s mathematical understanding, and (c) deciding how to respond on the basis of the child’s understanding (Jacobs, Clement, & Philipp, 2010). Authentic listening requires support of the talker through the listener’s attention (Weissglass, 1990) and a change in the views of both the talker and the listener as a result of the interaction (D'Ambrosio, 2004; Davis, 1997). Tyminski, Kastberg, Richardson, & Winarski (2010) have noted phases of listening within the development of authentic listening: readiness, hearing, understanding, and connecting. PSTs need to be able to develop authentic listening skills as well as ask questions of children that elicit their mathematical talk for listening.

Questions we will consider: Are noticing and listening skills necessary components of PSTs specialized content knowledge? What protocols can be developed to help PSTs develop such skills?

In our third session we will synthesize the current status of the working group and discuss modes of communication to sustain collaboration to investigate the research questions emerged from the first and the second sections throughout the year. A calendar of discussion chats will be established and published through an online forum.

Follow-Up Activities

Participants will establish an on-line forum for open discussion of topics of interest. In addition monthly online chat meetings will be established. Possible collaborations may include joint research projects, mini-conferences, and a book proposal to the Mathematics Teacher Education series at Springer, and the publication of joint research articles.

The Lesson Study Working Group met four previous times: Merida, Mexico (2006), Lake Tahoe (2007) and Morelia, Mexico, (2008) and Atlanta (2009). The outcome of the work of over 30 researchers at these meetings is a book under contract with Springer Publishers. At this the final meeting of the working group, chapter authors will share their research and practice as documented in the chapters of the book. Following is a summary of the work that will be discussed. Newcomers are welcome to one or all of the working group sessions. This will be followed by a discussion of future directions for research on lesson study.

Lesson Study Overview

Structures, History, and Variation

Lesson study incorporates characteristics of effective professional development programs identified in prior research: it is site-based, practice-oriented, focused on student learning, collaboration-based, and research-oriented (Bell and Gilbert, 2004; Borko, 2004; Cochran-Smith and Lytle, 1999, 2001; Darling-Hammond, 1994; Wang and O’Dell, 2002; Little, 2001; Hawley and Valli, 1999; Wilson and Berne, 1999). What separates lesson study from other instructional improvement approaches is that it places teachers at the center of the professional activity, with their interests and desire to better understand student learning based on their own teaching experiences. The idea is simple: teachers organically come together with a shared question regarding their students’ learning, plan a lesson to make student learning visible, and examine and discuss what they observe. Through multiple iterations of the process, teachers have many opportunities to discuss student learning and how their teaching affects it.

After identifying a lesson goal, teachers plan a lesson. The goals can be general at first (e.g., how students understand equivalent fractions), and are increasingly refined and focused throughout the lesson study process to become specific research questions at the end (e.g., strategies students use to compare 2/4 and 3/6). Teachers choose and/or design a teaching approach to make student learning visible, keeping their lesson goal in mind. The main purpose of this step is not to plan a perfect lesson but to test a teaching approach (or investigate a question about teaching) in a live context to study how students learn. As they plan, they anticipate students’ possible responses and craft the details of the lesson. Teachers come to know the key aspects of the lesson, to anticipate how students may respond to these aspects, and to explore different thinking and reasoning that may lie behind the possible responses. During planning, teachers also have an opportunity to study curricular materials, which can help teachers’ content knowledge development. During the lesson, teachers attend to student thinking and take notes on different student approaches. During the debriefing after the lesson, teachers discuss the data they have collected during the observation.

There are other professional development programs that incorporate many of the characteristics of lesson study (e.g., action research, teacher research). However, what sets lesson study apart is the live research lesson. The live research lesson creates a unique learning opportunity for teachers. Shared classroom experiences expose teachers’ professional
knowledge that may otherwise not be shared: teachers notice certain aspects of teaching and learning, and this implicit and organic noticing does not happen in artificially replicated professional development settings.

In Japan, lesson study has been widely used for over a century. Many Japanese educators attribute success in changing their teaching practice to participation in lesson study (Lewis, Perry, and Murata, 2006; Murata and Takahashi, 2002; Shimizu, et. al., 2005). As a foundational mechanism to support the improvement of teaching, lesson study is used to examine and better understand new educational approaches, curricular content, and instructional sequences introduced in Japan. In many cases, teachers play the central role in making new approaches adoptable and content accessible. Lesson study makes teaching approaches more practical and understandable to teachers through developing deeper understanding of content and student thinking. In this manner, lesson study works effectively to connect theory and practice.

While lesson study is known in the United States (and other parts of the world) as a small, school-based collaboration, typically in the subject area of mathematics, lesson study comes in many different shapes and sizes in Japan. There is small and school-based lesson study as well as large-scale, national-level lesson study (Murata and Takahashi, 2002; Lewis and Tsuchida, 1998; Shimizu, et. al., 2005). Different formats for lesson study meet different needs and interests of the teachers. A typical Japanese teacher has multiple opportunities to participate in lesson study throughout his/her professional career.

Introducing Lesson Study to the World

Lesson study came to attract the attention of an international audience in the past decade, and in 2002 it was one of the foci for the Ninth Conference of the International Congress on Mathematics Education (ICME). It subsequently spread to many other countries and more than a dozen international conferences and workshops were held around the world in which people shared their experiences and progress with lesson study as they adopted this new form of professional development in their unique cultural contexts (e.g., Conference on Learning Study, 2006; Fujita, et. al., 2004; Lo, 2003; National College for Educational Leadership, 2004; Shimizu, et. al., 2005).

Issues of fidelity of implementation

There are several issues and concerns around implementing lesson study in diverse settings. For example, there are unique issues of implementation with preservice or inservice teachers. Other issues include: content knowledge competency, variations in curricula, time and availability to meet, administrative support and cultural differences. As a result of these difficulties in maintaining fidelity of implementation with the Japanese model, lesson study is being adapted to meet unique needs in a variety of settings.

The limited depth of mathematical knowledge of some teacher groups attempting to implement lesson study, particularly at the elementary-level, has raised the question of whether lesson study work can be completely teacher-driven. Related to this issue is the role the outside coach or expert should or could play in such a lesson study community. A second issue is implementation within existing, traditional and/or rigidly structured curricula. Unlike the Japanese mathematics curriculum which provides a loosely defined framework for teachers to build off of, many curricula used in other countries are quite structured or scripted and not conducive to the planning cycles used in lesson study. A third issue is a lack of administrative support necessary to alter existing curricula, provide financial support, and schedule

---

opportunities to meet and plan. The daily schedule of most elementary teachers prevents regular meetings and opportunities to collaborate. A related issue is the limited extrinsic reward available. Lesson study presupposes blocks of time for teachers to work together. This frequently must be outside school hours and districts are often constrained by contracts that demand stipends and/or release time. Finally there may be fundamental differences in the cultures of teachers from different communities and countries. It was suggested that the fiercely independent nature of some cultures may limit success in building collaborative groups.

Lesson Study: Research and Practice

The body of knowledge about lesson study is growing, but remains somewhat elusive and composed of discrete research endeavors. While the literature suggests that lesson study can facilitate greater reflection and more focused conversations about teaching and learning than are often realized with other types of professional development (Lewis, 2002), as well as specific and authentic conversations about management, student learning, and impact of significant and subtle changes in lesson design (Marble, 2006), there is still much to be learned. Following are summaries of the work that will be shared.

Inservice Teachers

Three reports will be given within the group looking at lesson study with Inservice Elementary Teachers. Rachelle Meyer and Trena Wilkerson (Baylor University, US) conducted a multiple case study which examined the effects lesson study had on middle school mathematics teachers’ content knowledge. Participants for this study consisted of 26 middle school mathematics teachers, from a large urban school district, who formed eight lesson study groups. The researchers sought to examine the experiences and impact lesson study had on the participating teachers’ content knowledge in mathematics from the eight case studies. More specifically, the researchers focused on (1) the need for teachers’ content understanding while planning the research lesson and (2) the participating teachers’ growth in content knowledge. This qualitative research used seven measures to gather data which consisted of the following: two baseline surveys; transcripts from planning and reflection sessions; observation notes; lesson plans; and a reflective questionnaire. Analysis of the data consisted of both a within and across case comparison. For the within case analysis, each case was first treated as a comprehensive case in and of itself. Once the analysis of each case was completed, a cross-case analysis began in order to develop more sophisticated descriptions and more powerful explanations. Data revealed lesson study did improve teachers’ content knowledge for three of eight case studies as a result of teacher collaboration.

Lynn C. Hart (Georgia State University, US) and Jane Carriere (City Schools of Decatur, US) describe implementation of a lesson study project with third grade teachers in a small school district to study the development of the critical lenses (habits of mind) necessary for meaningful lesson study work. Adapting the lesson study process to meet school system needs, two outside facilitators stimulated development of the critical lenses through mathematics explorations and probing/what if questioning. Using a qualitative methodology and the group as the unit of analysis, data were coded for evidence of and change in the lenses. After one year, the 8 participating teachers showed a qualitative difference in two of the three lenses: the student lens and the curriculum developer lens. No change was seen in the researcher lens.

Jo Clay Olson (Washington State University, US), Paul White (Australian Catholic University), and Len Sparrow (Curtin University, Australia) suggest that while lesson study is an...
effective model for teacher professional development and growth in Japan, there is less evidence that such a model is viable in international settings. This chapter reports on the experiences of five elementary teachers with a lesson study approach to professional development over a year. Two groups were formed, but the results of their experiences were different. One group accepted the challenges highlighted by the lesson study process. They reflected on and changed their classroom practice in fundamental ways. The other team rejected the challenges and maintained their traditional pedagogy. System-wide requirements, for example state testing, constrained the development of one team while the ability to personalize insights from the lesson study process and critical reflection became a catalyst to personal professional growth for the other.

Diane Tepylo and Joan Moss (University of Toronto) examine the Mathematical Knowledge for Teaching (MKT) of four grades 5 and 6 teachers in a small-town elementary school as they participated in three cycles of lesson study on teaching fractions. The school, in a rural school board, is a dual-track school (English and French Immersion) resulting in classes in the English stream with 25-48% of students working on Individualized Educational Plans as compared to the 18% provincial average. The four teachers, Jeri, Brenda, Leslie and Francis, ranged in age from 23 to 49 with three months to eight years of teaching experience. Before this study, the teachers had little exposure to mathematics professional development and none had any experience with lesson study.

Preservice Teachers: The next section present work with preservice teachers. Maria Lorelei Fernandez (Florida International University, US) and Joseph Zilliox (University of Hawai‘I, US) present the work of two mathematics educators, each using a lesson study approach with prospective teachers of mathematics. One educator worked with prospective secondary teachers in a Microteaching Lesson Study context and the other worked with prospective elementary teachers during initial field experiences in K-6 schools. The lesson study experiences in both contexts incorporated important features of Japanese lesson study including operationalizing an overarching learning goal driving recursive cycles of collaborative planning, lesson observation by colleagues and other knowledgeable advisors, analytic reflection, and ongoing revision. The prospective teachers exposed their knowledge, beliefs and practices to the scrutiny of peers and other experts, developing and reconsidering their thinking and practices through collaboration on shared teaching experiences. Similarities and differences in the secondary and elementary prospective teachers’ experiences and learning in relation to elements comprising the lesson study approaches are discussed. Similarities included trajectories of their lesson plans toward more student-centered teaching, importance of negotiation for their learning, and value of the cooperative nature of the experiences for sharing varying ideas and perspectives. Differences included development of mathematics knowledge, extent of focus on classroom processes and management, use of videotaped lessons, conduct of oral reports of their group lesson study, and participation of knowledgeable advisors.

Aki Murata and Bindu Pothen (Stanford University, US) outline how lesson study is used in preservice elementary mathematics methods courses to support preservice teachers’ connections between their emerging practice and understanding. The course structure is described, and week-by-week course activities and assignments are summarized. Lesson study in preservice teacher education program has a potential to support on-going teacher learning by connecting the course experiences with field-based assignments. By continuously focusing on student learning of mathematics, research lesson teaching ties together the various experiences in the course to help preservice teachers develop new understanding of their practice. Pedagogical content
knowledge is meaningfully developed in the collaborative learning settings. Short summary of research findings on teacher learning is presented based on quantitative and qualitative data.

Paul W. Yu (Grand Valley State University, US) presents a theoretical framework based on a review of the literature across two different areas of research in the mathematics education of pre-service teachers: field based experiences (Zeichner, 1981) and Japanese lesson study (Stigler and Hiebert, 1999; Takahashi and Yoshida, 2004). Zeichner (1981) discusses two contrasting issues related to pre-service teachers’ field based experiences. First, these field-based experiences are perceived to be a necessary component for teacher preparation. In contrast, some scholars question the significance of the experience other than an enculturation into the existing socio-cultural norms of the teaching profession. An emerging framework for in-service teacher improvement is lesson study. The chapter reflects on the use of lesson study as a framework for pre-service teachers’ field-based experiences that takes place early in their collegiate coursework. The goal was to use lesson study to give students a different model for professional development, that is (1) collaborative, (2) focused on children’s understanding of mathematics, and (3) exposes the pre-service teachers to the nature of mathematics instruction. The chapter describes how lesson study was modified to accommodate the difference between pre-service and in-service teachers’ experiences, and reflects on the enactment of these modifications in the collegiate course.

Beyond K-12: The third group looks at lesson study in university settings. Alice Alston, Lou Pedrick, Kim Morris, and Roya Bassu, (Robert B. Davis Institute for Learning in the Graduate School of Education, Rutgers University, US) were engaged with teachers and administrators of partnering districts in implementing school-based professional development using a modified form of lesson study as part of a graduate course. During a semester a group of ten teachers resourced by two university researchers worked together to develop a series of mathematical tasks intended to embody concepts that are basic to their district’s curriculum and address specific mathematical goals that they had identified as important for their students. The series of tasks were implemented in six classes including grades 5 through 8 that were taught by members of the group during several weeks at the end of the term. The teacher-researchers, studying the videotapes, observer notes and student work from their session, select, transcribe and analyze critical events from each class that provide evocative examples of the mathematical strategies and representations of their students, These analyses are shared in follow-up discussions and compiled to produce an overall analysis of the development of the mathematical ideas as evidenced in the mathematical activity of the students across the four grades involved in the lesson study project. The research of the university educators is based on data that includes notes from the earlier sessions when goals were set and the tasks developed as well as the videotapes of the implementations, debriefing discussions, and the subsequent analyses and group discussions of the teachers. This analysis focuses on the teachers’ reflections and actions for evidence of a shift from surface characteristics of the classroom activity toward a closer attention to students’ thinking and subsequent implications for instruction.

Andrea Knapp (University of Georgia, US), Megan Bomer (Illinois Central College, US), and Cynthia Moore (Illinois State University, US) focus on the professional development of two Coaches (graduate students) of mathematics teachers and one classroom Teacher as they engaged in the lesson study process. The Coaches progressively designed, taught, and refined standards-based lessons which they co-taught with the classroom Teacher. Participants developed three aspects of mathematical knowledge for teaching (MKT): knowledge of content and teaching (KCT), knowledge of content and students (KCS), and specialized content knowledge (SCK).
Chapter 19: Working Group Paper  Volume VI, Page 1628

(Ball, 2005). KCT developed as the Coaches and Teacher collaborated during lesson study to place a stronger emphasis on inquiry in lessons. In particular, Coaches investigated reform curricula and research which enhanced the Teacher’s KCT. In addition, the group developed KCS as they listened to students and observed them on videotape. Furthermore, Coaches developed KCS from the Teacher as the Teacher shared with Coaches his knowledge of student difficulties. Finally, the Coaches and Teacher developed SCK by considering mathematical perturbations from the lesson with the Teacher. Thus, lesson study mutually enhanced the teaching abilities of both Coaches and the Teacher whom they supported.

The next chapter describes how Michael Kamen and Stephen Marble (Southwestern University, Georgetown, Texas) became interested in how to adapt lesson study to the university level. A pilot project with colleagues from Southwestern University was implemented that used a collaborative professional development model based on lesson study for structuring peer visitation. The project culminated in the facilitation of lesson study, with four research teams consisting of professors from five academic departments. The second and third projects involved two lesson study teams with instructors from other universities (Debra L. Junk, Texas Regional Collaboratives at The University of Texas-Austin; Sandi Cooper, Baylor University; Colleen Eddy, University of North Texas; Trena Wilkerson, Baylor University and Cami Sawyer, Awatapu College, Palmerston North, New Zealand). One of the teams developed a research lesson on teaching preservice teachers about assessment issues during hands-on science instruction, and the other was a research lesson designed to help preservice elementary teachers understand the importance of supporting children’s learning with invented mathematics problem-solving strategies. In this chapter the authors focus on the last of these three projects, an elementary mathematics methods research lesson.

The Importance of the Task within the Curriculum

Part Four of the book looks at the importance of the task in lesson study. Brian Doig and Susie Groves (Deakin University, Australia) and Toshiakira Fujii, (Tokyo Gakugei University, Japan) present an argument for focusing lesson study approaches to teacher professional development firmly on the type and rôle of the mathematical task (hatsumon) used in the mathematics classroom. Drawing on research conducted in Australia and Japan, the authors argue that not all elements of lesson study, or particularly the research lesson, are equal in the impact that they have on children’s learning. Further, it is demonstrated how Japanese educators place a strong emphasis on task selection, and that this effort is largely ignored by non-Japanese adapters of Lesson Study. Finally, the authors suggest that in order to use lesson study effectively in non-Japanese mathematics classrooms, it is necessary to build on the current practices of teachers that are commensurate with the elements of lesson study. Examples, from Japanese and Australian classrooms, are presented as illustrations of how the selection of the task is critical to the outcomes of the lesson.

Jacqueline Sack (University of Texas, Houston, US) and Irma Vazquez (University of St. Thomas) share how two teacher-researchers and a teacher apply the principles of lesson study in their research process for developing a 3-dimensional visualization program for elementary children. They share a common belief that children learn best through social constructivist approaches (Cobb et al., 2001) with explicit opportunities for differentiated instruction (Tomlinson and McTighe, 2006). While many lesson-study experiences offer teachers opportunities for personal professional development for deepening their pedagogical content knowledge, their focus is to develop and investigate new curricular materials that enable students...
to move among various visual and verbal representations (van Niekerk, 1997). They utilize a dynamic computer interface, Geocadabra (Lecluse, 2005) that simultaneously integrates several of these representations. The goal is to extend the body of knowledge on how children think and learn about geometric space, ultimately to publish instructional materials to support children’s development of 3-dimensional and 2-dimensional spatial reasoning skills. The study takes place in a linguistically- and academically-diverse inner-city school, during its after-school program, with third- and fourth-grade students, for one hour each week for each grade level. They illustrate our adaptation of lesson study as our process for lesson design, enactment, reflection, and iterative re-enactment.

Penina Kamina (SUNY College at Oneonta, US) and Patricia Tinto (Syracuse University New York, US) argue that practicing teachers are often at the heart of reform initiatives and often with little professional development or support. Teachers wrestle with shedding their old pedagogical beliefs, understanding mathematical content, and learning how to use curricular materials such as *Investigations* (Putnam, 2003). The discrepancy between the implementers’ prior experiences, National Council of Teachers of Mathematics (NCTM) principles, and *Investigations*’ objectives presented an important problem for study. A qualitative case study research design was used to explore teachers’ implementation of *Investigations*’ mathematics in fifth-grade classrooms. Data were collected in the form of lesson plans and audiotape and videotape of lesson study meetings. Results of this study showed that teachers that collaborated with each other in lesson-study meetings were quickly able to establish new classroom instructional approaches and implement new curriculum. Their enhanced content knowledge, pedagogical knowledge, and reformed pedagogical beliefs that emerged from participating in lesson study enabled these teachers to be versatile in implementing the *Investigations* curriculum.

**Unpacking Lesson Study: More than three easy steps**

Dolores Corcoran (St Patrick’s College, Dublin City University, IRE) presents results from a study to shed light on aspects of lesson study that emerged during its use as part of a primary teacher education programme in Dublin, Ireland. She describes five aspects to her role as broker and varying degrees of power associated with each of them. In an effort to make these more visible, she examines the junctures at which they appeared to interact with student teachers’ roles, by first listing the different roles she was aware of assuming throughout the program. She was a college lecturer /researcher/data manager. She was also lesson study co-coordinator/audio-visual technician and manager. She was Knowledgeable Other. She sought to influence students’ attitudes to mathematics and mathematics teaching by offering them opportunities to air and discuss their stories about learning mathematics. This aspect of her role focused on ‘affect’ in relation to learning mathematics and was welcomed by the group as an opportunity to strengthen the identity of participation of the members (Wenger, 1998, p. 215). Student teachers in the study showed marked changes in how they approached planning for, and teaching of, mathematics.

Mary Pat Sjostrom (Chaminade University of Honolulu, US) and Melfried Olson (University of Hawai`i at Mānoa, US) describe the experiences of one group of elementary school teachers as they engaged in a three-year professional development experience culminating in a one-year lesson study program. The partners in this project, university professors, school administrators and teachers, worked together to modify the professional development plan to serve the needs of the teachers and students. Although lesson study was not part of the original plan, it became the focus of year three. This case study illustrates the difficulties encountered in
introducing lesson study, and examines the way in which the components of the first two years, notably the Reflective Teaching Model, collaborative problem solving and analysis of student work, helped pave the way for success in lesson study in year three.

**Final Thoughts**

The research and practice on Lesson Study shared in this working group only begins to uncover the complexity of the process and the myriad of opportunities to learn more about teacher development in mathematics education. We have identified many salient themes and issues that will require in-depth study to tease out their impact on lesson study communities. We hope this will take us to the next phase on our work on lesson study.

“Facilitating sessions where teachers interact with and discuss representations of teaching”

Brief history of the Working Group
This is the first meeting at PMENA of this RMT working group. The idea of this working group emerged during a series of three-day conferences on representations of mathematics teaching held in Ann Arbor, Michigan in August 2009 and June 2010. These conferences were organized by project ThEMaT (Thought Experiments in Mathematics Teaching), an NSF-funded research and development project directed by Herbst and Chazan. ThEMaT originally created animated representations of teaching using cartoon characters to be used for research, specifically to prompt experienced teachers to relay the rationality they draw upon to justify or indict actions in teaching. The project also aimed to disseminate those animations to be used in teacher development and for that purpose held summer workshops in 2007 and 2008. The workshops evolved into the RMT conferences in 2009 and 2010, whose purpose was to gather developers and users of all kinds of representations of teaching to present their work and discuss issues that might be common to them. RMT conference participants included users of video, written cases, dialogues, photographs, comic strips, and animations. An outcome of the 2009 RMT conference was a special double issue of the journal *ZDM--The International Journal of Mathematics Education*, guest edited by Herbst and Chazan; the issue will appear in 2011 and contains 15 papers, currently at various stages of post-review production. Discussions at the 2010 conference created agendas for working groups and sessions in other, more prominent conferences. One of those agendas, based on a discussion about the facilitation of sessions with representations of teaching and the tools available to facilitate those sessions online and face-to-face, and for different clienteles (practicing teachers, preservice teachers, teacher leaders, others), stimulated this working group.

Issues in the psychology of mathematics education that will be the focus of the work
The working group is focused on elaborating a pedagogy of mathematics teacher education assisted by representations of teaching. Like other technological innovations, representations of teaching not only offer opportunities for teachers’ learning but also call for specialized pedagogical practices from teacher developers. The working group will engage in such elaboration in two ways. First, the work will consist of using some conceptual and technological tools (described below) to design some teacher development experiences. Second, reflections on such design work are expected to call attention for more and better tools.

For some years now, teacher educators worldwide have used classroom video records, samples of student work, narrative cases, and other artifacts to engage teachers in discussions about teaching (Fishman, 2003; Lampert & Ball, 1998; Merseth, 2003; Sherin & Han, 2004; Smith, Silver, & Stein, 2004; Tochon, 1999). These artifacts afford opportunities for teachers to learn from practice, whether this learning focuses on pedagogical or mathematical aspects of the work of teaching or on understanding students and their thinking. More recently, animations and comic books using cartoon characters have been created and used for similar purposes (Herbst, Chazan, Chen, Chieu, and Weiss, in press). In parallel, advances in information technologies have made it easy to create and manipulate rich media objects (graphics, photo, video) and share them in the Internet where they can be tagged, commented, and repurposed. This technology enables collaborative work across geographic boundaries. More importantly, it enables a different kind of work with records of teaching, particularly work that, by enabling more detailed and active experiences with the media, has the potential to increase learning opportunities for clients of teacher education.

Materials exist describing how to use some of these artifacts in teacher learning contexts (e.g., Merseth, 2003; Seago, Mumme, & Branca, 2004). The scholarly literature has also addressed facilitation in the context of describing teacher learning from professional development (e.g., Borko, 2004) and even the learning of the facilitators (e.g., Stein, Smith, & Silver, 1999). We choose not to review this literature here.

Our present purpose is to stimulate the development of pedagogical practices attuned to the possibilities that novel media—particularly cartoon-based representations of teaching—and new technologies offer for teacher development. Herbst, Chazan, Chen, Chieu, and Weiss (in press) have argued that cartoon-based representations of teaching can have virtues similar to video (e.g., the possibility of an animation to immerse the viewer in a timeline and cadence of events comparable to that of real action) as well as some of the virtues of written cases (e.g., the possibility of cartoons to represent selected facets of the individuality of people and settings rather than show by default as many of those facets as the recording technology allows). These characteristics add to available technologies that permit to create, annotate, and reuse computer graphics and interact with others about them. These tools make cartoon-based representations of teaching a malleable medium for learning in, from, and for practice (Lampert, 2010). In calling for the development of a pedagogy adapted to the use of representations of teaching we operate on the assumption that representations of teaching can do more than support usual teacher development activities. They can also create new spaces for the development of professional knowledge and skills. In a way this is analogous to how the availability of new technological artifacts (calculators, computers) not only permits the emergence of new ways of knowing but also requires novel pedagogical practices to fulfill their promise.

In this document we contribute to a discussion on a pedagogy of mathematics teacher education assisted by representations of teaching by proposing some basic categories for such pedagogy. We also provide examples that can get the working group started in the work of fleshing out such pedagogy. We start this discussion, however, with a more basic conceptualization of representations of teaching that can underscore the important role that cartoon-based representations can play in teacher development practice.

What is a Representation of Teaching

The expression “representation of mathematics teaching” suggests a semiotic mediation—a sign, or representamen (Peirce, 1955) pointing to mathematics teaching as the referent, the
object represented. That expression might trigger associations with the notion of representation in the teaching of mathematics. At first blush those associations could be dispelled just by noting that the preposition “of” refers not to the role that representations may play in teaching mathematics but to the representation of the practice of teaching mathematics itself and the role that these can play in the learning of teaching. But on second thought, the extant literature on mathematical representations might be of use in understanding what a representation is and what role it could play in the learning of teaching. We come back to it below, after we consider the object or referent in representations of teaching.

The question of what is mathematics teaching has been vastly addressed in the literature. The teacher’s work used to be seen as administering an unproblematic body of subject matter to children and, or alternatively, cultivating a personal relationship with children. But successive improvements in conceiving the subject of studies, students’ cognition and learning, and eventually the work of teaching itself, have contributed to portray a rather complex profession (see Doyle, 2006; Fenstermacher, 1994; Lampert, 2001). The conception of teaching proposed by Cohen (in press) asserting that teaching is a practice that deliberately attends to students’ learning of disciplinary subject matter by attending to the representations of disciplinary knowledge, the cognitions of students, and the instructional medium in which teacher and student interact, seems useful as a starting point in describing the object or referent in representations of teaching.

Representations of teaching could help the work of teacher developers by pointing to the many tasks of teaching that derive from the three domains of teacher work that Cohen describes. The notion that the work of the teacher includes attending to the representation of disciplinary knowledge includes tasks of teaching such as selecting or designing embodiments of mathematical ideas, formulating mathematical statements that are true, crafting mathematically compelling explanations, identifying errors, choosing problems for students that give opportunity to use target mathematical ideas, etc. The notion that the work of the teacher includes attending to the cognitions of students includes tasks of teaching such as eliciting students’ thinking, interpreting students’ conceptions, creating and issuing specific challenges to students’ conceptions, etc. The notion that the work of the teacher includes attending to the instructional medium includes a number of diverse tasks of teaching associated with shepherding interpersonal dynamics, communication through personal relationships, and the affordances and constraints of the institution where the work is done (e.g., using well the time allotted for class or the space allotted for public displays; see also Ball, Thames, and Phelps, 2008; Lampert, 2001). The work of learning to teach includes learning to attend to those three commonplaces, eventually acting in such a way as to exercise attentiveness to those different foci simultaneously and over relatively long expanses of time. From such a brief, initial description of mathematics teaching as the object of learning it should be apparent that we are talking about an object of study that potentially makes high demands on intellectual and performance capacity. Experiences that scaffold that learning, enabling learners of teaching to engage with and learn about some features of that complex practice while keeping others simple, may succeed in creating those capacities incrementally. Representations of teaching can display particular enactments of those tasks; cartoon-based representations of teaching, particularly those realized with non-descript characters, can help focus on the enactments and the tasks enacted rather than on the actors themselves (McCloud, 1994). Along those lines an analogy with representations of mathematical ideas can be quite productive.

Mathematical representations can help make some aspects of mathematical ideas salient by embodying the structure or function of those ideas in the structure and function of the sign system that performs the representation (see also Goldin, 2003; Resnick and Omanson, 1986; Schoenfeld, 1987). Peirce (1955) addresses this with the notion of the interpretant, a decodification of the sign into another sign (what some have called an internal representation). A representation of a mathematical object by a sign is thus realized through the creation of an interpretant that basically establishes how the sign points to the object (and what aspects of the sign predicate about the object).

Various kinds of mathematical signs (such as those in figure 2) can perform a representation of a mathematical idea (e.g., circle); they do so by creating an interpretant that makes the mapping between sign and object operational, by noting how the sign calls forth the object. Cartoon-based animations and comic strips (and for that matter also video clips of images of real people and written words and sentences) can do the same with respect to teaching. The role of any of those representations of teaching is to build the interpretant—to enable ways of thinking about teaching called forth by the sign that might progressively grasp the complexities of the practice itself. While the things represented, mathematical ideas on the one hand and the practice of mathematics teaching on the other, are quite dissimilar, we might learn something about what representations do by working through a metaphor between them. Like any metaphor one could push this one to limits where it would stop making sense, but like any metaphor, this metaphor can, within boundaries, help us understand the power of some representations of teaching in regard to the development of the interpretant.

\[
\{(x, y) \in \mathbb{R}^2 : (x - a)^2 + (y - b)^2 = r^2\}

<th>Figure 1. Several positions of a spinner</th>
<th>Figure 2. Other representations of circle realized with different semiotic resources (diagram, symbols, language)</th>
</tr>
</thead>
</table>

We’d like to propose an analogy between a particular representation of circle (the spinner alluded to in Figure 1) and the representation of the practice of mathematics teaching made possible through comic strips or animations of cartoons characters. Of course there are other representations of circle, such as those shown in Figure 2. The spinner in Figure 1 contrasts with all of those in Figure 2 in its dynamic nature. One could think of the spinner as creating a message over time that says, “this is a circle.” At any one moment in time the spinner only points at one point, as if writing one letter of that message. One has to look at it over some length of time to gather what the aggregate is doing. The spinner also contrasts with the other representations in regard to how it shows not just what the circle is but also how the points in the circle are obtained. Finally, this spinner also represents the circle without actually depicting any of its points—we see the circle by putting into the image a response of sorts to the stimulus provided by the rotating segment, but neither the segment is part of the circle nor the circle is really drawn there. In all these regards cartoon-based representations are like the spinner.

The spinner representation of the circle reminds us of Walt Whitman’s words “all music is what awakens from you when you are reminded by the instruments.” In Peirce’s terms, the representamen (or sign) is the collection of strokes at different locations, sorted over time; the referent or object is the mathematical notion of circle, say, the set of points on a plane at a fixed, given distance from a given point on that plane; the interpretant notes that the strokes are the same length and start from one common point at each moment while the other point makes over time a familiar figure. Indeed, through the interpretant, the moving strokes remind us where the circle’s points should be, and over time they remind us where the complete circle should be; finally the interpretant elides the moving strokes—they are not the circle. The moving strokes are like the instruments in Whitman’s quote, the notion of circle could be the orchestral arrangement handled by the orchestra director, while the points becoming the circle are the music we hear. It can also be noted that we see the circle through the work of the spinner partly because we have an idea of what the circle should be—the interpretant has some prior associations such as for example one between the sign in Figure 2a and a synthetic idea of the circle (e.g., an equivalence class of all the diagrams that look like that one).

Just as the spinner shows over time how the circle is made to someone who has a prior idea of what a circle is supposed to be like and without actually creating a physical sign for the circle itself but by evoking it from the viewer, a representation of teaching can point us to how teaching is done even if the signs themselves don’t show each of its actions but just point to them. A comic strip including a sequence of photographs of the teacher writing at the board can portray an explanation or the setting up of a task (see also Crespo, 2010). So can a comic strip containing snapshots of action in response to a problem such as those shown in Figure 3. The interpretant associates those signs with the actual events that could happen in practice, say when a student solves a problem about linear functions, and can not only fill the gaps in between frames but also predict the actions that might come after.

Figure 3. A solution to a linear function problem that reveals a misconception at play

Building the Interpretant

All communication about ideas, be that in mathematics instruction or in teacher education, happens through transacting representations; at the very least because language is also a semiotic system. In regard to transacting about the practice of teaching, we’d say that language can be quite an abstract semiotic system. Words such as constructivist or traditional may be useful to name chunks of action in the manner that the English word “circle” names the mathematical object; but those words are not like the spinner that tells you how a circle comes to be. For teacher education we need representations that help connect theory of what teaching is with practice on how to do it. Note, along those lines, that the spinner allows one to interact with the notion of circle, for example by permitting the construction of a different, static representation of the circle (such as the one on Figure 2a) by plotting a point at the mobile end of the spinner at various moments in time and then by using that representation to make conjectures about properties of the circle other than the constant distance from a center that defines it. Clearly a symbolic representation of circle, such as the one on Figure 2b also enables one to do things with the circle, and notice different properties. A diagrammatic representation of circle has been a preferred one for beginners for ages. In the case of teaching we ask what kind of sign can produce a representation of teaching that can be so generative of knowledge about teaching as the spinner is for the circle?

Why are these semiotic considerations of any use in thinking about a representations-based pedagogy of mathematics teacher education? Grossman et al. (2009) note the role that representations of practice play in professional education; while they distinguish between representations as those artifacts that display practice (e.g., video records), decompositions as those artifacts that unpack and elaborate on aspects of practice (e.g., a rubric that outlines the characteristics of an instructional explanation), and approximations as those artifacts that create opportunities to engage in practice (e.g., a simulation software that invites teacher candidates to act the teacher in front of virtual students), it seems to us that all of those are to some extent based on a representation of teaching. We prefer the words in their gerund form as representing, decomposing, and approximating practice and use them to designate the activity systems in which the interpretant employs the signs to transact and think about the object of consideration.

The work of mathematics teacher education, the pedagogy of teaching a practice assisted by representations of practice thus involves building the interpretant through activities of representing, decomposing, and approximating practice with different kinds of semiotic resources. It includes, in particular, developing teacher capacity for using signs to describe practice, for ‘reading’ a practice from signs, and for creating enactments of that practice within the grammar of a semiotic system. Such activities include exercises like “Ms. Shackleforth’s lesson,” (see Ghousseini, 2008) where teacher candidates are asked to supply the lines spoken by the teacher in a written dialogue where only student lines are provided. Clearly such approximation of practice does not preserve all the complexities of practice; but rather than discarding such approximations for what they miss, we could see them as building some opportunity for practice. In generating the teacher’s lines in a hypothetical classroom dialogue, clients have the chance to design the precise words that a teacher would say (rather than just the informational content of their response), offering an opportunity for them to consider the informational and relational entailments of teacher talk in the context of a specific mathematical discussion. While engaging with representations of teaching (doing things with signs) does not substitute engagement with actual teaching, the former scaffolds the latter much in the same way as engaging diagrammatically with a representation of a circle (such as drawing a stroke between...
a point on the circle and the center) enables the user to think about aspects of the circle (e.g., the notion of radius) without loss of generality.

What kinds of tasks can elaborate the three activities noted above (representing, decomposing, and approximating)? How can facilitation with such tasks engage teachers in grappling with important aspects of practice that they need to learn? This is where we want the working group to get started. A preliminary framework to guide the work of the group is provided below.

**A Pedagogical Framework for Facilitation**

The framework we propose includes four kinds of elements. One of those can be described at face value as *open-ended expressions* or boundary objects that can be used in transactions between teacher developers and their clients without needing to be completely defined. One of those expressions is “mathematical action” which we observed being used in a geometry class for future teachers and in the context of having the students watch an animation of geometry instruction. The college instructor’s goal was to have her clients flag moments that had mathematical significance hoping to get them to bring up things like “making a claim,” “offering a counterexample,” “extending a claim to a larger set of objects,” etc. Clearly, it would have defeated the purpose of the activity to give such a list (and its vocabulary) before watching the movie; and the work could have been stifled or miscued if the instructor had used better understood words (e.g., if she had said something like “flag moments where they are using a mathematical concept,” the students might have restricted themselves to uses of known mathematical vocabulary). Other open-ended expressions that can serve comparable purposes are “student thinking” and “teaching move.” Their usefulness in mobilizing the work with representations depends on their ambiguous nature—the work set up will then involve discovering or inventing their meaning.

![Figure 4. A student’s response to a problem inviting the teacher to make a move](image)

The first proposal of this framework is that a pedagogy for mathematics teacher education assisted by representations of teaching needs a set of usable open-ended expressions or boundary objects that the teacher developer can use to formulate, in rather non-descript ways (i.e., not calling attention to the words), tasks that the learner of teaching can do with representations. For example, a client could be offered the student solution to a problem sketched in Figure 4 and then asked to represent, using the cartoon character set, an answer to the question “What would be your next move?” This question is ambiguous in comparison with the more concrete “What would you say next?” and for that reason it might allow the client to make the cartoon teacher do other things than talking. A client could have the teacher erase the board, while another might...
have the teacher correct the construction, and another might have the teacher ask Alpha what they know about the relationship between radii and tangents. A discussion of those options and the possible justification for these moves could ensue without ever dwelling on the word *move*.

A second element of this framework is relatively expected and documented in earlier literature about facilitation. It consists of having a taxonomy of activity structures or activity types for mathematics teacher education. Clearly these activity types could have elements in common with those found in K-12 classrooms, such as triadic dialogue, homework review, etc. (see Lemke, 1990). But there are other activity types that are particular to the work of mathematics teacher education assisted by representations of teaching. A quite common activity type could be described as “working on the math.” Quite often, mathematics teacher developers who intend to show a video that displays students working on a mathematical task will first have their clients work on the mathematics that will be featured in the video. The goal of this activity is not necessarily to teach the mathematics at stake in the problem to the clients, and for that reason the clients may or may not be expected to complete the problem. Yet this activity is done for the clients to develop some familiarity with the mathematics at play in the representation so that they can attend to other things, such as student thinking, when they interact with the representation.

---

You are going to teach a lesson on tangents to circles. The lesson includes teaching the procedure for constructing a tangent to a given circle. In your plan you have sketched the procedure as follows.

1. Given, a circle with center O, and a point P
2. Draw segment OP, find its midpoint D
3. With compass centered at D draw a circle of radius DO, intersect the circle at points A and B
4. With straightedge, draw lines PA and PB, which are the required tangents

Your field instructor indicates that the procedure is okay but that it is not clear how your students will know that the lines are indeed tangents to the given circle. Script a few lines where you explain to the students why is it that the lines they constructed are the tangents to the given circle.

*Figure 5. A homework problem for clients to practice a task of teaching*

Another activity type we have used in the context of teacher education is a form of review of homework in which clients enact scripts of action that they conceive outside of class in response to practical problems, such as shown in Figure 5, in the context of learning to explain procedures. Usually those enactments give clients some practice in delivering a teaching move that had been planned; they also get other clients involved in giving feedback, and help raise more substantive questions about the task of teaching being learned. In the context of the teacher study groups organized by ThEMaT, an activity structure involved asking participants to watch animations and tap the table to stop the animation so they could make a comment. Stopping the video not only enabled the person who tapped the table to make a comment, but it also opened the floor to other participants to chime in. The video would only continue when the participants were no longer interested in following up. We bring these examples to illustrate the more general contention that a pedagogy for mathematics teacher education that uses representations of teaching needs to include a taxonomy of activity structures. These activity structures could...
specify in particular how the clients might interact with (manipulate, annotate, etc.) the representations being used.

A third element of the framework consists of problem types. By this we mean specific intellectual work that participants do within an activity type involving representations. An initial list of types derives from the three words used by Grossman et al. (2009): representing (the client might view), decomposing (the client might study), and approximating (the client might do). Clearly more is hinted—one could expect that participants would not just view a representation and be impressed by it; they might also describe a segment of it or point to special moments. In fact the wording of the tasks do matter (Morris, 2006). Likewise, a representation of teaching useful for decomposing teaching could look like a rubric that unpacks the characteristics of a task of teaching (e.g., how to explain a concept). The study of a decomposition of teaching could involve work such as judging a performance on that task of teaching using the decomposition. As noted above, completing dialogues or comic strips could be used as activity types for approximating teaching. Approximating teaching might include not only problems for clients to conceive the actions they might do by writing lines of dialogue but also rehearsing those actions by working on aspects of professional performance such as voice, use of interjections, posture, board writing, etc. Table 1 provides an initial list of problem types based on what Herbst & Chazan (2006) identified as attributes of cartoon-based representations of teaching.

<table>
<thead>
<tr>
<th>Problem Type Name</th>
<th>Sample Problem Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alternativity problem</td>
<td>What else could one do at this moment?</td>
</tr>
<tr>
<td>Generality problem</td>
<td>What would you call that teaching move?</td>
</tr>
<tr>
<td>Normativity problem</td>
<td>What should be done in these circumstances?</td>
</tr>
<tr>
<td>Projectiveness problem</td>
<td>How would you have felt if those were your students?</td>
</tr>
<tr>
<td>Reflectiveness problem</td>
<td>What do you think about this episode?</td>
</tr>
<tr>
<td>Temporality problem</td>
<td>At what moment would you say [such thing] happened?</td>
</tr>
</tbody>
</table>

All of the elements in Table 1 unpack the work that the viewer could do when confronting what Grossman et al. (2009) called a representation of teaching (and what we would call a representation used in representing and viewing teaching). But some of them can also be used in the context of decomposing and studying teaching—for example a normativity problem could be used along with a video record or animation to give learners a chance to learn a rubric about an activity of teaching. For example, they could be given a rubric that describes the components of an instructional explanation, and a video clip that purportedly contains one such explanation (not necessarily a good one); and they could be asked a normativity problem so that they apply the rubric. The problem types listed in Table 1 are only some examples. More generally, the question to the members of the working group is what are other types of problems that could be used along with representations of teaching and in activities such as representing, decomposing, or approximating teaching? Our contention in this paper is that a pedagogy of mathematics teacher education assisted by representations of teaching needs a taxonomy of problem types.

The final element of this emerging framework addresses the technological affordances needed to realize this pedagogy of mathematics teacher education. Clearly one could do many of these activities having only a video projector and playing media off a single computer. But there are important pedagogical considerations associated with more technology-intensive environments. For example, if every client could play the media at their leisure but contribute
comments to a common conversation, in face-to-face, chat, or forum, this could have the beneficial effect of diversifying the discussions, particularly in regard to temporality problems. Along those lines a recent study by Chieu, Herbst, and Weiss (in press) shows evidence that clients’ comments in forum or chat benefitted from having an embedded screen for the animation being discussed, which they could access at the same time as they interacted with peers in a forum or chat. This media-enabled-forum is one of several functionalities available in ThEMaT Online, a resource for teacher developers to use with their clients. Another functionality present in ThEMaT Online is a lesson sketching software that permits users to develop or contribute to a classroom episode using cartoon characters (Herbst et al., in press). Such lesson sketching software is the first step of what a virtual setting for teacher education could look like; Chieu and Herbst (in review) offer a longer term prospect with their design of a teaching simulator. An authoring tool, which is part of ThEMaT Online, allows teacher developers to create lessons and assessments by juxtaposing different functionalities like those in a sequence of activities. We expect the working group will be able to explore these functionalities, and the potential combinations that could be made with them; we also expect the working group to have suggestions of new functionalities to add.

More generally we think that the development of a pedagogy assisted by representations of teaching requires a menu of tools that facilitates the creation and delivery of experiences for clients as well as the collection of their work. It requires more than a course management system because the representations are not atomic objects. In order to pose temporality problems (see Table 1) for example, it is important to be able to find, tag, and communicate specific moments in the timeline of a representation of teaching. In general, we believe that the continuous development of the pedagogical functionalities of the ThEMaT Online system can be a scaffold in the process of developing a pedagogy of teacher development assisted by representations of teaching.

Plan for active engagement of participants in productive reflection on the issues

The plan includes starting with a brief exposition by the authors of the contents of the paper followed by a collective discussion framed around the following questions:

- On the facilitation of discussions or investigations assisted by representations of teaching: What are the possibilities and demands of a pedagogy assisted by representations? What considerations are needed to make when framing the encounter of an audience with an artifact, depending on who the audience is and the specifics of the artifact? What else can be done beyond the general “watch and we’ll talk”? How does the multidimensionality of representations (the fact that they involve representations of mathematics and of students’ thinking as much as those of teacher action) feature in the organization of encounters with representations? In particular, does it help to organize an earlier encounter with the mathematics of the representation?
- On learning technologies to navigate representations of teaching: What is available and what is needed? Web 2.0 technologies have brought up the possibility for users to do more than read or view media artifacts—they can record, share, tag, comment, rate, index, and mix media artifacts. Are those capabilities useful in enabling the work with representations of teaching? What other capabilities are desirable?
We estimate that the first meeting of the working group will be consumed by the exposition and the discussion. The second meeting will be organized around pairs of participants involved in the creation of exemplar sessions for a chosen clientele and around a particular representation of teaching. Participants are invited to bring a representation of teaching they would want to work with, and accompanying notes about facilitation. The organizers will provide some scaffolds in the form of virtual index cards (realized as Power point slides) that contain some of the elements of the taxonomy. People will divide in groups and design a lesson, session, tutorial, or assessment that implements elements of the taxonomy with the representation chosen. The purpose of this task is to push for the development of the taxonomies in a concrete context. Inasmuch as possible these materials will be shared among the members of the group. The third, and final, meeting will provide a forum for subgroups to share these emerging products and the extensions of the taxonomies that these products require. Participants will also discuss opportunities for follow-up activities.

**Anticipated follow-up activities**

We have been allotted a pre session slot at the AMTE Annual Meeting in 2011. We plan to use that slot to display the exemplars developed at the PMENA meeting and to engage in further work on (1) improving the exemplars and (2) using the exemplars to improve the taxonomies. We hope we will be able to use those products to propose a second iteration of this working group at next year’s PMENA.

The characteristics of the working group are such that people may expect collaboration and sharing of materials. We will strive to acknowledge all authors in these materials as well as in the development of the ideas.

**Endnotes**

1. The introductory content of this paper is taken from the first author’s Pattishall Award Lecture at the UM School of Education in May 2010. The work of project ThEMaT has been done with the support of NSF grants ESI-0353285 and DRL- 0918425. All opinions are those of the authors and do not necessarily represent the views of the foundation. We thank Emina Alibegovic for important comments.
2. We use the word “client” to refer to the students of teaching. Among other things, this choice prevents ambiguity with our references to students in the representations of teaching that those clients might be exposed in their teacher development opportunities.
4. ThEMaT Online is a set of representations of teaching and tools to manipulate them. The system is currently being designed for teacher educators to use with their clients. It can be previewed at http://grip.umich.edu/themat.

National reports have identified the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education. However, providing high quality mathematics education for all students goes beyond the recruitment of knowledgeable teachers. This working group is designed to offer an opportunity to examine the role that professional development and support play in the work and retention of mathematics teachers. Retention focuses on new teachers, especially those in urban area and mathematics teachers in hard-to-hire settings. Discussions concentrate on the study of interventions through professional development and support models. Efforts to deepen our understanding of the complex and multifaceted picture of why teachers leave and why they stay, and how efforts to retain teachers impact their work in the classroom and their decisions to stay or leave are developed through the sharing of research designs, data collection, and on-going results. This working group is appropriate for anyone who has work to share or who is thinking about supporting a retention project. Throughout, we address this very complex task both in terms of the opportunities and challenges for the mathematics education researchers to provide quantitative and qualitative input on a major political issue. It is hoped that this working group will enrich the dialogue about a national crisis in mathematics education.

Brief Overview of the STIR Working Group

Although teacher retention is a topic being included in many conferences and position papers, the Supporting Teachers to Increase Retention Working Group met for the first time in 2009 at PME-NA 31 in Atlanta, GA to investigate the relationship between Professional Development/Support and the retention of mathematics teachers. A total of 11 participants attended the three working group sessions focused on identifying the absences in the research on mathematics teacher retention in order to move forward in tackling this complex national issue. The emerging dialogue was based on the results of research studies and ideas of the participants. Participants shared their backgrounds and interests in retention issues, and discussed potential research directions with the ultimate goal of identifying key research issues that would constitute a research agenda for the group. Participants were interested in examining the on-going preparation, support and retention of grade 7-12 mathematics teachers from a variety of angles, including: (1) Impact of Professional Development on Teacher Retention; (2) Relationship between Content Knowledge and Retention; (3) Obtaining Research that examines the Dimensions of Professional Development and Support that impact Retention. The overarching issue of Mathematics Teacher Retention is often overlooked under the assumption that effective professional development would in essence lead to increased retention. However a closer look at what type of support helps teachers stay in their school, let alone their profession is necessary.

At PME-NA 32 in Columbus, OH, the group will elaborate on the research agenda that was outlined at PME-NA 31 in Atlanta, GA. To stimulate discussions, members of the group will be invited to provide summaries of on-going projects to be discussed during the group meeting sessions. To date these projects fall under the following categories: (1) Role of technology in support/retention; (2) Professional support community that reflect the building of networks and

contacts to support work, decisions, challenges, and opportunities that arise in the teaching of mathematics, including lesson study and electronically based communities of practice; (3) Role of leadership and/or career enhancement in retaining mathematics teachers, including the PD directed towards new teachers entering the field through alternative certifications, those coming from other careers and shifts in PD needed as new teachers move through the challenges of their first 5 years of teaching; (4) Content based Professional development with emphases on conceptual linking and problem solving; and (5) Research issues that arise in examining teacher retention.

Issues of Psychology of Mathematics Education to be focused on

The study of the relationship between Professional Development and Support Models on the Work and Retention of Mathematics Teachers in grades 7 – 12 merits careful examination. Several national reports have pointed to the need to increase the pool of highly qualified mathematics teachers as a way to improve mathematics education and maintain the United States’ economic competitiveness (National Academy of Sciences, 2007; Glenn Commission, 2000). However, providing high quality mathematics education for all students goes beyond the recruitment of mathematically knowledgeable teachers to encompass issues of teacher support, professional development, and retention. Over the past two decades, analyses of teacher employment patterns reveal that new recruits leave their school and teaching a short time after they enter. Ingersoll, using data from the School and Staffing Survey concluded that in 1999-2000, 27% of first year teachers left their schools. Of those, 11 percent left teaching and 16 percent transferred to new schools (Smith and Ingersoll, 2003). Earlier research revealed that teachers who leave first are likely to be those with the highest qualifications (Murnane and other 1991; Schlecty and Vance 1981). This “revolving door” is even higher in large urban districts; for example, 25% of the teachers new to Philadelphia in 1999-2000 left after their first year and more than half left within four years (Neild and other 2003). In Chicago, an analysis of turnover rates in 64 high-poverty, high-minority schools revealed that 23.3 percent of new teachers left in 2001-2002.

Reasons for the lack of retention of new teachers and teacher in high-poverty schools are often related to “working conditions” and lack of support (Ingersoll, 2001; Smith & Ingersoll, 2004; Johnson et al., 2004), though pay also plays a role (Hanushek, Kain, & Rivkin, 2001). This support includes professional and collegial support such as working collaboratively with colleagues, coherent, job-embedded assistance, professional development, having input on key issues and progressively expanding influence and increasing opportunities (Johnson 2006). Preparation, support, and working conditions are important, because they are essential to teachers’ effectiveness on the job and their ability to realize the intrinsic rewards that attract many to teaching and keep them in the profession despite the profession’s relatively low pay (Johnson & Birkeland, 2003; Liu, Johnson, & Peske, 2004).

Recently, a status report on teacher development focusing on professional development and support of teachers (Darling-Hammond et al, 2009) summarized findings and put forth recommendations for effective professional development. The basis for the paper included national surveys with self reported data, a meta-analysis of 1,300 research studies and specific studies. The conclusion is that “well designed” professional development can influence teacher practice and student performance. The paper focuses on what is or could be considered as well defined. One strand of the paper is that of effective support for new teachers. Although half of the states require support for new teachers (Education Week, 2008) it was found that rates of

participation in teacher induction programs varied by school types with highest rates in schools with least poverty and lowest in schools with high levels of poverty. Beyond the rates of participation and availability of support, there is the question of what is effective support. An ongoing large-scale research project was sited which is currently underway that aims to measure impacts in terms of classroom practices, student achievement and teacher mobility. Initial results seem to reflect the difficulty in identifying the impact of support.

Another study presently in its fourth year, Supporting Teachers to Increase Retention (STIR) is studying the relationship between retention and support of mathematics teachers across the State of California. This five year study is looking through the lens of 10 support models to relate retention to content knowledge, classroom practices, professional communities of support, leadership and needed support. Initial results are complex but are showing relationships between sustained professional development and support and teacher retention. Data collected to establish a base line for retention across a 5 years period preceding STIR showed that yearly attrition averaged 20% across all 10 sites and for the five year period the attrition average was 54% with sites reporting an attrition of mathematic teachers as high as 73%. In first year the attrition dropped from 20% to 14%. Additional data will be available in October 2010.

But, what is the relationship between the support and the retention? One of the 10 sites from this study observed that success of a retention initiative takes root in a variety of needs: the need to know your District and its teachers – a necessity that often relies on established, long-term relationships between the university and district leaders; the need to offer sustained support as opposed to punctual interventions in order to break the isolation of beginning teachers and create a sustainable community; the need to establish relevance in the professional development activities proposed by engaging participants in deep introspection of their own knowledge gaps; the need to involve all actors of the community to prevent miscommunication from annihilating attempts made towards change; the need to nurture the community created by moving its members forward into roles and responsibilities they are ready to take on; and last but not least, the need to refine even successful models to keep the momentum (Felter & Faughn, 2009).

As is indicated in the comments above, support comes from multiple sources. Another recent study from Peabody College, Vanderbilt University, finds that principals play a critical role in the support of new mathematics teachers (McGraner, 2009). But how do we successfully involve principals in supporting professional development that sustains retention?

An additional aspect of the issue at stake is the retention of mathematics teachers entering the profession through alternative certification as brought up by one working group participant. In a presentation to the group at PME-NA 2009, Brian Evans emphasized retention issues within the New York City Teaching Fellows program and provided us with the following literature review: “Teachers leave teaching in New York City for three reasons (Stein, 2002): retirement, leaving the profession, and transferring to a school outside New York City. […] A concern with alternative certification is lack of retention, especially in large urban areas such as New York City (Darling-Hammond, Holtzman, Gatlin, & Heilig, 2005). Sipe and D’Angelo (2006) found when surveying Fellows that about 70% of them intended to stay in education. NYCTF reports that 89 percent of Fellows begin a second year of teaching after the completion of their first year (NYCTF, 2008). Boyd, Grossman, Lankford, Michelli, Loeb, and Wyckoff (2006) reported that about 46% of Teaching Fellows stay in teaching after four years as compared to 55% to 63% of traditionally prepared teachers. Kane, Rockoff, and Staiger (2006) found that Teaching Fellows and traditionally prepared teachers have similar retention rates. Further, Tai, Liu, and Fan (2006) claim that alternative certification teachers, in general, have comparable commitment to the
teaching profession as do traditionally trained teachers. In a survey of 31 Teaching Fellows, 90 percent said they were considering leaving their high needs schools for better schools in or outside of New York City, or leaving the teaching profession altogether (Stein, 2002). [...] Similar to results found in other studies (Costigan, 2004; Cruickshank, Jenkins, & Metcalf, 2006; Evans, 2009), teachers were very concerned with student behavioral problems and unsupportive administration.” (Evans, 2009)

This working group is designed to offer a comprehensive, multifaceted examination of the on-going preparation, support and retention of grade 7-12 mathematics teachers based on the results of research studies and ideas of the participants. It is hoped that this working group will enrich the dialogue relating the “support gap” and the work and retention of teachers of mathematics. It is also expected that this working group will propose areas ripe for further research. In light of the National efforts to close “poor performing schools” this work to identify ways to improve retention of mathematics teachers becomes especially critical.

Year 1 & 2 of the working group: Proposals and Summary

A Summary Report from the first year of the working group is included below. This year’s proposal builds upon the proposal from last year by integrating participants’ research interests and focusing the discussions around 4 major themes relating to teacher retention. A reference list produced by collapsing the references from the proposal and work of the first year is found at the end of this proposal.

Summary Report: Activities of Working Group PME-NA meeting 2009

Day 1: Candice Ridlon (UMES, MD); Brian Evans (Pace University, NYC); Christine D. Thomas (Georgia State University, GA); Ellen Clay (Drexel University, PA); Allyson Hallman (UGA, GA) ; Michael Meagher (CUNY, NYC); Barbara Pence (SJSU, CA); Axelle Faughn (WCU, NC).

After an Introduction to the working group, participants introduced themselves and shared individual interests & concerns regarding the “support gap” and the work and retention of teachers of mathematics. Goals and Key questions from the proposal were presented, followed by a Review of the literature. Participants were then asked to consider the question “Can support impact teacher retention?”, and more specifically “What are the different aspects of support? How is impact measured? What are opportunities and challenges encountered when researching teacher retention?” A major task for our first session consisted in coming up with directions to work and identifying missing foci in literature. The list of themes and interests resulting from this initial brainstorming is provided later in this report.

Day 2: Douglas Owens (Ohio State University, OH); Drew Polly (UNC Charlotte, NC); Candice Ridlon ; Christine D. Thomas ; Barbara Pence ; Axelle Faughn.

The second meeting session of this working group had two major foci: Sharing Models of Support and Identifying categories from Day 1 list of questions.

A. Models of support

Although sharing models was a recurring activity throughout the three meeting session of the working group, the list below synthesizes the models that were shared over the three days:

- Brian Evans – NYCTF literature review
- Drew Polly – UNC Charlotte - Researcher-beginning teacher onsite mentorship

This presentation shares the findings of a study in which the researcher supported beginning teachers' mathematics instruction through mentorship activities. The researcher

provided opportunities to co-plan, co-teach and feedback on lessons to four teachers who were either new educators or new to their grade level. Analyses of field notes and interview data indicates that the teachers who sought more in class support during their mathematics teaching used more standards-based pedagogies and reported a greater satisfaction in teaching mathematics in a standards-based approach.

- Candice Ridlon – PD through reform curricula in Utah
- Axelle Faughn – Addressing content knowledge through MATM

This presentation offers an examination of the role that professional development plays in the work and retention of new teachers and/or teachers in hard-to-staff settings. Based in California and including 10 sites and more than 250 teachers, first and second year results from data collected through large group surveys, online logs and site level focus groups helps to explain why the attrition rate over the first year of the study dropped from 20% to 14%.

- Barbara Pence – CMP STIR 10 sites, 10 models
- Christine Thomas – Developing an online community of support

Four professors from Georgia State University, located in an urban environment in the United States, share their conceptualization, operationalization and implementation of a study of mathematics teachers in an online learning community in Second Life. This is a virtual professional learning community (PLC) that is located in Five Points at Georgia State University. Second Life is a multiple user virtual environment. It allows users to create and control a representation of themselves known as an avatar. They can use these avatars to explore and interact with a simulated reality. This simulated reality is limited only by imagination.

We use Second Life as a virtual learning environment for learning about and engaging in situated contexts designed to support induction year teachers in developing as exemplary teachers of mathematics. The teachers are able to experience and examine a broad range of classroom situations within Second Life. More specifically, teachers are able to convene and as a community interacting both with audio and with non-verbal cues within the Second Life environment. They are able to model best practices and reflect on their experiences within a virtual community of their peers

B. Categories from Day 1 along with the related list of questions

Participants organized the questions and interests identified during the first meeting into 4 main categories that emerged from the initial brainstorming: Impact of PD on Teacher Retention; Content Knowledge and Retention; Research issues and Retention; Equity and Retention. The revisited list of questions below provides an arrangement of interests under the 4 major themes, although it was clear from our discussions that these themes overlapped and that many questions could be considered from more than one angle and crossed over categories.

1. Can Professional Development impact Teacher Retention?
What is professional Development? What models are successful?
What type of teacher professional learning encourages transformations in teaching practices and rewards resulting in improved retention?
Is Coaching/Mentoring (induction) part of PD?
How does pre-service fit into the issue of retention?
Looking at induction as PD for first five years;
Retention and alternative certification (NYCTF, TFA);
Retention of beginning teachers;
Can we establish a continuum from pre-service to in-service experiences (Medical School
model)?
Support and retention through online learning communities for Secondary Teachers beyond induction;
   Is there a difference between rural/urban/hard-to-hire settings?
   Who are the participants? (In-service/Pre-service, Teacher Educators, Administrators…)
   What are the goals/activities of the online community?
   Can a community be exclusively online? Or is Face-to-face needed?
Retention and Leadership;
   What is leadership?
   How long should people stay in the classroom? And/or move into more influential positions in education?
Role of administrators in retention and professional development;
Guidelines for support - technology, school and state policies driving support, job-embedded professional development, or necessary time, content and opportunities for support
Role of videotaping in PD;

2. Content
Seeing success through Math Content to improve retention. Does knowing more mathematics give a better sense of success?
How do we define “Highly Qualified” (State/Federal/Teacher perceived)?
Would relaxing admissions standards into university teacher training graduate programs and increasing standards for completion help address teacher shortage? Programs can serve as filters…
Role of technology and retention; (gaining experience/competence/confidence with Instrumentation while learning and teaching mathematics)
Getting National Board Certified.

3. Research
Research issues related to data collection and interpretation;
Self-reported data;
Perception on leavers/movers;
Beginning teacher preparation and professional development: when to start “counting” for retention;
What are opportunities and challenges encountered when researching teacher retention?
How do we measure impact?
How many leave for a few years and then come back?
Question for participants: How do you keep track of retention?
   Do we start counting pre-service? Do we count somebody who moved to administration?

4. Retention and Equity (maybe considered as a sub-piece of each category above)
How to attract, recruit and maintain minorities into teaching?
What retention issues are similar/different when looking through the lenses of equity?
Effect of retention on schools/students
   Day 3: Nancy Schoolcraft (IN); Christine D. Thomas ; Douglas Owens ; Barbara Pence ; Axelle Faughn

In order to support discussions on the third meeting session of the working group, participants were invited to read Darling-Hammond’s report on teacher professional development and support. A reflection followed on the categories identified above (Professional Development; Content; Research; Equity) in the light of the report. Additional focus and questions emerged as we noted that PD must be sustained, long-term, and involve a community of learners: Mentoring necessitates careful pairing, could be done through videotapes and reflections; Decreasing the number of preps for beginning teachers could provide more time for planning and reflecting; We need to connect retention to student learning: Is seeing students succeed part of teacher perceived success that could help with retention? i.e., would evidence of increased students’ performance help build confidence & a sense of competence? Finally, advantages of “whole school” reforms and developing leadership in a single individual to bring PD back to their site were emphasized to increase onsite presence through lesson study, lesson planning, online community, coaching, and/or videotapes.

A final activity on day 3 consisted in sharing ideas on further work and dissemination. Participants indicated several directions we could take such as co-developing research and papers, co-presenting at future conferences (New Teacher Center; NCTM Research Pre-session; AERA; T^3; others?) establishing a website/webbase on teacher retention, and collecting papers for a Monograph on Mathematics Teacher Retention.

**Plans for the second year of the working group**

As can be seen in the summary of the working group, the core question of the relationship between Professional Development/Support and retention was a significant and central to all discussions but due to lack of directly related research, formed the springboard for lists of questions. This year, it is hoped that the work from last year along with an additional year of work and significant political actions will help to build a more focused and active research base. Specifically, it is anticipated that we will plan for active engagement of participants in productive reflection on the issues across projects. We hope to begin with the review of previous work for those who are new to the group and then move to breakout groups that will report out and collectively lead to the beginning of a collaborative publishable work. In advance of the conference, last year’s participants will be surveyed to identify any questions or shifts in foci that occurred this year. Additional people will also be contacted. Once the topics for the breakout sessions are identified, specific people will be contacted to chair breakout sessions. Reports will be anticipated from each of the breakout sessions. The general outline of the three days of the working group will include:

**Day 1 • Introductions**

- Review of last years work and update of work by those who are attending.
- Overview of each of the breakout groups. It is expected that we will form 4 groups.
- A 15 minute breakout discussion where participants can take part in one of two discussion and then switch to the next group.

**Day 2 • Introductions of new people**

- Continue with basic ground work for the remaining two breakout groups and discussions in each breakout group.
- Brief discussion of issues addressed in each group.

---

• Small group work that focuses on challenges and knowledge base for each group

Day 3 • Breakout group reports
• Discussion of where we go from here

Productivity of the working group will be a function of the advanced organization. But at this point, we anticipate that the breakout groups will address the questions generated from the year 1 discussions and listed initially in this proposal. That is:

1. Role of technology in support/retention;
2. Professional support community that reflect the building of networks and contacts to support work, decisions, challenges, and opportunities that arise in the teaching of mathematics, including lesson study and electronically based communities of practice;
3. Role of early career leadership and/or career enhancement in retaining mathematics teachers, including the PD directed towards new teachers entering the field through alternative certifications, those coming from other careers, and shifts in PD needed as new teachers move through the challenges of their first 5 years of teaching;
4. Content based Professional development with emphases on conceptual linking and problem solving.

The core questions of relating retention and professional development/support, equity and that of research issues that arise in examining teacher retention will be integrated across each of these breakout topics.

Description of anticipated working group breakout sessions listed by category

(1) **Category I:** Role of technology in support/retention.

This break-out session will be facilitated by Axelle Faughn (CMP-STIR Bakersfield). We will discuss issues pertaining to the role of technology in empowering teachers both in the classroom and the larger mathematics education community. Questions to be addressed include: (1) What model of PD has been provided that engaged participants in Technology use? (2) What trends are you noticing in technology use by teachers? (3) Are you able to relate technology to Retention or Leadership? (4) What constitutes technology in the work of mathematics teachers? (5) What are issues related to equity when working with instructional technologies? The session’s facilitator will provide data and material for participants to examine from several projects that make use of technology in their professional development. Throughout participants will consider how to measure impact by collecting carefully designed research evidence.

(2) **Category II:** Professional support community that reflect the building of networks and contacts to support work, decisions, challenges, and opportunities that arise in the teaching of mathematics, including lesson study and electronically based communities of practice.

**Discussion I.** This break-out session will address implementation strategies and techniques for implementing lesson study. Questions to be discussed include: (1) What is the timeline for planning, teaching and re-teaching? (2) How do teachers define/identify misconceptions by students? (3) How and what do teachers decide in changing their lesson? (4) Who is involved in the Lesson Study planning and implementation?

**Discussion II.** Online professional learning community: A platform for professional development and research on mathematics teacher retention in an urban environment – facilitated by Christine D. Thomas (Georgia State University)

---

In this working group session, we will share our evaluation and synthesis of the literature on Second Life, professional development within a PLC, and distance learning used in our participatory action research study of this Second Life project. The Second Life project that spans August 2009-May 2011 aims at: (1) sustaining mathematics teachers who are attempting to improve their teaching and students' learning and (2) conducting research for the dissemination of knowledge on retention of secondary mathematics teachers in these schools. We use this as an opportunity to share our understandings, interpretations, and analysis of the literature on the topic as it relates to the goals, and needs of the urban community and the mathematics teachers we serve. In addition, we share our beginning analysis, and initial findings of the study based on the baseline data collected.

(3) Category III: Role of early career leadership and/or career enhancement in retaining mathematics teachers, including the shifts in PD needed as new teachers move through the challenges of their first 5 years of teaching. Discussions under this category will be facilitated by Barbara Pence (CMP-STIR, San Jose State University). It is hoped that a representative from the New York City Teaching Fellows will co-chair this break-out session with Pence.

(4) Category IV: Content based Professional development with emphases on conceptual linking and problem solving and establishing collaboration with mathematicians – Facilitated by Imre Tuba (CMP STIR, San Diego State University)

**Anticipated Results of the Working Group**

To begin addressing the particular issues of retention and technology, retention and community, retention and leadership, and/or retention and content-based professional development, each participant will share their project by including a description of the work to date, the stage of development the project is in, research design and instrumentation, and a summary of initial findings. The organizers of the working group plan to solicit several papers emerging from this collaborative work, and possibly the development of a monograph synthesizing our work on mathematics teacher retention and support. The network will also be included in the development of a conference on Supporting Teachers to Increase Retention to take place in two years.

---

The working group focuses on the technological approaches to learning and teaching probability. We address several issues in the discussion such as the importance of learning probability, frameworks describing criteria for understanding probability, technology use in teaching and learning probability in conjunction with the visual characteristics of new learning form of probability. Among various representations used in mathematics and mathematics education, visual representations of probability concepts, the effects of the implementation of visual techniques, and more importantly the importance of visual exploration of probability and its contribution to learning probability will also be discussed.

Background

The focus of this discussion group will be situated at the intersection of the technology use in mathematics education, visual learning in mathematics education, and developing a conceptual understanding of probability. An enormous corpus of literature has been accumulated on technology use in mathematics education and visual learning of mathematics, and many researchers discussed the topics in the various national and international meetings such as PME, PMENA, and ICMI (Arcavi, 1999; Duval, 1999; Hitt, 1999; Hoyles, 2008; Kaput, 1999; Kaput & Hegedus, 2000; Leatham, & McGehee, 2004; McDougall, 1999; Moreno-Armella, 1999; Presmeg, 1999; Radford, 1999; Santos-Trigo, 1999; Thompson, 1999).

Moreover, a specific discussion group focused on the visual learning during the 2009 PME-NA meeting and the discussion was facilitated by two authors of this proposal. The discussion group in that meeting started by identifying the current situation and contemporary perspectives in technology use and visual learning mathematics education and looked for the possible collaboration opportunities. The group brainstormed on the use of technology in mathematics education, on the various forms of representations used in mathematics, and on the meanings of visualization. The proposed discussion will be a continuation of that discussion with the focus on probability.

The rest of the proposal includes a conceptual framework for the importance of learning probability, probabilistic thinking and reasoning, as well as some examples of software used in learning and teaching probability. We finalize the proposal by suggesting an outline for the meeting by addressing the topics to be discussed in each day.

The Importance of Learning Probability

Gal (2005) categorizes motivations for learning probability into two categories, namely internal and external reasons. Internal reasons are connected with the importance of probability within the broader discipline of mathematics. According to this view, learning probability is important because it serves as the foundation for other mathematical disciplines such as statistics and decision theory. In addition, since probability is important because of its connection to other
mathematical concepts (rational numbers, equations, integrals, and sets), solving problems in probability provides opportunity for further mastery of those concepts.

External reasons are connected with the fact that probability could be used to explain many natural and social phenomena. Probability models are at the core of many theories and models including the quantum-theoretic model of the atom, kinetic gas theory, and genetics. Many concepts in social science also use sophisticated probabilistic models. They include voting, choosing an insurance plan, crime, and racial discrimination.

Probabilistic Thinking and Reasoning

There are several frameworks and building blocks (“lists of criteria”) that describe probabilistic reasoning. The major frameworks mentioned in the literature are: core domain of probability concepts (Moore, 1990), probability thinking framework (Jones et al., 1997), and building blocks of probability literacy (Gal, 2005). These frameworks can be divided into two groups: prescriptive and descriptive.

Moore’s (1990) probability thinking framework is primarily prescriptive because it describes the pieces of knowledge that a person needs to have in order to be able to reason probabilistically. Moore (1990) describes the conditions that students need to satisfy in order to be able to move towards more difficult concepts including conditional probability. These conditions are: (1) learning to discern the overall pattern of events and not attempt a causal explanation of each outcome; (2) recognizing the stability of long run frequencies; (3) assigning probabilities to finite sets of outcomes and compare observed proportions to these probabilities; (4) overcoming the tendency to believe that the regularity described by probability applies to short sequences of random outcomes; and (5) applying an understanding of proportions to construct a math model of probability and develop an understanding of some “basic laws or axioms that include the addition rules for disjoint sets.” (p. 120). The first condition deals with the understanding of randomness and is relevant to this thesis.

Gal’s (2005) model consists of two parts which the author calls “the building blocks.” (p. 46). The first set of “building blocks” consists of the knowledge elements. The knowledge elements are prescriptive because, similar to the Moore’s model, it lists pieces of knowledge that students should have in order to master probability. The second part of the model consists of dispositions that play “a key role in how people think about probabilistic information or act in situations that involve chance and uncertainty, whether in the real world or in the classroom.” (Gal, 2005, p. 45). This part of the model is descriptive because it does not exclude dispositions that are detrimental for understanding probability. In Gal’s model, the knowledge elements are: (1) big ideas (variation, randomness, independence, predictability, and uncertainty); (2) figuring probabilities (ways to find or estimate the probability of events); (3) language (the terms and methods used to communicate about chance); (4) context (understanding the role and implications of probabilistic issues and messages in various contexts and in personal and public discourse); and (5) critical questions (issues to reflect upon when dealing with probabilities). Dispositional elements in Gal’s model are: (1) critical stance; (2) beliefs and attitudes; and (3) personal sentiments regarding uncertainty and risk (e.g., risk aversion).

One of the most comprehensive frameworks describing probabilistic reasoning is provided by Jones et al (1997). The framework is divided into four constructs: sample space, probability of an event, probability comparisons, and conditional probability. Furthermore, the framework recognizes four levels of reasoning: level 1- subjective, level 2 - transitional between subjective and naive quantitative, level 3 - informal quantitative, and level 4- numerical reasoning.

framework is descriptive, because, similar to Gal’s dispositions, it goes beyond the description of the knowledge of probability that students should possess.

All above-mentioned frameworks imply the following criteria for understanding of probability: (1) acknowledgment that not all phenomena can be viewed causally and deterministically; (2) understanding that random events might have a pattern that is stable in the long run, but that this pattern cannot be used to predict the next outcome; and (3) acknowledgment that randomness is a concept that permeates all aspect of life.

Examples of Software for Teaching and Learning Probability

Probability Explorer (Figure 1) is a research-based application developed by Stohl (2002) which enables students to explore variety of situations involving randomness and probability.

Figure 1

Figure 2
Probability Explorer is useful for designing the second aspect of probability understanding. By repeating experiments arbitrary many number of times and by various types of representations (graphs, pictures, pie charts), students can explore the idea that the frequencies are stable across many trials but that this information cannot be used to predict the next outcome. Tinker Plots (Figure 2) is a software developed by Konold and Miller (2005) that allows students to explore various aspects of randomness and probability including the link between theoretical and experimental probability, as well as exploring randomness in variety of contexts.

The Rationale and Goals of the Discussion Group

The goals of this discussion group are to explore and discuss the technological and visual approaches in learning and teaching probability, to improve awareness on the technology use in conceptual understanding of probabilistic concepts, and to set up a research agenda on the study of technology use in learning probability.

The discussion group will review theoretical discussions in learning probability, the past and current use of technology in learning probability and seek for opportunities for possible use of technology in the future. The discussion, then, will seek possible ways to deepen our understanding of our basic concerns in understanding and teaching probability and the contribution of technology to cope with these concerns. In addition, we will seek opportunities to implement open source technology in classrooms to learn and teach probability.

Objectives:
1) To identify building blocks for understanding probability in elementary and high school (focus on one or the other depends on the participants)
2) To determine contexts in which probability software is appropriate
3) To offer comprehensive analysis of existing software and how it could be used to learn the building blocks
4) To give suggestions for software developers

Questions To Format the Discussion:
1) What is special about learning probability? How is learning probability different from learning other subjects (e.g. algebra and geometry)?
2) For what features of probability is software suitable?
3) For what features is not suitable?
4) Can software be used to learn probability in different contexts or does the software limit the context?
5) If we agree that students should understand probability and randomness in real world, how can computers be used to understand the “real world”?
6) What is the role of new internet technologies in learning probability?

Format for the Discussion Group Meeting

Day 1:
- Theoretical discussion about learning probability
- Past research on learning probability
- Basic challenges in understanding probability concepts

Day 2:
- Possible solutions to the problems addressed in the first day
- Technology use learning probability
- Comparing real life and technology use in understanding probability
• Could simulation be a solution

Day 3:
• Wrap up the discussion and themes emerged in the first two days
• Suggestion for the future
• Setting a possible agenda for the future

Possible Future Agenda Items
• To set up a team for working on an open source software to learn probability
